#### Abstract

Acta Crystallographica Section C: Crystal Structure Communications specializes in the rapid dissemination of high-quality studies of crystal and molecular structures of interest in fields such as chemistry, biochemistry, mineralogy, pharmacology, physics and materials science. The numerical and text descriptions of each structure are submitted to the journal electronically as a Crystallographic Information File (CIF) and are checked and typeset automatically prior to peer review. The journal is well known for its high standards of structural reliability and presentation. Section C publishes approximately 1000 structures per year; readers have access to an archive that includes high-quality structural data for over 10000 compounds.

Two new mixed-valence iron phosphates, namely heptairon pentaphosphate hydrogen phosphate, $\mathrm{Fe}_{6.67}\left(\mathrm{PO}_{4}\right)_{5.35}\left(\mathrm{HPO}_{4}\right)_{0.65}$, and heptairon tetraphosphate bis(hydrogen phosphate), $\mathrm{Fe}_{6.23^{-}}$ $\left(\mathrm{PO}_{4}\right)_{4.45}\left(\mathrm{HPO}_{4}\right)_{1.55}$, have been synthesized hydrothermally at 973 K and 0.1 GPa . The structures are similar to that of $\mathrm{Fe}^{\mathrm{II}}{ }_{3} \mathrm{Fe}^{\mathrm{III}}{ }_{4}\left(\mathrm{PO}_{4}\right)_{6}$ and are characterized by infinite chains of Fe polyhedra parallel to the [101] direction. These chains are formed by the $\mathrm{Fe}_{1} \mathrm{O}_{6}$ and ${\mathrm{Fe} 2 \mathrm{O}_{6} \text { octahedra, alternating with }}^{2}$ the $\mathrm{Fe} 4 \mathrm{O}_{5}$ distorted pentagonal bipyramids, according to the stacking sequence $\cdots \mathrm{Fe} 1-\mathrm{Fe} 1-\mathrm{Fe} 4-\mathrm{Fe} 2-\mathrm{Fe} 2 \cdots$. The $\mathrm{Fe}_{3} \mathrm{O}_{6}$ octahedra and $\mathrm{PO}_{4}$ tetrahedra connect the chains together. $\mathrm{Fe}^{\mathrm{II}}$ is localized on the Fe 3 and Fe 4 sites, whereas $\mathrm{Fe}^{\mathrm{III}}$ is found in the Fe 1 and Fe 2 sites, according to bond-valence calculations. Refined site occupancies indicate the presence of vacancies on the Fe 4 site, explained by the substitution mechanism $\mathrm{Fe}^{\mathrm{II}}+2\left(\mathrm{PO}_{4}{ }^{3-}\right)=$ vacancies $+2\left(\mathrm{HPO}_{4}{ }^{2-}\right)$.

