Arthritis & Rheumatology

AN OFFICIAL JOURNAL OF THE AMERICAN COLLEGE OF RHEUMATOLOGY

ABSTRACT SUPPLEMENT

2015 ACR/ARHP ANNUAL MEETING

November 6–11, 2015

San Francisco, CA

American College of Rheumatology
Education • Treatment • Research

WILEY

Accreditation Statement: The American College of Rheumatology is accredited by the Accreditation Council for Continuing Medical Education (ACCME) to provide continuing medical education for physicians.

Designation Statement: The ACR designates this live educational activity for a maximum of *54.50 AMA PRA Category 1 Credits*™. Physicians should claim only the credit commensurate with the extent of their participation in the activity.

International Physicians: International physicians who register as part of a group and require *AMA PRA Category 1 Credit(s)*™ must provide the following information to your tour leader: full name, mailing address, telephone and fax numbers and e-mail address. The information will be used to verify your meeting attendance.

The American Medical Association has an agreement of mutual recognition of continuing medical education credit with the European Union of Medical Specialties. International physicians interested in converting *AMA PRA Category 1 Credit*™ to EACCME credit should contact the UEMS.

Health Professionals: Participants may claim hours to receive a Certificate of Participation for an activity designated for *AMA PRA Category 1 Credit(s)*™. For non-CME sessions, attendees may also request a certificate of participation.

Disclosure Policy
It is the policy of the American College of Rheumatology to ensure that its CME activities are independent and free of commercial bias. To ensure content objectivity and balance, and guarantee that the content presented is in the best interest of its learners and the public, the ACR requires that all individuals in a position to control content disclose all relevant financial relationships with any commercial interest if the relationship is financial and occurred within the past 12 months. This includes the relationships of spouse/partners. If there are relationships that create a conflict of interest, these must be resolved in accordance with the ACR's CME Resolution of Conflict policy prior to the participation of the individual in the development or presentation of CME content.

As an educational provider accredited by the Accreditation Council for Continuing Medical Education, the American College of Rheumatology must ensure balance, independence, objectivity and scientific rigor in all its educational activities. Therefore, all those in a position to control content (e.g., speakers and moderators) participating in an ACR-sponsored activity are required to disclose to the planning committee and audience any financial or other relationships including, but not limited to:

1. Stock, stock options or bond holdings in a for-profit corporation or self-directed pension plan
2. Research grants
3. Employment (full or part time)
4. Ownership or partnership
5. Consulting fees or other remuneration (payment)
6. Non-remunerative positions of influence such as officer, board member, trustee or public spokesperson
7. Receipt of royalties
8. Speakers' bureau
9. Other

None: Nothing to disclose

Abstract author disclosures are published online. Any individual who refuses to disclose relevant financial relationships is ineligible to serve as a planning committee member, presenter or author of an ACR CME activity, and cannot have control of, or responsibility for, the development, management, presentation or evaluation of the CME activity.

Abstract Embargo Policy
Accepted abstracts are made available to the public online in advance of the meeting and are published in a special online abstract supplement of the *Arthritis & Rheumatology* journal. Information contained in those abstracts may not be released until the abstracts appear online. Academic institutions, private organizations and companies with products whose value may be influenced by information contained in an abstract may issue a press release to coincide with the availability of an ACR abstract on the ACR website. However, the ACR continues to require that information that goes beyond that contained in the abstract (e.g., discussion of the abstract done as part a scientific presentation or presentation of additional new information that will be available at the time of the meeting) **is under embargo until 4:30 PM Pacific Time on Saturday, November 7, 2015.**

Violation of this policy may result in the abstract being withdrawn from the meeting and other measures deemed appropriate. Authors are responsible for notifying financial and other sponsors about this policy. If you have questions about the abstract embargo policy, please contact the public relations department at pr@rheumatology.org.

Copyright Policy
The annual meeting is a private event. Programs presented at the meeting are for the education of attendees and purchasers of recorded presentations as authorized by the American College of Rheumatology. The information and materials displayed and presented during this meeting are the property of the ACR and the presenter and cannot be photographed, copied, photocopied, transformed to electronic format, reproduced, or distributed without written permission of the American College of Rheumatology and the presenter. Any use of the program content for commercial purposes, which includes, but is not limited to oral presentations, audiovisual materials used by speakers, and program handouts without the written consent of the ACR is prohibited. This policy applies before, during and after the meeting. The ACR will enforce its intellectual property rights and penalize those who infringe upon it.

The names, insignias, logos and acronyms of the ACR, the ARHP and the Rheumatology Research Foundation are proprietary marks. Use of the names in any fashion, by any entity, for any purpose, is prohibited without the express written permission of the American College of Rheumatology. Attendees who have questions about the ACR's copyright policy should contact the public relations department at pr@rheumatology.org.

Media
Credentialed media attend the annual meeting to cover stories for consumer, trade and other media outlets, and are easily identified by their black press ribbons. Media has access to all general sessions and limited access (at the discretion of speakers) to Meet the Professor and Workshop sessions. Media may use hand-held audio recorders and still cameras; moving video recording is also permitted with the permission of the presenter(s). **The exception to this policy is that no photos or video are allowed in the Exhibit Hall and no photos or video are allowed in the Poster Hall without permission from the poster presenter.** Press who would like general photos of the Exhibit Hall can obtain these after the meeting from the ACR. Attendees who have questions about the ACR's media policies should contact the public relations department at pr@rheumatology.org.

Photographs and Video Recording Policy
As a courtesy to our presenters, ACR policy does not permit photographs or recordings during educational sessions, including poster sessions. The only exception to this is for registered media, who should review their registration materials for more information.

Abstract Reprint (Reproduction) Policy
Copyright law covers all annual meeting abstracts published by the American College of Rheumatology. All rights reserved. No abstracts may be reproduced in any form or by any means, except as permitted under section 107 and 108 of the 1976 United States Copyright Act, without the prior permission of the publisher.

For the purposes of this statement, the term **"ACR Abstracts"** refers to all annual meeting abstracts as published in *Arthritis & Rheumatology* and posted online, including the abstracts accepted for presentation during ARHP sessions and the late-breaking category.

For the purposes of this statement, the term **"ACR Posters"** refers to the accepted abstract **POSTER PRESENTATIONS** as presented in the poster hall during the annual meeting. **This does not include abstract text published in the online supplement of *Arthritis & Rheumatology*.** All ACR Posters are the property of the ACR or the presenting author and cannot be reproduced or distributed without written permission from the ACR and the presenting author.
For the purposes of this statement, the term "reproduce" includes all forms of reproduction including, but not limited to, print, electronic and photographed formats.

For the purposes of this statement, the term "presenting author" refers to the author who is designated as the individual who will present the work during the ACR annual meeting, as identified through the abstract submission process.

Abstract Reprint Approval Process
- Excerpts of **ACR Abstracts** or **ACR Poster Presentations** in their entirety may not be reproduced without the prior written permission of the publisher.
- Permission requests for abstract content and other permission inquiries should be addressed to:
  Permissions Department
  c/o John Wiley & Sons, Inc.
  111 River Street
  Hoboken, NJ 07030
  Fax: (201) 748-6008
  wiley.com/go/permissions
- Commercial entities seeking permission to reprint must obtain all materials from the author and/or publisher John Wiley & Sons, Inc.
- ACR cannot provide any materials.

Reproducing ACR Abstracts and ACR Posters for Dissemination Prior to the Annual Meeting
- Requests to reproduce abstracts for dissemination prior to the annual meeting **will not be approved.**
- Per the **ACR Embargo Policy**, academic institutions, private organizations and companies with products whose value may be influenced by information contained in an abstract may issue a press release to coincide with the availability of an abstract online.
- Permission to issue a press release does not require ACR approval. However, it must comply with the **ACR Embargo Policy**; violation of this policy may result in the abstract being withdrawn from the meeting or other measures deemed appropriate.
- For more information regarding press releases, please contact the ACR Public Relations Department at pr@rheumatology.org.

Reproducing ACR Abstracts and ACR Posters for Dissemination During the Annual Meeting
Following approval (see approval process above), an exhibiting organization may:
- Disseminate copies of individual ACR Abstracts from its exhibit space. Booklets of abstracts (e.g., two or more) may **not** be produced.
- Disseminate information summaries (title/date/time/poster number) of ACR Abstracts from its exhibit space.
- Summaries may not reference company or product names. Requests for approval must be submitted in writing to abstractreprints@rheumatology.org.
- Presenting authors may disseminate individual copies of their ACR Poster during their assigned poster presentation time.
- Dissemination must be limited to the area directly in front of their assigned poster space and may not interfere with other poster presentations.
- An electronic copy of the poster may be provided via a QR code generated by the presenter and included on the poster

Reproducing ACR Abstracts and ACR Posters for Dissemination After the Annual Meeting
ACR Abstracts
Following approval (see approval process above), the ACR permits ACR Abstracts (i.e., all abstract content published in the online supplement) to be reprinted and disseminated following the annual meeting.

- Booklets of abstracts (e.g., two or more) must include the following statement on the front of the booklet: ***Abstract(s) reprinted from the ACR/ARHP Annual Meeting held November 6-11, 2015. The American College of Rheumatology does not guarantee, warrant, or endorse any commercial products or services. Reprinted by (insert name of supporting company).***
- Booklets cannot contain corporate or product logos or any advertisements. No exceptions.

ACR Poster Presentations

Following approval from the presenting author and ACR, copies of actual ACR poster presentations (i.e. images of the poster presentation hung in the poster hall) may be reproduced.

- Reprint requests for the actual poster abstract text published in the *Arthritis & Rheumatology* supplement are considered **ACR Abstracts** and must submitted to Wiley (see approval process above).
- Requests to reproduce individual **ACR poster or booklets of poster presentations** (e.g., two or more) must be submitted via e-mail to abstractprints@rheumatology.org.
- Poster reproduction requests must include the following:
    - Abstract ID Number
    - Abstract Title
    - Presenting Author's Name
    - A copy of Presenting Author's written approval (Please Note: An e-mail approval from Presenting Author is acceptable)
- **IMPORTANT: The ACR does not retain and cannot provide poster presentation images.**
- The following statement must be listed under each Poster reprint: ***Poster reprinted from the ACR/ARHP Annual Meeting held November 6-11, 2015. The American College of Rheumatology does not guarantee, warrant, or endorse any commercial products or services. Reprinted by (insert name of supporting company).***

Use of the ACR Disclosure Key

It is suggested when referencing disclosures in the reprints, that the ACR's disclosure key be added to provide adequate context for abstracts:

None: Nothing to disclose

1. Stock, stock options or bond holdings in a for-profit corporation or self-directed pension plan
2. Research grants
3. Employment (full or part-time)
4. Ownership or partnership
5. Consulting fees or other remuneration (payment)
6. Non-remunerative positions of influence such as officer, board member, trustee or public spokesperson
7. Receipt of royalties
8. Speakers' bureau
9. Other

Use of the ACR Name

- The names, insignias, logos and acronyms of the ACR, the ARHP and the Rheumatology Research Foundation are proprietary marks.
- Use of the names in any fashion, by any entity, for any purpose, is prohibited without the written permission of the ACR.

Use of the ACR Scientific Program Content

- Information displayed or presented at all sessions during the annual meeting is the property of the ACR or the presenter. Information may not be recorded, photographed, copied, photocopied, transferred to electronic format, reproduced or distributed without the written permission of the ACR and the presenter.
- Any use of the program content, which includes but is not limited to oral presentations, audiovisual materials used by speakers and program handouts, without the written consent of the ACR is prohibited.
- This policy applies before, during and after the meeting.
- The ACR will enforce its intellectual property rights and penalize those who infringe upon it.

Table of Contents

ACR/ARHP ABSTRACT SESSIONS

SUNDAY, NOVEMBER 8, 2015

8:30 AM - 4:00 PM
ACR Poster Session A
(#1-895)

11:00 AM - 12:30 PM
ACR Plenary Session I
Discovery 2015
(#896-901)

2:30 - 4:00 PM
ACR Concurrent Abstract Sessions
(#901-906) Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis
(#907-912) Epidemiology and Public Health I: Rheumatoid Arthritis Comorbidities and Mortality
(#913-918) Fibromyalgia: Insights into Diagnostic Criteria and Symptom Epidemiology
(#919-924) Health Services Research I: Digital Health and Patient, Provider Factors in Rheumatic Disease
(#925-930) Imaging of Rheumatic Diseases I: Ultrasound
(#931-936) Innate Immunity and Rheumatic Disease
(#937-942) Miscellaneous Rheumatic and Inflammatory
(#943-948) Muscle Biology, Myositis and Myopathies I
(#949-954) Osteoarthritis – Clinical Aspects: Treatments and Epidemiology
(#955-960) Pediatric Rheumatology – Clinical and Therapeutic Aspects I: Juvenile Idiopathic Arthritis
(#961-966) Rheumatoid Arthritis – Human Etiology and Pathogenesis I
(#967-972) Rheumatoid Arthritis-Small Molecules, Biologics and Gene Therapy I: Biologics
(#973-978) Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment: Treatment of Ankylosing Spondylitis
(#979-984) Spondylarthropathies Psoriatic Arthritis – Pathogenesis, Etiology
(#985-990) Systemic Lupus Erythematosus – Clinical Aspects and Treatment I: Epidemiology and Prognosis
(#991-996**)** T cell Biology and Targets in Autoimmune Disease I

ARHP Concurrent Abstract Session
(#997-1002) ARHP: Exemplary Abstracts

4:30 - 6:00 PM
ACR Concurrent Abstract Sessions
(#1003-1008) Osteoarthritis – Clinical Aspects I: Imaging and Epidemiology
(#1009-1014) Education
(#1015-1020) Pain: Basic Aspects
(#1021-1026) Pediatric Rheumatology – Pathogenesis and Genetic
(#1027-1032) Quality Measures and Quality of Care
(#1033-1038) Rheumatoid Arthritis – Animal Models I
(#1039-1044) Rheumatoid Arthritis – Clinical Aspects I – Treatment Advances and Strategies
(#1045-1050) Rheumatoid Arthritis-Small Molecules, Biologics and Gene Therapy II: Small Molecular Targeted Therapies
(#1051-1056) Sjögren's Syndrome I: Basic Insights
(#1057-1062) Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment: Clinical Aspects and CoMorbidities
(#1063-1068) Systemic Lupus Erythematosus – Clinical Aspects and Treatment II: Patient-Reported Measures, Outcomes and Reporting
(#1069-1074) Systemic Lupus Erythematosus – Human Etiology and Pathogenesis: Genetics, Gene Expression, and Epigenetics
(#1075-1080) Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics I
(#1081-1086) Vasculitis I

4:30-6:00 PM
ACR/ARHP Combined Abstract Session
(#1087-1092) ACR/ARHP Combined Abstract Session: Rehabilitation

MONDAY, NOVEMBER 9, 2015

8:30 AM - 4:00 PM
ACR/ARHP Poster Session B
(#1093-1993)

11:00 AM - 12:30 PM
ACR Plenary Session II
Discovery 2015
(#1994-1999)

2:30 - 4:00 PM
ACR Concurrent Abstract Sessions
(#2000-2005) Antiphospholipid Syndrome: Recent Findings
(#2006-2011) Biology and Pathology of Bone and Joint: Osteoarthritis Pathogenesis
(#2012-2017) Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis II
(#2018-2023) Epidemiology and Public Health II: RA and Lifestyle Factors
(#2024-2029) Imaging of Rheumatic Diseases II: MRI, PET and CT
(#2030-2035) Infection-related Rheumatic Disease
(#2036-2041) Miscellaneous Rheumatic and Inflammatory Diseases Oral Session II
(#2042-2047) Pediatric Rheumatology – Clinical and Therapeutic Aspects II: Pediatric Systemic Lupus Erythematosus
(#2048-2053) Rheumatoid Arthritis (RA) – Clinical Aspects II: Infection, Malignancy and Other Comorbidites in RA
(#2054-2059) Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy III: Biosimilars
(#2060-2065) Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment: Clinical Aspects
(#2066-2071) Systemic Lupus Erythematosus – Clinical Aspects and Treatment III: Biomarkers
(#2072-2077) Systemic Lupus Erythematosus – Human Etiology and Pathogenesis: Modulators of Disease

ARHP Concurrent Abstract Session
(#2078-2083) ARHP II: Lupus

4:30 - 6:00 PM
ACR Concurrent Abstract Sessions
(#2084-2089) Biology and Pathology of Bone and Joint: Bone Remodeling
(#2090-2095) Epidemiology and Public Health III: Risk Factors, Treatment and Outcomes of Gout and Osteoarthritis
(#2096-2101) Genetics, Genomics, and Proteomics
(#2102-2107) Health Services Research II: Rheumatoid Arthritis Treatment and Healthcare Utilization
(#2108-2113) Metabolic and Crystal Arthropathies I: Therapeutics
(#2114-2119) Orthopedics, Low Back Pain and Rehabilitation
(#2120-2125) Reproductive Issues in Rheumatic Disorders: Basic and Clinical Aspects
(#2126-2131) Rheumatoid Arthritis – Clinical Aspects III: Cardiovascular Disease and RA
(#2132-2137) Rheumatoid Arthritis – Human Etiology and Pathogenesis II
(#2138-2143) Rheumatoid Arthritis – Small Molecules, Biologics and Gene Therapy IV: Safety of Targeted Therapies
(#2144-2149) Spondylarthropathies (SpA) and Psoriatic Arthritis (PsA) – Clinical Aspects and Treatment: Treatment of PsA and SpA
(#2150-2155) Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics I
(#2156-2161) Vasculitis II

ACR/ARHP Combined Abstract Session
(#2162-2167) ACR/ARHP Combined Abstract Session: Epidemiology and Pubic Health

ARHP Concurrent Abstract Session
(#2168-2173) ARHP III: Epidemiology and Public Health

TUESDAY, NOVEMBER 10, 2015

8:30 AM - 4:00 PM
ACR/ARHP Poster Session C
(#2174-3073)

11:00 AM - 12:30 PM
ACR Plenary Session III
Discovery 2015
(#3074-3079)

2:30 - 4:00 PM
ACR Concurrent Abstract Sessions
(#3080-3085) *2015 Rheumatology Research Foundation Edmond L. Dubois, MD Memorial Lectureship:* Systemic Lupus Erythematosus – Basic Science
(#3086-3091) Fibromyalgia: Clinical Issues
(#3092-3097) Pediatric Rheumatology – Clinical and Therapeutic Aspects III: Miscellaneous Pediatric Rheumatic Diseases
(#3098-3013) Rheumatoid Arthritis – Clinical Aspects IV: Biomarkers, Disease Progression and Treatment Response
(#3104-3109) Rheumatoid Arthritis – Human Etiology and Pathogenesis III
(#3110-3115) Rheumatoid Arthritis-Small Molecules, Biologics and Gene Therapy V: Immunogenecity
(#3116-3121) Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment: Psoriatic Arthritis – Comorbidities
(#3122-3127) Systemic Lupus Erythematosus – Clinical Aspects and Treatment V: Neuropsychiatric Lupus
(#3128-3133) Systemic Sclerosis, Fibrosing Syndromes and Raynaud's – Pathogenesis, Animal Models and Genetics II
(#3134-3139) Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics II

(#3200-3205) Sjögren's Syndrome II: Clinical Discoveries
(#3206-3211) Spondylarthropathies and Psoriatic Arthritis – Clinical Aspects and Treatment: Clinical Aspects, Imaging and Biomarkers
(#3212-3217) Systemic Lupus Erythematosus–Animal Models
(#3218-3223) Systemic Lupus Erythematosus–Clinical Aspects and Treatment VI: Novel Therapies
(#3224-3229) Vasculitis IV

ARHP Concurrent Abstract Session
(#3230-3235) ARHP IV: Clinical Practice and Patient Care

WEDNESDAY, NOVEMBER 11, 2015

9:00-10:30 AM
ACR Concurrent Abstract Sessions
(#3236-3246) Rheumatoid Arthritis (RA) – Clinical Aspects VI: Death Be Not Proud – Mortality and Treatment Outcomes in RA *(Includes 2014 Lee C. Howley, Sr. Prize for Arthritis Research Introductory Talk)*

ARHP Concurrent Abstract Session
(#3241-3246) ARHP V: Physical Activity

11:00 AM - 12:30 PM
ACR Concurrent Abstract Sessions
(#3247-3252) Pain: Clinical Aspects

(#3253-3258) Rheumatoid Arthritis – Clinical Aspects VII: Disease Activity and Updates in Measurement
(#3259-3264) Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's – Clinical Aspects and Therapeutics III

ARHP Concurrent Abstract Session
(#3265-3270) ARHP VI: Physical Function and Disability

ACR LATE-BREAKING ABSTRACT SESSIONS

TUESDAY, NOVEMBER 10, 2015

8:30 AM - 4:00 PM
ACR/ARHP Poster Session C
(#7L-15L) ACR Late-breaking Abstract Poster Presentations*

4:30 - 6:00 PM
ACR Concurrent Abstract Session
(#1L-6L) ACR Late-breaking Abstract Oral Presentations*

**Please Note: ACR Late-breaking abstracts are listed below in numberic order instead of presentation order.*

Abstract Number: 1

The Integrin Very Late Antigen-4 Plays a Key Role in the Recruitment of B Cells at the Inflammatory Foci

Estefanía Armas-González[1], Ana Díaz-Martín[2], María Jesús Domínguez-Luis[3], María Teresa Arce-Franco[2] and Federico Díaz-González[4], [1]Universidad de La Laguna, Pharmacology Department, Tenerife, Spain, [2]Hospital Universitario de Canarias, Rheumatology Service, Tenerife, Spain, [3]CIBICAN, Center of Biomedical Research of the Canary Islands, University of La Laguna, Tenerife, Spain, [4]Investigation Unit, Sociedad Española de Reumatológía, Madrid, Spain

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Experimental data suggest that B cells must migrate and accumulate into the synovial membrane to exert their pathogenic role in rheumatoid arthritis (RA). Leukocyte extravasation requires a number of coordinated adhesives events between circulating leukocytes and endothelial cells, a process known as the adhesion cascade. While the molecules involved in the sequential steps of the adhesion cascade for neutrophils and T lymphocytes have been well established, little is known about this process in B cells.

Objective: To determine the adhesion molecules involved in the interactions between B cells and endothelium under dynamic condition resembling those of postcapillary venules during the inflammatory response.

Methods:

The surface expression levels of very late antigen (VLA)-4, intercellular adhesion molecule (ICAM)-1 and L-selectin were assessed by double-colour staining flow cytometry analysis in CD20 + cells from the peripheral blood (PB) and synovial fluid (SF), simultaneously obtained from 10 RA and 8 psoriatic arthritis (PsA) patients. Dynamic interactions between B cells negatively immunoselected from buffy coats, and 12h TNF-a-activated human umbilical vein endothelial cell (HUVEC) monolayers were studied in a two-parallel plate flow chamber. To study molecules involved in the B-cells-HUVEC dynamic interaction, B cells were preincubated with monoclonal antibodies (mAbs) anti-CD20 or blocking mAbs anti- L-selectin, VLA-4 and ICAM-1; and HUVEC, with anti-vascular adhesion molecule (VCAM)-1.

Results:

Flow cytometry analysis showed that the VLA-4 surface expression level in B-cells from SF in both RA (105±30%) and PsA (135±45%) patients was not significantly different with respect to PB (considered 100%). Interestingly, the surface expression level of ICAM-1 was significantly higher in SF relative to PB, in both RA (280±85%;) and PsA (300±65%) patients, while L-selectin surface expression diminished in SF compared to PB in RA (40±5%) and PsA (45±5%). In flow chamber experiments, no differences were observed in the process of rolling when B cells were incubated with anti-CD20 antibodies, or with blocking mAbs anti-L-selectin and anti-ICAM-1 with respect to cells incubated with mAb matching controls. However, the presence of blocking anti-VLA-4 mAb or anti-VCAM-1 mAbs abrogated the interaction of B cells with activated endothelial cells.

Conclusion:

These results suggest that 1) B-cells with increased ICAM-1 expression and decreased L-selectin expression are preferentially recruited in the inflamed synovial microenvironment; and 2) the integrin VLA-4, vis-à-vis its endothelial counter receptor VCAM-1, plays a key role in the initial process of B-cell extravasation to inflammatory foci.

Abstract Number: 2

The Neutrophil Protein S100A12 Has Stronger Associations with a Comprehensive Ultrasound Score of Synovitis Than Vascular Endothelial Growth Factor in a Longitudinal Study of Rheumatoid Arthritis Patients

Hilde Haugedal Nordal[1,2] and Hilde Berner Hammer[3], [1]Broegelmann Research Laboratory, Department of Clinical Science, University of Bergen, Bergen, Norway, [2]Department of Rheumatology, Haukeland University Hospital, Bergen, Norway, [3]Department of Rheumatology, Diakonhjemmet Hospital, Oslo, Norway
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

S100A12, a neutrophil protein, has proinflammatory effects on immune cells and can activate endothelial cells. The mechanism of action suggests vascular endothelial growth factor (VEGF) as a marker of synovial neovascularization in rheumatoid arthritis (RA). S100A12 and VEGF have both been associated with disease activity in RA. We wanted to compare S100A12 and VEGF as biomarkers in a large longitudinal study of RA patients, and explore their association with inflammatory activity expressed as synovial power Doppler (PD) scores.

Methods:

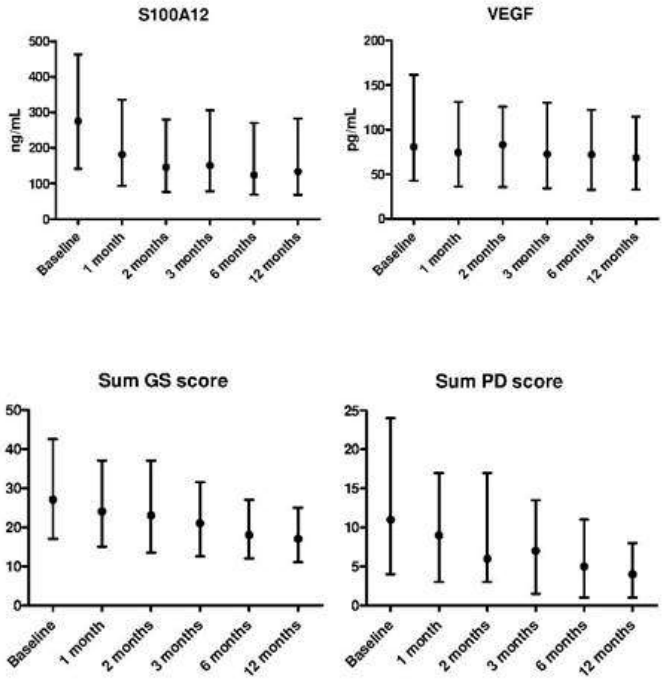
A total of 141 patients with RA (all met the ACR 1987 criteria, 81% women, mean (SD) age 52 (12) years, 79% anti-CCP positive) were examined clinically and with ultrasound (US) before starting biologic treatment (67% anti-tumor necrosis factor therapy) and after 1, 2, 3, 6 and 12 months. Inflammation of wrist (radiocarpal, intercarpal, radioulnar), metacarpophalangeals 1-5, proximal interphalangeals 2-3, elbow, knee, ankle, metatarsophalangeals 1-5, extensor carpi ulnaris and tibialis posterior tendons bilaterally, expressed as gray scale (GS) and PD scores, was scored semiquantitatively 0-3. C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) were analyzed by in-house methodology. Sera from all examinations were frozen at -80 ˚C and S100A12 was analyzed by an enzyme-linked immunosorbent assay and VEGF by multiplex analysis. A total of 141 blood donors were controls (81% women, mean (SD) age 52 (12) years). Mann-Whitney test was used to evaluate differences between patients and controls, Wilcoxon signed rank test to study changes from baseline and Spearman's rank test for correlation analysis.

Results:

At baseline, median (interquartile range) values of S100A12 were 275 (142-463) ng/mL in patients and 129 (75-222) ng/mL in controls ($p<0.0001$), while VEGF values were 81 (43-162) pg/mL in patients and 68 (46-108) pg/mL in controls ($p=0.08$). S100A12, VEGF, CRP, ESR, DAS28, sum GS and PD scores were reduced from baseline at all time points (all $p<0.0001$). S100A12 correlated with ESR and CRP at all times ($r=0.23$-0.56, $p\leq0.003$) except with CRP after 12 months. VEGF did not correlate with ESR/CRP at any examination, except with CRP at 2 months ($r=0.17$, $p=0.05$). S100A12 correlated with DAS28 at all times ($r=0.27$-0.35, $p\leq0.001$), with sum GS scores ($r=0.26$-0.39, $p\leq0.002$) except after 12 months, and with sum PD scores at all times ($r=0.17$-0.42, $p\leq0.04$). No correlations were found between VEGF and DAS28. VEGF correlated with sum GS scores ($r=0.18$-0.21, $p\leq0.03$) before 12 months and with sum PD scores ($r=0.17$-0.19, $p\leq0.05$) only before 3 months.

Conclusion:

S100A12 was a stronger biomarker than VEGF in RA patients treated with biologic medication during one year, having significant associations with clinical and US examinations. VEGF was expected to be associated with PD activity, but only weak correlations were presently found.



Figure

Median values with interquartile range (error bars) of the inflammatory markers S100A12 and vascular endothelial growth factor and sum ultrasound scores in patients during one year after starting with biologics. All values are significantly lower after baseline ($p<0.0001$)

VEGF= vascular endothelial growth factor, GS = gray scale, PD = power Doppler

Cytokine Production Patterns in Osteoporosis Suggest a Pro-Inflammatory Bias

Khaled Al-Jarallah[1], Fawaz Azizieh[2], Diaa Shehab[3], Raj Reghupathy[4] and Renu Gupta[5], [1]Medicine, Kuwait University, Kuwait, Kuwait, [2]Gulf University for Science and Technology, Kuwait, Kuwait, [3]Faculty of Medicine, Kuwait University, Kuwait, Kuwait, [4]Microbiology, Faculty of Medicine, Kuwait University, Kuwait, Kuwait, [5]Radioliogy, Faculty of Medicine, Kuwait University, Kuwait, Kuwait

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Considering the extent, predicted growth rates, and growing economic impact on health care, osteoporosis is a significant problem. In addition to hormones and nutrients, the immune system is suspected to play key roles in osteoporosis, primarily through the involvement of pro-inflammatory cytokines. Cytokines play important roles in the regulation of normal bone remodeling, as well as in bone resorption and formation during pathologic bone remodeling. The objective of this study was to measure levels of osteoclastogenesis stimulator cytokines TNF-a, IL-6, IL-12, IL-17 and osteoclastogenesis inhibitor cytokines IFN-g, IL-4, IL-10, IL-13 produced by peripheral blood mononuclear cells (PBMC) from postmenopausal osteoporotic women and normal healthy controls.

Methods:

The study population included 36 postmenopausal women that were grouped based on their bone mineral density (BMD) into normal (n=12), osteopenia (n=16) and osteoporosis (n=8). PBMC from these subjects were stimulated with the mitogen phytohemagglutinin and culture supernatants collected after incubation were used to measure the levels of 8 cytokines using the Multiplex system (Millipore) read on the Magpex ELISA platform.

Results:

PBMC from osteopenic women produced significantly higher levels of IL-6 and IL-17A as compared to women with normal BMD (p=0.037, 0.026), while osteoporotic women produced significantly lower levels of IL-4 and IL-13 as compared to women with normal BMD (p=0.013, 0.048) as well as women with osteopenia (p=0.049, 0.006), which is suggestive of a decreased anti-inflammatory or increased pro-inflammatory cytokine bias. Furthermore, osteoporotic women produced higher levels of the pro-inflammatory cytokine TNF-a (p=0.021), and lower levels of the anti-inflammatory cytokine IL-10 (p=0.033) compared to osteopenic women. Ratios of osteoclastogenesis stimulator cytokines to osteoclastogenesis inhibitor cytokines suggest a dominance of osteoclastogenesis stimulator cytokines in postmenopausal women with lower BMD.

Conclusion: These data are suggestive of a bias towards increased osteoclastogenesis stimulator cytokines and pro-inflammatory cytokines in women with osteoporosis.

The Influence of Adipokines on the Interaction of Rheumatoid Arthritis Synovial Fibroblasts with Endothelial Cells

Rebecca Hasseli[1], Klaus W. Frommer[2], Thomas Dr. Umscheid[3], Markus Prof. Dr. Schönburg[4], Stefan Rehart[5], Ulf Müller-Ladner[2] and Elena Neumann[2], [1]Justus-Liebig-University of Giessen, Kerckhoff-Klinik, Bad Nauheim, Germany, [2]Internal Medicine and Rheumatology, Justus-Liebig-University of Giessen, Kerckhoff-Klinik, Bad Nauheim, Germany, [3]William Harvey Klinik; Bad Nauheim, Germany, Bad Nauheim, Germany, [4]Department of Cardiac Surgery; Kerckhoff-Klinik, Bad Nauheim, Bad Nauheim, Germany, [5]Orthopedics and Trauma Surgery, Markus-Hospital, Frankfurt, Germany

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Rheumatoid Arthritis (RA) is a systemic chronic inflammatory disease. Adipose tissue, being an endocrine organ, plays an important role in inflammatory processes. Adipokines are immunomodulatory factors mainly secreted by the adipose tissue. In previous studies we could show that RA synovial fibroblasts (SF) are able to migrate long distances in vivo via the vasculature. Therefore, we analysed the role of adipokines on RASF and endothelial cell (EC) adhesion and interaction. Static and dynamic adhesion as well as the expression of selected adhesion molecules on RASF and EC after stimulation with adipokines (adiponectin, visfatin, resistin), glucocorticoids and methotrexate (MTX) were evaluated.

Methods:

Primary RASF and EC were stimulated with adiponectin (10 µg/ml), visfatin (100 ng/ml) and resistin (20 ng/ml) as well as with MTX (1.5 µM) and the glucocorticoids prednisolone (1 µM) and dexamethasone (1 µM). The interaction of both cell types under static conditions using a cell-to-cell-binding assay was analyzed. RASF adhesion to E-selectin was studied in a flow adhesion assay (flow rates: 18.4/30.5/60.5 ml/h) as flow conditions are required for selectins to be obtain their active conformation. The expression of selected adhesion molecules on RASF and EC after adipokine./MTX/glucocorticoid stimulation was analyzed by real-time PCR.

Results:

Prednisolone stimulation down-regulated mRNA expression of VCAM-1 (-3.3-fold) in RASF (n=3), which was also reduced after dexamethasone stimulation (8.3 fold). TNF-α used as proinflammatory control increased ICAM-1 mRNA expression (46.5 fold), while P selectin mRNA expression (-7.7-fold) was decreased in EC (n=3).Under static conditions, the adipokines increased adhesion of RASF to EC (Ad: 37%, Vis: 23%, Res: 32%; n=6), while prednisolone and MTX caused a minor decrease (-7% for both; n=4). Dexamethasone did not change RASF adhesion to EC under static conditions. Under flow conditions, visfatin increased RASF adhesion to E-selectin (28%/87%/29%;

n=3 for each flow rate), while dexamethasone decreased their adhesion to E-selectin (-33%/-35%/-41%; n=3 for each flow rate).

Conclusion:

Adipokines have an influence on the cellular expression of adhesion molecules on RASF and EC as well as their interaction. Adipokines increase adhesion of RASF to EC and therefore influence RASF migration. Therapeutics such as glucocorticoids and MTX antagonized these effects, which may represent a mechanism of the protective effects of these drugs observed in patients. Evaluation of the immunomodulatory role of adipokines and therapeutics in the pathogenesis and progression of RA may help to understand new metabolic-inflammatory pathways active in chronic inflammatory diseases such as RA.

Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Angiogenesis plays an important role in the pathogenesis of psoriasis. TNFa is an essential mediator that induces the expression of VEGF, which activates the endothelial cells, promoting angiogenesis.

Our aims were: **a)** to quantify the angiogenesis and the VEGF expression in healthy skin and in plaque psoriasis before and 6 months after starting adalimumab (ADA), and **b)** to correlate these parameters with clinical assessment scales.

Methods:

Prospective study of a series of patients with moderate/severe psoriasis who completed 6 months of treatment with

ADA.Two biopsies of healthy skin and of plaque psoriasis were performed, one before starting ADA and the other was performed at 6 months. In each sample, an immunohistochemical study to VEGF, TNF‡ and CD31 was performed. Quantification of angiogenesis (CD31) was analyzed using an Automated Cellular Imaging sistem (DAKO).

Results:

Twenty three patients (13 W/10 M; mean age of 37±12 years) with a mean evolution of psoriasis of 19,9±13.1 years were included. Six patients also had (26%) arthritis. Comparison of clinical and histological parameters at baseline and at 6 months of treatment with ADA is shown in TABLE. At the baseline visit the following values were significantly higher in skin biopsy with psoriasis than in healthy skin: **a)** levels of angiogenesis (endothelial area positive-CD31): 2274.2±833.1 vs 810.6±425.2 ($p<0.001$); **b)** positive expression of VEGF: 87% vs 8.7% ($p<0.001$) y **c)** positive expression of TNF_: 82.6 vs 4.3% ($p<0.001$). A significant clinical and histological improvement in the expression of TNF, VEGF and angiogenesis was observed after treatment with ADA**.** The clinical parameters of psoriasis and angiogenesis (VEGF, TNF and CD31) only showed a significant correlation between the improvement in PASI and basal CD31. Thus, patients with lower baseline PASI had a greater response to therapy ($r=0.590$; $p<0.003$).

Conclusion:

In this series, ADA reduces the levels of VEGF and angiogenesis in plaque psoriasis. This fact seems to suggest that a part of their effect is due to inhibition of angiogenesis.

TABLE

	Baseline	**month 6**	**p**

The Novel Role of Corticotropin-Releasing Hormone and Urocortin1 on

Sjogren's Syndrome

Yuichi Yokoyama[1], Kiyoshi Matsui[2], Sachie Kitano[2], Tetsuya Furukawa[3], Masahiro Sekiguchi[2], Naoto Azuma[2], Masayasu Kitano[2], Shinichiro Tsunoda[2], Tsuyoshi Iwasaki[4] and Hajime Sano[2], [1]Division of Rheumatology, Department of internal medicine, Hyogo College of Medicine, Nishinomiya, Japan, [2]Division of Rheumatology, Department of Internal Medicine, Hyogo College of Medicine, Nishinomiya, Japan, [3]Division ofRheumatology Department of internal medicine, Hyogo College of Medicine, Nishinomiya, Japan, [4]Department of Pharmacy, Hyogo University of Health Sciences, Kobe, Japan

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Corticotropin releasing hormone (CRH) is the principal regulator of hypothalamus pituitary adrenal (HPA) axis. CRH and urocortin1 (UCN1) are member of the CRH family. These biological actions are mediated via CRH type1 receptor (CRHR1) and CRH type2 receptor (CRHR2). CRH and UCN1 are expressed in the cells of the immune system. We previously reported that CRH closely connected with the pathogenesis of RA. However, the function of CRH and UCN1 are poorly understood in autoimmune disease. On the other hand, recently, it was reported that IL-21 plays an important role on Sjogren's syndrome (SS). The aim of this study is to reveal the biological function of CRH and UCN1 inducing IL-21 in SS.

Methods:

We investigated the expression of CRH, UCN1, CRHR1 and CRHR2 by immunohistochemistry (IHC) and reverse transcription with the polymerase chain reaction (RT-PCR) in the salivary gland of patients with SS. We analyzed the function of CRH and UCN1 by NS-SV-DC cell lines, which are immortalized normal salivary gland ductal cells established by transfection with SV40. We examined the mRNA expression of CRH, UCN1, CRHR1, and CRHR2 in NS-SV-DC cell lines by RT-PCR. NS-SV-DC cell lines were cultured in the absence or presence of CRH (10-100nM) or UCN1 (10-100nM). After 24h of culture,IL-21 and IL-23 levels were measured by Enzyme-linked immune Sorbent assay (ELISA). We examined the mRNA expression of IL-21, IL-21 receptor, IL-23α and IL-23 receptor in NS-SV-DC stimulated by CRH or UCN1.

Results:

We detected the expression of mRNA and the protein level of CRH, UCN1 and CRHR2 in the SS patient`s salivary gland by RT-PCR and IHC staining. Moreover we found the mRNA expression of CRH, UCN1 and CRHR2 in NS-SV-DC by RT-PCR. The culture supernatants stimulated by CRH or UCN1 in NS-SV-DC cell lines showed that IL-21 and IL-23 levels increased in a dose-dependent manner by ELISA. To stimulate NS-SV-DC cell lines by CRH and UCN1, we investigated the increasing mRNA expression of IL-21 and IL-23α by RT-PCR.

Conclusion:

The known function of IL-21 is facilitating differentiation, proliferation, survival of both B and T cells. IL-21 is elevated in the serum of patients with SS and is expressed by the lymphocytic infiltrating salivary gland. This is the first report that CRH and UCN1 were detected in salivary gland in patient with SS, and that CRH and UCN1 induce IL-21 and IL-23 production in NS-SV-DC cell lines. These results indicate that CRH or UCN1 play a crucial role of the IL-21 or IL-23 induction in salivary gland in pathogenesis of SS. Regulated IL-21 induction via CRH and UCN1 signal may be a novel therapeutic target in SS.

Influence of TNF on Anti-Inflammatory Tyrosine-Hydroxylase-Positive Synovial Cells in Rheumatoid Arthritis and Osteoarthritis

Zsuzsa Jenei-Lanzl, Markus Herrmann and Rainer Straub, Laboratory of Experimental Rheumatology and Neuroendocrine Immunology, Department of Internal Medicine, University Hospital Regensburg, Regensburg, Germany

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

In recent studies we demonstrated that catecholamines produced by tyrosine-hydroxylase-positive (TH+) synovial cells are able to mediate anti-inflammatory effects in rheumatoid arthritis (RA).[a] TNF has been shown to be toxic to catecholaminergic neurons in Parkinson´s disease (PD).[b] Therefore, the aim of this study was to analyze whether TNF exhibits also inhibitory effects on TH in the chronic inflamed synovium.

Methods:

Human mixed synovial cells were isolated from RA and osteoarthritis (OA) patients and “induced TH+ cells” (iTH+) were generated from human mesenchymal stem cells (MSC) as described previously.[a] Cells were cultivated under hypoxia (1% O_2), because the microenvironment of inflamed joints is hypoxic. TNF and the anti-TNF etanercept were administered in different concentrations and combinations. Expression and activity of TH was analyzed by immunofluorescence and TH activity assay. In addition, catecholamines were quantified via HPLC and the quality of catecholaminergic differentiation was investigated staining VMAT2, Nurr1, and βIII tubulin as markers.

Results:

In mixed synovial cell culture, TNF inhibited TH activity and catecholamine synthesis compared to untreated control in both OA and RA. In general, TNF did not disturb catecholaminergic differentiation of MSCs to iTH+ cells. However, TH staining of TNF-treated iTH+ cells was weaker, the TH activity and the amount of produced catecholamines lower. Similarly, expression of VMAT2, Nurr1, and βIII tubulin decreased after TNF-treatment in iTH+ cells. The effects of TNF were reversed by etanercept in both synovial cell and iTH+ cell cultures.

Conclusion:

This study shows TNF inhibition of TH expression and activity in TH+ synovial cells and differentiating iTH+ cells leading to the decrease of anti-inflammatory acting catecholamines. This might be a reason why resident synovial TH+ cells are not able to unfold their anti-inflammatory effects in RA.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: BAY 11-7085 is an inhibitor of IκBα phosphorylation that leads to NF-κB inactivation and downregulation of inflammation in mouse model of asthma, in articular chondrocytes as well as in synovial fibroblasts. Proliferation of synovial fibroblasts is one of the major causes of cartilage destruction in rheumatic diseases that needs to be counteracted. In our previous work, we observed that BAY 11-7085 induces apoptosis by inactivating PPAR-γ in human synovial fibroblasts. In this work, we investigated if autophagy was also involved in BAY 11-7085-induced synovial fibroblast cell death.

Methods: Primary human synovial fibroblasts were isolated from synovial membrane of osteoarthritis patients after joint surgery. Cells were seeded within 0.5 ml of DMEM medium with 10% FCS or without FCS in starvation condition. Synovial fibroblasts were stimulated with 15d-PGJ2, prednisolone, mifepristone, pepstatin A, rapamycin or NH_4Cl for 24 h, then BAY 11-7085 was added for two additional hours. MTS was performed for survival assay. Proteins such as LC3B, atg3, p62, glucocorticoid receptor (GR), phospho-glucocorticoid receptor pSer211, PPAR-γ, phospho-PPAR-γ pSer112, phospho-ERK1/2 on Tyr-204, caspase 8, α-tubulin and GAPDH were analyzed by western blotting. pPPAR-γ1, pCMV-MEK1 and pEGFP were overexpressed in HEK293 cells. *P* values were obtained using the Mann-Whitney test. A value of $P < 0.05$ was considered as statistically significant.

Results: Results have shown that BAY 11-7085 could induce autophagy within 2 hours of cell treatment and that it preceded BAY 11-7085-induced apoptosis. Of interest, BAY 11-7085 induced Serine 211 phosphorylation and degradation of glucocorticoid receptor (GR), suggesting that GR activation is involved in BAY 11-7085-induced autophagy. Glucocorticoid prednisolone induced both activation and degradation of GR, as well as autophagy in synovial fibroblasts. Of interest, BAY 11-7085-induced cell death was significantly decreased with glucocorticoid inhibitor mifepristone and with inhibitors of autophagy. BAY 11-7085-induced autophagy and GR activation were both downregulated by PPAR-γ agonists such as 15d-PGJ2 and MEK/ERK inhibitor UO126. Inhibition of autophagy markedly decreased endogenous and BAY 11-7085-induced ERK phosphorylation, suggesting a positive feed back loop between ERK activation and autophagy in synovial fibroblasts. Co-transfection of MEK1 with PPAR-γ1 in HEK293 cells caused known inhibitory phosphorylation of PPAR-γ1 (Serine 112) and enhanced GR degradation, in the absence or presence of prednisolone. Furthermore, GR was phosphorylated on Serine 211 and downregulated in

synovial fibroblasts during serum starvation-induced autophagy.

Conclusion: BAY 11-7085 induced human synovial fibroblast autophagy that acts as an agonist to promote BAY 11-7085-induced apoptosis. Furthermore, our results suggest that BAY 11-7085-induced autophagy in synovial fibroblasts is mediated through GR activation and PPAR-γ inactivation. Thus, modulation of autophagy and inflammation through GR and PPAR-γ regulation is a challenging approach to be further studied in rheumatic diseases.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Visfatin may represent a novel biomarker of disease severity. Serum visfatin levels are elevated in patients with early rheumatoid arthritis (ERA) and axial spondyloarthritis (AxSpA)[1,2]. Serum visfatin levels may be associated with the degree of inflammation, clinical disease activity and radiographic joint damage.

The aim of this study was to analyze serum levels of visfatin in patients with ERA and AxSpA compared to healthy controls (HC) and to investigate their relationship with disease activity and spinal involvement.

Methods:

The study included 23 patients with non-radiographic AxSpA (nr-AxSpA) according to the ASAS criteria with active sacroiliitis confirmed by MRI, 44 patients with radiographic AxSpA (with and without spinal involvement), 40 patients with ERA and age- and sex-matched healthy control (HC) for ERA (n=30) and AxSpA (n=43). Serum visfatin levels were determined by ELISA. Disease activity was assessed by the Disease Activity Score for 28 joints (DAS28) in ERA and Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) in AxSpA. For analysis of differences between groups Mann-Whitney U and for correlations of parameters Spearman's rank order tests were used.

Results:

Visfatin serum levels were significantly elevated in ERA patients compared to HC (1.92±1.17 vs. 1.36±0.93 ng/ml; p=0.034) and correlated positively with DAS28 (r=0.383, p=0.015) and CRP levels (r=0.456, p=0.003). In all patients with AxSpA, visfatin levels were significantly higher compared to HC (2.79±2.05 vs. 1.22±0.86 ng/ml; p<0.0001) and on the borderline of significance also compared to ERA patients (p=0.051). Furthermore, visfatin levels were significantly higher in patients with radiographic AxSpA compared to nr-AxSpA (3.23±2.24 vs. 1.94±1.28 ng/ml; p=0.013) and there was a borderline difference between radiographic AxSpA with and without spinal involvement (3.79±2.45 vs 2.55±1.79 ng/ml; p=0.067). Serum visfatin levels were not associated with CRP and BASDAI in AxSpA patients.

Conclusion:

Visfatin levels are elevated in both ERA as well as AxSpA patients compared to healthy controls. Although visfatin levels correlate with measures of inflammation in ERA patients, its levels rather reflect radiographic spinal involvement in AxSpA patients in this cross-sectional study. Therefore, we suggest that visfatin possibly plays a distinct role in the pathogenesis of both diseases.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Aminopeptidase N (CD13, EC 3.4.11.2) is a metalloproteinase expressed on the surface of fibroblast like synoviocytes (FLS), and as a soluble protein in serum and synovial fluid. CD13 is also expressed by multiple other cell types including monocytic lineage cells and endothelial cells. We have shown that CD13 can be released from FLS in culture, and that CD13 is higher in amount and activity in rheumatoid arthritis (RA) synovial fluids compared to osteoarthritis (OA). The goals of this study are to further explore potential roles for CD13 in the synovium in relation to monocytes and endothelial cells.

Methods: Synovium samples were cyrosectioned and stained for CD13 (antibody 591.1D7.34) and von Willebrand factor (VWF, rabbit anti-human DAKO) followed by secondary immunoflourescent antibodies. Co-localization was analyzed with ImageJ. Chemotaxis was performed in a modified Boyden chamber system using human dermal microvascular endothelial cells (HMVECs) or monocytes isolated from healthy donors. Chemotaxis was measured toward PBS, recombinant human CD13 (rhCD13) or an enzymatically inactive mutant CD13. Angiogenesis was measured using a HMVEC tube formation assay and a mouse Matrigel plug assay.

Results: CD13 on endothelial cells has been linked to angiogenesis; however, endothelial CD13 has not been examined in the synovium. We show that RA synovial sections stained more strongly for CD13 and showed stronger co-localization of CD13 and VWF than either OA or normal samples. A role for soluble CD13 (sCD13) has also not been determined in endothelial cell or monocyte migration. We therefore examined whether sCD13 could contribute to angiogenesis and/or monocyte chemotaxis. We found that CD13 was significantly chemotactic for monocytes over a range from 125ng/ml-500ng/ml CD13 with a peak chemotaxis at 500ng/ml (213.86±43.42 cells/well $p=0.05$). sCD13 was strongly chemotactic for HMVECS over a range from 0.5ng/ml-2000ng/ml with peak chemotaxis at 1000ng/ml (164.25±21.13 cells/well, $p=0.000173$). The enzymatically inactive mutant of CD13 was also chemotactic for HMVECs (135.02±11.47 cells/well, $p=0.012$) but to a lesser degree than the enzymatically active form (204.06±24.02 cells/well, $p=0.0078$). Depletion of CD13 from RA synovial fluid significantly decreased HMVEC chemotaxis. Furthermore, rhCD13 significantly increased HMVEC tube formation ($p<0.05$) in Matrigel, and rhCD13 significantly increased angiogenesis in a mouse Matrigel plug assay (PBS 0.099±0.025 g/dl/mg, CD13 1.49±0.62 g/dl/mg, $p<0.05$).

Conclusion: Soluble CD13 is shed from FLS and can act as a chemoattractant for T cells and monocytes, bringing these pro-inflammatory cells to the RA joint. CD13 is present on synovial endothelial cells, but sCD13 can also act as a pro-angiogeneic factor in the synovium in a manner that is partially independent of its enzymatic activity. The concentrations of CD13 used in these experimental systems correspond to levels of CD13 in the RA joint. In summary CD13 secreted by FLS in the RA joint may contribute to a pro-inflammatory milieu and lead to increased angiogenesis and migration of monocytes and T cells to the RA synovium.

Delta-like 1 Enhances the Production of Pro-Inflammatory Mediators By Fibroblast-like Synoviocytes

Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Notch signaling is known to regulate cell fate decision and differentiation during embryonic and post-natal development. I have been reported that a Notch ligand Delta-like 1 (DLL1) promoted osteoclastogenesis via Notch2 activation and DLL1 blockade in rheumatoid arthritis (RA) model mouse reduced the number of osteoclasts in the affected joints. This DLL1 blockade also suppressed the joint inflammation by suppressing the production of pro-inflammatory mediators such as IL-6, GM-CSF, and MMP-3. In arthritic mouse joint, DLL1 expressed on macrophages and stimulated Notch2 on fibroblast-like synoviocytes (FLS), which enhanced the production of IL-6 and MMP-3. In this study, the role of DLL1 on the production of pro-inflammatory mediators by RA FLS was evaluated.

Methods: The expression of Notch receptors and ligands on RA FLS was analyzed by flow cytometry. OA FLS was also analyzed. DLL1 expression was investigated by imunohistochemical analysis of synovial tissue. FLS were stimulated with anti-Notch2 monoclonal antibody or DLL1-transfected CHO cells and IL-6, GM-CSF, and MMP-3 in the supernatants were measured by ELISA.

Results: As similar to mouse joint cells, Notch2 was expressed on RA-derived FLS and DLL1 was expressed on macrophages in RA synovium but not on FLS. Meanwhile, little expression of Notch2 was detected on osteoarthritis-derived FLS. Activation of Notch2 on RA FLS enhanced the production of IL-6 and GM-CSF. DLL1 stimulation also enhanced the production of IL-6, GM-CSF, and MMP-3 by RA FLS.

Conclusion: These results suggest that DLL1 activates Notch2 on RA FLS and enhances the production of RA-related pro-inflammatory mediators similar to mouse FLS. Therefore, DLL1 blockade may be a novel strategy to treat RA by suppressing the production of pro-inflammatory mediators in the joint as well as osteoclastogenesis.

Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Blood relatives (Rel) of lupus patients have increased risk of SLE. Some have autoantibodies and SLE clinical features, but do not meet ≥ 4 ACR criteria needed to reach SLE classification (incomplete lupus, ILE). Some individuals with ILE may transition to classified SLE, yet many will remain ILE patients without major organ involvement. Using a unique resource of SLE patient family members, the goal of this study is to determine factors that distinguish ILE patients from unaffected Rel and SLE patients.

Methods: This study examined individuals enrolled in the Lupus Family Registry and Repository (LFRR) who only met 3 ACR classification criteria during medical record review and did not meet Systemic Lupus International Collaborating Clinics (SLICC) SLE classification, designated as ILE. ILE patients (n=77) were matched by race, gender, and age (± 5 years) to unaffected Rel and unrelated, unaffected controls (Ctls). We were able to subsequently match a subset of ILE patients (n=55) to medical record-confirmed SLE patients in the LFRR. Study participants provided clinical and demographic information, and completed the SLE-specific portion of the CTD Screening Questionnaire (CSQ). Plasma samples were assessed for autoantibody production and 52 soluble inflammatory mediators (BLyS, APRIL, cytokines, chemokines, and shed TNF receptors).

Results: ILE patients had significantly higher SLE-specific CSQ scores than unaffected Rel and Ctls ($p<0.0001$); CSQ scores in unaffected Rel > Ctls ($p=0.009$). Initial analysis revealed a number of soluble mediators that positively correlated with CSQ scores, including SCF ($p=0.0001$), BLyS ($p=0.0086$), MCP-3 ($p=0.0017$), and TNFRI ($p=0.0144$). Compared to unaffected Rel and Ctls, ILE patients had the highest levels of SCF ($p=0.0001$), BLyS ($p=0.0018$), MCP-3 ($p=0.0167$), and TNFRI ($p=0.0196$), as well as highest ANA titer ($p<0.01$) and number of lupus-associated autoantibodies ($p<0.01$). We subsequently examined factors that differentiated ILE patients matched to SLE patients in the LFRR (n=55). SLE patients had significantly higher rates of arthritis, serositis, and renal disease ($p<0.004$), as well as increased number of autoantibody specificities ($p<0.004$) and levels of BLyS ($p=0.0138$), IL-2Rα ($p=0.0201$), IP-10 ($p=0.0269$), and TNFRII ($p=0.0309$) compared to ILE patients. CSQ scores and SCF levels, which were elevated in ILE patients compared to Rel and Ctl, were equivalent compared to SLE patients. Yet, ILE patients had higher levels of the regulatory mediator TGF-β compared to SLE patients ($p=0.0454$).

Conclusion: ILE patients are distinguished from unaffected Rel by elevated number of autoantibodies and inflammatory mediators that correlate with SLE-specific CSQ scores, yet have fewer clinical criteria and increased levels of the regulatory mediator, TGF-β, compared to SLE patients. Identification of factors which discern relatives at increased risk of transitioning to classified SLE from relatives who remain unaffected may be beneficial to curtail inflammatory damage and identify individuals for prevention trials.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: The pathologic hallmarks of systemic lupus erythematosus (SLE or lupus) are altered immune responses to nuclear autoantigens with autoantibody production and subsequent tissue injury. Early studies suggested a critical role for adaptive immunity in the development of lupus; however, recent data have expanded this paradigm to a pathogenic role for innate immunity. For instance, TLR7/8 recognize the ssRNA of the self-antigen U1-small nuclear ribonucleorprotein (U1-snRNP) that is targeted by anti-U1-snRNP antibodies (Abs) in lupus. Indeed, we showed the production of IL-1β from human monocytes (MO) exposed to a combination of U1-snRNP and anti-U1-snRNP Abs by the activation of the caspase-1-containing NLRP3 inflammasome. Macrophage migration inhibitory factor (MIF), primarily produced from MO and macrophages, plays an important role in immune cell function by promoting the production of IL-1, IL-6 and TNF-α, which are increased in blood, skin and/or renal tissues in lupus patients. Recent data have shown an association between serum MIF levels and *MIF* gene polymorphisms with SLE-related organ damage as well as decreased glomerulonephritis in lupus-prone mice treated with MIF antagonists. However, little is known about the mechanisms underlying MIF production in SLE as well as the functional link between MIF and the NLRP3 inflammasome. We have addressed these questions using human MO.

Methods: Human primary MO were purified from peripheral blood mononuclear cells (PBMCs) of healthy donors and incubated in the presence or absence of U1-snRNP and/or anti-U1-snRNP Ab+ or healthy serum with or without the MIF inhibitor MIF098. Tissue culture supernatants and cells were analyzed for MIF, IL-1β, NLRP3 and NF-kB by ELISA, flow cytometry and Western blotting.

Results: A combination of U1-snRNP and anti-U1-snRNP Ab+ serum (hereafter snRNP immune complex or IC) induced the production of MIF and IL-1β from freshly purified human MO. However, U1-sNRNP, anti-U1-snRNP alone, or a combination of U1-snRNP and healthy serum did not induce the production of these cytokines from the same cells. The small molecule MIF inhibitor MIF098, which interferes with the binding of MIF to its receptor, decreased the production of IL-1β from MO in response to the snRNP IC, suggesting a co-stimulatory role for MIF in the activation of the NLRP3 inflammasome. Indeed, the MIF inhibitor MIF098 substantially reduced the expression of NLRP3, a critical component of the NLRP3 inflammasome, in MO in response to the snRNP IC. This phenomenon is likely mediated in part by the suppression of NF-kB activation, which can up-regulate the expression of NLRP3, since MIF098 also suppressed the activation of NF-kB. Moreover, adding exogenous MIF during the incubation of MO with snRNP IC increased IL-1β production.

Conclusion: These results are the first to demonstrate the inducible production of MIF from MO by lupus snRNP IC and support MIF action in regulating the NLRP3 inflammasome in human MO. These data also provide a functional link for an association of high expression *MIF* alleles with SLE and a rationale for targeting MIF in human disease.

Regulation of Neutrophil Extravasation By Interleukin-8-Induced Intravascular Reactive Oxygen Species Production during the Inflammatory Response

María Jesús Dominguez-Luis[1], Estefanía Armas-González[2], Maria Teresa Arce-Franco[3], Francisco Sanchez-Madrid[4] and Federico Díaz-González[5], [1]CIBICAN, Center of Biomedical Research of the Canary Islands, University of La Laguna, Tenerife, Spain, [2]Universidad de La Laguna, Pharmacology Department, Tenerife, Spain, [3]Rheumatology Service, Hospital Universitario de Canarias, Tenerife, Spain, [4]Immunology Service, Hospital Universitario de La Princesa, Madrid, Spain, [5]Investigation Unit, Sociedad Española de Reumatológía, Madrid, Spain

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

The extravasation and recruitment of leukocytes in damaged tissues is an essential component of the inflammatory response. Once in the inflammatory foci, neutrophils destroy invading microorganisms by bringing them into contact with chemicals, among which reactive oxygen species (ROS) are the most important. Correct cell extravasation requires the coordinated intervention of a number of adhesion molecules, including L-selectin, a molecule that plays a key role in the initial interaction between flowing neutrophils and endothelial cells. However, the mechanisms that control the regulation of the L-selectin ectodomain processing during the inflammatory response are still not well understood. **Objectives:** In this work we study the mechanisms involved in the intravascular ROS production by neutrophils, as well as the potential implication of these oxygen derivatives in the regulation of neutrophil/endothelial cell interactions during the early events of the inflammatory response

Methods:

The effect of ROS on L-selectin and CD11b basal surface expression on human neutrophils was studied by flow cytometry analysis. Neutrophil ROS production during neutrophil-HUVEC (human umbilical vein endothelial cells) interaction was assessed in dihydroethidium-preloaded neutrophils using a flow chamber. The role of Interleukin(IL)-8 in the neutrophil ROS production was studied using lL-8 blocking mAb or a synthetic CXCR1 inhibitor (SB225002). Physiologic antioxidants such as superoxide dismutase (SOD) and catalase, as well as the NADPH-oxidase complex inhibitor diphenyleniodonium chloride (DPI), were used to determine the role of ROS in the regulation of neutrophil rolling and extravasation.

Results:

Flow cytometry experiments showed that shedding of L-selectin can be triggered in response to ROS through an autocrine-paracrine TACE-dependent mechanism in neutrophils. Flow chamber experiments showed that intracellular ROS production by neutrophils: 1) is proportional to the distance a neutrophil travelled doing rolling; and 2) requires

Interleukin (IL)-8/CXCR1 interaction. In accordance with this result, the preincubation of neutrophils with physiological antioxidants (SOD and catalase) and an inhibitor of NADPH oxidase complex (DPI) increased the number of rolling cells, reducing the transmigration capability of neutrophils through activated-HUVEC

Conclusion:

Our data indicate that, in response to IL-8, neutrophils initiate intracellular ROS production during the rolling phase of the inflammatory response. By inducing L-selectin shedding, ROS could participate in the regulation of inflammation, thereby reducing the extravasation capability of neutrophils. These data could help to define new therapeutic targets for control inflammation in diseases such as Rheumatoid Arthritis.

Rantes/CCL5 Selectively Induces MMP-1 and MMP-13 Production in Rheumatoid Arthritis Synovial Fibroblasts Via PKC-Î´ and JNK Pathways

Solomon A. Agere, Nahid Akhtar and Salahuddin Ahmed, Department of Pharmaceutical Sciences, Washington State University College of Pharmacy, Spokane, WA

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

RANTES/CCL5 (RANTES) is a C-C chemokine that binds to its receptor (CCR5) and initiates inflammatory processes in rheumatoid arthritis (RA) by facilitating leukocyte infiltration. However, the role of RANTES/CCL5 beyond its chemotactic activity is not fully known. The present study was carried out to study the effect of RANTES/CCL5 on matrix metalloproteinase (MMP)-1 and MMP-13 expression using human rheumatoid arthritis synovial fibroblasts (RA-FLS).

Methods:

Human RA-FLS isolated from RA synovial tissues were serum-starved overnight followed by treatment with RANTES/CCL5 (20-100 ng/ml) for different time period. Conditioned media was collected and cells were lysed with RNA lysis buffer. Effect of RANTES/CCL5 on MMP and TIMP activation in the conditioned media from RA-FLS was evaluated using human MMPs protein array. MMP-1 and MMP-13 mRNA expression and protein synthesis was evaluated using qRT-PCR, ELISA, and Western blotting methods. Effect of RANTES/CCL5 on collagenase activity was studied using in-gel zymography. The inhibitory effect of RANTES/CCL5 antagonist, Met-RANTES (50-200 ng/ml), on RANTES/CCL5-induced MMP-1 and MMP-13 production was evaluated. RA-FLS were stimulated with

RANTES/CCL5 alone or the presence of signaling inhibitors for 5-30 mins to determine signaling mechanisms involved. Statistical value of $p<0.05$ was considered significant.

Results:

Results from human MMP antibody array showed that RANTES/CCL5 selectively induces MMP-1, MMP-13, TIMP-1, and TIMP-2 in RA-FLS ($p<0.05$; n=3). The confirmatory results using ELISA and qRT-PCR analysis showed that RANTES/CCL5 (20-100 ng/ml) significantly induced MMP-1 (~3-6-fold) and MMP-13 (~3-8-fold) expression in a dose-dependent manner ($p<0.05$ for 100 ng/ml). Collagen zymography results showed that RANTES/CCL5 induced collagenase activity in human RA-FLS dose-dependently ($p<0.05$; n=3). RA-FLS pretreatment with met-RANTES significantly reduced the ability of RANTES/CCL5 to induced MMP-1 and MMP-13 expression ($p<0.05$; n=3). Interestingly, silencing of RANTES/CCL5 gene using siRNA approach also markedly inhibited TNF-α-induced MMP-1 and MMP-13 production. Stimulation of RA-FLS with RANTES/CCL5 selectively activated PKC-δ and JNK pathways. In addition, pretreatment of RA-FLS with selective inhibitors for PKC-δ, ERK and JNK markedly inhibited RANTES/CCL5-induced MMP-1 and MMP-13 production.

Conclusion:

RANTES regulates MMP-1 and MMP-13 expression in RA-FLS via selective activation of PKC-δ, ERK, and JNK pathways and may also contribute to tissue destruction in RA.

Disentangling the Role of Hypoxia-Inducible Factor 1 and 2 in the Adaption Process of Human Microvascular Endothelial Cells to Pathophysiological Hypoxia

Martin Hahne[1], Peggy Kunath[2], Mathias Mursell[3], Cindy Strehl[2], Gerd Burmester[4], Frank Buttgereit[2] and **Timo Gaber**[2], [1]Miltenyi Biotec GmbH, Berlin, Germany, [2]Department of Rheumatology and Clinical Immunology, Charité – Universitätsmedizin Berlin, Berlin, Germany, [3]German Rheumatism Research Center (DRFZ), Berlin, Germany, [4]Department of Rheumatology and Clinical Immunology, Charité - Universitätsmedizin Berlin, Berlin, Germany

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Angiogenesis is a prominent feature of the pathogenesis of RA. Although new blood vessels deliver oxygen to the augmented inflammatory cell mass, the neovascular network is dysfunctional and fails to restore tissue oxygen homeostasis, so that the inflamed joint remains markedly hypoxic. At a cellular level, hypoxia is detected by a mechanism that regulates the amount of hypoxia-inducible factor (HIF)-1α and -2α. After translocation to the nucleus, HIF-1α or HIF-2α subunit bind its partner HIF-1β to form a functional, heterodimeric transcription factor, HIF-1 and HIF-2, which activate a gene program associated with angiogenesis, glycolysis, and adaptation to pH. The

distinct functions of HIF-1 and HIF-2 in the hypoxia-induced angiogenesis and metabolic switch of endothelial cells are still unknown.

Methods: For this purpose we investigated the adaption of Human Microvascular Endothelial Cell (HMEC)-1 to pathophysiologic hypoxic conditions (1% O_2). Angiogenesis assay and cytokine analyses were conducted to describe angiogenesis. Gene expression and ATP/ADP measurements were performed to visualize the bioenergetic switch under hypoxia. shRNA-technology enabled a specific knockdown of either HIF-1α or HIF-2α or the combination of HIF-1α and HIF-2α, in order to identify distinct functions of both transcription factors, which were assessed via microarray analysis.

Results: Hypoxia induced angiogenesis and a bioenergetic switch from oxidative phosphorylation towards glycolysis. Knockdown of either HIF-1α or HIF-2α leads to a reduced angiogenesis *in vitro*. Although HIF-1α and HIF-2α show overlapping functions during adaption of HMEC-1 towards hypoxia reduction of HIF-1α resulted in a diminished cellular energy supply due to a reduction in hypoxia-induced glycolytic enzyme gene expression thereby not altering pro-angiogenic factors VEGF, VEGF receptor 1 and 2, and IL8. In contrast, reduction of HIF-2α resulted in a reduction of hypoxia induced pro-angiogenic VEGF and IL8 gene and protein expression but induction of VEGFR1 without altering glycolytic enzyme gene expression. Finally, the results of HIF-1α / HIF-2α combined knockdown demonstrate that the lack of both factors significantly reduced cell survival as compared to the scramble control thereby diminishing both gene expression of pro angiogenic factors and glycolytic enzymes.

Conclusion: Our results indicate distinct but also overlapping functions of HIF-1α and HIF-2α in ECs which are of high interest regarding the intervention of tumour growth but also the chronicity of the inflammatory process in RA. Finally we clearly demonstrate a major impact of HIF-1α and HIF-2α on angiogenesis mediated either via the expression of pro-angiogenic factors in case of HIF-2α or via the glycolytic switch in case of HIF-1α. At least both are essential for endothelial cellular function. These findings open new possibilities for therapeutic approaches by targeting the specific hypoxia induced factors.

Session Time: 9:00AM-11:00AM

Background/Purpose:

TAK1 is one of the most important proteins in IL-1β signaling cascade that mediates downstream p38/JNK and NF-κB activation. In the present study, we evaluated the effect of EGCG, a potent anti-inflammatory compound, on TAK1 activation and its downstream consequent effects in human rheumatoid arthritis synovial fibroblasts (RA-FLS).

Methods: Human RA-FLS were treated with IL-1β for 30 minutes alone or in presence of EGCG. Cytoplasmic, nuclear, or whole cell extracts were prepared for Western blotting analysis to study the activation and cellular distribution of IL-1β signaling proteins proximal to IL-1 receptor as well as different phosphorylated forms of TAK1. Immunofluorescence was performed to study TAK1 nuclear translocation. EGCG and IL-1β-stimulated TAK1 interacting protein partners were identified using immunoprecipitation assay. *In silico* docking studies were performed using EGCG as a ligand and three-dimensional TAK1 structure was generated using ligand and protein preparation wizard of Schrodinger suit 2014.3. The ligand (EGCG) was docked using GLIDE module.

Results: Molecular docking studies on TAK1 structure *in silico* shows that EGCG occupies the binding pocket at C174 position, an ATP-binding site, which causes a reversible yet stable inhibition in TAK1 phosphorylation at Thr184/187site and kinase activity. Western blotting analysis showed that EGCG facilitates nuclear translocation of TAK1 in a dose dependent manner. Furthermore, we also observed overall reduction in cytoplasmic levels of TAK1 in response to EGCG treatment, which was further confirmed by immunofluorescence staining. Interestingly, TAK1 phosphorylation at Thr184/187 is not at all observed in the nuclear compartment while TAK1 phosphorylated at Ser439 mainly translocate to the nucleus in response to EGCG treatment. Ingenuity Pathway analysis predicted STAT3, ATM, SMAD7, and p300 (histone acetyltransferase) as the potential nuclear partners of TAK1. Further validation studies using immunoprecipitation assays in human RA-FLS confirmed the strongest interaction between TAK1 and p300 in addition to the other identified important nuclear proteins in RA-FLS. In parallel to these findings, EGCG inhibited histone H3K56 acetylation in a dose-dependent manner in RA-FLS. Additionally, these results confirmed that the interaction with p300 was significantly higher in EGCG and IL-1β treated RA-FLS, suggesting regulatory role of TAK1 in chromatin modifications.

Conclusion:

Our study provides a novel mechanism through which EGCG facilitates nuclear translocation of TAK1 and regulates transcriptional machinery involved in RA pathogenesis.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Pentagalloyl glucose (PGG) is a natural polyphenolic and water-soluble gallotannin that exhibits anti-cancer and anti-inflammatory activities. In the present study, we evaluated the efficacy of PGG in regulating interleukin-1β (IL-1β) stimulated human rheumatoid arthritis synovial fibroblasts (RA-FLS) and rat adjuvant-induced arthritis (AIA) model of inflammatory arthritis.

Methods: The effect of PGG on RA-FLS viability was tested using MTT assay. Human RA-FLS were pretreated with PGG (0.1–10 μM) for 2 hours followed by IL-1β (10 ng/ml) stimulation 24 hours (for IL-6 and IL-8 production) and 30 mins to study cell signaling mechanisms. Conditioned medium was used for the quantification of IL-6 and IL-8 by ELISA and cell lysates were prepared for the analysis of IL-1β signaling network proteins like Myd88, IRAK1, p-TAK1, and TRAF6. To test *in vivo* efficacy of PGG, we performed studies in a rat AIA model. PGG was administered at doses of 12.5 and 25 mg/kg body weight once daily (starting on day 8 of AIA induction). The severity of the arthritis was quantified by ankle circumferences measurement.

Results: PGG (0.1–10 μM) had no adverse effect on the viability of RA-FLS. Pretreatment of PGG inhibited IL-1β-induced IL-6 (55 and 91% at 1 and 5 μM) and IL-8 (61 and 94 % at 1 and 5 μM) production in human RA-FLS in a dose-dependent manner ($p<0.01$; $n=4$). Evaluation of the signaling pathways using Western immunoblotting showed that PGG had no inhibitory effect on MyD88 expression, an adaptor protein in IL-1 receptor signaling pathway that mediates the innate immune responses. Similarly, among the downstream proteins proximal to IL-1β receptor such as IRAK1/TAK1/TRAF6, PGG was unable to inhibit IL-1β induced TRAF6 expression or rapid degradation of IRAK-1. However, PGG selectively inhibited the phosphorylation of TAK1 at Thr184/187, a site critical for its kinase activity and downstream activation of MAPK and NF-κB pathways in RA-FLS. In our rat AIA studies, arthritis peaked around day 19 and therapeutic administration of PGG at the daily doses of 12.5 and 25 mg/kg p.o. from day 8 markedly inhibited the severity of arthritis as evident from the reduction in ankle circumferences by ~30 and 45%, respectively, when compared to the untreated arthritic rats. In addition, there was no body weight loss observed with PGG treatment.

