### Non-renal DCD/ECD

**O-296 SEPTUAGENARIAN AND OCTOGENARIAN DONORS PROVIDE EXCELLENT LIVER GRAFTS FOR TRANSPLANTATION**

Tom Darius 1, Diethard Morbaliu2, Raymond Aerts3, Ina Joachmans4, Brussels, Belgium; 1Dep of Gastroenterology and Hepatology, 3Dept of Cardiothoracic Surgery, 2Dept of Transplantation, University Hospitals of Leuven, Belgium

**Background:** Wider utilization of liver grafts from donors ≥70 yo could substantially expand the donor pool, but their use remains limited by fear of poor postoperative courses. We analyze the results of liver transplantation (LTx) using livers from donors ≥70 yo at our center.

**Methods:** From February 2003 to August 2010, 450 LTx were performed. Of those ≥70 (15%) were performed using donors ≥70 yo. Their outcome was compared to that of LTx using donors <70 yo.

**Results:** Cerebrovascular causes of death predominated in donors ≥70 yo (85% versus 47% in donors <70 yo) (p<0,001) whereas traumatic causes of death predominated in donors <70 yo (36% versus 14% in donors <70 yo) (p<0.002). Unlike grafts/donors <70 yo, older grafts/donors had no additional risk factor (steatosis, high sodium, hemodynamic instability). Both groups were comparable for cold and warm ischemia times. No difference was noted in posttransplant peak transaminase, incidence of primary non-function, hepatic artery thrombosis, biliary strictures, and retransplantation between both groups. Thirty and five-year patient survival were 80% and 80% in recipients of livers ≥70 yo and 88% and 80% in recipients of livers <70 yo (p=0.74). Recipients of older grafts were 9 years older than recipients of younger grafts (p<0.001) and tended to have a lower laboratory MELD score (p=0.074).

**Conclusion:** Short and midterm survival following LTx with donors ≥70 yo can be excellent providing that donors and recipients are adequately selected. Septuagenarian and octogenarian victims of cerebrovascular ischemia and bleeding represent a large pool of potential donors whose wider use could substantially reduce the mortality on the waiting list.

**O-297 APPLICABILITY OF DONATION AFTER CARDIAC DEATH LIVER TRANSPLANT USING MAESTRIECHT TYPE 2 DONORS**

A.J. Hessheimer1, C. Fondevila2, E. Flores3, A. Ruiz4, N. Mestres5, D. Calatayud6, S. Sánchez7, R. García8, J. Ferrer9, J. Fuster10, M. Navasa11, A. Rímo12, P. Taur13, B. Miranda14, J.C. García-Valdecasas15, Surgery, Hospital Clinic, Barcelona, Spain; 2Transplant Coordination, Hospital Clinic, Barcelona, Spain; 3Liver Unit, Hospital Clinic, Barcelona, Spain; 4Anesthesiology, Hospital Clinic, Barcelona, Spain

Unlike Maastricht type 3 donation after cardiac death (DCD) donors, in whom cardiac arrest (CA) is induced by the removal of life support, type 2 donors arrest unexpectedly, typically outside the hospital. These donors have significant potential to expand the donor pool (US Institute of Medicine, 2006).

**Aim:** Analyze the results of type 2 DCD livers were used for transplant as well as all potential liver donors treated under our center’s type 2 DCD protocol.

**Methods:** Cardiac arrest was extrahospitalary. Potential donors arrived with cardiorespiratory support (CRS). Death was declared and femoral vessels canulated to establish normothermic extracorporeal membrane oxygenation (NECMO), which was maintained until organ recovery.

**Results:** From 4/02 to 12/10, there were 80 activations of our type 2 DCD protocol; 34 liver transplants were performed (42%). Causes for rejecting a type 2 DCD liver were classified as absolute or relative, the latter including a prolonged phase (CA >15 min, CRS >150 min, NECMO >4 hours), high CIT, ALT during NECMO, and poor macroscopic liver aspect at recovery. Overall, 130 livers (33%) were turned down due to relative contraindications. Among transplanted livers, median follow-up was 24 months (range 0-111). One-year graft and patient survival rates were 71% and 82%, respectively. Ischemic cholangiopathy developed in three patients (8%), who were retransplanted at 5, 8, and 13 months.

