

# The spin-orbit alignment of the Fomalhaut debris disk

Olivier Absil  
University of Liège

Seminar at ESO – Santiago – September 30<sup>th</sup>, 2011

# Exoplanets galore

- 600+ exoplanets discovered so far
  - Many more unconfirmed Kepler candidates
- « Hot Jupiters » are most emblematic
- Planetary transits
  - Radius
  - Composition
  - Spin-orbit orientation

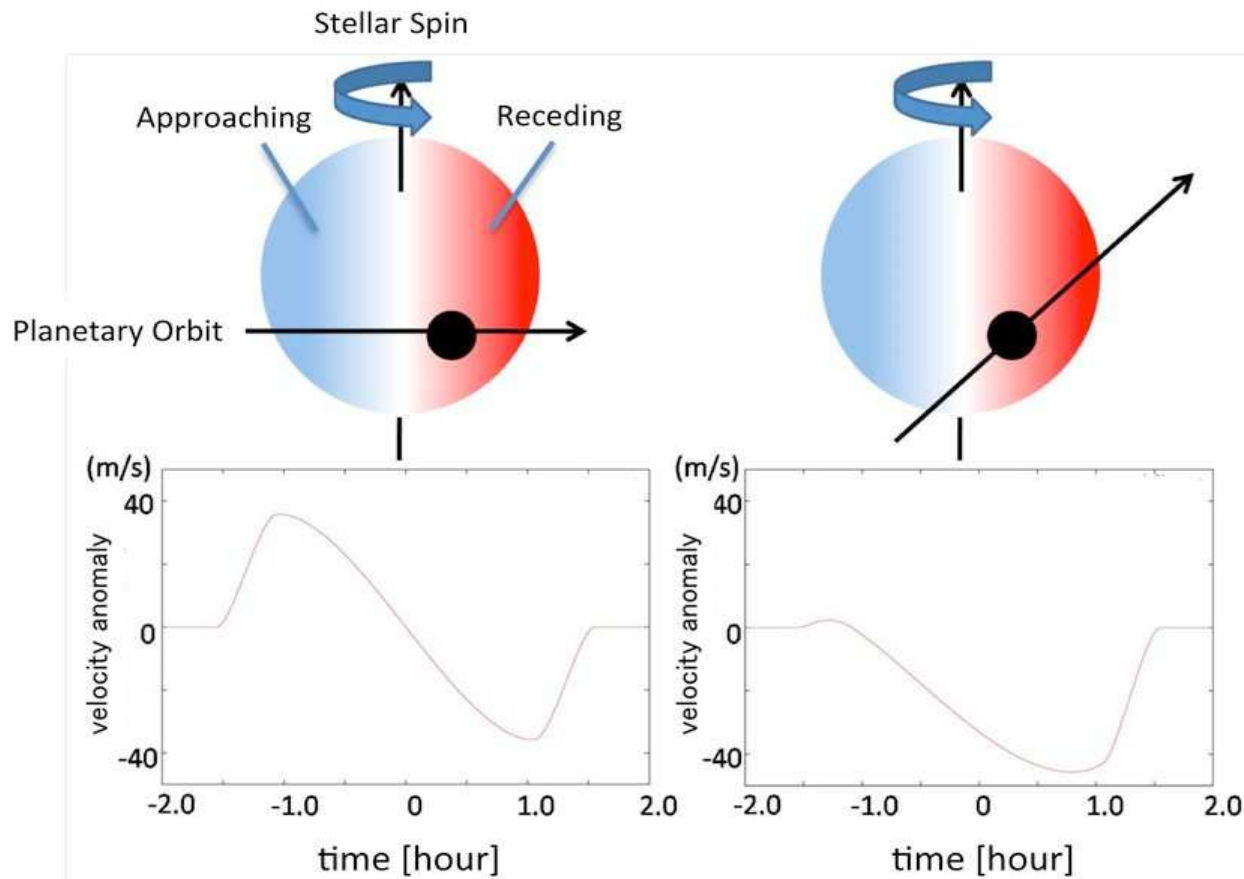

# The Rossiter-McLaughlin effect

- Takes place during (planetary) transit
- Planet hides small fraction of one velocity component on photosphere
- Small bump moves through spectral line
- Creates RV anomaly