## Comment

Only a few phosphates in nature contain iron in both valence states. The more common minerals with these chemical features are barbosalite-lipscombite $\left[\mathrm{Fe}^{\mathrm{II}} \mathrm{Fe}^{\mathrm{III}}{ }_{2}\left(\mathrm{PO}_{4}\right)_{2}(\mathrm{OH})_{2}\right]$, beraunite $\left[\mathrm{Fe}^{\mathrm{II}} \mathrm{Fe}^{\mathrm{III}}{ }_{5}\left(\mathrm{PO}_{4}\right)_{4}(\mathrm{OH})_{5} \cdot 6 \mathrm{H}_{2} \mathrm{O}\right.$ ], rockbridgeite $\left[\mathrm{Fe}^{\mathrm{II}}\right.$ $\left.\mathrm{Fe}^{\mathrm{III}}{ }_{4}\left(\mathrm{PO}_{4}\right)_{3}(\mathrm{OH})_{5}\right]$ and whitmoreite $\left[\mathrm{Fe}^{\mathrm{II}} \mathrm{Fe}^{\mathrm{III}}{ }_{2}\left(\mathrm{PO}_{4}\right)_{2}(\mathrm{OH})_{2} \cdot-\right.$ $4 \mathrm{H}_{2} \mathrm{O}$ ]. They generally occur in granitic pegmatites as secondary minerals which are produced by the alteration of primary iron phosphates. Gorbunov et al. (1980) obtained the first synthetic iron phosphate with both $\mathrm{Fe}^{\mathrm{II}}$ and $\mathrm{Fe}^{\mathrm{III}}$, with the formula $\mathrm{Fe}^{\mathrm{II}}{ }_{3} \mathrm{Fe}^{\mathrm{III}}{ }_{4}\left(\mathrm{PO}_{4}\right)_{6}$. Redhammer et al. (2004) refined the structure of a similar compound containing a very small amount of sodium, $\mathrm{Na}_{0.1} \mathrm{Fe}_{7}\left(\mathrm{PO}_{4}\right)_{3}$, and demonstrated that this phosphate was isotypic with the vanadate howerdevansite, $\mathrm{NaCu}^{\mathrm{II}} \mathrm{Fe}^{\mathrm{III}}{ }_{2}\left(\mathrm{VO}_{4}\right)_{6}$ (Hughes et al., 1988). Lightfoot \& Cheetham (1986) and Vencato et al. (1994) have shown that the reduction of $\mathrm{Fe}^{\mathrm{III}}$ in $\mathrm{Fe}^{\mathrm{II}}{ }_{3} \mathrm{Fe}^{\mathrm{III}}{ }_{4}\left(\mathrm{PO}_{4}\right)_{6}$ can induce the formation of isostructural hydrogen phosphates, with compositions $\mathrm{Fe}^{\mathrm{II}}{ }_{7-x} \mathrm{Fe}^{\mathrm{III}}{ }_{x}\left(\mathrm{PO}_{4}\right)_{2+x}\left(\mathrm{PO}_{3} \mathrm{OH}\right)_{4-x}(0<x<4)$.

In order to explore the stability of lithium iron phosphates, we decided to perform hydrothermal experiments in the $\mathrm{Li}-$ $\mathrm{Fe}^{\mathrm{II}}-\mathrm{Fe}^{\mathrm{III}}\left(+\mathrm{PO}_{4}\right)$ system, between 673 and 973 K , under a pressure of 0.1 GPa . In these experiments, various iron phosphates crystallized as, for example, $\mathrm{Fe}_{3}\left(\mathrm{PO}_{4}\right)_{2}$ (sarcop-side-type), $\mathrm{Fe}_{7}\left(\mathrm{PO}_{4}\right)_{6}, \mathrm{Fe}_{3}\left(\mathrm{PO}_{4}\right)_{2}(\mathrm{OH})_{2}$ and $\mathrm{Fe}_{4}\left(\mathrm{PO}_{4}\right)_{3}(\mathrm{OH})_{3}$ (Dal Bo, 2011). $\mathrm{Fe}_{7}\left(\mathrm{PO}_{4}\right)_{6}$ is a stable phase between 673 and 973 K ; electron-microprobe chemical analyses performed on 11 samples have shown variations of the $\mathrm{Fe}: \mathrm{P}$ ratio from ca 7:6 to 6:6. In order to understand the variation of this ratio, singlecrystal X-ray structural investigations were performed on two samples synthesized at 973 K (denoted H. 339 and H.347).