**Conclusion:** This is largest series of type 2 DCD liver transplants to date. Based on protocol activations, the applicability of type 2 DCD liver was less than 10%. Thirty percent of livers were turned down based on relative contraindications. It is possible that with better means of preservation ex vivo, we may be able to improve the viability of these grafts and improve the applicability of this procedure.

**O-298 LIVER TRANSPLANTATION FROM DONATION AFTER CARDIACIRCULATORY DEATH (DCD) DONORS: BELGIAN EXPERIENCE 2003-2009**

Arnaud De Rover1, Hieu Le Dinh1, Olga Cicarelli2, Jan Leruf2, Peter Michielsen1, Dirk Ysebaert3, Valerio Lucidi4, Vincent Donckier5, Hans Vanvlierbergh6, Xavier Rogiers7, Roberto Troisi8, Diethard Morbaliu9, Frederik Nevens10, Jacques Pierene11, Olivier Detry12, 1Dept of Abdominal Surgery and Transplantation, Centre Hospitalier Universitaire Saint Luc, Brussels, Belgium; 2Dept of Hepatobiliary Surgery and Transplantation, University Hospital Antwerp, Antwerp, Belgium; 3Dept of Hepatobiliary Surgery and Transplantation, Erasme University Hospital, Brussels, Belgium; 4Dept of Hepatology and Abdominal Transplantation, University Hospital Ghent, Ghent, Belgium; 5Dept of Hepatology and Abdominal Transplantation, University Hospital Gasthuisberg Leuven, Leuven, Belgium

**Introduction:** The Belgian experience with DCD liver transplantation (LT) was retrospectively updated with the aim to evaluate patient and graft survivals, and biliary complications.

**Patients and methods:** From 2003 to 2009, 111 DCD-LTs had been performed in Belgium. The characteristics of donors, recipients, transplantation procedure and outcomes were retroactively reviewed.

**Results:** Mean donor age was 47.6±15.5 years (range: 13-79). Donor causes of death were anoxia (36.1%), head trauma (31.5%), stroke (36%) and euthanasia (5.4%). Mean duration of treatment withdrawal to aortic cold perfusion was 24±4.13 min, mean cold ischemia time (CIT) was 367±128.9 min. Mean recipient age was 55.9±11.2 years (range: 17-73). The most frequent indications for LT were cirrhosis (49.5%) and hepatocellular carcinoma (35.6%). The rate of primary non function was 4.5%. Overall patient and graft survival was 86% and 80% at 1 year, 75% and 65% at 3 years, respectively. Thirty-seven patients (33.3%) developed biliary complications with the need for endo- or surgical management in twenty-eight and retransplantation in seven. In univariate analysis, HUI indication, younger donor age, elevated donor bilirubin level, absence of hepatic adenomatosis to the donor, CIT, secondary WIT (liver implantation), were significantly (p<0.05) associated with transplant failure. Risk factors for biliary complications were short donor ICU stay, elevated donor bilirubin level, long duration between switch off to cold perfusion, long CIT, while local allocation decreased the risk. In multivariate analysis, elevated donor bilirubin level and duration of donor hepatectomy were associated with transplant failure while higher donor bilirubin level, CIT and Meld score were associated with occurrence of biliary complications.

**Conclusions:** In an era of organ shortage, DCD transplantation is a valuable treatment option with an adequate selection of donors and recipients.

**O-299 ISCHEMIC CHOLANGIOPATHY IN LIVER TRANSPLANTATION USING DONATION AFTER CARDIAC DEATH DONORS: ANALYSIS OF A MATCHED CONTROL STUDY IN A SINGLE LARGE VOLUME CENTER**

Michelle L. DeOliveira1,2,9, Wael Jassem1, Roberto Valent13, Shirin E. Khorsandi4, Andrea Prachalski1, Sarita Nairn1, Mohamed Fefa1, Nigel Heslen1, 1Liver Transplantation & HPB Surgery Institute for Liver Diseases, King’s College Hospital, London, United Kingdom; 2Visceral & Transplantation Surgery, University Hospital of Zurich, Zurich, Switzerland; 3Transplantation, San Martino University Hospital, Genoa, Italy

**Background:** Shortage of available organs is a limiting factor in liver transplantation (LT) due to the results of type 3 DCD donors after cardiac death (DCD) offers potential to increase the organ pool. The early results with DCD liver grafts were associated with a greater incidence of non-anastomotic biliary complications, leading to several programs to abandon this source of organs. The UNOS data