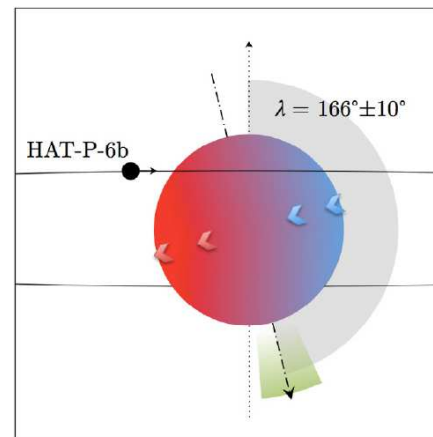

# The Rossiter-McLaughlin effect

- Access to **projected** star/orbit inclination

# RM detected for hot Jupiters

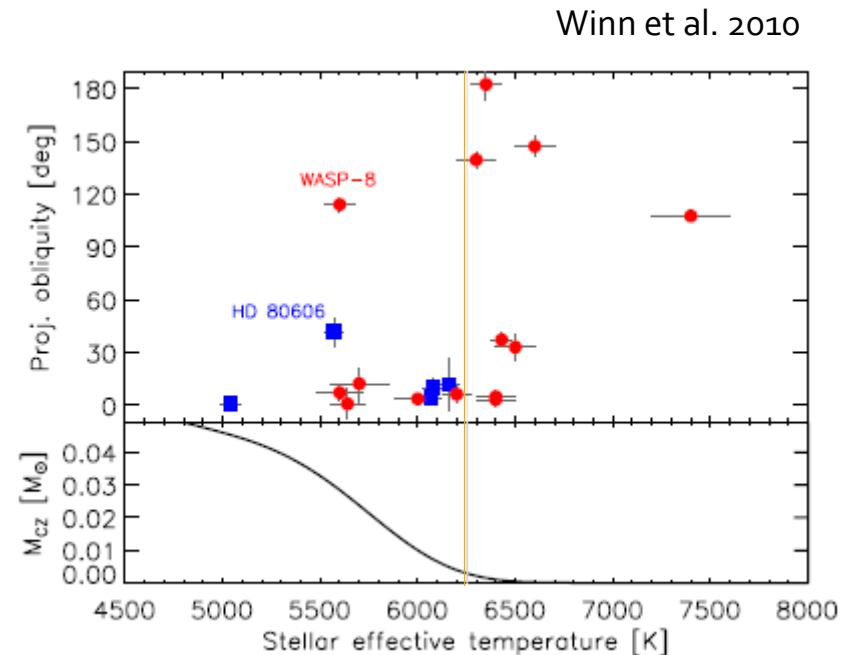

- First detection by Queloz et al. (2000)
  - HD 209458b aligned
- 40+ systems observed
  - 18 significantly misaligned
  - 9 on retrograde orbits
- Detection not easy
  - Significant error bars ( $\sim 10^\circ$ ) on relative inclination

Example: HAT-P-6b  
(Hébrard et al. 2011)

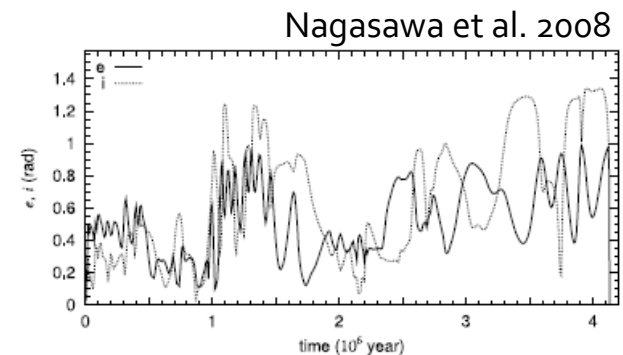

# First statistical trends

- Misalignments more frequent for hot stars ( $>6250\text{K}$ )
  - Due to tidal dissipation in stellar convective zone?
  - Exceptions: light planets and long periods
- Most hot Jupiters may have « arrived » misaligned