The present paper reports the crystal structures of $\mathrm{Fe}^{\mathrm{II}}{ }_{2.67}$ $\mathrm{Fe}^{\mathrm{III}}{ }_{4}\left(\mathrm{PO}_{4}\right)_{5.35}\left(\mathrm{HPO}_{4}\right)_{0.65}(\mathrm{H} .339)$ and $\mathrm{Fe}^{\mathrm{II}}{ }_{2.23} \mathrm{Fe}^{\mathrm{III}}{ }_{4}\left(\mathrm{PO}_{4}\right)_{4.45^{-}}$ $\left(\mathrm{HPO}_{4}\right)_{1.55}$ (H.347). Both structures were refined in the space group $P \overline{1}$ (No. 2) and are similar to those of corresponding iron phosphates and iron hydrogen phosphates reported in the literature (Redhammer et al., 2004; Vencato et al., 1994). The structures are characterized by isolated $\mathrm{PO}_{4}$ tetrahedra and four different types of Fe polyhedra. $\mathrm{Fe} 1, \mathrm{Fe} 2$ and Fe 3 occur in octahedral environments, whereas Fe 4 occurs in a fivefold distorted trigonal bipyramid. $\mathrm{Fe} 1, \mathrm{Fe} 2$ and Fe 4 are connected to each other by edge sharing to form infinite chains parallel to the [101] direction (Fig. 1). These chains are characterized by the stacking sequence $\cdots \mathrm{Fe} 1-\mathrm{Fe} 1-\mathrm{Fe} 4-\mathrm{Fe} 2-\mathrm{Fe} 2 \cdots$, and the Fe 3 octahedra connect the chains in the $b$ direction by sharing corners with the Fe 4 and Fe 1 sites. As can be seen in Fig. 2, the $\mathrm{PO}_{4}$ tetrahedra connect the chains together by corner sharing.

Refinement of the site-occupancy factors indicates that all Fe sites are fully occupied by iron, except for Fe 4 which contains 0.8369 (18) and 0.614 (2) $\mathrm{Fe}^{\text {II }}$ in samples H. 339 and H.347, respectively.

The charge deficit induced by this partial occupancy is compensated by the replacement of $\mathrm{PO}_{4}{ }^{3-}$ by $\mathrm{HPO}_{4}{ }^{2-}$, according to the substitution mechanism $\mathrm{Fe}^{\mathrm{II}}+2\left(\mathrm{PO}_{4}{ }^{3-}\right)=$ vacancies $+2\left(\mathrm{HPO}_{4}{ }^{2-}\right)$. Consequently, the general chemical formula of these phosphates can be expressed as $\mathrm{Fe}^{\mathrm{II}}{ }_{1+2 x} \mathrm{Fe}^{\mathrm{III}}{ }_{4}\left(\mathrm{PO}_{4}\right)_{4 x+2}\left(\mathrm{HPO}_{4}\right)_{4-4 x}$, in which $x=0.84$ (sample

Figure 1
A representation of three infinite chains of Fe polyhedra. Key: $\mathrm{Fe}^{1 \mathrm{O}_{6}}$ and $\mathrm{Fe}_{2} \mathrm{O}_{6}$ polyhedra are dark grey, $\mathrm{Fe}^{2} \mathrm{O}_{5}$ polyhedra are white, Fe 3 atoms are represented by white spheres and O atoms are represented by dark spheres.

Figure 2
The crystal structure of $\mathrm{Fe}^{\mathrm{II}}{ }_{2.67} \mathrm{Fe}^{\mathrm{III}}{ }_{4}\left(\mathrm{PO}_{4}\right)_{5.35}\left(\mathrm{HPO}_{4}\right)_{0.65}$. Key: $\mathrm{Fe} 1 \mathrm{O}_{6}$ and $\mathrm{Fe} 2 \mathrm{O}_{6}$ polyhedra are dark grey, $\mathrm{Fe}_{3} \mathrm{O}_{6}$ and $\mathrm{Fe} 4 \mathrm{O}_{5}$ polyhedra are light grey and $\mathrm{PO}_{4}$ tetrahedra are dark.
H.339) or 0.61 (sample H.347). The substitution mechanism observed in the title compounds is completely different from that described by Lightfoot \& Cheetham (1986) and Vencato et al. (1994), which corresponds to $\mathrm{Fe}^{\mathrm{III}}+\mathrm{PO}_{4}{ }^{3-}=\mathrm{Fe}^{\mathrm{II}}+$ $\mathrm{HPO}_{4}{ }^{2-}$. In this last case, the charge deficit is produced by reducing $\mathrm{Fe}^{\mathrm{III}}$ into $\mathrm{Fe}^{\mathrm{II}}$, whereas in samples H .339 and H .347 this deficit is produced by the appearance of vacancies on the Fe4 five-coordinated site.