Conclusion: Our study provides novel evidence that PGG interferes with IL-1β signaling in RA-FLS by selectively inhibiting TAK1 activation and ameliorates rat AIA. These findings suggest PGG or its synthetic analogs may be developed for the comprehensive pre-clinical testing for their anti-rheumatic activity.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

In rheumatoid arthritis (RA), synovial tissue macrophages (MΦ) are inherently involved in disease pathogenesis by producing inflammatory mediators and matrix-destructive enzymes. Depending on their polarization, MΦ show proinflammatory (classically activated M1 MΦ) or regulatory/wound-healing (alternatively activated M2 MΦ) behavior. Epigenetic mechanisms play a crucial role in the plasticity of cells and aberrant epigenetic regulation of pathogenetically relevant processes is a hallmark of many human diseases such as RA. In this study we examined if the epigenetic regulator Enhancer of Zeste Homolog 2 (EZH2) mediates differentiation and polarization of RA macrophages.

Methods:

Peripheral blood monocytes from healthy controls (HC) or RA patients were treated with M-CSF to obtain monocyte-derived MΦ (MDM). Efficient *in-vitro* MΦ differentiation was confirmed by CD68 staining (>95%). M0 MΦ were transfected with siRNA for histone 3 lysine 27 (H3K27) methyltransferase EZH2 or the H3K27 demethylase JMJD3 and/or stimulated with LPS+IFNγ or IL-4 to drive M1 or M2 polarization, respectively. Multicolor flow cytometry, quantitative real-time PCR (qPCR) and Western blot were performed to analyze MΦ polarization and gene expression.

Results: M1 MDM induced M1 markers CD40 and CD64 and the activation marker CD80 whereas M2 MDM upregulated CD206 (RA n=8 and HC n=9), thus confirming polarization. RA M0 MDM showed much higher expression of CD64 than HC MΦ (64±16% vs. 35±23% CD64+ cells; $p<0.01$) indicating skewing towards a proinflammatory M1 phenotype in RA. JMJD3 was significantly induced in both M1- and M2-polarized MDM (3.45±1.3- and 2.1±0.66-fold, $p<0.005$) whereas EZH2 was upregulated only in M1-polarized MDM (9.25±3.1-fold, $p<0.0001$)(n=9 HC) which was confirmed at the protein level by Western blot. Silencing of EZH2 (n=5 each) significantly inhibited M1 polarization (i.e. reduced numbers of $CD80^+$, $CD64^+$ and $CD40^+$cells), whereas, interestingly, unpolarized M0 MDM showed increased expression of CD40 and CD80 ($p<0.05$ all). Consistent with this, EZH2 silencing resulted in increased expression of VEGF (2.2±0.6-fold) and IL1B (3.4±2-fold) in M0 MDM, but inhibition of IL1B induction in M1 MDM (-75±15%) (all $p<0.05$). Looking for potential targets of EZH2 that might mediate the observed effects on MΦ polarization and cytokine expression, we analyzed genes involved in MΦ plasticity and interferon signaling (KLF4, STAT1, STAT3, STAT6, IRF4 and IRF5). Silencing of EZH2 increased STAT1 mRNA and STAT1 protein in M0 and M1 MDM ($p<0.05$), with no change observed for STAT1 phosphorylation. In contrast, we found reduced phospho-STAT3 in EZH2-silenced M1 MDM with levels of total STAT3 remaining unchanged.

Conclusion: Our data show an intrinsic shift of RA MDM towards a proinflammatory M1-like phenotype and induction of EZH2 in M1-polarized MΦ. We found EZH2 silencing to skew MΦ plasticity towards an inflammatory/activated phenotype under neutral conditions but attenuation of the inflammatory phenotype in a proinflammatory milieu. Mechanistically, different arms of the JAK/STAT pathway appear to be involved in these processes underpinning the importance of EZH2 in inflammatory MΦ signaling.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: AMP-activated protein kinase (AMPK) is a highly conserved, regulator of cellular energy status. In inflammation, AMPK inactivation is associated with increased glucose consumption through aerobic glycolysis, and up-regulation of pro-inflammatory effector responses. Pseudostarvation of cells via AMPK activation by hypoglycaemic therapy, i.e. Metformin, reverses these effects. AMPK activity has a cascade effect on other mediators of cell metabolism, including Acetyl-CoA Carboxylase (ACC). Once activated, phosphorylated AMPK (P-AMPK) in turn phosphorylates ACC (P-ACC). AMPK/ACC interactions play a central role in the regulation of cellular lipid homeostasis. Here we demonstrate AMPK activation in RA synovial tissues (RAST), and inhibition of pro-inflammatory responses in stimulated primary RA synovial fibroblast cells (RASFCs) following pharmacological AMPK activation by Metformin *in vitro*.

Methods: P-AMPK, AMPK, P-ACC and ACC expression in RAST and RASFCs were analyzed by immunoblotting, normalized against β-actin. RASFCs were stimulated with LPS or TNFα (10 ng/ml) in the presence of Metformin (0 – 62.5 μM) and assessed for wound healing and invasion capabilities. Culture supernatants were evaluated for IL-6 and IL-8 production by ELISA. RAST, obtained from RA patients during arthroscopy, were stained by immunohistochemistry for Phosphorylated ACC (P-ACC) and ACC, and by Immunofluorescence for P-AMPK and AMPK.

Results: Western blot analysis showed that P-AMPK was present in RAST, and cultured RASFCs. P-AMPK expression was upregulated in the presence of Metformin (10 μM & 50 μM). Stimulating cells, with either LPS or TNFα (10 ng/ml), in the presence of Metformin (10 μM & 50 μM) increased P-AMPK, expression was greater than what was observed following LPS or TNFα stimulation alone. Additionally, LPS stimulated cells in the presence of Metformin (10 μM & 50 μM) showed P-ACC expression, which was not observed in LPS stimulated cells alone. *In vitro* immunofluorescence staining of RASFCs showed P-AMPK upregulation both in the presence of Metformin (50 μM) compared to basal and TNFα (10 ng/ml) stimulated RASFCs. Positive immunohistochemistry staining of RAST for P-ACC, indicated that AMPK is activated and in its phosphorylated state, with maximal expression localized around blood vessels. Stimulation of RASFCs with LPS or TNFα (10 ng/ml) in the presence of Metformin (15 – 62.5 μM) decreased IL-6 and IL-8 production in a dose dependent manner. RASFCs stimulated with either LPS or TNFα (10 ng/ml) in the presence of Metformin (15 – 62.5 μM) showed a dose dependent decrease in the ability of the cells to heal an induced wound or invade through matrigel.

Conclusion: Our findings indicate that RAST and RASFCs are capable of responding to pharmacological alterations in cellular metabolic pathways. Metformin both activates AMPK and downregulates pro-inflammatory effects in RA. AMPK activation occurs in concert with P-ACC around blood vessels but not in the lining layer where matrix metalloproteinase mediated joint destruction occurs, in keeping with an anti-inflammatory role for activated AMPK. AMPK activation therapy pathways may therefore be a suitable future strategy in the treatment of Rheumatoid Arthritis.

Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

To investigate the role of high mobility group box 1 protein (HMGB1) and the receptor for advanced glycation end products (RAGE) in the pathogenesis of primary gouty arthritis (GA).

Methods:

(1) Enzyme-linked immunosorbent assay(ELISA) was used to determine the level of plasma HMGB1 in 68 acute gout (AG), 48 intercritical gout (IG) and 45 healthy control (HC). (2)Real-time quantitative polymerase chain reaction (RT-qPCR) was employed to study the expression of HMGB1 and RAGE mRNA in peripheral blood mononuclear cells (PBMCs) in 68 AG,48 IG and 94 HC, and the differences of gene expression in two groups were compared .(3)Western blot(WB)was used to measure HMGB1 in PBMCs from 18 AG, 13 IG and 21 HC,REGE in PBMCs from 12 GA and 8 HC, and the otherness of protein expression in two groups were compared .(4)Analysis of T test or Wilcoxon test and Spearman's correlations were used for statistical analysis.

Results:

The level of plasma HMGB1, PBMCs HMGB1, RAGE mRNA and protein were significantly higher in GA patients than those in HC (plasma HMGB1 (ng/mL): 222.00±178.32 *vs* 106.99±175.79 *vs* 23.88±34.05; PBMCs HMGB1 mRNA: 0.235±0.954 *vs* 0.044±0.117 vs 0.019±0.029; PBMCs RAGE mRAN F0.0015±0.0035 *vs* 0.0013±0.0009 *vs* 0.0005±0.0003; HMGB1 protein:3.59±2.49 *vs* 1.89±2.00 *vs* 0.74±0.78 G*P*<0.05)),while the level of plasma HMGB1 and PBMCs HMGB1 mRNA were significantly higher in AG patients than those in IG patients (*P*<0.05), the level of PBMCs RAGE protein was higher in GA patients than that in HC (2.94±0.67 *vs* 1.61±0.51; *P*<0.05), and the level of PBMCs RAGE mRNA was higher in AG patients than that in IG patients (*P*>0.05) . In the GA patients, the level of plasma HMGB1 was positively correlated with white blood cell, neutrophile granulocyte, mononuclear cell and erythrocyte sedimentation rate (r=0.34,0.44,0.39,0.33; *P*<0.05),while negatively correlated with apolipoprotein A1(r=-0.28; *P*<0.05); the level of PBMCs HMGB1 mRNA was positively correlated with RAGE mRNA, white blood cell counts, neutrophil counts, lymphocyte counts, total cholesterol, low density lipoprotein and apolipoprotein B100

(r=0.29,0.36,0.26,0.28,0.29; P<0.05),while negatively correlated with high density lipoprotein (r=-0.30;P <0.01); the level of PBMCs RAGE mRNA was positively correlated with Lymphocyte counts, total cholesterol and apolipoprotein B100 (r=0.35,0.35,0.44; P<0.05).

Conclusion:

HMGB1 and its signaling pathway might play an important role in the pathogenesis of gouty arthritis, which may also be involved in regulating the lipid metabolism of gout.

Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Microvesicles (MVs) (100-1000 nm diameter) are subcellular particles that are enriched in nucleic acid, including microRNA (miR), which may be transferred from cell to cell as a novel form of intercellular communication. In this study, we wished to characterize the microRNA content of microvesicles purified from the synovial fluid of patients with osteoarthritis or rheumatoid arthritis. Furthermore, we wished to determine whether predominant miR species identified in RA SF MVs may be transferred to recipient fibroblast-like synoviocytes (FLS) in vitro.

Methods:

Discarded synovial fluid (SF) from patients with established diagnoses of osteoarthritis (OA) (n=5) or rheumatoid arthritis (RA) (n=5) obtained during routine clinical care was transferred into tubes containing acid-citrate-dextrose and stored at 4°C until further processing. SF was treated with thromboplastin D, centrifuged at 300 g x 10 minutes and 3000 g x 15 minutes to remove cells and cellular debris, respectively, and filtered through a 0.8 mm filter. Next, SF was placed into ultracentrifuge tubes diluted with sterile PBS in a 1:8 ratio and ultracentrifuged at 100,000 g x 90 min using a Beckman 70.1Ti rotor. Purified MV pellets were resuspended in sterile PBS at one-fifth the original volume and quantified using a Nanosight LM10 instrument. MicroRNA from purified MV pellets was purified using a miRNeasy Serum/Plasma Kit (Qiagen), reverse transcribed, and subject to miRNA analysis using miScript miRNA PCR Serum/Plasma Arrays. PCR array data were analyzed using the Qiagen GeneGlobe Data Analysis Center online

software tool, normalizing to global CT mean of expressed miRNAs, using a cutoff of CT=37. Purified RA SF MVs were incubated with OA FLS for 16 hours, and pri-miR, pre-miR, and mature miR expression by FLS was determined by qPCR.

Results: Purified RA SF MVs purified in this manner were significantly greater than OA SF MVs (OA vs. RA 24.95 vs. 53.55 million/ml, p=0.0001). A total of 39 miRs showed greater than 2-fold statistically significant differences in expression between groups ($p<0.05$). Of these miRs, hsa-mir-223-3p expression was significantly upregulated in the RA SF MV group (102.4 fold regulation, p=0.005) when compared with the OA SF MV group. Addition of purified RA SF MVs to cultured human FLS induced expression of mir-223, but not pri-miR-223 or pre-mir-223, indicating that mir-223 in FLS was of exogenous (i.e. microvesicle) origin.

Conclusion: Microvesicle numbers in RA synovial fluid are greater than in OA synovial fluid, consistent with other previously published reports. We found significantly increased expression of mir-223-3p in RA SF MV, likely reflecting myeloid cell activation in the inflamed joint, and demonstrated that mir-223 may be transferred to recipient FLS in vitro.

Session Title: Epidemiology and Public Health Poster I: Comorbidities and Outcomes of Systemic Inflammatory Diseases

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Lower vitamin D levels are associated with increased disease activity in systemic lupus erythematosus (SLE) and individuals with SLE have increased prevalence of vitamin D deficiency. However, there

have been no prospective studies on whether vitamin D is associated with transitioning to clinical SLE. We examined whether vitamin D supplement use, 25-hydroxyvitamin D (25[OH]D) levels and single nucleotide polymorphisms (SNPs) in vitamin D genes were associated with transitioning to SLE in individuals at risk for the disease.

Methods: 436 individuals who reported having a relative with SLE but who did not have SLE themselves at baseline were followed-up an average of 6.3 (± 3.9) years later. At both visits, detailed demographic, environmental, clinical, and therapeutic information was collected by questionnaire, and a blood sample was obtained. The 56 individuals (77% ANA positive, 77% European American (EA), 88% female) who transitioned to SLE (> 4 cumulative ACR criteria) were verified by medical record review. 25[OH]D levels were measured by ELISA. Vitamin D deficiency was defined as 25[OH]D <20 ng/ml. Twelve SNPs in 7 vitamin D genes were typed by Immunochip. Ancestry was determined by principal components analysis of the full Immunochip data. Generalized estimating equations (GEE), adjusting for correlation within families, were used to test associations between the vitamin D variables and the categorical outcome of transitioning to SLE. GEE analyses examining the association between SNPs in an additive model and transitioning to SLE was limited to 294 EA, adjusting for age, sex and ancestry.

Results: Mean baseline 25[OH]D levels were not different between those who transitioned to SLE and those who did not transition to SLE (23.0 versus 24.1 ng/ml, p=0.42), nor was vitamin D supplement use (10.7% versus 12.9%, p=0.65). Adjusting for age, sex, race and season of blood draw, transitioning to SLE was not associated with baseline 25[OH]D levels (adjusted OR=0.98, 95% CI 0.95-1.02), being vitamin D deficient (adjusted OR=1.92. 95% CI 0.64-5.77), nor taking vitamin D supplements at baseline (adjusted OR=0.70, 95% CI 0.28-1.79). SNPs in *CYP27A1, GC, DHCR7/NADSYN1, CYP2R1, VDR, CYP27B1* and *CYP24A1* were also not associated with transitioning to SLE. However, significant effect modification (interaction p-value=0.02) indicated that in those not taking vitamin D supplements, each additional minor allele in rs12794714 in *CYP2R1*was associated with a decreased risk of transitioning to SLE (adjusted OR= 0.71, 95% CI 0.40-1.25); in those taking supplements, each additional allele resulted in increased risk of transitioning to SLE (adjusted OR= 5.76, 95% CI 0.73-45.75).

Conclusion: 25[OH]D levels at baseline were not associated with transitioning to SLE at follow-up. However, the large effect size of vitamin D deficiency and the interaction between supplement use and *CYP2R1* on SLE risk suggests that vitamin D may play a role that is not adequately marked by 25[OH]D levels. To our knowledge, this is the first prospective study examining the association between vitamin D and SLE disease onset, and indicates that vitamin D does not play a strong role in transitioning to SLE.

Session Title: Epidemiology and Public Health Poster I: Comorbidities and Outcomes of Systemic Inflammatory Diseases

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The generalizability and validity of in longitudinal observational studies is contingent on participant characteristics. If attrition is not random, it is important to identify any systematic differences b etween patients who continue to participate versus those who drop out. The purpose of this analysis was to compare characteristics of rheumatoid arthritis (RA) patients who continue to participate in the Ontario Best Practices Research Initiative (OBRI) to those of patients who have dropped out prior to reaching their 3 yr follow up.

Methods: Currently, 61 rheumatologists in Ontario (51% of active rheumatologists in Ontario) recruit patients into the OBRI. As of January 2015, 1533 patients had consented and were eligible to participate. 175 (11.4%) patients dropped out before reaching their 3 yr follow up assessment. Among the drop outs, 109 (7.1%) withdrew consent, 38 (2.5%) were lost to follow up, and 28 (1.8%) refused to re-consent after 2 yrs of follow up. In addition to the drop outs, 38 (2.5%) patients had died. 1320 (86.1%) patients remained active participants. Patient characteristics and disease activity at enrollment were compared in the 175 patients who dropped out versus the 1320 patients who continued to participate. A survival curve was generated to look at time of drop out over the 3 year follow up period.

Results: Patients who dropped out were similar to those who remained active with respect to age, gender, race, education, employment status, having private insurance, disease duration, number of comorbidities, and living alone. Compared to patients who dropped out, patients who continued to participate had higher household incomes, lower disease activity scores, and were more likely to be taking a biologic at the time of enrollment (Table 1). The survival curve shows that the majority of patients drop out within the first two years (Figure 1).

Conclusion: Patients with higher disease activity at enrollment were more likely to drop out. The OBRI attrition rate was 11.4% during the first three years of follow up, with 4.7% of patients dropping out in the first year, 3.5% in the second year and 3.2% in the third year. OBRI attrition rates were lower than those reported in the BRASS cohort (4.31% per 6 month follow up cycle) [1] and the ARAMIS cohort (6% per year) [2]. The lower number of drop outs in the OBRI cohort could be attributed to the time invested in rheumatologist site visits by our study monitors and the biannual follow-up by our OBRI telephone interviewers.

Higher Scores of Women Compared to Men for Most Clinical Measures of Rheumatoid Arthritis (RA) Status: Greater Differences for Patient Self-Report Scores Than for Rheumatologist Estimates: A Cross-Sectional 3 Center Study from Routine Care

Isabel Castrejón[1], Martin Bergman[2], Yusuf Yazici[3], Annie Huang[1], Joel A. Block[1] and Theodore Pincus[1], [1]Rheumatology, Rush University Medical Center, Chicago, IL, [2]Division of Rheumatology, Taylor Hospital, Ridley Park, PA, [3]NYU Hospital for Joint Diseases, New York, NY

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Epidemiology and Public Health Poster I: Comorbidities and Outcomes of Systemic Inflammatory Diseases

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Higher scores for women compared to men have been reported for all 7 rheumatoid arthritis (RA) Core Data Set measures (1, 2). Most of these measures predict premature RA mortality (3), but women with RA (and the general population) live 5-10 years longer than men. These findings suggest that higher scores for women may result in part from an ascertainment bias of more candid responses rather than poorer clinical status in women. We sought to probe this possibility by comparing differences between females and males in scores on a patient self-report MDHAQ/RAPID3 (multidimensional health assessment questionnaire/routine assessment of patient index data) vs physician estimates on a RheuMetric checklist.

Methods: All patients (with all diagnoses) at 3 settings complete a MDHAQ at each visit in the waiting area before seeing the rheumatologist. The 2-page MDHAQ includes physical function (FN) in 10 activities of daily living, three 0-10 visual analogue scales (VAS) for pain (PN), patient global estimate (PATGL), fatigue (FT), RADAI self-report joint count, and demographic data. RAPID3 (0-30) is the sum of 0-10 scores from FN, PN, and PATGL. In addition, the rheumatologist completes a RheuMetric checklist, which includes 4 0-10 VAS estimates for overall status, inflammation (reversible), damage (irreversible), and distress (e.g. fibromyalgia and depression). Mean differences between scores of women and men on the patient self-report MDHAQ and physician RheuMetric were compared, using t-tests to estimate statistical significance.

Results: Overall 461 patients were analyzed, 173, 147, and 141 from 3 sites. Females and males were similar in age and education level (Table). All 0-10 MDHAQ scores were ≥0.5 units higher in females than males, $p<0.05$ for pain, RAPID3, and RADAI self-report joint count. RheuMetric physician 0-10 estimates also were higher in females than males, but differences were 0.2 or less for estimates overall global status, inflammation, and damage ($p>0.05$). Only physician estimate of distress differed by 0.6 units ($p=0.02$) (Table).

Conclusion: Female RA patients have higher scores than males, with greater differences for patient self-report measures compared to physician measures other than for distress. These data suggest that higher MDHAQ scores in females may be attributable in part to an ascertainment bias of greater candor rather than clinical severity in females. Further studies of mechanisms for gender differences are needed.

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Abstract

Background/Purpose: Sedentary behavior is associated with increased risk of functional decline and disability. Individuals with rheumatoid arthritis (RA) spend more time in sedentary activity than healthy adults. Despite the association of RA with other deleterious health states, the assessment of sedentary behavior in clinical settings has not been well-developed in this patient population. We examined 3 potential approaches to identify the most sedentary individuals in adults with RA using a modified version of the Yale Physical Activity Survey (YPAS).

Methods: 172 adults with RA were enrolled in IMPAACT (Improving Motivation for Physical Activity in Arthritis Clinical Trial). Participants wore an accelerometer for 7 days then completed the modified YPAS for the same 7-day accelerometer period. Daily sedentary time was estimated from YPAS in three ways: 1) a categorical estimate of hours/day spent sitting (<3, 3-6, 6-8, >8 hrs/day); 2) a subjective continuous estimate of sedentary time calculated by subtracting hours sleeping and time spent in physical activity from a 24-hour day; and 3) rank order of the subjective continuous estimate. Each estimate was compared to objective accelerometer-derived sedentary time, defined as time registering counts of less than 100/minute during waking hours.

Results: On average, the 172 participants had RA for 13 years. Mean Disease Activity Score-28 was 6.4 and mean age was 55 years. 83% were female. Accelerometer-derived sedentary time was greater than 8 hours/day in 93% of participants. The 4 sitting categories had a significant increasing linear trend with objective sedentary time but over half the participants categorized themselves as sitting more than 8 hours/day. A significant linear relationship was observed between the continuous YPAS-derived sedentary time and objective sedentary time (Pearson $r = 0.29$, $p<0.001$); but a Bland-Altman plot demonstrated systemic bias. There was a significant linear relationship between the ranked YPAS-derived continuous estimate and ranked accelerometer sedentary time (Spearman = 0.26, $p <0.001$). Rank-order was an unbiased predictor.

Conclusion: All three approaches showed a significant relationship between self-reported and objectively measured sedentary time. The self-reported sitting category might be more informative with a category to capture sitting > 10 hours/day. The continuous YPAS-derived sedentary time estimate was a biased estimator. The unbiased rank of the YPAS-derived continuous sedentary the best use of the detailed YPAS information. This patient-reported approach using the modified YPAS shows promise to be a useful tool to identify the most sedentary patients at highest risk for functional decline. Providing a practical and accurate tool to identify the most sedentary individuals could lead to increased awareness and patient monitoring of sedentary behavior by clinicians.

Session Title: Epidemiology and Public Health Poster I: Comorbidities and Outcomes of Systemic Inflammatory Diseases

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose : Seropositive and seronegative rheumatoid arthritis (RA) differ in course and prognostic feature. The overall incidence of orthopaedic surgery in patients with RA has previously been shown to decline over time. The purpose of this study was to investigate whether there were differences in the time trends for orthopaedic surgery in rheumatoid factor (RF) positive and RF negative RA.

Methods: A population-based dynamic cohort of all known patients with RA in a defined geographic area was investigated. The patients had a clinical diagnosis of RA made by a rheumatologist, and fulfilled the 1987 ACR criteria for RA. Data on orthopaedic surgery procedures between 1998 and 2011 were retrieved from a regional health care register. Incidence rates of orthopaedic surgery procedures after RA diagnosis during the period from 1998 through 2011 were estimated separately for RF positive and RF negative patients. The incidence rates for 1998-2001 were compared to those of 2002-2006 and 2007-2011.

Results: A cohort of 2095 patients with RA (72 % women, 69 % RF positive) was investigated. There were 1702 orthopaedic procedures during a total follow-up of 21,123 person-years (py). Patients with RF positive RA were treated more extensively with methotrexate and biologic disease modifying anti-rheumatic drugs than those with RF negative RA. The incidence of orthopaedic surgery procedures overall declined significantly over time for RF positive RA, and there was a corresponding decline in small joint surgery and large joint surgery (Table). In patients with RF positive RA, the incidence of large joint surgery was reduced already in 2002-2006 compared to 1998-2001, whereas a decline in small joint surgery was apparent only in the final period (2007-2011). The incidence rate ratio (IRR) for orthopaedic surgery overall in this subset compared to 1998-2001 was 0.83 (95% confidence interval (CI) 0.73-0.95) in 2002-2006, and 0.68 (95% CI 0.59-0.79) in 2007-2011. On the other hand there was no significant decline among patients with RF negative RA in the incidence of all orthopaedic surgery procedures, with similar findings for small joint surgery or large joint surgery (Table). In patients with RF negative RA, the IRR for surgery overall compared to 1998-2001 for 2002-2006 was 0.90 (95% CI 0.68-1.18), and for 2007-2011 0.80 (95% CI 0.60-1.06).

Conclusion: The overall incidence of orthopaedic surgery declined over time in patients with RF positive RA, with significant decreases in both large and small joint surgery. In contrast, there was no major decline in RF negative RA. Patients with seropositive RA may benefit more from improved management and modern anti-rheumatic pharmacotherapy in terms of reduction of joint damage and the need for joint surgery.

Incidence of orthopaedic surgery per 1000 py (95 % CI) in the population-based RA cohort

	1998-2001	**2002-2006**	**2007-2011**	**P**
RF positive RA				
All orthopaedic surgery	114.2 (103.6-125.5)	94.9 (86.6-103.9)	78.1 (70.0-86.8)	<0.0001
Small joint surgery	57.6 (50.2-65.8)	52.2 (46.0-58.9)	36.2 (30.8-42.3)	<0.0001
Large joint surgery	54.7 (47.5-62.7)	41.4 (35.9-47.4)	40.5 (34.8-46.9)	<0.0001
RF negative RA				
All orthopaedic surgery	61.4 (49.5-75.3)	55.0 (45.9-65.5)	49.3 (40.6-59.3)	0.12

Session Date: Sunday, November 8, 2015

Session Title: Epidemiology and Public Health Poster I: Comorbidities and Outcomes of Systemic Inflammatory Diseases

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Limited information exists whether RA patients are likely to develop more morbid conditions after RA diagnosis compared to those without RA and the trajectory of multimorbidity over the course of RA remains unclear. We aimed to examine the accumulation of incident morbidities after onset of RA compared to patients with hypertension (HTN)- a highly prevalent chronic non-inflammatory condition.

Methods: Using claims data from a U.S commercial health plan, we identified new onset RA patients with ³2 ICD-9 codes of RA, >7 to <365 days apart, and new initiation of ³1 DMARD after ³12 months of enrollment. HTN Patients were identified similarly using ICD-9 codes of HTN and new initiation of ³1 HTN medication. The index date was defined as first prescription of a DMARD or respective HTN medication. We excluded patients with any prior use of DMARDs, HTN medication, or other chronic conditions any time prior to the index date. RA and HTN patients were 1:4 matched on age, sex, obesity status, and index date. Beginning on the index date, patients were followed for development of any of the 16 chronic conditions according to the widely used Deyo-adapted Charlson Index (Table). We calculated incidence rates (IR) per 1,000 patient-years (PY) for each condition. Cumulative percentage of patients developing at least one additional chronic condition over time was plotted separately for RA and HTN patients using Kaplan-Meier curves.

Results: We includeda total of 4,803 RA and 19,212 HTN patients. Mean age was 49 years , 71% was female, 0.5% obesity. Mean time of follow up was 25 months in the RA and 32 months in the HTN cohort. In the RA cohort the highest IR was found for chronic pulmonary disease (66.2/1,000 PY) compared to HTN (47.3/1,000 PY; $p<0.01$). The IR of cancer was higher in RA patients (RA 32.6/1,000 PY vs. HTN 25.3/1,000 PY $p<0.01$) whereas the IR for diabetes was higher in the HTN cohort (RA 27.9/1,000 PY vs. HTN 40.1/1,000 PY $p<0.01$; **table**). The cumulative incidence of patients with ³1 co-morbidity was higher for RA patients within the first two years of follow-up (FU) (16.8% vs. 14.6% up to 1 year, 24.6% vs. 21.4% up to 2 years; $p<0.01$), after 3 years of FU Kaplan Meier curves revealed no significant differences between RA and HTN patients (log rank test $p=0.35$).

Conclusion: Within the first 2 years after disease onset, a higher incidence of multimorbidity was observed in RA

patients. The highest IR was found for pulmonary disease, which might have an important impact on many outcomes including morbidity and mortality.

Table. Incidence rate of 16 different morbid conditions per 1,000 person-years for the rheumatoid arthritis (RA) and the hypertension (HTN) cohorts.

Chronic morbid condition	Rheumatoid Arthritis cohort n=4,803		Hypertension cohort n=19,212		p-value

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Epidemiology and Public Health Poster I: Comorbidities and Outcomes of Systemic Inflammatory Diseases

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: With markedly improved control of the acute effects of inflammatory arthritis, the major causes of morbidity and premature death now arise from the complications of chronic inflammation. Alberta's First Nations (FN) population has an increased prevalence of rheumatoid arthritis (RA), ankylosing spondylitis (AS) and psoriatic disease (PsD includes psoriasis and psoriatic arthritis) relative to the non-FN population. These conditions are reported to be more severe in FN which may result in higher rates of inflammatory complications. Our objective was to compare incidence rates of recognized complications of inflammation, namely cardiovascular disease (CVD, including myocardial infarction, stroke, venous thrombotic events), hospitalized infections, osteoporotic hip fracture, and malignancy (lymphoma, breast, colon), and conditions newly hypothesized to be secondary to chronic inflammation (diabetes, chronic obstructive pulmonary disease, COPD) in FN and non-FN populations.

Methods: ICD-9-CA and ICD-10-CM codes from population-based healthcare administrative data (physician billing claims and hospitalizations, years 1993 to 2011) were used to define incident cohorts of patients with RA, AS, and PsD using validated definitions. FN identity was determined from the Alberta Health Care Insurance Plan Registry File. Complications were determined using validated algorithms of ICD-9-CA and ICD-10-CM codes, with prevalent cases excluded. Incidence rates of complications were calculated for each disease cohort overall (per 1,000 person-years), and stratified by FN status to calculate the incidence rate ratio.

Results: The disease cohorts include 27,587 persons with RA, 5,120 persons with AS and 4,279 persons with PsD, with FN representing 6.1%, 5.0% and 3.7% of the cohorts respectively. Persons with RA had the highest frequency of CVD, hospitalized infection, osteoporotic hip fracture, malignancy and COPD compared to persons with AS and PsD, but persons with PsD had higher incidence rates of diabetes (Table 1). FN persons with RA, AS and PsD were not at increased risk for complications of inflammation (Table 2).

Conclusion: There were no significant increases in rates of complications in FN persons compared to non-FN in our population-based cohort.

Table 1. Incidence Rate (per 1,000 person-years) of Inflammatory Arthritis Complications

Complication	**RA (n=27,587)**	**AS (n=5,120)**	**PsD (n=4,279)**
CVD	14.0	8.3	10.4
Hospitalized Infection	29.7	19.8	22.4
Osteoporotic Hip Fracture	4.7	2.2	3.0
Malignancy	6.5	4.0	5.4
Diabetes	4.8	2.9	5.9
COPD	12.0	6.6	11.2

Table 2. Incidence Rate Ratio (95% confidence interval) for Inflammatory Arthritis Complications in the First Nations relative to non-First Nations Populations			
Complication	**RA**	**AS**	**PsD**
CVD	0.7 (0.4 to 1.2)	NR	1.9 (0.5 to 8.1)
Hospitalized Infection	1.3 (0.9 to 1.8)	1.2 (0.4 to 3.8)	0.5 (0.1 to 3.8)
Osteoporotic Hip Fracture	0.8 (0.3 to 2.0)	NR	NR
Malignancy	0.6 (0.3 to 1.4)	NR	NR
Diabetes	2.2 (0.8 to 6.2)	4.6 (0.5 to 40.9)*	NR
COPD	1.1 (0.6 to 1.8)	0.8 (0.1 to 5.8)	1.1 (0.2 to 8.4)*
Results are for fiscal year 2009 unless indicated by * where fiscal year 2008 is reported NR not reported due to <5 events in the First Nations group during the entire study period

Risk of Chronic Obstructive Pulmonary Disease in Rheumatoid Arthritis: A Population Based Cohort Study

Katherine McGuire[1], J Antonio Avina-Zubieta[2], Eric C. Sayre[1], JM Esdaile[3] and Diane Lacaille[4], [1]Arthritis Research Canada, Richmond, BC, Canada, [2]Arthritis Research Canada / University of British Columbia, Vancouver, BC, Canada, [3]Rheumatology, Arthritis Research Canada, Richmond, BC, Canada, [4]Arthritis Research Centre, University of British Columbia, Vancouver, BC, Canada

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Epidemiology and Public Health Poster I: Comorbidities and Outcomes of Systemic Inflammatory Diseases

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

A link between chronic obstructive pulmonary disease (COPD) and inflammation has been established in a number of studies. This raises the question of whether chronic inflammatory conditions, such as RA, predispose to COPD. The objective of this study was to evaluate the risk of incident COPD in RA compared to the general population.

Methods:

We conducted a retrospective cohort study of a population based incident RA cohort, identified between 1996-2006 and followed until 2010, using administrative health data. All incident RA cases in British Columbia were selected using previously published criteria. Controls were randomly selected from the general population, matched 1:1 to RA cases on birth year, gender and calendar year of inclusion. Individuals with inpatient or outpatient visits for COPD prior to index date were excluded. COPD outcome was defined as a hospitalization with a COPD code, which has been validated. All data were obtained from the Ministry of Health, including all visits to physicians, hospitalizations and dispensed medications.

Incidence rates and 95% CI were calculated for the RA cohort and controls, along with incidence rate ratios (IRR). Multivariable Cox proportional hazard models (PHM) were used to estimate the risk of COPD in RA compared to the general population after adjusting for potential confounders. Sensitivity analyses were performed to test the robustness of the results to the possible confounding effect of smoking, as it is a risk factor for both RA and COPD unavailable in administrative data, assuming a prevalence of 10% or 20% and an OR of 1.3 or 3.0, which covers the smoking rate of 16% for BC and of 12.5% observed in our prior RA survey.

Results:

The population cohorts included 24625 RA cases (67% female; mean [SD] age 57.2[17.1] years) and 25537 controls contributing 170401 and 184416 person-years of follow-up, respectively. The incidence rate of COPD was greater in RA than controls (Table 1), yielding an IRR of 1.75. After adjusting for potential confounders, RA cases had a 42% greater risk of developing COPD than controls (Table 1). The increase in risk did not differ according to age or gender. The increased risk in RA remained significant after modelling for smoking.

Conclusion:

In our population-based cohort, individuals with RA had a 42% greater risk of developing COPD compared to the general population. This has important clinical implications for clinicians and people living with RA, supporting good control of inflammation, smoking cessation, and testing for COPD, as indicated.

Table 1: Risk of COPD in RA compared to general population controls

	RA cohort (N=24625)	Controls (N=25537)
No. of incident cases of COPD	892	551
Incident rate of COPD per 1000 patient-years	5.23	2.99
Incident rate ratio (95% CI), RA vs. controls	1.75 (1.57-1.95)	
	aHR (95% CI) for COPD	
PHM adjusted for age and sex RA vs. general population	1.70 (1.53-1.89)	
PHM adjusted for baseline GC use, no. physician visits, prior hospitalizations, asthma, cardiovascular disease and hyperlipidemia, in 1 yr prior to index date RA vs. general population	1.42 (1.27-1.60)	
Multivariable PHM stratified by gender RA vs. general population	Males	1.42 (1.19-1.69)
	Females	1.45 (1.25-1.68)
Multivariable PHM stratified by age RA vs. general population	<60 years	1.53 (1.15-2.03)
	>60 years	1.37 (1.20-1.56)
PHM Sensitivity Analyses modeling potential confounding effect of smoking, RA vs. general population controls	Prev.:10% OR: 1.3	1.39 (1.23-1.56)
	Prev.:10% OR: 3.0	1.23 (1.10-1.39)
	Prev.:20% OR: 1.3	1.41 (1.26-1.59)
	Prev.:20% OR: 3.0	1.14 (1.01-1.29)

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Epidemiology and Public Health Poster I: Comorbidities and Outcomes of Systemic Inflammatory Diseases

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: It has been shown that patients with Rheumatoid Arthritis (RA) are at increased risk for certain malignancies, among them lung cancer. We aimed to investigate the association between lung cancer and different RA phenotypes based on rheumatoid factor (RF) and anti-citrullinated peptide antibody (ACPA) status.

Methods: We used the population-based case-control study EIRA (Epidemiological Investigation of Risk factors for Rheumatoid Arthritis). Patients with RA diagnosis and controls (matched for age, sex, calendar period and area of residence) were included during 1996-2013. The data were linked to the Swedish nationwide cancer register. Cox regression was used to calculate RR. Due to the significant correlation between smoking and RA as well as presence of RF and ACPA, stratified analyses based on smoking status were performed, in order to account for effect modification.

Results: A total of 3547 RA patients and 5586 controls were included in the study**.** The mean age (SD) was 52 (13) years and the percentage of female was 72%. Significantly more RA patients than controls were diagnosed with lung cancer after RA diagnosis (58 vs. 26 per 100,000 patient-years, respectively, p=0.002). RA itself gave twice an increased risk for developing lung cancer when adjusted for age and sex (RR=1.9, 95% CI=1.2-3.2, p=0.01), but the statistical significance disappeared when smoking was included in the model. However, after stratification according to smoking status, RA was significantly associated to lung cancer development in never or ex-smokers (RR=2.4, 95% CI=1.0-6.2, p=0.05) but not in current smokers (RR=1.2, 95% CI=0.6-2.3, p=0.6).

In RA patients, higher age, smoking, RF positivity, RF and/or ACPA positivity and double seropositivity were significant risk factors for lung cancer (table 1). In a stratified by smoking status analysis RF positivity was significantly associated to lung cancer in non-smokers (table 2).

Conclusion: In this study RA, especially RF positive RA, was associated to the development of lung cancer in never or ex-smokers. Although not statistically significant, patients who developed lung cancer were more often positive for RF and/or ACPA irrespective of smoking status.

Variable	RR (95% CI)	P-value
Sex (female vs. male)	0.6 (0.3-1.2)	0.64
Age	1.1 (1.1-1.2)	<0.0001
Smoking (current vs. never/ex)	3.2 (1.6-6.6)	0.002
Smoking (ever vs. never)	3.6 (1.1-12.0)	0.03
Silica exposure (yes vs. no)	2.2 (0.7-6.9)	0.18
RF (pos vs. neg)	4.6 (1.6-13.0)	0.004
ACPA (pos vs. neg)	1.9 (0.9-4.0)	0.11
ACPA and/or RF (pos vs. neg)	7.0 (1.7-28.9)	0.008
Double pos (RF and ACPA) vs. double neg	6.8 (1.6-28.8)	0.01

Table 1. Risk factors for developing lung cancer after RA diagnosis (results of the Cox regression analysis adjusted for age and sex).

	Non-Smokers (never or ex-smokers)			Smokers (current)		
Variable	N. patients (seropositive with lung ca/total with lung ca)	RR (95% CI)	P-value	N. patients (seropositive with lung ca/total with lung ca)		
RF (pos vs neg)	11/12	7.4 (1.0-57.4)	0.06	17/20	2.4 (0.7-8.2)	0.16
ACPA (pos vs neg)	9/12	2.3 (0.6-8.7)	0.20	14/20	1.2 (0.4-3.1)	0.74
ACPA and/or RF pos vs double neg	11/12	5.5 (0.7-42.5)	0.10	19/20	5.8 (0.8-43.2)	0.09
Double pos (RF and ACPA) vs double neg	9/10	6.1 (0.8-47.9)	0.09	12/13	4.8 (0.6-36.5)	0.14

Table 2. Risk for developing lung cancer after RA diagnosis for different RA phenotypes according to the presence of RF and ACPA in non-smokers and smokers.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Epidemiology and Public Health Poster I: Comorbidities and Outcomes of Systemic Inflammatory Diseases

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: This study was conducted in a large health care claims database to determine whether there is a difference in the incidence rate (IR) of pulmonary embolism (PE) among the bDMARD-treated rheumatoid arthritis (RA) population compared with the non–bDMARD-treated RA population and the general non-RA population.

Methods: This retrospective cohort study was performed using a large health care claims database (2001-2013). The study consisted of three cohorts: RA biologic treated, RA biologic naive, and general non-RA population. These cohorts were matched by age and sex. Patients were considered bDMARD exposed if they had one or more prescription claims for a biologic DMARD continuously for at least 90 days after the first RA diagnosis, and they were considered bDMARD naive if they had no bDMARD claims at any time after the first RA diagnosis and 365 days before the first RA diagnosis. The non-RA cohort consisted of those who did not have any exposure to bDMARDs or any arthritis diagnosis claims throughout the study period. Patients who were younger than 18 years of age or who had a history of PE were excluded. Cox regression analysis was used to derive the incidence rate ratio (IRR) comparing the 3 study cohorts, adjusting for age, sex, baseline comorbidity score, and oral steroid use.

Results: For each of the 3 cohorts, 25,373 patients were identified. Most patients were female (~70%) and 34 to 65 years of age (~75%). Certain comorbidities (CHF, CV disease, and diabetes) were seen more often in the RA population than in the general population. The IR of PE was 0.38 (95% CI, 0.33-0.44) in bDMARD-treated patients, 0.31 (95% CI, 0.27-0.34) in bDMARD-naive patients, and 0.10 (95% CI, 0.07-0.14) in the general population per 100 person-years. The adjusted IRR of PE for bDMARD-treated patients was 2.3 times that for the general population ($p < 0.0001$; 95% CI, 1.59-3.23) and 1.05 times that for non-bDMARD RA patients ($p = 0.5743$; 95% CI, 0.88-1.25). The adjusted IRR of PE for non-bDMARD RA patients was 2.2 times that for the general population ($p < 0.0001$; 95% CI, 1.53-3.04). Age ($p < 0.0001$, IRR = 1.03; 95% CI, 1.022-1.037), baseline comorbidity score ($p < 0.0001$, IRR = 1.17; 95% CI, 1.13-1.20), and baseline oral steroid use ($p< 0.0001$, IRR = 1.43; 95% CI, 1.20-1.71) were all significantly associated with the risk for PE.

Conclusion: The IR of PE was 2-fold to 3-fold higher in the RA population than in the general population. However, after adjusting for baseline covariates, we did not identify any statistical difference between bDMARD-treated and bDMARD-naive RA patients. Age, steroid use, and comorbidities are important risk factors for PE in RA patients.

Session Date: Sunday, November 8, 2015

Session Title: Epidemiology and Public Health Poster I: Comorbidities and Outcomes of Systemic Inflammatory Diseases

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Cardiovascular and lung disorder morbidities are more common in people with inflammatory arthritis (IA) than in the general population. However, little is known about the impact of these morbidities on daily functioning including physical activity. The aim of this study was to investigate the levels of physical activity in people with and without these morbidities.

Methods: This study was conducted in a large population-based study in the UK (UK Biobank), including people aged 40 to 70. Age, gender, and smoking status were recorded at inclusion. Inflammatory arthritis (rheumatoid arthritis (RA), psoriatic arthritis (PsA) and ankylosing spondylitis (AS)) and morbidity data including cardiovascular diseases (heart attack, angina, stroke) and lung disorders (emphysema, bronchitis, and asthma) was identified on the basis of self-report and participants were categorised as follows: no IA and no morbidity (noIA-noM), no IA and morbidity (noIA-M), IA and no morbidity (IA-noM) or IA and morbidity (IA-M). Participants completed the International Physical Activity Questionnaire and were classified as doing "low physical activity (lpa)", "moderate physical activity (mpa)" or "vigorous physical activity (vpa)". Multinominal logistic regression analysis was applied to assess the association between health status group (noIA-noM=base case) and physical activity group (lpa=reference), adjusted for gender, age and smoking, and presented as relative risk ratios (adjRRR, (95%CI)). Adjusted probabilities for each activity level are presented in figure.

Results: This study included 400,261 (81.5%) people with noIA-noM, 83,246 (17.0%) people with noIA-M, 5,800 (1.2%) people with IA-noM, and 1,790 (0.36%) people with IA-M. Percentage female gender was, respectively, 55%, 51%, 63%; and 63% and mean (SD) age ranged from 56 (8) to 59 (7) years. Within each group, the percentage of participants doing lpa, mpa or vpa was, respectively: lpa (24.9%, 29.3%, 34.9%, 42.9%); mpa (38.4%, 36.9%, 35.6%, 32.0%) or vpa (36.7%, 33.8%, 29.5%, 25.1%). The expected risk for people with a cardiovascular/lung disorder morbidity and/or IA doing moderate or vigorous activity was lower than those without these diseases. Furthermore, people with IA, but no morbidity, were less likely to do mpa or vpa than people without IA, but having these morbidities. adjRRRs (95%CI) for noIA-M, IA-noM and IA-M were respectively: for mpa (0.82 (0.80-0.83); 0.66 (0.62-0.71); 0.49 (0.44-0.55)) and even lower for vpa (0.78 (0.77-0.79); 0.59 (0.55-0.63); 0.42 (0.37-0.47)). Adjusted probabilities are shown in figure.

Conclusion: In this large population-based study we observed that people with both IA and morbidities were less active compared to those without morbidities or those with no IA and morbidities. It is therefore important to evaluate morbidities in clinical studies when investigating functional ability.

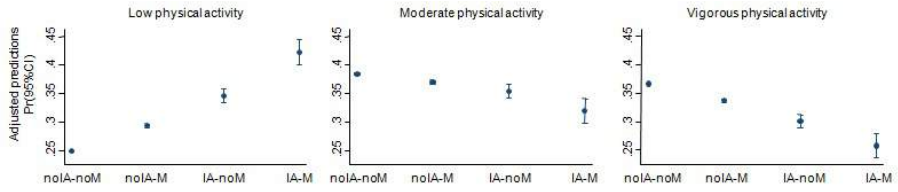

Figure. Adjusted predicted probabilities by physical activity group. Probabilities adjusted for age, gender and smoking status.

Session Title: Epidemiology and Public Health Poster I: Comorbidities and Outcomes of Systemic Inflammatory Diseases

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Cardiovascular disease is a major cause of morbidity and mortality in patients with Rheumatoid Arthritis (RA). Patients with RA do also have an increased risk of infections. Previous studies suggest that recent infection may trigger myocardial infarction and stroke, and this mechanism may be particularly important in patients with underlying low-grade inflammation such as RA. Our objective was to examine whether RA-patients have increased risk of cardiovascular events (CVE) following hospitalized pneumonia compared to patients with pneumonia without RA.

Methods: We conducted this population-based cohort study of adults with a first-time hospitalization with pneumonia between 1997 and 2011 in Northern Denmark. Information on RA, comorbidity, pneumonia and CVE was obtained from medical databases. Comorbidity data included the 19 conditions in the Charlson Index, alcoholism and previous diagnosis of CVE. We defined CVE as stroke or acute myocardial infarction. Data on mortality was ascertained from the Danish Civil Registration System. Cox regression was used to compute Hazard Ratios (HR) for CVE following hospitalization comparing patients with and without RA, controlling for sex, age, level of comorbidity, prior CVE, alcoholism, and antibiotic therapy before admission.

Results: A total of 75,087 patients were hospitalized with pneumonia. Among them 1677 (2.2%) had RA. All-cause mortality after 30 or 90 days did not differ between RA- and non-RA-patients with crude 30- and 90-day MRRs of 0.98

(95% CI: 0.87-1.11) and 0.99 (95% CI: 0.89-1.10) and adjusted MRRs of 0.99 (95% CI: 0.87-1.12) and 0.98 (95% CI: 0.88-1.09), respectively (table 1). A larger proportion of the RA-patients had prior CVE 18.1% (95% CI: 16.3-20.0) vs non-RA-patients 15.3% (95% CI: 15.1-15.6). Overall, we found no substantially higher risk of CVE following pneumonia among RA patients compared with non-RA patients (table 2). However, 8 to 30 days after pneumonia CVE risk tended to be increased in RA patients, with corresponding crude and adjusted HRs for CVE of 1.41 (95%CI: 0.94-2.12) and 1.32 (95%CI: 0.88-1.98) (table 2).

Conclusion: A larger proportion of RA patients with a first time hospitalization with pneumonia had prior CVE compared to pneumonia patients without RA. The risk of new CVE 8 to 30 days after pneumonia admission tended to be increased in RA patients.

Table 1 Characteristics of 75087 patients hospitalized for pneumonia from 1997 to 2011 in Northern Denmark

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Epidemiology and Public Health Poster I: Comorbidities and Outcomes of Systemic Inflammatory Diseases

Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: The increased risk for cardiovascular (CV) disease in rheumatoid arthritis (RA) is well established. However, there are relatively few contemporary cohort studies with long term follow up studying this risk.

Methods: The CARRÉ study is an ongoing prospective cohort study investigating cardiovascular morbidity and mortality in 353 patients with longstanding RA. Cardiovascular end points, defined as a verified medical history of coronary, cerebral or peripheral arterial disease, were assessed at baseline, 3, 10 and now 15 years of follow up. Incidence density rates per 100 patient years were calculated and cox regression analyses were performed to investigate the associations between baseline characteristics and incident CV disease.

Results: During 15 years of follow up 99 (28%) individuals developed at least one CV event. The mean follow up time was 9.0 ± 4.1 years with a total time at risk of 3186 patient years. This resulted in an incidence rate of 3.1 per 100 patient-years. Risk factors for developing a CV event were an elevated blood pressure, dyslipidemia and renal dysfunction after adjustment for age, gender, prevalent CVD.

Conclusion: The incidence rate was 3.1 CV events per 100 person years in RA patients approximately double that of the general population (Peters et al. 2009). Further research will include a direct comparison of these patients to a control group representative of the general population to generate hazard ratios of CV events in this study population.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Epidemiology and Public Health Poster I: Comorbidities and Outcomes of Systemic Inflammatory

Diseases

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose : Our aim was 1) to analyze the association between demographic and traditional cardiovascular risk factors (CVRF) and cardiovascular disease (CVD) in subjects affected with rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), psoriasis (Ps), psoriatic arthritis (PsA), Crohn's disease (CD), or ulcerative colitis (UC), and 2) to compare the standardized prevalence of CVD among these conditions.

Methods : Subjects included in this cross-sectional study were collected as part of the Immune-Mediated Inflammatory Disease Consortium between 2007-2010. Demographic and clinical data was collected using standardized questionnaires during a clinical interview with close questions and review of medical records. Multivariate logistic regression models adjusted by demographic (gender, age, educational level, elapsed time from IMID diagnosis) and traditional CVRF [dyslidepemia (DL), type 2 diabetes (T2D), obesity (OB), ever smoking] were constructed for each IMID. **Results** for each variable were combined using inverse variance weighted metaanalysis. Standardized prevalence for each IMID, adjusted by demographic and traditional CVRF [per 100 patients, with 95% confidence intervals (CI)] was calculated using marginal analysis.

Results: 9951 patients were included (**Table 1**). **Table 2** shows the association between demographic and traditional CVRF and CVD in each IMID. When results from the 6 cohorts were combined, males, lower educational level, older age and more time elapsed from disease diagnosis, and presence of DL and T2D were independently associated with a higher risk of CVD. SLE exhibited the highest standardized prevalence, followed by RA, Ps, CD, PsA and UC (**Figure 1**).

Conclusion : The contribution to CV risk of demographic and traditional CVRF is different for each IMID. SLE showed the higher standardize prevalence of CVD when compared to other IMIDs.

Impact of Obesity on the Disease Course of Rheumatoid Arthritis

Yang (Linda) Liu[1], Gilaad Kaplan[2], Bertus Eksteen[3] and Cheryl Barnabe[1], [1]Cumming School of Medicine, University of Calgary, Calgary, AB, Canada, [2]Division of Gastroenterology, University of Calgary, Calgary, AB, Canada, [3]Division of Hepatology, University of Calgary, Calgary, AB, Canada

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Epidemiology and Public Health Poster I: Comorbidities and Outcomes of Systemic Inflammatory Diseases

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Obesity results in a higher risk for the development of rheumatoid arthritis (RA) but is associated with less radiographic damage. The evidence for the effect of obesity on disease outcomes and course has not been synthesized but is important to understand as it may be a modifiable risk factor that impacts RA progression and response to treatment.

Methods: A Medline search was performed (to May 2015) using 'Obesity' and 'Body Mass Index' as MeSH terms, and with relevant terms and acronyms in the title and abstract search. The results of this search were combined with a strategy to identify rheumatoid arthritis studies. Articles were selected for inclusion if they described composite disease activity measures or states (DAS28, SDAI, CDAI), individual disease activity measures (tender and swollen

joint counts, ESR, CRP, patient global assessment), patient reported outcomes (pain, HAQ, fatigue, quality of life scales), or mortality rates, stratified by body mass index (BMI) category or in relationship to BMI on a continuous scale. Meta-analysis was completed using the generic inverse-variance approach with random effects models based on the most adjusted models presented using RevMan version 5.3.

Results: A total of 1,281 records were screened. After applying inclusion criteria, a total of 24 articles were identified that reported on a disease activity measure of interest, 3 reported on the association with obesity and mortality in RA, and 8 articles described remission by obesity status. Only 6 out of 19 studies reporting on DAS28 found higher DAS28 scores at baseline for obese patients in comparison to normal weight subjects, but 6 out of 8 studies found significantly higher scores in obese subjects during follow-up. Obese patients demonstrated lower odds of achieving remission (pooled OR 0.57, 95%CI 0.45 to 0.72, Figure 1) and sustained remission (pooled OR 0.49, 95%CI 0.32 to 0.74). Of the 12 studies that reported on ESR and CRP, only 3 found an association between BMI and baseline ESR and none found a significant association for CRP. Obese patients had a worse baseline HAQ score in 6 out of 14 studies, worse patient global assessment of health in 5 out of 11 studies, and higher levels of pain in 5 out of 8 studies. Three studies measured the total SF-36 Score, or Physical and Mental Component Scores, with obese patients having worse quality of life. There was not an increased mortality risk for obese patients (n=3 studies).

Conclusion: Obesity decreases the odds of achieving remission in RA, and is associated with increased pain, impaired functional ability, and decreased quality of life. Interventions to reduce BMI should be investigated for the ability to improve disease outcomes.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Epidemiology and Public Health Poster I: Comorbidities and Outcomes of Systemic Inflammatory Diseases

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: In the general population, higher body mass index (BMI) is associated with cardiovascular (CV) disease. However, an obesity paradox has been observed in rheumatoid arthritis (RA), where lower BMI is associated with adverse outcomes while obesity appears to be protective. This relationship may be confounded by weight-loss among sicker individuals. We sought to comprehensively examine independent associations between baseline BMI and recent weight loss with CV mortality in RA.

Methods: Patients in the Veterans Affairs RA Registry were followed from enrollment until death or December 2013. BMI was obtained from medical records ±14 days of each visit. Enrollment BMI was categorized as underweight (<22 kg/m^2), normal (22-25 kg/m^2), overweight (25-30 kg/m^2) and obese (>30 kg/m^2). An annualized rate of BMI change was determined from the slope of BMI over time from visits in the preceding 13 months (categories: <0, 0-2, 2-3, and >3 kg/m^2 lost/year). Vital status and cause of death were determined through the National Death Index. Associations with CV mortality were examined using multivariable competing-risks regression.

Results: There were 1,652 patients with 99 CV deaths occurring over 5,851 patient-years of follow-up. Patients were predominantly male (91%), had established disease (mean 11.7±11.4 years), and were positive for RF (80%) or anti-CCP antibody (78%). Mean BMI at enrollment was 28.6±5.7 kg/m^2 with 9% underweight, 18% normal, 38% overweight, and 35% obese. Associations with CV mortality are shown in Table 1. In age- and gender-adjusted models (Model A), enrollment BMI category was not associated with CV mortality. In a multivariable model adjusting for comorbid conditions (Model B), an obese BMI at enrollment was associated with greater CV mortality (Hazard ratio [HR] 1.55, 95% confidence interval [CI] 1.05-2.27, P = 0.026). Annualized recent weight loss of more than 3 kg/m^2/year was also independently associated with CV mortality (HR 1.66, 95% CI 1.24-2.22, P = 0.001). Cumulative incidence of CV death by weight loss categories is shown in Figure 1.

Conclusion: Obesity at enrollment and greater rates of weight loss are independently associated with CV mortality in RA. These results suggest that weight loss rather than low body weight per se may drive the observed Òobesity paradoxÓ in RA with regard to CV risk. Preventive strategies for CV mortality in RA should focus on maintaining a normal BMI.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Epidemiology and Public Health Poster I: Comorbidities and Outcomes of Systemic Inflammatory Diseases

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid Arthritis (RA) is associated with excess mortality. Indigenous North Americans (INA) in our region have high RA prevalence rates and young age at onset yet experience disparities in arthritis treatment. We determined if comorbidity and mortality were increased in INA with RA and the factors associated with mortality in RA.

Methods: Using administrative health data from our region (years 2000-2010; population 1.1 million), a previously validated case definition for RA, and the INA identifier from Indian Affairs, we identified cohorts of incident (N=4195) and prevalent (N-8095) RA. Comorbidity was determined using a modified Charlson Comorbidity Index (mCCI) categorized as 0, 1, 2, 3 or more, and the John Hopkins mental and physical Major Adjusted Disease Groups (mADG, pADG). Regional income quintiles were used as a proxy for socioeconomic status. Death, age at death and cause of death were identified in prevalent and incident RA; duration of RA at death was determined in incident RA. Crude all-cause mortality rates were adjusted to age and sex or to age, sex and last visit mCCI. Annual mortality rates between INA and nonINA and persons with or without RA were compared using Student T tests. Cox proportional hazards models evaluated contributors to death in RA controlling for age, sex, ethnic group, income quintile, and comorbidity. Odds Ratio(OR) with 95% confidence limits (CL) are reported.

Results: In spite of a young onset age (INA 42 vs nonINA 55 yr $p<0.001$), INA were more likely to have nonRA comorbidity (mCCI >0) than nonINA at baseline (39% vs 31% OR 1.43 CL 1.25-1.64 $p<0.0001$) but equally likely to have multiple comorbidities at last visit (both 22% OR 0.99 CL 0.84-1.16). More INA than nonINA reported mADG at baseline (27% vs 19% OR 1.59 CL 1.37-1.84) and last visit (26.9% vs 22.8% OR 1.29 CL 1.12-1.49). pADG rates were similar at baseline (39% vs 42% OR 0.9 CL 0.79-1.02) and last visit (49% vs 52% OR 0.9 CL 0.79-1.02). Between 2000-2010 1068 prevalent RA patients died (96 (9%) INA; 972 (14%) nonINA including 301 incident RA (23 (4%) INA; 278 (8%) nonINA). Prevalent RA INA were much younger at death than nonINA (56 (CL 54-59)vs 77 (CL 76-77) years; $p<0.0001$), a trend seen for males and females each year even after adjusting for mCCI. Cause of death was similar for INA and nonINA with a trend to less cancer deaths and more “other” deaths in INA. Age and sex (and mCCI) adjusted mortality rates decreased in the general population yet increased for persons with RA. Age, sex

and mCCI adjusted annual mortality rates were higher in INA than nonINA with RA. In cox proportional hazards models, increasing comorbidity, both pADG (1.64 (1.29-2.08)) and mADG (1.56 (1.19-2.04)), older age, female sex and lower income predicted death, but INA ethnicity did not.

Conclusion: Persons with RA, in particular INA, have increased mortality partly explained by increasing mental and physical comorbidity. The high rate of comorbidity at an early age and young age at death in INA RA is striking. The independent influence of mental comorbidity on mortality suggests a complex social-biologic phenomenon of particular relevance to INA given their unique social stressors that needs to be addressed as an early step to improving outcomes for this vulnerable population.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Epidemiology and Public Health Poster I: Comorbidities and Outcomes of Systemic Inflammatory Diseases

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is associated with increased all-cause and cause-specific mortality, including mortality from cardiovascular (CV) disease, respiratory causes, infections and malignancy. Evidence of improved overall mortality in RA is growing and decrease in CV mortality has been suggested in some studies including our own. Recent trends in non-CV mortality are not well understood. We aimed to assess trends in non-CV mortality including mortality from respiratory disease, neoplasms and other causes in patients with incident RA in 2000-2007 compared to the previous decades.

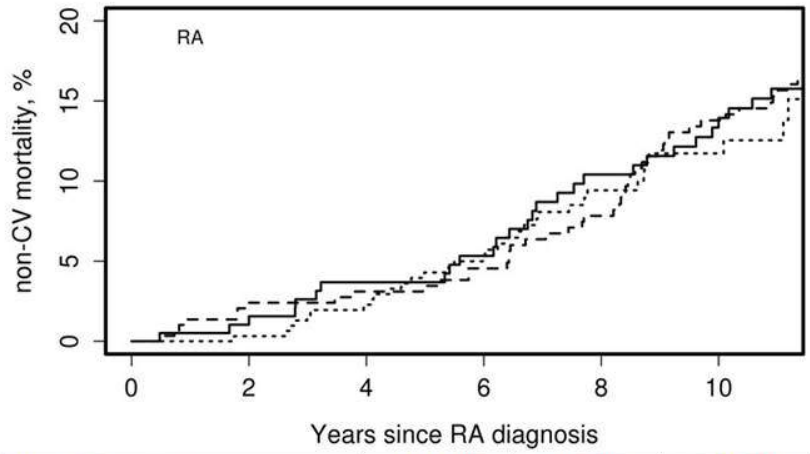
Methods: The study population comprised a retrospectively identified population-based incidence cohort of patients with RA (age>18 years, 1987 ACR criteria met in 1980-2007). All subjects were followed until death, migration, or 1/1/2014. Underlying causes of death were obtained from state and local death certificates as well as the National Death Index Plus and grouped according to ICD-9 and ICD-10 chapters. Kaplan-Meier methods were used to estimate mortality rates. Cox proportional hazards models, adjusting for age and sex, were used to compare cause-specific mortality by decade.

Results: The study included a total of 813 RA patients (mean age 55.9 years; 68% female; 66% rheumatoid factor [RF] positive). Figure shows non-CV mortality by decade of RA incidence and the table summarizes these data. In patients

with incident RA during the 2000–2007 period, there was no statistically significant difference in 10-year mortality from non-CV causes overall (hazard ratio [HR] 0.92; 95% Confidence Interval [CI] 0.60 – 1.42; p=0.71), including mortality from respiratory disease (HR 1.51; 95% CI 0.56 – 4.09; p=0.42), neoplasms (HR 0.69; 95% CI 0.36 – 1.31; p=0.25) and other causes (HR 0.84; 95% CI 0.38 – 1.86; p=0.66) compared to those with RA incidence in 1990–1999.

Conclusion: Our findings suggest that there has been no significant improvement in mortality from non-CV causes overall among patients with incident RA in 2000-2007 compared to patients with incident RA in the previous decades. However, the trends in individual non-CV causes including respiratory disease, neoplasms and other causes may be heterogeneous and require caution in interpretation due to limited statistical power in our study. Lack of improvement in non-CV mortality in RA may be contributing to the persistent excess in relative mortality in RA vs non-RA subjects, suggesting a need for improved control of non-CV comorbidities in RA. More studies are needed to understand the underlying reasons for this lack of improvement in mortality from non-CV causes in RA patients.

Figure. Mortality from Non-Cardiovascular (non-CV) causes in patients with Rheumatoid Arthritis (RA) with incidence date in 1980-89 (solid line) 1990-99 (dashed line), 2000-07 (dotted line).



Year of RA incidence	1980-1989	1990-1999	2000-2007
Number of patients	202	296	315
Mean follow-up, years	17.6	14.5	8.6
Non-cardiovascular deaths	77	79	33
- Respiratory	10	11	8
- Neoplasms	26	37	14
- Other causes	41	31	11
10-year non-cardiovascular mortality, %	13.9±2.6	13.8±2.1	11.7±2.1
- 10-year respiratory mortality, %	1.7±1.0	2.3±0.9	3.3±1.2
- 10-year neoplasm mortality, %	7.0±1.9	8.3±1.7	5.3±1.4

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Epidemiology and Public Health Poster I: Comorbidities and Outcomes of Systemic Inflammatory Diseases

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Observational studies have shown an increased risk of mortality in patients with RA, though none have done so with patients from all 50 US states nor is it clear how this risk may vary over time. We examined this risk since 1998 by calendar year, duration of RA, and treatment.

Methods: RA and non-inflammatory rheumatic disease (NIRD) patients were studied from 1998 through 2011 in the National Data Bank for Rheumatic Diseases (NDB), a longitudinal observational study following patients from all regions of the US through biannual questionnaires. Patients were required to have at least 2 observations or 1 observation and died before 2012; those recruited through FDA-mandated safety registries were excluded. Mortality was confirmed through National Death Index-matched death records. We calculated standardized mortality rate ratios (SMRRs) of RA vs. NIRD based on age-, race- and sex-stratified US population data (CDC.gov). Cox regression models with time varying covariates were used to investigate the risk of mortality among diagnoses.

Results: Among 15,791 RA patients, 3,531 patients died (22.4%). The mean (median) time in the study was 5.0 (4.0) years with a total of 79,841 patient-years of follow-up. For the 4,058 NIRD patients, 947 patients died (23.3%) with a mean (median) time in the study of 5.0 (3.9) years with a total of 20,500 patient-years of follow-up. The overall SMRR for RA vs. NIRD patients was 1.48 (95% CI 1.38-1.78). For RA duration ≤5 years, the SMRR was 1.35 (1.20-1.52). For earlier calendar cut-offs, the SMRR was 1.56 (1.38-1.63) for before 2008 and 1.74 (1.42-2.15) for before 2004. Adjusted for age, age^2 and sex, the hazard ratio (HR) for RA vs. NIRD was 1.40 (1.30-1.50). Adjusting for additional confounders such as HAQ, pain, patient global, employment, marital status, BMI, and smoking, resulted in an HR of 1.27 (1.17-1.38). Worse disease activity markers, higher comorbidity index, and smoking were all associated with an increased risk of mortality, as opposed to higher education, being employed, and married. When analyzing RA patients only, hierarchical DMARD/biologic treatments showed only cytotoxic DMARD use being associated with an increased risk compared to monotherapy MTX (Table).

Conclusion: In this large US cohort, the risk of mortality for RA patients remained elevated compared to NIRD patients. We found trends that the SMRRs decreased over the last 14 years, yet unlike other US studies, we found no associated mortality benefit of biologics over MTX monotherapy after adjusting for multiple confounders.

Table. Cox regression model for mortality in RA patients

	HR	[95% Conf.	Interval]	P-value

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Epidemiology and Public Health Poster I: Comorbidities and Outcomes of Systemic Inflammatory Diseases

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Patients with rheumatic diseases (RD) have an increased mortality risk compared to the normal population. The current prospective follow-up study investigated the prevalence of depressive symptoms and quality of life and their impact on prognosis.

Methods:

764 consecutive patients attending the rheumatology outpatient department of the University Hospital Würzburg underwent a comprehensive cardiovascular (CV) risk assessment. Quality of life and depressive symptoms were investigated by SF-36 and PHQ-9 (range 0-27 score points), respectively. A PHQ score >14 points is considered indicative for severe depressive symptoms. Patients were followed over 5 years for incident CV events and death of any cause.

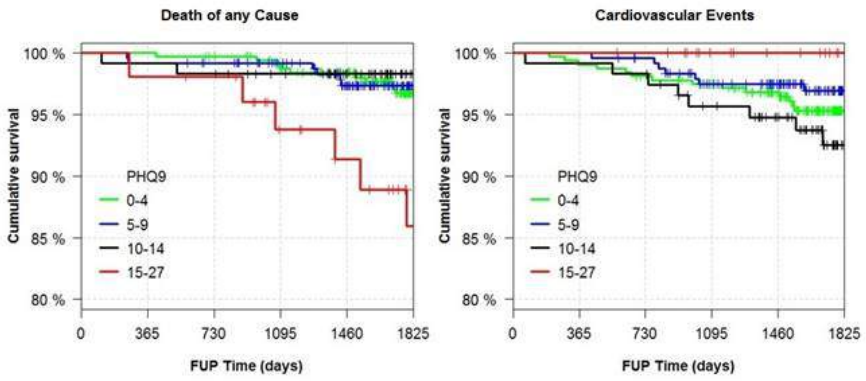
Results:

352 subjects suffered from rheumatoid arthritis (RA: 79.5% female, 64.9% RF positive, mean age 54.3 (SD 14.3)), 260 from systemic autoimmune disease including connective tissue disease and vasculitis (SAI: 76.9 % female, mean age 51.4 (SD 14.5)), and 152 patients had spondyloarthritides including psoriatic arthritis (SpA: 35.5 % female, mean age 44.7 (SD 12.3)).

Severe depressive symptoms were prevalent in 7% (tab 1) of patients. There were no significant differences in the three groups regarding PHQ-9 subgroups (χ^2-Test: p=0.214).

n (%)	PHQ9			
	0-4 (minimal)	5-9 (mild)	10-14 (moderate)	15-27 (severe)
RA	154 (46.1)	110 (32.9)	48 (14.4)	22 (6.6)
SAI	109 (44.3)	85 (34.6)	35 (14.2)	17 (6.9)
SpA	54 (36.7)	47 (32)	34 (23.1)	12 (8.2)
total	317 (43.6)	242 (33.3)	117 (16.1)	51 (7.0)

Within 5 years, 18/10/0 patients died in the 3 groups (RA/SAI/SpA). Patients with severe depressive symptoms had a hazard ratio (HR) of 5.11 (95% CI 2.01–12.97) for death of any cause compared to the patients with less severe depressive symptoms. By contrast, the risk of CV events in the severe depressive group was similar compared with the other groups (p=0.73).



IMG1: Kaplan-Meier plot: Survival and CV events in PHQ-9 groups.

The 4 physical sections of SF-36 revealed an influence on the risk of death: HR for low tertile 3.95 (95% CI 1.67–9.31) if compared versus mid and high tertile combined. The 4 non-physical sections did confer prognostic information.

Conclusion:

RD patients with severe depressive symptoms as assessed by PHQ-9 exhibit an increased mortality risk, but not an increased risk for CV events.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Epidemiology and Public Health Poster I: Comorbidities and Outcomes of Systemic Inflammatory Diseases

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Depression and anxiety have detrimental effects on quality-of-life, treatment response and disease outcomes. Whilst psychological morbidity has been described in individual rheumatic diseases, less is known about the comparative burden across the spectrum of rheumatic conditions. The prevalence of depression and anxiety in the general population is 3.8% and 5% respectively. We sought to quantify major depressive disorder (MDD), suicidal ideation, and generalised anxiety disorder (GAD), in a cross-section of rheumatology outpatients.

Methods:

All data were collected using electronic records from an inner city hospital in London, UK. MDD/GAD were identified using the Patient Health Questionnaire (PHQ9) and Generalised Anxiety Disorder questionnaire (GAD7) respectively. Suicidal ideation was identified using PHQ9 item 9: having "thoughts that you would be better off dead or of hurting yourself in some way".

Results:

Between February 2013 and February 2015, 1281 patients with a confirmed diagnosis were screened (mean age 53.6 (SD15.8); 24.6% male). Overall, 29.7% of patients reported significant psychological morbidity: 21.9% screened positive for MDD; 6% of patients reported suicidal ideation. GAD was found in 23.1% of patients; 10% reported severe anxiety symptoms (GAD7≥15). Depression correlated with increased pain (rho = 0.46, $p<0.001$) and fatigue (rho = 0.44, $p<0.001$). Anxiety correlated with increased pain (rho = 0.38, $p<0.001$) and fatigue (rho = 0.33, $p<0.001$). MDD was most prevalent in early inflammatory arthritis (EIA) (29.7%), and least prevalent in patients with vasculitis (17.5%). Fewer AxSpa reported severe MDD (8%), whilst the highest levels were reported in CTD (10.9%), EIA (10.8%) and PsA (10.8%). Severe anxiety was not significantly different across the diseases however GAD was substantially more prevalent in EIA (35.1%). Patients with PsA reported the most suicidal ideation (10%).

Conclusion:

Psychological comorbidity is highly prevalent across rheumatic diseases. The slightly higher levels of MDD and GAD in EIA may relate to the recent diagnosis, reflecting a period of adjustment to chronic illness and lifestyle and medication changes. The high prevalence of suicidal ideation in PsA may reflect the impact of visible cutaneous disease upon self-esteem and mood. Reporting suicidal ideation within the PHQ9 can imply anything from a fleeting thought of suicide, to a detailed plan. There is a need for greater awareness of mental health comorbidities in patients attending rheumatology clinics. These findings help delineate the magnitude of the problem and inform departments of the likely level of provision that will be needed. Integrating mental health services into musculoskeletal clinics offers a unique opportunity to improve clinical care, and based upon the burden of disease in our population, this approach is justifiable.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Epidemiology and Public Health Poster I: Comorbidities and Outcomes of Systemic Inflammatory Diseases

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Treatment responses and outcomes vary among rheumatoid arthritis (RA) patients. There is limited evidence on the contribution of social determinants of health (SDH) to remission in RA. This study aimed to determine the contribution of socioeconomic, environmental, and behavioral factors to remission in RA patients.