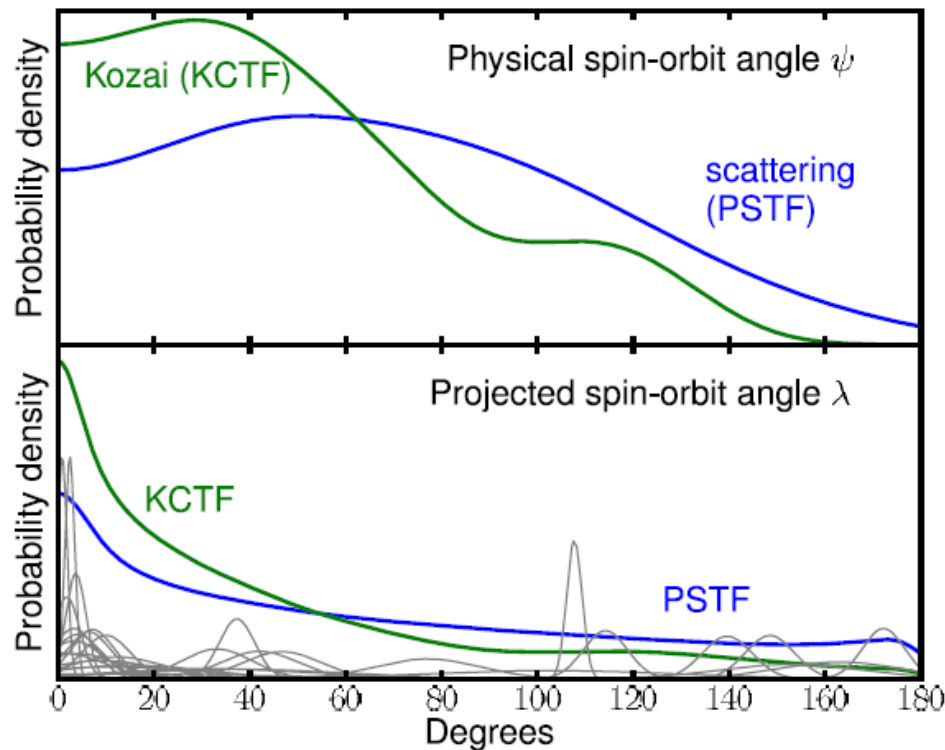

# Possible explanations

- Disk-driven migration not possible
- Kozai mechanism
  - Requires distant 3<sup>rd</sup> body on inclined orbit ( $40^\circ < i < 140^\circ$ )
  - Secular oscillations of eccentricity and inclination for inner planet
  - Circularisation by tidal friction
- Planet-planet scattering
  - Instabilities in multiple (packed) planetary systems
  - Orbit crossing  $\rightarrow$  high eccentricities / inclinations
  - Circularisation by tidal friction

# Kozai or scattering?

- Strongly debated issue (Morton & Johnson 2011)
  - Need 2× more observed systems to conclude

# Alternative scenarios

- Misalignment may date back to formation (disk)
- Early stellar encounter (Bate et al. 2010)
  - Stellar cluster → chaotic environment
  - Interactions → misalignment + truncation
- Magnetosphere-disk interactions (Lai et al. 2011)
  - Magnetic protostar exerts warping/precessional torque on inner disk before disruption
  - Disk resists warping → back-reaction torque
- Interaction with gas-rich birth cluster (Thies et al. 2011)
  - Passage of young star through gas reservoir → capture of gas onto existing disk
  - Disk can be tilted up to retrograde