Since Li was present in the starting material used for the synthesis experiments, we decided to perform another refinement in which the Fe 4 site is occupied simultaneously by Fe and Li . This refinement shows a site population of $0.44 \mathrm{Li}+$ 0.56 Fe , but the bond-valence sum of 1.41 , calculated from the $\mathrm{Fe} 4-\mathrm{O}$ bond lengths, is in poor agreement with the expected value of 1.56 . In the final refinement cycle, we consequently adopted the most realistic model, in which the Fe 4 site is occupied by $\mathrm{Fe}^{\mathrm{II}}$ and vacancies, without any significant amount of lithium.

The final site populations, calculated from the observed site occupancies and assuming charge balance, are $\mathrm{Fe}^{\mathrm{III}}$ on the Fe 1 and Fe 2 sites, $\mathrm{Fe}^{\mathrm{II}}$ on the Fe 3 site, and $\mathrm{Fe}^{\mathrm{II}}$ plus vacancies on the Fe 4 site. Bond-valence sums, calculated by using the empirical parameters of Brown \& Altermatt (1985), confirm the distributions of $\mathrm{Fe}^{\mathrm{II}}$ and $\mathrm{Fe}^{\mathrm{III}}$ among the different crystallographic sites. Indeed, the $\mathrm{Fe} 1, \mathrm{Fe} 2, \mathrm{Fe} 3$ and Fe 4 bondvalence sums are 3.01, 3.07, 1.82 and 1.96 (H.339) or 3.09, 3.10, 2.07 and 1.94 (H.347), respectively. The bond-valence sums for P1, P2 and P3 are 4.92, 4.95 and 5.04 (H.339), or 4.93, 4.96, 5.03 (H.347), respectively.

## Experimental

Both single crystals used for the structure refinement were synthesized under hydrothermal conditions. The starting materials were
prepared by mixing $\mathrm{Li}_{3} \mathrm{PO}_{4}, \mathrm{FePO}_{4}$ and Fe in the molar proportions 1:5:1 (H.339) and 1:11.5:1 (H.347), and then homogenizing this mixture in an agate mortar. About 25 mg of each mixture were sealed in gold tubes with outer diameters of 2 mm and lengths of 25 mm , containing 2 mg of pure water. The gold capsules were then inserted in a Tuttle-type pressure vessel (Tuttle, 1949) and maintained at a temperature of 973 K and a pressure of 0.1 GPa . After 7 d , the gold tubes containing the samples were quenched in the autoclave to room temperature in a stream of cold air. Black crystals of H .339 were found in association with colourless crystals of $\mathrm{LiFePO}_{4}$ and green crystals of $\mathrm{Li}_{3} \mathrm{Fe}_{2}\left(\mathrm{PO}_{4}\right)_{3}$. Black crystals of H .347 crystallized in association with light-green crystals of $\mathrm{LiFe}\left(\mathrm{P}_{2} \mathrm{O}_{7}\right)$ and $\mathrm{Li}_{3} \mathrm{Fe}_{2}\left(\mathrm{PO}_{4}\right)_{3}$.