Methods:

Data were collected from the Ontario Best-practices Research Initiative (OBRI) Rheumatoid Arthritis Registry, a Canadian clinical registry of early and established RA patients followed in routine care. Remission at the 6-month follow-up visit was measured by three ways, based on disease activity measures DAS28 (Disease Activity Score-28), SDAI (Simple Disease Activity Index) and CDAI (Clinical Disease Activity Index). The SDH variables assessed include age, sex, socioeconomic status, health behaviors, social support, living condition, and psychosocial factors. The association between these variables and remission was evaluated by logistic regression analyses, controlling for clinical factors such as RA duration, RA medications, baseline disease activity and functional disability. Subgroup analyses were performed on early RA, with disease duration ≤1year, and established RA patients respectively. All statistical analyses were performed in SAS9.4.

Results:

Out of the 2305 patients at cohort entry, 1291 reached the 6-month follow-up visit, at which time, 26.9% achieved CDAI remission, 40% achieved DAS28 remission, and 41% achieved SDAI remission. Among the 406 early RA patients, alcohol consumption was independently associated with CDAI (OR 1.76 95%CI 1.01-3.05), SDAI (OR 1.79 95%CI 1.01-3.17), and DAS28 remission (OR 1.77 95%CI 1.06-2.93), while depression was negatively associated with SDAI (OR 0.23 95%CI 0.08-0.65) and DAS28 remission (OR0.34 95%CI 0.15-0.80), after adjusting for confounders (Table 1). Such findings were not observed in established RA patients with >1 year of RA or in all patients (early and established RA) combined. With the exception of education in the early RA group (Table 1), none of the socioeconomic factors was significantly associated with remission.

Conclusion:

In early RA, remission at 6 months into cohort entry was positively associated with alcohol consumption and negatively associated with depression. Previous studies have found a protective effect of alcohol against developing RA[1]. This study shows in addition a protective effect of alcohol on RA remission. This highlights the potential role of health behaviors in achieving positive treatment outcomes.

1. Scott IC, Tan R, Stahl D, Steer S, Lewis CM, Cope AP. The protective effect of alcohol on developing rheumatoid arthritis: a systematic review and meta-analysis. *Rheumatology (Oxford)*. 2013;52(5):856-867.

Table 1. Summary of social determinants of health factors associated with remission at the 6-month follow-up.

		Social Determinants of Health Factors Associated with Remission[§]				
	Outcome measures	Age	Alcohol Consumption	Smoking	Depression	Higher Education
Early RA patients' (RA duration ≤1yr)	CDAI Remission		+			
	SDAI Remission		+		–	+
	DAS28 Remission		+	–	–	
Established RA patients' (RA duration >1yr)	CDAI Remission					
	SDAI Remission	–				
	DAS28 Remission	–		+		

[§] In the multivariable analysis, variables with a $p<0.2$ in univariate analyses were included for adjustments. Factors tested in the univariate analyses include SDH factors (sex, employment status, neighborhood income, private insurance status, marital status, urban/rural residency, and the frequency of interruption to social interaction due to RA) and clinical factors (RA medication type, baseline disease activity, and baseline functional disability status).
[†] $p<0.05$ for variables with a '+' or '-' sign. A '+' sign represents a positive association with remission. A '-' sign represents a negative association with remission.

Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Previous research has attempted to study the association between weather and joint pain. Inconclusive results may be due, in part, to infrequent measures of pain and poor quality weather data. Patients' own smartphones present an opportunity for frequent data collection with parallel usage of global positioning satellite (GPS) technology to pull local weather data. This pilot study aimed to assess the feasibility and acceptability of symptom and weather data collection using a smartphone application (app).

Methods: Twenty adult patients with rheumatoid arthritis were recruited from a single rheumatology centre. The app was co-designed with 14 participants in conjunction with a pre-existing platform by uMotif. Patients were asked to report six symptom scores every evening (pain, morning stiffness, tiredness on waking, fatigue, wellbeing and overall disease severity) on a 1–5 scale for the past 24 hours, for 60 consecutive days. In addition, they reported four other factors (mood, physical activity, time spent outside and perceived influence of the weather). All ten scores were collected on a single screen using a visual 'motif' (figure). GPS data was collected hourly and weather data was pulled from the closest Met Office weather station. Weather variables were summarised for each patient-day.

Ongoing engagement was measured as: the number of study withdrawals; mean completion rate (mean proportion of days with at least one score out of time in study); and the proportion of eligible patients who completed 0–1, 2–4 or 5–7 entries per week. The completeness of weather data was measured as the proportion of days any weather data was collected.

Results: 5 male and 15 female patients were recruited (mean age 54.7). Dropout rate was 30%, (weeks 0, 1, 4, 4, 5 and 6) and reasons given were personal, technical and health issues. At the time of reporting, full eight week follow-up data were available for 11/14 patients. Mean completion rate was 73%. Patients reported scores ≥ 5 days per week 64% of the time and 86% of the time patients reported scores ≥ 2 times per week. Weather data were available for 80% of symptom reports.

Conclusion: Patient engagement with the app was high. Although six patients withdrew from the study, the remainder regularly reported symptoms over a two-month period.Weather data were successfully extracted from GPS data. This pilot study is proof of concept that this novel mode of data collection can be used for research and will inform a future larger study. Concurrent qualitative work will assess reasons for dropout and motivators for ongoing engagement.

Table Proportion of patients with regular data entry, by week

Week number	Number of patients in study	Number of participants entering data (percentage) 0–1 times per week	2–4 times per week	5–7 times per week
1	19	0 (0%)	4 (21%)	15 (79%)
2	18	1 (6%)	3 (17%)	14 (78%)
3	18	3 (17%)	4 (22%)	11 (61%)
4	18	4 (22%)	3 (17%)	11 (61%)
5	16	3 (19%)	4 (25%)	9 (56%)
6	14	4 (29%)	4 (29%)	6 (43%)
7	12*	2 (17%)	3 (25%)	7 (58%)
8	11*	1 (9%)	2 (18%)	8 (73%)

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Epidemiology and Public Health Poster I: Comorbidities and Outcomes of Systemic Inflammatory Diseases

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

The data sources available to answer comparative effectiveness and safety questions shortly after medication licensure may be limited. Social media may provide a unique resource to complement traditional data sources.

Methods:

We used the TREATO platform to crawl all publically-available social media data including Facebook, blogs, and discussion boards for posts mentioning inflammatory arthritis (e.g. rheumatoid, psoriatic arthritis). Safety events were self-reported by patients and mapped to medical ontologies, resolving synonyms. Disease and symptom-related treatment indications (e.g. arthritis, joint pain) were manually redacted and excluded. The unit of analysis was unique terms in posts. The focus of the analysis was more recently licensed US drugs (tofacitinib,tocilizumab).

Pre-specified conditions were selected based upon safety signals from clinical trials and reported as pairwise odds ratios (ORs); RA drugs were compared with Fisher's exact test. Empirically-identified events were analyzed using disproportionality analysis [similar to methods used to analyze FDA AERS data], and reported as relative reporting ratios (RRRs) and proportional reporting ratios (PRRs).

Results:

As of 6/2015, there were 549,939 arthritis-related posts discussing tofacitinib (n=543), etanercept (n=17,173), adalimumab (n=12,418), abatacept (n=2,776), and tocilizumab (n=821). Posts were predominantly U.S. (75%) and had patient authors (86%). The most common sources were Facebook, Arthritis Foundation, RemedySpot, Dailystrength, ArthritisCare and RA Warrior. The age distribution was <19(17%), 19-29(22%), 30-39(20%), 40-49(17%), 50-54(18%), and 65+ (6%). Common tofacitinib themes are shown as a word cloud (Figure).

For herpes zoster posts (n=888), ORs were significantly increased for tofacitinib compared to other RA therapies (Table); ORs for certolizumab-associated shingles mentions were higher as well (not shown). ORs for mentions of perforated bowel (n=11) were higher for tocilizumab vs. other therapies.

RRRs and PRRs associated with tofacitinib were highest for conditions related to baldness and hair regrowth, infections and cancer. Ongoing work is evaluating the clinical validity of the cases based upon available narratives and refining the analysis to restrict to confirmed cases.

Conclusion:

Social media is a challenging yet promising data source that may be used to complement traditional approaches for comparative effectiveness research for new medications shortly after licensure.

Table: Pairwise relative risks for posts mentioning herpes zoster and perforated bowel associated with RA-related medications in social media data sources

Outcome	Contrast	Relative Risk
Herpes Zoster	Tofacitinib vs. etanercept	2.88 (1.15 – 7.20)
	Tofacitinib vs. adalimumab	2.70 (1.07-6.79)
	Tofacitinib vs. infliximab	3.88 (1.47-10.23)
	Tofacitinib vs. methotrexate	3.24 (1.32-7.95)
	Certolizumab vs. etanercept	5.04 (3.02 – 8.41)
	Certolizumab vs. adalimumab	4.71 (2.78-7.98)
	Certolizumab vs. infliximab	6.77 (3.69-12.40)
	Certolizumab vs. golimumab	5.28 (1.56-17.82)
Perforated Bowel	Tocilizumab vs. infliximab	27.26 (5.29-140.37)
	Tocilizumab vs abatacept	18.73 (2.19-160.19)
	Tocilizumab vs. methotrexate	55.21 (16.00 – 190.42)
	Tocilizumab vs. adalimumab	26.95 (6.45-112.62)

Session Date: Sunday, November 8, 2015

Session Title: Epidemiology and Public Health Poster I: Comorbidities and Outcomes of Systemic Inflammatory Diseases

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Multimorbidity is a major problem in rheumatoid arthritis (RA) but is difficult to measure. Polypharmacy (PP) - co-prescribing an individual multiple medications – is considered a surrogate marker for the burden of multimorbidity. We evaluated the inter-relationships between PP, disease characteristics and acute hospital admissions in a retrospective cohort study of RA patients managed at one large UK specialist centre.

Methods: Routinely captured data were retrospectively analysed. All patients under care at the centre in May 2013 with a diagnosis of RA were included. Information on PP was extracted from the electronic record. Cox proportional hazards were used compare hospitalization risk according to levels of PP over the subsequent 18-months. Follow up was censored at date of first admission or study end, whichever came first. Further analysis explored relationships between DMARD prescribing and hospitalisation risk. All acute admissions were manually reviewed by two independent clinicians and adjudicated to determine whether an adverse drug reaction (ADR) or drug interaction was implicated.

Results: 1,101 RA patients were studied; their baseline features are shown in the table. The mean number of medications was 5, 29% of patients were on 6-9 medications and 11% on ≥10 medications. PP correlated with increasing age, longer disease duration, higher disease activity and disability (Table). In total 173 patients had at least one unplanned admission during follow up (overall incidence 11/100 patient years (95% CI 9 to 13). Patients on ≥10 medications had an age and gender adjusted hazard ratio for hospitalisation of 3.1 (95% CI 2.1 to 4.5) compared to those on <6. Different DMARD prescription strategies were not significantly associated with hospitalisation risk; steroid use associated with a doubling in risk 2.3 (95% CI 1.6 to 3.1). The most common reason for hospitalisation was infection 44/173 (28%), which was not significantly different across PP strata (p= 0.242). In half of all admissions, an ADR was a possible contributing factor. However, only 4 admissions were definitely a direct result of an ADR. Of these, 2 were related to over anticoagulation, 1 in the setting of co-prescription of leflunomide with warfarin.

Conclusion: PP is prevalent in RA patients and correlates to more severe disease as well as a higher rate of hospitalisation. What is unclear is whether or not PP is harmful. Review of the individual hospitalisations revealed very few admissions definitely attributable to an adverse drug reaction. However, there were many possible relationships (e.g. in cases of infection in patients on DMARDs), making a true understanding of the causal relationship between PP and hospitalisation unclear. Irrespective, PP does appear to reflect comorbidity well and represents a useful tool to adjust for confounding in epidemiologic analyses.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Epidemiology and Public Health Poster I: Comorbidities and Outcomes of Systemic Inflammatory Diseases

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) are at an increased risk for serious hospitalized infectious events (HIEs). Research suggests that tumor necrosis factor alpha inhibitors (TNFi), as well as oral glucocorticoids (GCs) both increase the risk of HIEs. Limited information is available regarding the contribution toward HIEs when taking into account the dose-level of oral glucocorticoids when used concomitantly among new users of TNFi.

Methods: We conducted a retrospective cohort study using an administrative claims database. Among incident and prevalent adult RA patients newly exposed to TNFi, patients were assigned to 3 fluid study cohorts: no GC exposure; low-dose GC (≤ 7.5 mg); high-dose GC (>7.5 mg). Patients were required to have at least 1 inpatient or outpatient diagnostic claim for RA (ICD-9-CM 714.0) with an accompanying claim for an incident TNFi and at least 6 months of continuous enrollment prior to TNFi initiation and 6 months after. Patients could be considered exposed to GCs multiple times during follow-up-time and may contribute time to different categories of exposure. Follow-up continued until disenrollment, HIE, discontinuation of TNFi, end of study (June 30, 2014), or 2 years after the index-date. The primary outcome was incident HIE and was attributed to the GC exposure category at the time of the outcome. Incidence rates and 95% confidence intervals per 100 person years were estimated for HIEs.

Results: The mean age and sex distribution (% of female) of RA-TNFi patients for the no GC, low-dose GC, and high-dose GC were 53.7 and 77%, 55.1 and 76%, and 55.1 and 74%. The risk of HIEs increased with increasing GC dose, with a higher incremental risk from high dose to low dose than from low dose to no dose (Table). The risk of HIEs is highest among patients ages >65 years of age but the elevated dose-related effects are comparable for those <65 and those > 65.

Conclusion: We found that both high dose and low dose steroids significantly increase the risk of HIEs. Although steroid doses under 7.5 mg are often considered to be relatively low risk for infection, physicians should bear in mind

that even low dose steroids significantly increase the risk of HIEs among patients newly initiating TNFi therapy.

Session Title: Epidemiology and Public Health Poster I: Comorbidities and Outcomes of Systemic Inflammatory Diseases

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Synthetic glucocorticoids (steroids) are commonly used in RA to rapidly inhibit pro-inflammatory cytokines. They are frequently used as "bridge therapy", quickly dampening down the immune response allowing slower-acting DMARDs time to effectively reduce disease activity. Early steroid use is variable. The purpose of this study was to compare characteristics and outcomes over time of patients exposed to early steroid use in a large early RA cohort.

Methods: Data are from the first 18 months of patients entering and followed in CATCH (Canadian early ArThritis CoHort). Inclusion criteria were symptoms ≤12-months, fulfillment of ACR 1987 and/or 2010 RA criteria and steroid use was recorded. Patients were stratified based on steroid use within first 3 months of study entry. Sociodemographic and RA characteristics between groups at baseline and selected outcomes (CDAI, DAS28, MD global, RAPID III and biologic starts) at 3, 6, 12, and 18 months were compared using t-test. Outcomes for patients receiving no, intra-articular/intra-muscular (IA/IM) only, oral only (PO), or both forms of steroids were evaluated at each time point.

Results: At baseline, patients who received steroids were older and less likely to be employed but not statistically different by race, weight, or SES. Steroid users had shorter symptom duration, higher acute phase reactants, and reported more pain and fatigue (Table 1). Both patient-reported outcomes (PROs: patient global, HAQ, RAPID III, RADAI pain and VR12) as well as clinically reported observations (CLINROs: MD global, joint counts, and DAS28) were significantly worse in those who received steroids. Steroid use was more frequent in participants enrolled at large study sites (>100 enrolled) and in those concomitantly taking MTX. Composite measures are worse over time in patients receiving both forms of steroids at months 3-12, and there is a trend toward more biologic use thereafter (Table 2).

Conclusion : Patients receiving steroids within the first 3 months tend to be older, with shorter disease duration and higher indicators of disease activity. These data suggest steroids are being used to intensify treatment in patients with

poor prognostic factors to control more active disease. Despite early use of both parenteral and oral steroids, biologic use in the long term is still required in patients with more active disease at baseline.

Table 1: Characteristics of participants by steroid use in first three months.

Session Title: Epidemiology and Public Health Poster I: Comorbidities and Outcomes of Systemic Inflammatory Diseases

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Glucocorticoids have long been linked to the development of osteonecrosis, mostly in heavily exposed patients from specialty clinics. We tested the hypothesis that oral glucocorticoids were associated with osteonecrosis in a dose-dependent relationship in people with chronic inflammatory diseases and modified by age and inflammatory disease.

Methods: We performed a retrospective cohort study using The Health Improvement Network, a population-representative medical records database from the United Kingdom. The study population included people at least 2 years old diagnosed with asthma; inflammatory bowel disease (IBD); juvenile, psoriatic, or rheumatoid arthritis; psoriasis; or systemic lupus. Those with prevalent glucocorticoid use, prior osteonecrosis, malignancy, or other high-risk diseases were excluded. Prednisone-equivalent dose was classified in tertiles by age. The association between time-varying oral glucocorticoid exposure and incident osteonecrosis was estimated using discrete time failure models and expressed as an adjusted hazard ratio (aHR). Hypothesis testing was 1-sided, since glucocorticoids were unlikely to decrease the rate of osteonecrosis.

Results: There were 428 cases of osteonecrosis among 920,321 eligible subjects. After adjusting for age, sex, inflammatory disease, history of fracture, and number of drugs prescribed, any glucocorticoid exposure was most strongly associated with osteonecrosis among adults ages 18-49 (aHR 2.0, 90% CI 1.4, 2.8, P<0.001)(Table). A dose response with cumulative glucocorticoid exposure was seen in adults (high vs. low dose, ages 18-49: aHR 3.2, 90% CI 1.6, 6.3, P=0.003; ages 50 and older: aHR 1.6, 90% CI 1.0, 2.6, P=0.048). Models examining maximum dose, dose intensity (integrating dose and duration), and weight-based dosing were similar. No significant association was seen for children in any model. Low-dose glucocorticoid exposures, corresponding to average doses <7.5 mg daily prednisone equivalents and maximum doses <30 mg daily in adults, were not associated with osteonecrosis at any age. Arthritis, IBD, and systemic lupus were independent risk factors (Table), but disease did not modify the effects of glucocorticoid dose on osteonecrosis.

Conclusion: High dose glucocorticoids are associated with osteonecrosis in adults, most strongly in those ages 18-49, but not in children. Underlying disease is an important risk factor but does not magnify the effect of glucocorticoid dose on osteonecrosis risk.

Table. Primary multivariable analysis of oral glucocorticoid exposure and osteonecrosis, stratified by age

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Epidemiology and Public Health Poster I: Comorbidities and Outcomes of Systemic Inflammatory Diseases

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Ankylosing Spondylitis Disease Activity Score (ASDAS) is a complex score for monitoring disease activity and ASDAS calculator is required for estimation. This study aimed to develop a simplified version which may be useful in AS patients in India.

Methods:

Consenting AS patients (modified New York and/or Assessment in Ankylosing Spondylitis 2009 criteria) were recruited between Jan 2012 and Dec 2014; n=254. Sociodemographic data and disease characteristics (Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankylosing Spondylitis Functional Index (BASFI), and Ankylosing Spondylitis Quality of Life (ASQoL), erythrocyte sedimentation rate (ESR) by Westergren's method, and C-reactive protein (CRP)by nephelometry were collected. Simplified ASDAS (SASDAS) was calculated as the simple sum ofpatient global assessment (using visual analogue scale), back pain (BASDAI question no. 2), peripheral pain and swelling (BASDAI question no. 3), morning stiffness (BASDAI question no. 6), and either ESR in millimeters per hour

(for SASDAS-ESR) or, CRP in mg/L (for SASDAS-CRP); this sum was divided by 10 to obtain the final score.

Results:

Most patients (224/254, 88.18 %) were males with median age of 30 years. Median disease duration was 4 years. SASDAS-ESR and SASDAS-CRP showed excellent correlation with the ASDAS-ESR and ASDAS-CRP respectively (r^2=0.78 and 0.58 respectively; p<0.0001). SASDAS-ESR showed good correlation with back pain (r=0.19), morning stiffness (r=0.21), peripheral pain (r=0.21), and CRP (r=0.50); SASDAS-CRP showed good correlation with BASFI (r=0.32), and ESR (r=0.55) (all p<0.0001). Using established ASDAS cut-off values, the corresponding cut-off points between inactive disease, moderate disease activity, high disease activity, and very high disease activitywith optimum sensitivity and specificity for SASDAS-ESR were 1.83, 2.45 and 4.45; the corresponding points for SASDAS-CRP were 0.79, 1.50, and 3.26. While SASDAS-ESR agreed with ASDAS-ESR in the extremes of the condition only, SASDAS-CRP agreed with ASDAS-CRP throughout the range of disease activity. Both the SASDAS scores showed excellent correlation with BASDAI scores.

Conclusion:

SASDAS-ESR and SASDAS-CRP are reliable scores for assessment of disease activity in Indian AS patients. These are easy to calculate and can be useful in daily clinical practice in resource constraint countries.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Epidemiology and Public Health Poster I: Comorbidities and Outcomes of Systemic Inflammatory Diseases

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Disclosure: T32 grant: the National Institutes of Health under Ruth L. Kirschstein National Research Service Award T32 AR007505 from the NIH NIAMS. The CARRA Registry is supported by grants from National Institute of Arthritis and Musculoskeletal and Skin Diseases (RC2AR058934), Friends of CARRA, and the Arthritis Foundation, as well as by the Duke Clinical Research Institute. The content is solely the responsibility of the authors and does not necessarily represent the official views of the National Institute of Arthritis and Musculoskeletal and Skin Diseases or the National Institutes of Health.

Background/Purpose: A significant number of patients with juvenile dermatomyositis (JDM) develop long term morbidity, such as calcinosis or lipodystrophy, however, the factors contributing to the development of such morbidities are not well understood.

Methods: Data from 426 patients with JDM enrolled in the Childhood Arthritis and Rheumatology Research Alliance (CARRA) Registry were analyzed to evaluate potential risk factors for morbidity, including age at diagnosis, sex, race, ethnic status, insurance status, family income, time to treatment, disease duration, functional status measures (CHAQ, ACR functional status, CMAS, physician and patient global assessments), and a history of calcinosis or lipodystrophy.

Results: By univariate analysis, black or minority race, annual family income less than $25,000 per year, negative ANA, and delay in diagnosis greater than 12 months were associated with the development of calcinosis or lipodystrophy. Multivariate analysis demonstrated that disease duration and delay to diagnosis are independent predictors of either calcinosis or lipodystrophy. Black race (OR 2.42, 1.11-5.27), disease duration (OR 1.22, 1.12-1.33), and delayed diagnosis (OR 1.02, 1.00-1.04) were independent risk factors for the development of calcinosis alone. Minority subjects with JDM in the CARRA Registry are more likely than Caucasian subjects to have low family income and no health insurance, and this subgroup had lower scores on measures of function and disease outcome.

Conclusion: Race and socioeconomic status are associated with worse morbidity and outcomes in patients with JDM. Future studies are needed to further clarify these associations so that efforts may be developed to address health disparities in patients with JDM and improve their disease outcomes.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Epidemiology and Public Health Poster I: Comorbidities and Outcomes of Systemic Inflammatory Diseases

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disease that affects frequently in their 20s and 30s. However, SLE could develop in other age group such as childhood-onset or late-onset. We aimed to investigate the influence of age of disease onset on clinical features, disease activity, and outcomes in adult patients with SLE.

Methods: We analyzed 917 adult patients with SLE from 1998 to 2012. The patients were classified into two groups based on the age at disease diagnosis: adult-onset SLE (≥18 and <50 years) and late-onset SLE (≥50 years). The American College of Rheumatology (ACR) criteria for SLE classification, the SLE Disease Activity Index (SLEDAI-2K), adjusted mean SLEDAI-2K (AMS), incidence rate of SLE flares (defined by ≥4 points increase of the SLEDAI-2K compared with that of previous visit), and prescribed medication were compared between two groups. As outcomes, organ damage and mortality were compared using SLICC/ACR Damage Index (SDI) and age- and sex adjusted standardized mortality ratio (SMR), respectively.

Results: Of the 917 SLE patients, 885 (91.4%) patients were adult-onset (mean age 29.4, range 18-49 years) and 32 (3.5%) patients were late-onset (mean age 55, range 50-68 years). After the mean follow-up years of 6.4, the number of cumulative ACR criteria was significantly lower in patients with late-onset compared with adult-onset SLE (4.6±1.2 vs 5.5±1.4, p<0.001). The mean SLEDAI-2K at enrollment (3.3±2.9 vs 5.4±4.2, p<0.001) and adjusted mean SLEDAI-2K over time (2.7±2.1 vs 4.3±2.6, p<0.001) were significantly lower in patients with late-onset compared with adult-onset SLE. The incidence rate ratio of SLE flares (late-onset/adult-onset SLE patients) was 0.44. The use of glucocorticoids and immunosuppressants was similar between two groups, but the use of azathioprine was lower in late-onset SLE patients (9.4% vs 29.8%, p=0.021). The percentage of cumulative SDI≥1 was higher in patients with late-onset compared with adult-onset SLE, but none reached statistical significance (50% vs 43.4%, p=0.576). A total of 42 patients died (6 in late-onset and 36 in adult-onset SLE group). The leading cause of death in both groups was SLE-related diseases, followed by infection. As compared to general population, the age- and sex adjusted SMR in late-onset and adult-onset SLE group was 1.58 (95% CI 0.58-3.43) and 3.34 (95% CI 2.34-4.63), respectively.

Conclusion: Compared with adult-onset SLE, late-onset SLE showed significantly mild clinical features and lower disease activity during follow-up. However, the percentage of patients with organ damage in patients with late-onset SLE was similar to that of adult-onset. The mortality of late-onset SLE was not higher than general population, although the mortality of adult-onset was three times higher than general population. Our results suggest that the clinical prognosis of late-onset SLE is better than adult-onset SLE.

	ACR criteria		**AMS**		**SDI**		**Age- and sex adjusted SMR**
	mean±SD	p-value	mean±SD	p-value	mean ±SD	p-value	(95% CI)

Session Title: Epidemiology and Public Health Poster I: Comorbidities and Outcomes of Systemic Inflammatory Diseases

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Tuberculosis (TB) represents a major global health problem, responsible for ill health among millions of people each year (1). TB has a higher incidence among patients with autoimmune rheumatic diseases than in the general population; in such patients, it frequently presents as extrapulmonary or disseminated disease. According to WHO surveillance reports, although steadily decreasing during the last years, the incidence of TB in Romania in 2005-2014 has been by far the highest among all EU countries.

Objectives: To assess the characteristics and risk factors of active TB infection in a cohort of patients with systemic lupus erythematosus (SLE).

Methods: Data of all SLE patients followed up in our clinic during 2005 – 2014 were retrospectively analyzed. Clinical and demographic characteristics and treatment before diagnosis of TB were recorded. The incidence of active TB infection was compared to data from the general population. Univariable logistic regression was used to assess the influence of various factors on the risk of developing TB.

Results: Four hundred SLE patients were evaluated in our clinic during the 10-year interval; of them, 18cases of active TB per 4291 patient-years (time of exposure, PY) were identified, accounting for an incidence of 419.5/100.000 PY, which is 4.4 times the incidence of TB in our region in the period 2005-2014.

Ten of the 18 cases had extrapulmonary or disseminated TB; delayed diagnosis and more severe forms were observed in them. Two patients repeatedly had recurrent TB infection after 2, respectively 3 years from the first TB diagnosis. High-dose glucocorticoids (hd-GC) and cyclophosphamide (CYC) treatment were significantly associated with TB: OR (95% CI) 9.6 (1.2-77.5), p=0.03 for hd-GC and 3.3 (1.2-9.1), p=0.02 for CYC. Duration from the most recent hd-GC treatment was significantly shorter in patients who developed TB, compared to those who did not: mean (range) 5.6 (0-15) months vs. 56.5 (0-321) months; (median (IQR): 0 (14) months vs. 28.5 (88) months), p=0.022 (Mann-Whitney U test), suggesting that hd-GC is the most important risk factor for TB.

Fever was the most important red-flag for the diagnosis of TB, OR (95% CI) 73.1 (15.2-352.7), p<0.001. Other frequent manifestations were weight loss and cough. No association was found between TB and age, disease duration or socio-economic status.

Conclusion: We found an increased incidence of active TB infection with a majority of extrapulmonary TB in a large cohort of Romanian SLE patients. Cyclophosphamide treatment and high dose of glucocorticoids were important determinants for the increased risk of TB in SLE patients. These results suggest that in a country with a high TB burden, TB screening and treatment of latent TB would be useful before initiation of immunosuppressive treatment.

Abstract Number: 56

Utilizing City-Wide Electronic Health Record Data to Assess Care

Fragmentation in Patients with Systemic Lupus Erythematosus (SLE)

Kathryn Jackson, Theresa Walunas, Anh Chung and Rosalind Ramsey-Goldman, Northwestern University, Chicago, IL
First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Epidemiology and Public Health Poster I: Comorbidities and Outcomes of Systemic Inflammatory Diseases

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Care fragmentation is associated with poor health outcomes and is hard to assess in a single-site data registry. The Chicago HealthLNK Data Repository (CHDR) is a city-wide database of de-duplicated patient Electronic Health Record data from 6 institutions in Chicago, with the capability to match patient data from outside registries to supplement registries and provide a multi-institution view of a patient population. The Chicago Lupus Database (CLD) is a registry of 880 patients meeting ≥3 of the 1982/1997 revised ACR classification criteria for SLE. CLD participant data was combined with CHDR to understand factors influencing fragmentation.

Methods:

Using a HIPAA compliant algorithm[1], patients from the CLD were hashed and matched into the CHDR to create a comprehensive set of patient visits from all institutions. Patients' demographics, insurance, fragmentation (defined as having ≥ 1 visit at ≥ 2 institutions) and visit data were pulled from the CHDR. Differences between groups were computed using chi-squared tests and odds ratios. Multivariate regression was used to assess factors contributing to percent inpatient visits and probability of death.

Results:

625 patients from the CLD matched with a CHDR patient having at least 2 visits from 2006-2012. 92% were female; 52% white and 32% black; 65% private and 21% public insurance; 29% had fragmented care. Sex had no effect on fragmentation. Blacks were more likely to have fragmented care than whites (OR: 2.52 CI: 1.68,3.79). Fragmented care was increased for both blacks (OR: 2.81 CI: 1.44,5.50) and whites (OR: 2.01 CI: 1.09,3.68) on public compared to private insurance. Overall, 6% of patient visits were inpatient. Table 1 shows percent change in inpatient visits for categories of fragmentation, race, and insurance; in the multivariate model, fragmentation, black race, public and no insurance all contributed to higher percent of inpatient visits. For each percent increase in inpatient visits, the odds of death increase by 1.05 (CI: 1.03,1.07).

Conclusion:

By combining a disease specific registry with a city-wide database, this study examines factors contributing to care fragmentation among SLE patients, and whether fragmented care impacts health outcomes in patients with a complicated chronic illness. For blacks and whites, public insurance correlated with fragmented care and increased inpatient visits, which is suggestive of more serious health impacts due to SLE. With the expansion of public insurance, patients with chronic illness seeking care at multiple sites may need improved care coordination or access to primary care to avoid more severe situations, hospitalization and increased likelihood of death.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Epidemiology and Public Health Poster I: Comorbidities and Outcomes of Systemic Inflammatory Diseases

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To determine if age, gender and racial discrepancies exist, and to determine the occurence of comorbidities among patients hospitalized with ischemic stroke with Systemic Lupus Erythematosus (SLE) in comparison to the general population.

Methods: We queried the Healthcare Cost and Utilization Project's (HCUP) Nationwide Inpatient Sample (NIS) between 2004 and 2010 and separated the hospitalizations due to or with ischemic stroke using ICD 9 diagnostic codes previously established by HCUP. Among this population, we identified the patients with SLE and calculated the average age of patients with and without SLE at the time of hospitalization for ischemic stroke. In addition, we calculated the gender and racial distribution of occurrence of ischemic stroke among SLE patients compared to the general population using the above database. We also looked at the Charlson comorbidity index (CCI) among these populations. Using SAS 9.2, survey procedures were used to identify univariate predictors of ischemic stroke.

Results: A total of 790,912 (weighted N=3,900,707) patients who were hospitalized with ischemic stroke were available for analysis out of which 3428 (weighted N= 16,828) had SLE. On univariate analysis, the average age of ischemic stroke in the general population was 70.9+_0.02 years, whereas in the SLE population, the average age of ischemic stroke was 56.5+-0.30 years ($p<0.0001$). Among the general population, 53.61% of all ischemic stroke population was females; whereas among the SLE population, 85.98% of the population was females ($p<0.0001$). Of the general ischemic stroke population, 55.7% were white, 22.6% were black and 21.7% belonged to other races. Among the SLE population, 44.9% were white, 35.6% were black and 19.5% belonged to other races ($p<0.0001$). The average CCI for the SLE population was 3.48+-0.03 compared to 2.67+-0.00 among the general population ($p<0.0001$).

Conclusion: There are significant discrepancies in age, gender and racial distribution among patients with SLE hospitalized with ischemic stroke compared to the general population. Patients with SLE are at increased risk of stroke approximately 13 years before the general population. The preponderance of SLE among female patients explains the increased incidence of ischemic stroke in females compared to the general population. Higher proportion of African American patients with SLE was hospitalized with ischemic stroke compared to the general population. The higher CCI is elucidated by the fact that SLE is a multisystemic disease, thus increasing the risk for comorbidities.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Epidemiology and Public Health Poster I: Comorbidities and Outcomes of Systemic Inflammatory Diseases

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The attributed cause of end-stage renal disease (ESRD) in the United States Renal Data System (USRDS) is often used to identify systemic lupus erythematosus (SLE) patients in U.S. studies of ESRD incidence and quality of care. We aimed to compare the attributed ESRD cause from the USRDS to the validated SLE status of patients in the Georgia Lupus Registry (GLR) who had progressed to ESRD.

Methods: Data from the USRDS were linked to the GLR to identify SLE patients (diagnosed through 12/04) who progressed to ESRD (through 9/12). The percentage of these SLE patients whose ESRD was subsequently attributed to SLE in the USRDS was calculated, overall and by patient characteristics.

Results: Among 251 SLE patients who progressed to ESRD, 78.9% had their ESRD attributed to SLE in the USRDS. Of the remaining 53 patients, most had their ESRD attributed to hypertension, diabetes mellitus, and non-SLE-related glomerulonephritis (Figure). Attribution of ESRD to SLE did not differ by sex or race but was lower among older vs. younger patients (P<0.001; Table). Only 20.0% of those aged ≥50 had ESRD attributed to SLE. Having Medicaid or no insurance was associated with greater attribution of ESRD to SLE than having private insurance (P=0.02), as was having two or more providers state a SLE diagnosis (P=0.008).

Conclusion: These estimates indicate that USRDS-based studies may underreport ESRD in U.S. SLE patients. However, observed patterns of differential attribution of ESRD cause, particularly by age, suggest that providers may be correctly attributing ESRD to causes other than SLE and lupus nephritis among some SLE patients.

Figure. Attributed cause of ESRD among 251 SLE patients in the Georgia Lupus Registry who progressed to ESRD (through 2012). HTN, hypertension; DMII, diabetes mellitus type II; FSGS, focal segmental glomerulosclerosis; Other GN, glomerulonephritis not attributed to SLE. Other includes tubular necrosis, IgA nephropathy, scleroderma, diabetes mellitus type I, multiple myeloma, other renal disorder, and uncertain etiology.

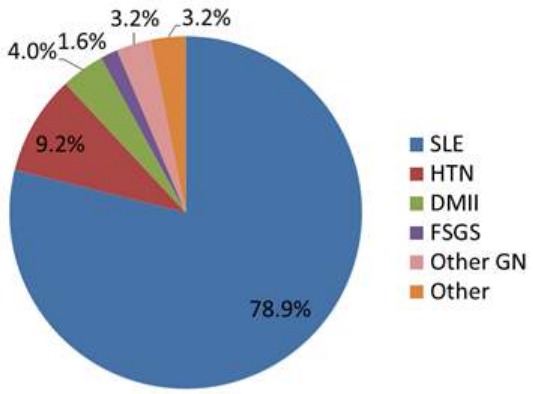

Table. Attribution of ESRD to SLE among Georgia Lupus Registry patients who initiated ESRD treatment through 2012, by selected patient characteristics

Patient subgroup	% attribution of ESRD to SLE (95% CI)
Overall	78.9 (73.3-83.8)
Demographics	
Age at SLE diagnosis	
<18	93.9 (86.3-98.0)
18-30	87.9 (79.4-93.8)
>30	52.6 (40.9-64.0)
Sex	
Male	81.6 (65.7-92.3)
Female	78.4 (72.3-83.7)
Race	
Black	79.3 (73.5-84.3)
White	72.2 (46.5-90.3)
Insurance at start of ESRD

Variation in Heart Failure Hospitalizations Among U.S. Medicaid

Recipients with SLE 2000-2010, By Race and Ethnicity

Medha Barbhaiya[1], Candace H. Feldman[1], Hongshu Guan[1], Jose A. Gomez Puerta[2], Michael A. Fischer[3] and Karen H. Costenbader[1], [1]Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [2]Grupo de Inmunología e Inmunogenética, GICIG, Universidad de Antioquia, Medellín, Colombia, Medellín, Colombia, [3]Division of Pharmacoepidemiology and Pharmacoeconomics, Brigham and Women's Hospital, Boston, MA

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Epidemiology and Public Health Poster I: Comorbidities and Outcomes of Systemic Inflammatory Diseases

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Heart failure (HF) is a leading cause of hospital admissions. In the US, Blacks have higher HF prevalence than other racial/ethnic groups. Cardiovascular disease (CVD) risks are elevated in SLE, but racial/ethnic variation in HF prevalence in SLE has not been well studied. We examined rates and adjusted risks of HF admissions among SLE patients overall and by race/ethnicity within Medicaid, the US health insurance program for the poor.

Methods: Within Medicaid Analytic eXtract (MAX), containing billing claims from 2000-10 for Medicaid patients from the 29 most populated US states, we identified patients aged 18-65 with prevalent SLE (≥3 ICD-9 codes 710.0, ≥30 days apart) with ≥6 months of continuous enrollment prior to the 3rd diagnosis code (index date). Baseline data from the 6 months prior to index date included age, sex, race/ethnicity, zip code, year, SLE-related and other comorbidities (based on ICD-9 codes). Those missing race/ethnicity were excluded. Within MAX inpatient claims, ICD-9 codes identified multiple types of HF as primary or secondary discharge diagnoses (Chen J, *Circulation,* 2013). Subjects were followed from index date to first HF admission, death, Medicaid disenrollment, or end of follow-up. HF admission rates per 1000 person-years with 95% CIs were calculated overall and within subgroups. Fine and Gray proportional hazards regression models, accounting for the competing risk of death, were used to calculate subdistribution hazard ratios (HR) for HF hospitalization, adjusting for sociodemographics and comorbidities.

Results: Of 57,292 patients with prevalent SLE, 93.2% were female. Racial/ethnic breakdown was: 41% Black, 39% White, 15% Hispanic, 3% Asian, 1% Native American. Mean follow-up was 3.67 (±3.03) years, 2,596 (5%) patients had ≥1 HF hospitalization, and 3,972 (7%) patients died. The HF admission rate was 12.76 (95%CI 12.28, 13.26) per 1,000 person-years for the entire cohort. Asians and Hispanics had the lowest HF admission rates: 7.49 (95%CI 5.76, 9.73) and 8.75 (95%CI 7.78, 9.84) per 1,000 person-years. Blacks had the highest rates: 17.56 (95%CI 16.68, 18.48) per 1,000 person-years. After adjustment, the HR for HF admission was 1.84 (95%CI 1.68, 2.02) among Blacks vs. Whites, and 1.82 (95%CI 1.66, 1.99) after further comorbidity adjustment (Table). Sensitivity analyses restricting to the primary discharge diagnosis (1,560 events) yielded similar results for Blacks vs. Whites: HR 2.06 (95% CI 1.83, 2.32), and 2.10 (95%CI 1.86, 2.40) after further comorbidity adjustment.

Conclusion: Rates of HF hospitalization were high in all racial/ethnic groups of SLE Medicaid patients. In multivariable models, Black SLE Medicaid patients had nearly two-fold higher risks of HF hospitalization than Whites and higher risks than all other groups. Future analyses will seek to differentiate prevalent vs. incident HF and examine different HF etiologies.

Table. Multivariable Subdistribution Hazards Ratios for First Hospitalizations for Heart Failure* among 57,292 Medicaid Patients with SLE in the US, by Race and Ethnicity, 2000-2010				
Racial/Ethnic Group	**Events**	**Person-years**	**Model 1** **HRsd**(95% CI)**	**Model 2** **HRsd**(95% CI)**
Black, n=23,586	1,465	83,413	**1.84 (1.68, 2.02)**	**1.82 (1.66, 1.99)**
White, n=22,444	772	78,482	Ref.	Ref.
Hispanic, n=8,825	277	31,644	1.07 (0.93,1.24)	1.10 (0.92, 1.23)
Asian, n=1,779	56	7,474	0.94 (0.71,1.25)	0.92 (0.69, 1.22)
Native American, n=658	26	2,418	1.21 (0.82,1.79)	1.16 (0.78, 1.72)

*ICD-9 codes for HF: 402.01, 402.11, 402.91, 404.01, 404.11, 404.91, 404.03, 404.13, 404.93, and 428.xx, but excluding 398.91 rheumatic heart disease (Chen J, Circulation, 2013).

**HRsd= Subdistribution hazard ratios accounting for the competing risk of death.

Model 1: adjusting for age, sex, calendar year, US region, ZIP-code level socioeconomic status (Ward MM, *J Rheum*, 2007), and SLE Risk Adjustment Index (includes lupus nephritis, Ward MM, *J Rheum*, 2000) during the 6 months prior to the index date.

Model 2: additionally adjusting for Charlson comorbidity index, as well as angina, percutaneous coronary intervention, hypertension, obesity and smoking during the 6 months prior to the index date.

Mortality of Systemic Lupus Erythematosus in Puerto Rico Assessed By Multiple-Cause-of-Death Analysis

Mariangelí Arroyo-Ávila[1], José G. Conde[2] and Luis M. Vilá[1], [1]Department of Medicine, Division of Rheumatology, University of Puerto Rico Medical Sciences Campus, San Juan, PR, [2]School of Medicine and Research Centers in Minority Institutions Program, University of Puerto Rico Medical Sciences Campus, San Juan, PR

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Epidemiology and Public Health Poster I: Comorbidities and Outcomes of Systemic Inflammatory Diseases

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic autoimmune disorder that is associated with a high morbidity and mortality. The specific causes of death vary among ethnic groups or geographical locations. The purpose of this study was to determine the mortality profile related to SLE in Puerto Rico using multiple-cause-of-death analysis.

Methods: Public use, multiple-cause-of-death mortality files from the National Center of Health Statistics were used to select death records of residents in Puerto Rico listing SLE (International Classification of Diseases, 10th Revision, codes M32.1 or M32.9) as an underlying cause of death (UCD) or as a non-underlying cause of death (NUCD) for years 2003-2013 . Demographic data, gender-specific age-adjusted mortality rates, and associated causes of death were analyzed. Causes of death were classified into four groups: SLE-related complications, infectious diseases, cardiovascular diseases, diabetes mellitus, and malignancy. Proportionate mortalities were used to investigate associations between causes of death, calculating the ratio of observed to expected deaths (O:E ratio) for selected comorbidities. Mann-Whitney, chi-square and Fisher's exact tests were used to evaluate statistical associations.

Results: In total, 393 SLE-related deaths were identified. Median age was 52 years (53 for females and 45 for males; p=0.216). Three hundred and forty five (87.8%) deaths occurred in women, for a female to male ratio of 7.2. The age-adjusted mortality rate for SLE-related deaths for women was 166.5 deaths/million and 27.8 deaths/million for men (relative risk = 6.0; $p < 0.001$). In 308 deaths (78.37%), SLE was listed as the UCD. Those listed with SLE as the UCD were younger (median age 51 vs. 57 years, p =0.008) and were more likely to die at a medical center (82.2% vs. 68.2%, p= 0.007) compared to those listed with SLE as a NUCD. In multiple-cause of death analysis, the most common causes of SLE-related deaths (UCD and NUCD) were infectious diseases (42.5%), SLE-related complications (37.4%), cardiovascular diseases (27.9%), diabetes mellitus (12.2 %), and malignancy (5.6%). For men, SLE related complications (54.2% vs. 35.1%, p=0.016) and cardiovascular diseases (41.7% vs. 26.1%, p=0.038) were more common than in women. No significant differences were observed for infectious diseases, diabetes mellitus, and malignancy between men and women. Among infectious diseases, bacterial infections were reported in 130 death certificates and sepsis in 124. The overall O:E ratio was >1 for bacterial infections (1.86, $p < 0.001$) and renal failure (1.45, p = 0.002). The O:E ratio for malignant hypertensive disease , ischemic heart, cerebrovascular diseases and malignant neoplasms was < 1.

Conclusion: In Puerto Rico, SLE deaths were more commonly associated with infectious disorders, particularly bacterial infections and sepsis. Adhering to prevention and control measures of infection could be crucial in improving SLE survival in this population.

Session Title: Epidemiology and Public Health Poster I: Comorbidities and Outcomes of Systemic Inflammatory Diseases

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The epidemiology and natural history of sarcoidosis is not well-characterized as only coding-based studies without detailed clinical information from individual medical record review have been reported. This study aimed to assess the predictors of mortality of sarcoidosis, using data from a population-based cohort.

Methods: An inception cohort of patients who were diagnosed with sarcoidosis in 1976-2013 in a geographically well-defined population was identified based on comprehensive individual medical record review. Diagnosis required histopathological confirmation and diagnostic radiologic features of intrathoracic sarcoidosis, compatible clinical presentation, and exclusion of other known causes of granulomatous inflammation. Histopathological confirmation required presence of non-caseating granuloma without evidence of acid-fast bacilli or fungi. The only exception to the requirement of histopathological confirmation was stage I pulmonary sarcoidosis that required only radiographic evidence of symmetric bilateral hilar adenopathy with or without mediastinal lymphadenopathy. Cases of isolated granulomatous disease of the skin without other features of sarcoidosis were not included. Data were collected on demographic, clinical presentation, laboratory investigations and mortality. Univariable Cox models were used to identify prognostic factors of death.

Results: In 1976-2013, 345 incident cases of sarcoidosis were identified. 50.4% of the cohort was female and the mean age of the cohort was 45.6 years. During follow-up (median: 12.2 years; 5002 total person-years), 50 patients died.

Age, male sex, absence of intra-thoracic disease, and hepatic, cardiac, splenic or neurological involvement in conjunction with intra-thoracic disease were predictive factors for mortality in univariable models after adjustment for age, sex and calendar year of sarcoidosis diagnosis (Table 1).

Conclusion: Age, male sex, absence of intra-thoracic disease, and hepatic, cardiac, splenic or neurological involvement in conjunction with intra-thoracic disease were prognostic factors associated with mortality in patients with sarcoidosis.

Table 1: Predictors of mortality among patients with sarcoidosis

Characteristic	Hazard ratio* (95% CI)	p-value
Age, per 10 year increase	2.48 (1.97, 3.13)	<0.001
Male sex	1.98 (1.04, 3.79)	0.038
Calendar year of diagnosis, per 1 year increase	0.98 (0.94, 1.02)	0.25
Black (vs white ethnicity)	3.16 (0.72, 13.81)	0.29
Other (vs white ethnicity)	1.33 (0.32, 5.58)

Patient Perception of Disease Burden in Diffuse Cutaneous Systemic Sclerosis

Dinesh Khanna[1], Yannick Allanore[2], Christopher P. Denton[3], Marco Matucci-Cerinic[4], Janet E. Pope[5], Barbara Hinzmann[6], Siobhan Briody[7], Janethe de Oliveira Pena[8] and Oliver Distler[9], [1]Division of Rheumatology, University of

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Epidemiology and Public Health Poster I: Comorbidities and Outcomes of Systemic Inflammatory Diseases

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Diffuse cutaneous SSc (dcSSc) is associated with high morbidity and mortality, and reduced quality of life. Patient priorities are rarely discussed, with physicians traditionally focusing on organ involvement rather than skin changes. Using discursive approaches and ethnography, a unique, qualitative research methodology, we evaluated the impact of dcSSc symptoms on patients' daily lives, and examined how disease burden shapes patient outlook.

Methods:

Patients were recruited via healthcare professionals (HCPs) or patient associations. In France, Italy, the UK and US, patients filmed daily short (~15-minute) video diaries about their lives over 7 days. On Days 1 and 7, patients took part in a moderator-led discussion of their experiences, and an observation session to understand the impact of living with dcSSc. In Germany and Spain, patients participated in 60-minute telephone interviews. Patients were also assigned tasks to encourage reflection on their feelings about dcSSc. Video footage and transcribed discussions were reviewed, and the data were categorized and assessed for themes, patterns, and indicators of emotion, ambivalence, and conflict.

Results:

Twenty-three patients (mean age 54; 83% women) were recruited. Of these, 17 made video diaries, and 6 took part in telephone interviews. The majority of video diaries and interviews took place in patients' homes, and on average 5.25 hours of video footage were collected per patient.

The results of the study show that time to diagnosis may be delayed, as patients trivialize their symptoms and HCPs often attribute symptoms to other causes. Patients also have a poor understanding of their diagnosis, and information to aid understanding is rarely provided. DcSSc is associated with a high treatment burden; on average this patient sample received 10 tablets of prescribed drugs per day. Importantly, while patients were aware of the seriousness of organ involvement, they reported that skin changes, pain, and fatigue have a dominant effect on daily life, impairing their ability to perform routine tasks. Skin tightening in the lower limbs and feet lead to deformity and loss of mobility, while Raynaud's phenomenon, calcinosis, and digital ulcers cause significant pain, as well as loss of function. Furthermore, skin tightening around the mouth impacts the ability to eat, and dental hygiene. Changes in esthetic appearance lead to embarrassment, loss of identity, withdrawal from social life, and depression. Patients experience dcSSc as a series of losses, including independence and self-esteem, and the unpredictability of the disease makes the patient journey and acceptance of the condition difficult. Moreover, patients tend to have small support networks and support services are not offered as part of standard care.

Conclusion:

Patients with dcSSc have high treatment and emotional burdens, with skin complications, pain, and fatigue profoundly impacting their daily lives. Patients place the most emphasis on these issues rather than the chance of organ

involvement. There is an unmet need for patient information at the time of diagnosis and for emotional support services throughout their journey with dcSSc.

Association of Smoking and Cognitive Function in Patients with Fibromyalgia

Lin Ge[1,2], Terry H. Oh[3], Ann Vincent[4], Arya Mohabbat[5], li Jiang[6], Mary Whipple[7], Samantha McAllister[8], Zhen Wang[9] and WenChun Qu[10], [1]Physical Medicine and Rehabilitation, Mayo Clinic, Rochester, MN, [2]Rheumatology, Guang An Men Hospital, China Academy of Chinese Medical Science,, Beijing, China, [3]Physical Medicine & Rehabilitation, Mayo Clinic, Rochester, MN, [4]General Internal Medicine, Mayo Clinic, Rochester, MN, [5]Department of Medicine, Mayo Clinic, Rochester, MN, [6]Rehabilitation, The Third Affiliated Hospital，Sun Yat-sen University,China, Guangzhou, China, [7]Fibromyalgia and Chronic Fatigue Clinic, Mayo Clinic, Rochester, MN, [8]Mayo Clinic, Rochester, MN, [9]Health Sciences Research, Mayo Clinic, Rochester, MN, [10]Department Physical Medicine and Rehabilitation, Department of Anesthesiology Division of Pain Medicine, Mayo Clinic, Rochester, MN
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

To evaluate the association between smoking and cognitive function in patients with fibromyalgia (FM).

Methods:

We surveyed 668 patients with FM from May 2012 through November 2013. Patients were categorized by smoking status (non-smoker and smoker). Primary outcomes included cognitive symptoms (MASQ). Secondary outcomes include fatigue (MFI-20), sleep (MOS-sleep Scale), depression (PHQ-9), anxiety (GAD-7), overall FM symptom severity (FIQ-R), and quality of life (SF-36). Univariate and multivariate analyses were used.

Results:

Ninety-four (14.07%) patients self-identified as smokers. Smokers were associated with several demographic variables, including lower education, unmarried status, and younger age. Smokers reported worse cognitive functions, including total functional score and 4 out of 5 domains of the MASQ (all $p<0.05$) Secondary outcomes showed worse sleep (MOS-sleep scale $p=0.01$), anxiety (GAD-7 total $p=0.001$), depression (PHQ-9 $p=0.04$), FM symptom severity (FIQ-R total score $p<0.01$), and QoL in bodily pain(BP) and mental health(MCS) (SF-36: BP $p=0.03$; MCS $p=0.02$).

Conclusion:

The results of this study indicate that smokers with FM report worse cognitive function. Although the cause-effect relationship between smoking and cognition is unclear, clinicians who care for patients with FM should be aware of this association.

Abstract Number: 64

Nociceptive Flexion Reflex Threshold: Possible Surrogate Marker of Symptom Severity in Fibromyalgia

Dennis Ang[1], Christopher France[2] and James Slaven[3], [1]Section on Rheumatology and Immunology, Wake Forest University, Winston Salem, NC, [2]Psychology, Ohio University, Athens, OH, [3]Biostatistics, Indiana University, Indianapolis, IN

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Central sensitization has been demonstrated in patients with fibromyalgia (FM) using an objective assessment of spinal nociception called the nociceptive flexion reflex (NFR). This reflex is measured (electromyographically) as the withdrawal of a proximal leg muscle (biceps femoris) in response to an electrical stimulus applied over the sural nerve. The lowest level of electrical stimulation that generates a measurable withdrawal response is called the NFR threshold. A low NFR threshold (i.e., augmented nociceptive responsivity) has been demonstrated in FM when compared to healthy controls. In this report we sought to determine the prospective association of the change in the NFR threshold with global FM severity (as measured by the Fibromyalgia Impact Questionnaire/FIQ-total score).

Methods:

This is a secondary data analysis of a 12-week randomized clinical trial of the effect of cognitive behavioral therapy (CBT) on nociceptive responsivity and global FM severity. Female subjects who met the 1990 Classification Criteria for FM were randomized to 1 of 2 treatment arms: six weekly sessions of CBT or usual care (UC). Subjects were evaluated at 3 time points: baseline, week 6 (post-intervention) and week 12. For these analyses, the predictor was the *baseline-to-week 6 change* in NFR threshold and the primary outcome was the FIQ-total at *week 12*. Linear regression analyses were controlled for treatment group assignment, baseline use of opiates, anticonvulsants and serotonin-

norepinephrine reuptake inhibitor (SNRI), and other potential confounders. We considered a variable as a potential confounder if the variable was associated with boththe predictor and the primary outcome.

Results:

The 32 female participants had a mean (± standard deviation) age of 47 ± 12 years; 81% were white, 94% had ≥ high school education, and 44% were employed. At baseline, the sample had a mean disease duration of 12 ± 6 years; 16 (50%) were on opiates; 9 (28%) were on anticonvulsant; and 7 (22%) were on SNRI. Based on the Patient Health Questionnaire-8 (score ≥ 10), 16 (50%) of the participants had probable depression. The mean FIQ-pain score was 5.0 ± 2.3, and the mean FIQ total score was 61 ± 16, suggesting a moderate-to-severely ill patient population. The mean change in NFR threshold (week 6 minus baseline) was - 1.76 ± 13.32 mA, suggesting a reduction in nociceptive responsivity for the entire group.

	Model Parameter	p-value
Unadjusted Model		
NFR threshold change	β = -0.51	0.09
Adjusted model 1		
NFR threshold change	β = -0.60	0.08
Treatment Group (CBT vs. UC)	β = -5.15	0.56
Adjusted model 2		
NFR threshold change	**β = -0.70**	**0.07**
Treatment Group (CBT vs. UC)	β = -7.39	0.44
SNRI (yes)	β = -6.94	0.53
Opiates (yes)	β = 1.53	0.86
Anticonvulsants (yes)	β = 9.17	0.37

None of the other baseline variables were associated with both the predictor and the primary outcome.

Conclusion:

Our study is the first to demonstrate that a prior change in NFR threshold predicted future global disease severity in FM. Specifically, a reduction in nociceptive responsivity was (marginally) associated with better clinical status in female FM patients. If corroborated in a larger study, the change in NFR threshold may be a surrogate marker of improvement (or worsening) of overall FM symptomatology.

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Character count for abstract text: 1733 (1017 Characters Remaining)

Background/Purpose: The number of people receiving disability payments in the United States has increased substantially. Rheumatic diseases are common causes of disability. Rheumatologists are often asked to evaluate patients for disability, even though the symptoms are often largely subjective. This situation is particularly challenging in evaluating fibromyalgia in patients.

We We evaluated our patients' claims over the past year in those applying for Social Security Disability.

Methods: A rheumatologist and a rheumatology nurse reviewed each claim sent to the Social Security Administration for disability status in 2013 and 2014 to determine how often we agreed that the claimant with fibromyalgia deserved to receive disability status. We defined disability as the inability to work at any job, indefinitely.

Results: Of the 31 Social Security applicants with fibromyalgia, the physician and the rheumatology nurse agreed that only 5 (16%) were incapable of working even in a sedentery position. Admittedly, this was a subjective determination. The evaluation process took into account the number of physical complaints, severity of pain, health assessment questionnaire, and physical examination. Sometimes patients, revealed they could perform tasks in their personal lives, but claimed incapable of doing at work. However, chronic fatigue and the level of pain can not be assessed objectively.

Of the patients with a diagnosis other than fibromyalgia, such as lupus and rheumatoid arthritis, 18 subjects requested Social Security disability, and 7 (39%) were thought by the physician and the nurse to be totally incapable of working.

Conclusion: In the majority of cases, the rheumatologist and nurse did not agree with the Social Security disability claim, especially in fibromyalgia patients. Because of the subjective nature of fibromyalgia symptoms, such as fatigue and pain, it may be difficult to render an accurate judgment regarding disability. But job modifications and periodic days off, permitted by the Family Leave Act, may be better alternatives to try before granting total disability status

Fibromyalgia Patients Identify More Causes of Disease Flare Ups Than RA Patients

Robert S. Katz[1], Lauren Kwan[2], Hannah Leavitt[2] and Jessica L. Polyak[2], [1]Rush University Medical Center, Chicago, IL, [2]Rheumatology Associates S.C., Chicago, IL

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Flare-ups are a frequent and painful part of FMS and RA. We compared FMS and RA patients with respect to stresses that the patients belive may have caused their diseases to flare.

Methods: 211 office patients with FMS or RA (150 FMS:130 women and 20 men; mean age 51±12, 61 RA:45 women and 16 men; mean age 55±15) completed a questionnaire as to whether the following conditions cause their disease to flare: lack of sleep, fatigue, emotional stress, physical stress, depression, anxiety, traumatic events, overdoing it, being overworked, feeling overwhelmed, illness, personal changes, and confrontations with friends or family members. The chi-square test of association was done to compare FMS and RA patients with respect to their responses, using a 0.05 significance level.

Results: For most of the conditions, FMS patients were significantly more likely than RA patients to report that a stress caused their disease to flare, including emotional stress (58% vs. 43%, p= 0.042), physical stress (54% vs. 34%, p= 0.010), lack of sleep (53% vs. 33%, p= 0.007), illness (39% vs. 12%, p < 0.001, anxiety (31% vs. 16%, p= 0.027),depression (25% vs. 10%, p = 0.012), and traumatic events (25% vs. 12%, p = 0.026).

Conclusion: FMS patients were significantly more likely than RA patients to identify specific stresses as a cause of disease flare-ups, such as emotional and physical stress. Fibromyalgia patients are more somatically sensitive and more often recognize stresses that aggrevate their symptoms. Stress reduction strategies might help fibromyalgia patients.

Higher Levels of Pro-Inflammatory and Lower Levels of Anti-Inflammatory Cytokines Are Present in Fibromyalgia Patients

Robert S. Katz[1], Hannah Leavitt[2] and Daniel Pickrell[2], [1]Rush University Medical Center, Chicago, IL, [2]Rheumatology Associates, Chicago, IL

First publication: September 29, 2015

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Abnormalities in the central processing of pain may play a role in fibromyalgia and cytokines could be targets for new therapies. We measured cytokine levels in the blood of patients with fibromyalgia.

Methods: 35 Fibromyalgia patients followed in a rheumatology office practice had their blood analyzed for cytokine levels by the University of Miami Immunology Lab. Normal levels were established in healthy controls by the lab. The following cytokines were measured: Pro-inflammatory: TNF alpha, TNF beta, TNF receptor I, TNF receptor II, interferon gamma , IL 1 alpha, IL 1 beta, IL 6. Anti-inflammatory: IL 4, IL 5, IL 10, IL 13. IL 17, IL 23.

Results: Abnormally high and low cytokine levels were:

	Anti-inflammatory		Pro-inflammatory		
	IL-10	IL-23	Ifn-g	TNF-alpha	TNF-beta
Patient Mean	4.1	7.2	42.6	39.3	34.1
Normal Mean	13.6	17.6	1.9	9.2	14.6

Conclusion: Higher levels of certain pro-inflammatory cytokines and lower levels of anti-inflammatory cytokines were found in these fibromyalgia patients. The significance of abnormal cytokine levels in fibromyalgia is unclear but cytokines could be important in the etiology of the disorder.

Disclosure: R. S. Katz, None; **H. Leavitt**, None; **D. Pickrell**, None.

The Stroop Word-Naming Test in Fibromyalgia Patients

Robert S. Katz[1], Alexandra Katz Small[1,2] and Kelli Davis[3], [1]Rush University Medical Center, Chicago, IL, [2]University of Illinois College of Medicine, Chicago, IL, [3]Rheumatology Associates S.C., Chicago, IL

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The Stroop Word-Naming Test has demonstrated decreased word-naming speed in many patients with fibromyalgia who experience the symptoms of fibrofog. The slower processing of information may disturb the synchrony of other neural circuits and lead to some of the symptoms of cognitive dysfunction termed "fibrofog."

Methods: We administered this test to rheumatic disease patients in a rheumatology office practice. Impairment of concentration due to distraction is present in many fibromyalgia patients, particularly using the auditory consonant trigram of neuropsychological tests. We have attempted to treat fibromyalgia patients with fibrofog symptoms with stimulants, including methylphenidate, Adderall, and Vyvanse.

Results: 18 rheumatic disease patients in a rheumatology office practice were given the Stroop Word-Naming Test. The test was administered by a rheumatology nurse. 13 of 18 (72%) patients had a diagnosis of fibromyalgia and met the 2010 ACR criteria. 5 of 18 patients (28%) had other rheumatic diseases. Of the patients with fibromyalgia, 7 of 13 were taking stimulant medication, including methylphenidate, Adderall (amphetamine and dextroamphetamine), or Vyvanse (lisdexamfetamine). The 5 rheumatic disease controls were not taking stimulant medication. Of the fibromyalgia patients, 12 were female and 1 was male. In the control group, 3 were female and 2 were male. The mean age of the fibromyalgia group was 52 years old (32-68). The mean age of the control group was 35 years old

(32-43). The education level of the participants was 5 high school graduates, 7 had some college experience, 3 had a bachelor's degree, 2 had a master's degree, and 1 had a law degree.

In the fibromyalgia patients not taking a stimulant for fibrofog, the mean Stroop score was 70.8 (47-89). In the fibromyalgia patients taking methylphenidate, amphetamine and dextroamphetamine, or lisdexamfetamine, the mean

Stroop score was 80.7 (range 53-113). The control group without fibromyalgia, none of whom were taking an ADHD type stimulant medication, had a mean Stroop score was 93.4 (83-111).

Conclusion: Fibromyalgia patients have reduced word-naming speed based on the Stroop Word-Naming Test. This test is simple to administer. Those fibromyalgia patients taking stimulant medication usually reserved for ADHD, but used clinically for some patients with fibrofog symptoms because of a significant effect of distraction on their cognitive ability, performed better than the fibromyalgia group not taking ADHD type medication, but still performed worse than the control group.

Fibromyalgia patients appear to be a beat behind in their cognitive functioning. This slower processing of certain kinds of information can be assessed through the Stroop Word-Naming Test.

Abstract Number: 69

Fibrofog in Mild and Severe Variants of Fibromyalgia

Robert S. Katz and Frank Leavitt, Rush University Medical Center, Chicago, IL
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: : A triad of symptoms defines cognitive dysfunction in fibromyalgia known as fibrofog. The set of primary signs are short-term memory loss, a general loss of mental sharpness, and a disturbance in mental clarity. The stability of this symptom triad is uncertain, in a disorder than is marked by a high degree of symptom variability. The purpose of this study is to determine if the level of disease intensity needs to be taken into account, when assessing the symptom triad that defines fibrofog.

Methods: Participants were 61 female patients with a clinical diagnosis of fibromyalgia with a mean age of 50. 7±14.0 years and a mean education of 15.2±2.2 years. Data on memory loss was collected on a 0-10 point Likert scale with anchor points of no problems to severe problems. Data on mental sharpness and mental clarity were derived from the 16 item Mental Clutter Scale. Disease intensity was measured on a 4 point scale ranging from usual symptom status to symptoms severely intensified.

Results: For analytical purposes, disease intensity was collapsed into two categories; low and high disease intensity. The percentage of high and low disease intensity was 60.7% (37/61) and 39.3% (24/61) respectively. Comparisons between low and high disease intensity on short term memory, mental sharpness and mental clarity are shown in Table 1. As can be seen, high disease intensity was related to more severe problems with memory, significant reductions in mental sharpness ($p<0.001$), and severe disturbances in mental clarity ($p<0.001$). The mental clarity score of 3.33 in the low intensity group is approximately one standard deviation below the normative range for fibromyalgia patients with cognitive dysfunction (normative mean: 5.0±2.3).

Conclusion: Patients with fibromyalgia can and do present with mild to severe symptom variants. These symptom variants are associated with marked differences in the manifestations of the cardinal features of fibrofog. In the milder

symptom variants of fibromyalgia, symptom expression of fibrofog is likely to be muted. In fibromyalgia, knowledge of disease intensity is likely critical for accurately assessing the presence of fibrofog and needs to be taken into account.

Table 1. Comparison of Female Fibromyalgia Patients with High and Low Disease Intensity on the Cardinal Features of Fibrofog.

	Fibromyalgia (n=61)			
Disease Intensity	High	Low	(n=37)	(n=24)
Short Term Memory Problems[c]	5.86±2.29***	3.37±2.58***		
Decline in Mental Sharpness[c]	6.17±1.91	3.95±2.49***		
Disturbance in Mental Clarity[c]	5.47±2.27	3.33±2.33***

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: –The Brazilian registry on fibromyalgia syndrome (EPIFIBRO) included 810 patients who satisfied the American College of Rheumatology Classification Criteria for Fibromyalgia (ACR1990) at the time of diagnosis. Objectives – 1. To determine how many patients fulfill the ACR1990 and the 2010 Preliminary Diagnostic Criteria for Fibromyalgia (ACR 2010); 2. To determine if there is correlation between the impact of FM measure by the Fibromyalgia Impact Questionnaire (FIQ) and by the Polissymptomatic Distress Scale (PDS); 3. To describe data on the follow-up evaluation of the patients enrolled in the registry.

Methods: A transversal study on a multicenter cohort of Brazilian Fibromyalgia patients. The analysis included the following evolution parameters: Pain and Fatigue Analogical Numerical Scales (PNS and FNS); FIQ and PDS at entry and at the last registered evaluation. Statistical analysis included descriptive statistics and the Pearson Correlation Scale. In order to analyze the follow-up measures 30% up or down variation was defined as the minimal clinically significant difference.

Results: The mean value observed for the PNS was 8.4 ± 1.9, for FNS was 7.9 ± 2.3, for FIQ was 68.5 ± 17.1 and for PSD was 22.19 ± 5.8. In order to establish the concordance of the ACR1990 and the ACR2010 criteria 613 patients were analyzed. The fulfillment of diagnostic criteria was observed in 386 (62.9%) patients for the ACR 1990, 529 (86.2%) for the ACR 2010 and 347 patients (56.6%) for both criteria, while 39 (6.3%) only met the ACR 1990 and 185 (30.1%) only met the ACR 2010. There is a low correlation between PNS and PDS and a moderate correlation between PNS and FIQ (r = 0.359; 0.687). There was no correlation between FNS and PDS or FIQ (r = 0.073; 0.017). It was also found a moderate correlation between the FIQ and the PDS (r = 0.576). There were 314 patients with more than one evaluation. Eighty-eight patients with less than a month from the entry were excluded resulting in 226 patients with at least one follow up parameter registered (FIQ – 222; PDS – 199; both 195). Patient registry included 221 females (97.78%) and only 5 male subjects (2.21%) with a mean age of 51.58 ± 10.56 years old. The mean time of follow up was 9.11 ± 7.47 months (1–44). The mean value of the initial FIQ score was 66.10 ± 19.59 and the final value was 67.06 ± 19.13. The mean initial score of the PDS was 22.53 ± 5.57 and the final one was 19.67 ± 6.67. There were no differences on both parameters. When considering the FIQ, 37 patients (16.6%) improved, 21 worsened (9.45%), and 164 (73.87%) were stable. Concerning the PDS, 39 patients (19.59%) improved, 9 worsened (4.52%), and 151 were unchanged (75.87 %). In 146 patients there was a concordance of the FIQ and PDS results (74.87%).

Conclusion: There was a weak correlation between the ACR1990 and ACR2010. It was observed a moderate correlation between the FIQ and the PDS used to evaluate the Fibromyalgia Syndrome impact. Most Brazilian Fibromyalgia patients from EPIFIBRO Registry did not show changes in follow up parameters over time. FIQ and PSD showed good correlation in this follow up study.

Fibromyalgia Dysautonomia and Distress. Correlation Between the Newly Developed Composite Autonomic Symptoms (COMPASS-31) Questionnaire and the Fibromyalgia Polysymptomatic Distress Scale

Laura-Aline Martinez-Martinez[1], Maya Chacón Pérez[2], Paola Reyes-Loyola[3] and Manuel Martínez-Lavín[3], [1]National Institute of Cardiology. SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

A consistent line of investigation suggests that dysautonomia may explain the multisystem fibromyalgia features, and that fibromyalgia is a sympathetically maintained neuropathic pain syndrome. The sympathetic nervous network is the main component of the stress response system (Arthritis Res Ther. 2007;9:216).

The ACR 2010 preliminary fibromyalgia diagnostic criteria is based on the Polysymptomatic Distress Scale. According to its developers, this scale is able to assess illness severity while still allowing a dichotomous diagnosis (Arthritis Care Res. 2010;62:600). We noted that Polysymptomatic Distress Scale items have clear dysautonomia connotations.

COMPASS-31 is a newly developed questionnaire to appraise dysautonomia. In contrast to the old COMPASS questionnaire, this new version has simplified scoring algorithm, and is suitable for widespread use in autonomic research and practice (Mayo Clin Proc. 2012;87:1196).

The objectives of our study were: 1) To correlate COMPASS-31 with the Polysymptomatic Distress Scale and with the Fibromyalgia Impact Questionnaire in 3 different groups of adult women: patients with fibromyalgia, patients with rheumatoid arthritis or healthy controls. 2) To compare the burden of dysautonomia symptoms in these 3 groups of individuals.

Methods: ,

To date, we have studied 25 women with fibromyalgia (ACR 1990 + ACR 2010 criteria), 19 with active rheumatoid arthritis (ACR criteria) and 24 healthy controls. All participants filled out the following questionnaires: COMPASS-31, Fibromyalgia Impact Questionnaire, and Polysymptomatic Distress Scale.

Results:

Age was similar in the 3 studied groups (mean: 41 years). In fibromyalgia patients there was correlation between COMPASS-31 scores and Polysymptomatic Distress Scale (Spearman Rho = 0.583, $p = 0.002$) and between COMPASS-31 and Fibromyalgia Impact Questionnaire (Rho = 0.525, $p = 0.007$). Remarkably, there was a strong correlation between COMPASS-31 scores and pain VAS values (Rho = 0.721, $p < 0.0001$). Patients with rheumatoid arthritis did not display such COMPASS 31 - pain VAS values correlation (Rho = - 0.024, $p = 0.92$). Patients suffering from fibromyalgia had much higher COMPASS-31 values (39.7 ± 15.3) when compared with rheumatoid arthritis patients (9.5 ± 8.5) and healthy controls (9.05 ± 8.7) $p < 0.0001$.

Conclusion:

Patients suffering from fibromyalgia have much more dysautonomia symptoms when compared to rheumatoid arthritis patients. In fibromyalgia, but not in rheumatoid arthritis, pain is closely related to autonomic dysfunction. There is correlation between the Polysymptomatic Distress Scale and COMPASS-31. Therefore, dysautonomia rather than "polysymptomatic distress" may be fibromyalgia's underlying pathogenesis. COMPASS-31 may become a useful clinical instrument to evaluate fibromyalgia's multisystem features.