# How to discriminate?

- Use debris disks
  - ~25 have been resolved
  - More with Herschel
- Resolved image
  - Inclination / position angle
  - Materialises the plane of planetary formation
- Need stellar orientation

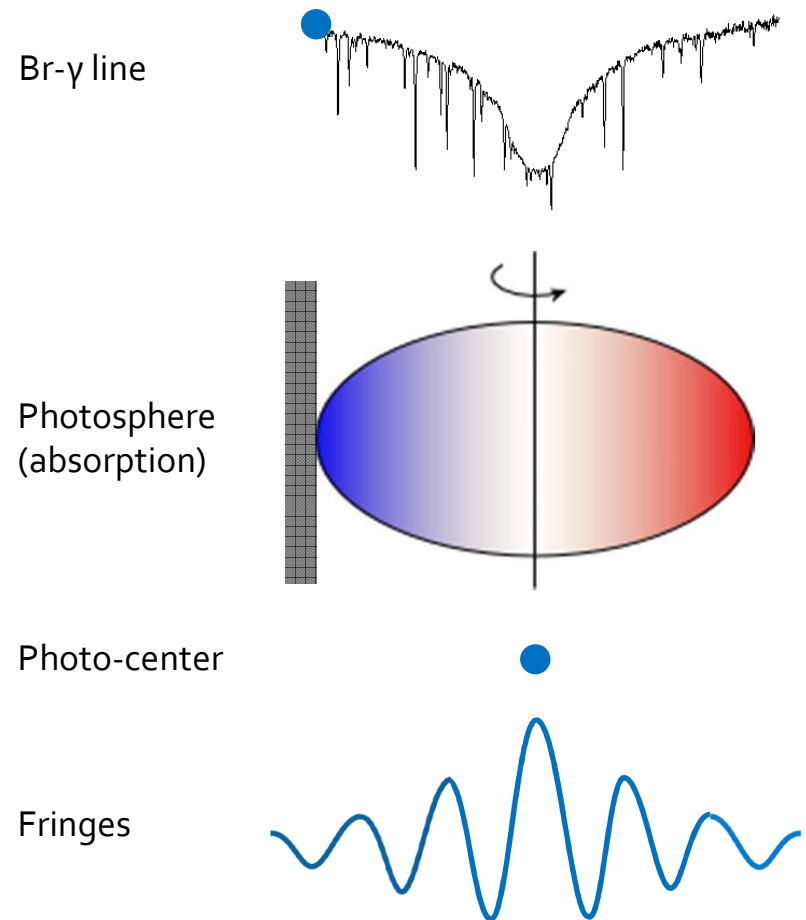

# How to get stellar orientation?

- Inclination from  $P_{\text{rot}} \times v \sin i / 2\pi R_*$  (Watson et al. 2011)
  - $P_{\text{rot}}$  from photometry or Ca II lines (low precision)
  - $v \sin i$  from high resolution spectroscopy
  - $R_*$  from spectra, interferometry, ...
  - Result: no misalignment in 8 systems (FGK stars)
    - BUT: final error bars generally  $\geq 10^\circ$
    - New Herschel resolved disks  $\rightarrow$  1<sup>st</sup> misaligned case?
- Position angle from spectro-interferometry
  - Only for rapidly rotating stars (A / early F)
  - Subject of this talk