A chemical analysis has been performed with a CAMEBAX SX100 electron microprobe ( 15 kV acceleration voltage, 5 nA beam current). The standard used to calibrate both Fe and P was graftonite from Kabira (sample KF16, Fransolet, 1975). The average of ten point analyses for H .339 gives $\mathrm{P}_{2} \mathrm{O}_{5} 44.90$, $\mathrm{FeO} * 20.00, \mathrm{Fe}_{2} \mathrm{O}_{3}{ }^{*} 33.68$, $\mathrm{H}_{2} \mathrm{O}^{*} 0.68$, i.e. total $99.27 \mathrm{wt} \%$ [* indicates values calculated to maintain charge balance, assuming the substitution mechanism $\mathrm{Fe}^{\mathrm{II}}+$ $2\left(\mathrm{PO}_{4}{ }^{3-}\right)=$ vacancies $\left.+2\left(\mathrm{HPO}_{4}{ }^{2-}\right)\right]$. The chemical composition, calculated on the basis of six P atoms and four $\mathrm{Fe}^{\text {III }}$ atoms per formula unit, corresponds to $\mathrm{Fe}^{\mathrm{II}}{ }_{2.64} \mathrm{Fe}^{\mathrm{III}}{ }_{4}\left(\mathrm{PO}_{4}\right)_{5.28}\left(\mathrm{HPO}_{4}\right)_{0.72}$. For H.347, the average of 12 point analyses gives $\mathrm{P}_{2} \mathrm{O}_{5} 46.57$, FeO * 15.11 , $\mathrm{Fe}_{2} \mathrm{O}_{3}{ }^{*} 34.93, \mathrm{H}_{2} \mathrm{O} * 1.80$, i.e. total $99.68 \mathrm{wt} \%$. The chemical composition, calculated on the basis of six P atoms and four $\mathrm{Fe}^{\mathrm{III}}$ atoms per formula unit, corresponds to $\mathrm{Fe}^{\mathrm{II}}{ }_{2.08} \mathrm{Fe}^{\mathrm{III}}{ }_{4}\left(\mathrm{PO}_{4}\right)_{4.16}\left(\mathrm{HPO}_{4}\right)_{1.84}$. Both formulas are in fairly good agreement with the compositions calculated from the structural data, which are $\mathrm{Fe}^{\mathrm{II}}{ }_{2.67} \mathrm{Fe}^{\mathrm{III}}{ }_{4}\left(\mathrm{PO}_{4}\right)_{5.35^{-}}$ $\left(\mathrm{HPO}_{4}\right)_{0.65}(\mathrm{H} .339)$ and $\mathrm{Fe}^{\mathrm{II}}{ }_{2.23} \mathrm{Fe}^{\mathrm{III}}{ }_{4}\left(\mathrm{PO}_{4}\right)_{4.45}\left(\mathrm{HPO}_{4}\right)_{1.55}(\mathrm{H} .347)$.

All atoms were refined anisotropically in both structures. The refined site-occupancy factors then indicated low electronic densities on the Fe 4 site, thus showing that this site was not fully occupied by $\mathrm{Fe}^{\mathrm{II}}$. Therefore, $\mathrm{Fe}^{\mathrm{II}}$ and vacancies were refined on the Fe 4 site. The low amounts of $\mathrm{HPO}_{4}{ }^{2-}$ groups occurring in sample H .339 prevented any determination of H -atom positions; however, one H -atom position was located in sample H .347 by a difference Fourier map.

For both compounds, data collection: CrysAlis PRO (Agilent, 2012); cell refinement: CrysAlis PRO; data reduction: CrysAlis PRO; program(s) used to solve structure: SHELXS97 (Sheldrick, 2008); program(s) used to refine structure: SHELXL97 (Sheldrick, 2008); molecular graphics: ATOMS (Dowty, 1993); software used to prepare material for publication: OLEX2 (Dolomanov et al., 2009).

The authors thank Dr Simon Philippo (National History Museum of Luxembourg) for his financial support in the
realization of a PhD thesis, and analyst T. Theye, Stuttgart, Germany, for help with the electron-microprobe analyses. FH thanks the FNRS (Belgium) for the position of 'Chercheur qualifié', and for grant Nos. 1.5.113.05.F and 1.5.098.06.F.

Supplementary data for this paper are available from the IUCr electronic archives (Reference: FN3113). Services for accessing these data are described at the back of the journal.

## Special details

Experimental. Absorption correction: CrysAlisPro, Agilent Technologies, Version 1.171.35.21 (release 20-01-2012 CrysAlis171 .NET) (compiled Jan 23 2012,18:06:46) Empirical absorption correction using spherical harmonics, implemented in SCALE3 ABSPACK scaling algorithm.

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.
Refinement. Refinement of $\mathrm{F}^{2}$ against ALL reflections. The weighted R-factor wR and goodness of fit $S$ are based on $\mathrm{F}^{2}$, conventional $R$-factors $R$ are based on $F$, with $F$ set to zero for negative $F^{2}$. The threshold expression of $F^{2}>2 \operatorname{sigma}\left(F^{2}\right)$ is used only for calculating R-factors(gt) etc. and is not relevant to the choice of reflections for refinement. R-factors based on $\mathrm{F}^{2}$ are statistically about twice as large as those based on F , and R - factors based on ALL data will be even larger.