Abstract Number: 72

Performance of the New Survey Criteria for Fibromyalgia Under

Conditions of Low and High Symptom Activity

Robert S. Katz and Frank Leavitt, Rush University Medical Center, Chicago, IL
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: In 2010, new criteria for fibromyalgia were proposed. In 2011, the questionnaire was adjusted so that patients provided the necessary information to satisfy the following criteria: Widespread Pain Index score (WPI) ≥ 7 and a Symptom Severity Score (SS) ≥5, or WPI of 3 to 6, and an SS score ≥ 9. In addition, a 0-31 Fibromyalgia Symptom Scale (FS) was developed by adding the 19 items of the WPI to the 12 items of the SS scale. Fibromyalgia symptoms wax and wane. The purpose of this study is to determine if the level of disease activity needs to be taken into account, when applying the new criterion sets in survey research.

Methods: The original questionnaire contained two scales; in one, patients record areas of pain and tenderness on a 19 point pain drawing; in the second, patients describe symptom severity on a 12 point range. The survey questionnaire (SQ) simplified the clinician somatic symptom report, by reducing it to yes-no answers to 3 symptoms (Lower abdominal discomfort, depression and headaches). Disease activity was measured on a 4 point scale ranging from usual symptom status to Symptoms severely intensified. The SQ was administered to 61 randomly selected women with a clinical diagnosis of fibromyalgia (FMS).

Results: The mean age of the FMS sample was 50.7±14.0 years with 15.2±2.2 years of education. The modified criteria were satisfied by 54.1% of the women who carried a clinical diagnosis of fibromyalgia. The FSS scale using a threshold score ≥ 13 was satisfied by 68.9% of the same women. For further analytical purposes, disease activity was collapsed into two categories; low and high disease activity. Performance of the modified criteria and FSS scale when disease activity is taken into account is shown in Table 1. As can be seen, sensitivity of both measures improved by over 30% when disease activity was high (67.6% versus 33.3%-modified measure; 81.1% versus 50.0%- FS scale).

Conclusion: Symptom variability is a problem for the new criterion sets for fibromyalgia and needs to be taken into account. People will engage in survey research at different levels of disease activity and are considerable more likely to satisfy the new criteria in periods or symptom exacerbation, often referred to as flare-ups. Taking symptom intensity into account is likely to generate more homogenous groupings within the fibromyalgia spectrum. In the low disease activity state, many patients are likely to function below the level of the new criteria.

Table 1. Performance of the New Modified Criteria[a] and the FSS criteria[b] in Classifying Patients with a Clinical Diagnosis of Fibromyalgia at Two Levels of Symptom Intensity.

	Modified Criteria		FSS criteria	
Symptom Intensity	Low	High	Low	High
Sensitivity[c]	8 (33.3%)	25 (67.6%)**	12 (50%)	30 (81.1%)**
False Negatives[d]	16 (66.7%)	10 (27.0%)	12 (50%)	7(18.9%)

**p<0.01

[a]Modified Criteria: Widespread Pain Index score (WPI)≥ 7 and a Symptom Severity Score (SS) ≥5 , or WPI of 3-6, and a SS score ≥ 9

[b] Fibromyalgia Symptom Scale Criteria: FS ≥ 13, with a 0-31 range.

[c]Sensitivity – test is positive for individual with clinical diagnosis of fibromyalgia.

[d]False Negative - test is negative for individual with clinical diagnosis of fibromyalgia.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The high concordance of systemic lupus erythematosus (SLE) with fibromyalgia (FM) suggests common underlying mechanisms related to pain and distress in both patient groups. This study was aimed to evaluate roles of NMDAR antibodies in development of FM in SLE patients.

Methods: Sera from 104 SLE patients, 112 FM patients, and 110 healthy controls were analyzed to detect titers of antibodies to N-terminus of 2B subunit of NMDAR (GluN2B). Clinical, laboratory data and concomitant diseases were found by reviewing the patient charts. We underwent clinical examination and neuropsychiatric evaluation, and interviewed SLE patients using a structured questionnaire that included FM and neuropsychiatric symptoms.

Results: 18 patients (17.3 %) of total 104 SLE patients were revealed having FM. The titer of anti-GluN2B antibodies was significantly higher in SLE patients than FM patients and healthy controls ($P < 0.001$). In SLE patients, patients with concomitant FM showed higher titers of anti-GluN2B antibodies ($P < 0.05$). The titers of anti-GluN2B antibodies were correlated with tender point count (Spearman's rho = 0.238, $P = 0.016$) and widespread pain index (Spearman's rho = 0.276, $P = 0.005$), but not with other symptom scales. Anti-GluN2B antibody-positive SLE patients were more likely to have NPSLE and concomitant FM ($P < 0.05$). In multivariate analysis, Anti-GluN2B antibody was independent predictor of concomitant FM and NPSLE.

Conclusion: This is the first study to present that antibodies to NMDAR may be associated with pathogenesis of FM in SLE patients.

Session Date: Sunday, November 8, 2015

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The study's purpose was to advance the understanding and treatment of fibromyalgia (FM) for patients in a chronic pain management center. FM is a chronic disorder that causes widespread musculoskeletal pain and fatigue, as well as a number of other symptoms. FM pain ranges from mild to incapacitating. Given the many possible co-morbidities associated with FM, we set out to examine clinical characteristics of FM patients compared with those with chronic pain but without FM. We did this to identify and better match patients to appropriate therapy.

Methods: This was a retrospective study with a case-control design based on data collected from July 1999 to February 17, 2015 in multiple chronic pain clinics in the United States. Patients were assigned to the case group of FM patients based on specific inclusion criteria. Propensity-score 1:1 matching was used to match controls (non-malignant chronic pain patients without FM) to cases based on identified confounders. A final sample of 1,070 controls and 1,069 cases was obtained to investigate co-morbidities, procedures, and regions of pain associated with FM. Items from a pain health assessment were also used to investigate patient-reported measures such as impairment, pain, fatigue, and quality of sleep. Pearson's chi-square and odds ratios were used to assess the significance and magnitude of relationships, two-sample t-tests were used for patient procedures, and a mixed model with repeated measures was implemented for patient-reported outcomes. Confidence intervals and effect sizes were included for each individual analysis.

Results: Nine additional International Classification of Diseases, Clinical Modification (*ICD-9*-CM) diagnoses were found to have odds ratios with large effect sizes (Cohen's $d > 0.8$). These diagnoses included chronic pain syndrome, latex allergy, muscle spasm, fasciitis, cervicalgia, thoracic pain, shoulder pain, rheumatoid arthritis, and cervical disorders (all $p < 0.0001$). Six diagnoses were found to have a moderate effect size (Cohen's $d > 0.5$): cystitis, cervical degeneration, anxiety, joint pain, lumbago, and cervical radiculitis. Current Procedural Terminology (CPT) procedure codes for musculoskeletal pain, specifically, trigger point injections, were shown to be used to treat FM cases in 5.9 more instances than controls, on average. There was insufficient evidence to suggest that patient-reported items from the pain health assessment were significantly different between cases and controls.

Conclusion: Multiple co-morbidities, diagnoses, and procedures were associated with FM patients in this study. Pain management physicians are uniquely positioned to treat FM patients. When coding procedural work they are driven by billing codes associated with each procedure and sometimes miss the fact they are dealing with a FM patient. Our goal is develop an alert system of diagnoses and procedures that would help doctors in differentiating FM patients from other painful conditions. Doing so is more practical and realistic than the current symptom severity scale and widespread pain index, both of which are rarely obtained in the pain management clinical setting.

Abstract Number: 75

Fibromyalgia and Positional Cervical Cord Compression Differ Only By Autonomic Nervous System Consequences: A Double-Blinded, Prospective Study

Andrew Holman, Pacific Rheumatology Reseach, Seattle, WA
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

In 1998, C Muhle and D Resnick proposed a corollary to cervical spinal stenosis caused by intermittent abutment of the cervical spinal cord from dynamic shifting of degenerative discs with flexion and extension of the neck.[1] This positional cervical cord compression (PC3) has been documented in 54-71% of patients with fibromyalgia (FM)[2,3] and was an exclusion criterion in the pramipexole FM randomized controlled trial[4]. In animal models, PC3 is a potent sympathetic nervous system arousal[5].

In humans, PC3 is so difficult to distinguish from FM (without dynamic imaging) that its validity and impact have been questioned. Given PC3 and FM symptom overlap, a blinded study was conducted.

Methods: Patients diagnosed with fibromyalgia per American College of Rheumatology 1990 classification criteria were recruited from the Seattle area and after consent, were provided standard, non-contrast cervical spine magnetic resonance imaging (MRI) with two additional saggital flexion and extension views with spinal canal diameter measurement at each disc level. PC3 was defined by a canal narrowing below 10 mm at any level WITH clear visual abutment of the cervical spinal cord by the commensurate disc and ligamentum flavum[2].

Double-blinded to the MRI results, subjects were assessed by history, physical examination, and a variety of surveys, including the Multidimensional Health Assessment Questionnaire (MDHAQ), Fibromyalgia Impact Questionnaire (FIQ), Short Form Health Survey (SF-36), Epworth Sleepiness Scale (ESS), Fatigue Severity Scale (FSS), Health Assessment Questionnaire (HAQ), 16-item Quick Inventory of Depressive Symptoms (QIDS) as well as autonomic nervous system (ANS) assessment by 5-minute, frequency domain, heart rate variability (HRV) of parasympathetic, sympathetic and total power measures (Omegawave Ltd, Espoo, Finland). Statistical analysis was conducted using Wilcoxon rank-sum for continuous variables and Fisher's exact test for categorical variables.

Results: Fifty-four patients with FM participated in this study (92% women, mean age 45.2 years). PC3 was identified in 31 of 54 subjects (57.4%). All three ANS HRV measures demonstrated statistical significance. Consistent with animal model data, parasympathetic score was lower 0.145 ± 0.067 for PC3+ patients and higher 0.198 ± 0.098 for PC3- patients (p=0.029). Sympathetic score was higher 61.0 ± 17.5 for PC3+ patients and lower 46.2 ± 15.8 for PC3- patients (p=0.005). Total power score was lower 440 ± 492 for PC3+ patients and higher 1633 ±4232 for PC3- patients (p=0.022). No clinical, historical or survey measures distinguished PC3-FM+ patients from PC3+FM+ patients.

Conclusion: This study provides the first evidence that intermittent, positional abutment of the cervical cord is a potent sympathetic arousal in humans. It also highlights the challenge of diagnosing and addressing PC3 without imaging. Further investigation will to sort out the role of PC3 in the diagnostic conundrum of FM, its pathogenesis and its treatment algorithms.

Evaluating Weather's Effect on Fibromyalgia Patients Using the Revised Fibromyalgia Impact Questionnaire and the Brief Pain Inventory

Daniel Kim[1], Ruth Chan[1], Marcal Plans[2] and Kevin Hackshaw[1], [1]Rheumatology & Immunology, Ohio State University, Columbus, OH, [2]Food Science and Technology Department, Ohio State University, Columbus, OH

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The objective of this study was to evaluate whether weather had an affect on fibromyalgia symptoms as measured by the Revised Fibromyalgia Impact Questionnaire (FIQR) and the Brief Pain Inventory (BPI), which had not been reported previously.

Methods: 67 female patients with fibromyalgia from the Ohio State University Rheumatology clinic were recruited to participate in the study. We received survey results back from 30 patients. Patients were given questionnaires for the FIQR and BPI to fill out every day for 7 consecutive days. Data was collected from February 1, 2015 through February 7, 2015. We recorded daily weather parameters (temperature, humidity, and barometric pressure) during evening time for Columbus Ohio from the National Weather Service website beginning on January 31, 2015 to Feb 8, 2015. After the data was centered to remove the bias effect for each patient, linear correlation between temperature, humidity, and barometric pressure was done using Pearson correlation coefficient. Analysis of covariance (ANCOVA) was used to correlate each patient trend with the weather parameters. Finally, principal component analysis (PCA) was used to recognize patterns in our data.

Results: No significant effect of weather on fibromyalgia symptoms was found using ANCOVA as measured by FIQR and BPI. PCA showed weak significant correlations between the second and the third principal components with the barometric pressure (0.26) and the humidity (-0.15), respectively. They accounted for only 6.6% and 5%, respectively, of the variability in our dataset which are too low to extract strong conclusions from.

Conclusion: This study investigated whether weather parameters of temperature, humidity, and barometric pressure could affect fibromyalgia symptoms using FIQR and BPI to measure symptoms, which had not been done before. We did not find any statistically significant effect of weather on fibromyalgia symptoms as measured by FIQR and BPI.

PCA of the FIQR and BPI showed low correlation with barometric pressure and humidity but they accounted for only 6.6% and 5% of the variability in our dataset, which are too low to extract strong conclusions from.

Exploratory Analysis of Somatic Symptoms in Fibromyalgia By Multidimensional Scaling and Latent Class Analysis

Marco Antivalle[1], Michele Battellino[1], Alberto Batticciotto[1], MariaChiara Ditto[1], Alessandra Mutti[1], Valentina Varisco[1], Federica Rigamonti[1], Fabiola Atzeni[1] and Piercarlo Sarzi-Puttini[2], [1]Rheumatology, L. SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Attempts to individuate subsets of fibromyalgia patients based on the aggregation of different symptoms have so far produced conflicting results. The 2010 preliminary diagnostic criteria for fibromyalgia (1), with the suggestion of the symptoms to be considered in the diagnosis, offers a frame for further investigation on this topic.

Methods:

338 patients (314 F; 24 M, mean age 45.47±11.37 yrs) diagnosed with fibromyalgia (FM) according to 2010 criteria were studied. FM was evaluated by tender points (TP), Widespread Pain Index (WPI), and Symptom Severity Scale (SS). The clustering in a two-dimentional space of the 41 somatic symptoms to be considered according to 210 criteria was assessed by Multidimentional Scaling analysis (MDS) by the ALSCAL routine of IBM SSPS 20.0 package, and the existence of an undelying classificative structure was explored by Latent Class Analysis (LCA) by the R poLCA package.

Results:

In the whole population, fibromyalgia scores were: TP 12.92±4.46, WPI 11.43±4.1 SS 9.04±2.10. Among somatic symptoms, muscle pain, muscle weakness, fatigue and thinking difficulties showed the highest similarity (Dice $\geq$ 0.8). Multidimensional scaling analysis was performed on the 41 somatic symptoms reported by the diagnostic criteria: the model was found to account for a substantial proportion of the variability of data (RSQ = 0.893); Kruskal stress was = 0.167. The Euclidean distance model (Fig. 1, left panel) showed at least 3 individualized grouping of symptoms: Group A symptoms, comprising muscle symptoms, fatigue and thinking difficulties, were prevalent in the majority (N = 225, 66.6%) of patients, while Group B (mainly digestive and urinary symptoms), and Group C (miscellaneous symptoms, including depression) symptoms were prevalent in 17.2% (N=58) and 16.3% (N=55) respectively. Group A patients reported the lowest total number of symptoms (16.8±5.4 vs 21.5±6.6 in group B and 23.0±7.9 in group C, p <0.001), and the lowest WPI (11.0±3.8 vs 11.5±4.5 and 14.1±4.6, p = 0.01); Group C showed also the highest TP count

(15.1±2.9 vs 12.9±3.9 in group A and 12.0±5.0 in group B). Fatigue, waking unrefreshed, and cognitive symptoms intensity were not different in the 3 groups ($p > 0.05$).Latent Class Analysis by poLCA showed that modeling the data from 1 to 3 latent classes produced only a small improvement in the model estimate (AIC coefficient from 15538.65 to 14578.15).

Conclusion:

The results of our study are consistent with the hypothesis of the existence of separate subsets FM patients, characterized by different clusters of symptoms stratified on the common core of altered pain sensation. The definite characterization of these subsets requires further studies, and more complex modeling of data with consideration of covariates.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster I

Session Type: ACR Poster Session A

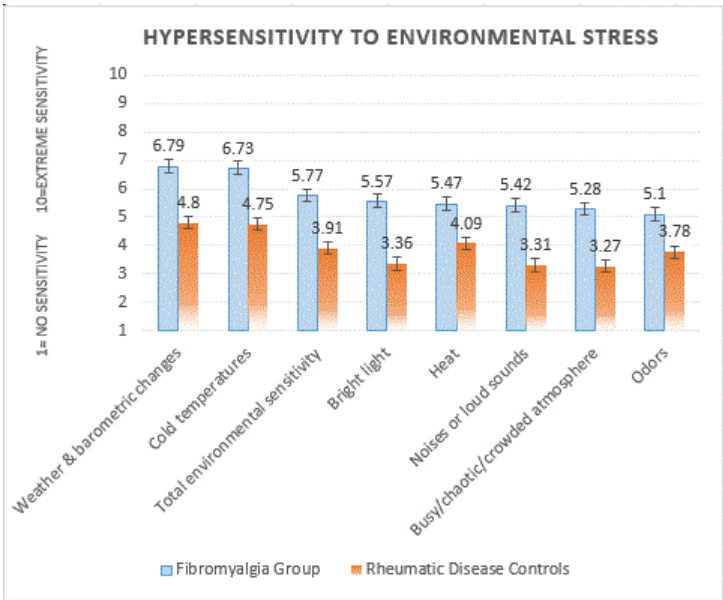
Session Time: 9:00AM-11:00AM

Background/Purpose: We inquired about hypervigilence and hypersensitivity to various environmental stresses in patients with fibromyalgia and in rheumatic disease controls.

Methods: 103 fibromyalgia patients with fibromyalgia and 124 rheumatic disease controls without fibromyalgia followed in a rheumatology office practice filled out a questionnaire regarding their sensitivity to various

environmental factors, including noises and loud sounds; light, certain artificial lighting or changes in brightness; certain odors and fragrances; cold temperatures; heat; busy, chaotic, or crowded atmospheres; weather or barometric pressure changes.

Results: See Chart



Conclusion: In every category of environmental stress, fibromyalgia patients were more sensitive than rheumatic disease controls. This supports the theory that fibromyalgia patients have a form of hypervigilence and are more sensitive to environmental stresses. Whether this hypervigilence was present before the onset of fibromyalgia is not assessed by this questionnaire, but hypervigilence and sensitivity to environmental stress potentially may play a role in both the etiology and exacerbation of symptoms in fibromyalgia.

Paresthesias in Fibromyalgia Patients

Robert S. Katz[1], Lauren Kwan[2], Kelli Davis[2] and Jessica L. Polyak[2], [1]Rush University Medical Center, Chicago, IL, [2]Rheumatology Associates S.C., Chicago, IL

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster I

Session Type: ACR Poster Session A

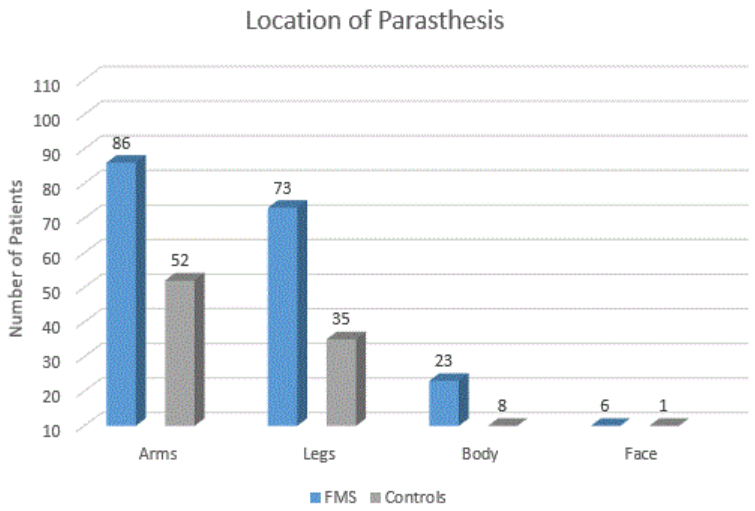
Session Time: 9:00AM-11:00AM

Background/Purpose: Paresthesias are common in patients with fibromyalgia. We evaluated the symptoms of numbness and tingling in fibromyalgia patients and rheumatic disease controls without fibromyalgia.

Methods: 104 fibromyalgia patients meeting the 2010 ACR criteria for fibromyalgia and 124 rheumatic disease controls without fibromyalgia answered a questionnaire regarding the presence of paresthesias. They were asked if they had numbness or tingling; whether it was constant, intermittent, or frequent; and also the location of their numbness and tingling; the intensity; whether there were color changes in the hands or feet; skin temperature changes; symptoms related to rubbing the area; symptoms related to putting on socks or gloves; and numbness and tingling related to activity.

Results: 104 fibromyalgia patients and 124 rheumatic disease controls without fibromyalgia responded to the questionnaire during an office visit in a rheumatology practice. 45% of the fibromyalgia patients compared with 19% of the controls indicated that they had frequent paresthesias, 55% of fibromyalgia patients versus 33% of the controls indicated that they had intermittent paresthesias, and 20% of fibromyalgia patients versus 9% of controls answered that they had constant paresthesias. 51% of the fibromyalgia patients versus 41% of the controls experience color changes in the hands and feet, 61% of fibromyalgia patients versus 45% of the controls had skin temperature changes, 28%.

On a 1-10 visual analog scale with 10 being very severe, fibromyalgia patients were 5.51 and controls were 4.83.



Conclusion: Fibromyalgia patients more often experience paresthesias than rheumatic disease controls. The paresthesias are more commonly frequent or constant compared with rheumatic disease controls without fibromyalgia. The paresthesias are often widespread and frequently associated with color changes in the hands and feet, skin temperature changes, symptoms when rubbing the area, symptoms with putting on socks or gloves, and paresthesias related to activity.

The subjective sensations of numbness and tingling, without a neurological deficit, appear to be a common component of the fibromyalgia syndrome. We suggest that fibromyalgia-related paresthesias be further described, such as using a term like “paresthesias of unknown etiology”or Idiopathic paresthesias (IP).

Similar to other syndromes based on subjective symptoms, such as irritable bowel syndrome and migraine, the terms “paresthesias of unknown etiology” or “idiopathic paresthesias” may describe patients with and without fibromyalgia who do not have a clear neurological basis for these symptoms.

A descriptive name might be reassuring to patients who otherwise feel that the physician thinks they are “crazy,” or that their paresthesias might be part of a more serious neurological syndrome (such as multiple sclerosis), despite reassurance from a neurologist or other practitioner.

The Value of Routine Use of Creatine Kinase and Thyroid Stimulating Hormone Tests in Patients with Suspected Fibromyalgia: Results of a Cross-Sectional Study

Nadine Boers[1], Nathan den Broeder[1], Judith van Vliet[2], Ronald F. van Vollenhoven[3], **Nienke Lesuis**[1] and Alfons A. den Broeder[1], [1]Rheumatology, Sint Maartenskliniek, Nijmegen, Netherlands, [2]Neurology, Canisius Wilhelmina Ziekenhuis, Nijmegen, Netherlands, [3]Department of Medicine, Unit for Clinical Therapy Research, Inflammatory Diseases (ClinTRID), The Karolinska Institute, Stockholm, Sweden

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Creatine kinase (CK) and Thyroid stimulating hormone (TSH) are frequently used tests in the diagnostic work-up of fibromyalgia (FMS) to exclude thyroid disease or myopathy. However, the diagnostic values of these tests in this clinical context are still unclear.

Methods:

All patients with suspected fibromyalgia, referred to the study hospital between November 2011 and April 2014 were asked to participate. Patients received a protocolized workup for FMS and exclusion of other disease using history, physical exam, neurological questionnaire, and additional testing when necessary. Patients with a previous diagnosis of thyroid disorder or a history of CK related disease were excluded.

Mean CK and TSH, percentage of abnormal CK and TSH values and the final diagnosis in patients with an abnormal CK or TSH value were used as outcome measures. An abnormal CK was defined as a CK >200 U/l for men and >170 U/l for women. Abnormal TSH was defined as a TSH <0.4 or >4.0 mE/l. Free Thyroid Hormone (FT4) was assessed when TSH was abnormal (reference values FT4: 8-22 pmol/l). The final diagnoses (ICD-9 code) were obtained from the patients' files.

Results:

375 patients with suspected FMS were included (patient characteristics: table 1). Mean CK and TSH in these patients were 96 ± 50 mE/L and 1.8 ± 1.4 U/L respectively.

26 (6.9%; 95%-confidence interval (95%-CI) 4.3%-9.5%) patients had a borderline abnormal CK, considered clinically irrelevant. In 2 (0.5%; 95%-CI -0.2%-1.2%) patients CK value was clearly elevated and therefore retested, resulting in a normal CK value at this second test. In none of the patients with an abnormal CK a CK-related diagnosis was made and the final diagnosis was fibromyalgia in most of them (n=25).

13 (3.5%; 95%-CI 1.6%-5.3%) patients had an elevated TSH and 5 (1.3%; 95-CI 0.2%-2.5%) a lowered TSH, with one patient also having an abnormal FT4 value. However, the latter was deemed insignificant by the treating

rheumatologist and the final diagnosis of all these patients was fibromyalgia.

Table 1 Characteristics of the patient population

Characteristic	**Study population (n = 375)**
Female sex, *n(%)*	354 *(94%)*
Mean age, *years (range)*	42 *(18-75)*
Second opinion, *n(%)*	107 *(29%)*
Previous diagnosis of fibromyalgia, *n(%)*	188 *(50%)*
ICD-9 diagnosis, *n(%)*	358 *(95)*
Fibromyalgia	17 *(5)*
Other	

Conclusion:

This study shows that abnormal CK and TSH values are rare in patients with suspected FMS referred to the hospital, and not resulting in another diagnosis as explanation for the complaints. Therefore, it seems that routine testing of CK and TSH levels, in secondary care, in all patients with suspected FMS does not contribute positively to the diagnostic process.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Autonomic nervous system (ANS) dysfunction is thought to play a role in the pathophysiology and symptoms of FM. Evaluation of the ANS may be done through heart rate variability (HRV) analysis. While HRV

has been shown to be abnormal in patients with FM, this is the largest study to examine relationships between HRV measures and clinical measures.

Methods: 230 patients (Age: 49.1 ± 12.2, 94% female) meeting 1990 ACR fibromyalgia criteria who were part of a randomized control trial of psychological interventions also had assessments of HRV measures at baseline prior to randomization. HRV was obtained via 30-minute Holter monitor recording which included periods of supine positioning, orthostatic challenge, and experimental pain testing. Time domain and frequency domain measures of HRV were calculated and analyzed with CardioScan Premier 12 software (DM Software, Stateline, NV). Age, sex, race, BMI, along with comorbidities diabetes mellitus and hypertension were adjusted for during analyses.

Results:

At baseline, a time domain measure of greater HRV, as reflected by the square root of the mean of the sum of the differences between adjacent N-N intervals (RMSSD), was significantly correlated with better sleep quality and lower fatigue ($\beta = -.15$, $p = .02$ and $\beta = -.129$, $p = .04$, respectively). Frequency domain measures of greater HRV, as reflected by total low-frequency power (LF) and total high-frequency power (HF) were found to be significantly correlated with lower anxiety ($\beta = -.13$, $p = .03$ and $\beta = -.14$, $p = .02$, respectively), better sleep quality ($\beta = -.13$, $p = .03$ and $\beta = -.15$, $p = .01$, respectively), lower fatigue ($\beta = -.13$, $p = .02$ and $\beta = -.14$, $p = .02$, respectively), and better mental health ($\beta = .16$, $p = .007$ and $\beta = .15$, $p = .01$, respectively). Similar associations were demonstrated in the supine positioning and orthostatic challenge periods ($p < .05$ for each), with the exception of LF component in supine positioning correlation to anxiety ($p = .11$) and HF component of orthostatic challenge correlation to fatigue ($p = .09$). LF and HF components during the pain-testing period did not reveal significant associations with clinical measures ($p > .05$ for each).

Conclusion: This study demonstrates that better clinical status is associated with greater HRV in a population of patients with fibromyalgia. Further work is needed to clarify whether changes contribute to the pathogenesis of FM, are caused by the FM, or are epiphenomena.

Immediate Benefits of a Multidisciplinary Educational Program for Fibromyalgia on Patients' Pain Related Self-Efficacy and Health Locus of Control

Amrita Kaur Bath[1], Carmen E. Gota[2], Anabelle Morales Cavolo[3] and Sara Davin[4], [1]Internal medicine, Fairview Hospital- Cleveland Clinic, Cleveland, OH, [2]Orthopedic and Rheumatologic Institute, Cleveland Clinic, Cleveland, OH, [3]former Cleveland Clinic fellow, Cleveland, OH, [4]Neurologic Institute, Cleveland Clinic, Cleveland, OH

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: To evaluate the effect of an intensive, brief, multidisciplinary educational intervention on self – efficacy and locus of control specific self-management constructs, in patients who suffer from fibromyalgia (FM).

Methods: Patients and family actively participated in a brief educational program involving discussion about clinical, pathophysiologic, and therapeutic aspects of FM; exercise instruction, orientation on the cognitive behavioral model of pain and stress, review of psychosocial contributors to chronic pain, family education, and introduction to relaxation techniques. Patients completed Pain Related Self Efficacy Questionnaire (PSEQ) and Multidimensional Health Locus of Control Scale (MHLC Form C subscale) questionnaires before and immediately after the program.

Results: From May 2014 to April 2015, 77 female patients, who met the ACR 2010 preliminary criteria for FMS, mean age 48.3 (10.9), 44.2% employed, with poly symptomatic distress score of 21.6 (5), participated in an 3.5 hour educational program. Fibromyalgia impact questionnaire revealed severe levels of symptomatology 62 (18.2), and patients had moderate depressive symptoms by patient heath questionnaire 9, 13.9 (6.5). The program was rated very or extremely helpful by 79.7% of patients, with 78.6% reporting getting answers to most or all their questions. Results showed significant increases in PSEQ ($p<0.0001$), and decreases in external locus of control MHLC "chance" ($p<0.0001$).

Conclusion: These results show that a brief multidisciplinary educational program in FM can significantly enhance self efficacy related to pain and external attributions in patients with severe FM and moderate depression. Our study supports the utility of short education programs on positive coping for FM patients.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster I

Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

The 2011 modification of the preliminary 2010 American College of Rheumatology criteria for fibromyalgia require the self-report of multi-site pain in addition to a number of additional symptoms: fatigue, sleep disturbance, somatic symptoms and cognitive problems. As part of the ACTTION[1]initiative - developing a new taxonomy for pain conditions, including fibromyalgia – the current study aimed to investigate whether there is sexual dimorphism between the presence of multi-site pain (MSP) and these additional features.

Methods:

Three UK-based population studies were used for the current analysis: the 1958 Birth Cohort, EpiFunD and SHAMA studies. MSP was defined as the presence of pain in at least eight body sites, (as indicated on 4-view body manikins with a total of 35 designated sites), regardless of location.

Amongst those reporting MSP, the relationship between gender and: fatigue (lowest tertile of SF-36 Vitality (VT) Scale), sleep disturbance (Estimation of Sleep Problem Scale score 12-20), presence of somatic symptoms (Somatic Symptom Scale) and poor mood (highest tertile of General Health Questionnaire, lowest tertile of SF-36 Mental Health (MH), and Hospital Anxiety and Depression Scales (HADS)), were assessed using logistic regression models including terms for gender. **Results** are presented as Odds Ratio (OR), with 95% Confidence Intervals (CI).

Results:

There were 26,452 participants across the three study populations (mean age range: 42-55 yrs, proportion male: 43-52%). The prevalence of MSP ranged between 12 and 17% and, within these groups, 35-47% were male.

Amongst those reporting MSP; females reported higher levels of sleep disturbance [OR 1.2, 95% CI 1.002-1.7] and more somatic symptoms compared to males [mean 1.8, CI 1.7-1.9 vs. 1.5, 1.3-1.6]. There was also some indication that females reported higher levels of fatigue [SF36 VT 1.7, 0.97-2.9], poorer mental health [GHQ 1.4, 1.2-1.6; SF36 MH 1.3, 0.8-2.3], in addition to higher levels of anxiety [HADs 1.2, 0.9-1.7], although differences were small and not always statistically significant. There was, however, no indication that females exhibited higher levels of clinical/borderline depression [HADS 0.8, 0.6-1.1].

Conclusion:

Amongst those with MSP, sex differences in the reporting of features typical of fibromyalgia are generally small and not always statistically significant, though females exhibit more sleep problems and higher levels of fatigue.

Session Date: Sunday, November 8, 2015

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

To determine the prevalence and characteristics of fibromyalgia patients who are prescribed opiod drugs.

Methods:

Consecutive patients who met the ACR 1990 criteria for fibromyalgia, seen in a tertiary care center, were dichotomized based on current prescription of opioid drugs (yes/no). Demographic and clinical data were compared. The following questionnaires were used: fibromyalgia impact questionnaire (FIQ), patient health questionnaire (PHQ-9), health assessment questionnaire disability index (HAQ-DI).

Results:

Of 240 patients 38.3% were prescribed opioid medications. Patients who were prescribed opiates as treatment, compared to those who were not, had significantly ($p \leq 0.05$) lower employment rates 31.5% vs 48.6%, were less college educated 23.4% vs 41.7%, had higher pain scores, FIQ pain 8.2 (1.7) vs 7.3 (2.1), depression PHQ-9 13.2 (6.3) vs 11.5 96.1), disability HAQ DI 1.4 (0.5) vs 1 (0.6), and reported severe fibromyalgia impact, FIQ 73.1 (15.1) vs 64.8 (18.3). They were also taking more medications for fibromyalgia 4.8 (1.9) vs 2.1 (1.8), had more surgeries 5.1 (3.9) vs 3.2 (3), and more doctor visits in the past 6 months 11.9 (11.5) vs 7.7 (8.4).

Conclusion:

Opioid use identifies about 1/3rd of tertiary care FM patients, a group with low socioeconomic status, and high use of medical resources. Our study suggests that clinicians prescribe opiates for FM patients who have severe disease, despite taking other drugs for FM. The high pain scores reported at the time of taking narcotic medications also raise questions about the benefit of prescribing these drugs in FM.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Genetics, Genomics and Proteomics Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Congenital heart block (CHB) may affect children of women with anti-Ro/SSA and anti-La/SSB autoantibodies. The most recognized manifestation of CHB is an atrioventricular (AV) block, but atrial and ventricular arrhythmias, a prolonged isovolumetric contraction time and cardiomyopathies also affect a substantial proportion of the babies. The potentially lethal cardiac manifestations develop *in utero* during gestational weeks 18-24, and the risk of giving birth to a child with CHB is 1-2% in anti-Ro/SSA-positive pregnancies. A recurrence rate of only 12% despite persisting maternal autoantibodies suggests that additional factors influence disease development. The purpose of this study was to identify fetal genetic susceptibility factors for CHB, and to understand their functional impact on pathogenesis.

Methods:

We performed a genome-wide association study of >500,000 single nucleotide polymorphisms (SNP) in a population-based cohort of families with children diagnosed with CHB and analyzed transmission of SNPs based on genotypes of index cases (n=92) and first degree relatives (n=256). CHB-associated SNPs ($p \leq 1x10^{-4}$) were replicated in a population-based case-control analysis ($n_{controls}$=1122). Expression quantitative trait loci (eQTL) analysis was performed in cardiac tissue of genes present in the regions surrounding replicating SNPs (±500 kb) across both data sets. Human and mouse tissue expression of genes and proteins was assessed by qPCR, RNAseq, Western blot, immunohistochemistry and immunofluorescence staining. Functional analysis *in vitro* using primary cultured cardiomyoctes from genetically modified neonatal mouse pups was performed with time lapse Ca^{2+} recordings. Doppler echocardiography was used to assess cardiac disease phenotypes *in utero*.

Results: We discovered *DNAJC6* as a novel fetal susceptibility gene associated with CHB, with decreased cardiac expression of *DNAJC6* associated with the disease risk genotype. Auxilin, the putative tyrosine-protein phosphatase encoded by *DNAJC6,* was remarkably higher expressed in the fetal compared to the adult heart both before and during the risk period for CHB (>10 fold, $p < 0.001$). In human fetal cardiomyocytes we observed auxilin in the cytoplasm in a vesicular pattern, co-localized with clathrin, suggesting that the cellular function of auxilin in cardiomyocytes, as

already described for neurons, is within the clathrin-mediated endocytic process. Analysis of auxilin-deficient cardiomyocytes of neonatal mice revealed abnormal connectivity and Ca^{2+} homeostasis in culture. Doppler echocardiography of auxilin-deficient fetal mice *in utero* revealed several CHB-related manifestations *in vivo*, including AV-block, abnormal heart rhythm with atrial and ventricular ectopias and a prolonged isovolumetric contraction time as a sign of decreased myocardial performance.

Conclusion:

In conclusion, our study identifies auxilin as the first susceptibility gene in CHB modulating cardiac function, and connects the decreased auxilin expression observed for the susceptibility allele with clinical fetal CHB features.

Session Date: Sunday, November 8, 2015
Session Title: Genetics, Genomics and Proteomics Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: The rheumatoid arthritis (RA) risk locus *CCR6* SNP rs3093024, is in tight linkage disequilibrium with rs3093023 which has been associated with RA risk. RA is more common in females with an increased risk of disease and flares during the postpartum or postmenopausal periods—times of rapidly falling estrogen levels. We previously reported that these two SNPs in *CCR6* are associated with changes in the expression of CCR6 and, downstream, those of CCL20, IL17RA and IL17A in a SNP-dependent fashion in response to 17-β-estradiol (E2) treatment. In the present study, we set out to determine the effects of these *CCR6* SNPs on the expression of CCR6, CCL20, IL17RA and IL17A during estrogen withdrawal, which has been implicated in RA pathogenesis, as well as mechanism(s) underlying *CCR6*SNP function and estrogen-dependent gene expression regulation by functional genomic studies.

Methods: "Human Variation Panel" lymphoblastoid cell lines (LCLs) consisting of LCLs from 300 subjects were used to obtain genome-wide mRNA expression and SNP data. A panel of LCLs with six wild-type (WT; homozygous) and six variant (V; homozygous) genotypes for these SNPs, were used for functional genomic study. Cells were treated with E2 and the estrogen receptor α (ERα) antagonist fulvestrant. Changes in mRNA and protein expression after treatment were determined. ChIP assays were used to determine ERα binding to estrogen response elements (EREs) before and after ER blockade.

Results: Knockdown of CCR6 resulted in down-regulation of NF-κB p65 and phosphorylated IκB, indicating that *CCR6* plays a role in inflammatory pathways. CCR6, CCL20, IL17RA and IL17A expression was altered in a *CCR6* SNP estrogen-dependent fashion. Specifically, CCR6 and IL17RA were significantly up-regulated in response to E2 treatment, but only in cells homozygous for the *CCR6* SNP V alleles. Conversely, the expression of CCL20 and IL17A, which are the ligands for CCR6 and IL17RA respectively, were significantly increased in response to E2 treatment, but only in cells homozygous for WT alleles for the *CCR6* SNPs. However, this pattern of gene expression could be ‘’reversed’’ in a *CCR6*SNP-dependent fashion in the presence of the ERα antagonist fulvestrant, compatible with our DNA-ERα protein binding observations for two EREs near the rs3093023 SNP. When E2 was present, cells homozygous for the V allele for rs3093023 displayed elevated ERα binding compared with cells homozygous for the WT allele. However, a reversal of ERα binding was observed in the presence of fulvestrant.

Conclusion: We observed differential ERα binding before and after ER blockade which might be associated with underlying mechanisms for the SNP and estrogen-dependent variation of CCR6 expression and, downstream, the expression of CCL20, IL17RA and IL17A--all of which play roles in the pathogenesis of RA. These observations also suggest that the expression of immune mediators could potentially be pharmacologically manipulated in a SNP-dependent fashion. Our findings suggest a novel molecular mechanism that may play an important role in the interplay between estrogen and immune mediators in RA—a disease that displays striking variation in incidence and disease activity which might be related to hormonal status.

Session Title: Genetics, Genomics and Proteomics Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: In many rheumatologic and autoimmune diseases African Americans (AA) have a higher prevalence and greater disease severity than other ethnicities. We posit that population-specific natural selection have influenced allele frequencies at some loci and thereby contribute to the higher prevalence and severity of systemic lupus erythematosus (SLE) in AA. The Gullah population of coastal South Carolina and Georgia has lower European admixture and higher ancestral homogeneity from the Sierra Leone (SL) area in Far-West Africa than other AA populations. The shorter genetic distance between the Gullah and SL suggests that population genetic signals, such as regions under recent selection, may be more easily detected in the Gullah than in other AA populations. The goal of this study was to leverage the evidence for recent natural selection to increase the statistical power to detect novel SLE-predisposing loci in the Gullah.

Methods: We computed a genome-wide association study (GWAS) on 151 Gullah SLE cases and 119 Gullah controls adjusting for admixture estimates. We also computed the likelihood ratio test for allelic differences between 277 Gullah population controls and 400 SL population controls adjusting for admixture. The intersection of SNPs from the case-control and test of selection that met standard quality control were 193,008 SNPs. We combined the evidence of association with SLE in the Gullah from the case-control analysis with evidence of selection by summing the chi-square statistic from a SNPs allele frequency test with its case-control association chi-square to create an overall chi-square statistic with 2 df (Ayodo et al, 2007). We used HaploReg for functional annotation of variation.

Results: Several genomic regions with multiple SNPs with suggestive evidence for association with SLE ($P<5.0E-04$) were found, including an intergenic region at 1p31.1, *TLE4*, and *PCNXL4*. When combined with the allele frequency differences, *XCR1-CCR1* showed multiple SNPs with $P<0.0005$. However, several other regions showed multiple SNPs with increased significance ($P<0.005$) when the association and selection evidence was combined, including the *HLA, PKHD1, GAS2L3* and *FHOD3*. Interestingly, the strength of significance increased for several SNPs in the *PCNXL4* region. This was also the region with the highest regulatory potential, with multiple marks of active promoters and transcription start sites in different immune-related cell lines.

Conclusion: We report novel loci with suggestive evidence for association with SLE in a genetically homogeneous AA population, by combining evidence of natural selection with association to detect SLE risk variants in Gullah AA. These loci merit focused association replication efforts in SLE and this approach is generalizable to several other rheumatic diseases with ethnic differences in prevalence. Clearly the link with evidence of selection will only increase the power for a subset of SLE-predisposing to those that may have been historically adaptive. Such distinctions help not only identify new risk loci but may help provide insight into the evolution of rheumatic and autoimmune diseases in humans.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Genetics, Genomics and Proteomics Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Studies of patients with rheumatoid arthritis (RA) to identify genetic biomarkers of anti-tumor necrosis factor (TNF) response have been conducted mostly in Caucasian populations. These studies have used anti-TNF response at a single follow up time point as the phenotype with which single nucleotide polymorphisms (SNP) associations have been tested. There has been little overlap in findings across studies. To identify genetic biomarkers of anti-TNF response among Japanese RA patients, we have performed a genome-wide association study (GWAS) using response at 2 follow up time-points for a more reliable clinical phenotype over time.

Methods: Disease Activity Scores based on 28 joint counts and C-reactive protein (DAS28) were assessed at baseline (before initial therapy), and after 3 and 6 months in 487 Japanese RA patients starting anti-TNF therapy for the first time or switching to a new anti-TNF agent. A genome-wide panel of 1,133,484 SNPs was genotyped and additional SNPs were imputed. Using change in DAS28 scores from baseline (ΔDAS28) at both 3 and 6 months as the response phenotype, a longitudinal genome-wide association analysis was conducted using Generalized Estimating Equations (GEE) models to accommodate the repeated measures of the outcome, adjusting for baseline DAS28, time since initiation of therapy, type of anti-TNF agent and concomitant methotrexate.

Results: A total of 4,253,138 autosomal SNPs passed quality thresholds for association analysis. Suggestive evidence of association ($p<1x10^{-6}$) with ΔDAS28 was observed at 3 chromosomal regions (6q15: rs284515, $p=6.6x10^{-7}$; 6q27: rs75908454, $p=6.3x10^{-7}$ and 10q25.3: rs1679568, $p=8.1x10^{-7}$), extending to numerous SNPs in linkage disequilibrium (LD) with the index SNPs across each region. Potential candidate genes in these regions include *MAP3K7* (6q15) a key player in TNFα-mediated inflammatory pathway signaling, *GFRA1* (10q25.3) which was associated with anti-TNF response in an independent study, and *WDR27* (6q27).

Conclusion: In this first GWAS of anti-TNF response among Japanese RA patients using a longitudinal analysis approach, three genomic regions demonstrated suggestive association with response to anti-TNF therapy. Using more than one assessment of response enhanced the power to detect these associations.

Session Title: Genetics, Genomics and Proteomics Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: We investigated the association between human leukocyte antigen (HLA)-DRB1 alleles and systemic lupus erythematosus (SLE) susceptibility and whether each allele has a significant effect on clinical manifestations and autoantibody profiles in a Korean population.

Methods: All SLE patients (n=1,089) and control subjects (n=2,161) were Korean. We performed a two-stage analysis in a discovery set (group 1: 475 SLE and 1,119 controls) and a replication set (group 2: 614 SLE and 1,072 controls) using high-resolution HLA-DRB1 typing. The odds ratio (OR) of risk alleles associated with SLE was calculated by a regression method, which was adjusted for age, sex, and disease duration.

Results: We found that four HLA-DRB1 alleles [two confirmed alleles; **15:01* (P=1.11×10^{-13}), **09:01* (P=1.59×10^{-5}), two novel alleles; **08:03* (P=8.80×10^{-8}), **07:01* (P=1.14×10^{-6})] and were associated with susceptibility to SLE. Double copies of these risk alleles (OR 3.38) were associated with a higher risk of developing SLE than a single copy (OR 1.95), showing additive genetic effects. In addition, three novel HLA-DRB1**12:02* (P=6.35×10^{-4}), **11:01* (P=1.24×10^{-3}), **13:02* (P=8.88×10^{-3}) alleles were significantly protective against SLE. The HLA-DRB1**15:01* allele alone (OR 2.20) and double-copies of risk alleles (OR 3.71) increased the risk for anti-Sm production. In addition, SLE patients with double-copies of risk alleles showed more diverse clinical manifestations.

Conclusion: We demonstrated that four HLA–DRB1 risk alleles were associated with SLE in a Korean population, and also promote the production of anti-Sm and diverse clinical manifestations

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Genetics, Genomics and Proteomics Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Gout is caused by chronic hyperuricemia, leading to uric acid deposition. Humans and apes have relatively high serum uric acid (sUA) levels due to inactivating mutations in the enzyme uricase, which took place during hominid evolution, preventing the conversion of uric acid into more soluble allantoin. Uric acid is eliminated primarily by excretion through the kidneys. Most gout patients exhibit reduced renal excretion of uric acid. In the kidney, most of the uric acid is reabsorbed back into the bloodstream through URAT1, a uric acid transporter that is essential for maintaining sUA levels. From our studies on URAT inhibitors, we identified phenylalanine 365 as important for inhibitor affinity. We now find that this residue also affects the affinity of URAT1 for the substrate uric acid. Evolutionary changes in this amino acid appear to track with alterations in uricase function. Our objective was to determine whether URAT1 may have been subject to adaptive evolution for controlling and maintaining the relatively high sUA levels in humans.

Methods: Ancestral URAT1 sequences were inferred by analyzing modern transporter sequences within an evolutionary framework. Briefly, extant sequences were collected and used to infer a phylogenetic tree. Ancestral sequences were then computationally inferred from the tree and then synthesized and cloned in the laboratory. Modern and ancestral URAT1 genes were transiently expressed in HEK-293T cells to measure URAT1-dependent transport of uric acid. The affinity of each construct for uric acid was determined.

Results: Among the URAT1 orthologs, residue 365 is phenylalanine in humans, apes, and monkeys, but is tyrosine in most other mammals. Ancestral sequence analysis reveals that the tyrosine to phenylalanine replacement occurred deep in the primate lineage. Human URAT1 has a significantly higher affinity for uric acid (K_m ~ 150 μM) compared to rat URAT1 (K_m~ 800 μM). Point mutant chimeras between the 2 transporters show that human phenylalanine 365 confers a higher affinity to uric acid. The transport activities of ancestral and other modern orthologous URAT1 proteins also indicate that phenylalanine 365 is important for high uric acid affinity. Remarkably, the known decrease in primate uricase activity tracks concomitantly in evolutionary history with the alterations that increase uric acid affinity of URAT1 during primate evolution.

Conclusion: Human URAT1 phenylalanine 365 is important for high affinity transport of uric acid, while URAT1 orthologs and ancestors that carry tyrosine 365 have low affinity transport of uric acid. Evolutionary analysis shows that the tyrosine-to-phenylalanine conversion in URAT1 coincides with the inactivating mutations in uricase that took place between 45–90 million years ago, suggesting that this URAT1 mutation occurred due to adaptive positive selection for elevated uric acid levels in humans and their closest relatives. We posit that phenylalanine 365, along with other residues, plays an important role in URAT1-dependent uric acid homeostasis.

Session Title: Genetics, Genomics and Proteomics Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Interleukin-6 (IL-6) cytokine signaling is key in Rheumatoid Arthritis (RA) pathophysiology. Blocking IL-6 receptor (IL6R) has proven to be a highly effective treatment to prevent joint damage. This study was performed to investigate the association between the genetic variation at*IL6R* gene and the severity of joint damage in RA.

Methods: *IL6R* gene tagging SNPs (n=5, Figure 1) were genotyped in a discovery group of 527 RA patients from 5 different university hospitals from Spain. For each marker, a multivariate linear regression analysis was performed to test for association with joint damage and also to adjust several covariates including years disease evolution, autoantibody status and gender. Haplotypes combining the SNPs were also estimated and tested for association with the level of joint destruction. Using an independent cohort of 705 RA patients from 6 university hospitals we performed a validation study of the SNPs associated in the discovery phase.

Results: In the discovery group we found a highly significant association between *IL6R* SNP rs4845618 and the level of joint destruction in RA (*P*=0.0058, Table 1), and a moderate association with SNP rs4453032 (*P*=0.02, Table 1). The resulting haplotype from both SNPs was more significantly associated with joint damage (*P*=0.0037). Using the validation cohort, we replicated the association between the two IL-6R SNPs with the degree of joint destruction in RA (*P*=0.007 and *P*=0.04, meta-analysis *P*=0.00011 and *P*=0.0021, respectively, Table 1), and the haplotype association (*P*=0.0058, meta-analysis *P*=6.64 e-5).

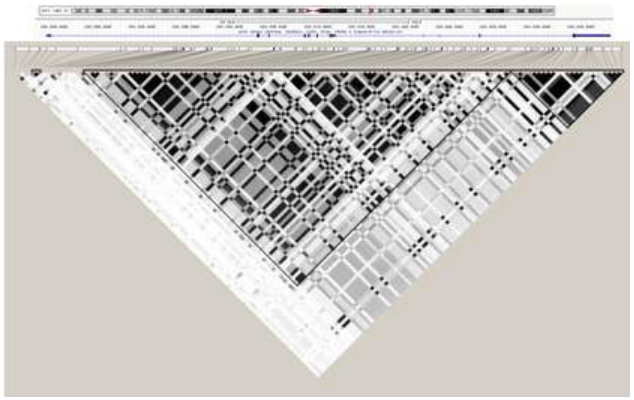

Figure 1. LD pattern at IL6R locus. The two main haplotype blocks covering most common genetic variation at *IL6R* gene (in blue) are indicated by solid line triangles.

Table 1. Association of *IL6R* markers with the severity of joint damage in RA. Significance values for *IL6R* SNPs in the discovery, replication cohorts as well meta-analysis of the two cohorts.

SNP	Basepair	MAF	*P*-Discovery	*P*-Replication	Meta-analysis *P*
rs4845618	154400015	0.44	0.0052	0.007	0.00011
rs4453032	154414086	0.4	0.51	-	-
rs4845374	154426947	0.17	0.02	0.04	0.0021
rs6698040	154432948	0.21	0.11	-	-
rs4379670	154439865	0.16	0.25	-	-

Conclusion: We show for the first time that genetic variation at *IL6R* gene is associated to joint damage in RA.

Session Title: Genetics, Genomics and Proteomics Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Ankylosing spondylitis (AS) is a highly heritable rheumatic disease causing chronic inflammation of axial spine, joints and various organs. The presence of HLA-B*27 is strongly associated with development of AS, explaining most of the genetic associations between AS and the major histocompatibility complex (MHC) locus on human chromosome 6. Here, we investigated residual effects outside HLA-B within the MHC region.

Methods: We obtained high-density genotyping array Immunochip data for the extended MHC locus in 3,820 unrelated Korean subjects (comprising 654 cases of AS and 3,166 controls) who were ethnically homogeneous and showed no evidence of systemic bias or potential population substructure. The patients with AS satisfied the modified New York criteria for AS diagnosis. Using the SNP2HLA script and the Korean HLA reference panel, we imputed the two- and four-digit classical alleles and amino-acid residues of *HLA-A*, *-B*, *-C*, *-DRB1*, *-DPB1* and *-DQB1*, as well as MHC SNPs (spanning 25–35 Mb). AS associations of all markers with minor allele frequency ≥1% and imputation quality (PLINK INFO) ≥0.1 were assessed using logistic regression, adding the top ten principal components as covariates. AS associations at HLA amino-acid positions (or multiple markers) were assessed using log likelihood ratio tests (LRT).

Results: We imputed 5,658 polymorphic variations including 158 classical alleles and 663 amino-acid variants in *HLA-A*, *-B*, *-C*, *-DRB1*, *-DPB1* and *-DQB1*, as well as 4,837 MHC SNPs. The most significant associations were identified at amino-acid positions 97 ($P_{LRT}=7.20\times10^{-479}$) and 114 ($P_{LRT}=2.54\times10^{-484}$) in the epitope-binding site of *HLA-B*, highlighting the risk effect of the HLA-B*27 allele (OR=243) and the protective effects of other classical alleles (OR≤0.67). A secondary effect was located at the leucine at amino-acid position 116 in the epitope-binding site of HLA-C ($p=3.76\times10^{-15}$) in a conditional logistic regression analysis adding the two amino-acid positions 97 and 114 as covariates. This residue was highly correlated with the HLA-C*15:02 allele and had a large effect in HLA-B*27-negative patients (OR=6.6; 95% CI=3.8-11.4; $p=1.52\times10^{-11}$). After conditioning on the three AS-associated amino-acid positions, we could not find any MHC SNPs or HLA variants associated with AS susceptibility ($p>1.32\times10^{-5}$).

Conclusion: We identified associations of *HLA-C* in addition to *HLA-B* with AS susceptibility in the Korean population. This updates the list of AS susceptibility loci and provides new insight into AS pathogenesis mediated by MHC class I molecules.

Session Date: Sunday, November 8, 2015
Session Title: Genetics, Genomics and Proteomics Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Next generation sequencing (NGS) represents a revolution in the field of molecular medicine, and offers a new approach to deciphering the pathogenesis of complex diseases. Paediatric-onset SLE (pSLE) is a very rare and more severe phenotype than its adult-onset counterpart, and is possibly associated with a greater contribution of genetic aetiological factors. A few monogenic causes of SLE have been described, including: complement deficiencies, defects of apoptosis and the so-called interferonopathies. The frequency of these Mendelian subtypes in a large cohort of pSLE has not been assessed previously.

Methods:

We designed an NGS panel comprising 200 genes including proven disease-associated as well as prospective candidate genes, and analysed 85 children under 11 years of age who fulfilled ACR criteria for SLE. As a first step, we focussed on rare (ExAC database frequency of < 1% for homozygous variants and < 0.01% for heterozygous variants) null / frameshift variants, and missense substitutions predicted *in silico* as damaging by both SIFT and POLYPHEN.

Results:

We identified three patients with biallelic mutations in genes of the complement pathway - one with a homozygous missense variant (p.Gly164Ser) and one with compound heterozygous variants (p.Gly164Ser/p.Leu41CysfsTer97) in *C1QC*, and one with a homozygous frameshift variant (p.Ile15AsnfsTer7) in *C1QA*. Four further patients harboured heterozygous variants (in *C1QC*, *C2*, *C5* and *C9*) which were predicted as pathogenic. Copy number variant analysis in these genes has not yet been undertaken. A *TREX1* p.Ser82LeufsTer9 variant, previously observed in a patient with Aicardi-Goutières syndrome, was identified in one patient in combination with a missense variant of unknown significance. One patient carried a heterozygous variant in *ACP5* - predicted as pathogenic by *in silico* analysis but not seen previously in SPENCD. In total, 11 patients harboured heterozygous rare variants in 2 or 3 panel genes (8 and 3 patients respectively). No likely pathogenic variants were identified in *DNASE1*, *DNASE1L3* or *PRKCD*.

Conclusion:

This first-step analysis of candidate gene variants in a population of 85 pSLE patients revealed three cases of C1Q deficiency – associated with a 1 in 4 risk of recurrence, and which had not been diagnosed previously. The significance of heterozygous variants in other genes is difficult to determine at this stage. The association of 2 / 3 very rare heterozygous variants in a single patient raises the possibility of an oligogenic burden in the pathogenesis of pSLE. Functional experiments are mandatory to understand the impact of these rare variants. Future work will also involve increasing the number of patients analysed, and consideration of intronic and splicing variants. However, we already conclude that an NGS panel approach can diagnose unappreciated monogenic forms of pSLE.

Session Title: Genetics, Genomics and Proteomics Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Several studies have demonstrated excessive paternal transmission of psoriasis and psoriatic arthritis (PsA). This phenomenon is thought to be mediated by genomic imprinting. We previously compared whole blood methylation patterns among PsA patients from Newfoundland, Canada and identified 90 significant CpG sites that differentiate patients with paternally and maternally-transmitted disease. This study aimed to validate previously-identified CpG sites in an independent sample of PsA patients with paternally and maternally-transmitted disease from Toronto, Canada.

Methods: All PsA patients included in the study satisfied the CASPAR criteria and had a parent with either psoriasis or PsA. Forty-six (46) PsA patients with paternally-transmitted disease were compared to 48 PsA patients with maternallytransmitted disease at 136 CpG sites on 10 different chromosomes. Percent methylation was measured at each CpG site by Sequenom EpiTyper technology, which involves bisulfite conversion followed by mass spectrometric analysis. Generated β values ranging from 0% (fully unmethylated) to 100% (fully methylated) were compared between groups using the nonparametric Mann-Whitney U test. Logistic regression models adjusting for age and sex were run to confirm the unadjusted results.

Results: PsA patients with paternally-transmitted disease were 52% female, and at the time of sample collection had a mean (SD) age of 47.7 (12.6) years, psoriasis duration of 23.7 (13.3) years, PsA duration of 14.1 (9.7) years, PASI score of 5.3 (7.2) and tender joint count of 4.9 (7.8). Patients with maternally-transmitted disease were 53% female, and had a mean age of 50.3 (11.1) years, psoriasis duration of 23.1 (12.2) years, PsA duration of 14.9 (12.0) years, PASI score of 4.5 (5.3) and tender joint count of 6.8 (8.5). Three CpG sites were significantly differentially methylated in the Toronto patients with paternally and maternally-transmitted disease. The most significant site was located within an intron of the CROCC (rootelin) gene on 1p36.13 and was hypomethylated in paternally-transmitted disease (p=0.014). Two sites within the 5' UTR of the PACSIN1 gene on chromosome 6p21.3 were also significantly hypomethylated in paternallytransmitted disease (p=0.040 and p=0.047). After adjustment for age and sex, CpG methylation at CROCC remained significantly associated with paternally-transmitted disease (OR=0.77, 95% CI 0.60-0.99, p=0.04).

Conclusion: CpG methylation at the CROCC locus on chromosome 1p36.13 differentiates PsA patients with paternally and maternally-transmitted disease. Although CROCC is not known to be imprinted in humans, these data suggest it may play some role in the excessive paternal transmission of psoriatic disease. Further validation of these results in somatic and germ line cells are necessary.

The ABCG2 polymorphism Is Associated with Hyperuricemia in a Community-Based Korean Cohort

Jae-Bum Jun[1], Hye-Jin Jeong[2], Chang-Nam Son[3], Ji-Min Kim[3], Sang-Hyon Kim[3], So-Young Bang[4] and Sang-Cheol Bae[1], [1]Rheumatology, Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea, [2]Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea, [3]Division of Rheumatology, Department of Internal Medicine, Dongsan Medical Center, Keimyung University School of Medicine, Daegu, South Korea, [4]Department of Rheumatology, Hanyang University Guri Hospital, Guri, South Korea

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Genetics, Genomics and Proteomics Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Hyperuricemia is known as a risk factor of diverse diseases such as gout, hypertension, metabolic syndrome, diabetes mellitus, and cardiovascular diseases. Recent genome-wide association studies (GWASs) have identified that 28 genetic loci are associated with hyperuricemia among individuals of European ancestry. For example, SLC2A9, ABCG2 and SLC22A12 modulate serum uric acid levels (SUAs) in the renal urate-transport system. The purpose of the present study is to find novel loci associated with hyperuricemia using data from a GWAS conducted on healthy Koreans.

Methods: We conducted a GWAS using data from a community-based cohort study where 3,647 subjects aged 40 - 69 were recruited by the Korea National Institute of Health (KNIH). The community-based cohort consisted of subjects who did not suffer from any of six major diseases (hypertension, hyperlipidemia, diabetes, heart diseases, brain diseases, and cancers). Epidemiologic information includes 249 traits such as epidemiological surveys, physical examinations, and laboratory tests. A total of 3,647 participants, including 234 hyperuricemia cases (SUA level was 7 or higher) and 3,413 controls, were genotyped by Illumina HumanOmni1-Quad BeadChip GWAS array at KNIH.

Results: In the multivariate regression analysis of clinical variables, significant variables were male gender ($P = 5.0 \times 10^{-10}$), body mass index (BMI) ($P = 1.5 \times 10^{-7}$), current alcohol ($P = 7.8 \times 10^{-7}$), fasting plasma glucose (FPG) (P = 0.035), and creatinine ($P = 2.7 \times 10^{-14}$). We identified new hyperuricemia susceptible loci (rs2054576 in ABCG2, $P = 4.7 \times 10^{-8}$) that passed a genome-wide significance threshold, adjusted by clinical variables (male, BMI, current alcohol, FPG, and creatinine).

Conclusion: It was first identified that rs2054576 in ABCG2 is associated with hyperuricemia. ABCG2 is a transporter that is located in the apical border membrane of renal proximal tubule cells and plays a role in uric acid secretion. Our results should be validated through replication studies among other Korean subjects or various ethnic groups.

Session Title: Genetics, Genomics and Proteomics Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Effective long term uric acid lowering therapy with the xanthine oxidase inhibitors (XOI) allopurinol and febuxostat exists. When compliant with therapy, it is unclear why some patients need higher or lower doses of XOI yet achieve the same serum uric acid (SUA) goal. We pursued genomic sequencing (GS) of genes related to XOI metabolism and clearance to determine if any SNVs relate to differences in dose needed.

Methods: Subjects with a diagnosis of Gout based on the 1977 American College of Rheumatology Classification Criteria for the disorder, who were on stable doses of a XOI, and who were at their goal SUA level were enrolled. When available up to 3 pre- and post-treatment SUA values were recorded. GS was performed on whole blood samples for genes related to metabolism of allopurinol, specifically *XO*, aldehyde oxidase 1 (*AOX1*), and molybdenum cofactor sulfurase (*MOCOS*). The gene *SLC22A12* was sequenced because it impacts oxypurinol clearance. For the metabolism of febuxostat, the genes uridine diphosphate glucuronsyltransferase (*UDT*) 1A1 and 1A4 were sequenced. The primary outcome was to detect any relationship between single nucleotide variants (SNVs) in any of these genes to XOI dose. The secondary outcome was to detect a relationship between SNVs and change in SUA, specifically the difference between average pre- and post-treatment values.

Results: Time and funding permitted sequencing of our first 80 subjects. The average patient age was 68.3 ± 11.2 years old. The majority were men and 76% were Caucasian. The GS error rate was 0.293 ± 0.048%. Of 1.8 ± 0.5 million base pairs mapped, 145 SNVs were identified; no indels were identified. For the primary outcome, 5 SNVs were associated with a lower XOI dose (allopurinol ≤ 300 mg daily) to reach a goal SUA (all $p < 0.05$): rs13419410, rs6760292, rs34929837, rs45612738, and rs4541294. One SNV, rs7599556 was associated with a higher XOI dose (allopurinol > 300 mg daily) to reach a goal SUA. Of these SNVs, rs34929837 is an exonic missense mutation affecting XO (Lys395Met) and lies in the Flavin adenine nucleotide (FAD) domain of the enzyme. Rs45612738 is a synonymous codon in *XO* (Gly378=). All other SNVs were intronic with the majority in *XO*. For the secondary outcome, 1 SNV was associated with a smaller change in SUA with a lower XOI dose: rs6760292 ($p < 0.05$). This SNV is intronic and located in *XO*. Four SNVs were associated with larger changes in SUA with febuxostat 80 mg daily (all $p < 0.05$): rs7599556, rs75995567, rs145877467, and rs78467837. Both rs145877467 and rs78467837 are synonymous codons in *AOX1*(Pro1245= and Ser1264= respectively).

Conclusion: Though the sample size is modest, we identified multiple SNVs that were associated with a lower XOI dose and one related to a higher XOI dose to reach a goal SUA. One of the exonic alleles detected, rs34929837, leads

to an amino acid substitution in the FAD co-factor domain of xanthine oxidase. Additional work is needed to assess the impact of this change but our data may start to explain why some patients need different doses of XOI and yet achieve the same serum uric acid (SUA) goal.

Session Title: Genetics, Genomics and Proteomics Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Previous studies showed a significant influence of the mtDNA haplogroups on prevalence, radiographic progression and cartilage integrity of knee OA patients from different worldwide cohorts. The aim of this study is to analyze the influence of the mitochondrial variants on the risk of incident knee OA in patients from CHECK as well as in an updated cohort of OAI patients.

Methods:

We assessed the mtDNA haplogroups in 1003 DNA samples from CHECK and 3681 Caucasian samples from the OAI. Incident knee OA was defined as a KL score <2 at baseline and a KL≥2 during 8 (CHECK) and 4 (OAI) years follow-up. Patients suitable for incident knee OA study (KL≤1 at baseline) consisted in 768 and 2409 respectively. Statistical analyses included chi-square contingency tables and logistic regression models considering age, gender, body mass index (BMI), bilateral KL=1 (CHECK) or contralateral knee OA (OAI) at baseline and mtDNA variants as variables of interest.

Results:

After 8 and 4 years respectively, patients from CHECK had more radiographic change compared with the OAI group (p<0,001) so that 418 (54,4%) patients from CHECK and 326 (13,5%) patients from OAI underwent incident knee OA.

Patients carrying the haplogroups of the mitochondrial cluster TJ were significantly underrepresented in the incident knee OA group of both cohorts when compared with the most common mtDNA haplogroup H/HV (OR=0,598; CI=0,357-0,999; p=0.05 for the CHECK cohort and OR=0,658; CI=0,467-0,927; p=0.017 for the OAI cohort). In addition, bilateral KL=1 at baseline in the CHECK cohort and contralateral knee OA in the OAI cohort were risk factors to develop incident knee OA (p<0,001). For both cohorts BMI was a risk factor too (p=0,023 and p<0,001 respectively) (Tables 1 and 2). The AUC of the regression models ranged from 0,643 to 0,688.

Conclusion:

The mitochondrial genome contributes to the development of incident knee OA in two well-defined follow-up cohorts, one of them an early-stage OA cohort (CHECK). The assignment of the mitochondrial polymorphisms common to the major mtDNA clusters could be used as complementary genetic biomarkers to predict the risk of incident knee OA.

Session Title: Genetics, Genomics and Proteomics Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Amino acid (AA) positions 11, 71 and 74 inside HLA-DRB1 confer susceptibility to rheumatoid arthritis (RA). AAs from these positions form 16 haplotypes, hierarchically classified according to their effect (risk to protective) on RA susceptibility and radiographic severity. However, the mechanism of action remains unknown. The effect of these haplotypes on non-radiographic measures of disease activity/outcomes has not yet been systematically tested.

Hypothesis: The effect of HLA-DRB1 AAs on severity is mediated via inflammation.

Aim: To test association of individual AAs with CRP, tender joint count (TJC), swollen joint count (SJC), DAS28 and HAQ score.

Methods: Genetic data from patients with inflammatory polyarthritis from the Norfolk Arthritis Register (NOAR) were analysed using Generalised Linear Latent and Mixed Modelling to incorporate multiple records per patient over time. The associations of individual AAs, individual positions and individual haplotypes were systematically tested with all outcome variables in univariate and multivariate analyses. Correction for multiple testing in univariate analysis was carried out using the Benjamini-Hochberg (false-discovery rate) method. Validation studies were carried out in the Early Rheumatoid Arthritis Study (ERAS) cohort.

Results:

2,158 patients had genetic and phenotypic data available for analysis in NOAR. Valine at position 11 showed the strongest association with CRP, SJC and DAS28, was marginally associated with HAQ, but not with TJC. The same risk hierarchy observed for susceptibility and radiographic severity was also observed with CRP levels and non-radiographic measures of RA activity/outcome at the AA and haplotype level, although not with TJC.

The valine-containing haplotypes VKA (valine 11, lysine 71, alanine 74) and VRA (valine 11, arginine 71, alanine 74) were significantly associated with increased CRP levels, whereas the serine-containing haplotype SEA (serine 11, glutamic acid 71, alanine 74) was associated with reduced levels. The multivariate haplotype model was significantly associated with CRP levels. When effect sizes for association with CRP were plotted against effect sizes for susceptibility, a significant correlation was observed. A similar pattern was also demonstrated for SJC and DAS28, but not for TJC.

The results replicated in ERAS.

Conclusion: Our findings demonstrate an association between objective disease activity measures and AAs at position 11. At diagnosis, patients with RA can be stratified into 16 genetic categories to predict levels of inflammation, SJC and DAS28 during the disease course. These findings describe a genetic basis for the increased inflammatory response leading to radiographic progression.

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriatic Arthritis (PsA) is an inflammatory arthritis that is associated with psoriasis. In the UK, it is estimated to present in approximately 14% of psoriasis patients. PsA is a complex disease that is influenced by both genetic and environmental factors. Genetic studies have aided the discovery of PsA risk loci, the majority of which also confer risk for psoriasis. We have recently reported evidence of specific loci that confer risk for PsA and not psoriasis, including a variant at *IL23R* which was also found to be independent of the psoriasis variant reported at the same locus.

Methods: In this study, we attempted to identify additional PsA-specific risk variants by genotyping 32 single nucleotide polymorphisms (SNPs) which included those found to have nominal significance in our recent Immunochip study ($P < 1x10^{-4}$) as well as SNPs selected from other studies. These were analysed in 914 PsA cases and 6945

controls from the UK, Crete, Spain and Germany which were independent from those genotyped as part of the Immunochip study. Genotyping was performed using the Life Technologies QuantStudio genotyping platform and association testing was carried out using PLINK. SNPs and samples with poor call rates (<0.9) were excluded prior to analysis.

Results: We found a significant association for the SNP rs12044149 mapping to *IL23R* ($P = 4.03x10^{-6}$). A very weak association was found with the psoriasis variant rs9988642, which has been reported at the same locus ($P = 0.04$). This supports the evidence previously reported of rs12044149 being distinct from rs9988642 and associated with PsA, as demonstrated by the conditional analysis carried out in our Immunochip study [1].

Conclusion:

For the first time we have been able to successfully validate a PsA-specific risk variant at the IL23R locus in an independent cohort. This now gives us a total of four PsA-specific associations that have been identified. Such variants could potentially provide us with a marker to identify psoriasis patients who are prone to developing PsA. IL23 is a target for the psoriasis drug ustekinumab which has also shown efficacy in PsA during clinical trials. It would be interesting to explore whether disease-specific risk variants identifies those PsA patients likely to respond to the drug.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Genetics, Genomics and Proteomics Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Human leukocyte antigen (HLA) genes code for proteins that allow the immune system to distinguish self from foreign cells. These genes have important indications in rheumatology, as well as other autoimmune disorders, transplantation, cancer, and pharmacotoxicity. The gold standards for HLA-typing are Sequence Specific Oligonucleotide Probe and

Sequence Specific Primed PCR typing (PCR-SSOP and PCR-SSP), both of which are manually-intensive and costly. Multiplexing samples with next-generation sequencing (NGS) could easily reduce costs. Unfortunately, HLA genes are the most variable in the human genome and also have high sequence similarity, each of which pose considerable challenges to new technologies. However, nascent assays and bioinformatic methods are emerging in support of more cost-effective platforms for finding new biomarkers of inflammatory disease and for typing patients in the clinic. Here we apply new and traditional methods to investigate the HLA B27 allele, which has known links to a large family of inflammatory diseases.

Methods:

We obtained 90 samples from RA patients and compared the HLA allele calls on three platforms: 1) GenDx's NGSengine for the NGSGo kit for Illumina's MiSeq, 2) SNP2HLA [1] for both the Affymetrix Axiom and the Illumina Omni 5 microarrays, and 3) the Luminex PCR process. We stratified the sample populations by principal components to identify 47 samples of European ancestry to call alleles using array genotypes against a European reference panel. We measured HLA B27-positive status in those 47 samples to check for enrichment in both the NGS-based and the array-based calls.

Results:

Alleles were called and compared to the Luminex calls for two-digit and four-digit precision, and with the exception of DRB1, NGS-based allele calls were 97-100% concordant. However, two-digit precision suffices for testing B27 status, which will be positive for all 4-digit precision alleles ranging from HLA-B*27:01-HLA-B*27:117. The microarray approach measured 19% of the RA subjects as B27-positive, and the NGS technique measured 12%. This is enriched, compared with 3.65 (+/- 1.7)% observed in typical European populations [2]. The less accurate array-based technique found the association and the NGS technique confirmed it. Notably, the NGS-based technique can assay the same number of loci as the high-throughput gold standard option but at close to half the cost and with fewer ambiguities. Some NGS-based options have already been submitted for CLIA-validated clinical use. Alternatively, the array-based techniques are offered at a cost that is an order of magnitude lower than the gold standard and can be used on legacy datasets, presenting a lower cost option for association discovery.