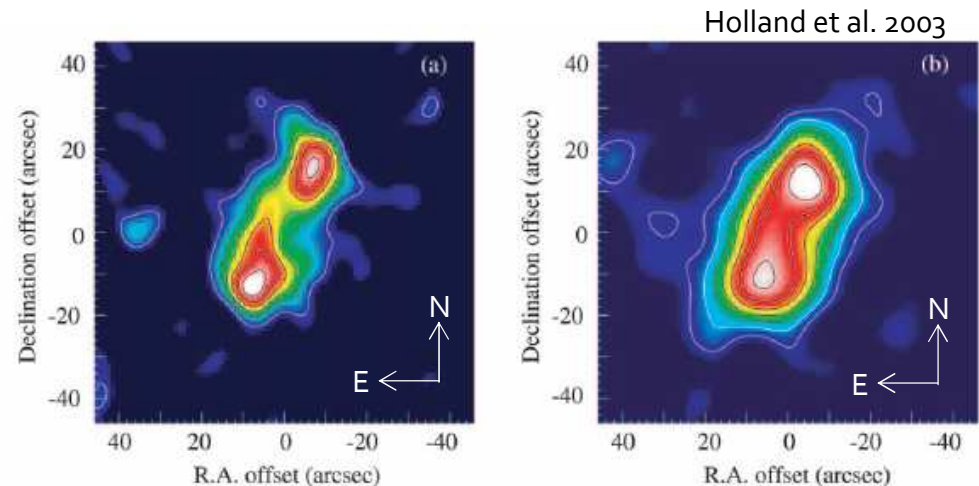

# PA from spectro-interferometry

- Requirements
  - Rapidly rotating star
  - Deep absorption line
  - Partly resolved photosphere ( $\geq 1$  mas)
- Displacement of photocenter across the Br- $\gamma$  line
  - Signature in fringe phase versus wavelength
  - 2D phase  $\rightarrow$  position angle

# The Fomalhaut planetary system

- Fomalhaut: A<sub>4</sub>V, 7.7 pc
- Debris disk resolved at various wavelengths
  - Ring at 140 AU
  - Brightness asymmetry
  - Sharp inner edge
  - Off-centered by 15 AU
- Candidate planet at 115 AU
  - Orbital movement

# Fomalhaut with VLT/AMBER

- Fomalhaut
  - $v \sin i = 93 \text{ km/s}$
  - Angular diam:  $\theta = 2.2 \text{ mas}$
- AMBER
  - 3 × Auxiliary Telescopes
  - Baselines:  $\sim 100\text{m}$
  - Medium spectral resolution ( $R=1500$ ) in K band
- Measure wavelength-differential phase
  - Deduce 2D differential astrometry

# 2D differential astrometry

- Clear signature inside Br- $\gamma$  line
  - Precision:  $\sim 3 \mu\text{as}$

# Spin-orbit alignment

- Photosphere position angle:  $155^\circ \pm 3^\circ$ 
  - But inclination not constrained (needs advanced model)
- Disk position angle:  $156.0^\circ \pm 0.3^\circ$
- By-product: discriminate front side / back side
  - Assuming planet prograde and stellar spin not flipped

# Backward scattering dominant?

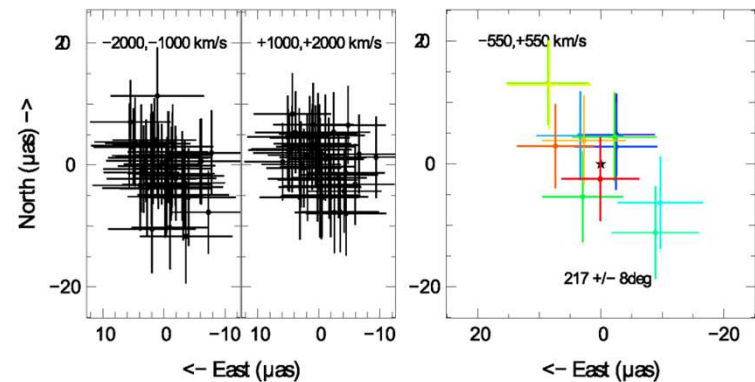

- Possible only with big grains
  - Similar to lunar phases
- Small grains ejected?
  - What about further collisions?

Min et al. 2010

# Future work: mini survey

- 6 more potential targets for VLT/AMBER
  - + a few more to the North
- Zeta Leporis
  - Position angle retrieved while  $\theta = 0.75$  mas only
- Beta Pictoris
  - Star aligned with inner or outer disk?

# Fomalhaut with VLT/PIONIER

- Detection limits based on closure phases
  - 7 OBs in total (~3h)
  - 7 spectral channels within K band