## Crystal data

$\mathrm{Fe}_{6.23}\left(\mathrm{PO}_{4}\right)_{4.45}\left(\mathrm{HPO}_{4}\right)_{1.55}$
$M_{r}=919.26$
Triclinic, $P \overline{1}$
$a=6.3445$ (2) $\AA$
$b=7.9353$ (3) $\AA$
$c=9.2829(3) \AA$
$\alpha=105.303(3)^{\circ}$
$\beta=108.176(3)^{\circ}$
$\gamma=101.700(3)^{\circ}$
$V=407.03(2) \AA^{3}$

## Data collection

Agilent Xcalibur Eos
diffractometer
Radiation source: Enhance (Mo) X-ray Source
Graphite monochromator
Detector resolution: 16.0087 pixels $\mathrm{mm}^{-1}$
$\omega$ scans
Absorption correction: analytical
[CrysAlis PRO (Agilent, 2012), based on expressions derived by Clark \& Reid (1995)]

## Refinement

Refinement on $F^{2}$
Least-squares matrix: full
$R\left[F^{2}>2 \sigma\left(F^{2}\right)\right]=0.027$
$w R\left(F^{2}\right)=0.085$
$S=1.14$
2378 reflections
170 parameters
0 restraints
Primary atom site location: structure-invariant direct methods
$Z=1$
$F(000)=445.53$
$D_{\mathrm{x}}=3.750 \mathrm{Mg} \mathrm{m}^{-3}$
Mo $K \alpha$ radiation, $\lambda=0.7107 \AA$
Cell parameters from 11179 reflections
$\theta=2.5-30.4^{\circ}$
$\mu=6.13 \mathrm{~mm}^{-1}$
$T=293 \mathrm{~K}$
Isometric crystal, black
$0.15 \times 0.10 \times 0.06 \mathrm{~mm}$
$T_{\text {min }}=0.573, T_{\text {max }}=0.786$
21571 measured reflections
2378 independent reflections
2167 reflections with $I>2 \sigma(I)$
$R_{\text {int }}=0.031$
$\theta_{\text {max }}=30.5^{\circ}, \theta_{\text {min }}=2.5^{\circ}$
$h=-9 \rightarrow 9$
$k=-11 \rightarrow 11$
$l=-13 \rightarrow 13$

Secondary atom site location: difference Fourier map
Hydrogen site location: inferred from
neighbouring sites
$w=1 /\left[\sigma^{2}\left(F_{0}^{2}\right)+(0.0503 P)^{2}+0.6294 P\right]$
where $P=\left(F_{\mathrm{o}}{ }^{2}+2 F_{\mathrm{c}}{ }^{2}\right) / 3$
$(\Delta / \sigma)_{\max }<0.001$
$\Delta \rho_{\text {max }}=0.96$ e $\AA^{-3}$
$\Delta \rho_{\min }=-0.68$ e $\AA^{-3}$

## Special details

Experimental. Absorption correction: CrysAlisPro, Agilent Technologies, Version 1.171.35.21 (release 20-01-2012 CrysAlis171 .NET) (compiled Jan 23 2012,18:06:46) Analytical numeric absorption correction using a multifaceted crystal model based on expressions derived by R.C. Clark \& J.S. Reid. (Clark, R. C. \& Reid, J. S. (1995). Acta Cryst. A51, 887-897)
Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.
Refinement. Refinement of $\mathrm{F}^{2}$ against ALL reflections. The weighted R-factor wR and goodness of fit $S$ are based on $\mathrm{F}^{2}$, conventional R-factors $R$ are based on $F$, with $F$ set to zero for negative $F^{2}$. The threshold expression of $F^{2}>2 \operatorname{sigma}\left(\mathrm{~F}^{2}\right)$ is used only for calculating R-factors(gt) etc. and is not relevant to the choice of reflections for refinement. R-factors based on $\mathrm{F}^{2}$ are statistically about twice as large as those based on F , and R - factors based on ALL data will be even larger.