Conclusion:

Existing, legacy microarray data can guide exploration and hypotheses at reduced costs, and should be confirmed with gold standard or CLIA-validated NGS technologies, the latter of which poses a viable candidate for reducing costs, time and effort in a clinical setting.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Genetics, Genomics and Proteomics Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Uric acid (UA) has been associated with blood pressure (BP) and hypertension. During the final stage of purine metabolism, xanthine oxidoreductase (XOR) breaks down hypoxanthine to xanthine, and xanthine to UA, while reactive oxygen species (ROS) are formed. These ROS inactivate the vasodilator nitric oxide. We hypothesize that variants in the XOR gene, responsible for the production of UA, are associated with elevated BP and hypertension. The aim of the present study is to investigate the association of variants in the XOR gene with BP and the development of hypertension.

Methods:

Analyses were conducted in the prospective Flemish FLEMENGHO and European EPOGH study (n=2769). 28 tagging SNPs that are in disequilibrium (r^2>0.80) with 387 SNPs covering the entire gene were selected. 24 SNPs remained after exclusion of 4 SNPs not meeting the Hardy-Weinberg equilibrium. Minor allele carriers were determined by using the European HAPMAP population as reference. The minor allele homozygotes and heterozygotes were compared with the major allele homozygotes. BP was measured by trained observers at baseline (1985-2004) and repeatedly during follow-up (1991-2013). The relation between variants of the XOR gene and changes in pulse pressure (PP) and mean arterial pressure (MAP) over time; and incidence of hypertension, were analysed using multivariable mixed models and cox-regression, respectively. Family clusters were modelled as random effect. Analyses were corrected for multiple testing by the Benjamini Hochberg correction, the false discovery rate was set at 0.25.

Results:

Follow-up data for BP were available at 1, 2, or ≥3 occasions in 2769, 1450, and 1035 participants, respectively (median follow-up: 8.79 yrs (IQR: 6.54)). The rise in PP from baseline to the last available measurement was significantly associated with SNP rs11904439, in the crude and confounder adjusted model (adjusted P=<0.01), averaging 8.55 mm Hg (SD 13.6) in minor *G* allele carriers and 6.33 mm Hg(SD 13.6) in AA homozygotes. The association remained significant after correction for multiple testing. No association with change in MAP was found. Among 2050 participants normotensive at baseline, 753 (36.7%) developed hypertension during follow-up (median follow-up: 10.7 yrs (IQR: 7.3)). Multivariably, two SNPs, rs148756340 and rs11904439, were associated with onset of hypertension. For SNP rs148756340 the minor *G* allele carriers had a higher risk of hypertension compared to AA homozygotes (adjusted HR: 1.69; 95% CI 1.11 to 2.57, p=0.01). For SNP rs11904439 minor *G* allele carriers had a higher risk of hypertension compared to AA homozygotes (adjusted HR: 1.33; 95% CI 1.04 to 1.70, p=0.02). For both SNPs the association remained significant after correction for multiple testing.

Conclusion:

Two SNPs, rs11904439 and rs148756340, of the XOR gene were associated with change in PP over time and/or the development of hypertension. This suggests that UA production may be associated with BP and the development of hypertension. Because of the exploratory nature of this study and because it is unknown if the SNP has an effect on the enzyme activity, further investigation is required.

Session Date: Sunday, November 8, 2015

Session Title: Genetics, Genomics and Proteomics Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

A lack of well-characterised clinical cohorts has impeded research of the genetics of axial disease in psoriatic arthritis (PsA). We sought to determine genetic biomarkers of psoriatic spondyloarthritis (PsSpA) occurrence in patients with PsA.

Methods:

A cross-sectional observational study was conducted of all PsA patients attending a teaching hospital. Axial radiographs were examined for the presence of PsSpA, defined as: sacroiliitis grade ≥3 unilaterally, or grade ≥2 bilaterally; and/or ≥1 syndesmophyte of the cervical and/or lumbar spine.

All PsA cases were genotyped using the Illumina Infinium HumanCoreExome Beadchip. In order to determine genetic risk factors for axial disease in PsA, comparisons were made between PsA cases with and without: PsSpA; sacroiliitis; and spondylitis. Multivariate modelling was adjusted for sex, age and disease duration at radiographic assessment. Associated single nucleotide polymorphisms (SNPs) within 100 kb of each other were considered as one locus, and an index SNP identified.

Results:

The study enrolled and genotyped 515 PsA cases fulfilling CASPAR criteria. Of 436/515 with complete radiographs to determine PsSpA, 144/436 (33.03%) had PsSpA and 292/436 (66.97%) did not have PsSpA. Genetic analyses were performed on these 436 cases only.

No single nucleotide polymorphisms (SNPs) passed the conventional genome-wide significance ($5x10^{-8}$); a total of seven SNPs were in tier 1 (defined as p-value $<1x10^{-5}$). Notable associations include rs11950551 with PsSpA (OR 3.03; 95%CI 1.88, 4.89; p-value $5.42x10^{-6}$) (*Table 1*) that maps close to gene *CD180,* belonging to a family of toll-like receptors important in B-cell signalling (*Figure 1*). Secondly, an insertion on chromosome 4 (rs202217778) within the *SMAD1* gene is associated with sacroiliitis (OR 3.98; 95%CI 2.18, 7.27; p-value $7.36x10^{-6}$) but not spondylitis (*Table 1*, *Figure 1*). *SMAD1*has a key role in bone morphogenesis and immune responses.

Forty eight SNPs showing association with psoriasis, PsA or AS in Genome Wide Association Studies, were specifically compared in PsA cases with and without PsSpA. Of note, none of the SNPs were associated with PsSpA.

Conclusion:

We have identified suggestive evidence for association of 24 independent loci associated with axial disease in patients with PsA (PsSpA). The genetic loci associated with sacroiliitis did not overlap either with those associated with vertebral spondylitis in PsA, or with known AS loci. The findings need investigation in validation datasets and the functional influence of confirmed variants on biological pathways may warrant further exploration.

Session Title: Genetics, Genomics and Proteomics Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid Arthritis (RA) patients with serum anti-citrullinated peptide antibodies (ACPA) have a strong and specific genetic background. We performed a genome-wide association study (GWAS) of ACPA-positive RA with erosive disease to identify additional disease susceptibility genes.

Methods: A total of 924 ACPA-positive RA patients with joint damage in hands and/or feet, and 1,524 healthy controls were genotyped in 582,591 single-nucleotide polymorphisms (SNPs) in the discovery phase. In the validation phase, the most significant SNPs in the GWAS representing new candidate loci for RA were tested in an independent cohort of 863 ACPA-positive patients with joint damage and 1,152 healthy controls. All individuals from the discovery and validation cohorts were Caucasian and from Southern European ancestry.

Results: In the discovery phase, 60 loci not previously associated with RA risk showed evidence for association at $P < 5e\text{-}4$ and were tested for replication in the validation cohort. A total of 12 loci were replicated at the nominal level ($P < 0.05$, same direction of effect as in the discovery phase). When combining the discovery and validation cohorts, an intronic SNP in Solute Carrier family 8 gene (*SLC8A3*) was found to be associated with ACPA-positive RA at a genome-wide level of significance RA (OR(95%CI): 1.42(1.25-1.6), $P_{combined} = 3.19e\text{-}8$, Figure 1).

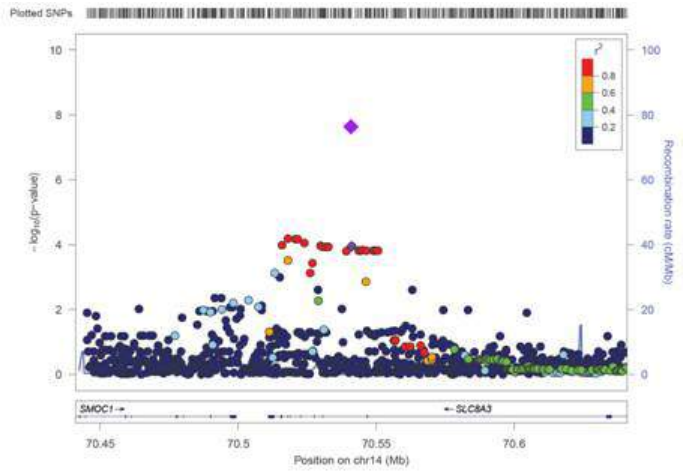

Figure 1. Association results for *SLC8A3* locus with ACPA-positive RA. Significance -log10(P-value) of association of SNPs at SLC8A3 locus with ACPA-positive RA. The genome-wide significant marker is plotted as a purple diamond, and all the remaining markers as color-coded according to their LD with this SNP.

Conclusion: *SLC8A3* was identified as new risk locus for ACPA-positive RA. This study demonstrates the advantage of analyzing relevant subsets of RA patients to identify new genetic risk variants.

Session Date: Sunday, November 8, 2015
Session Title: Genetics, Genomics and Proteomics Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: *PTGER4*(prostaglandin E receptor 4) is implicated in immune regulation and bone metabolism. The aim of this study was to analyze the role of single nucleotide polymorphisms (SNPs) located in this locus in radiological joint damage in rheumatoid arthritis (RA).

Methods: 6 independent cohorts of RA patients of European and North-American descent were included in this study, comprising 1,789 patients with 5,083 sets of X-rays. Three cohorts from Madrid (Spain) were used for identification: *Hospital Clínico San Carlos* Rheumatoid Arthritis Cohort, the *Hospital Universitario de la Princesa* Early Arthritis Register Longitudinal cohort, and the *Hospital Universitario de La Paz* early arthritis cohort. On the other hand, the Leiden Early Arthritis Clinic Cohort (The Netherlands), Wichita (US) and National DataBank (US and Canada) cohorts were used for replication. First, the *PTGER4* rs6896969 SNP was genotyped using Taqman assays and available Illumina Immunochip data. The latter was also used to obtain genotyping data from the *PTGER4* gene and adjacent regions (Chr 5: from 38,957,820 bp to 41,336,050 bp; GRCh37/hg19). The effect of the SNPs on radiological joint damage was assessed using two models: a *continuous effect model* that analyzes the overall effect of each SNP in radiological damage, assuming a stable effect over time, and a *time-varying effect model* that analyzes the effect of the SNP in the slope (progression) of the radiological damage. Linkage disequilibrium (LD) structure of the locus was assessed and for each LD block (r^2>0.9), 1 SNP with a p value <0.05, preferably located in a region with transcriptional properties, was selected for replication. **Results** from the different cohorts were pooled using inverse variance-weighted meta-analysis, and the pooled p values were adjusted using the Bonferroni method, based on the number of effectively independent SNPs tested, and in the fact that we performed a *continuous* and a *time-varying effect* analysis for each SNP (threshold p value=$1.3x10^{-4}$).

Results: The rs6896969 polymorphism showed a significant association with radiological damage in the *continuous effect* pooled analysis of the Spanish cohorts, although no significant association was observed in the replication cohorts or when the results from the 6 cohorts were pooled. In the analysis of the *PTGER4* region, 12 and 20 SNPs,

from the *continuous* and *time-varying effect* models, respectively, were analyzed in the replication cohorts. Only the rs76523431 variant showed a significant association with higher radiographic progression in the *time-varying effect* analysis (overall pooled $p=2.10x10^{-5}$, $I^2=0.13$).

Conclusion: The *PTGER4* gene could play a role in RA radiological progression.

Does the Timing of Phenotype Assessment Influence Association Results in Pharmacogenetics Studies of Anti-TNF Response in Rheumatoid Arthritis?

Kyoko Honne[1], Nicholas Jewell[2], Takeo Sakurai[3], Masahiro Iwamoto[4], Seiji Minota[4] and **Damini Jawaheer**[5], [1]Division of Rheumatology and Clinical Immunology, Jichi Medical University, Shimotsuke, Japan, [2]UC Berkeley, Berkeley, CA, [3]Inoue Hospital, Takasaki, Japan, [4]Department of Internal Medicine, Division of Rheumatology/Clinical Immunology, Jichi Medical University, Shimotsuke, Japan, [5]Children's Hospital Oakland Research Institute, Oakland, CA

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Genetics, Genomics and Proteomics Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Pharmacogenetics studies of anti-tumor necrosis factor (TNF) response among patients with rheumatoid arthritis (RA) have routinely used assessment of response at a single time-point, ranging between 3 and 12 months after initial treatment, to define the phenotype. Given the general lack of consistency in the findings from published studies, we have examined whether differences in the timing of anti-TNF response assessment in the same patients can influence the results of a genome-wide association study (GWAS) investigating associations between anti-TNF response and single nucleotide polymorphisms (SNPs).

Methods: Disease Activity Scores based on 28 joint counts and C-reactive protein (DAS28) were assessed at baseline (before initial therapy), and after 3 and 6 months in 487 Japanese RA patients starting anti-TNF therapy for the first time or switching to a new anti-TNF agent. DNA samples from these patients were genotyped using a genome-wide panel of 1,133,484 SNPs and additional SNPs were imputed. Change in DAS28 scores from baseline were evaluated at 3 months (ΔDAS28-3) and at 6 months (ΔDAS28-6). Association analyses between anti-TNF response at one follow up and each SNP were performed using 2 separate multivariate linear regression models, with ΔDAS28-3 (model 1) and ΔDAS28-6 (model 2) as the outcome (response) variable. A longitudinal Generalized Estimating Equations model (model 3) was also used to allow inclusion of response at both 3 and 6 months in the outcome variable. All models adjusted for baseline DAS28, type of anti-TNF agent and concomitant methotrexate. In model 3, time since initiation of therapy was also adjusted for.

Results: At 3 months (model 1), five SNPs were moderately associated with ΔDAS28-3 ($p<1x10^{-5}$). At 6 months (model 2), a SNP at 6q15 was associated with ΔDAS28-6 at a genome-wide significance level ($p=2.5x10^{-8}$). This SNP mapped close to the *MAP3K7* gene which is a key player in TNFα-mediated inflammatory pathway signaling. Four other chromosomal regions showed evidence of moderate association with ΔDAS28-6 ($p<1x10^{-5}$), including a SNP at 10q25.3 which mapped to the *GFRA1* gene ($p=5.3x10^{-6}$). There was no overlap between the regions of association identified when using as phenotype response at 3 months (model 1) vs. response at 6 months (model 2). On the other hand, when response at both 3 and 6 months were included in the phenotype (model 3), suggestive association with anti-TNF response was observed at two of the same loci identified in model 2: 6q15 ($p=6.6x10^{-7}$) and 10q25.3 ($p=8.1x10^{-7}$). A third region mapping to the *WDR27* gene at 6q27 showed suggestive evidence of association in model 3 ($p=6.3x10^{-7}$), but not in models 1 and 2 (ΔDAS28-3: $p=7x10^{-4}$; ΔDAS28-6: $p=5.5x10^{-5}$).

Conclusion: The timing of anti-TNF response assessment significantly influences the results of genetic association studies, especially since clinical response is known to fluctuate over time. Using more than one assessment of response provides a more reliable clinical phenotype and, in our dataset, enhanced the power to detect associations.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Genetics, Genomics and Proteomics Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

The *rs396991* polymorphism of *FCGR3A* alters the Fcγ Receptor Type IIIA function by enhancing or diminishing the affinity to the Fc of immunoglobulins (1) by the substitution of a valine (V) for a phenylalanine (F) at amino acid position 158. *FCGR3A* polymorphism has already been associated with the biological Disease Modifying Anti-Rheumatic Drugs (bDMARDs) response in patients with rheumatoid arthritis and Psoriatic Arthritis (1,2). Our study was carried out to evaluate the influence of the *FCGR3A – 158 V/F*polymorphism on the therapeutic response to anti

TNFα in the DESIR (Devenir des SpondyloarthrItes (SpA) Récentes) cohort.

Methods:

All patients included in the DESIR cohort fulfilling the Assessment of SpondyloArthritis international Society (ASAS) diagnosis criteria for axial SpA and who received TNFα blockers at least 8 weeks were included in our study. Univariate and multivariate analyses by Chi square test and logistic regression were performed to assess whether *FCGR3A-158V/F*polymorphism was associated with ASAS 40 response after at least 8 weeks of treatment (3).

Results:

Among the 147 patients who received TNF blockers in DESIR cohort, 139 could be genotyped of whom 52 patients (37%) were responders. *FCGR3A-158V/V* polymorphism was significantly associated with a lower response rate (17% of responders for VV genotype vs 38 % of responders for VF genotype and 47 % of responders for FF genotype, p=0.016). In multivariate analysis (taking into account of the presence of radiographic sacroiliitis, abnormal VS or CRP levels, HLA–B27 positivity, peripheral arthritis, psoriasis, and smoking status at baseline), *FCGR3A-158V/V*polymorphism was independently associated with a lower response rate to TNF-α blockers (risk of response to TNF-blockers in case of V allele carriage: OR (95% CI) = 0.44 (0.20 to 0.96) (p=0.041).

Conclusion:

In the Desir cohort, *FCGR3A158 VV*genotype was associated with a lower response rate to TNF-α blockers in SpA. This association has already been described in previous publications in rheumatoid arthritis patients (1). A higher affinity to the Fc region of antiTNFα could influence their clearance from the circulation. Further studies involving more axial SpA patients should be performed to confirm this association.

This work received an institutionnal support by the French society of rheumatology.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Genetics, Genomics and Proteomics Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Genome-wide association studies (GWASs) and large follow-up studies in European-descent or Asian subjects have identified a number of susceptibility loci for systemic lupus erythematosus (SLE) to date. Despite this tremendous progress, a significant portion of genetic component of SLE still remains to be uncovered. The purpose of this multi-stage study was to identify new susceptibility loci for SLE in individuals of European ancestry.

Methods: In Stage 1, a new GWAS of SLE was conducted in a North American case-control sample of European ancestry (~1,200 subjects) genotyped on Affymetrix Genome-Wide Human SNP Array 6.0. In Stage 2, the top new suggestive GWAS hits were further investigated by *in silico* evaluation in an additional dataset of European-descent subjects (>2,500 individuals) followed by meta-analysis. In Stage 3, the top meta-analysis findings were evaluated for replication in another dataset of European-descent subjects (>10,000 individuals).

Results: Our GWAS revealed the most significant associations at the major histocompatibility complex (MHC) locus on chromosome 6p21 ($P<5x10^{-8}$), followed by those on chromosomes 2q32 (*STAT4*) and 8p23 (*BLK*). Several other SLE signals/loci previously reported in Caucasians and/or Asians were also confirmed in our Stage 1 sample. Stage 2 meta-analyses identified a new genome-wide significant locus on chromosome 12q12 (meta $P=3.1x10^{-8}$), which was replicated in Stage 3.

Conclusion: We conducted a new GWAS of SLE and, through a multi-stage approach, we have discovered and replicated a new SLE locus at 12q12. Publicly available databases suggest that this new SLE signal falls within a genomic region with regulatory function and near biologically relevant genes.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Genetics, Genomics and Proteomics Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Human leukocyte antigen-G (HLA-G) is a non-classical class I molecule expressed in the immune cells, the spleen, and the lungs, and plays a key role in immunosuppression. HLA-G binds to inhibitory leukocyte immunoglobulin-like receptor (LILR)B1, LILRB2, and killer cell immunoglobulin-like receptor (KIR)2DL4. LILRA3, a soluble member of the LILR family and also binds to HLA-G, has a deletion polymorphism. Although the function of LILRA3 remains elusive, some evidence suggests that LILRA3 might work as an antagonist of other LILRs including LILRB1 or LILRB2. *HLA-G* gene contains a 14bp insertion polymorphism in the 3'UTR, which has been shown to influence the splicing and affect mRNA stability, thereby leading to low expression of HLA-G. Previous studies reported association of *HLA-G* 14bp ins/ins genotype with systemic lupus erythematosus in the European and Asian populations. In this study, we examined whether *HLA-G* 14bp ins/del polymorphism is associated with systemic sclerosis (SSc), either in itself or in combination with *LILRA3* genotypes.

Methods: 379 Japanese patients with SSc and 765 healthy Japanese controls were examined. All patients fulfilled the American College of Rheumatology criteria. 127 were classified as diffuse cutaneous (dc) SSc, while 230 as limited cutaneous (lc) SSc. 45 patients as having pulmonary hypertension (PH). *HLA-G* 14bp ins/del was genotyped by PCR

with the product size of 224 or 210bp. *LILRA3* ins/del was genotyped by PCR-sequence specific primers method. This study was reviewed and approved by the ethics committees of each participating institute.

Results: The results are shown in Table 1. Although significant association of *HLA-G* ins/del polymorphism was not observed with overall SSc nor with dc/lc subsets, significant increase of *HLA-G* ins allele was observed in SSc patients with PH when compared with healthy controls (P=0.047, OR 2.32, dominant model) or with PH(-) SSc (P=0.019, OR 1.75, allele model; P=0.021, OR 2.88, dominant model). *LILRA3* ins/del was not associated with PH. However, when *HLA-G* association was examined with respect to the *LILRA3* genotypes, more striking association of *HLA-G* 14bp ins with PH was observed in the subjects with *LILRA3* del/del genotype (P=0.010, OR 2.13, allele model, and P=0.016, OR 3.36, dominant model vs healthy controls; P=0.0044, OR 2.40, allele model, P=0.033, OR 2.47, recessive model, P=0.010, OR 4.14, dominant model vs PH(-) SSc). In contrast, significant association of *HLA-G* was not detected in the patients and controls having one or two copies of *LILRA3* allele.

Conclusion: Association of *HLA-G* 14bp ins with SSc patients with PH was detected. The association was more striking in *LILRA3* null individuals, suggesting a possibility that the predispositional effect of *HLA-G* low expression allele becomes manifest when its soluble receptor LILRA3 is deficient.

Table 1. Association of *HLA-G* 14bp insertion polymorphism with pulmonary hypertension in overall SSc and controls and with respect to *LILRA3* genotypes.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Genetics, Genomics and Proteomics Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Occurrence and progression of complex autoimmune diseases are orchestrated by interactions between genes and environment, in part mediated by epigenetic mechanisms. It is yet unclear how these interactions operate over time for different disease sub-phenotypes. We aimed to investigate how epigenetic modifications might contribute to different development phases of an autoimmune disease, using ACPA (antibodies to citrullinated protein antigens)-positive rheumatoid arthritis (RA) as a disease model and an epigenome-wide DNA methylation analysis of two sets of monozygotic (MZ) twins.

Methods:

Five healthy twin pairs discordant for presence of ACPA but not having RA and seven twin pairs discordant for ACPA-positive RA were included in this study. The selected twin pairs belong to a population based twin cohort (Twingene) which is part of the Swedish twin register ACPA status is defined by testing sera with CCP2 ELISA assay (Immunoscan CCPlus). None of the healthy twins have reported chronic rheumatic joint disease (rheumatoid arthritis) at time point of blood donation. During a median follow up of 3 years (IQR 2-4) they all continued to lack an RA diagnosis (or other rheumatic joint disease diagnosis e.g. polyarthritis) in the Swedish National Patient Register. The ACPA positive RA twins have also tested positive for ACPA while their co-twin have tested negative for ACPA. The RA twins reported RA at the time of blood donation and this was verified by review of the medical records. Co-twins of these ACPA positive RA twins did not report RA and this was again verified by linkage to the Swedish National Patient Register. Genome wide gene specific methylation was analysed by CHARM methodology.

Results:

CHARM analysis of the healthy twin pairs, discordant for ACPA, revealed 17 genome wide significant (family wise error rate (FWER) <0.2) differentially methylated gene regions (DMRs), after cell-type distribution correction. Profiling of the seven twin pairs discordant for ACPA-positive RA identified 36 significant DMRs (where one associated with an exosome component) after cell-type distribution correction. Interestingly, one ACPA-discordant associated DMR associated to a protocadherine (PCDH) gene showed a high probability to be also found in ACPA-positive RA. None of the identified DMRs were found in the proximity of previously known genetically associated genes, including MHC, suggesting a successful neutralization of genetic influence in our design with MZ twins.

Conclusion:

We describe here novel associations between DNA methylation and different phases of ACPA-positive RA, prompting further studies to address the potential pathogenic relevance of these epigenetic modifications for RA.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Genetics, Genomics and Proteomics Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

In the last years the role played by the mtDNA haplogroups in the pathogenesis of OA attracted much attention. The aim of this study is to perform a meta-analysis to investigate the association between mtDNA haplogroups and the risk of radiographic OA progression

Methods:

For this work we collected previously published and personal data involving the study of the mtDNA haplogroups on the radiographic progression of OA in terms of KL grade. Meta-analysis was performed using R 2.15.0 software with the package *meta* added. Combined effect was estimated using a random-effects model using hazard ratios (HR) with 95% confidence interval (CI) as the outcome variable.

Results:

A total of 3 studies, involving 1603 OA patients (progressors and non-progressors) were involved. All the studies were based on the analysis of the mtDNA clusters TJ and the risk of radiographic progression. A significant association with a lower risk of radiographic OA progression was found for the mtDNA cluster TJ when compared with both HV (HR=1,3063; 95% CI=1,0673-1,5989; p-value=0.0096) and KU (HR=1,3359; 95% CI=1,065-1,6757; p-

value=0.00123) considering the three cohorts combined (Figures 1 and 2)

Conclusion:

The current meta-analysis suggest that the mtDNA cluster TJ correlates with a lower risk of radiographic OA progression in terms of KL grade. The assignment of the polymorphims characteristic of the mtDNA cluster TJ could be potential complementary genetic biomarkers to predict the risk of OA progression.

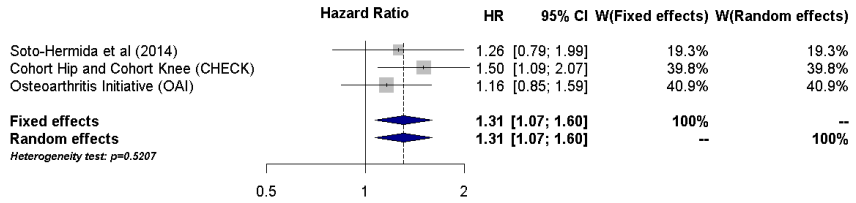

Figure 1. Forest plot showing the comparison between the mtDNA cluster HV and TJ on the risk of radiographic OA progression

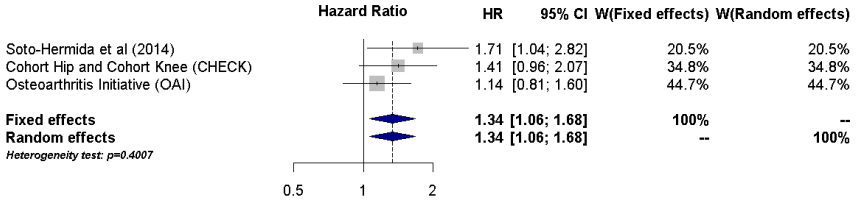

Figure 2. Forest plot showing the comparison between the mtDNA cluster KU and TJ on the risk of radiographic OA progression

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Genetics, Genomics and Proteomics Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Group of monogenic autoinflammatory syndromes is characterized by recurrent episodes of fever and inflammation.

Methods:

The study included 90 pts (37 boys, 63 girls) at the age from 1 to 17 y. (8.2 (4.7; 11.5) followed with a diagnosis of systemic JIA. The median age of disease onset was 3.0 (1.5; 5.1) y., disease duration – 4.4 (1.0; 7.6)y.

The commonest features were fever (100%), arthritis or arthragia (100%), rash (96%), hepato- and splenomegaly (96%), lymphadenopathy (94%), headache (62%), abdominal pain (58%), eye manifestations (21%). The patients were selected according to the clinical manifestations, with subsequent obligatory genetic counseling in the Department of Rheumatology of the Scientific Center for Children's Health. Pts' DNA was sequenced in all coding exons and intronic flanks of the TNFRSF1A and NLRP3 genes whose mutations cause autoinflammatory syndromes, TRAPS and CAPS, respectively.

Results:

In 13/90 (14.4%) pts genetic autoinflammatory syndrome was established. In 10/13 pts, we found mutations in TNFRSF1A: in 8/10 pts - the most frequent mutations *c.362G>A (p.R92Q)* located in exon 4 and associated with the mild progression of TRAPS. One TRAPS pt. had a frameshift mutation *c.792delT* (*p.Lys265Serfs*87*) in exon 9 of *TNFRSF1A* gene. Another pt. revealed a *TNFRSF1A* mutation known *c.374G>A* (C96Y).

The median age of disease onset was 5.1 years. A family history was present in 3 patients: 2 girls with R92Q variant and 1 – with C96Y mutation. 3 pts with symptomes of CAPS identified mutations in *NLRP3* gene. None of the mutations were previously described in the databases for mutations. One pt. with a clinical picture of the CINCA, had a mutation *c.796C>T* (*p.Leu266Phe*) in exon 04 of NLRP3 gene. 2 other pts had mutations *c.2861C>T* and *c.2173C>A*, respectively. Pts with *c.2173C>A* mutation has CINCA/NOMID phenotype and dramatic effect of canacinumab. In 7 (7.5%) pts we identified NLRP3 gene polymorphism *c.2113C>A,* associated with elevated levels of IL1.

Conclusion:

Our results suggests for a relatively frequent incidence of CAPS and TRAPS in Russian systemic JIA patients. The number of genetically confirmed patients with periodic fever syndromes in Russia is very low. In order to identify more patients in the future, it is important to organize educational programs for increasing the knowledge on these diseases, to establish a network for genetic testing of periodic fever syndromes and to carry out differential diagnoses.

Longitudinal, Incremental Direct Medical Costs of Giant Cell Arteritis for the First Five Years Following Diagnosis: A General Population-Based Cohort Study

Natalie McCormick[1], Carlo Marra[2] and J Antonio Avina-Zubieta[3], [1]Pharmaceutical Sciences, University of British Columbia, Vancouver, BC, Canada, [2]Pharm Sciences, Univ of British Columbia, Vancouver, BC, Canada, [3]Arthritis Research Canada / University of British Columbia, Vancouver, BC, Canada

Session Title: Health Services Research Poster I: Diagnosis, Management and Treatment Strategies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Giant cell arteritis (GCA) is the most common form of adult vasculitis, but estimates of the healthcare costs of GCA are extremely scarce. We determined the incremental (extra) direct medical costs of a general population-based cohort of incident GCA for the first five years after diagnosis. We also assessed the changes in costs over calendar time (1996-2010).

Methods:

Data Source: Our administrative data captured all provincially-funded outpatient encounters and hospitalizations (1990-2010), and all dispensed medications (1995-2010), for ALL residents of the province of British Columbia, Canada.

Sample:We assembled a population-based cohort of all incident cases of GCA who satisfied the following criteria: a) ≥ 40 years of age; b) new diagnosis of GCA on at least one hospitalization or rheumatologist visit, or two non-rheumatologist visits, between January 1996 and December 2010; and c) use of oral glucocorticoids between 1 month before and 6 months after the second GCA visit (or first if from hospital or rheumatologist). Ten controls matched by age at diagnosis (±2 years), sex, and calendar year of diagnosis were selected for each case from the general population.

Cost Calculation: Costs for outpatient services and prescriptions were summed directly from billing data. Case-mix methodology was used for hospitalizations.

Statistical Analysis: We estimated the unadjusted incremental costs of GCA (difference in per-patient-year (PY) costs between cases and controls), then used generalized linear models to further adjust for socioeconomic status, urban/rural residence, and Charlson-Romano comorbidity index.

Results: We matched 797 incident GCA cases to 7,970 controls (72% female, mean age 76 ±9.2 years, median Charlson-Romano comorbidity index of 0). Unadjusted incremental costs of GCA for the first five years after diagnosis averaged $26,348 per-PY (2010 Canadian), with 78% from hospitalizations, 15% from outpatient, and 6% from medications. 59% of cases (vs. 26% of controls) were hospitalized during the first year after diagnosis, with GCA cases averaging 0.46 more admissions than controls (even after the index admission was excluded).

Following adjustment, 5-year costs for GCA cases were 1.9-times higher than matched controls (95% CI: 1.7-2.0, see **Table**). These incremental costs decreased over calendar time, even after inflation adjustment, averaging $41,113 per-PY for cases diagnosed over 1996-2002 (early period), and $19,033 per-PY for cases diagnosed over 2003-2010 (later period). Incremental hospitalization costs had the biggest change, decreasing by 61%, from $34,732/PY in the earlier period to $13,531/PY in the later

Conclusion:

The absolute costs of GCA have recently decreased, by 54%. Still, even after adjusting for pre-existing comorbidities, patients with newly-diagnosed GCA incur two-times more medical costs than age-matched individuals without GCA from the general population.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Health Services Research Poster I: Diagnosis, Management and Treatment Strategies
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Considering rheumatoid arthritis (RA) is a chronic disease that lasts for decades, patient education is of upmost importance. RA patients seeking information on the web has been exponential during the last 15 years. The aim of this study was to assess the content, authorship, and scope of the information currently available on the internet in relation to this topic and compare it with a report published in 2001*.

Methods: Two internet search engines were used to perform the task: WebCrawler, to replicate the referent study published in 2001*, and Google, since it is now the most widely used search engine. We conducted the search using the phrase "rheumatoid arthritis" as an average patient would do. Information was evaluated from the first 30 pages of each search carried out. All the websites that were used to collect data from were critically assessed afterwards in relation to relevance, scope, authorship, type of publication, and financial objectives. Significant differences were assumed if 95% confidence intervals did not overlap between referent and current studies.

Results: The search returned 316 hits using WebCrawler (85% considered relevant). We found significant differences between the referent study* and ours. There was a decrease in; advertisements (48% vs. 2%), hits posted by profit industries (51% vs. 18%), financial interest regarding "primary sold products" (42% vs. 9%), and promoting alternative therapies (45% vs. 27%). While an increase was noted in; "mainly RA information" (8% vs. 58%), support groups (<1% vs. 6%) and discussing "conventional treatment" (8% vs. 49%). University and/or hospital owned Web pages remained unchanged (5% vs. 8%).

Regarding Google, the search returned 326 hits, and when compared with our WebCrawler search we found significant differences: lower relevance (58% vs. 85%), more news articles (17% vs 7%), more "only RA discussed" (73% vs. 58%), and less "alternative therapy" (18% vs. 27%). Concerning Universities and hospitals providing information for patients, the proportion is almost the same (7% vs. 8%). Yet Mayo Clinic appeared in the 1st position, Arthritis Foundation in the 3rd position, the American College of Rheumatology in the 8th position, Johns Hopkins in the 21st position, UCSF in the 77th position, and Washington University in the 197thposition.

Conclusion: It seems that surfing the net is in some ways more reliable and trustworthy now, for RA patients, than it was 15 years ago, with significantly less advertisements and less focus on only alternative therapies. Yet there is a window of opportunity for rheumatology centers and universities to have a more prominent social involvement in patient education for rheumatic diseases.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Health Services Research Poster I: Diagnosis, Management and Treatment Strategies
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

We extracted a large cohort of rheumatoid arthritis (RA) patients, on which we plan to apply big data analytics for earlier diagnosis of RA. To help validate this cohort, we performed an initial study to answer a health services question regarding lipid surveillance and cardiovascular risk reduction in the RA community. Cardiovascular disease is the leading cause of death among people with RA. This disease risk is double to that of the general population. Our research was supported with resources from the Department of Veterans Affairs (VA).

Methods:

We worked with clinical data from the VA. This dataset is one of the largest clinical repositories available, and provides detailed patient information for approximately 35 million patients who have received care at more than 150 medical centers over the past 15 years. Using the VA repository of 35 million patients, we identified a cohort of roughly 155,000 patients with any RA ICD code (714.x). We used a previously published algorithm by JA Sing to define a RA cohort, by selecting patients with an ICD code 714.x and either a positive rheumatoid factor or a positive anti-CCP. This resulted in a cohort of 29,713 rheumatoid arthritis patients with an estimated specificity and positive predictive value of about 90%. The RA cohort contained 3,978 women (13%) and 19,826 Caucasians (67%), with an average age of 66, and with 19,761 (67%) on a disease-modifying antirheumatic drug.

Results:

A total of 6,632 patients (22%) had their LDL cholesterol checked at least once while receiving care within the VA system. In addition, 421 (90%) of patients whose LDL was at least 190, 1,331 (85%) of patients whose LDL was at least 160, and 3,555 (72%) of patients whose LDL was at least 130 were placed on statin therapy.

Conclusion:

In this RA cohort, 22% had their LDL checked at least once during their follow-up in the VA. This suggests the need for improvements in lipid screening among rheumatoid arthritis patients in this population. However, this value is likely an underestimate, since it does not include patients who had their LDL checked outside the VA system. In addition, 78% of all people with RA and an LDL at least 130 were on statin therapy. We did not consider cardiovascular risk factors to

determine the appropriate pharmaceutical management strategy. In addition, we did not consider reasons why patients may not have been on a statin.

Our research incorporated a large and comprehensive data set, whose size and attributes create analytic and data mining issues that are beyond the capabilities of traditional software tools. We are currently working on machine learning tools for big data analytics, which we hope to use for early disease prediction of RA.

The Effect of the Formal Approval of Colchicine on Utilization of Emergency Department and Rheumatology Outpatient Services By Patients with Gout

Leah Krull[1,2], Erin Patton[3,4] and Harry D. Fischer[5,6], [1]Internal Medicine, Mount Sinai Beth Israel, New York, NY, [2]Medicine, Mount Sinai Icahn School of Medicine, New York, NY, [3]Rheumatology, Mount Sinai Icahn School of Medicine, New York, NY, [4]Medicine/Rheumatology, Mount Sinai Beth Israel, New York, NY, [5]Division of Rheumatology, Mount Sinai Beth Israel, New York, NY, [6]Medicine/Rheumatology, Mount Sinai Icahn School of Medicine, New York, NY

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Health Services Research Poster I: Diagnosis, Management and Treatment Strategies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Although colchicine has been used in the management of gout for decades, it had never undergone the formal approval process by the Food and Drug Administration (FDA). In 2006 the FDA announced its Unapproved Drugs Initiative. This initiative encouraged manufacturers of colchicine to study the safety and efficacy of their product, and to formally apply for FDA approval. In 2009 one brand name colchicine became the sole FDA approved colchicine product in the United States. In 2010 all unapproved colchicine products were removed from the market. With the availability of only one colchicine product, the cost increased significantly. Each pill was estimated to be 50 times more expensive. Concerns were raised that this price increase would result in decreased access for patients with gout who need colchicine. The inability to afford, and therefore utilize colchicine, could result in more frequent and prolonged flares of gout. Patients with acute gout often present to an emergency department (ED) or rheumatology office for treatment. The number of visits to the ED and rheumatology outpatient office by gout patients may correlate with gout flares.

Methods:

A retrospective cohort study comparing the number of patients presenting to the ED and outpatient rheumatology practice at our institution was compared during two distinct time periods: January 1, 2008 to December 31, 2008 when unapproved inexpensive colchicine was still available, and January 1, 2012 to December 31, 2012 when only one approved more expensive colchicine was available. A diagnostic code search was performed for ICD-9 codes 274.0,

274.01, and 274.9 as the primary diagnosis. The total number of visits for both gout and non-gout diagnoses in each time period and setting were calculated for comparison.

Results:

The number of visits to the ED for gout was 73 out of 85,500 total ED visits in 2008. This increased to 91 out of 122,200 total ED visits in 2012. This was not found to be statistically significant. In the rheumatology outpatient setting there were 225 gout visits out of a total of 7,827 total office visits in 2008. This decreased to 112 out of 10,377 total office visits in 2012. In this patient population there was a statistically significant lower incidence of gout in 2012 compared to 2008 with a risk ratio of 2.66 (95% CI 2.13-3.33, p-value <0.0001). Combining ED visits and outpatient rheumatology there was again a statistically lower incidence of gout presentations in 2012 compared to 2008 with a risk ratio of 2.08 (95% CI 1.74-2.49, p-value <0.0001). These findings suggest it was about twice as likely to present with gout in 2008 compared to 2012.

Conclusion:

There have been concerns that a significant increase in cost would reduce access to colchicine for patients with gout resulting in possibly more frequent and prolonged flares of gout. Our study did not show an increase in ED utilization by patients with gout during the period of increased cost, and outpatient rheumatology visits actually decreased. This may in fact be partially due to the availability of newer medications for the long-term management of gout.

Same Day Rheumatology Access Clinic in an Academic Health Care Center

Muhammad Ijaz[1,2], Alireza Meysami[1], Amita Bishnoi[1] and Bernard Rubin[3], [1]Rheumatology, Henry Ford Hospital, Detroit, MI, [2]Rheumatology, Wayne State University/Detroit Medical Center, Detroit, MI, [3]Rheumatology, Henry Ford Health System, Detroit, MI

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Health Services Research Poster I: Diagnosis, Management and Treatment Strategies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Open access clinics have been studied extensively in the primary care setting [1], but there is limited data regarding rheumatology open access clinics. To improve rheumatology clinic access for patients, we created a same day clinic. We anticipated an improvement in access, no show rates, and a unique learning opportunity for fellows to see more acute rheumatologic conditions than in conventional academic clinic practice.

Methods:

A rheumatology fellow-based same day clinic (SDC) was created at a tertiary care academic health center. Clinic appointments were made available forty-eight hours before the appointment using an electronic scheduling system, or through a call center. Patients could also contact their PCP to refer them electronically. Same day appointments are available five days a week at one of four clinics staffed by the division of rheumatology at Henry Ford Hospital. Second year fellows were assigned to SDC, supervised by a senior staff attending, who were on call and exempted from routine clinics. To gauge improvement in access, we compared the time to third next available appointment for both follow up and new patients, before and after SDC implementation. Press-Ganey patient satisfaction surveys were used to evaluate patient satisfaction. We also compared the no-show rates in clinic before and after SDC implementation. Educational value for the fellows was assessed by a focused questionnaire.

Results:

Implementation of same day clinics improved access with a decreased time to third next available appointment from 30.9 days in June, 2014, to 20.8 days in March, 2015. Although the overall patient satisfaction score did not change; measures including the access score and the ability to get the desired appointment improved from 81.9 to 87.5, and 78.8 to 90 respectively from July, 2014, to February, 2015. The no show rate remained unchanged, and it was specifically high in February, 2015, due to brutal winter weather in Michigan, and implementation of new insurance market exchanges. The fellows reported enhanced educational value from exposure to patients with acute, non-emergent complaints. Many new consults seen by the fellows in SDC were followed in their respective continuity clinics, although many patients did not require a second visit.

Conclusion:

Implementation of a same day clinic (SDC) in an academic rheumatology practice improved access, access score, and the ability to get a desired appointment. We did not see improvement in overall patient satisfaction scores or no show rates. Further improvement and refinement is anticipated as we expand this SDC model to our other rheumatology clinic sites across several counties. A preliminary survey of the current fellows showed positive educational benefits, and as the model expands to more clinic locations in the future, we anticipate statistical improvement that can be measurable and actionable. In addition, SDC could provide some financial benefit for health care system by minimizing the number of unnecessary ER visits and hospital admissions.

Identifying the Investment Needed to Generate a Durable Prednisone Dose Decrement

Martha Delgado[1], Lorena Wilson[2], James D. Katz[3] and Ann Biehl[4], [1]the National Institute of Arthritis Musculoskeletal and Skin Diseases, the National Institutes of Health, Bethesda, MD, [2]National Institute of Arthritis and Musculoskeletal and Skin Diseases, The National Institutes of Health, Bethesda, MD, [3]Department of Medicine, Division of Rheumatology, The George Washington University, Washington, DC, [4]Department of Pharmacy, National Institutes of Health Clinical Center, Bethesda, MD

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Health Services Research Poster I: Diagnosis, Management and Treatment Strategies
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Assessment of the total cost of care requires clinical, epidemiological, patient-centered, and economic data. However, barriers to a value-driven outcome assessment include the resource-intensive nature of activity-based costing. One aspect of the total cost of care is direct costs. Government-based outpatient care enables an analysis that controls for all direct costs apart from medication costs. The aim of our study is to understand one aspect of the direct cost of care upon a given steroid decrement.

Methods:

We reversed the Branching Decision Tree for identification of expenses attributable to clinical care by restricting our assessment to a given steroid taper. Our analysis identifies drug costs over the preceding 10 weeks as the basis for allocating direct care costs to specific encounters. This timeframe is chosen because it is the average interval between outpatient appointments. We identified patients for analysis at the time that they were instructed by the rheumatologist to reduce prednisone dosage. Patients were enrolled over a 6-month period at a community outpatient clinic. Captured data included diagnosis, current and new prednisone dose, and other rheumatology medications. We extended our analysis to a 10-week prospective durability ascertainment of the success of the intervention. We stratified the analysis based upon a diagnosis of Rheumatoid Arthritis (RA) or Other Autoimmune diseases (OTHER).

Results:

Direct costs invested over a ten-week period for all patients tapering prednisone were $1659.30 (Table 1), which normalizes to $434.37/mg decrement (Table 1). A greater normalized cost was invested per patient for RA as compared to OTHER. There was a 97% completion rate for data collection in the prospective arm of the study. We observe a 76% durability response towards maintaining the recommended reduced steroid dose 10 weeks after the incident date in RA patients as compared to 85% for OTHER patients (Table 1). In general, a two or three-fold greater direct investment antecedent to steroid decrement was associated with a durable response over the ensuing ten weeks for either disease category.

Conclusion:

Our analysis demonstrates that outpatient drug costs for RA are most fruitful to target when looking to contain direct health care costs. On the other hand, the prospective arm of the study suggests that higher direct costs are associated with durable steroid decrement outcomes regardless of inflammatory disease classification. The advantage of this study is that reimbursement, coverage levels, and access to care are all controlled for because our protocol-based health care delivery model renders this a unique opportunity to assess relatively pure direct costs. A disadvantage of this study is that indirect costs are not analyzed. Future research is needed to ascertain whether the higher invested direct costs are offset by the drop in future indirect costs consequent to a durable steroid-sparing benefit.

Table 1. AVERAGE DRUG COST AND NORMALIZED DRUG COST INVESTED IN THE PRECEDING 10 WEEKS PER MG PREDNISONE DECREMENT AND TEN-WEEK OUTCOME OF PREDNISONE TAPER				
Category	Number of Patients	Per Patient Avg. Drug Cost	Avg. Decrement (mg)	Average Cost/mg decrement
All patients	38	$1659.30	3.82	$434.37
All RA patients	25	$2195.57	2.65	$828.52
RA patients with Durable response	19	$2543.14	2.67	$952.49
RA patients with lack of Durable response	6	$1094.93	2.58	$424.39
All Other autoimmune patients	13	$627.98	5.88	$106.80
Other autoimmune patients with Durable Response	11	$678.40	5.36	$126.57
Other autoimmune patients with lack of Durable Response	2	$350.65	8.75	$40.07

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: A physician estimate of a patient's global status (DOCGL) often is most often the most efficient of all 7 rheumatoid arthritis (RA) core data set measures to distinguish active from control treatments in clinical trials(1). DOCGL is designated to assess inflammatory activity. However, DOCGL may be influenced by damage, as seen in comorbid osteoarthritis (OA), and distress, as seen in fibromyalgia and chronic pain syndromes. Indeed, it may be suggested that the expertise of a rheumatologist is directed to a form of "triage" in chronic diseases, to recognize the extent to which a patient's signs and symptoms may be explained by inflammation, damage, and/or distress. Therefore,

3 new physician 0-10 visual analog scales (VAS) developed to estimate subsets of DOCGL. We analyzed physician scales for overall global status, inflammation, damage and distress in patients with RA, osteoarthritis (OA), and fibromyalgia (FM).

Methods: Patients seen in routine care at one academic clinical setting are assigned 4 0-10 VAS estimates for overall DOCGL, inflammation or reversible problems, damage (to any organ) or irreversible problems, and/or distress, as seen in fibromyalgia, depression, chronic pain syndrome, etc. A cross-sectional analysis was performed of a random visit between September and December 2014 of consecutive patients with 3 primary diagnoses: RA (n=108), OA (n=131), and FM (n=51). The medians and interquartile ranges (IQR) of non-normally distributed data and Spearman correlations were computed to estimate associations of the overall DOCGL with subscales and PATGL in the 3 diagnosis groups.

Results: Median DOCGL ranged from 3 to 5, highest for patients with FM (5.0), followed by OA (4), and RA (3.5). The highest median score for inflammation was for patients with RA (1.5), for damage in patients with OA (4.2) and for distress in patients with FM (5.2) (Table). The highest correlation with DOCGL was seen for the inflammation scale in RA, damage in OA, and distress in FM. DOCGL was correlated significantly with PATGL in RA and OA, but not in FM.

Conclusion: Physician estimates for inflammation, damage, and distress differ according to different rheumatic diagnoses. These 3 subscales supplement the overall physician global estimate as a quantitative summary of the history and physical examination, to estimate levels of inflammation, damage, and distress in an individual patient, analogous to triage function in acute injury, to support clinical decisions in patients with chronic rheumatic diseases in usual care.

Validity of the Inpatient Diagnosis of Systemic Lupus Erythematosus: Clarifying Hospital Readmission Rates

Sadiq Ali[1], Stephen Mullis[2], Amer Al-Khoudari[1] and Dennis Ang[1], [1]Section on Rheumatology and Immunology, Wake Forest University, Winston Salem, NC, [2]Department of Internal Medicine, Wake Forest University, Winston Salem, NC

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Health Services Research Poster I: Diagnosis, Management and Treatment Strategies
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is assumed to be associated with one of the highest hospital readmission rates among chronic illnesses. Based on a recently published (Arth Rheumatol (2014) 66:2828) electronic database analysis of Medicare/Medicaid hospital discharges, 16.5% of patients with the ICD-9-CM code 710.0 for SLE were readmitted to any hospital within 30 days. Our long-term research goals are to determine the 30-day all-cause readmission rate for adults with SLE in our tertiary care hospital, and to identify the risk factors for readmission. The aim of the current report was to determine the validity of SLE diagnosis among our hospitalized patients with an ICD-9-CM code of 710.0.

Methods: Potential admissions were identified through the electronic medical record system (EMR). From October 1, 2012 to December 30, 2014, index admissions were defined as hospital admissions from adult patients (≥ 18 years of age) who had a primary or secondary ICD-9-CM diagnosis of 710.0. Individual charts were then manually reviewed by a single rheumatology fellow to determine if the patient fulfilled the 1997 ACR revised criteria for SLE. Chart review included analysis of all documents dated as far back as the implementation of the EMR in 1997, including clinical visits, imaging studies and laboratory results.

Results: 1003 index admissions met our inclusion criteria, obtained from 433 unique patients. Only 196 (45%) of 433 patients fulfilled criteria for SLE. 237 (55%) patients did not meet criteria: 185 (43%) patients had an inappropriate diagnosis of SLE (i.e., chart review contained sufficient data to support an alternate diagnosis), 34 (8%) patients had limited cutaneous lupus, and 18 (4%) patients had insufficient data to either confirm or refute a diagnosis of SLE.

Conclusion: Our initial result demonstrates a 55% rate of miscoding of hospital records for adult patients with a primary or secondary diagnosis of SLE designated by the ICD-9-CM code 710.0. Our result brings into question the use of ICD-9-CM coding to evaluate readmission data in SLE.

Serum Uric Acid Levels and Gout Flares in a US Managed Care Setting

Aki Shiozawa[1], Erin Buysman[2], Stephanie Korrer[2] and Hyon Choi[3], [1]Global Outcomes and Epidemiology Research, Takeda Pharmaceuticals International, Inc, Deerfield, IL, [2]Health Economics and Outcomes Research, Optum, Eden Prairie, MN, [3]Massachussetts General Hospital/Harvard Medical School, Boston, MA

Session Title: Health Services Research Poster I: Diagnosis, Management and Treatment Strategies
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Gout is a common chronic inflammatory condition due to hyperuricemia. Gout patients typically have the clinical manifestation of acute painful flare attacks. While the role of lowering serum uric acid (sUA) levels in the prevention of flares is clearly recognized in recent gout care guidelines, only a limited number of published studies exist about the association. To provide further evidence on the topic, we sought to assess the risk of flares in patients with gout according to detailed categories of sUA levels in a US managed care population.

Methods:

We conducted a retrospective cohort study using administrative claims data from a large US health plan of commercially insured and Medicare Advantage enrollees. Patients were required to have evidence of gout (ICD-9-CM code 274.xx) based on medical and pharmacy claims between January 2009 and April 2012. The 12 months prior to the index gout claim were used to assess baseline sUA levels and patient characteristics. Gout flares were assessed during a variable observation period which lasted up to 2 years following the index gout claim; patients who initiated urate-lowering therapy (ULT) in the follow-up period were censored after the first claim for ULT. Flares were identified based on diagnoses for gout or joint pain followed within 7 days by claims for NSAIDs, colchicine, corticosteroids, or joint aspiration/drainage. Patients were assigned to cohorts determined by baseline sUA level. Incidence rate ratios were calculated for occurrence of first gout flare (using a sUA < 5.0 mg/dL reference cohort as denominator). A Kaplan-Meier analysis and a Cox proportional hazards model were used to assess the relationship between baseline sUA levels and risk of flares.

Results:

This study included 18,008 patients (mean age = 55 years; 78 % male) with gout. Patients were assigned to cohorts as follows: sUA < 5.0 mg/dL (N=1,953, reference); sUA 5.0 to 5.9 mg/dL (N=2,046); sUA 6.0 to 6.9 mg/dL (N=2,739); sUA 7.0 to 7.9 mg/dL (N=3,487); sUA 8.0 to 8.9 mg/dL (N=3,677); and sUA ≥ 9.0 mg/dL (N=4,106). The incidence rate ratios for gout flares during the observation period were 1.0 (reference), 1.3, 1.9, 2.4, 3.4, and 5.0, respectively (all $p < 0.01$ in comparison to the reference cohort). In a Cox proportional hazards model that adjusted for baseline characteristics, cohorts with baseline sUA ≥ 6.0 mg/dL had a significantly higher risk of flares (HRs ranged from 1.7 to 3.9, all $p<0.001$ in comparison to reference cohort). The time to first flare in a Kaplan-Meier analysis was shorter for cohorts with higher baseline sUA levels (Figure 1).

Conclusion:

This large contemporary study of gout patients in a managed care setting confirms that patients with sUA levels ≥ 5.0 mg/dL (unadjusted analysis) or ≥ 6.0 mg/dL (multivariate analysis) are at an increased risk of experiencing a gout flare with rising sUA levels. These findings underscore the need to treat to target as recommended by recent gout care guidelines.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Health Services Research Poster I: Diagnosis, Management and Treatment Strategies
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Remission of disease is the primary goal in chronic inflammatory arthritis, especially in rheumatoid arthritis. Traditional disease-modifying drugs like methotrexate and anti-tumor necrosis factor (anti TNF) therapy are

increasingly prescribed. General practitioners (GP) have to be faced with these treatments. The aim of the study is to explore GPs' perceptions of using these treatments in regular day-to-day practice.

Methods:

Semi structured interviews conducted with 14 GPs following patients under methotrexate and anti-TNF therapy, were analysed independently by researchers using inductive thematic analysis.

Results:

Four themes were identified: role of the GP in care delivery to patients under these treatments; their experiences and difficulties with these treatments; their perception of therapy education programmes; improving care delivery practices. The GP's role revolves around repeat prescription of methotrexate and managing for comorbidities, such as vaccination. In regular day-to-day practice, GPs note good tolerance and efficacy with these treatments. However, the increased risk of infection remains a top-of-mind concern and represents a hindrance to the use of these treatments. The most predominant difficulties are drug interactions and how to handle stopping anti-TNF therapy during bacterial infection, especially for GPs in rural area where there is limited access to specialist care. These GPs also report limited access to therapy education programmes. All the GPs voiced the need for a support tool to help them manage these therapies in routine practice.

Conclusion:

Methotrexate and anti-TNF therapies bring specific management issues that warrant tight cooperation between GPs and specialists. This study finds that it seem essential to facilitate dedicated training for GPs and to deploy a support tool.

An Economic Evaluation of Tofacitinib (Xeljanz) Treatment in Rheumatoid Arthritis: Modeling the Cost of Treatment Strategies in the US

Lindsay Claxton[1], Matthew Taylor[1], Michelle Jenks[1], Gene Wallenstein[2], Alan Mendelsohn[3], Jeffrey Bourret[3], Amitabh Singh[3] and Robert Gerber[2], [1]York Health Economics Consortium, University of York, York, United Kingdom, [2]Pfizer Inc, Groton, CT, [3]Pfizer Inc, Collegeville, PA

Session Date: Sunday, November 8, 2015

Session Title: Health Services Research Poster I: Diagnosis, Management and Treatment Strategies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Tofacitinib is an oral Janus kinase (JAK) inhibitor for the treatment of rheumatoid arthritis (RA). An economic model was developed to evaluate the treatment costs of an RA strategy, including tofacitinib compared with strategies of biologic therapies that are commonly prescribed in the US. The model aimed to address the economic impact of monotherapy and combination therapy in MTX-inadequate responder (IR) patients and combination

therapy in TNFi-IR patients.

Methods: A decision-tree economic model was developed to evaluate costs over a one- or two-year time horizon. The model assessed patients with moderate to severe RA undergoing treatment with tofacitinib 5 mg BID or similarly labeled biologic therapies, either as monotherapy or with methotrexate (MTX), in scenarios where patients had an inadequate response to MTX therapy or after a first TNFi failure (combination therapy only). Response to treatment was modeled as ACR20/50/70 response. ACR response rates at 6 month intervals were sourced from US Prescribing Information, and safety event rates from a meta-analysis. Following an adverse event or a lack of response, it was assumed that 75% of patients switched to the next line of treatment (first to abatacept, and then to rituximab). Cost inputs included drug, monitoring, drug administration, and treatment for minor and serious adverse events. The patient population was based on the total number of all members (i.e. RA and non RA) in an organization; members with RA treated with biologic therapies were estimated using epidemiological data. The economic endpoints were: cost per member per month (PMPM), cost per ACR20 responder, and total costs. Sensitivity analysis adjusted for absolute ACR20 rates (lowering for tofacitinib and increasing for biologics).

Results: Results based on an organization size of 1 million with MTX-IR patients (n=1505) and TNFi-IR patients (n=602) are presented in Table 1. In the MTX-IR population, the monotherapy strategy with tofacitinib alone was associated with the lowest PMPM, cost per ACR20 responder and total costs over 1 and 2 years compared with the TNFi and non-TNFi biologics. Similar results were observed for combination therapy. In the TNFi-IR population, tofacitinib + MTX was associated with a lower PMPM, cost per ACR20 responder and total costs over 1 and 2 years compared with adalimumab + MTX. Tofacitinib strategies with no rebate (0%) were still associated with lower costs compared with adalimumab and etanercept with 20% rebates. Lower costs with tofacitinib were supported by sensitivity analysis.

Table 1: Economic model results (sorted lowest to highest cost based on two-year total costs)						
	Cost PMPM		Cost per ACR20 responder		Total costs	
	One year	Two years	One year	Two years	One year	Two years
MTX-IR patients						
Tofacitinib monotherapy	$4.09	$4.38	$47,830	$96,381	$49,066,725	$105,103,278
Tofacitinib + MTX	$4.21	$4.50	$57,973	$111,334	$50,510,949	$107,966,327
Tocilizumab monotherapy	$4.79	$5.01	$56,536	$111,104	$57,451,755	$120,319,824
Tocilizumab + MTX	$4.85	$5.03	$67,342	$125,179	$58,232,653	$120,752,673
Certolizumab monotherapy	$5.09	$5.22	$73,974	$134,103	$61,079,342	$125,271,312
Certolizumab + MTX	$5.10	$5.27	$65,748	$124,384	$61,230,332	$126,452,249
Etanercept monotherapy	$5.25	$5.41	$66,813	$126,544	$63,056,328	$129,880,666
Adalimumab monotherapy	$5.34	$5.41	$78,393	$140,025	$64,082,494	$129,901,536
Etanercept + MTX	$5.28	$5.48	$60,823	$119,203	$63,332,567	$131,423,554
Adalimumab + MTX	$5.37	$5.50	$67,805	$128,061	$64,428,338	$132,081,552
TNFi-IR patients						
Tofacitinib + MTX	$1.68	$1.80	$57,492	$110,596	$20,180,138	$43,127,524
Adalimumab + MTX	$2.15	$2.18	$77,344	$138,937	$25,753,046	$52,222,968

Conclusion: Tofacitinib 5 mg BID following MTX failure is predicted to be a low cost per patient treatment option when used either as monotherapy or combination therapy compared with biologic regimens. Tofacitinib + MTX in TNFi-IR patients was also predicted to be a low cost treatment option compared with adalimumab + MTX. Tofacitinib was associated with the lowest cost per ACR20 response.

Experiences with a Structured Questionnaire for Administrative Personnel

to Discriminate Urgent and Non-Urgent Rheumatic Patients Referred from Primary to Secondary Care

Omar Ghazal and **Michael Schirmer**, Internal Medicine, Clinic VI, Medical University of Innsbruck, Innsbruck, Austria
First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Health Services Research Poster I: Diagnosis, Management and Treatment Strategies
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: To gain experiences with a structured questionnaire for discriminating urgent and non-urgent rheumatology appointments by administrative personnel, designed to include all forms of rheumatic diseases. Second, to discuss the results in view of current literature on referral strategies of rheumatic patients from primary to secondary care, including immune-mediated rheumatic diseases.

Methods: In our rheumatology unit a rheumatology urgency score (RUS) has been calculated on the basis of a multi-dimensional questionnaire with five main domains: Administrative information (referral mode, subjective urgency), clinical signs, time of maximal symptom presentation, available laboratory and imaging findings. This questionnaire has been routinely used since july 2013 for assigning appointments at initial consultation, with urgency defined as RUS $\geq$ 4 points. Anonymous score sheets including appointment assignments were provided by the administrative personnel for retrospective analysis. Literature search was last updated in january 2015 to identify evidence for effective strategies reducing waiting times and underlying causes for prolonged waiting times.

Results: Consecutive questionnaires from 153 referrals have been analyzed. Questionnaires with RUS $\geq$ 4 points were calculated and considered as urgent for 75% of the patients (n = 115). Based on the bimodal distribution curve of waiting times, the cut-off between short and long waiting times was defined as 23 days. Mean waiting time for urgent patients was shorter with 14.4 days (±13.1 days) than for non-urgent appointments with 24.6 days (±15.4 days) ($p<0.001$). 27.5% of all appointments were assigned independently from RUS, with 40.5% of questionnaires with RUS <4 resulting in a fast appointment and 16.1% of questionnaires with RUS $\geq$ 4 points resulting in a slow appointment. Without these incorrect assignments, waiting times were shorter for urgent than for non-urgent patients with 8.6 and 38.0 days, respectively ($p<0.001$). Administrative information, clinical signs, time of maximal symptom presentation, laboratory and imaging findings were available in 99.3 %, 94.1%, 77.1%, 33.3%, and 17% of the questionnaires, respectively.

According to the literature, effective strategies resulting in a reduction of referral delay are rapid access services, early arthritis clinics, triage of referrals with use of referral forms and educational programs for primary care physicians. None of the strategies specifically included patients with immune-mediated rheumatic diseases.

Conclusion: The rheumatology urgency score resulted in a bimodal distribution of waiting times, thus distinguishing between urgent- and non-urgent appointments. To achieve better quality in assignment of urgent appointments, administrative personnel has to be further instructed and motivated. RUS has to be further validated in a prospective approach taking into account the subjective and objective physicians' feed-back of urgency and final diagnoses.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Health Services Research Poster I: Diagnosis, Management and Treatment Strategies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Despite the availability of effective therapies for fracture prevention, osteoporosis screening and treatment rates in practice are low. Fracture liaison services are effective at reducing secondary fractures, but primary prevention models are limited. The Salt Lake City VA Health Care System (SLCVAHCS) partnered with primary care providers (PCPs) to develop a bone health team (BHT) to improve the management of patients at risk for osteoporosis. This analysis compared patients enrolled in the BHT to similar patients with standard management.

Methods: Patients enrolled in the community-based outpatient clinics (CBOCs) of the SLCVAHCS from Feb 1, 2012 – Feb 1, 2015 were included if 1) the patient was enrolled in a CBOC PCP panel for 1 year prior to the date of implementation of the BHT, 2) had one PCP visit during this interval and 3) men age ≥70 and women age ≥65. Exclusion criteria were 1) no PCP assignment; or, 2) death in the pre-index period. The primary intervention was placement of a BHT e-consult. Primary outcomes were: completion of dual energy x-ray absorptiometry (DXA) scan; 25(OH) D measurement; diagnosis of osteopenia or osteoporosis; and initiation of osteoporosis medication. All patients started out as unexposed, but some went on to receive the primary intervention; patients were followed until the earliest of: occurrence of a primary outcome; or, the end of the observation period. Between group differences were analyzed using a Cox proportional hazards model with enrollment in BHT as a time-dependent exposure. Multivariable regression models adjusted for age, sex, multiple co-morbidities, baseline pharmacologic agents, site of CBOC, and PCP discipline.

Results: Of the 7,644 patients evaluated, 975 were enrolled in the BHT. This cohort was predominantly male (97.8%) with an average age of 79.8 years. Patients enrolled in BHT were significantly younger, more likely to live in rural areas, and more likely to have a physician as a PCP versus those not enrolled in BHT. More patients in BHT had diabetes, a prior diagnosis of osteoporosis and osteopenia, prior treatment with osteoporosis medications, and a greater likelihood of having been seen by a nurse practitioner. Fewer patients in the BHT had been seen by a physician's assistant, had vitamin D deficiency, or had prior vitamin D testing. In both univariate and multivariable regression analyses, patients in BHT were significantly more likely to undergo DXA, 25(OH) D testing, be diagnosed with osteopenia or osteoporosis, and be treated with osteoporosis therapy (Table).

Table: Univariate and Multivariable Cox Proportional Hazards regression results of BHT Intervention Compared to Standard Management

	Univariate Results				Multivariable Results			
		95% Confidence Interval				95% Confidence Interval		
Outcome	**HR**	**Lower**	**Upper**	**P-value**	**HR**	**Lower**	**Upper**	**P-value**
DXA	111.4	90.9	136.4	<.0001	176.1	125.9	246.3	<.0001
25 OH	1.403	1.258	1.564	<.0001	1.817	1.574	2.098	<.0001
Medication	13.78	10.76	17.64	<.0001	20.24	13.31	30.78	<.0001
Osteopenia	36.34	29.01	45.52	<.0001	51.39	34.62	76.29	<.0001
Osteoporosis	11.22	9.01	13.98	<.0001	18.06	12.50	26.08	<.0001

Conclusion: BHT implementation significantly increases the rate of screening, diagnosis, and treatment of osteoporosis in CBOCs of the SLCVAHCS. The impact on fragility fractures will require longer follow-up. Similar programs could be considered to improve the primary prevention of osteoporosis in other primary care settings.

Session Time: 9:00AM-11:00AM

Background/Purpose: RA generally is regarded by physicians and the public as a more severe problem than OA. However, OA has been ranked as the 11th highest contributor to global disability among all diseases (1), and costs of OA and RA each have been found to account for about 1% of the US gross domestic product (2), explained in part by the higher prevalence of OA vs RA. Nonetheless, the standardized mortality ratio (SMR) (which is independent of prevalence) for OA is reported as 1.55 (3), and quite similar to the SMR for RA of 1.5-1.6 (4). Therefore, the severity of OA may be underestimated. We compared patient MDHAQ/RAPID3 (multidimensional health assessment questionnaire/routine assessment of patient data 3) and physician global estimates in patients with a primary diagnosis

of osteoarthritis (OA) or rheumatoid arthritis (RA) at 4 rheumatology clinical settings.

Methods: Patients were seen in routine care at 4 clinical settings: Liverpool Hospital, New South Wales, Australia, Rush University Medical Center, Chicago, IL, NYU Medical Center, New York, NY, and Arthritis and Rheumatology, a solo private practice, Ridley Park, PA. At each site, patients complete an MDHAQ at each visit in the waiting area while waiting to see the rheumatologist. The MDHAQ includes scores for physical function (0-10), pain (0-10), and patient global estimate (0-10), and RAPID3 composite scores of these 3 RA core data set measures (0-30). The physician assigns a global estimate for each patient (DOCGL). Patients with OA were compared to RA patients at each site for mean or median MDHAQ demographic measures, self-report physical function, pain, patient global estimate, RAPID3, and fatigue scores, as well as physician global estimates.

Results: Median scores for patients with OA were higher than for RA in 11 of 16 comparisons of MDHAQ scores (Table). Median DOCGL was higher in OA at 2 sites. Median physical function scores ranged from 1.7 to 2.7 for RA and 1.7 to 3.3 for OA; pain scores from 4 to 5 for RA and 5 to 7 for OA; patient global estimates from 4 to 5 for RA and 5 to 6 for OA; DOCGL from 0 to 4 for RA and 1 to 5 for OA; RAPID3 scores from 9.7 to 11.8 for RA and 11.7 to 16.8 for OA (Table).

Conclusion: Among treated patients, levels of patient physical function, pain, patient and physician global estimates, and RAPID3 in OA patients are in the same range as in RA patients. The findings likely reflect in part better treatments for RA. However, the severity of OA may be underestimated. Better information concerning OA may lead to improved clinical management and resource allocation for OA.

Potential Use of Healthcare Databases for Post-Marketing Surveillance Registry: an Example Using Ustekinumab

Huifeng Yun[1], Shuo Yang[2], Fenglong Xie[3], Lang Chen[4], Kevin L. Winthrop[5] and Jeffrey R. Curtis[4], [1]Epidemiology, University of Alabama at Birmingham, Birmingham, AL, [2]Clinical Immunology/Rheumatology, University of Alabama at Birmingham, Birmingham, AL, [3]Rheumatology & Immunology, University of Alabama at Birmingham, Birmingham, AL, [4]University of Alabama at Birmingham, Birmingham, AL, [5]Oregon Health and Science University, Portland, OR
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Health Services Research Poster I: Diagnosis, Management and Treatment Strategies
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Underreporting and inherent deficiencies are common using spontaneous reports for post-marketing surveillance. The U.S. Food and Drug Administration (FDA) has recommended sponsors to collect information from multiple sources including creating or working with registries or other observational data for post-marketing surveillance. For new costly drugs, traditional registries are expensive to create, slow to recruit, and are potentially subject to selection biases as to the types of patients enrolled. The current study evaluated the feasibility of utilizing one or more healthcare databases to support safety surveillance of a new biologic medication, with ustekinumab (UST) as an example.

Methods:

Using patients from Medicare 2006-2012, Marketscan 2008-2013, and Optum research database 2008-2013, we identified new users of UST using both non-specific and or specific drug codes. New users were defined as no previous use of UST with all available data. Eligible patients were required to meet the following criteria: 1) ≥ 19 years of age; 2) ≥ 1 one inpatient or dermatologist-given diagnosis code for psoriasis; 3) continuously enrolled with medical and pharmacy coverage during the 6 months prior to UST initiation and throughout follow up. We evaluated the accrual of new UST users by calendar time in each data system.

Results:

We identified 1636, 6159, and 2735 new UST users in Medicare, Marketscan and Optum databases, respectively (Figure). These patients had median follow-up of 1.5-2.5 years, and they were censored mainly because our study observation period ended, and not because patients dis-enrolled from the health plan. Marketscan provided the largest data source of new UST users, whereas the number of new users was comparable between Medicare and Optum. Within 1 year of FDA licensure, approximately 3,000 new users were identified, and by 2 years, almost 6,000 users were identified. As of the end of 2013, more than 10,000 UST new users were available.

Conclusion:

Utilizing one or more healthcare databases to support post-marketing surveillance for a new biologic shortly after its licensure is feasible, and it yields relatively large sample sizes to study uncommon safety events. This approach can complement more traditional registry-based approaches to detect important safety signals and maximize power for long

term comparative safety analyses.

Session Title: Health Services Research Poster I: Diagnosis, Management and Treatment Strategies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

RA patients with inadequate treatment response often cycle non-biologic DMARDs before initiating a biologic

DMARD. Early and aggressive treatment is a key feature of a treat-to-target approach and a previous study showed that switching to a biologic DMARD compared to cycling another non-biologic DMARD resulted in improved clinical outcomes (Dewitt et al., 2013). This study assessed the economic outcomes and treatment patterns among patients who used 1, 2, or ≥3 non-biologic DMARD(s) before receiving a biologic therapy.

Methods:

Adult patients with ≥2 RA diagnoses (International Classification of Diseases: 714.xx), ≥1 claim for a non-biologic DMARD, and ≥1 claim for a biologic DMARD were identified from a large commercial claims database (2008-2013). The initiation date of the first biologic DMARD was defined as the index date. Based on the number of distinct non-biologic DMARDs initiated between the first RA diagnosis and the index date, patients were classified into three cohorts: those who used 1, 2, or ≥3 non-biologic DMARDs. Baseline characteristics were measured 6 months pre-index date and compared between the three cohorts. All-cause healthcare costs (in 2014 USD) were compared in the follow-up period (12 months post biologic initiation) using multivariable gamma models adjusting for baseline characteristics. Discontinuation of the index biologic DMARD and time to switching to a new DMARD were compared using multivariable Cox proportional hazards models.

Results:

The 1, 2, and ≥3 non-biologic DMARD cohorts included 6,215, 3,227, and 976 patients, respectively. At baseline, patients in the ≥3 non-biologic cohort had the least severe RA, as indicated by the lowest claims-based index for RA severity (CIRAS) score (1 vs 2 vs ≥3: 6.1 vs 5.9 vs 5.8). During the study period, there was a significant association between number of non-biologic DMARDs and higher all-cause total healthcare costs (adjusted mean difference: 1 vs 2: $772, p<0.001; 2 vs ≥3: $2,390, p<0.001); the all-cause medical and pharmacy costs were also significantly higher with the increasing number of non-biologics (Table 1). Patients who cycled more non-biologic DMARDs were also more likely to switch treatment after biologic initiation (1 vs 2: adjusted hazard ratio (HR)=0.89, p=0.005; 2 vs ≥3: adjusted HR=0.89, p=0.087). There were no differences in index biologic discontinuation between the 3 cohorts.

Conclusion:

RA patients who cycled more non-biologic DMARDs had increased economic burden in the 12 months following biologic initiation and were more likely to switch therapy. These results highlight the importance of timely switching to biologic DMARDs for the treatment of RA.

Table 1. Comparison of healthcare costs among patients who used 1, 2, or ≥3 non-biologic DMARDs before the initiation of biologic therapy

	Unadjusted average healthcare costs			Adjusted difference in average healthcare costs			
	Patients who used 1 non-biologic DMARDs (N = 6,215) [A]	Patients who used 2 non-biologic DMARDs (N = 3,227) [B]	Patients who used ≥3 non-biologic DMARDs (N = 976) [C]	1 vs. 2 non-biologic DMARDs Difference [A] - [B]		2 vs. ≥3 non-biologic DMARDs Difference [B] - [C]	
Total all-cause healthcare costs (2014 USD), mean	$32,493	$33,420	$36,422	-$772	**	-$2,390	**
All-cause medical costs	$15,211	$15,459	$17,600	-$107	**	-$1,491	**
Inpatient costs	$3,603	$3,903	$4,831	$14	**	-$631	**
Emergency department costs	$342	$399	$369	-$45	**	$54	**
Outpatient costs	$11,265	$11,157	$12,400	$10	**	-$1,096	**
Rheumatologist visit costs	$2,712	$2,638	$2,388	$215	**	$175	**
All-cause pharmacy costs	$17,282	$17,960	$18,822	-$900	**	-$796	**

Rheumatologists' Approaches to Diagnosis and Treatment of Depression

Erica Heiman, Barton Wise and Richard L. Kravitz, Department of Internal Medicine, UC Davis Medical Center, Sacramento, CA
First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Health Services Research Poster I: Diagnosis, Management and Treatment Strategies
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Depression in patients with rheumatic disorders contributes to morbidity, mortality, and health care utilization. We set out to examine rheumatologists' approaches to and perceptions of depression in everyday practice.

Methods:

A questionnaire was mailed to 470 practicing rheumatologists in California; 226 (55%of eligible respondents, after removing those returned to sender and who reported they were not in active clinical practice) were included in the final analyses. Respondents provided information on demographics, practice characteristics, attitudes towards mental health, and practices related to depression. Logistic regression models were constructed to assess the relationship of rheumatologists' personal and practice characteristics with their usual depression-related practices (medication management, referral to primary care, and referral to psychiatry).

Results:

Among responding rheumatologists, 51% reported that at least half their patients suffered from depression, many of them untreated. Nearly all providers (99%) reported addressing mental health issues during at least some visits. When these issues were raised, it was usually the physician who initiated the discussion (69%); only 9% reported regular use of a formal screening tool. Rheumatologists were equally likely to prescribe antidepressants, refer to a psychiatrist, or return the patient to the primary care physician; about 60% reported applying each of the 3 strategies to at least half of their patients. In logistic regression models, greater number of visits per week and greater percentage of patients with fibromyalgia were associated with more prescription of antidepressants ($p<.05$).

Conclusion:

Our findings point towards a gap in care provision. Rheumatologists see a great need for mental health services but too often lack the skills and time to address mental health issues.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Health Services Research Poster I: Diagnosis, Management and Treatment Strategies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Disease progression in longitudinal studies of rheumatoid arthritis (RA) is usually assessed by examining a measure of disease over time fixed time intervals. We sought to use a multi-state model: (1) to provide a descriptive analysis of patients' disease states defined by the DAS-28 disease index throughout the first three years of treatment; (2) to determine the time spent in each disease state; and (3) to estimate the probabilities of changing between disease states.

Methods: Patients were selected from an ongoing prospective study of RA if they had active disease (>= 1 swollen or tender joint) and at least 2 follow-up visits to their rheumatologist. The DAS-28 score was collected at each visit and assigned to one of four category scores, from remission to high disease activity, using the ACR criteria. A multi-state (4-state) Markov model was fitted to describe patient progression through disease states over time to account for the irregular time intervals in our data considering time as a continuous variable allowing us to examine real-world disease course over time. Multiple piecewise transition parameters for the Markov model were fit to determine if patients have differential transitions at different time periods.

Results: There were 3014 visits in 586 patients with visits distributed arbitrarily over the 3-year follow-up window. At baseline, about 50% of patients were in high disease activity, but patients respond rapidly, moving out of this health state spending on average 0.17 years, 95% CI (0.19, 0.23) there. At baseline about 8% of patients were in DAS-28 remission, which rose rapidly at 0.5 years 25% probability and 1 year with about 40% of patients in remission. Once a patient achieved remission, the mean duration before moving to another disease state was 0.81 years, 95% CI (0.67, 0.97). By 1.5 years after initiation of treatment, patients in each disease state remained relatively constant indicating no net movement between health states. The piecewise model indicated that patients at 6-months had a differential movements through disease states then at any other time point. Patients starting in the highest disease state took the longest about 1.1 years to reach their first remission compared to 0.9 and 0.8 years for the moderate and low groups.

Conclusion: Individual patients transition between disease states in the first 3 years of treatment at differential times; the first 6-months are critical with the first year seeing rapid movement between states. Within the first 6-months, dramatic reductions are realized in patients with high disease activity in parallel with an observed increase in the proportion of patients achieving remission. Our analysis indicates the critical first year of treatment before a steady disease state with no net movement will be reached. Major changes in the first year of treatment could be a result of treat-to target strategy.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Health Services Research Poster I: Diagnosis, Management and Treatment Strategies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) have high coronary heart disease (CHD) burden and accelerated atherosclerotic status. However, limited data suggest that these patients may be screened less frequently than other patients with similar CHD risk. To evaluate the rate of lipid testing and management among RA patients and compare it both to the general population and diabetes (DM) patients.

Methods: We used a mix of private and public health plans claims data from 2006 to 2010 with medical and pharmacy coverage. Eligible participants were required to 1) have at least 12 months of continuous medical and

pharmacy coverage (baseline period), and 2) have 2+ physician diagnosis and relevant medications to categorize them as having 1) RA and DM; 2) RA only; 3) DM only; 4) Neither RA nor DM. Patients with prevalent myocardial infarction (MI)/stroke/CHD during baseline were excluded. Each of these groups had a follow up time of 2 years. We calculated the proportion of patients with low density lipoprotein (LDL) lab test during the 2 year follow-up. In a subgroup analysis, we determined the proportion of patients with lab results available with LDL ≥ 130 mg/dL that initiated treatment with statins. We use chi-square tests to compare differences between the 4 cohorts in the proportion tested for LDL and initiating statins.

Results: There were 428,109 eligible patients distributed between the 4 cohorts (Table). Overall, 60% were women. The overall age distribution was: 12% ≤ 40; 29%, 41-65; and 59% >65 years old. RA patients were less frequently tested for LDL compared to DM patients, with or without RA (p-value <0.001 for all comparisons) (Table). Conditional on having LDL ≥ 130 mg/dL, RA patients were less likely to be started on a statin compared to DM patients (p-value < 0.001), and were marginally more likely to be initiated on statins compared to the general population (p-value = 0.045). There was no difference in the statin prescription trend between DM and RA patients vs. only RA patients (p-value =0.083)

Conclusion: RA patients are less frequently screened and managed for hyperlipidemia compared DM patients. Despite higher CHD risks in RA patients, hyperlipidemia screening and treatment rates in RA patients were no better than the general population. Further studies to investigate the reasons and potential interventions to ameliorate this care gap among RA patients are needed.

Table: Frequency of lipid testing among patients with rheumatoid arthritis, diabetes, both or neither condition

Outcome	RA Only	Diab Only	RA & Diab	Neither
	N =20,148	N = 100,971	N = 3,358	N = 303,632
Screening: LDL checked during 2-year period, %	46	63	62	45
Treatment: statin initiation (among subgroup of patients with lab results available and LDL ≥ 130 mg/dL not already on therapy), %	13	26	28	9

Delivering a One-Stop, Integrated, Patient-Centred Service for Patients with Rheumatic Diseases. the Finnish Approach

Elena Nikiphorou[1], Paula Väre[1], Kirsi Paalanen[1], Jelena Borodina[1], Arto Kokko[2], Pekka Hannonen[1] and Tuulikki Sokka-Isler[3], [1]Jyvaskyla Central Hospital, Jyvaskyla, Finland, [2]Jyvaskyla Central Hospital, Jyväskylä, Finland, [3]Rheumatology, Jyvaskyla Central Hospital, Jyvaskyla, Finland

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Health Services Research Poster I: Diagnosis, Management and Treatment Strategies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Rheumatology is mainly an outpatient specialty. Prompt diagnosis & treatment to prevent long-term disability in an integrated, multi-disciplinary approach to care are crucial. In reality though, not many clinics provide this level of service.

Methods:

Descriptive report & patient satisfaction survey of a rheumatology clinic model which was first developed in 1996 to enhance the patient 'journey' through rheumatology services. A patient-satisfaction survey assessed several aspects of care including quality of services, consultations, treatment & patient education. All patients visiting the rheumatology department over a 3-week period were invited to participate.

Results:

All primary care referrals are screened by a rheumatologist to pre-schedule laboratory/radiology tests for the visit. Upon arrival to the clinic, patients check-in at an electronic desk, then are guided by a receptionist to complete the electronic Go-TreatIT monitoring system (assesses patient-reported outcomes e.g. pain, fatigue) at private stations within the clinic. Of all the collected data the program then generates commonly used comparable values e.g. HAQ, DAS28 & BASFI. The patient is reviewed by a doctor in a 30-60 minute consultation depending on whether it is a 1st or follow-up visit, then by a nurse (for diagnosis/treatment education, vaccinations, assessment of psychological status etc). An ultrasound machine & capillaroscopy are available for use in clinic. Patients can be scheduled on the same day to see a nutritionist, physiotherapist, podiatrist or other professionals as needed. An 'early-RA treatment path' is available to ensure early, intensive treatment (with combination triple DMARD therapy, intra articular & oral steroids). Steps in the process will be diagrammatically shown.

Survey: From 141 recipients, 86% completed a questionnaire;67% female;12% were on their first visit. Mean age:54.3 yrs; 37% retired. 51% had a diagnosis of RA; the remaining included ankylosing spondylitis, psoriatic arthritis, fibromyalgia, lupus, vasculitis. Most valued was the information & education provided by doctors/nurses & addressing patients' current issues. 93 % of patient 'agreed' that their medical care was high quality, 77 % 'strongly agreed'. The mean score overall assessment of the service was 90.6/100. Only 6% gave negative feedback. The main complaint was difficulty with using the electronic check-in tool (not GoTreatIT). Some patients expressed disappointment for not finding the cause for their symptoms. None of the patients felt they lacked education on their disease or medication. 92% strongly agreed they were given sufficient education. 6% of patients felt that they were overwhelmed with information, 82% were content with the amount of information given. The multi-disciplinary approach was valued & only 3% would rather see doctor and nurse on separate days.

Conclusion:

The specific clinic model provides an ideal setting for a one-stop service, avoiding unnecessary visits, collecting important patient data & enhancing the patient experience & journey through the system.

Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) have an increased risk of cardiovascular disease (CVD) as compared to the general population. The European League Against Rheumatism (EULAR) recommends that rheumatologists engage in assessing the CVD risks in RA patients. Multiple barriers such as limited time and lack of familiarity of CVD screening guidelines challenge the feasibility of this practice. Furthermore, recent data suggest that primary care providers fail to assess RA patients consistently or aggressively. At a tertiary referral center, we implemented an innovative system to provide RA patients direct access to cardiology for a CVD risk assessment. In the new RA-CVD clinic workflow, the rheumatologist can screen for CVD risk factors during a clinical visit and refer RA patients using a prescribed order set. Next, the patient is evaluated by cardiology and the 10-year risk for atherosclerotic cardiovascular disease (ASCVD) score is calculated to help guide therapy decisions. In this study, we examined patient access, lipid profiles and medication use before and after the intervention.

Methods: We devised an order set within the electronic medical record (EMR) that was available to all rheumatologists starting January 2015. The order set included a referral to the RA-CVD clinic, electrocardiogram, lipid profile or vertical auto profile (VAP), and hemoglobin A1C. For this study, we reviewed all RA patients presenting to our hospital for new or follow up appointments pre- and post- implementation of the program. Chart review was performed to identify elevated lipid profiles (LDL>130) and statin use. Our cardiology team devised a specific protocol to best risk assess these patients per EULAR guidelines.

Results: Since the launch of our program, 722 RA patients have been seen by the rheumatology practice, 99 (14%) of these patients agreed and were then referred to the RA-CVD clinic. Screening for diabetes and hypercholesterolemia has improved by 60% with the implementation of the program. To date, 13 patients have undergone full risk assessment, however not all patients have been seen partially due to cardiology appointment lag time. Of these patients, 5/13 (38%) patients were started on a statin based on their ASCVD score.

Conclusion: Our study suggests that the creation of a RA-CVD workflow significantly increased the rates of risk factor screening and appeared to provide a forum for necessary interventions. However, lack of cardiology access may limit the strength this program.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Health Services Research Poster I: Diagnosis, Management and Treatment Strategies
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Early detection of axial Spondyloarthritis (axSpA) is challenging given the lack of pathognomonic clinical findings. Clinical overlap with mechanical back pain leaves axSpA a poorly recognized disease entity. Given that effective treatments are now available, early detection of axSpA is critical. To enable primary care detection, the aim of this study was to evaluate an inter-professional model of care (MOC) for detection of axSpA with respect to three essential screening elements: 1) assignment to high vs low risk groups on the basis of clinical characteristics of patients; 2) agreement on mechanical versus inflammatory back pain; 3) interpretation of radiographic sacroiliitis.

Methods:

Patients with >3 months of back pain and age of onset ≤45 years were referred to the program. Exclusion criteria included: leg dominant pain, neurological symptoms, or an established diagnosis of an inflammatory condition. A comprehensive examination was completed by an Advanced Practice Physiotherapist (APP). Investigations included: HLA B27, CRP, ESR, and radiographs of the SI joints. Patients completed an initial assessment with an APP and were subsequently reviewed by a Rheumatologist with experience in axSpA. The APP and Rheumatologist independently categorized each patient's risk of axSpA into 'low', 'medium', or 'high' as well as the risk of mechanical back pain. Each patient's radiographs were interpreted independently by the APP and the Rheumatologist. Final axSpA diagnosis was determined by the Rheumatologist using the Assessment of Spondyloarthritis (ASAS) criteria.

Results:

A total of 123 patients were evaluated using the inter-professional MOC. Fifty-nine percent were female, with a mean age of 35.5 years (±9.6 years). Mean duration of back pain was 7.2 years (+/-8.5, range 3 months to 37 years). Agreement of risk categorization between APP and Rheumatologist was 79.7%, with Kappa coefficient= 0.57 (CI 0.38-0.77). Sensitivity and specificity for the APP (versus final diagnosis) was 71.4% (CI 30.3-94.9%) and 75% (CI 61.9-84.9%) respectively; with a positive predictive value of 25% (CI 9.6-49.4%) and negative predictive value of 95.7% (CI 84.3-99.3%). Radiographic interpretation for the presence of sacroiliitis, as per modified New York Criteria (mNYC), was fair to moderate (Kappa=0.39 left, Kappa=0.42 right) between the APP and Rheumatologist. Patients assigned by the APP and Rheumatologist to the low and high risk groups did not differ with respect to the following:

age, gender, inflammatory back pain, extra articular features, family history, HLA B27 status, ESR, CRP, or radiographic sacroiliitis.

Conclusion:

Using the ASAS criteria and Rheumatologists' final diagnosis as a gold standard, an inter-professional MOC demonstrated high negative predictive value and fair agreement with radiographic interpretation for sacroiliitis consistent with the literature. No significant differences were identified between clinical characteristics when assigning risk scores for axSpA. These preliminary findings suggest that an inter-disciplinary team is an effective MOC when screening for axSpA and represents a possible model for earlier detection within primary care.

Limitations of Treat-to-Target in Rheumatoid Arthritis: Joint Damage Appears As Severe As Inflammation in Contemporary Care at One Site

Theodore Pincus[1], Alex D. Luta[2], Isabel Castrejón[1], Annie Huang[1], Ruchi Jain[1], Sarah L. Everakes[3] and Joel A. Block[4], [1]Rheumatology, Rush University Medical Center, Chicago, IL, [2]Georgetown University, Washington, DC, [3]Internal Medicine, Rush University Medical Center, Chicago, IL, [4]Rush University Medical Center, Chicago, IL

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Health Services Research Poster I: Diagnosis, Management and Treatment Strategies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Treatment of rheumatoid arthritis is directed to "treat-to-target," with intensification of therapy in patients with moderate/high disease activity according to a quantitative index toward low disease activity or remission. However, remission or even low disease activity is unusual in even 50% of patients. One study suggests a partial explanation, as about 20% of patients with high index scores whose therapy is not intensified had clinically important joint damage (1). We analyzed physician estimates of inflammation and damage in RA patients in two ways: a) quantitative physician 0-10 visual analog scales (VAS); and b) estimates of the proportion(s) of clinical management decisions attributable to inflammation, damage, and/or distress, totaling 100%.

Methods: All patients seen at a one academic site completed an MDHAQ/RAPID3, and rheumatologists completed a RheuMetric physician checklist which includes 4 0-10 VAS for overall global estimate, inflammation, damage, and distress. A second type of scale asks doctors to estimate the proportion of the decision concerning management that is attributable to inflammation, damage, or distress, totaling 100%. Only the inflammation and damage VAS and proportions are analyzed in this study. Cross tabulations were computed with categories 0-1.9, 2-3.9,4-5.9,6-7.9,and 8-10 for the 0-10 VAS, and 0-19%, 20-39%, 40-59% 60-79%, and 80-100% for the proportion of the decision attributable to inflammation or damage.

Results: Among 72 patients studied, a 0-10 inflammation VAS was estimated as 8-10 in 6% of patients, versus 6-7.9 in 4%, 4-5.9 in 14%, 2-3.9 in 38%, and 0-1.9 in 39% of patients. Overall, only 24% of patients had scores ≥4 for

inflammation. Damage was estimated at 8-10 in 10% of patients, 6-7.9 in 10%, 4-5.9 in 18%, 2-3.9 in 40%, and 0-1.9 in 22%; 37% of patients had damage scores ≥4 . The proportion of clinical management attributable to inflammation was estimated as 80-100% in 10% of patients, 60-79% in 15%, 40-59% in 24%, 20-39% in 18%, and 0-19% in 33%. Damage was estimated as impacting 80-100% of the clinical decision in 36%, 60-79% in 8%, 40-59% in 24%, 20-39% in 18%, and 0-19% in 14% of patients. Overall, inflammation accounted for more than 40% of clinical decisions in 49% of patients, while damage accounted for more than 40% of decisions in 68% of patients.

Conclusion: In one setting, damage appears to impact clinical decisions in contemporary treatment of patients with RA as much as inflammation. This finding may explain in part why clinical trials of established patients indicate only 60% ACR20 responses with all 10 approved biological agents for RA, and may also explain in part why fewer patients than might be expected are in remission. The data suggest that quantitative assessment of physician VASs to assess inflammation and damage (and distress) may be informative in routine care.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Health Services Research Poster I: Diagnosis, Management and Treatment Strategies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To plan a quality improvement project, we need to understand the practice patterns of physicians. We undertook an online survey of physicians (MDs) (Rheumatologists, Nephrologists and General practitioner) taking care of SLE patients through the Lupus Society of Illinois (LSI) to determine the patterns of medical care provided to SLE patients.

Methods: A 13-item survey was designed to collect data using item development guidelines for surveys. A cover letter explaining the study purpose, improving patient care, was emailed by LSI, and included the link to the survey. This was sent electronically to Rheumatologists and Nephrologists. All data obtained were tabulated; descriptive and stratified data were analyzed using chi square tests and p²0.05 on two-tailed tests.

Results: 86 MD's completed the survey, 97% were Rheumatologists; 46 MDs practiced in academic setting, 27 in private practice, and the remainder in both settings. Mean (SD) age was 55 (12) years. Descriptives for the whole group and stratified by academic or private practice are shown in Table 1. Laboratory tests ordered at each follow up visit were significantly different among academicians as compared to private practice MD's (Table 1). In 8-11% of patients seen in private practice, the laboratory tests ordered routinely at each SLE patient care visit may be unnecessary or avoidable.

Conclusion: There may be avoidable costs associated with laboratory tests ordered at each SLE patient care visit. Physician education about indications for serial routine testing for ANA, ENA and Sjogrens autoantibodies may be indicated to reduce health care costs.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Health Services Research Poster I: Diagnosis, Management and Treatment Strategies
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Willingness to pay (WTP) is a technique used for valuing health benefits and individual preferences. Brazil's national public health system (Sistema Único de Saúde) grants the population access to costly and effective drugs for the management of rheumatoid arthritis (RA). The aim of this study was to establish WTP valuations for highly effective drug treatments in Brazilian RA patients.

Methods: This cross-sectional multicenter study enrolled adult RA patients (ACR 1987 or ACR/EULAR 2010 criteria) from rheumatology outpatient clinics of the Brazilian public health system. Consecutive patients were asked to reveal the maximum monetary value they would be willing to pay, on a monthly basis, for a hypothetical new intravenous drug offering a 90% improvement in their general health, thus a highly effective drug. Two WTP elicitation tools were used: a payment scale and an open-ended format. Demographic, social and clinical data were gathered from each subject. Disease activity was estimated by DAS28 score and physical function was assessed by HAQ-DI. Descriptive statistics were calculated.

Results: From April 2014 to May 2015, 688 patients (87% female) were assessed in eight Brazilian centers from all over the country. Mean disease duration was 12.7 (8.7) years; mean DAS28 = 3.5 (1.4); mean HAQ-DI = 1.23 (0.8). Subjects had a median of 6 (0 to 21) years of schooling and median household income of US$ 610.3 (0 to 7,909.9) per month. Median WTP values were US$ 22.9 (Q1=11.5; Q3=91.6) on payment scale, and US$ 38.2 (Q1=22.9; Q3=76.3) on open-ended format. On payment scale, 4.2% (28/665) of the respondents assigned zero values for WTP. Overall, 12.4% (83/688) of the subjects added commentaries expressing no willingness to pay at all, regardless of the value (if any) assigned to the elicitation tools. The ratio between median WTP value (open-ended format) and median household income was 6.3%.

Conclusion: This study set WTP valuations of highly effective intravenous drug treatments for chronic, moderately active RA, in outpatient clinics of the Brazilian public health system. The typical population attending to those clinics had low educational and income profile, and had free access to health resources, including medicines, seldom expecting to pay directly for their treatment. The stated WTP values were low, in face of the well known high costs of treating RA patients. Nonetheless, as a proportion of household income, WTP values were in line with the average expenditure of Brazilian families with health resources.

Identification and Documentation of Secondary Osteoarthritis in Patients with Primary Inflammatory Arthritides Using a Patient MDHAQ/RAPID3 and a Physician Estimate of Joint Damage to Recognize Patient Complexity and Inform Management Decisions

Kathryn A. Gibson[1], Annie Huang[2], Katherine J. Bryant[3] and Theodore Pincus[2], [1]Liverpool Hospital, Liverpool, Australia, [2]Rheumatology, Rush University Medical Center, Chicago, IL, [3]University of New South Wales, Sydney, Australia

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Health Services Research Poster I: Diagnosis, Management and Treatment Strategies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with inflammatory arthritides may have secondary osteoarthritis (OA), which affects decisions concerning clinical management. For example, in one study, about 20% of patients with DAS28 scores >3.2, suggesting that therapy should be intensified according to treat-to-target, did not have intensification because of clinically important joint damage (1). We analyzed patient MDHAQ/RAPID3 scores and physician RheuMetric checklist estimates of damage (as well as overall global estimate, inflammation and distress) to identify and document secondary OA in patients with inflammatory arthritides seen in a busy clinical setting.

Methods: All patients seen at one rheumatology site complete a MDHAQ/RAPID3, and the rheumatologists complete a RheuMetric physician checklist. The MDHAQ includes scores for physical function (0-10), pain (0-10), and patient global estimate (PATGL) (0-10), compiled into a RAPID3 (0-30) score. The 1-page physician RheuMetric checklist includes a standard 0-10 visual analog scale (VAS) for physician global estimate (DOCGL), and 3 further 0-10 VAS for the levels of inflammation or reversible findings (DOCINF), damage or irreversible findings (DOCDAM), and patient distress (e.g. fibromyalgia, depression) (DOCDIS), as well as primary, secondary and tertiary rheumatic diagnoses. Patients with RA, ankylosing spondylitis, psoriatic arthritis, and inflammatory arthritis were classified as "inflammatory arthritides", and were further classified as having or not having comorbid secondary OA. Mean MDHAQ scores and RheuMetric estimates were computed in the two groups; statistical significance was analyzed using 2-tailed t-tests with significance at $p<0.05$.

Results: Overall, 159 patients with inflammatory arthritides were studied, 31 with secondary OA and 128 with no secondary OA. Patients with secondary OA were older ($p=0.043$) and had marginally lower levels of education ($p=0.267$) (Table). All MDHAQ scores were higher in patients with comorbid OA, significantly for physical function ($p=0.004$) and pain ($p=0.043$). RAPID3 scores were 10.8 (moderate severity) in patients with no secondary OA and 14.1 in those with comorbid OA ($p=0.026$). Mean physician damage estimates were 2.9 and 4.2 in patients with no vs comorbid OA ($p=0.013$), and mean physician overall global estimates were 3.6 and 4.5, respectively, in the 2 groups ($p=0.040$). Physician estimates for inflammation and distress did not differ significantly in the 2 groups (Table).

Conclusion: Secondary OA in patients with inflammatory arthritides can be identified and documented on simple MDHAQ and RheuMetric forms in busy clinical settings. This documentation provides evidence of patient clinical complexity and may explain management decisions in certain patients which appear at variance with "treat-to-target" guidelines.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Health Services Research Poster I: Diagnosis, Management and Treatment Strategies
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Understanding the relative cost of tumor necrosis factor inhibitors (TNFi) can improve resource allocation from a payer's perspective. Limited data exists in the VA System on the cost per treated patient across the commonly used TNFi therapies for chronic inflammatory arthritides (CIA). To determine the annual drug and administration cost to the US Department of Veterans Affairs (VA) for etanercept (ETN), adalimumab (ADA), and infliximab (INF) per treated patient targeting rheumatoid arthritis (RA), psoriatic arthritis (PsA), or ankylosing spondylitis (AS).

Methods: The Veterans Health Administration (VHA) databases were used to identify adult patients with ≥1 claim for ETN, ADA, or INF between Jan 1, 2008 and Dec 31, 2011. The patient's first claim for ETN, ADA, or INF ≥1 year following VA enrollment was the index claim and defined the index drug. Patients were required to have a diagnosis of RA (ICD-9-CM 714.0x), PsA (696.0x), or AS (720.0x) and excluded if they had multiple CIAs codes or other conditions (psoriasis, Crohn's disease, ulcerative colitis, juvenile idiopathic arthritis, non-Hodgkin's lymphoma, or chronic lymphocytic leukemia) treated with these agents during the one year prior to and the 30 days following index. Veterans without claims or ≥1 claim(s) for the index drug during the 180 days pre-index period were classified as initiating or continuing patients, respectively. One-year cost of biologics was calculated based on Federal Supply Schedule (ADA) or Big Four (ETN, INF) pricing as of November 2014. Administration costs were based on VA-specific fixed costs per infusion ($169.09) and dispensing costs for subcutaneously administered ($25) biologics.

Results: A total of 10,065 patients with RA (mean age 61.4, ETN: n=5,149; ADA: n=4,155; INF: n=761), 871 patients with PsA (mean age 56.5, ETN: n=490; ADA: n=334; INF: n=47), and 1,511 patients with AS (mean age 51.8, ETN: n=732; ADA: n=675; INF: n=104) were included in the study. The VA incurred greater cost per treated patient for INF users compared with ADA and ETN users across CIAs. Specifically, the one-year cost per treated patient was$15,056, $16,617, and $16,827 for ETN, ADA, and INF in RA; $15,035, $16,016, and $20,465 for ETN, ADA, and INF in PsA; and $14,239, $14,832, and $18,536 for ETN, ADA, and INF in AS. ETN had lower one-year cost per treated patient compared with both ADA and INF across indications in both the cohort of patients initiating and continuing therapy.

Conclusion: Compared with ETN and ADA, INF had higher annual drug and administration cost per treated patient across the investigated CIAs to the US Department of VA.

Abstract Number: 140

Identifying Psoriatic Arthritis and Ankylosing Spondylitis Patients Responsible for the Highest Costs of Care: Data from a Large US Cohort

Jacqueline B. Palmer, Yunfeng Li, Vivian Herrera and Minlei Liao, Novartis Pharmaceuticals Corporation, East Hanover, NJ

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Health Services Research Poster I: Diagnosis, Management and Treatment Strategies
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: The economic burden of psoriatic arthritis (PsA) and ankylosing spondylitis (AS) in the biologics era is not well understood in the US population. Using a large US medical and pharmacy claims database, we investigated the characteristics, healthcare utilization, costs and treatments of PsA patients with high medical costs.

Methods: Claims data from the MarketScan Commercial and Medicare Supplemental Databases were used to stratify PsA and AS patients into 2 groups based on overall costs: ≥90% quantile (top 10% cost group) and <90% quantile (bottom 90% cost group). Patients included were aged: ≥18 years with ≥2 diagnostic claims for PsA (n=10,832) or AS (n=4,288) between October 1, 2011, and September 30, 2012 (first diagnosis is index date) and were continuously enrolled with medical and pharmacy benefits for 12 months before and after the index date. Baseline demographics, individual comorbidities and an elixhauser comorbidity score were captured. Direct costs included hospitalizations, emergency room and office visits, and pharmacy costs. The Wilcoxon rank sum test was conducted on continuous variables and the chi-square test on categorical variables.

Results: The study included 10,832 PsA patients and 4,388 AS patients. For the PsA top 10% (N=1,083) and bottom 90% groups (N=9,740), mean all-cause medical costs were about 13 times higher $30,591±$51,862 vs. $2,277± $4,138 respectively. Biologics costs were only about 2 times higher $27,254±$18,026 and $12,595±$14,581, respectively. For the AS top 10% (n=428) and bottom 90% groups (n=3,860), mean all-cause medical costs were 20 times higher $42,703±$78,942 vs. $2,491±$4,561, respectively; mean biologics costs were 2 times higher $18,261± $16,048 vs. $10,373±$13,552, respectively. In the PsA cohort, the top 10% cost group was older (mean age 54.7±10.8 y vs 51.6±11.9 y; *P<0.01*), had higher rates of diabetes mellitus (26.5% vs 15.2%, P<0.01), hypertension (43.2% vs 31.4%), hyperlipidemia (29.8% vs 23.8%), and ischemic heart disease (14.4% vs 5.8%) all *P*<0.01. The high cost group also had a higher rate of biologics use (83.4% vs 58.7%; *P<0.01*), compared with the bottom 90% cost group, respectively. The top 10% AS cost group, similarly, was older (mean age 52.1±12.6 y vs 48.7±13.4 y; *P<0.01)* and had higher Elixhauser comorbidities scores (mean, 2.9±2.3 vs 1.8±1.5; *P<0.01*) compared to the bottom 90% cost group, respectively. They also had higher biologics (70.4% vs 50.5%) and oral DMARDS (26.6% vs 21.3%) use all *P*≤0.01, compared with the bottom 90% cost group, respectively.

Conclusion: PsA and AS patients with high costs of care were generally older and more affected by comorbidities than their counterparts with lower costs. Medical costs seem to be the biggest drivers in the high cost subgroup of patients. In AS patients medical costs were almost 20 times higher in the high cost group. PsA high cost patients had 13 times higher medical costs. This study highlights that the majority of patients with AS and PsA have relatively low disease management costs, however there are a subgroup of more costly patients that may require more individual management due to high comorbidity and biologic use.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Health Services Research Poster I: Diagnosis, Management and Treatment Strategies
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Hypertension is the most common and most modifiable cardiovascular disease (CVD) risk factor, yet it is uncontrolled in ½ of US adults. Hypertension management protocols are predicted to save more lives than any other systems intervention. However, hypertension protocols are untested in most specialty clinics. Our prior work reported that rheumatologists addressed high blood pressures (BP) in <1/3 of visits, highlighting the need for effective population management strategies given the link between many rheumatologic conditions and CVD. Our objective was to pilot a protocol intervention to facilitate timely primary care follow up for patients with elevated BP readings at rheumatology visits.

Methods: We implemented a pre-post intervention pilot at three academic rheumatology clinics. All adult (≥18 years-old) rheumatology patient visits with BP ≥140/90 during the intervention period (Nov 2014-May 2015) were compared to all pre-intervention visits with BP ≥140/90 (Jan 2012-Sept 2014). Intervention elements included: (1) Defining elevated BP (≥140/90) and rheumatologic CVD risk for the medical assistant/nursing staff (45 min education) and patients (BP brochure), (2) electronic health record (EHR) alerts for staff to re-measure BPs if ≥140/90 (3) EHR prompting brief patient education and timely follow-up order if 2nd BP confirmed ≥140/90, and (4) individualized feedback for patients (BP recorded on brochure) and staff (monthly audit feedback). We assessed the primary outcome of timely (<4 weeks per Medicare metric) blood pressure follow-up in primary care among patients who received regular primary care in this system allowing EHR tracking. We performed a multivariate logistic regression to compare the bivariate timely primary care follow up outcome pre-post intervention controlling for baseline sociodemographics, comorbidities, visit utilization and rheumatology clinic.

Results: We compared the post-intervention cohort of 649 visits with elevated BPs (≥140/90) to 4,818 visits pre-intervention with elevated BPs. Pre-intervention, <2% of visits had BPs re-measured, versus 67% of post-intervention visits, $p<0.001$. Among patients receiving primary care within the system, 42% of post-intervention patients with confirmed high BP completed timely primary care follow-up versus 29% pre-intervention, $p=0.002$. In multivariate logistic regression, the post-cohort had nearly two-fold higher odds of timely follow-up (OR 1.9, 1.4-2.5).

Conclusion: Our intervention supported usual care rheumatology clinic staff to improve timely BP follow up as a population management strategy to reduce CVD risk in rheumatology patients. We plan to examine the impact of the intervention on patients' awareness of CVD risk, subsequent BP management, and hypertension control. Future work will adapt and test this intervention in other specialties and healthcare systems.

Table 1. Pilot intervention visit-level outcomes with Odds Ratios and 95% CI's

	Pre-Intervention n=4,818	Post-Intervention n=649	p
BP Re-measurement	<2% (77/4818)	67% (433/649)	<0.001
Timely Primary Care Follow-up (<4 weeks)	29% (740/2526)	42% (53/125)	<0.002
Unadjusted OR Timely Follow Up	OR=1.8	(1.2-2.6)	<0.001
Adjusted OR Timely Follow Up	OR=1.9	(1.4-2.5)	<0.001

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Health Services Research Poster I: Diagnosis, Management and Treatment Strategies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Chronic inflammatory arthritis affects around 1% of the general population. Disease-modifying drugs like methotrexate (MTX) and in second-line anti tumor necrosis factor (anti-TNF) therapy are increasingly prescribed, which sometimes puts general practitioners (GP) on the frontline of management for these treatments and their adverse effects. The aim of this study was to explore GPs difficulties with MTX and anti-TNF therapies in routine practice.

Methods:

A questionnaire was sent to 1190 GPs across our local region. We collected and compiled their characteristics, their difficulties in routine practice, and their expectations in terms of facilitating management for these treatments.

Results:

Response rate was 24.9%, i.e. 296 responses, including 11 GPs who refused to participate. Our analysis thus focuses on a dataset of 285 respondents: 57% (n=162) are men, 36% (n=103) are urban-community GPs, 55% (n=157) work in

a medical group clinic. Of the 230 GPs following patients on MTX (81%), 113 report difficulties with treatment-related management, chiefly with how to manage infectious episodes (30% of respondents), the onset of side effects (23% of respondents) and drug interactions (31% of respondents). GPs with less than 10 years in practice experience are more difficulties than GPs with more years in practice (66.7% *vs* 46.6% for 10–30 years in practice and 33.9% for 30-plus years in practice; p=0.002). Just 22% (n=41) of GPs surveyed claimed they are ready to initiate MTX therapy. Of the 189 respondent GPs (66%) following patients on anti-TNF, 127 report exactly the same difficulties but with a higher frequency (infectious complications: 53%; side effects: 29%; drug interactions: 39%). 57.2% of GPs (163/285) perceive anti-TNF therapy have a positive risk–benefit ratio, and 36,2% (105/285) expressed no opinion. 80% of the respondents to this survey (228/285) want dedicated further training.

Conclusion:

This study found that over half of GPs following patients on MTX or anti-TNF therapy experience difficulties managing for these treatments. Dedicated further training on these treatments is a key priority for action.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Health Services Research Poster I: Diagnosis, Management and Treatment Strategies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Fiber optic intubation is the preferred method of airway management during anesthetic procedures for patients with RA. The purpose of our study was to determine the frequency of fiber optic intubation in surgical procedures of patients with RA and cancer.

Methods: All RA patients who attended a preoperative anesthesia consultation at a large cancer center from 2007 to 2014 were eligible for this study. We included adults (> 18 year of age) with diagnosis of RA made by a physician or patients with self-reported history of RA and disease modifying anti-rheumatic drugs (DMARDS) use, including prednisone (past or current). Only first procedure in this time period per patient was included. Cervical spine imaging within 1 year prior to procedure was included. All subluxation reported were reviewed by radiologist for second review and to document to appropriate distances.

Results: In relation to cancer, we found 409 patients (83.4%) had malignancies and 122/409, 29.8% had two or more

cancers diagnosed since admission. A total of 81/490, 16.5% had non-malignant tumors such as thyroid or pancreatic cysts, primary hyperparathyroidism, large lipomas, or benign breast nodules. The patients were followed-up for a mean of 34.5 months (95% CI 32.2 – 36.9). A total of 99 deaths occurred during the period of observation and 3/99 (3%) deaths occurred within 30 days from the date of the procedure. None had spinal cord compression complications. Among those who died, the median age was 67 years (range 36 – 86). Patients who died within 30 days from date of surgery had a median age of 71 years (range 63 – 85) and all three had major surgical procedures: esophagectomy, cystoprostatectomy, or wide neck dissection. Age was not a factor associated with mortality when both groups were compared. Hospital mortality (deaths occurring ≤ 30 days after admission) was 0.6%. None of the patients had spinal cord compression.76% of the patients had imaging done. 12.7% had subluxations C1-C7; 5.3% had RA related C1- C2 subluxation; 8.2% had C2-C7 subluxation. We found different types of RA subluxations: anterior atlanto-axial distance (AAD) in 21 patients was abnormal (3- 13.2 mm); posterior atlanto-axial distance (PAAD) was also abnormal (18-26.8 mm); subaxial distance in 4 patients ranged between 5mm to 16 mm; cranial settling was observed in 3 patients. Other spine abnormalities found were erosions, osteoarthritis, spondylolisthesis, spontaneous fusions, and post-operative fusions. The most common type of intubation was endotracheal in 387 (79.1%). Only 66 out of 492 (13.6%) had fiber optic intubation. There was evidence of neurological post-operative neurological injury in one case (0.2%).

Conclusion: Although fiber optic intubation could reduce the risk of neurological complications in patients with RA and cancer undergoing surgical procedures, few received this airway management. Patients with RA and cancer could be the target of an intervention to educate providers and reduce the risk of neurological complications during surgical procedures. More research is needed to consider this to standardize the airway management in these patients.

One-Year Costs Following Switching Versus Dose-Escalation Among Prevalent Tumor Necrosis Factor Inhibitors Used for Rheumatoid Arthritis

Tao Gu[1], **Derek Tang**[2], Gaurav Deshpande[1], Debra F Eisenberg[1] and David J. Harrison[3], [1]HealthCore, Wilmington, DE, [2]Amgen, Inc., Thousand Oaks, CA, [3]Amgen Inc., Thousand Oaks, CA

Session Date: Sunday, November 8, 2015

Session Title: Health Services Research Poster I: Diagnosis, Management and Treatment Strategies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Switching a biologic treatment or escalating biologic doses are common approaches used upon biologic treatment failure. The objective of this study was to estimate the one-year costs after switching to another tumor necrosis factor inhibitor (TNFi) versus increasing the dose of the same TNFi among patients with rheumatoid arthritis (RA).

Methods: This was a retrospective cohort study using administrative data for individuals in the HealthCore Integrated Research Databases (HIRD^{SM}). Initially, patients were included if they aged 18-63 with ≥1 claim for INF or ADA

between Jul 1, 2009 and Jan 31, 2013, had ≥1 claim for RA during the 6 months prior to INF/ADA initiation, continuously enrolled between 6 months prior to and 12 months following INF/ADA initiation, and were not exposed to RA-related biologics 6 months prior to INF/ADA initiation or another condition for which RA-related biologics were approved to treat. Subsequently, INF/ADA patients switching to ADA/INF or ETN, or increasing the dose of the current drug in the subsequent year after treatment initiation were identified for further evaluation. Dose-escalation was defined for infliximab as having ≥120% of the expected infusions or an increase of ≥100 mg in dose; and for adalimumab as reaching a 40 mg weekly dose. Patients initiating ETN were not included in this analysis because dose-escalation in ETN has not been allowed per the approved US label. Patients who both dose-escalated and switched to a biologic of interest during the one-year follow-up were classified based on the first event. Costs were obtained from plan and patient paid amounts for biologic drug and administration and adjusted to 2013 dollar value.

Results: Of those who initiated ADA (n=1,437), 103 (7.2%) patients switched to INF/ETN and 103 (7.2%) patients increased their dose. Of those who initiated INF (n=539), 18 (3.3%) patients switched to ADA/ETN and 195 (36.2%) patients increased their dose. The average age was 48.6 (±10.2 [SD]) years and 74.7% were female. ADA initiators who dose-escalated on average incurred $8,843 higher costs compared with those who switched to another TNFi ($30,425 vs. $21,582, p<0.0001). INF initiators who dose-escalated on average incurred $9,022 higher costs compared with those who switched ($27,506 vs. $18,483, p=0.0007).

Conclusion: RA patients on ADA or INF incurred significantly higher costs when they dose escalated compared with switching to a new TNFi. The cost implications of increasing dose should be a consideration when making biologic treatment modifications in RA.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Health Services Research Poster I: Diagnosis, Management and Treatment Strategies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Real world studies comparing the healthcare utilization of anti-TNFs vs. non-TNFs as the next alternative after the failure of the first anti-TNF are scarce. This study aimed to compare healthcare costs, resource utilization, and treatment patterns in RA patients who discontinued an anti-TNF and subsequently switched to an alternative anti-TNF versus those who switched to a non-TNF.

Methods: Adult patients who had ≥2 RA diagnoses and used at least one anti-TNF (adalimumab, etanercept, infliximab, golimumab, or certolizumab) on or after initial RA diagnosis were identified from a large commercial

claims database. Patients who switched to an alternative anti-TNF or a non-TNF (abatacept, rituximab, or tocilizumab) following the initial anti-TNF during 2006-2012 were selected into anti-TNF and non-TNF cohorts. The switching date was defined as the index date. Patient and disease characteristics during the 6-month pre-index (baseline) period were compared. All-cause and RA-related healthcare costs and resource utilization over a 12-month post-index (study) period were compared between the two cohorts using multivariable two-part gamma models and negative binomial models, respectively, adjusted for age, gender, region, insurance plan, index year, comorbidities, co-medications, initial anti-TNF and treatment duration. Treatment patterns (switching and discontinuation) were compared using Cox proportional hazards models.

Results: A total of 2,904 and 934 patients were included in the anti-TNF and the non-TNF cohort, respectively. At baseline, patients in the anti-TNF cohort (vs. non-TNF cohort) were younger (50 vs. 51 years, p<0.01), had less comorbidity burden (Charlson Comorbidity Index 1.3 vs. 1.4, p<0.01), and had a shorter initial anti-TNF duration (1.0 vs. 1.3 years, p<0.01). During the study period, all-cause costs were significantly lower for the anti-TNF cohort compared to the non-TNF cohort with medical ($11,474 vs. $15,846; adjusted diff = $4,590; p<0.01) and pharmacy ($24,433 vs. $29,294; adjusted diff =$5,524; p<0.01) costs contributing to the total cost differences ($35,907 vs. $45,139, adjusted diff = $9,654; p<0.01) (Table 1). RA-related costs were also lower in the anti-TNF cohort compared to the non-TNF cohort (Table 1). Patients in the anti-TNF cohort were likely to have fewer outpatient visits (all-cause: 23.4 vs. 30.2 visits/patient/year, adjusted incident rate ratio = 0.77; p<0.01). Inpatient admissions and emergency department utilization as well as discontinuation and switching rates were not significantly different between the two cohorts.

Conclusion: For patients discontinuing anti-TNF therapy, switching to an alternative anti-TNF was associated with lower medical and pharmacy costs, fewer outpatient visits, and similar treatment patterns, as compared to switching to a non-TNF biologic.

Table 1. Healthcare costs (2014 USD) during the 12-month post-index period

	Average Healthcare Costs (mean ± SD)		Adjusted Difference in Average Healthcare Costs (95% CI)

Session Title: Health Services Research Poster I: Diagnosis, Management and Treatment Strategies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Given high cardiovascular disease (CVD) risks in SLE patients, lipid testing and statin prescription are widely advocated for those with elevated risks. We examined rates of lipid testing and statin prescription filling among SLE patients within Medicaid in recent years.

Methods: Within Medicaid Analytic eXtract (MAX), containing billing claims from 2007-10 for Medicaid patients from the 29 most populated US states, we identified patients aged 18-65 years with prevalent SLE (>3 ICD-9 codes of 710.0, >30 days apart). We required 6 months of continuous Medicaid enrollment (baseline period) prior to the 3rd code (index date). Baseline data included age, year, sex, race/ethnicity, US region of residence. Subjects were followed from index date until death, Medicaid disenrollment or end of follow-up (12/31/2010). Within claims, CPT codes identified lipid testing and NDC codes identified statin prescription filling. We calculated rates per 1000 person-years for lipid testing and statin prescription filling, and rate ratios (with 95% CIs) to compare rates between sociodemographic groups. We tested for trends in lipid testing and statin prescription rates over time using Cochrane Armitage tests.

Results: Of 37,999 patients with prevalent SLE, 93% were female. Mean age was 41.2 (+ 12.1) years. Race/ethnicity were: 42% Black, 36% White, 16% Hispanic, 2% Native American. Mean follow-up was 19.4 (+ 12.7) months; 746 patients died. In the entire cohort, 11,969 patients (32%) had >1 lipid testing and 6885 (18%) had >1 filled statin prescription. Lipid testing did not differ by sex, but statin prescription was slightly more frequent among men than women. The highest rates of lipid testing were seen among Hispanic and Asian patients (vs. White), older patients (ages 55-65 vs. younger), those living in the West (vs. other regions), and those receiving corticosteroids (vs. not). (**Table**) The highest rates for filled statin prescriptions were observed in older patients (ages 55-65 vs. younger), and those receiving corticosteroids. Black and Native American patients had lower rates of both lipid testing and statin prescription (vs. White patients). No geographic variation in statin prescribing was seen. Rates of both lipid testing (from 235.1 [227.3, 243.2] to 474.6 [450.9, 499.5] per 1000 person-years, p trend <0.0001) and statin prescription (from 81.7 [77.7, 86.0] to 286.4 [268.4, 305.5] per 1000 person-years, p trend <0.0001) increased significantly between 2007-10.

Conclusion: In this large SLE cohort, 32% of patients had >1 lipid testing and 18% filled > 1 statin prescription between 2007-10. Rates of both lipid testing and statin prescription increased significantly during this time. Rates were higher among older patients and those on corticosteroids. Given high CVD and mortality risks among Black and Native American SLE patients, it is noteworthy that these groups had low rates of lipid testing and statin prescriptions.

Fatigue, Coping, Sleeping Disorders and Productivity Were Still Not Frequently Reported in Rheumatoid Arthritis Trials Published in 2014-2015: A Systematic Literature Review

Levent Kilic[1], Abdulsamet Erden[1], Laure Gossec[2] and Umut Kalyoncu[1], [1]Rheumatology, Hacettepe University Faculty of Medicine, Ankara, Turkey, [2]Rheumatology, Pitié Salpetriere Hospital, Paris, France

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Health Services Research Poster I: Diagnosis, Management and Treatment Strategies
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: In a systematic literature review (SLR), frequency of patients reported outcomes (PROs) related with rheumatoid arthritis (RA) was evaluated between 2005 and 2007 (1). Relatively low frequent outcome measures at this SLR were fatigue, utility, psychological status, coping, sleeping disturbance, productivity losses, wellbeing and leisure. Although pain and function are essential domains for patients, priority of patients also include fatigue,

emotional well-being, sleep, coping and physical well-being (2). Objective of this study was to assess frequency and changing trend of PROs related with RA at the last 2 years.

Methods: Literature search was performed in PUBMED MEDLINE database on 01 January 2015. Publications were identified through a search that used the following exploded MeSH term: (''arthritis, rheumatoid'' (MeSH)) with a limitation to ''humans'', ''all adults: 19+ years'', ''English'', ''published in the last 2 years'' and ''clinical trials''. Publications were limited to articles referenced in PUBMED in the last 2 years. Demographic characteristics of patients, study design, treatments assessed and all PROs assessed. **Results** were compared with previous SLR (1).

Results:Of the 479 publications identified by the literature search, 250 were included in the analysis. Of the 250 publications, 113 (45.2%) were randomized controlled trials. One hundred-forty different tools were reported in this SLR. Function (83.4% vs 68.0%), pain (55.9% vs 40.0%), patient global assessment (63.3% vs 49.2%) and quality of life (19.2% vs 18.4%) were still essential PROs. Frequency of fatigue (13.7 vs 14.4), psychological status (7.3 vs 9.6), productivity losses (5.5 vs 6.4) and sleeping disturbance (1.8 vs 2.4) were not changed over time. On the other hand, frequency of morning stiffness (26.6 vs 10.0), coping (6.4% vs 2.0%) and utility (16.5 vs 5.2) were decreased. Although fatigue assessed with valid tools (VAS 7.2%, FACIT 4.8%), other less frequent domains (psychological status, productivity losses, sleeping disturbance, coping) did not have constant and specific tools for RA.

Conclusion: Eight years later, we still did not determine any significant change about PROs in RA trials. Priority of patients, for instance fatigue, psychological status, productivity losses, sleeping disturbance, coping were not sufficiently appear RA trials. One of the major challenge of those PROs was also related with tools. Tools about psychological status, productivity losses, sleeping disturbance and coping had high heterogeneity and low specificity for RA.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Health Services Research Poster I: Diagnosis, Management and Treatment Strategies

Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: To study the clinical and patient reported outcomes of the Virtual Monitoring Clinic (VMC), which is novel nurse-led telemonitoring cum pharmacy medication home delivery service for monitoring stable Rheumatoid Arthritis (RA) patients treated with disease-modifying antirheumatic drugs (DMARDs).

Methods: Patients with stable RA enrolled into the VMC programme were followed up prospectively. The primary outcomes evaluated at 1-year were: Disease Activity Score-28 (DAS28), Routine Assessment of Patient Index Data 3 (RAPID3), and patient satisfaction score assessed using an 11-point Likert scale.

Results: Of the 251 patients enrolled, 186 completed 1year of follow-up. 2.3% of the annual workload from the specialist outpatient clinic was freed up as a result of the VMC programme. Statistically significant improvement was seen in the mean satisfaction score (7.70 to 8.16, $p<0.05$), with 63% of the patients opting for VMC as their preferred mode of follow-up. There was a marginal increase in mean DAS28 and RAPID3 scores (2.56 to 2.78 ($p<0.05$) and 5.28 to 6.03 ($p<0.05$) respectively). However, given that at 1-year more than 60% (72.0% based on DAS28 scores and 63.4% based on RAPID3 scores) of the patients' condition remained stable or had improved, and the disease was in remission or low activity for the majority of patients (73.1% measured by DAS28 and 53.2% measured by RAPID3), our assessment was that the VMC preserved or improved RA disease activity for the majority of patients.

Conclusion: The VMC is an effective and well-accepted approach for the management of patients with stable RA.

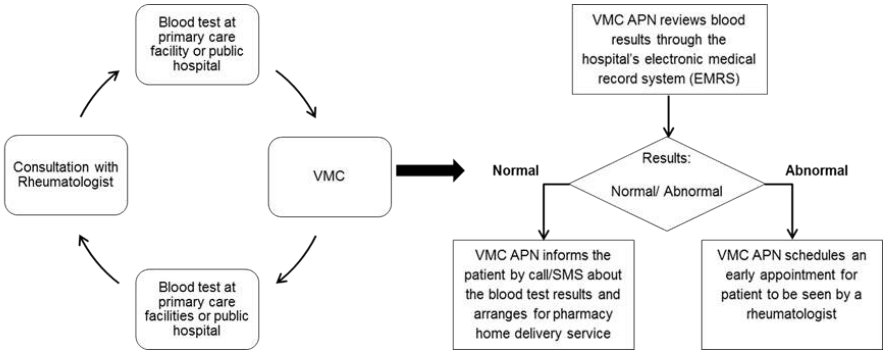

Figure 1. Flowchart illustrating the Virtual Monitoring Clinic (VMC) Workflow

Table 1. Change in the DAS28

	Follow-up DAS28				
Baseline DAS28	Remission	Low Activity	Moderate Activity	High Activity	Total
Remission	66 (65.3)	23 (22.8)	11 (10.9)	1 (1.0)	101 (54.3)
Low Activity	13 (26.5)	19 (38.8)	17 (34.7)	0 (0)	49 (26.3)
Moderate Activity	5 (14.3)	10 (28.6)	20 (57.1)	0 (0)	35 (18.8)
High Activity	0 (0)	0 (0)	1 (100)	0 (0)	1 (0.5)

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Health Services Research Poster I: Diagnosis, Management and Treatment Strategies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Belimumab, a B-lymphocyte stimulator, was FDA-approved March 2011 for the treatment of adult patients with active, autoantibody-positive SLE receiving standard of care (SOC) medications. Using data from a large, privately-insured US administrative claims database, we sought to identify and characterize a cohort of SLE patients who initiated belimumab treatment.

Methods: A retrospective cohort analysis was conducted in the US Truven Health MarketScan® Commercial Claims and Encounters Database (study ID 204489). Patients were aged 18-64 years at first belimumab infusion (index date) during the study period (2010 - end of available 2014 data). SLE diagnosis was based on ICD-9 code 710.0 documented prior to/on index date. We included patients with complete medical and pharmacy benefits ≥6 months prior to and ≥12 months after the index date. Demographic and clinical characteristics, SOC medication use, healthcare utilization and estimates of SLE disease and flare severity during the 6 month pre-index period were evaluated. Belimumab discontinuation was defined as ≥84 day gap in infusions.

Results: N=762 patients met the inclusion criteria. Mean age at index date was 44 years (SD 11) and 94% were female. Pre-index period diagnosed co-morbidities included musculoskeletal (67%), cardiovascular (41%), central nervous system (39%), mucocutaneous (27%), hematologic (22%) and lupus nephritis (7%) disease. Medications prescribed in the pre-index period included oral corticosteroids (73%), antimalarials (66%), immunosuppressants (60%) and NSAIDs (30%); not mutually exclusive. In the pre-index period, ~80% of patients were prescribed ≥2 SOC medications (excluding NSAIDs), and the mean prednisone-equivalent dosage for the cohort was 7.3 mg/day (SD 13.7); 34% had a mean prednisone-equivalent dose ≥7.5 mg/day. Healthcare utilization in the 6-month pre-index period included ≥1 inpatient visit (12%), emergency department visit (28%) and outpatient procedure (47%) or laboratory test (48%). A disease severity algorithm estimated mild, moderate, and severe disease in the pre-index period for 32%, 55%, and 13% of patients, respectively. Ninety-four percent experienced ≥1 flare in the pre-index period, with the most severe flare classified as mild (17%), moderate (71%) and severe (12%). Mean number of belimumab infusions in the post-index period was 12 (SD 9), with mean 11 months of belimumab use (SD 9). Belimumab was discontinued by

25% of patients during the ≥12-month post-index period, and 60% of patients received belimumab for ≥6 months.

Conclusion: In this large sample of belimumab treatment initiators, there was a high frequency of oral corticosteroid/immunosuppressant use in the 6 months prior to initiating belimumab treatment. Polytherapy was the norm, but ~20% were on either one medication or none. Prior to belimumab treatment, most patients had moderate to severe disease, and nearly all experienced ≥1 flare. More than 50% of patients continued belimumab treatment for ≥6 months. Reasons for discontinuation were not ascertainable in this data source, and future analyses are planned to assess the comparative effectiveness of adding belimumab to SOC treatment.

A Preliminary Consensus on Core Outcome Domains for Total Joint Replacement Clinical Trials: An Omeract-Based Study

Jasvinder A. Singh[1] and Michael Dohm[2], [1]University of Alabama at Birmingham, Birmingham, AL, [2]Orthopaedic Surgery, Univ of Arizona, Tucson, AZ, Tucson, AZ

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Health Services Research Poster I: Diagnosis, Management and Treatment Strategies

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Outcomes Measures in Rheumatology Trials (OMERACT) has developed a framework based on the WHO's International Classification of Functioning, Disability, and Health (ICF) conceptual model. It proposes four core areas to assess the impact of disease, namely Death, Life Impact, Resource Use/Economic Impact and Pathophysiological Manifestations and within each area to select one or more domains applicable to every condition of interest. The objective of this study was to perform a survey of important stakeholders to develop preliminary recommendations for core domains to be reported in TJR clinical trials.

Methods:

We surveyed two groups of experts, who rated potential core domains (mapped to Outcomes Measures in Rheumatology Trials (OMERACT) filter 2.0 framework) for their relevance to TJR clinical trials during the 2014 American Academy of Orthopaedic surgeons [AAOS] and the 2014 OMERACT meetings. Ratings were on a 1 to 9 scale, 1-3 indicating domain of limited importance, 4-6 being important, but not critical domain, and 7-9 being critical domain.

Results:

17 stakeholders at the AAOS and 19 stakeholders at OMERACT meeting completed the survey. At the two meetings,

86% and 36% were arthroplasty researcher/surgeons, 0% and 10% were patients and 58% and 31% were 55 years and older, respectively. The following domains were rated as candidates for critical core domains by both groups, with a median score of 7 and above (median score from AAOS vs. OMERACT): Joint pain (9 vs. 9), functional ability (8 vs. 9), joint-specific quality of life (8 vs. 7), patient satisfaction (7 vs. 8), revision surgery (8 vs. 7), adverse events (9 vs. 8), death (9 vs. 7.5), serious adverse events (8.5 vs. 8), reoperation (8 vs. 8), and cost (7 vs. 7).

Table 1. Preliminary Core Areas/Domains for TJR Clinical Trials	AAOS Median [IQR]	OMERACT Median [IQR]	Both combined Median [IQR]
Ratings for the Main Domains to be reported in every TJR clinical trial			
Joint Pain	9 [8, 9]	9 [9, 9]	9 [8, 9]
Function or functional ability (ability to function in society, work; work productivity, employability; disability; work disability)	8 [8, 9]	9 [8, 9]	9 [7, 9]
Generic Quality of life (including fatigue, sleep, mood, stress, anxiety, depression)	6 [4, 9]	7 [5.75, 8.25]	7 [5, 8]
Joint-specific Quality of life	8 [7, 9]	7 [5, 7.25]	7 [6, 8]
Patient Satisfaction (satisfaction with the outcome, satisfaction with the procedure)	7 [5, 8]	8 [7, 9]	7.5 [5.75, 9]
Patient expectation of surgical outcome	5 [4, 8]	5 [4, 7]	5 [4, 7]
Revision surgery	8 [6, 9]	7 [7, 9]	8 [6, 9]
Adverse events	9 [8, 9]	8 [7, 9]	8 [7, 9]
Death	9 [8, 9]	7.5 [5, 9]	8 [6, 9]
Ratings for Additional domains for consideration			
Serious Adverse events	8.5 [7, 9]	8 [8, 9]	8 [7, 9]

Residual Synovitis in Ultrasound (US) Is Associated with an Evolution Towards Rheumatoid Arthritis (RA) in Patients with Inflammatory Polyarthralgia without ANTI-Citrulinated Antibodies (ACPA)

Pascal Zufferey[1,2,3], Claudia Rebell Jr.[4], Alexandre Dumusc[5], Mauro lucini[4], Juerg Hains[6], Alexander K. So Sr.[7] and Charles Benaim[8], [1]Rheumatology, Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland, [2]Pierer Decler, Chuv, Lausanne, Switzerland, [3]Rhu /Dal .Chuv, Rheumatology, Lausanne, Switzerland, [4]DAL, RHU/CHUV, lausanne, Switzerland, [5]RHU/CHUV, lausanne, Switzerland, [6]DAL, RHU/CHUV, Lausanne, Syria, [7]Service De Rhumatologie, CHUV, Lausanne, Switzerland, [8]DAL, MPR, Lausanne, Switzerland

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Imaging of Rheumatic Diseases Poster I: Ultrasound, Optical Imaging and Capillaroscopy
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

In ACPA positive patients, subclinical synovitis as observed by US has been demonstrated in pre RA patients and seems to be predictive for future development of RA [1]. No such study has yet been conducted in ACPA negative patients.

The primary aim of the study was to assess the value of the US as a screening tool to detect early joint involvement in ACPA- patients complaining of polyarthralgia and to analyse whether such subclinical synovitis is predictive for the future development of an inflammatory disease, in particular RA. The secondary aims were to look for additional clinical and biological predictors of RA development in ACPA- patients

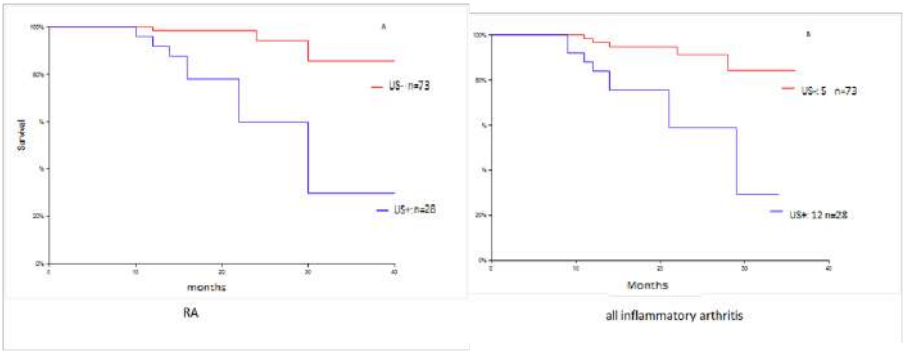
Methods:

This is a retrospective observational study of 101 consecutive ACPA- patients with poly-arthralgia who did not meet the ACR / EULAR 2010 criteria for RA or classification criteria for another inflammatory rheumatology disease before the US examination. These patients were all seen in investigation in our ambulatory unit between 2009 and 2013. To detect significant US synovitis, we applied the criteria of the SONAR score validated among RA patients and controls [2](total B mode score >8, > 2 synovitis: grade 2). For the follow-up, the same diagnostic criteria as baseline were used.

Results:

At baseline (30%) had significant synovitis according to the SONAR criteria. The mean (SD) follow-up time was 18 (7) months in both groups. 17 patients developed a clear inflammatory arthritis (11 RA, 6 another inflammatory arthritis disease). Significant US synovitis at baseline was significantly associated with evolution to RA: 7/28 versus 4/69 (<0.005), sensitivity: 64% specificity: 76%, LR: 2.7. Elevated CRP and clinical synovitis appeared to be additional

predictors of such an evolution. Figure depicts the arthritis free curves (a: before RA, b: before all inflammatory arthritis) according to the presence or not of US synovitis at baseline



Conclusion:

Our study suggests that US can be used as a predictor for the evolution to RA in patients presenting inflammatory polyarthralgia without ACPA.

Anti-CCP Positive Patients without Clinical Synovitis Progress If Ultrasound Positive

Jackie L. Nam[1], Elizabeth M.A. Hensor[1], Laura Hunt[1], Philip G. Conaghan[2], Richard J. Wakefield[1] and Paul Emery[3], [1]NIHR-Leeds Musculoskeletal Biomedical Research Unit and Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom, [2]University of Leeds & NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds, United Kingdom, [3]NIHR-Leeds Musculoskeletal Biomedical Research Unit, University of Leeds, Leeds, United Kingdom

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Imaging of Rheumatic Diseases Poster I: Ultrasound, Optical Imaging and Capillaroscopy

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

To determine whether ultrasound can identify which anti-cyclic citrullinated peptide (anti-CCP) antibody positive

patients with musculoskeletal (MSK) symptoms and without clinical synovitis progress to inflammatory arthritis (IA).

Methods:

In a prospective study, anti-CCP positive patients with new nonspecific MSK symptoms and no clinical synovitis underwent imaging with ultrasound of 32 joints (wrists, MCPs and PIPs of the hands and MTPs of the feet) and were monitored for the development of IA. Grey scale (GS) and power Doppler (PD) findings were scored 0-3 using a standard semi-quantitative method. Cox proportional hazards regression was used to measure associations between (1) the baseline ultrasound findings and subsequent diagnosis of IA using the set of 32 joints and (2) the baseline ultrasound findings within each joint and subsequent development of clinical synovitis within that joint.

Results:

Consecutive patients (n=136; mean age 51 years, 100 females) were followed up for median 18.3 months (range 0.1-79.6). At baseline, 96% had GS and 30% had PD signal in ≥1 joint(s). IA developed in 57(42%) patients after median 8.6 months (range 0.1-52.4). Patients with PD≥2 were at higher risk of progression to IA than those without PD [75% (15/20) vs. 31.9% (29/91), hazard ratio (HR) (95% CI) = 3.7(2.0, 6.9), p<0.001], and progression occurred earlier (median 7.1 vs. 52.4 months). Patients who scored GS ≥2 in the wrists and/or hands at baseline were at higher risk of developing IA than those with no GS in those joints [HR (95% CI) = 2.3(1.0, 4.9), p=0.038]. At the individual joint level, the trend for progression to clinically-detected synovitis was more significant [HR (95% CI) = 31.3(15.6, 62.9), p<0.001 for PD≥2 and HR (95% CI) = 9.4(5.1, 17.5), p<0.001 for GS≥2].

Conclusion:

Ultrasound features of joint inflammation may be detected in anti-CCP positive patients with MSK symptoms without clinical synovitis. Our findings suggest that ultrasound findings predict progression to clinical disease. The risk of clinically-detected synovitis is particularly high in joints showing power Doppler signal.

Utility of Ultrasound Synovitis Assessment As a Predictor of Flares in Clinically Inactive Joints

Tomas Cazenave[1], Christian A. Waimann[2], Natalia Zamora[1], Gustavo Citera[1] and Marcos G. Rosemffet[1], [1]Rheumatology, Instituto de Rehabilitación Psicofísica, Buenos Aires, Argentina, [2]Rheumatology, Hospital Dr. Hector Cura, Olavarria, Argentina

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Imaging of Rheumatic Diseases Poster I: Ultrasound, Optical Imaging and Capillaroscopy

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Several ultrasound (US) studies have shown a high frequency of inflammation in clinically

inactive joints of rheumatoid arthritis (RA)patients. There is controversy in the conduct to be followed in these situations, raising the question of whether a change in the therapeutic approach can prevent the clinical flare of this joints. ***Objective:***To determine the utility of US assessment of clinically inactive joints to predict short-term joint flares in patients with RA.

Methods: :A cohort study including patients with diagnosis of RA (ACR-EULAR 2010 criteria) was designed. Patients were evaluated at baseline and at 3 months, including clinical and ultrasonographic examination of 28 joints. Power Doppler (PD) signal and grayscale (GS) synovitis were graded from 0 to 3, according to standards OMERACT, yielding an overall US score (US-global) resulting from addition of both scores (range 0 -6, 6 being the highest degree of US synovitis). At baseline, the joints were classified as active vs. inactive according to clinical examination (swollen vs. non-swollen). Baseline inactive joints of patients who did not change their treatment were identified. Primary endpoint was defined as the presence of joint clinical flare (development of joint swollening in physical examination in a previously non-swollen joint) at three months follow-up. To evaluate the ability of US to predict joint flare multivariable logistic regression using the US score at baseline as the independent variable adjusted by the presence or absence of joint pain was developed. Based on the multivariate model, the area under the curve (AUC) and the probability of having a joint flare for the different levels of basal US involvement was calculated.

Results: We included a total of 49 patients. The disease duration was 8 ± 5 years, 85% were women, with a mean age of 53 ± 10 years.The mean of DAS28 was 4.8 ± 1.5. A total of 1372 joints were assessed, of which 1079 (79%) were clinically evaluated inactive. These joints showed a mean overall US score of 0.6 ± 0.8 (PD = 0.1 ± 0.3; GS = 0.5 ± 0.6). In patients without treatment variations between visits (n=24; 49%), 518 non-swollen joints at baseline were analyzed separately. Of these joints, 28 (5%) developed a flare at 3 months. In multivariate analysis the presence of pain and the grade of US involvement at baseline were associated with greater likelihood of joint flare (OR: 3.5; 95%CI=1.1-11.4 and OR: 2; 95%CI=1.4-2.9, respectively). **Figure 1**shows the probability of developing joint flare at 3 months according to the US baseline score and the presence of pain.

US Score	Probability of flare	
	Pain present	Pain absent
6	87%	65%
5	77%	48%
4	62%	32%
3	45%	19%
2	29%	10%
1	17%	5%

Conclusion: US evaluation could be helpful for decision-making in non-swollen joints. The likelihood of developing a flare at three months varies from 5% to 87% depending on the US findings and the presence of joint pain.

Session Date: Sunday, November 8, 2015

Session Title: Imaging of Rheumatic Diseases Poster I: Ultrasound, Optical Imaging and Capillaroscopy

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Up to 20% of patients with RA have coexisting fibromyalgia(FM). This can make treatment decisions challenging in clinical practice as disease activity scores can be high despite limited clinical evidence of active synovitis. Recent work has suggested that a tender joint count (TJC) minus swollen joint count (SJC)(each out of 28) of ≥7 identifies patients with co-existing FM ('fibromyalgic' RA) with high sensitivity and specificity. Ultrasound (US) of joints particularly power Doppler is predictive of outcomes in RA patients. The aim of this study was to determine whether RA patients with active disease also meeting existing criteria for fibromyalgia had significantly less joint inflammation on ultrasound than those who did not.

Methods: 47 RA patients with DAS28 scores >2.6 were recruited. Patients completed questionnaires including the Widespread Pain Index(WPI), PHQ9(depression), GAD7(anxiety), PHQ15(somatisation), FACIT-fatigue, HAQ and global health assessment VAS. The TJC, SJC, Symptom Severity Score(SSS) and the number of FM soft-tissue tender points were recorded by a physician. Patients underwent a 22-joint US scan by a second blinded physician of the wrists, MCPJs and PIPJs bilaterally. Grey scale(GS) and power Doppler(PD) scores were recorded for each joint on a semiquantitative scale (0-3) for each patient. FM patients were grouped according to the ACR 1990 classification criteria and TJC-SJC >7 individually and in combination. Differences between groups were tested using the Mann-Whitney U test. Significance was set at $p<0.05$

Results: GS scores were significantly lower in patients meeting ACR (GS score 16.7,p=0.025), TJC-SJC (16.7,0.034) or both criteria (15.4, 0.022) than in those who did not (21.8). PD scores were not significantly different for the individual criteria but when combined the scores for patients meeting both criteria were significantly lower compared with patients not meeting these criteria (PD score 2.94 vs 8.33, p=0.028). Significantly higher scores were seen for depression, anxiety, disability and somatization scores in patients meeting either or both FM criteria compared with those who did not.

Conclusion: Our findings show that RA patients who meet the 1990 ACR criteria for FM and who have a TJC minus SJC of ≥7 have significantly lower levels of synovitis on GS and PD US. This suggests that it may be possible to use clinical measures to identify patients not in DAS28 clinical remission into those with higher or lower levels of synovitis on US. Thus there may be a role for composite tools in clinical practice to stratify patients into those who may benefit from continued escalation of immunosupression and those who may benefit from alternative management strategies focussing on improving levels of depression, anxiety and fatigue. We are currently conducting a larger study to explore this further.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Imaging of Rheumatic Diseases Poster I: Ultrasound, Optical Imaging and Capillaroscopy

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Currently, one of the main goals of rheumatoid arthritis (RA) treatment is to attain remission. Stricter criteria as CDAI, SDAI ACR/ EULAR Boolean have been proposed. Patients with RA, who achieve clinical remission may have residual joint inflammation, which can be detected by ultrasonography (US). However the degree of agreement that stricter criteria present with US findings in patients in remission is not well known, especially on feet assessment. The aim of this study was to assess subclinical synovitis by US and to evaluate the degree of agreement between the remission status as measured by different strict criteria and the absence of activity using US of hands and toes.

Methods: US examination was performed consecutively on 100 patients with RA fullfiling 2010 ACR EULAR criteria

that were in clinical remission (DAS 28-ESR<2.6) for at least 6 months. We evaluated if strict criteria were met (CDAI, SDAI, Boolean, Boolean without VAS general health patient). A rheumatologist specialized in musculoskeletal US, blinded to clinical activity, performed a systematic evaluation on grayscale and power Doppler technique with multifrequency linear transducer (10-18MHz) in longitudinal and transverse sections. The radiocarpal joint, second and third metacarpophalangeal, second and third proximal interphalangeal in both hands and second to fifth metatarsophalangeal joints were assessed bilaterally. Absence of activity was defined as absence of exudative synovitis grade II and III, and power Doppler grade II and III in all the evaluated joints.

Results: 100 US were performed in 1.800 joints of 100 patients. 80% were women (n = 80) and the mean age was 52.7 standar desviation (SD) 12. There were no differences in age, sex, disease duration, treatment, or rheumatois factor andanti-citrullinated protein antibodies positivity between patients with ultrasound activity and without it. The mean DAS28-ESR was 2 SD 0,47, 22% were receiving biologic therapy, the mean disease duration was 8.5 IQR 5-14 years and the mean duration of remission was 11.3 months SD 6. Table 1 shows the remission status in the evaluated patients. Table 2 shows the degree of agreement among different criteria and the absence of activity assessed by ultrasound of hands and feet.

Table 1

	Ultrasound with activity in hands	Ultrasound with activity in foot	Ultrasound without activity in hands	Ultrasound without activity in foot
	n (%)	n (%)	n (%)	n (%)
Remission by B*oolean* n:45	26 (58)	8 (18)	19 (42)	37 (82)
Remission by *Boolean* without VAS n:71	30 (42)	18 (25)	41 (58)	53 (75)
Remission by SDAI n:70	34 (48)	19 (27)	36 (52)	51 (73)
Remission by CDAI n: 62	51 (82)	17 (27)	11 (18)	45 (72)

Table 2

Remission criteria	Agreement	CI 95
Boolean ACR/EULAR	k- 0,1	-0,3-0,09
Boolean without VAS	k 0,4	O,22-0,53
SDAI	k 0,27	0,11-0,42
CDAI	k -0,07	-0,21-0,07

Conclusion: Residual joint inflammation was detected by US in patients in clinical remission on both hands and feet. There was no agreement between the remission status measured by the strict criteria and the absence of activity assessed by US of hands and feet in this study population. Only acceptable agreement was found in hands, with the Boolean criteria that excludes VAS.

Session Date: Sunday, November 8, 2015

Session Title: Imaging of Rheumatic Diseases Poster I: Ultrasound, Optical Imaging and Capillaroscopy

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: It has been seen that patients with rheumatoid arthritis (RA) who achieve remission measured by DAS28 persist with subclinical synovitis in hands and toes when evaluated by ultrasound (US). Unfortunately US is not available in every rheumatology center. Recently, strict criteria like the CDAI, SDAI and ACR EULAR Boolean have been proposed. Therefore it would be interesting to know the accuracy of each set of crteria for assessing the absence of sublinical activity. The aim of this study was to evaluate the accuracy of CDAI, SDAI and ACR EULAR Boolean criteria in RA patients using as gold standard the absence of activity detected by US.

Methods: US examination was performed consecutively on 100 patients with RA fulfilling 2010 ACR EULAR criteria and that were in clinical remission (DAS 28-ESR<2.6) for at least 6 month. Then we evaluated if strict criteria were met (CDAI, SDAI, Boolean). A rheumatologist specialized in musculoskeletal US, blinded to clinical activity, performed a systematic evaluation on grayscale and power Doppler technique with multifrequency linear transducer (10-18MHz) in longitudinal and transverse sections. The radiocarpal joint, second and third metacarpophalangeal, second and third proximal interphalangeal in both hands and second to fifth metatarsophalangeal joints were assessed bilaterally. It was considered as a case if absence of grade II-III exudative synovitis and / or Power Doppler II-III using OMERACT's definitions was found. We defined controls as the ones with at least one of these signs of activity. We evaluated the sensitivity, specificity, positive likelihood ratio, positive predictive value (PPV) and negative predictive value (NPV).

Results: One hundred US were performed in 1.800 joints of 100 patients. 80% were women (n = 80) and the mean age was 52.7 SD 12 and the mean DAS28-ESR was 2 SD 0,47. There were no differences in age, sex, disease duration, treatment, or rheumatoid factor and anti-citrullinated protein antibodies positivity between patients with ultrasound activity and without it. 22% were receiving biologic therapy and the mean disease duration was 8.5 IQR 5-14 years and the mean duration of remission was 11.3 months SD 6. Of the US screening 58 didn't have signs of activity and 42 had synovitis and / or PD grade II-III. Table 1 shows the status of activity and Table 2 shows the results.

Table 1

	Ultrasound without activity in hands and toes
	n (%)
Remission *by Boolean* ACR/EULAR criteria n:45	16 (36)
No Remission by *Boolean* ACR/EULAR criteria n:55	26 (47)
Remission by SDAI n:70	29 (41)
No remission by SDAI n:30	13 (43)
Remission by CDAI n: 62	26 (41)
No remission by CDAI n:38	16 (42)

Table 2

	Sensitivity	Specificity	PPV	NPV	Positive LR
	% (CI 95)	% (CI 95)	% (CI 95)	% (CI 95)	
Boolean	38 (29-48)	50 (40-60)	36 (26-45)	53 (43-63)	0,8 (0,5-1,2)
ACR/EULAR					
CDAI	62 (53-71)	38 (28-47)	42 (32-52)	58 (48-68)	1 (0,8-1,3)
SDAI	69 (60-78)	29 (20-38)	41 (32-51)	57 (47-66)	1 (0,8-1,3)

Conclusion: We found that in this population, which is in remission by DAS28, no one of the three set criteria is of great value for detecting the absence of activity when using US as gold standard.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Imaging of Rheumatic Diseases Poster I: Ultrasound, Optical Imaging and Capillaroscopy
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Different remission criteria are available for patients with rheumatoid arthritis (RA). None of the criteria includes imaging remission, even though studies have shown that many RA patients in sustained clinical remission have synovitis detectable by ultrasound (US), i.e. grey scale synovial hypertrophy and/or Doppler signal in the synovium.

We aim to investigate the agreement between different clinical remission criteria and remission defined by US in patients with RA receiving biological therapy in routine care.

Methods: A total of 117 RA patients in sustained remission (i.e. DAS28 $\leq$2.6 for $\geq$ 1 year and no radiographic progression the last year) on biological therapy were recruited. All patients underwent US of 24 joints for grading of grey scale (GS) synovial hypertrophy (0-3) and synovial Colour Doppler activity (CD) (0-3). Imaging remission was defined in two ways: either GS=0 and CD=0 in all 24 joints, or GS$\leq$1 and CD=0 in all 24 joints.

Results: Baseline characteristics are shown in table 1. At baseline patients received the following disease-modifying antirheumatic drugs (DMARDs): methotrexate (MTX; 72%), sulphasalazine (3%), azathioprine (2%), leflunomide (2%), no DMARDs (21%) and the following treatment with biological therapy: abatacept (2%), adalimumab (28%), certolizumab (3%), etanercept (28%), golimumab (3%), infliximab (27%), tocilizumab (9%).

For patients fulfilling DAS28 remission criteria, US defined remission was present in 9% (GS=0 and CD=0 in all 24 joints, termed “very strict” US remission) or 29% (GS $\leq$ 1 per joint and CD=0 in all 24 joints, termed “strict” US remission) and 24% had CD>1 in at least 1 joint (table 1). For patients fulfilling other criteria for clinical remission (CDAI, SDAI and ACR/EULAR remission), patients were in very strict US remission in 12%, 12% and 10%, respectively and in strict US remission in 28%, 29% and 20%, respectively. CD activity > 1 in at least 1 joint was present in 22%, 25% and 22% of patients, respectively. The anatomical distribution of the GS synovial hypertrophy was 31% in metacarpophalangeal joints, 27% in metatarsophalangeal joints, 19% in wrists, 10% in knees, 7% in elbows and 6 % in ankles. Thus, 33% of the total GS synovial hypertrophy was observed in the feet, which are not included in the DAS28 remission criteria.

There were no significant differences in US findings (GS or CD) between patients in remission vs patients not in remission, no matter which clinical remission criteria were used.

Conclusion:

Subclinical synovitis was frequently detected by US in RA patients treated with biological drugs in routine care showing poor agreement between the clinical remission criteria and US remission. Further studies are needed to evaluate the benefit of US remission as a goal for treat to target strategies on patient-reported outcomes and radiographic progression.

Tabel 1: Baseline characteristics and agreement between clinical remission and ultrasound remission

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Imaging of Rheumatic Diseases Poster I: Ultrasound, Optical Imaging and Capillaroscopy

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Musculoskeletal ultrasound (MUS) allows for direct visualization of diverse pathologic features such as cortical bone erosions, synovial thickening, and synovial vascularity in the joints affected by rheumatoid arthritis (RA) with high sensitivity, specificity, and accuracy. Therefore, MUS can be a highly sensitive tool for the evaluation of disease activity in RA. However, disease activity in RA is currently measured using traditional clinical measures such as disease activity scores (DAS-28), Clinical Disease Activity Index (CDAI), Simplified Disease Activity Index (SDAI) and Routine Assessment of Patient Index Data (RAPID-3). A limited number of studies have attempted to correlate the measures of clinical disease activity with ultrasound scores.

Purpose: To assess the correlation of different clinical activity scores with a standardized semi-quantitative US score of the dominant hand in RA patients.

Methods: This was a single center study of patients from the RA clinic at the University of Rochester. The DAS-28CRP, CDAI and SDAI are collected as a standard of care in an established RA clinic. Recently, we added RAPID 3 and offered MUS evalaution for all RA patients seen in this clinic. Clinical measures were done by AA and LGM and MUS by RT and BM. MUS was done using a GE Logiq (2014) and the following joints were assessed: dorsal wrist, 2nd, 3rd, 4th and 5th MCPs and the 2nd, 3rd, 4th and 5th PIP. MCP joints 2-5 were scanned from a dorsal aspect, and PIP joints 2-5 were scanned from a volar aspect. The scans were retrospectively scored for presence of synovitis on gray scale and the presence of Power Doppler signal (0=none; 1=mild; 2=moderate and 3=severe) for each joint, with a total score for the hand ranging from 0-54.

Results: To date, a total of 20 patients have completed all the clinical and ultrasound assessments. This cohort is comprised of 11 females and 9 males, of which 17 were sero-positive and 11 had erosive disease. The median age was 62. Scores for all parameters were available for 18 subjects (2 images could not be retrieved). In this cohort, a total of 11 patients were in remission based on DAS-28, 3 had LDA, 3 had moderate disease activity and 1 was with severe disease activity. Using CDAI, we noted that 6 patients were in remission, 7 were with LDA, 4 had moderate and 1 severe disease activity scores. By SDAI criteria, we recorded 7 in remission, 7 with LDA, 3 with moderate and 1 with severe disease activity. Based on RAPID-3, only 4 were in remission, 4 had LDA, 3 moderate and 7 had severe disease activity. The median MUS scores correlated with disease activity scors for remission, LDA, moderate and severe disease activity by DAS-28, CDAI and SDAI as shown in Table 1.

Conclusion: MUS of the dominant hand of patients with RA can provide an easy, inexpensive and accurate measure of disease activity in RA patients. MUS additionally provides the ability to visualize joint damage.

Table 1: median MUS scores for each level of clinical disease activity

	Remission	LDA	Moderate	Severe
DAS-28CRP	1	5	7	24
CDAI	2	4	9	24
SDAI	0.5	4.5	11	24
RAPID-3	0	3	9	6

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Imaging of Rheumatic Diseases Poster I: Ultrasound, Optical Imaging and Capillaroscopy

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Power Doppler Ultrasound (PD) is widely used to assess the activity of rheumatic diseases (especially in Rheumatoid Arthritis). Up to now a series of qualitative / semiquantitative scales have been proposed in order to facilitate a reliable evaluation of a PD image most of them in two to four steps. A true quantitative assessment of PD image is rarely done; in most of the cases it is performed by manual selection of the worst case scenario frame (i.e. the frame with the highest amount of Doppler signal) from a recorded cine-loop. The feasibility of this technique is questionable: in a previous work we demonstrated the inferiority of manual vs. computerized selection both in terms of quality of the process and the time spent. However the independent software solutions for quantitative analysis of Doppler image (i.e. the analysis of the total number of colorized pixels from a region of interest) are now available; we are able to measure in a timely manner not just the ratio between the colorized and grey pixels (CTR) from a certain region in a single frame but all CTRs of all frames captured in a cine-loop (Continuous Quantitative Assessment – CQA). The objective of our study was to assess the ability of CQA technique to identify changes of PD signal earlier than the classical semiquantitative assessment.

Methods:

24 cases of active RA have been examined according to AIUM guidelines for dorsal aspect of radiocarpal and midcarpal joints. A cine-loop of 4 seconds has been recorded for each case before the administration of an i.v. dose of dexamethasone and after 0.5, 1, 2, 6 and 24 hours. All the recordings have been evaluated independently both in semiquantitative (SQ) and in CQA technique (by using a registred software (RETINA®). For CQA we computed mean and peak CTRs. C-reactive protein was measured before and after 24 hour of therapeutical intervention: a 20% decrease defined the reponders. A one-way repeated measures ANOVA was conducted to determine whether there were statistically significant differences between SQ and CQA scores. Responsiveness of SQ and CQA scores was calculated using Relative Reduction (RR) over time.

Results: 23 cases presented a 20% decrease of CRP level and have been included in the analysis. The therapeutic intervention elicited statistically significant changes in SQ and CQA scores for synovitis (tenosynovitis was not included in this study) as described in the table.

Timepoint	No of responders identified by SQ	No of responders identified by Mean CQA	No of responders identified by Peak CQA	P (SQ vs Mean CQA)
0	NA	NA	NA	NA
0.5	0	2	2	<0.05
1	1	4	5	<0.05
2	1	7	8	<0.05
6	2	9	9	<0.05
24	4	12	15	<0.05

The responsiveness of SQ was inferior to any CQA score ($p<0.05$). However the mean and peak CQA scores correlated well (0.78 for $p<0.001$) – no separate scores seems to be needed.

Conclusion:

To the best of our knowledge, this is the first study to document the difference between semiquantitative and continuous quantitative PD assessment techniques. The CQA seems to offer the opportunity to identify the therapeutic response earlier than the current approach. The method should be tested in different therapeutic scenarios and in larger groups, too.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Imaging of Rheumatic Diseases Poster I: Ultrasound, Optical Imaging and Capillaroscopy

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Cine-loop analysis is an ultrasound technology that allows the acquisition of images in a digital form as a sequence of a determined frame number. The images can be reviewed as many time as necessary in order to identify the one with the highest level of information. **Up to now, in musculoskeletal sonography, this was the prefered technique**used to select the best Doppler frame (i.e. the image with the highest level of Doppler signal). The frame is subsequently analyzed in quantitative way (the proportion of total colorized pixels from the total number of existing pixels in a definite region). In order to compare the quantitative Doppler data from different time points a very precise selection of the best Doppler image from a recorded cine-loop is needed. Our study examined the ability of both experienced and in-training sonographers to select the best Doppler image from such a cine-loop using a computerized analytical system as gold standard.

Methods:

The study analised 480 frame selections done in two distinct exercises as following: twenty cine-loops have been recorded using standardized scans; one region of interest (ROI) was marked on each scan and the colorized pixels / total pixels ratio (CTRatio) was computed for each frame of the loop by using an independent software (Retina®). From each loop a number of 4 different frames have been extracted: the one with the highest CTR (named CTR100) and 3 with 5%, 10% and respectively 20% lower level of CTR (named CTR95, CTR90 and CTR80) . All frames emerged from the same loop have been randomly presented to six experienced and six in training sonographers; the request was to select the frame with the highest CTR from each package (twenty packages in total). A similar exercise was performed with CTRs decreasing in steps of 2% (CTR100, CTR98, CTR96, CTR94).

Results:

In the first exercise the CTR100 have been correctly identified in 79.1% cases while in 15.8% of cases CTR95 have been wrongly indicated as CTR100 and in 4.6% of cases theCTR90 was selected. In the 2ndexercise the subjects indicated as CTR100 the following frames: CTR100 in 67% of CTR98 in 18.3%, cases, CTR 96 in 11,6% and CTR94 in 3.1% of cases.

The experienced sonographers performed better than in=training colleagues in both exercises (correct selection in 95 to 75% of cases vs. 90 to 50% of cases in 1st exercise, respectively 90 to 65% of cases vs 75 to 45% of cases in the 2nd exercise).

Conclusion:

Using the computerized analyses as the gold standard, we demonstrated a large heterogeneity across sonographers regarding their ability to identify the best Doppler image (i.e. the one with the highest CTR) even from a small group of frames. The ability is even more questionable when the differences are small. When the quantitative Doppler signal is assessed in the same patient at different timepoints this lack of ability might induce a significant error. When computerized analyses is feasible it should be used in place of the manual selection.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Imaging of Rheumatic Diseases Poster I: Ultrasound, Optical Imaging and Capillaroscopy
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

To determine hand disability and articular damage in patients with Rheumatoid arthritis (RA) and to define their relation with musculoskeletal ultrasonography (US) findings, clinical and laboratory parameters.

Methods:

The study included 43 RA patients (22 women, 21 men) with a mean age of 55.72±11.76 years. Demographic and clinical parameters including disease duration, duration of morning stiffness, number of tender and swollen joints were recorded. Grip strength, lateral, tip and three-fingered pinch of the dominant hand was measured. The rheumatoid arthritis articular damage (RAAD) score was used to assess the articular damage and deformities of the dominant hand. Hand disability was assessed by special hand disability index (HDI) of Standford Health Assessment Questionnaire (HAQ) and upper extremity Quick Disabilities of Arm, Shoulder, and Hand (QuickDASH) questionnaire was applied to evaluated the disability of upper extremity. C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) were evaluated as laboratory parameters. Musculoskeletal ultrasonography (US) was performed in the selected joints: wrist, metacarpophalengeal (MCP) MCP I, II,III and proximal interphalengeal (PIP) PIF I, II and III; which are most likely to be affected by RA. The presence of synovitis and tenosynovitis and erosions were examined by the grey-scale US (GSUS) and also the presence of synovitis and tenosynovitis in the selected joints were examined by power Doppler US (PDUS).

Results:

GSUS sinovitis sum score was correlated with RAAD, QuickDASH, (respectively r=0.315, p=0.039, r=0.744, p=0.001) GSUS tenosinovits sum score was correlated with RAAD, HDI, DASH, and disease duration (respectively r=0.448, p=0.003, r=0.281, p=0.068, r=0.400, p=0.008, r=0.367, p=0.016). GSUS erosion sum score was correlated with RAAD and disease duration (respectively r=0.403, p=0.007, r=0.455, p=0.002), PDUS tenosinovitis sum score was correlated with lateral pinch and tip pinch (respectively r=0.335, p=0.037, r=0.310, p=0.055).

Conclusion:

Our results suggest that pinch measurements, hand disability, articular damage scores seem to be the most related variables with US findings. Therefore US assessment of the dominant hand should be included in the evaluation and follow-up of the patients with RA.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Imaging of Rheumatic Diseases Poster I: Ultrasound, Optical Imaging and Capillaroscopy

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Ultrasonography (US) is increasingly accepted as an important tool in diagnosis and management of rheumatoid arthritis (RA). However, it is not well known to what extent US adds information to clinical examination at the individual joint level. Our objective was to assess concordance between clinical joint examination and US in detecting synovitis at the individual joint level in a cohort of early RA patients.

Methods: 228 patients with early RA who fulfilled the 2010 ACR/EULAR classification criteria were recruited at 11 Rheumatology centers between 2010 and 2013. Patients were required to have symptom duration <2 years (from onset of joint swelling) and to be DMARD na•ve with indication for DMARD treatment. 44 joints were assessed for swelling by a rheumatologist or trained research nurse. US examinations were performed by experienced and well-calibrated sonographers, using a validated gray-scale (GS) and power Doppler (PD) semi-quantitative scoring system with scores 0-3 for GS and PD in each of the following 36 joints: MCP 2-5, radio-carpal (RCJ), distal radio-ulnar (DRUJ), inter-carpal (ICJ), PIP 2-3, elbow, knee, talo-crural and MTP 1-5 bilaterally. We defined US synovitis (US+) as GS ³2 and/or PD ³1. For the wrist the US comparison with clinical joint swelling included one or several of the RCJ, DRUJ and ICJ. Joints were assessed bilaterally and analysed on an aggregated level. Kappa values between clinical joint swelling and US synovitis were calculated for all joints. We specifically assessed the proportion of joints with US synovitis that were not clinically swollen, and vice versa.

Results: The mean age (SD) of the 228 patients was 51.1 (13.8) years, mean (SD) disease duration 7.1 (5.4) months and 62.3% were female. Mean (SD) DAS was 3.47 (1.13) the median (25, 75 percentiles) number of swollen joints was 9 (4, 14), and the median (25, 75 percentiles) number of joints with US synovitis was 7 (3,11). A total of 8208 joints were examined by US. Agreement between US and clinical examination was best in the elbow, wrist and knee (kappa 0.68, 0.53, 0.51, respectively). The proportion of joints with US synovitis that were not clinically swollen ranged from 16% (PIP2) to 76% (MTP1). The six joints with the largest and smallest discrepancies are presented in the table. Similarly, a significant proportion of clinically swollen joints had no US synovitis, ranging from 23% (wrist and elbow) to 70% (ankle).

Table: Comparison of US synovitis and clinical joint swelling in selected joints*						
Joint		Swollen	Not Swollen	Kappa	Proportion of joints with US synovitis and no clinical swelling	Proportion of swollen joints without US synovitis
MTP1	US+	35	112	0.18	76%	43%
	US-	26	282			
MTP5	US+	30	66	0.30	69%	43%
	US-	23	337			
MCP4	US+	28	53	0.33	65%	46%
	US-	24	351			
Wrist	US+	139	62	0.53	31%	23%
	US-	42	213			
PIP3	US+	90	21	0.42	19%	53%
	US-	100	245			
PIP2	US+	100	19	0.45	16%	50%
	US-	100	237			
*Joints are sorted by the proportion of joints with US synovitis and no clinical swelling.						

Conclusion: In this study of patients with early RA we found the level of agreement between US and clinical examination to be somewhat higher in medium to large joints compared to small joints. However, substantial discrepancies between clinical joint swelling and US pathology were found for most joints, and these findings support that US provides additional information compared to clinical examination in most joint areas.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Imaging of Rheumatic Diseases Poster I: Ultrasound, Optical Imaging and Capillaroscopy

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Though rheumatoid arthritis (RA) commonly affects ankle joints, ankle joints are not included in widely used composite measures of disease activity with 28-joint counts. Furthermore, precise clinical examination (CE) is difficult because of its complex anatomical structure. Aim of this study is to clarify the utility of ultrasonographic assessment (US) for evaluating ankle joints by means of comparison to CE in daily clinical practice for RA.

Methods: Sixty RA patients (female 85.0%, age 60.9 ± 15.2 y.o., disease duration 6.92 ± 8.02 years, DAS28-ESR 3.93 ± 1.63) were included. US, CE and patient's visual analog scale for pain (pVAS) of each bilateral ankle were assessed. Bilateral tibiotalar joints and three tendon sites (anterior sites; tibialis anterior, extensor hallucis longi, extensor digitorum longi, medial sites; tibialisposterior, flexor digitorum longi, flexor hallucis longi, lateral sites; peroneus longi and brevis) were assessed by gray scale (GS) and power Doppler (PD) US. Intra-articular synovitis(synovitis) and tenosynovitis were separately assessed using semiquantitative grade (0-3). Positive US findings were defined as GS score ≥2 and/or PD score ≥1, and positive CE findings were defined as joint swelling and/or tenderness.

Results:

A total of 120 ankles were evaluated. Positive US findings were found in 19 (15.8%) tibiotalar joints, 5 (4.2%) anterior sites, 16 (13.3%) medial sites, 13 (10.8%) lateral sites, respectively. When positive US findings were defined as a gold standard, sensitivity and specificity of positive CE findings were 0.68 and 0.81 for synovitis, respectively, and 0.76 and 0.88 for tenosynovitis, respectively. The concordance rate of CE and US were poor ($\kappa = 0.39$) for synovitis, whereas were moderate ($\kappa = 0.58$) for tenosynovitis. When we devided the cases into 4 groups based on the existence of synovitis and tenosynovitis, the group with both US-based synovitis and tenosynovitis showed the highest pVAS (Table). Positive CE findings were highly detected in the joints where US tenosynovitis was positive.

Table. pVAS and clinical examination of ankle among the groups divided according to US-based ankle involvement.

US findings	n	pVAS*	Swollen**	Tender**
Synovitis (-), Tenosynovitis (-)	89	10.8±19.2	9 (10.1%)	6 (6.7%)
Synovitis (+), Tenosynovitis (-)	6	33.3±29.1	2 (33.3%)	1 (16.7%)
Synovitis (-), Tenosynovitis (+)	12	41.2±28.1	9 (75.0%)	7 (58.3%)
Synovitis (+), Tenosynovitis (+)	13	73.2±21.6	8 (61.5%)	6 (46.2%)

＊ P<0.0001 ANOVA test, ＊＊P<0.0001 Kruskal-Wallis test

Conclusion: CE and pVAS often reflect tenosynovitis rather than intra-articular synovitis. US sensitively detects RA involvement in the ankle joints, particularly intra-articular lesions, which are often missed by CE.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Imaging of Rheumatic Diseases Poster I: Ultrasound, Optical Imaging and Capillaroscopy

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Ankle involvement is frequent in rheumatoid arthritis (RA), with at least 90% of patients affected anytime during the disease course though ankle involvement may often be subclinical. *Imaging, especially ultrasound (US), plays a fundamental role in ankle assessment, given that it assesses both joint and peri-articular soft tissue inflammation. Considering that* ankle involvement in RA is underrecognized we decided to investigate the prevalence and characteristics of subclinical ankle involvement in patients with RA by US.

Methods: Sixty-two RA patients without clinical history of ankle involvement and 60 healthy age and sex-matched controls were included. Both RA patients and healthy controls underwent clinical examination including a 28 joint assessment and a comprehensive ankle assessment to exclude tendon or joint involvement. Age, gender, disease duration, visual analogue scale (VAS) for pain and global activity, body mass index (BMI), Disease Activity Score for 28 joints (DAS28), rheumatoid factor (RF), anti-CCP antibodies, erythrocyte sedimentation rate (ESR) and C-Reactive Protein (CRP), were also recorded.

All participants underwent US examination, which was performed by experienced sonographers using both greyscale and power Doppler (PD) technique. Ankles were scanned at the anterior, medial and lateral views, in transverse and longitudinal scans recording the following US pathological findings: exudative or proliferative tenosynovitis/synovitis, presence of peritendinous, intratendinous or intra-articular PD and tendinous ruptures. All US scanning techniques and definitions were used as proposed by the EULAR working group for musculoskeletal ultrasound and OMERACT ultrasound task force.

Results: Sixty-two patients with RA were included (40 female) and 60 healthy sex and age-matched controls. Subclinical ankle involvement was found in 25 of 62 RA patients (40.3%). In 13 ankles (4 intra-articular, 6.45%, and 9 peri-articular, 14.5%) a positive PD was found. In the control group, ankle involvement was seen in 10 (16.6%) patients, with a statistically significant difference (p=0.03) with respect to the study group. No PD was found in this group (p=0.03). Tibio-talar joint proliferative synovitis with positive PD signal, and proliferative tenosynovitis of the tibialis anterior, tibialis posterior and peroneous longus were more frequently seen in the RA group (p=0.002). No correlation between DAS28 and ankle US findings was seen (r=0.13), though DAS28 and the total number of joints with positive PD showed a tendency for positive correlation (r=0.270). No correlation was found between BMI, RF or ACPA with any US finding (r=0.136).

Conclusion: Our results indicate that both grayscale US and PD findings suggestive of subclinical ankle involvement were more frequently found in RA patients. The use of US should be strongly recommended to avoid underestimating ankle involvement in RA patients.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Imaging of Rheumatic Diseases Poster I: Ultrasound, Optical Imaging and Capillaroscopy

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

We have previously reported that patients with subclinical synovitis defined by synovial hypertrophy grade >2 (SH>2) plus power Doppler (PD) signal had higher disease activity, higher levels of serum inflammatory/angiogenic biomarkers [Ramírez J, Arthritis Research and Therapy 2014 Jan 8;16(1):R5] and less were on corticosteroid treatment. The aims of this study were to validate this ultrasound criteria for subclinical synovitis (SH>2+PD) in a different cohort of patients with chronic inflammatory polyarthritis in clinical remission on anti-TNF therapy.

Methods:

Patients diagnosed with RA or polyarticular PsA in clinical remission (DAS28-ESR<2.6) on anti-TNF therapy were included. Ultrasound scans of both hands were performed in all patients, with scoring of Synovial hypertrophy (SH) (grades 0-3) and power Doppler (PD) (grades 0-3). Angiogenic and proinflammatory cytokines were determined by Multiplex ELISA in patients with RA and PsA in remission and compared with the levels of two control cohorts: 22 active RA patients (DAS28>3.2) and 20 healthy controls.

Results:

We included 77 patients [47 PsA and 30 RA, mean age (standard deviation, SD) 57.3 (11.5) years, disease duration 15.7 (8.3) years, DAS28 1.85 (0.41), time of remission 4.2 (3.3) years] of whom 42 were on etanercept, 25 adalimumab and 10 on infliximab. Forty (51.9%) patients were on monotherapy and 38 (49.3%) were receiving tapered doses of TNF antagonists.

Globally, 31 patients had PD signal and 12 had SH>2 plus PD, meeting the criteria of ultrasound-defined subclinical

synovitis. Despite no clinical differences were found, patients with criteria of sonographic subclinical synovitis had significantly higher levels of IL-6, IL-20, PIGF and SDF1.

Interestingly, the serum biomarker profile in PsA in remission was similar to the healthy control, whereas serum biomarker profile in RA in remission was more similar to that of active RA patients.

11 out of 30 RA patients in clinical remission (p=0.0001) versus only 1 PsA patient met criteria for sonographic subclinical synovitis. In line with these findings, significantly more PsA patients were receiving tapered dose of biologics (63.8%), and more frequently as monotherapy (72.3%), compared with RA patients in clinical remission (26.6% and 20%, respectively).

Conclusion:

We have shown that sonographic criteria for subclinical synovitis in patients with chronic inflammatory polyarthritis in remission are useful to identify patients with higher burden of local and systemic inflammation. It remains to be demonstrated if patients meeting that criteria have a higher rate of joint flare and radiographic progression. Finally, our findings suggest that clinical remission under anti-TNF therapy is qualitatively better in PsA than in RA.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Imaging of Rheumatic Diseases Poster I: Ultrasound, Optical Imaging and Capillaroscopy

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Tenosynovitis is frequent in rheumatoid arthritis (RA) patients. One study indicates that tenosynovitis detected by modern imaging has prognostic value with respect to subsequent radiographic progression. The OMERACT ultrasound

(US) study group has in 2012 proposed a new tenosynovitis scoring system. However, the validation of the score is limited, eg. the sensitivity to change during treatment has not been tested.

In a 6-months follow-up study of 51 RA patients with ultrasonographic tenosynovitis, initiating treatment intensification with disease-modifying anti-rheumatic drug (DMARD) and/or biological treatment, to validate the semi-quantitative OMERACT US-scoring system of tenosynovitis by testing its interreader reliability, sensitivity to change, and comparison to clinical evaluation.

Methods:

Fifty-one RA patients, planned for treatment intensification, were included: 43 women (age: mean 55.6; standard deviation (SD) 13.1) and 8 men (mean 49.1; SD 9.34). Thirty-four patients were anti-rheumatoid factor positive and 30 had early RA (duration <1 year). US (by grey-scale (GS) and color Doppler (CD)) and clinical assessment of the flexor and extensor tendon sheaths of the clinically most affected hand and foot was performed at baseline and after 3 and 6 months. Tenosynovitis was assessed using the semi-quantitative scoring system (0-3) proposed by the OMERACT US group for GS and CD calculating a sum score (0-39) for each patient. In 20 patients, US was done independently by 2 physicians at baseline and 6 months, to assess the inter-observer agreement. A GE Logiq E9 with a linear 6-15 ML probe was used. CD frequency was 7.5 MHz, a pulse repetition frequency = 0.4 and gain just below the noise limit. The same Doppler settings were used for all examinations. A binary score for clinical tendon involvement(0-1) was also performed at the same locations as the US score, with reference to published recommendations, calculating a sum score (0-13).

Results:

The interreader agreement, as assessed by the intra-class correlation coefficient (ICC) was very good at baseline (Bas) and for changes (Ch) for GS sum scores (ICC Bas=0.89 ; Ch=0.89) and CD (ICC Bas=0.95 ; Ch=0.90) tenosynovitis. The smallest detectable change (SDC) for change in scores was 0.97 for GS and 0.93 for CD. Tenosynovitis scores had decreased significantly at months 3 and 6 (Table 1). The sensitivity to change, as expressed by the standardized response mean from month 0-6, was high for GS and CD tenosynovitis (0.90 and 0.76, respectively), and moderate (0.59) for the clinical score (Table 1).

Conclusion:

The semi-quantitative OMERACT ultrasound scoring system of tenosynovitis showed high inter-observer agreement and sensitivity to change for both GS and CD.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Imaging of Rheumatic Diseases Poster I: Ultrasound, Optical Imaging and Capillaroscopy

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Gaenslen's test positivity is characterized by tenderness upon lateral compression (squeezing) of the metacarpophalangeal (MCP) or metatarsophalangeal (MTP) joints. Joint ultrasonography (US) is a useful clinical tool that has increasingly been applied in routine practice in Rheumatology, given its sensitivity over clinical examination for detection of inflammation. The aim of this work was to evaluate the agreement between Gaenslen's test and MTP US findings.

Methods: Consecutive patients referred to the Early Arthritis Clinic in the Rheumatology Unit, in whom arthritis was identified and feet US performed, were included. The following parameters were assessed at the first consultation: (1) spontaneous pain reported by the patient; (2) squeeze test of the MTPs joints; (3) ultrasound MTP synovitis defined as ≥ grade 2 synovial hyperthrophy and/or ≥ grade 1 power-Doppler, identified by an experienced sonographer. Chi-square and Cohen's kappa tests were used to analyse concordance between both methods.

Results: One hundred patients (200 feet) were included (64% women and a mean age of 53±16 years) with half of the patients referring forefoot symptoms spontaneously. None of them presented Morton's neuroma in US, and significant hallux valgus was identified in 8 feet (4%). The Gaenslen's test was positive in 45.0% cases. Among patients with negative Gaenslen's test, 83.6% were free of US changes. The agreement proportion was lower when Gaenslen's test was positive, with 44.4% having normal US. This difference of proportions was statistically significant ($Chi2=33.882$; $p<0.001$; $Kappa=0.401$), revealing a sensitivity and specificity of 73.5% and 69.7%, respectively. A negative predictive value of 83.6% was obtained for Gaenslen's test.

Conclusion: In this study a negative Gaenslen's test of MTP corresponded to a normal US in 84% of the cases. Thus, Gaenslen's test has a high negative predictive value, and may be used as a screening test to exclude MTP involvement in patients with Early Arthritis, without the need for US examination. Positive Gaenslen's test is not regularly related with US abnormalities and may, therefore, justify US examination. Further studies with larger samples are warranted.

Table 1. Distribution of patient's feet, according to squeeze test and ultrasound of MTPs

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Imaging of Rheumatic Diseases Poster I: Ultrasound, Optical Imaging and Capillaroscopy

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Few prospective ultrasound (US) cohort studies of rheumatoid arthritis (RA) patients treated by biologic or targeted synthetic DMARDs (b/tsDMARDs) are reported. We have been prospectively investigating the course of active RA patients by US after b/tsDMARDs being introduced in Kyushu region, Japan from June, 2013. This is an interim report to explore the characteristic of RA patients classified as therapeutic responders evaluated by US after b/tsDMARDs being introduced.

Methods: A total 150 RA patients were consecutively recruited from 12 rheumatology centers in Kyushu region in Japan from June 2013 to June 2015. They gave their informed consent to be subjected to the protocol that was approved by the Institutional Review Board of Nagasaki University. Disease activity was consecutively evaluated by both US and clinical composite measures such as DAS28, SDAI every 3 months after introduction of b/tsDMARDs therapies. Twenty-two joints including MCP, PIP and wrist joints of bilateral hands were assessed by US for gray scale (GS) and power Doppler (PD) on semi-quantitative scale from 0 to 3 (each total scores from 0 to 66, respectively). The present

data come from the first 6 months observation. We divided the patients into 2 groups by the mean total US scores at 6 months and the patients, total GS or PD score lower than the mean, were classified as therapeutic responders evaluated by US (US responders). We tried to find the characteristic of US responders at 6 months by multivariate logistic regression analysis.

Results: Eighty-six (30 patients in TNF inhibitors, 30 patients in tocilizumab, 23 patients in abatacept, 3 patients in tofacitinib, respectively) out of 150 patients, who completed the first 6 months observation, were evaluated. In overall, total GS and PD scores improved significantly at 6 months as compared to the baseline ($p < 0.001$, respectively). The mean total GS scores at 6 months were 8 (declined from 13 at baseline) whereas PD scores were 3 (declined from 8 at baseline), respectively. Among the baseline variables including age, gender, disease duration, ACPA (%), RF (%), the use of prednisolone (%), the use of MTX (%), bDMARDs-naïve (%), ESR (mm/hr), CRP (mg/dl), DAS28-ESR, SDAI, total GS score and total PD score, multivariate logistic regression analysis identified that total GS score at baseline (odds ratio 0.84, 95% C.I. 0.76-0.92, $p < 0.001$) is the only predictor of GSUS responder at 6 months. In case of PD, total PD score at baseline (odds ratio 0.86, 95% C.I. 0.77-0.94, $p < 0.001$) and bDMARDs-naïve (odds ratio 3.83, 95% C.I. 1.29-12.32, $p = 0.015$) were the predictors of PDUS responder at 6 months.

Conclusion: The clinical characteristic of patients at baseline involves in US disease activity at 6 months treated by b/tsDMARDs. Physicians are recommended to pay attention to this information to consider the efficacy of DMARDs therapies.

Session Title: Imaging of Rheumatic Diseases Poster I: Ultrasound, Optical Imaging and Capillaroscopy
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: The feet are often involved in rheumatoid arthritis (RA), but physical examination of the metatarsophalangeal (MTP) joints to detect arthritis is challenging especially in case of obesity, oedema and

malalignment. Ultrasound has proven to be more sensitive than physical examination to detect (subclinical) synovitis in the MTP joints. Our aim was to determine the frequency of subclinical synovitis in the MTP joints by ultrasound among patients in DAS28 remission or low disease activity, and to assess the evolution of ultrasound synovitis in the feet and DAS28 over time in newly diagnosed RA patients who are treated to target.

Methods: A multicentre cohort of newly diagnosed RA patients (ACR 1987 criteria) was followed prospectively for one year. Patients were treatment naïve for synthetic DMARDs, biological DMARDs and glucocorticoids, and symptom duration was less than one year. All patients were treated to target with regular visits. Demographics, clinical (SJC28, TJC28) and laboratory (ESR, RF, ACCP) parameters were recorded at each visit. Ultrasound examination of the dorsal aspect of MTP2-5 joints was performed at baseline, three months and one year. Images were scored on greyscale (GS;0-3) and power Doppler (PD;0-3). An ultrasound positive MTP joint was defined by GS>1 and/or PD>0. Simple descriptive statistics were used and longitudinal course of DAS28 and number of ultrasound positive MTP joints were plotted for each patient.

Results: At baseline, 174 patients were included of whom 159 completed one year follow-up. At baseline, 109 (73%) patients had at least one ultrasound positive MTP joint. Overall, mean(sd) DAS28 decreased from 4.9(1.3) at baseline to 2.3(1.2) at one year, while the number of ultrasound positive MTP joints decreased from median(interquartile range) 1(0-4) at baseline to 0(0-0) at one year. Discordance in evolution of DAS28 and ultrasound positive MTP joints over one year was seen in 9 patients (6%). After one year of follow-up, 98 (62%) patients were in DAS28 remission (DAS28<2.6) of whom 23 (23%) still had at least one ultrasound positive MTP joint. Twenty-nine patients had low disease activity (DAS28≤3.2) of whom 7 (24%) had at least one ultrasound positive MTP joint.

Conclusion: Most patients (94%) improved both in DAS28 score and number of US positive MTP joints during follow-up. However, 23% of the early RA patients in DAS28 remission still had ultrasound synovitis in at least one MTP joint at one year. Monitoring of MTP joints by ultrasound and subsequent steering of treatment might be considered to prevent for example progressive radiological damage.

Table 1. Baseline characteristics and ultrasound findings

	Visit 1 (n = 174)
Age, mean (sd) years	55 (14)
Women, %	64
RF positive, %	66
ACCP positive, %	60

	Visit 1 (n = 174)	*Visit 2 (n = 165)*	*Visit 3 (n = 159)*
DAS28, mean (sd)	4.9 (1.3)	2.9 (1.3)	2.3 (1.2)
SJC, median (IQR)	6 (3-11)	1 (0-4)	0 (0-1)
TJC, median (IQR)	6 (2-10)	1 (0-4)	0 (0-2)
ESR, median (IQR)	27 (12-47)	10 (5-22)	8 (3-17)
DAS28 remission, %	5	43	62
DAS28 LDA, %	7	16	18

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Imaging of Rheumatic Diseases Poster I: Ultrasound, Optical Imaging and Capillaroscopy
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Joint destruction is the primary lesion by bone and cartilage damage in RA. By X-ray examination, cartilage destruction is evaluated as a joint space narrowing, although it is not the direct evaluation of cartilage itself. The aim of the study was to clarify the relationship between the finger joint cartilage evaluated by ultrasound (US) imaging and clinical characteristics in RA.

Methods: We examined 29 RA patients in clinical remission (DAS28-CRP < 2.6). The cartilage layer of metacarpophalangeal (MCP) and proximal interphalangeal (PIP) joints for 2nd to 5th fingers was bilaterally visualized from a dorsal view, with joints in approximately 90 degrees flexion. Cartilage thickness (CT) was measured with

integrated tools on static images, and thickness was compared with other clinical and laboratory parameters.

Results: CT in MCP joints ranged from 0.0 to 0.8 mm (average 0.4 mm), and CT in PIP ranged from 0.0 to 0.5mm (average 0.2mm), respectively. The sum of total CT from 8 fingers ranged from 2.7 to 6.8 mm (average 4.8 mm). CT measured by ultrasound was not correlated with age, DAS28-CRP, functional disability score, positivity of rheumatoid factor and anti-CCP-antibody. However, there was significant relationship between CT and disease duration (r=-0.438, p=0.017). Moreover, CT was reduced in RA patients with elevated serum matrix metalloproteinase-3 (MMP-3) values compared with those with normal MMP-3 values (4.2 versus 5.0, p=0,046).

Conclusion: The US method of direct visualization and quantification of cartilage in MCP and PIP joints can be valid and useful in RA, and our results supported the importance of MMP-3 in the pathophysiology of cartilage destruction.

Session Title: Imaging of Rheumatic Diseases Poster I: Ultrasound, Optical Imaging and Capillaroscopy

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Calprotectin (S100A8/9, MRP8/14) has been demonstrated as a promising biomarker of clinical and laboratory disease activity in rheumatoid arthritis (RA). In addition, two small previous studies have shown that calprotectin might by associated with ultrasound-determined synovitis [1,2]. The aim was to evaluate associations between calprotectin and conventional disease markers as well as ultrasound parameters of disease activity in a larger cohort of RA patients.

Methods:

A total of 160 patients with RA (128 females, median disease duration 4.8 years) were recruited in this study. All patients underwent clinical (DAS28, CDAI, SDAI) and ultrasound examination (German US-7 score) [3]. The levels of serum calprotectin and CRP were measured at the time of ultrasound assessment. Clinical and laboratory measures were correlated with ultrasound findings using Spearman´s correlation coefficient. Multiple regression analysis was used to determine the predictive value of calprotectin, CRP and DAS28 to determine GS and PD synovitis scores.

Results:

We found that calprotectin was significantly associated with DAS28 (r=0.332, p<0.001), SDAI (r=0.318, p<0.001), CDAI (r=0.294, p<0.001) and particularly with CRP levels (r=0.551, p<0.001). Moreover, calprotectin significantly correlated with GS (r=0.366, p<0.001) and PD synovitis scores (r=0.350, p<0.001). In multiple regression analysis, DAS28 and calprotectin, but not CRP, were strong predictors of GS (β=0.598, p<0.001; β=0.371, p<0.001, resp.) (adjusted R2=0.680) and PD synovitis scores (β=0.379, p<0.001; β=0.346, p<0.001, resp.) (adjusted R2=0.633).

Conclusion:

Calprotectin is associated with clinical, laboratory and ultrasound parameters of synovial inflammation and may have an additional role in monitoring disease activity in RA.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Imaging of Rheumatic Diseases Poster I: Ultrasound, Optical Imaging and Capillaroscopy

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic, inflammatory disease that is complicated by accelerated atherosclerosis associated with the risk of adverse cardiovascular (CV) events and death. Traditional risk factors do not fully explain the increased CV risk in RA. RA-related inflammation that is responsible for joint damage may be implicated in the development of accelerated atherosclerosis. Carotid intima-media thickness (cIMT) has been

approved as a surrogate marker of early atherosclerosis. The goal of the study was to assess (1) prospectively cIMT in patients with established RA, (2) the relationship between cIMT and RA activity estimated by clinical examination and ultrasonography of joints.

Methods: The study group consisted of 40 consecutive RA patients, 33 (82,5%) female and 7 male (17,5%) with the mean (SD) age 52.3 (9.8) (range 24-68) and disease duration 18.6 (9.6) years (range 6.5-45). The assessment of cIMT was performed twice, in the space of six years (the initial in 2008 and consecutive in 2014) and was determined by high-resolution B-mode ultrasonography. The activity of RA was estimated by clinical examination [with disease activity score in 28 joints (DAS28)] and ultrasonography of joints (synovial hypertrophy in 24 small joints). At the consecutive visit, high disease activity was observed in 7 (17,5%) patients, and low RA activity or remission in 23 (57,5%). Most patients, 35 (87,5%) were treated with biological disease modifying antirheumatic drugs (DMARDs) during the six years period and only synthetic DMARds were used in 5 (12,5%) patients.

Results: The mean (SD) cIMT value was significantly greater at consecutive than initial assessment [0.86 (0.45) vs 0.75 (0.13) mm, p= 0.02]. The number of RA patients with advanced atherosclerosis (presence of plaques) increased from 6 (15%) at the initial to 9 (22,5%) at the consecutive assessment (NS). The number of patients without atherosclerosis (cIMT < 0.6 mm) deceased from 4 (10%) at the initial to 3 (7,5%) at the consecutive assessment. The value of cIMT correlated positively with the age of patients (p< 0,001) and the two cIMT values correlated with each other (p=0,01). There was no correlation between cIMT value and parameters of RA activity (DAS28 and synovial hypertrophy in ultrasonography). There was a positive correlation between DAS28 value and the number of joints with synovial hypertrophy assessed in ultrasonography.

Conclusion: During the six-years course of established RA, progression of atherosclerosis was observed, estimated by significantly greater mean cIMT value, as well as increased number of patients with atherosclerotic plaques. Progressive atherosclerosis occurred in spite of intensive RA treatment, including biological DMARDs. The process seems to be dependent on the age and was not correlated with the current RA joint activity.

Session Title: Imaging of Rheumatic Diseases Poster I: Ultrasound, Optical Imaging and Capillaroscopy

Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Recent studies have shown the relationship between psoriasis (Ps) and subclinical atherosclerosis (athero). Currently, a new automated ultrasound software, based on radio frequency, called RF-QIMT technology ,proved to be a useful method for assessing subclinical atherosclerosis with the measurement of the intima-media thickness (IMT) in carotid arteries. Aim: To compare the carotid IMT in patients with ordinary Ps and psoriatic arthritis (PsA) through the RF-QIMT. **Methods:** Total of 30 patients with Ps (n = 15), and APs (n = 15) (CASPAR, 2006) were enrolled in this case-control study. Patients with diabetes mellittus, dyslipidemia, previous cardiovascular events and smokers were excluded. We evaluated the measurement of waist circumference, blood pressure, body mass index (BMI) and disease activity, including PASI. Moreover, they were assessed for cardiovascular risk with the Framingham score and the measured the IMT of both common carotids adopting an automatic software (called RF-QIMT) and laboratory tests, including fasting glucose, total cholesterol and fractions and ESR. **Results:** Mean age and disease duration was 50.1 ± 9.8 years and 17.8 ± 11.3 years and 54 ± 13 and 14 ± 9.2 years in patients with Ps and APs, respectively, with a slight predominance of men in those with skin disease (50% vs. 43.8%), but no statistical difference between the groups (p> 0.05). In addition, there was no statistical difference between the groups regarding BMI (28.1 ± 6.1 vs. 26.4 ± 5.6 kg / m2), waist circumference (97.6 ± 13.2 vs. 97.8 ± 14.8 cm and ESR (24.8 ± 17.4 vs. 30.2 ± 29.1 mm). Ps patients had significantly higher PASI than those with APs (9.3 ± 9.7 and 2.5 ± 4.8). On the other hand, APs patients had greater Framingham score (13% vs. moderate risk in Ps 60% the APs, p <0.05). There was no statistical difference in relation to the average values of IMT (0.641 ± 0.744 vs. 0,144mm in Ps ± 0,197mm in APs), the standard deviation (SD) of the six average values indicated by the system, were ranging from 12,6µm to 11,13µm, respectively. Despite, it was found that 60% of the patients with Ps and 80% of those APs had higher IMT measurement than expected (p <0.05). There was no statistically significant correlation between IMT and BMI, CA, PASI and ESR variables. However, there was a statistically significant correlation (r = 0.5; p <0.05) between the IMT measurement and the Framingham score. **Conclusion:** The results show that patients with Ps and APs have high rates of subclinical atherosclerosis, which can be measured by the new adopting an automatic software (called RF-QIMT) of evaluating the IMT, moreover there was correlation and validation with cardiovascular risk score.

Session Title: Imaging of Rheumatic Diseases Poster I: Ultrasound, Optical Imaging and Capillaroscopy
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Ultrasound (US) as well as conventional radiography (CR) are established imaging modalities for the assessment of cortical bone lesions including erosions and osteophytes. Several studies compared both methods in different joint regions, however, midfoot joints have not been addressed so far. Therefore, the diagnostic value of high resolution US was compared to CR in the detection of osteophytes and erosions in the midfoot joints in patients suffering from inflammatory (IJD) and non-inflammatory joint disease (NIJD).

Methods:

Patients with current foot radiographs were included and stratified in two cohorts: IJD and NIJD. The midfoot joints of both feet (talonavicular, calcaneocuboid, medial / intermediate / lateral naviculocuneiform, and 1st to 5th tarsometatarsal joints) were evaluated by US and CR. US was performed with a high end ultrasound device (Logiq E 9, *GE Healthcare, Buckinghamshire, UK)* with a linear hockey stick probe with 8-18 MHz by one author (W.H.) with long standing experience in musculoskeletal US, whereas CR images were evaluated by an expert in musculoskeletalal radiology (P.H.). Both investigators were blinded to diagnoses and results of the complementary imaging modality. US: Presence of osteophytes (cortical protrusions > 1 mm) and erosions (a cortical break > 1 mm according to the OMERACT definition) were analysed for each joint utilizing a dorsal longitudinal scan. Power Doppler (PD) activity was scored on a semi quantitative scale from 0 to 3. CR: X-rays of each foot (posterior–anterior and lateral view) were performed and presence of osteophytes, erosions and joint space narrowing (JSN) were analysed for each joint.

Results:

A total of 2445 joints in 124 patients (90 with IJD, 34 with NIJD) were assessed. US detected significantly more osteophytes (n=344; 14.1%) than CR (n=13; 0.5%), p<.001 by Chi^2. Only 8 osteophytes were observed by both methods. Osteophytes were most frequently detected in the intermediate and lateral naviculocuneiform joints (19.5% and 17.3%) by US, whereas no osteophytes could be identified in these joints by CR. Of the 13 osteophytes dectected by CR, 5 were present in the 1st tarsometatarsal joint and 4 in the talonavicular joint. US identified 60 vs. 3 erosions by CR, only 1 erosion was detected by both methods. There was no significant agreement between US and CR in detecting erosions and osteophytes (κ-statistic .029 - .035). While CR demonstrated a higher prevalence of JSN in IJD (14.8%) compared to NIJD (8.8%), p<.001 by Chi^2, there were more erosions observed by US in IJD (2.9%) than in NIJD (1.3%), p=.026 by Chi^2. Contrary to results from other joint regions, PDUS demonstrated no significant difference of the rate of midfoot joints with hyperperfusion comparing patients with IJD (8.5%) and NIJD (7.8%), p=.839 by Chi^2.

Conclusion:

High resolution US of the midfoot is a valuable tool for the detection of structural bony lesions in the midfoot. Sonography is superior to CR in the identification of osteophytes and erosions in patients suffering from IJD and NIJD.

Session Title: Imaging of Rheumatic Diseases Poster I: Ultrasound, Optical Imaging and Capillaroscopy

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

In studies of rheumatoid arthritis using ultrasonography (US), findings of synovial thickening are often reported in semiquantitative scores. For synovial biopsies of small joints, selection by US score has been suggested. However, it is not known how consistently US scores translate into a specific measurable synovium thickness in a cohort of RA patients. The aim of this study was to assess consistency of the scoring and the relationship to measurable synovial thickness.

Methods:

Consecutive CCP+ clinic patients fulfilling the 2010 ACR/EULAR RA criteria with ≥1 tender/swollen joint were enrolled. US examinations of dorsal and ulnar wrist and MCPs 2-5 were obtained. All patients were independently scanned by two experienced rheumatologists. A GE Logiq E9 unit was used, with gray scale (GS) frequencies of 15-18 MHz. Measurements were taken using the machine's calipers at maximal joint distension in the dorso-palmar plane. Anatomic landmarks included the hyperechoic bony cortex (or deep hyperechoic duplication of the fibrous joint capsule, if present and visible); intervening hypoechoic synovial tissue; and hyperechoic fibrous joint capsule superficially. Still images were scored for GS synovitis (0-3) by both rheumatologists independently. Tenosynovitis within the extensor carpi ulnaris (ECU) tendon sheath was scored as present (1) or absent (0).

Results:

10 sets of images were scored (7 female and 3 male; biologics, n=3; DMARDs alone, n=4; steroids alone, n=1). 45 joints/regions were measured for maximum depth of synovial thickening (MCP = 35, wrist = 8 and ECU = 2).

Excellent inter operator and inter-reader agreement was achieved for semiquantitative scoring with weighted kappas of 0.98 (95% CI 0.93, 1.00, $p<0.001$, PABAK 0.99)

Average synovial thicknesses for the semi-quantitative scores at each joint region are shown below and were significantly different across the semiquantitative US scores (independent samples Kruskal-Wallis test $p<0.001$). 26 of 28 joints (92.9%) scoring GS ≥2 had a synovial depth of ≥2mm. All wrist joints (6/6) with ≥2 GS synovitis had ≥2mm depth, while 20 of 22 MCP joints with ≥2 GS synovitis had ≥2mm depth.

Joint	Semi-quantitative GS Score	n	Mean synovial thickness in cm	SD	Median	Min	Max	Lower quartile	Upper quartile
MCP	1	13	0.130	0.071	0.1	0.07	0.3	0.09	0.125
	2	14	0.239	0.037	0.235	0.18	0.29	0.21	0.28
	3	8	0.451	0.125	0.475	0.26	0.62	0.343	0.558
Wrist	1	2	0.185	0.078	0.185	0.13	0.24	0.13	n/a
	2	4	0.455	0.149	0.405	0.34	0.67	0.348	0.613
	3	2	0.615	0.078	0.615	0.56	0.67	0.56	n/a
Ulnar	1	2	0.110	0.014	0.110	0.10	0.12	0.1	n/a

Conclusion:

The vast majority of hand and wrist joints graded semiquantitatively at 2 or 3 had at least 2 mm synovial thickening and would be theoretically amenable to biopsy (with a typical 2 mm instrument such as Quick-Core®). Even though experienced rheumatologists can reach excellent inter-reader reliability for semiquantitave US scores, we found significant variation of the actual measured synovial thickness within a given score category. The same score can translate into different mean measured synovial thickness across different joint areas. Greater synovial thickness was measured for wrist joints than MCP joints for a given category. This needs to be taken into account when planning synovial biopsies of small joints.

Considerable Discrepancy Between Patient's Assessment and Ultrasonography Assessment on the Most Affected Joint in Rheumatoid Arthritis

Ryusuke Yoshimi[1], Yukihiro Toyota[1], Naomi Tsuchida[1], Yumiko Sugiyama[1], Yosuke Kunishita[1], Daiga Kishimoto[1], Reikou Kamiyama[1], Kaoru Minegishi[1], Maasa Hama[1], Yohei Kirino[1], Mitsuhiro Takeno[1,2], Atsuhisa Ueda[1] and Yoshiaki Ishigatsubo[1,3], [1]Department of Internal Medicine and Clinical Immunology, Yokohama City University Graduate School of Medicine, Yokohama, Japan, [2]Department of Allergy and Rheumatology, Nippon Medical School, Tokyo, Japan, [3]Center for Rheumatic Diseases, Yokosuka City Hospital, Yokosuka, Japan

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Imaging of Rheumatic Diseases Poster I: Ultrasound, Optical Imaging and Capillaroscopy
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Musculoskeletal ultrasonography (US) is a useful tool for the diagnosis and monitoring of rheumatoid arthritis (RA). It is also helpful for promoting patient-clinician communication by visualizing real-time disease activity. Although patients often request assessment of the most symptomatic joints, there is no evidence for benefits associated with assessment of a selected joint on demand from patients. Here we investigated whether the patient's subjective evaluation for the most affected joint agrees with US assessment.

Methods: Power Doppler (PD) US was performed in 8 joints, including bilateral MCP 2, MCP 3, wrist and knee joints, as a routine examination in a cumulative total of 406 patients with RA. At the examination, patients declared the most symptomatically affected joint. In patients who had the most affected joint except the routine 8 joints, the joint was additionally scanned. PD signals and gray-scale (GS) images were scored semiquantitatively from 0 to 3 in each joint. If PD or GS score of the declared joint was the highest of the scores of scanned joints, the patient's evaluation was regarded as agreeing with US assessment.

Results: Forty-nine patients were asymptomatic. The remaining patients were divided into two groups based on the most symptomatic joints. Group A consisted of 209 patients having the most symptomatic joint among the routine 8 joints, whereas 148 patients having the most symptomatic joint other than the routine 8 joints were included in Group B. In five patients (3.4%) of Group B, PD signals were detected in the most symptomatic joints (shoulder, elbow, MCP 1, and 2 ankles), despite the negative results in the routine 8 joint assessments. In the symptomatic group (Group A and B), the agreement rates of the patient's evaluation with PD and GS scores were 64.4% and 60.2%, respectively. The agreement rate with PD score in Group B was significantly lower than in Group A (51.4% vs 73.7%, $P = 1.9 \times 10^{-5}$). The agreement rate with GS score in Group B was also significantly lower than in Group A (45.3% vs 70.8%, $P = 1.3 \times 10^{-6}$). Among the cases having positive PD score in any joints ($n = 285$), the agreement rate with PD score was 55.4% in the symptomatic group (Figure 1). The agreement rate with PD score in Group B ($n = 109$) was significantly lower than Group A (n = 176) (33.9% vs 68.8%, $P = 1.2 \times 10^{-8}$). Among the cases having positive GS score in any joints ($n = 352$), the agreement rate with GS score was 59.7% in the symptomatic group (Figure 1). The agreement rate with GS score in Group B ($n = 144$) was significantly lower than Group A ($n = 208$) (43.8% vs 70.7%, $P = 5.6 \times 10^{-7}$).

Conclusion: This study suggests that agreement between patient's subjective evaluation and US assessment on the most affected joints was quite poor, especially in case the most symptomatic joint was not included in the routine 8 joints.

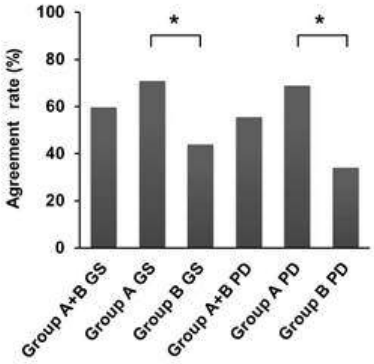

Figure 1 The agreement rates of the patient's evaluation with US assessment on the most affected joints in RA cases with positive US scores.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Imaging of Rheumatic Diseases Poster I: Ultrasound, Optical Imaging and Capillaroscopy

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Ultrasonography (US) has become a support tool for the daily management of rheumatologic patients. However, when and how to use it remains a subject of discussion. *Objective:*To determine the added value of articular US joint count, compared to clinical joint count for measuring disease activity in patients with rheumatoid arthritis (RA).

Methods: A cross-sectional study including patients with diagnosis of RA (ACR-EULAR 2010) was designed. Patients underwent clinical and US assessment. The clinical examination included 28 joint count visual analog scale (VAS) for global disease activity and erythrocyte sedimentation rate (ESR). Ultrasound evaluation was conducted by two rheumatologists with experience in US who were blind to clinical examination, and included the assessment of 28 joints (according to the DAS28 index). The Power Doppler (PD) signal and gray-scale (GS) were graded from 0-3, according to the OMERACT standards. Swollen joint counts were calculated according to five criteria: One clinical count (Clinical) and four US counts. For the latter, joint swelling was defined according to different standards: a) US Global-OMERACT (PD≥1 presence and / or EG≥1); b) Presence of PD≥1 (US- PD1); c) Presence of PD≥2 (US-PD2); d) Presence of PD = 3 (US-PD3). Additionally DAS28 and the percentage of patients in remission (DAS28≤2.6) were calculated for each joint count criteria.

Results:

We included a total of 49 consecutive RA patients. The mean disease duration was 8 ± 5 years, 85% were women, with a mean age of 53 ± 10 years.

Table 1 shows the different joint counts and their resulting activity rates. The use of the US Global-OMERACT criteria was the method that most frequently detected inflammation. The US swollen joint counts using only the degree of signal PD were not superior to clinical evaluation in the detection of patients with active disease.

Different SJC (28 joints)	SJC (Mean ± SD)	p*	**DAS28** (calculated according to different joint counts)	p&	**Remission** (according to DAS28)
Clinical	5.6 ± 4.8	0.01	4.8 ± 1.5	<0.01	3 (6%)
US-OMERACT	15.6 ±6.1		5.3 ± 1.3		0 (0%)
US-PD1	5.9 ± 4.9		4.8 ± 1.5		3 (6%)
US-PD2	3.2 ± 3.3		4.6 ± 1.4		4 (8%)
US-PD3	0.4 ± 0.8		4.3 ± 1.3		5 (10%)

SJC: swolen joint count

* US-OMERACTwas significantly higher than the other joint counts. & The DAS28 calculated according to US-PD3 count was significantly lower than that calculated by the US-OMERACT.

Conclusion:

In our study US evaluation according to OMERACT criteria was the most sensitive method to detect joint inflammation. However, clinical joint count demonstrated to be a reliable method. Only 6% of patients classified in remission according to clinical examination, were reclassified as active after US assessment. Furthermore, the use of PD signal without GS quantification did not show superiority over clinical examination for the detection of patients with disease activity.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Imaging of Rheumatic Diseases Poster I: Ultrasound, Optical Imaging and Capillaroscopy

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Even though Doppler ultrasound (US) is used for diagnosing inflammation in arthritides, it is well-known that Doppler signals may be seen in healthy wrist and finger joints (1). Tenosynovitis has been shown to be frequent in rheumatoid arthritis and to predict erosive disease (2). Detailed knowledge of the distribution of feeding vessels in fingers is important to distinguish normal from pathological findings. However, there is no knowledge about Doppler signals in relation to healthy tendon sheaths and the possible pitfalls this may generate.

To investigate presence of feeding vessels in relation to the healthy flexor and extensor tendon sheaths of the wrist by use of 3D Doppler US.

Methods:

Twenty healthy participants were recruited; 10 women in the age 27-54 years and 10 men in the age 27-59 years. None of the participants had finger pain, history of arthritis or any known finger tendon disease, or were smokers.

The participants had US of the palmar and dorsal side of the right wrist. US was carried out using a General Electric Logiq E9 with a 3D ultrasound probe. The Doppler settings were adjusted according to published recommendations (3) with a Doppler frequency of 8.3 MHz and pulse repetition frequency of 0.4. The same Doppler settings were used for all examinations. Specific probe positions on the wrist were selected before study initiation at two different levels (Lister's tubercle and pisiforme). Two scans were made at each position to minimise the risk of missing Doppler findings due to different parts of the cardiac cycle being sampled as the sweep was made. Each tendon sheath was divided into specific areas and the visualized 3D Doppler findings in relation to the tendon sheath were plotted on a schematic drawing (Figure 1A and 1B).

Results:

The overall distribution of feeding vessels was comparable at the level of Lister's tubercle and the level at the pisiforme for the extensor tendons. For the flexor tendons, feeding vessels were more frequent at the level of Lister's tubercle, as shown in figure 1(A and B). Overall feeding vessels were less frequent for compartment V and VI at the level of Lister's tubercle. Feeding vessels were seen less at the superficial location for the extensor tendons, except for compartment I. Radial and dorsal vessels were rare in the tendon sheath of flexor digitorum superficialis and profundus.Intertendineus feeding vessels were mainly seen in the tendon sheath of flexor digitorum superficialis and profundus.

Conclusion:

Feeding vessels in close relation to the extensor and flexor tendon sheaths were common in the wrist of healthy participants and may be a cause of misinterpretation due to artefacts. These vessels should be taken into consideration when diagnosing tenosynovitis in the wrist.

Session Title: Imaging of Rheumatic Diseases Poster I: Ultrasound, Optical Imaging and Capillaroscopy

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Even though Doppler ultrasound(US) is used for diagnosing inflammatory changes it is well-known that Doppler signals are seen in healthy wrist and finger joints. Tenosynovitis has been shown to be frequent in rheumatoid arthritis and to predict erosive disease. Detailed knowledge of the distribution of feeding vessels in fingers is important to distinguish normal from pathological findings. However, there is no knowledge about Doppler signals in relation to healthy tendon sheaths and the possible pitfalls this may generate.

To investigate presence of feeding vessels in relation to the healthy flexor tendon sheaths of the fingers by use of 3D Doppler US.

Methods:

Twenty healthy participants were recruited, 10 women in the age 23-67 years and 10 men in the age 26-54 years. None of the participants had finger pain, history of arthritis or any known finger tendon disease. One participant was a smoker.

The participants had US of the right second and third flexor tendon of the finger (10 men, 10 women). US was carried out using a General Electric Logiq E9 with a 3D ultrasound probe. The Doppler settings were adjusted according to published recommendations with a Doppler frequency of 8.3 MHz and pulse repetition frequency of 0.4. The same Doppler settings were used for all examinations. Specific probe positions on the fingers were selected before study initiation. Two scans were made at each position to minimise the risk of missing Doppler findings, due to different parts of the cardiac cycle being sampled as the sweep was made. Each tendon sheath was divided into specific areas and the visualized 3D Doppler findings in relation to the tendon sheath were plotted on a schematic drawing (Figure 1A).

Results:

The overall distribution of feeding vessels between the 2nd and 3rd flexor tendon were comparable and is shown in

Figure 1A.

The feeding vessels were predominantly seen at ulnar and radial locations, except in the distal part of the metacarpal bones, where the palmar location was common (Figure 1B+C). Palmar vessels were more frequent distally than proximally in the fingers and the dorsal vessels were extremely rare.

Conclusion:

Doppler findings in close relation to the tendon sheaths, due to feeding vessels, were common in flexor tendons of the fingers in healthy participants and may be a cause of misinterpretation. These vessels should be taken into consideration when diagnosing tenosynovitis.

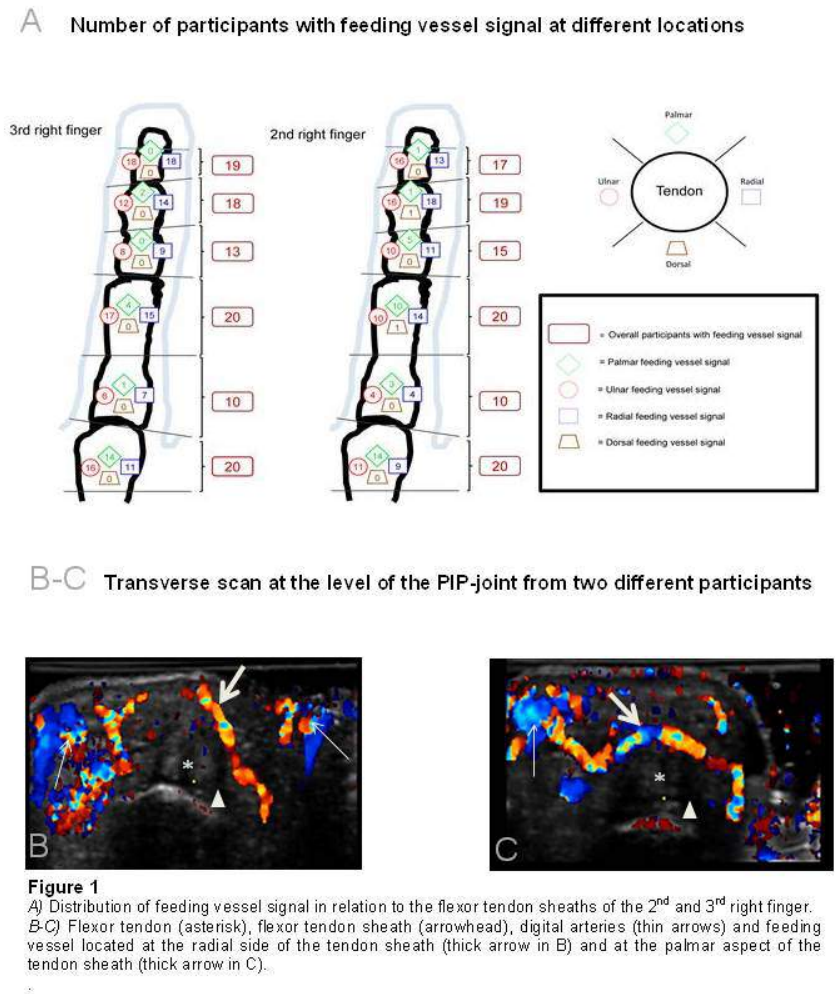

Figure 1
A) Distribution of feeding vessel signal in relation to the flexor tendon sheaths of the 2nd and 3rd right finger. *B-C)* Flexor tendon (asterisk), flexor tendon sheath (arrowhead), digital arteries (thin arrows) and feeding vessel located at the radial side of the tendon sheath (thick arrow in B) and at the palmar aspect of the tendon sheath (thick arrow in C).

Session Title: Imaging of Rheumatic Diseases Poster I: Ultrasound, Optical Imaging and Capillaroscopy

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Published studies indicate clinicians may miss the intrasynovial knee space during therapeutic injections in excess of 30% of attempts using landmark guided techniques due to small synovial fluid volumes or inexperience of the operator. The purpose of this study was to determine if the fluid volume in the knee available for aspiration or injection could be increased by pneumatic displacement into a target area confirmed using ultrasound imaging.

Methods: 40 knees from 37 consecutive patients from an academic rheumatology practice were studied. All of these patients previously had a medial (27) or lateral (13) knee aspiration or therapeutic injection using a pneumatic compression device. Ultrasound (US) examination was performed during inflation to 100 mmHg and then during deflation. The hook and loop secured device encircled the knee except for a 6 x 9 cm target area available for a US probe or needle placement and was inflated with a hand held manometer. Live images from a GE LOGIQ Book XP ultrasound machine using a 12L-RS probe were recorded onto a Surface Pro laptop computer and analyzed blinded. The fluid compartment (anechoic region) images were analyzed using a histogram based thresholding program which identified the area and linear distance of the anechoic fluid compartment during inflation and deflation.

Results: The study cohort included 28 female and 9 male patients with the following diagnoses: 25 RA, 8 OA, 2 Psoriatic arthritis, and 1 each with SLE and gout. The mean age was 58.6 years (range 23-86) and mean BMI was 26.9 kg/m^2(range 19.1-35.6). The mean increase during inflation vs deflation of the anechoic fluid area was 309% (range 14%-2,048%), $p< 0.001$, and the increase in linear distance during inflation was 182% (range 0%-552%), $p<0.001$ using paired T test analysis. Since none of these patients required a joint aspiration or injection at the time of their study visits, the volume of fluid displaced during a clinically indicated joint aspiration or injection would have likely have been larger than reported in this study.

Conclusion: Quantitative digital image analysis of ultrasound recorded images demonstrate a significant increase in fluid displacement from the synovial space of the knee into a target area available for joint aspiration or injection during inflation to 100 mmHg of a pneumatic compression device. Pneumatic compression may facilitate more successful knee aspirations or injections by increasing the fluid volume in the medial or lateral knee joint space available for needle access and increasing the target area for needle placement.

Session Date: Sunday, November 8, 2015
Session Title: Imaging of Rheumatic Diseases Poster I: Ultrasound, Optical Imaging and Capillaroscopy
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Injury of the lateral circumflex femoral artery (LCFA) is a potential cause of bleeding during invasive hip procedures due to its close proximity to the femoral acetabular joint. However, the LCFA is not routinely cited as a structure to avoid during intra-articular hip injections. The purpose of this study was to evaluate the risk of LCFA injury during ultrasound guided hip joint injection.

Methods:

1) We searched the PUBMED database (1967 to Apr 2015) for existing literature on basic techniques for ultrasound guided hip joint injection using the following search string: [“injection” OR “arthrocentesis” OR “aspiration”] AND [“hip” OR “intra-articular” OR “acetabulofemoral” OR “coxofemoral”] AND [“ultrasound” OR “ultrasonography” OR “ultrasound-guided” OR “image-guided”]. 52 non-English studies were excluded. 5 textbooks on musculoskeletal ultrasound were also reviewed. Resulting literature was screened for mention of the LCFA. 2) 18g spinal length needles were inserted under ultrasound guidance into the hip joints of 4 human cadavers. The tissues were dissected with the needles in place to expose the LCFA in relationship to the needle. 3) Rheumatologists trained for 8 months in ultrasound used electronic calipers to mark a planned needle trajectory from skin to hip joint on a live human ultrasound image during a musculoskeletal ultrasound final Observed Structured Clinical Examination (OSCE). Doppler imaging was subsequently used to locate the LCFA, and the closest distance between the planned needle trajectory and arterial signal was recorded.

Results:

1) 709 articles and 5 textbook chapters were reviewed; 11 discussed the technique of ultrasound guidance for hip injection. Of these 11 citations, 7 highlighted the femoral vascular bundle as a structure to avoid but only one specified routine use of Doppler imaging or specifically to avoid the LCFA. 2) In 3 out of the 4 human cadaveric dissections, the needle inserted into the hip under ultrasound guidance also made direct contact with the LFCA. 3) Of 27 OSCE participants, only 2 chose to activate Doppler imaging before marking their simulated hip injection trajectory. The electronic needle trajectory markings were subsequently found to pass through LFCA region Doppler signal in 6 (22%) cases. Among all 27 participants, the mean shortest distance from needle trajectory to arterial signal was 4mm (range 0-11mm).

Conclusion:

The risk of LCFA injury during ultrasound guided hip joint injection is substantial. Although the clinical significance of LCFA injury remains unclear, for high risk individuals (such as those on chronic anticoagulation), we suggest routine use of Doppler imaging as a part of standard hip injection protocols. Further study is required to determine if a more oblique or transverse approach to the hip will reduce the risk of accidental vascular injury.

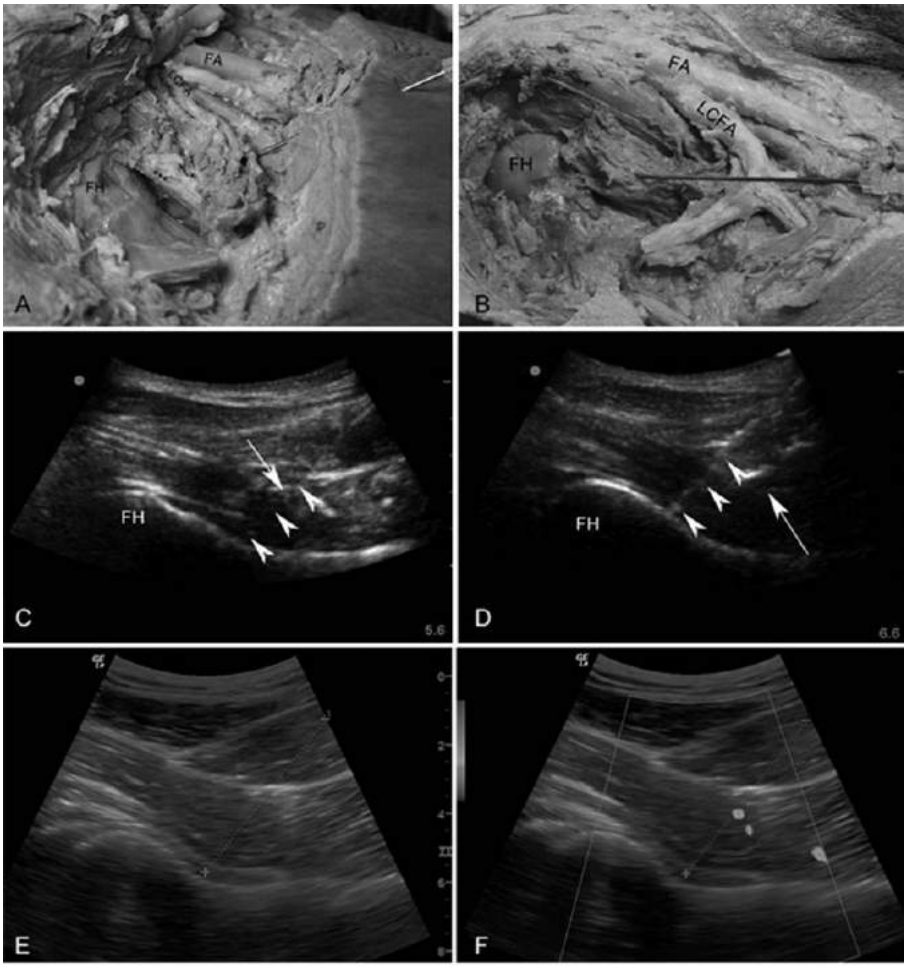

Figure 1. A) Injection of human cadaveric hip joint under ultrasound guidance using anterior longitudinal approach with subsequent dissection. Needle comes in close proximity to lateral circumflex femoral artery (LCFA); surrounding femoral head (FH) and femoral artery (FA) are also exposed. B) Similar dissection as Fig 1 A but with a more oblique approach to needle entry. Injury of the lateral circumflex femoral artery is avoided. C) Ultrasound of image A, showing needle (arrowheads), femoral vessels (arrow), and femoral head (FH). D) Ultrasound of image B. E) Simulated hip injection during OSCE. Electronic calipers mark examinee's planned needle trajectory from skin to hip joint. F) Doppler imaging is subsequently activated and reveals close proximity of LCFA to needle.

Session Title: Imaging of Rheumatic Diseases Poster I: Ultrasound, Optical Imaging and Capillaroscopy

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Trapeziometacarpal (TMC) joint is a common site of osteoarthritis (OA)(rhizarthrosis). Its diagnosis is based on clinical and radiological (X-ray) features. It is not clear the usefulness of ultrasound (US) for the diagnosis of rhizarthrosis. The objective of the present study was to evaluate the utility of US for the diagnosis of rhizarthrosis, compared with X-ray.

Methods: A retrospective analysis of all consecutive patients who had undergone X-ray and US of both hands, no more than 30 days apart, between January 2012 and December 2014 was performed. Demographic and clinical data were recorded. All US examinations were performed by an experienced rheumatologist, blinded to X-ray data, using a MyLab 70 (Esaote) machine provided with 6-18 MHz broad band multifrequency linear transducer. TMC joint was evaluated for the presence of osteophytes, defined as protrusions of cortical bone from the margins of the joint observable in two perpendicular planes. US findings at TMC joint were also graded on a 0 to 3 scale (0= abscence of degenerative changes; 1= mild : presence of osteophytes ≤ 2 mm; 2= moderate: presence of osteophytes > 2 mm; 3= marked: presence of osteophytes > 2 mm associated with loss of normal joint architecture). X-rays were read by another experienced rheumatologist, blinded to US data, to determine the presence of asymmetrical joint space narrowing and/or osteophytes at TMC joint. Using Eaton's criteria, X-ray rhizarthrosis was also graded from 1 to 4 (Stage 1: Normal joint space or slight widening. Subluxation < 1/3; Stage 2: Decreased TMC joint space. Small (< 2 mm) osteophytes or loose bodies. Subluxation < 1/3; Stage 3: More decreased TMC joint space. Subchondral cysts or sclerosis. Osteophytes or loose bodies ≥ 2 mm. At least 1/3 of subluxation; Stage 4: Stage 3 in addition to involvement of the scaphotrapezial joint).

Results: A total of 378 TMC joints from 189 patients were included for the final analysis. One hundred twenty-eight (67.7%) patients were female and mean age (SD) was 64.1 (14) years. X-ray and US diagnosis agreed in 365 out of 378 (96.5%) TMC joints (figure 1). In 71 TMC joints both imaging methods disregarded OA and in 294 both methods confirmed the diagnosis of rhizarthrosis (unweighted kappa value: 0.895 ;95% CI: 0.84-0.95). Intraclass correlation coefficient for rhizarthrosis grades for both imaging modalities was 0.9 (95% CI: 0.88-0.92). Table shows the distribution of Eaton's X-ray stages and US grades of rhizarthrosis.

Conclusion: US and X-ray showed an excellent agreement for the diagnosis of rhizarthrosis and excellent correlation for the severity of the involvement. US might be used for the diagnosis and severity classification of OA of the TMC joint.

Table. Distribution of Eaton's X-ray stages and US grades of rhizarthrosis.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Imaging of Rheumatic Diseases Poster I: Ultrasound, Optical Imaging and Capillaroscopy
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: To investigate the prognostic value of baseline B-mode and Power Doppler (PD) ultrasound assessment of the median nerve in CTS patients with or without surgical treatment, regarding their short and long-term

clinical outcomes.

Methods: Prospective study on 135 patients with suspected CTS, undergoing baseline and two follow-up visits after 3 and 28 months. Clinical, neurophysiological (NCS) and sonographic evaluation was performed at each visit. Cross-sectional Areas (CSA) were sonographically measured at 4 levels at forearm and wrist, and CSA wrist-to-forearm ratios were calculated. PD-signals were subjectively graded from 0-3. Clinical outcomeswere evaluated using the Boston-Questionnaire, DASH-Questionnaire, as well aspatient's assessment of pain and physicians' global assessment according to visual analogue scales (painVAS, physVAS). We conducted multivariate logistic regression models to determine the predictive values of baseline CSA and PD assessments.

Results: Short-term Follow-up visit was completed by 111 Patients and 105 Patients were available for long-term follow-up. At 3 months, 121 wrists (in 80 Patients) have received the final diagnosis of CTS. 13 and 10 CTS Patients showed improvement regarding their BQ at short-term and long-term follow-up, respectively. According to regression analysis, we found that CSA, measured at the level of the Carpal Tunnel inlet, predicted short-term clinical improvement (≥25% according to BQ) in the subgroup of CTS patients undergoing carpal tunnel surgery (OR 1.842, $p < 0.05$), but not in patients treated conservatively ($p=0.804$). CSA or PD assessmentsdid not predict short-term improvement of painVAS, physVAS or DASH, and none of the ultrasound parameters was useful for the prediction of long-term clinical outcomes.

Conclusion: Ultrasound assessment of the median nerve CSA is of limited value to predict short-term clinical outcomes of CTS patients undergoing carpal tunnel release, whereas long-term outcomes are not predicted by sonography results.

Rheumatologists and Musculoskeletal Ultrasound: Discrepancy Between Attitudes, Desire and Reality in Routine Practice in South East England

Antigoni Grigoriou[1] and Patrick Kiely[2], [1]Rheumatology, St George's Univeristy Hospitals NHS Foundation Trust, London, United Kingdom, [2]Rheumatology, St George's University Hospitals NHS Foundation Trust, London, United Kingdom

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Imaging of Rheumatic Diseases Poster I: Ultrasound, Optical Imaging and Capillaroscopy

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

The use of musculoskeletal ultrasound (MSK US) in routine care is expanding. The number of rheumatologists using or seeking to learn the technique is also increasing, though it is unclear how US is being incorporated into routine work practices (RWP). This survey sought to gain an insight into the use of MSK US in a region of Southern England.

Methods:

A questionnaire was designed by the authors to collect information on training, access & service delivery, indications and attitudes towards use of MSK US in RWP. All rheumatology consultants (RC), trainees (RT) and specialist nurses (SN) working in 19 Hospitals (Hs) (4 Medical School Universities, 15 District General) in London South, Kent, Surrey and Sussex regions of England were invited to complete the survey. Data were analysed using simple descriptive and summary statistics.

Results:

A total of 70 questionnaires (51%) were returned (RC 61%, RT 27%, SN 12%) with at least one response from all 19 Hs.

Training: Of the 70 responders (Rs), 42% report having had formal training in the use of US, however only 12% had support for this and 10% have a formal MSK US certificate.

Access & service delivery:MSK US scans are most usually performed by radiologists (64%). In 11 Hs there are also US machines in the rheumatology department, of which 8/11 are currently used for routine care. The routine waiting time for a MSK US is up to 6 weeks.

10 of the 29 Rs who have had training (34%) perform US scans themselves. They report greatest confidence scanning the hands (90%), followed by feet (70%) and 20% are confident to scan all joints. US guided injections are given by 50% and US guided synovial biopsies performed by 20%.

The maximum number of joints scanned in one session varies from 5 – 40 joints, taking an average time of 20 minutes per scan.

Indications:MSK US are requested for diagnostic purposes by 92%, guided injection by 80%, assessment of treatment response by 52%, research purposes by 8% and 75% request a scan at least 1 – 5 times a week. The proportion of Rs requesting MSK US per disease groups is: Inflammatory Arthritis (IA) >85% and soft tissue 63%.

Attitudes: More than 60% of the Rs report that MSK US results often lead to a change in their management plans and that it enhances patients' satisfaction. 82% think it appropriate that RC should perform MSK US scans as part of their RWP. 50% of the RC and 72% of the RT think that proficiency in use of US should be a mandatory part of the rheumatology training curriculum. 51% of the Rs indicated a willingness to learn the technique.

Free text responses revealed concerns about available time and proper training but others commented that MSK US is beneficial in an early IA setting.

Conclusion:

This cross-sectional, observational, multicentre survey demonstrates widespread use of MSK US by rheumatologists in routine care in the South East Coast region of England. 82% of Rs think it appropriate that RC should perform MSK US in RWP and 57% believe training in this should be a mandatory part of the curriculum. In contrast 42% of Rs have had formal training, but only 10% of them have incorporated MSK US into RWP, the majority relying on radiology colleagues to do the scans. This illustrates a discrepancy between attitudes, desire and reality of MSK US use in routine rheumatological practice.

Abstract Number: 185

Success Rate and Utility of Ultrasound Guided Synovial Biopsies in Clinical Practice

Aurélie Najm, Benoît Le Goff and Yves Maugars, Rheumatology, Rheumatology, Nantes, France
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Imaging of Rheumatic Diseases Poster I: Ultrasound, Optical Imaging and Capillaroscopy
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Histological and bacteriological analysis of synovial tissue (ST) can be useful in the diagnosis of arthritis of undetermined origin. Ultrasound can assist this biopsy in directing the needle to relevant sites within the joint as well as allowing an evaluation of synovial inflammation and thickness.

The aims of this study were to describe the indications for US guided synovial biopsies in clinical practice, to determine the rate of success in acquiring ST using this approach and to determine how frequently the synovial biopsy can lead to a definite diagnosis.

Methods: Synovial biopsies of small and large joints were performed under US guidance (Philips HD11 XE) between January 2007 and December 2014 using a semi-automatic core biopsy needle (Tru-cut^{R}).

The patient cohort was characterized clinically. Crystal microscopy, bacteriological (with PCR for Whipple or Lyme disease), mycobacteriological and fungal analysis were performed according to the clinical presentation. Histological features of biopsies were described.

The biopsy procedure was considered as successful if synovial tissue was found at histological examination.

Results: Seventy-two patients underwent 74 synovial biopsies. Fifty-three percent were men and average age was 58,7 years (+/- 16,97).

Biopsies were performed in the following joints: knee (n=42; 56%), ankle (n=7; 10%), wrist (n=7; 10%), shoulder (n=6; 8%), hip (n=4), sterno-clavicular (n=3), elbow (n=3), pubic symphysis (n=1), acromio-clavicular (n=1), first metatarsophalangeal (n=1).

Patients presented with a chronic (> 3 months) monoarthritis in 42 cases (56%), an acute monoarthritis in 17 cases (23%), a chronic polyarthritis in 13 cases (18%), an acute polyarthritis, a chronic tenosynovitis and a chronic bursitis in 1 case respectively.

Biopsies were performed to rule out the diagnosis of septic arthritis in 64 cases (85%) or of villonodular synovitis in 11 cases (15%).

US guided biopsy attempt succeeded in 85% of cases (63 on 74 biopsies performed). Failed biopsies retrieved fibrin deposition or adipose tissue.There was no difference on success rate between small and large joints.

Ten of the 63 biopsies (17,5% of patients) leaded to a definitive diagnosis: 2 septic arthritis (no bacteria found on cultures, but a typical histological aspect), 2 villonodular synovitis, 1 case of amyloid arthritis on a patient having no known myeloma, 1 joint localization of a mantle cell lymphoma, 1 gouty arthritis, 1 osteochondromatosis, 1 Whipple disease (positive PCR on synovial tissue, with negative PCR on synovial fluid) and 1 Lyme arthritis (positive PCR on synovial tissue). The histological analysis of the 54 other biopsies showed a non-specific cell infiltrate with lymphocytes and/or macrophages.

One patient presented a knee hemarthrosis 48 hours after the US guided biopsy.

Conclusion: Ultrasound guided synovial biopsies in clinical practice are performed on patients with heterogeneous features. The rate of success in acquiring synovial tissue is high. The procedure, when successful, leads to a definite diagnosis in more than 1 on 6 patients with an arthritis of undetermined origin.

B Flow, a Novel Ultrasound Modality in the Assessment of Synovitis in RA

Darren Tabechian[1], Laura C Coates[2], Jennifer H. Anolik[1] and Ralf G. Thiele[1], [1]University of Rochester Medical Center, Rochester, NY, [2]LIMM, Section of Musculoskeletal Disease, University of Leeds, Leeds, United Kingdom
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Imaging of Rheumatic Diseases Poster I: Ultrasound, Optical Imaging and Capillaroscopy
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

B flow is a vascular ultrasound (US) technique in which the high resolution aspect of gray scale US is optimized to demonstrate movement of one tissue (particularly of erythrocytes) against the background of stationary structures. Though power Doppler can demonstrate relatively low flow structures such as synovial vessels and the neovascularization characteristic of active synovitis, it is in part a flow-direction dependent technique. B flow has been shown to demonstrate carotid artery stenosis as well as color Doppler techniques while more accurately depicting background non-vascular anatomy [1]. The goal of this study is to evaluate the utility of B flow in the assessment of inflammatory arthritis.

Methods:

In a cohort of 10 patients with CCP positive RA (fulfilling the 2010 EULAR/ACR classification criteria) with at least one swollen joint, 120 joints (wrists and MCP joints) were assessed by gray scale US. 51 of the 120 joints were determined to have grade 1 or greater synovitis and underwent power Doppler and B flow interrogation. Two sonographers independently scanned all patients with a GE logic E9 and a 15Mhz matrix array transducer for PD imaging. B flow was performed with an 18 MHz transducer with settings for venous flow. Image scoring for both PD and b flow was performed by the same 2 rheumatologist sonographers (DT and RT) using a reference scoring atlas [2]

Results:

51 joints were assessed by PD and B flow. There was a good to very good agreement between B flow and PD scores (quadratic weighted kappa 0.62 and prevalence-adjusted and bias-adjusted kappa (PABAK) using quadratic weights k= 0.86, $p<0.0005$). B flow scores were generally lower than PD scores (median B flow score 1, IQ range 0, 2, median PD score 2, IQ range 1, 2). 28 joints showed perfect agreement between modalities giving a percentage exact agreement of 54.9%. 20 of 51 (39.2%) joints had higher PD scores while only 3 of 51(5.88%) had higher B flow scores. Inter-reader reliability was high in both modalities (b flow intraclass correlation coefficient (ICC) 0.978 vs PD ICC 0.964).

Conclusion:

In this pilot study, B flow correlated well with PD in the assessment of rheumatoid synovitis in small and medium sized joints with similarly excellent inter-rater reliability. Both ultrasonographers felt that there were fewer sonographic artifacts with B flow imaging compared to PD and this may explain the lower scores seen on B flow. The ability to clearly demonstrate the background gray scale anatomy while displaying the vascular structures of interest offers advantages over Doppler techniques as artifactual findings can be more clearly recognized and excluded from interpretation.

Detection of Power Doppler Ultrasound Signals in Rheumatic Diseases Using Superb Microvascular Imaging (SMI): Comparison with Conventional Power Doppler Ultrasound

Kazuhiro Yokota[1], Takuma Tsuzuki Wada[2], Yuji Akiyama[2] and Toshihide Mimura[3], [1]Department of Rheumatology & Applied Immunology, Faculty of Medicine, Saitama Medical University, Irama, Japan, [2]Department of Rheumatology & Applied Immunology, Faculty of Medicine, Saitama Medical University, Iruma, Japan, [3]Department of Rheumatology and Applied Immunology, Faculty of Medicine, Saitama Medical University, Saitama, Japan

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Imaging of Rheumatic Diseases Poster I: Ultrasound, Optical Imaging and Capillaroscopy

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The detection of power Doppler (PD) ultrasound signals in joints may be considered as the presence of joint inflammation, *i.e.*, synovitis which is a predictor of erosive progression in rheumatoid arthritis (RA). Superb Microvascular Imaging (SMI), a novel ultrasonography, is based on the sensitive Doppler technology with low-motion artifacts than conventional power Doppler ultrasound (cPDUS); furthermore, it can detect low-velocity blood flow signals with high resolution frame rates. Therefore, we evaluated PD ultrasound signals in patients with rheumatic diseases using SMI and cPDUS, and compared the correlations of these signals to clinical and laboratory assessments by these two imaging modalities. Moreover, we also investigated PD ultrasound signals in the difference between

synthetic and biological disease-modifying antirheumatic drugs in patients with RA.

Methods: Twenty-seven patients with RA and 11 non-RA patients with rheumatic diseases were enrolled. We assessed PD signals in the finger, hand, elbow, and knee joints (total 26 joints) by the SMI and cPDUS findings using Aplio 300 (Toshiba Medical Systems). The signals were semiquantified into 4 grades (OMERACT standard, grades 0–3). These individual scores added together to calculate the total SMI score or total cPDUS score (0-114).

Results: The total SMI score was significantly higher than the total cPDUS score in patients with RA (SMI 12.3±11.5 vs. cPDUS 5.2±8.1, $p<0.001$). On the other hand, there was no significant difference between the total SMI and cPDUS scores in patients with non-RA (SMI 0.6±0.7 vs. cPDUS 0.3±0.6, $p=0.1320$). Serum CRP and MMP-3 levels, and HAQ-DI score significantly correlated with the total SMI score in patients with RA (CRP: $r=0.51$, $p=0.006$; MMP-3: $r=0.52$, $p=0.006$; HAQ-DI score: $r=0.41$, $p=0.040$). However, these data did not show up the result of correlation with the total cPDUS score (CRP: $r=0.22$, $p=0.260$; MMP-3: $r=0.26$, $p=0.205$; HAQ-DI score: $r=0.21$, $p=0.295$). In non-methotrexate-treated patients with RA, the total SMI score was significantly higher than the total cPDUS score (n=19, SMI 13.3±11.8 vs. cPDUS 4.1±6.2, $p=0.001$). In contrast, in methotrexate-treated patients with RA, there was no significant difference between the total SMI and cPDUS scores (n=8; SMI 10.0±10.5 vs. cPDUS 7.8±12.1, $p=0.188$).

Conclusion: Our results suggest that SMI can detect PD ultrasound signals more sensitively than cPDUS in patients with RA. Furthermore, it is a requirement for us to pursuit the result of analysis using SMI and cPDUS.

Whole-Body Synovial Uptake of a 99mtc-Labelled RGD Peptide Is Highly Correlated with Power Doppler Ultrasound

Toby Garrood[1], Matthew Morrison[2], Dharsha Shivapatham[3], Khaldoun Chaabo[1], Fahim Ul-Hassan[4], Jim Ballinger[4], Gary Cook[5] and Andrew P. Cope[6], [1]Rheumatology, Guy's and St. Thomas' NHS Foundation Trust, London, United Kingdom, [2]GE Healthcare, Amersham, United Kingdom, [3]Department of Rheumatology, Guy's and St. Thomas' NHS Foundation Trust, London, United Kingdom, [4]Nuclear Medicine, Guy's and St. Thomas' NHS Foundation Trust, London, United Kingdom, [5]Imaging Sciences, Kings College London, London, United Kingdom, [6]Academic Department of Rheumatology, King´s College London, London, United Kingdom

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Imaging of Rheumatic Diseases Poster I: Ultrasound, Optical Imaging and Capillaroscopy

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Musculoskeletal ultrasound, and specifically power Doppler ultrasound (PDUS), is more sensitive than clinical examination for the assessment of active synovitis in patients with rheumatoid arthritis (RA). In addition, PDUS is predictive of radiographic progression, response to therapy in patients with active disease and of flare in patients in remission. In clinical practice its routine use for assessing large numbers of joints is limited by time constraints. ^{99m}Tc-NC100692 (Maraciclatide) is a tracer consisting of a peptide containing the RGD motif which binds

with high affinity to the integrins $\alpha_v\beta_3$ and $\alpha_v\beta_5$ which are expressed on neoangiogenic blood vessels including those seen in the rheumatoid synovium. This proof-of-concept study aimed to investigate whether uptake of ^{99m}Tc-NC100692 is seen in the joints of patients with active RA and whether this correlates with PDUS.

Methods: 5 patients with active RA (DAS28 >3.2) were recruited. Patients underwent clinical examination including 66/68 swollen/ tender joint counts followed by ultrasound examination of 38 joints with grey scale (GS) and power Doppler (PD) quantification. Each joint was scored on a semi-quantitative scale of 0-3 for GS and PD and a total score for each calculated for each patient. Within 24 hours of the ultrasound patients were injected with 75µg of ^{99m}Tc-NC100692 (740MBq). Whole body planar views and dedicated views of the hands and feet were taken at multiple time points over 3 hours. Images were scored by an observer blinded to the ultrasound findings as positive or negative uptake for each joint (binary score), and in addition a fully quantitative score was obtained for each joint by drawing a region of interest around the joint and correcting for background. The scores were summed to derive a total score for each patient. Ultrasound and ^{99m}Tc-NC100692 scores were tested for correlation with Pearson's correlation coefficient.

Results: Specific uptake of ^{99m}Tc-NC100692 was seen in the joints in all patients with optimal uptake seen at around 2 hours. Specific uptake was also seen in inflamed tendon sheaths at the wrist and ankle. Significant correlation was not seen between DAS28 scores and US scores. Strong correlation was seen between PDUS and whole-body fully quantitative (r^2=0.93, p=0.008) and binary (r^2=0.88, p=0.019) ^{99m}Tc-NC100692 scores . GSUS also correlated strongly with quantitative whole-body ^{99m}Tc-NC100692 scores (r^2=0.79, p=0.042). The imaging procedure was well-tolerated.

Conclusion: We have shown for the first time that a ^{99m}Tc-labelled RGD peptide can specifically image inflamed joints in RA patients. Despite the small numbers, in this pilot study uptake was strongly correlated with PDUS. ^{99m}Tc-NC100692-based planar imaging has the unique advantage of the capacity to image the whole body and hence the total synovial inflammatory load in a single quick acquisition. Furthermore the imaging equipment to perform these scans is widely available in nuclear imaging departments. Hence ^{99m}Tc-NC100692 has potential as an alternative modality for quantifying synovial inflammation in RA patients. Larger studies are planned to investigate ^{99m}Tc-NC100692 imaging in RA patients with a range of disease activities.

Session Date: Sunday, November 8, 2015

Session Title: Imaging of Rheumatic Diseases Poster I: Ultrasound, Optical Imaging and Capillaroscopy

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Indocyanine green (ICG) -enhanced fluorescence optical imaging (FOI) is a novel diagnostic tool for the assessment of inflammatory arthritis through visualizing vascular beds. Ultrasound (US) can detect joint injury of rheumatoid arthritis (RA) with high sensitivity. We previously reported that US synovitis scores correlate with serum biomarkers such as angiogenesis factors. This study is undertaken to explore the utility of FOI comparing with US and serum biomarkers.

Methods:

Twenty-five active RA patients (mean disease durations 7.5 years and DAS28-ESR 5.90) who fulfilled 2010 RA classification criteria were consecutively enrolled in this study. They gave their informed consent to be subjected to the protocol that was approved by the Institutional Review Board of Nagasaki University. Both FOI and US were performed at the same day. Interpretation of FOI images using Xiralite system was done for an early phase (phase 1, P1), an intermediate phase (phase 2, P2), a late phase (phase 3, P3) and an early electronically generated composite image (CI) from 18 joints including bilateral 2^{nd} -5^{th} metacarpophalangeal (MCP) joints, proximal interphalangeal (PIP) joints and wrist joints (Figure 1). The same joints were scored by gray scale (GS) and power Doppler (PD) by US. FOI assessments of P1, P2, P3, CI as well as GS score and PD score were semi-quantitatively classified from 0 to 3 as described (total scores of each parameter are 0 to 54 from the 18 joints, respectively). Bone erosion was also assessed by US. Forty-five serum biomarkers at the time of FOI/US examinations were measured by multi-suspension cytokine array.

Results:

Positive finding (≥ grade 1) were found in 122, 206, 140, 139 and 148 out of 450 joints in P1, P2, P3, CI and PDUS, respectively. FOI scores were significantly high in the joints where bone erosion was detected by US as compared to those without bone erosion ($p<0.0001$). Among individual patients, each total FOI scores clearly correlated with both GS and PD scores ($r=0.46$-0.71) as well as with DAS28-ESR ($r=0.66$-0.72). In addition, serum IL-6, VEGF and TNF- correlated with FOI scores. Comparing with PDUS ≥ grade 1 or PDUS ≥ grade 2 as the reference, the positive predictive value (PPV) of FOI scores (≥ grade 1) in whole joints were 82.0 (P1), 66.5 (P2), 75.7 (P3) and 76.3 % (CI) toward PDUS ≥ grade 1 or 66.4 (P1), 44.7 (P2), 54.3 (P3) and 56.1 % (CI) toward PDUS ≥ grade 2, respectively.

Conclusion:

Since FOI scores correlate with US scores as well as serum biomarkers, FOI is considered to detect joint inflammation of RA patients with high accuracy. However, the significance of each phase of FOI may be different and need to be further clarified.

Session Title: Imaging of Rheumatic Diseases Poster I: Ultrasound, Optical Imaging and Capillaroscopy

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Dupuytren's contracture is a rheumatic disease characterized by an fibrotic reaction in the palmar aponeurosis, resulting in disability. Medical treatment with up to 3 injections of collagenase clostridium histolyticum (CCH) chemically disrupts the cord to reduce contracture. Transient swelling in the surrounding tissue and, rarely, rupture of the underlying tendon may occur. Ultrasound evaluation, particularly with elastography, may have the possibility to improve clinical decision making, as elastography allows grading of the tensile strength (softness or firmness) of tissues. This pilot study explored Dupuytren's cord changes with a single treatment of CCH; serial

elastography measurements were performed to determine if such follow contributes to clinical decision making.

Methods:

This IRB approved protocol first established the elastographic regional pattern of normal hands as well as untreated Dupuytren's contractures by studying 5 normal subject hands and 5 Dupuytren's contracture hands (MCP or PIP contracture angle > 20^{o} but < 90^{o}). We assessed the response of 10 Dupuytren's cords treated with ultrasound-guided injection of CCH for reduction of contracture. Research staff collected serial physical examinations and Unité Rhumatologique des Affections de la Main (URAM). A separate, blinded, researcher conducted ultrasound imaging. Measurements were taken at baseline, followed by days 1, 2, 3, 15, and 30, to follow the treatment protocol for administration of CCH. The region of the cord was designated the upper segment (UpS) and the region of the underlying tendon was designated the lower segment (LwS). Elastographic regional patterns were graded with a scale used for grading organ based lesions, where grade1 demonstrates mostly red region ("soft tissue") and < 10% blue regions, grade 2 demonstrates > 25% green regions and > 10% but < 25% blue regions, grade 3 demonstrates 25-50% green region and > 25% but <50% blue region and grade 4 demonstrates > 50% blue regions ("hard tissue"); this grading 1-4 was labelled the elastography score (ES). Statistical analysis of response was performed with Shapiro-Wilk test and student t-test.

Results: The normal hand had an average ES of 5.08 in the UpS and an ES of 16 in the LwS. In contrast, the untreated Dupuytren's hand had an average ES of 12.36 in the UpS and an ES of 15.6 in the lower segment. The normal hand ES UpS vs untreated Dupuytren's hand UpS had $p < 0.01$ but the normal hand ES LwS and untreated Dupuytren's hand ES LwS did not. In the treated Dupuytren's hands, the ES UpS at baseline 11.6 decreased to 9.1 in the first 24 hours of treatment and by day 30 was 8.8 and the ES LwS changed from 14.4 to 12.7; the contracture changed from 35.6^{o} to 23^{o} and the URAM scale changed an average of 2 points. The normal hand ES UpS vs treated ES UpS had $p < 0.01$.

Conclusion: This pilot established an elastographic regional scoring system for normal and pathologic tissue affected by a fibrotic disorder and demonstrated that the elastographic regional scoring system could detect response to treatment. This has significant clinical implications for the treatment of Dupuytren's contracture as well as for other rheumatologic fibrotic disorders. Further study with a larger cohort is needed.

High Specificity of Spectral Nail Assessment in Psoriatic Arthritis Patients

JOSE ALEXANDRE MENDONÇA, 4Rheumatology Unit, Hospital da Pontificia Universidade Católica (PUC) de Campinas, Campinas, Brazil, Porto Alegre, Brazil; Rheumatology, Instituto de Pesquisa Clínica of Campinas – IPECC, Campinas, Brazil

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Imaging of Rheumatic Diseases Poster I: Ultrasound, Optical Imaging and Capillaroscopy

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Ultrasound evaluation of synovitis and enthesitis has changed the management of rheumatic diseases. In the present study we compare Power Doppler (PD) and Spectral Doppler (sD) ultrasonography indices (semiquantitative gray scale and PD scores and resistance index (RI) in the nails of patients with psoriatic arthritis (PsA) and their controls. Potential associations between sD measurements and clinical parameters were also investigated[1,2,3].

Methods: A cross sectional study was done and 44 patients with PsA, if they fulfilled the CASPAR criteria, 10 healthy controls and 6 patients with hands osteoarthritis (OA) were enrolled. Clinical parameters were recorded while US evaluation was performed in patients and controls nails. Nail bed measurements and semiquantitative gray scale (GS) and PD scores were derived for all nails examined, while RI was measured using sD.

Results: Statistically significant lower RI was found in patients with PsA as compared to their controls ***(p<0.001)***. RI measurements in our sample presented high sensibility and specificity for PsA. Area under the **ROC curve** was **0.858** ***(p<0.01)***. Choosing a **cut off point of 0.395** for RI measurements, the test indicates that RI values below **0.4** are associated with **100% sensitivity and 96% specificity** for entheseal inflammatory activity. Lower RI was observed even in PsA patients with no symptom of nail involvement. GS and PD semiquantitative scores were also significantly higher in PsA patients as compared to their controls ***(p<0.05)***. ROC analyzes demonstrated that RI measurements using sD presented high sensibility and specificity for PsA.

Conclusion: Nail sD indices are significantly different in PsA patients independently on the presence of clinically evident nail involvement. These sD parameters might find a place in early diagnosis, monitoring of disease activity and response to therapy in PsA patients.

Abstract Number: 192

Comparison of Bone Scan with Xiralite (FOI) in Patients with Rheumatoid Arthritis and Psoriatic Arthritis

Joerg Polter, Susanne Drynda and **Jörn Kekow**, Clinic for Rheumatology, Vogelsang-Gommern, Germany

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Imaging of Rheumatic Diseases Poster I: Ultrasound, Optical Imaging and Capillaroscopy

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

In recent years Xiralite, an ICG-enhanced fluorescence optical imaging (FOI) technology, has gained growing importance as a non-radioactive imaging technique for the detection of inflammatory processes in joints [1]. It was the objective of our study to compare this new technique with conventional bone scans and with clinical findings in rheumatoid arthritis (RA) and psoriatic arthritis (PsA) patients.

Methods:

420 joints of 14 RA patients and 350 joints of 11 PsA patients were analysed by Xiralite, bone scan, and clinical evaluation. Due to the Xiralite system, both hands were the ROI in the study.

Results:

In the RA cohort, 94 out of 420 joints (22%) were identified as inflamed using the bone scan. By means of Xiralite, 97 (23%) inflamed joints were detected. In the clinical examination, 82 joints (19.5%) were found to be swollen.

In PsA patients 48 (14.5%) and 63 (19%) joints were found inflamed using the bone scan and Xiralite, respectively, and 42 out of 330 joints (13%) were swollen.

In 11 out of 14 RA patients (78.5%) and 8 out of 11 PsA patients (75%) the Xiralite and the bone scan produced consistent results in at least 50% of the number of inflamed joints. In 9 RA patients and 4 PsA patients the consistency of both methods was even 75% and higher.

Conclusion:

Our data show comparable numbers of inflamed joints identified by Xiralite and the traditional bone scan with a high degree of consistency. Both techniques have been found equivalent for the identification of affected joints and superior to clinical evaluation. In PsA Xiralite identifies even more inflamed joints than to a bone scan.

Going Back to Basics – Redefining the Normal Pattern in Nailfold Capillaroscopy in a Large Healthy Population: Results of the German “Rheuma-Truck” Cohort

Moritz Schröder, Department of Rheumatology and Hiller Research Institute, Heinrich-Heine University, Duesseldorf, Germany

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Imaging of Rheumatic Diseases Poster I: Ultrasound, Optical Imaging and Capillaroscopy

Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Capillaroscopy is as a useful diagnostic tool in various connective tissue diseases characterized by microangiopathy and vasculitis. Different pathological patterns especially for systemic sclerosis are described and validated. However, the morphologic pattern of healthy individuals ("normal") has been disregarded. The normal pattern with its high negative prediction for the development of systemic sclerosis in individuals with Raynauds phenomenon is important for the everyday clinical use and for predictive trials.

Methods:

"Rheuma-Truck" was a mobile rheumatology office located in different city centers of Germany offering a screening for rheumatic diseases including questionnaires, lab-tests and imaging. We performed 200x magnification nailfold capillaroscopy of the 3rd to 5th finger of both hands in visitors without known prediagnosed rheumatic disease. The pictures were evaluated by experts based on the morphological findings. Documented morphologies were hairpin shaped capillaries (HC), tortuous capillaries (TC), ramification, elongation, calibre variations, bulging. Descriptive statistics for mentioned morphologies were obtained as the mean value ± standard deviation (SD), minimum (min), maximum (max), percentiles. Furthermore a possible impact of age, gender, and smoking was evaluated.

Results:

9771 pictures of 748 visitors were evaluated. The mean age of the examined individuals (75% female, 25% male) was 53,6 years. HC was the most documented morphology (mean 76% ± 23%, min 0%, median 80%, max 100%) followed by TC (mean 21% ± 23%, min 0%, median 20%, max 100%). Only 30% of the examined normal fingers showed 100% HC but 97% exclusively HC and TC. Ramification (2,9% ± 8,2%, min 0%, median 0%, max 100%); elongation (1,8% ± 6,4 %, min 0%, median 0%, max 60%); calibre variations (0,8% ± 4,5%, min 0%, median 0%, max 80%) and bulging (0,3% ± 3,0%, min 0%, median 0%, max 60%) are rare. Giant capillaries were seen in 0,07% of the fingers.

Conclusion:

HC dominate the normal pattern but TC are frequently seen in "normal" with significant ($p<0,001$) increasing probability in age and male. There is no significance for the age or gender after adding the results for HC and TC, suggesting a physiologic alteration without prediction for connective tissue diseases. Hence "normal" is defined (2 SD range of the mean) as 80-100% HC and/or TC, <10% calibre variations, <6% bulging, <19% ramifications, <15% elongation and no giant capillaries. This definition should be used as a reference in future trials and clinical use to enlarge the prediction for healthy individuals.

Events Upstream of Caspase-1 Activation in NLRP3-Mediated Cell Death in NOMID

Jehad H. Edwan, Raphaela Goldbach-Mansky and Robert A. Colbert, National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, MD

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Innate Immunity and Rheumatic Disease Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Gain-of-function mutations in NLRP3 cause a spectrum of autoinflammatory diseases known as cryopyrin-associated periodic syndromes (CAPS), with neonatal-onset multisystem inflammatory disease (NOMID) being the most severe form of CAPS. These mutations cause excess production of the proinflammatory cytokine IL-β, which is responsible, at least in part, for the phenotype. IL-1β is produced in a pro-form and processed to a mature form by active caspase-1. NLRP3 is a key component of a multiprotein complex known as the inflammasome that mediates the maturation and release of IL-1β, in part through caspase-1 activation, and can induce rapid cell death resulting in the release of other proinflammatory mediators such as apoptosis-associated speck-like protein containing a CARD (ASC). Two pathways to cell death have been implicated. One is caspase-1 dependent 'pyroptosis' and the other is caspase-1-independent 'pyronecrosis'. The precise molecular mechanisms, as well as the role of NLRP3 mutations in cell death, remain to be elucidated. Our recent data (manuscript in revision) provide evidence that caspase-1 inhibition only partially reduces IL-1β release and fails to abrogate cell death in cells from NOMID patients, while cathepsin B inhibition prevents both cell death and IL-1β release. Here we investigated the consequences of caspse-1 and cathepsin B inhibition on the link between released IL-1β and cell death.

Methods: Whole blood cells from NOMID patients and healthy controls were studied. Cells were stimulated with LPS in the presence of inhibitors of caspase-1 or cathepsin B, followed by addition of ATP. Cell supernatants were collected and incubated with IL-1β-capturing beads that bind to both pro- and processed IL-1β. Cells and beads were evaluated by flow cytometry. Supernatants and/or cell lysates from LPS stimulated cells were also evaluated using western blot analysis for IL-1β captured on beads and ASC.

Results: By flow analysis we confirmed that inhibition of cathepsin B in NOMID and healthy control monocytes, results in a significant decrease in IL-1β release and cell death while caspase-1 inhibition fails to inhibit cell death and only partially abrogates IL-1β release. Analysis of IL-1β in supernatants suggests that when caspase-1 is inhibited, only the pro form of IL-1β is found in the supernatant. However, cathepsin B inhibition completely prevents the appearance of IL-1β in supernatants. Furthermore, caspase-1 inhibition has no effect on ASC release, whereas cathepsin B significantly reduced ASC release in both NOMID patients and healthy controls.

Conclusion: These data suggest that cell death in NOMID patients and ATP induced cell death in healthy controls is caspase-1 independent, but requires cathepsin B activation, implicating the pyronecrosis pathway. In addition, our data provide evidence that pro-IL-1β is released from dying/dead cells despite caspase-1 inhibition. These results place caspase-1 activation downstream of cell death events, and disassociate IL-1β processing and cell death in NOMID patients.

Activation of the Pyrin Inflammasome through the RhoA Signaling Pathway in Familial Mediterranean Fever (FMF) and Hyperimmunoglobulinemia D Syndrome (HIDS)

Yong Hwan Park, Geryl Wood, Daniel Kastner and **Jae Jin Chae**, Metabolic, Cardiovascular, and Inflammatory

Disease Genomics Branch, NIH/NHGRI, Bethesda, MD
First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Innate Immunity and Rheumatic Disease Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Mutations in the genes encoding pyrin and mevalonate kinase (MVK) cause the autoinflammatory diseases familial Mediterranean fever (FMF) and hyperimmunoglobulinemia D syndrome (HIDS), respectively. The inflammation of both diseases is mediated by interleukin-1β (IL-1β). Recently it has been reported that pyrin forms an inflammasome, a multiprotein complex that mediates the maturation of IL-1β by activating caspase-1, in response to bacterial modifications of RhoA. However, the precise molecular mechanism of pyrin inflammasome activation, as well as the mechanism by which FMF-associated mutations activate pyrin, remain to be elucidated. Thus, here we investigated the molecular mechanism of pyrin inflammasome activation and the molecular pathogenesis of FMF and HIDS.

Methods: We studied IL-1β production in immune cells from wild type mice and from several knockout and knockin mouse strains, as well as from FMF and HIDS patients and healthy controls, in response to LPS and/or various other bacterial toxins, and in the presence of pharmacologic agents targeting the Rho GTPase or adenylate cyclase pathways. Protein interactions were studied by immunoprecipitation.

Results: The Clostridial TcdB and C3 toxins, which inactivate RhoA, activate IL-1β maturation by a pathway that is *Mefv*-, *Asc*-, and *Caspase-1*-dependent, but *Nlrp3-, Nlrc4-,* and *Aim2*-independent. IL-1β secretion induced by the Clostridial toxins or from bone marrow-derived macrophages (BMDMs) of FMF knockin (KI) mice is inhibited both by the bacterial CNF toxin, which activates RhoA, and by colchicine. Colchicine also inhibits the constitutive IL-1β secretion from peripheral blood mononuclear cells (PBMCs) of FMF patients. In addition, the constitutive IL-1b secretion from FMF patients' PBMCs or BMDMs of FMF-KI mice is potentiated by cAMP, which has a role in suppressing RhoA through PKA-mediated direct phosphorylation. RhoA inhibition-induced inflammasome activation is mediated by reduced activities of downstream RhoA-effector kinase, serine/threonine protein kinase C-related kinase (PKN/PRK). The kinase domain of PKN binds to pyrin directly and phosphorylates two serine residues (S208 and S242 of human pyrin). The phosphorylated pyrin is recognized by 14-3-3 proteins, which negatively regulate the pyrin inflammasome. The binding affinity of 14-3-3 proteins as well as PKN for FMF-associated mutant pyrin is substantially lower than for wild-type pyrin, and the constitutive IL-1β secretion from FMF or HIDS patients' PBMCs or macrophages of FMF-KI mice is attenuated by activating PKNs. Defects in prenylation, seen in HIDS, lead to RhoA inactivation and consequent pyrin inflammasome activation. Taken together, these data suggest that the inflammations in FMF or HIDS are caused by the constitutive activation of the pyrin inflammasome due to the decreased interaction of pyrin with 14-3-3 proteins.

Conclusion: These data directly implicate Rho GTPase in the regulation of the pyrin inflammasome, and suggest that this pathway is also important in HIDS.

The Pyrin Domain-Only Protein POP1 Inhibits NLRP3-Dependent

Inflammatory Disease

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Innate Immunity and Rheumatic Disease Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: In response to infections and tissue damage NLRP3 and ASC-containing inflammasome protein complexes are assembled, which promote caspase-1 activation, IL-1b and IL-18 processing and release and pyroptosis. Caspase-1 is also responsible for the release of ASC danger particles, which perpetuate and propagate inflammasome responses to bystander cells. However, excessive or persistent activation causes inflammatory diseases, including Cryopyrin Associated Periodic Syndrome (CAPS). Hence, a well-balanced inflammasome response is crucial to maintain homeostasis. Therefore inflammasome regulatory proteins likely exist to maintain an appropriate level of activity and in particular, to limit its activity during the resolution phase of this response. We propose that PYD-only protein POP1 is one of these proteins.

Methods: Available datasets of CAPS patients in the NCBI Gene Expression Omnibus database were analysed for POP1 expression. Monocyte/macrophage-expressing POP1 transgenic (TG) mice were generated and crossed with conditional NLRP3^{A350V} and Lysozyme M-Cre recombinase (CreL)-expressing mice. Offspring were analysed for CAPS by measuring body weight, survival and histological analysis. ASC-GFP particles were sorted by flow cytometry and used to trigger secondary inflammasome responses, which were analyzed in vitro and in vivo. Cytokines were analyzed by ELISA.

Results: Here we show that the PYD-only protein POP1 inhibits ASC-dependent inflammasome assembly by preventing inflammasome nucleation, and consequently interferes with caspase-1 activation, IL-1b and IL-18 release, pyroptosis and the release of ASC danger particles. Mice lack POP1, but transgenic POP1 expression in monocytes and macrophages protects mice from systemic inflammation triggered by ASC danger particles and CAPS-linked NLRP3mutations. CAPS patients exhibit reduced POP1 expression, suggesting that impaired POP1 expression may contribute to excessive inflammasome-driven inflammation. We further show that POP1 expression itself is regulated by IL-1b and propose that POP1 provides a regulatory feedback loop that shuts down excessive inflammatory responses and thereby prevents systemic inflammation.

Conclusion: POP1 provides a unique mechanism evolved in humans to enable more control for the essential inflammasome-mediated host defense system, thereby guarding against excessive and out of control responses that can cause inflammatory disease.

Synergy Between Hematopoietic and Radioresistant Stromal Cells Is Required for Autoimmune Manifestations of Dnase II Deficient Mice

Rebecca Baum[1], Kerstin Nundel[1], Sudesh Pawaria[1,2], Shruti Sharma[1], Patricia Busto[1], Tara Robidoux[1], Katherine A. Fitzgerald[1], Ellen M. Gravallese[3] and Ann Marshak-Rothstein[1], [1]Medicine, University of Massachusetts Medical School, Worcester, MA, [2]Department of Medicine, University of Massachusetts Medical School, Worcester, MA, [3]Lazare Research Bldg Ste 223, University of Massachusetts Medical School, Worcester, MA

Session Date: Sunday, November 8, 2015
Session Title: Innate Immunity and Rheumatic Disease Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Toll-like receptors (TLRs) dependent on Unc93b1 and cytosolic sensors dependent on STING detect microbial and endogenous nucleic acids to initiate inflammatory responses that resolve infection, but also contribute to autoimmune diseases. In the DNase $II^{-/-}$ $IFNaR^{-/-}$ (double knock out, DKO) mouse model, DNA accrual results in STING-dependent inflammatory arthritis as well as Unc93b1-dependent autoimmune manifestations, including ANA production, extramedullary hematopoiesis, and splenomegaly. While the role of hematopoietic cells in driving autoimmunity is well established, the contribution of stromal elements to disease pathogenesis is just beginning to be appreciated. Here we utilized bone marrow chimeras to determine the contribution of hematopoietic vs. radioresistant host cells to autoimmune manifestations in DKO mice.

Methods: Lethally irradiated Het (DNase $II^{+/-}$ $IFNaR^{-/-}$) or DKO mice were reconstituted with Het or DKO stem cells to generate four experimental groups: Het (donor)→Het (recipient), DKO→DKO, Het→DKO and DKO→Het. Additionally, Unc93b1$^{-/-}$ DNase $II^{-/-}$ $IFNaR^{-/-}$triple KO (Unc93b1 TKO) mice were used to generate DKO→Unc93b1 TKO and Unc93b1 TKO→DKO chimeras. Complete hematopoietic repopulation by donor BM cells in all groups was verified by flow cytometry using appropriate markers. Inflammation was assessed by clinical scoring (scale of 1-12), histologic scoring in ankle joints (scale of 1-4), and by measuring matrix metalloproteinase 3 (MMP-3) protein levels in the sera. Splenomegaly, ANA production, and extramedullary hematopoiesis were evaluated as other indicators of disease.

Results: As expected, Het→Het chimeras showed no evidence of arthritis while DKO→DKO mice showed significant inflammation in distal joints. Remarkably, neither the DKO→Het nor Het→DKO mice developed any clinical or histologic signs of arthritis over a 10-month period. Serum MMP3, a surrogate marker for inflammation, reflected the arthritis scores and further confirmed absence of inflammation in the DKO→Het and Het→DKO chimeras. The massive splenomegaly and extramedullary hematopoiesis observed in DKO mice were absent in the Het→Het chimeras and present in DKO→DKO mice. Surprisingly however, the Het→DKO and DKO→Het mice failed to develop splenomegaly or extramedullary hematopoiesis. Furthermore, autoimmune manifestations dependent on Unc93b1 were present in the DKO→Unc93b1 TKO mice but absent in Unc93b1 TKO→DKO chimeras.

Conclusion: These data reveal that both hematopoietic and radioresistant host cells must be DNase II-deficient in order for STING-dependent inflammatory arthritis to develop. Additional features of autoimmunity in these mice known to depend on Unc93b1, and therefore on endosomal TLRs, also require DNase II deficiency in both donor and host compartments, but require functional TLRs only in hematopoietic cells. These findings point to a critical interplay between endosomal and cytosolic nucleic acid receptors in the development of systemic autoimmunity, and suggest that targeting both hematopoietic and non-hematopoietic cells may be advantageous in autoimmune settings.

CL-L1 and CL-K1 Complement Associated Pattern Recognition Molecules in Systemic Lupus Erythematosus

Anne Troldborg[1], Steffen Thiel[2], Lisbeth Jensen[3], Magdalena Janina Laska[2], Søren Hansen[4], Bent Deleuran[5,6], Jens Christian Jensenius[2] and Kristian Stengaard-Pedersen[5], [1]clinical medicine, Aarhus University, Aarhus, Denmark, [2]Biomedicine, Aarhus University, Aarhus, Denmark, [3]Biomedicin, Aarhus University, Aarhus, Denmark, [4]Department of cancer and inflammation research, University of Southern Denmark, Odense, Denmark, [5]Rheumatology, Aarhus University Hospital, Aarhus, Denmark, [6]Biomedicin, Aarhus University, 8000, Denmark
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Innate Immunity and Rheumatic Disease Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: The complement system is one of the key players in the pathogenesis of systemic lupus erythematosus (SLE). Collectin liver 1 (CL-L1) and collectin kidney 1 (CL-K1) are recently discovered complement pattern recognition molecules. They form hetero-complexes termed CL-LK that collaborate with associated serine proteases to activate the lectin pathway of complement. The objective of this pilot study was to explore the involvement of CL-LK in a cross-sectional cohort of SLE patients by measuring plasma concentrations and analyze for associations between the plasma concentrations and characteristic SLE manifestations.

Methods: Prospectively, blood samples (citrated plasma), ACR classification criteria and SLE disease activity index score (SLEDAI) were collected from 58 SLE patients. Concentrations in plasma of CL-L1 and CL-K1 were determined in the SLE patients and in age and gender matched healthy controls using time resolved immuno-flourometric assays developed in house.

Results:

RESULTS	SLE Patients (n=58) Median plasma conc. ng/ml (range)	Healthy Controls (n=65) Median plasma conc. ng/ml (range)	Mann-Whitney P value
CL-L1	252(159-365)	306(195-510)	< 0.001
CL-K1	326(221-447)	337(248-495)	0.033

Both the CL-L1 and CL-K1 concentrations were lower in SLE patients than healthy controls ($p < 0.001$ and 0.033). Patients with low complement component 3 (C3) demonstrated a negative correlation between C3 and CL-L1 and CL-K1 ($p=0.022$ and 0.031). The concentrations of CL-L1 and CL-K1 were highly correlated in both SLE patients and in healthy controls ($r=0.576$ and $r=0.592$). We found no significant correlation between disease activity score or organ damage score and plasma concentrations of CL-L1 or CL-K1.

Conclusion : In a cross-sectional cohort of SLE patients, we found differences in the plasma concentrations of CL-L1 and CL-K1 compared to a group of healthy controls. We observed a strong correlation between concentrations of CL-L1 and CL-K1 in both SLE patients and healthy controls substantiating the idea of CL-L1 and CL-K1 being present as heterocomplexes in plasma.

The altered concentrations found in SLE patients and associations to elements of the disease, like hypocomplementemia, support the hypothesis that the lectin pathway plays a role in the pathogenesis of SLE.

Session Title: Innate Immunity and Rheumatic Disease Poster I

Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Spondyloarthritis (SpA) is a major form of chronic inflammatory arthritis characterized by inflammation of axial and peripheral joints and by pathologic new bone formation leading to ankylosis. Consistent genetic, experimental, and clinical evidence indicates that IL-23/IL-17 immune axis plays a pivotal role in the pathophysiology SpA. It remains, however, unknown which IL-23 responsive cells are the major cellular source of IL-17 in SpA. Innate lymphoid cells (ILCs) are an emerging family of innate immune cells that produce various cytokines, including IL-17 and IL-22, and play critical roles in regulation of inflammation and tissue remodelling. In this study we investigated the presence and phenotype of ILCs in the peripheral blood and inflamed peripheral joints of patients with SpA.

Methods: Paired peripheral blood (PB), synovial fluid (SF) and synovial tissue (ST) were obtained from SpA patients with actively inflamed knee joints. ILCs (lineage negative, $CD45^{+}CD127^{+}CD161^{+}$) were analysed by flow cytometry.

Results: ILCs were present in all three compartments of patients with SpA. Analysis of ST revealed a significantly increased frequency of total ILCs in the joint compared with PB ((median (IQR) 0.37 (0.12-1.12)% of the lymphocyte population in ST versus 0.06 (0.04-0.09) % of the lymphocyte population in PB, p=0.016). Deep immunophenotyping of ILC subsets showed a statistically significant increase in the frequency of ILC1 ($CRTH2^{-}NKp44^{-}ckit^{-}$) in ST (37.8%; 74.43-20.47%) versus SF (7.27%; 0.6-25.1 %, p=0.008) and PB (3.45%; 1.45-9.25%, p=0.004). The second most prominent ILCs in the joint were NCR-negative ILC3 ($CRTH2^{-}NKp44^{-}ckit^{+}$), composing 33.45% (9.54-50.64%) of the total ILCs. NCR-positive ILC3 ($CRTH2^{-}NKp44^{+}ckit^{+}$) and ILC2 ($CRTH2^{+}$) populations were present in synovium at lower frequencies.

Conclusion: We observed in the inflamed ST of patient with spondyloarthritis an absolute and relative enrichment of both ILC1 and NCR-negative ILC3 as compared to PB and SF. As studies in other tissues such as gut and tonsil revealed that these IL-23 responsive ILC subsets can be an important source of IL-17 and /or IL-22 (1, 2), we will investigate the cytokine production by these synovial ILCs.

Mast Cell Regulation of Aortic IL-6 Expression Involves Histamine-1 Receptor, Suppressor of Cyotkine Signaling-1 and IL-10

Vineesh Raveendran[1], **Jason Springer**[2], Donald Smith[3], Mehrdad Maz[4] and Kottarappat Dileepan[1], [1]Department of Medicine, University of Kansas Medical Center, Kansas City, KS, [2]Division of Allergy, Clinical Immunology and Rheumatology, University of Kansas Medical Center, Kansas City, KS, [3]University of Kansas Medical Center, Kansas City, KS, [4]Division of Rheumatology, University of Kansas Medical Center, Kansas City, KS

Session Title: Innate Immunity and Rheumatic Disease Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: IL-6 plays an important role in the pathogenesis of large vessel vasculitis. Lipopolysaccharide (LPS), acting through toll-like receptor 4, enhances both the aortic expression as well as serum levels of IL-6. Previous work by our group has demonstrated that systemic mast cell degranulation will inhibit both the serum and aortic expression of IL-6 in LPS injected mice. Mast cells release many vasoactive substances including histamine, proteases, and IL-10 . Our hypothesis is that the inhibitory effect of mast cells on aortic IL-6 production is mediated through histamine and/or IL-10.

Methods: Two month-old male C57BI6 (WT) and Histamine 1 Receptor (H1R) -/- mice were randomized into four groups, and given intraperitoneal injections with normal saline (control), compound 48/80 (mast cell degranulation agent, 1mg/kg), LPS (1mg/kg) or C48/80+LPS. Mice were sacrificed 24-h later, and levels of the stable metabolites of prostaglandin I_2 (PGI_2) and thromboxane A_2 (TXA_2) in the urine, and IL-6 and IL-10 in sera were quantified.

Results: MC degranulation did not increase PGI_2 in control or in LPS-treated mice of either genotype. LPS injection increased PGI_2 in both genotypes, but the increase was higher in H1R-/- mice. Both C48/80 and LPS increased TXA_2 in WT mice, but only LPS treatment enhanced TXA_2 in H1R-/-mice indicating importance H1R in this pathway. Treatment with C48/80 did not further enhance prostanoid production over LPS. LPS treatment increased serum IL-6 in both genotypes, but the changes were significant only in WT mice. Interestingly, LPS-induced IL-6 production was significantly reduced by MC degranulation in WT mice, but not in H1R-/- mice. In WT mice the inhibition of IL-6 was associated with enhanced aortic expression of SOCS1. In comparison to WT, the basal and induced levels of IL-10 were markedly higher in H1R-/- mice.

Conclusion: Mast cells differentially regulate LPS-induced inflammatory response in WT and H1R -/- mice. These results suggest that MCs regulate LPS-induced systemic and aortic inflammatory response involving H1R, SOCS-1 and IL-10.

Innate Lymphoid Cells Are Present at Normal Human Enthesis Providing a Potential Mechanism for Spondyloarthropathy Pathogenesis

Richard Cuthbert[1], Evangelos M. Fragkakis[1], Peter Millner[2], Robert Dunsmuir[2], Yasser El-Sherbiny[1] and Dennis McGonagle[1], [1]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom, [2]Department of Spinal Surgery, National Health Service, Leeds, United Kingdom

Session Title: Innate Immunity and Rheumatic Disease Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The pathogenesis of murine spondyloarthropathy (SpA) has been intimately linked to the presence of IL-23 responsive, innate like lymphocytes at peripheral and spinal enthesis. Human SpAs are associated with SNPs in genes related to the IL-23 pathway and drugs that block IL-12/23 have shown efficacy. We hypothesised that the normal human enthesis has a population of resident innate lymphoid cells (ILCs) that could be key in governing entheseal immune homeostasis.

Methods: Normal spinal enthesis were harvested from patients undergoing spinal decompression surgery and enzymatically digested prior to sorting or flow cytometry. Cellular immunophenotyping and cell sorting was performed on enthesis samples harvested from 6 patients; ILC3s were identified as lineage (CD3- TCRγδ- TCRαβ- CD19- CD14- CD11c- CD1a- CD303- FcεRI- CD34- CD123-) and CRTH2 negative with positive expression of CD45, CD127, CRTH2, CD117. ILC2 were identified as lineage negative with positive expression of CD45, CD127 and CRTH2. The expression of RORγt transcript was tested in sorted populations by RTqPCR. Anterior cruciate ligament femoral enthesis was obtained from subjects with knee OA and injured enthesis undergoing repair were also collected and analysed by immunohistochemistry (IHC).

Results: All sorted samples contained ILC3s, median proportion 0.09% (range 0.015-0.63). Transcript analysis confirmed the expression of RORγt transcript in sorted ILC3 populations, with ILC3s expressing 51-fold greater relative expression in comparison to unsorted digests. 5 of 6 sorted samples contained ILC2s, median proportion 0.20% (range 0-0.49). RORγt expression was detected in knee OA and there was widespread expression of RORγt in inflammatory infiltrates in injured enthesis as shown by IHC.

Conclusion: Our findings show that ILCs are present in the normal human spinal enthesis and may be greatly increased in frequency following injury. These findings provide strong evidence of ILC presence in normal human enthesis and suggest a potential link between cellular dysregulation of the IL-23/17 axis and SpA pathology at sites of micro damage.

Bone Accrual in the Dnase II-Deficient Model of Autoimmunity Requires Sting, As Well As Hematopoietic and Stromal Elements

Session Title: Innate Immunity and Rheumatic Disease Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: We have previously identified a role for cytosolic DNA sensors in bone by analyzing mice that develop inflammatory polyarthritis and trabecular bone accrual in the setting of DNA accumulation. In this model, DNA accrues in macrophages due to deletion of DNase II and is detected by cytosolic sensors that signal through stimulator of interferon genes (STING). This results in inflammatory cytokine and Type I IFN production. Type I IFNs in DNase $II^{-/-}$mice lead to anemia-driven embryonic lethality; thus co-deletion of the type I IFNR is essential (DNase II/IFN-IR double deficient (DKO) mouse). Although macrophages are implicated as a critical cell type in this model, new evidence suggests that a stromal component also plays an important role in the observed bone phenotype.

Methods: Histologic analysis of long bones was performed to confirm phenotypes. Macrophages were expanded from bone marrow (BM) of wild type (WT) and STING-deficient mice, transfected with poly(dA:dT) and RNA was analyzed by Nanostring using probe sets for genes in both innate immune and bone-related pathways. RNA was also prepared from whole BM from control and DKO mice, and similar Nanostring analyses were performed. We utilized bone marrow chimeras to determine the contribution of hematopoietic vs. radioresistant host cells to the bone phenotype. Lethally irradiated Het (DNase $II^{+/-}$ $IFNaR^{-/-}$) or DKO mice were reconstituted with Het or DKO stem cells to generate four groups: Het (donor)→Het (recipient), DKO→DKO, Het→DKO and DKO→Het. Complete reconstitution was verified by FACS analysis.

Results: As previously reported (A&R 2014; Vol 66:11S, 788), we found that trabecular bone accumulates in long bone and spleen in DKO mice, two sites of DNA accrual in macrophages. MicroCT, CFU assays for osteoblast precursors, and histomorphometry all supported a predominant role for osteoblasts in this bone phenotype. We showed that STING deficiency abrogated both arthritis and bone accrual in DKO mice. We now show that in total BM from DKO mice, expression of STING itself as well as of Ifi204, a cytosolic DNA sensor in the STING pathway, is up-regulated. BM-derived macrophages were prepared from WT and STING-deficient mice and transfected with poly(dA:dT), resulting in a trend toward up-regulated expression of genes known to promote osteoblast differentiation. STING deficiency abrogates up-regulated expression of these genes. Finally, analysis of bone marrow chimeras demonstrated that only DKO→DKO mice developed trabecular bone accrual, demonstrating that both hematopoeitic and stromal elements are required for expression of the bone phenotype.

Conclusion: Trabecular bone accrual is a feature of the autoimmune DKO mouse model. We have identified candidate factors that may drive osteoblast differentiation and function in this model, the expression of which depend on STING. Furthermore, macrophages contribute to the bone phenotype. However, bone marrow chimeras demonstrate that both hematopoietic and stromal elements are required. Identification of novel pathways linking innate immunity and bone may allow for new targets to treat bone loss in autoimmune disease.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Innate Immunity and Rheumatic Disease Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Autoimmunity is a diverse group of complex conditions that can include certain congenital genetic defects leading to loss of self-tolerance with subsequent imbalances of immune homeostasis and pro-inflammatory bias. Recently we reported a monogenic disorder of interstitial lung disease, renal disease, and arthritis with accompanying autoantibodies. This syndrome was found to be mediated by mutations in the coatomer subunit alpha (*COPA*) gene, which belongs to the coatomer-1 (COPI) complex involved primarily in the retrograde transport of proteins from the golgi apparatus to the endoplasmic reticulum (ER). These mutations result in an increase in ER stress, an increase in basal levels of autophagy, and an over activation of mTOR ultimately resulting in a pro-inflammatory environment, particularly increased levels of IL-1β.

Methods: In an effort to provide more rational treatment for COPA syndrome patients we hypothesize that modulation of the autophagy axis will result in a decrease in the pro-inflammatory environment.

Results: Here we show that treatment of COPA mutant expressing cells with autophagy modifying drugs, including rapamycin and chloroquine, result in normalization of autophagosome size, retention of IL-1β and a decrease in caspase-1 activity.

Conclusion: Taken together these data suggest that repairing the underlying cellular defect in ER stress, autophagy, and excessive mTOR activity will alleviate the pro-inflammatory environment, particularly increased IL-1β levels, and lead to a more balanced immune phenotype in COPA syndrome patients.

Histone Methylation Profiling in Peripheral White Blood Cells As a Candidate Biomarker for Behcet's Disease

Yoshimi Aizaki[1,2], Yasuto Araki[1,2], Kojiro Sato[1], Yuji Akiyama[1] and Toshihide Mimura[1,2], [1]Department of Rheumatology and Applied Immunology, Faculty of Medicine, Saitama Medical University, Saitama, Japan, [2]Project Research Division, Research Center for Genomic Medicine, Saitama Medical University, Saitama, Japan

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Innate Immunity and Rheumatic Disease Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Behcet's disease (BD) is a chronic recurrent, multisystem inflammatory disorder. The phenotypic characteristics include oral aphtha, genital ulcers, uveitis and skin lesions. No specific laboratory tests have been known in BD. Reported in BD have been an increased number of γδ T cells in the peripheral blood and hyperactivity of neutrophils. Although a line of evidence has suggested genetic contributions to the disease, etiopathogenesis of BD is still unclear and non-genetic factors, like environment, infection or epigenetics may play pivotal roles in the pathogenesis. Epigenetic mechanisms including posttranslational histone modifications are known to regulate gene expression without altering the genomic sequence. The association of specific histone modifications with gene expression is very well defined, such as tri-methylation of histone 3 lysine 27 (H3K4me27), which may be characteristic of repressed genes, or tri-methylation of histone 3 lysine 4 (H3K4me3), which may present in many active genes. Histone modifications in major rheumatic diseases, such as rheumatoid arthritis, have been investigated, while studies on histone modifications in BD are limited. From the functional point of view, it is important to analyze differences of histone modifications in each functional subclass of the entire peripheral blood nucleated cells. To examine the histone modifications of peripheral blood mononuclear cells (PBMCs) and neutrophils in BD, we have established a novel method analyzing histone methylation in each subset by fluorescence-activated cell sorting (FACS).

Methods: PBMCs and neutrophils were obtained from 13 patients with BD and 12 healthy controls (HC). Diagnosis of BD was made according to the criteria of Behcet's Disease Research Committee of Japan, Ministry of Health, Labour and Welfare of Japan. Four immune cell types were stained surface epitopes: CD4+ T cells, CD8+ T cells, γδ T cells, and CD16+CD66b+ neutrophils. Flow cytometry for H3K4me3 and H3K4me27 were normalized using isotype controls. All samples were analyzed on a FACSCalibur cytometer. As a quantitative measure of H3K4me3 and H3K27me3, mean fluorescence intensity (MFI) was used.

Results: H3K27me3 and H3K4me3 were detected in CD4+ T cells, CD8+ T cells, γδ T cells, and CD16+CD66b+ neutrophils. H3K27me3 MFI levels were not significantly different in those four immune cell types in BD and HC. In contrast, H3K4me3 MFI levels of BD in γδ T cells were significantly increased compared with HC. H3K4me3/H3K27me3 MFI ratio was significantly lower in neutrophils of BD and higher in γδ T cells of BD than that of HC. H3K4me3 MFI and H3K4me3/H3K27me3 MFI ratio of active BD were significantly increased in γδ T cells as compared to inactive BD.

Conclusion: Difference in histone modifications could be detected by FACS in peripheral white blood cells in BD patients. Aberrant histone methylation may be associated with the pathogenesis of BD. It is suggested that histone methylation could be a new candidate-biomarker for BD.

Mode of Action of Therapeutic Anti-Citrullinated Protein Antibodies Revealed: Inflammation Reduction Due to Inhibition of Netosis

Session Title: Innate Immunity and Rheumatic Disease Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Neutrophils together with aberrant Neutrophil Extracellular Trap (NET) formation contribute to the induction and propagation of inflammation. A growing number of studies indicate that Peptidyl Arginine Deiminases (PADs)-mediated conversion of arginine to citrulline residues in proteins are essential for NETosis, generation of auto-antigens, autoimmunity, and the breaking of tolerance in rheumatoid arthritis (RA). In RA patients, enhanced NETosis is observed in circulating and synovial neutrophils, and NET components are observed in blood and joints. We developed a novel first in class NET-inhibiting anti-citrullinated protein antibody (tACPA) treatment for RA.

Methods:

Human neutrophils from blood donors have been used in order to visualize the NETosis-inhibiting properties of tACPA. Furthermore, collagen antibody-induced (CAIA) as well as collagen-induced (CIA) arthritis mouse models have been used in order to test the therapeutic properties of tACPA.

Results:

In the CAIA mouse model, tACPA prevents the onset and/or exacerbation of inflammation, and prevents or strongly reduces joint damage. Therapeutic administration of tACPA resulted in the arrest of inflammation and prevented a further increase of the inflammatory response. Histological analysis of inflamed joints from tACPA-treated mice revealed a significant decrease in neutrophil influx as well as a decrease in joint damage, as compared to control animals. We identified the epitopes recognized by tACPA to be citrullinated domains of histone-2A, 3 and 4. Since neutrophils together with aberrant NET formation contribute to the induction and propagation of inflammation, we investigated whether tACPA's cellular mode of action could be through blocking NET formation or its activity by binding to citrullinated histone-2A, 3 and 4. Other groups have already demonstrated that PAD activity and citrullinated epitopes are essential for NET formation. For this purpose, we isolated neutrophils from blood of healthy human donors and induced NETosis with PMA or calcium ionophore A-23187. Treating neutrophils that undergo NETosis with tACPA led to a 40-60% NET reduction if compared to non-treated cells (n>34 different donors). This observation has been confirmed by Myeloperoxidase activity as well as immunohistochemistry read-outs.

Conclusion:

We have identified antibodies directed against a citrullinated epitope in murine and human histone-2A, 3 and 4. In RA mouse models, we demonstrate that tACPAs exhibit a strong anti-inflammatory activity and prevent the occurrence of swelling and joint damage. We propose that the therapeutic effect of tACPA acts through the inhibition of NET and auto-antigen formation, clearance of formed NETs and toxic histones. In RA patients, extinguishing auto-antigen production offers an orthogonal approach for treating this destructive autoimmune disease, potentially without impacting systemic immunity.

Citryll is developing tACPAs for first in man PoC trials for diseases where dysregulated NETs and NETosis are driving or contributing to disease progression. A particular suited RA patient subpopulation for tACPA therapy are those patients with activated PAD4 enzymes and increased NETosis.

Session Title: Innate Immunity and Rheumatic Disease Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Immune regulation is necessary for limiting excessive immune responses and for preventing autoimmune diseases. Nuclear factor (NF)-κB signalling plays an important role in the regulation of immune responses. We have previously demonstrated that the activation of the non-canonical NF-κB pathway in dendritic cells (DC) via CD40 stimulation is important for the induction of the immunoregulatory enzyme indoleamine 2,3-dioxygenase (IDO). Non-canonical NF-κB signalling is also important for the expression of Autoimmune Regulator (AIRE) in the thymus, which is essential for establishment of central tolerance. We have recently found extrathymic AIRE-expressing cells (eTACs) in glandular tissue from Sjögren's syndrome patients and in rheumatoid arthritis inflamed synovial tissue. eTACs are mainly antigen presenting cells, including DC, that can induce peripheral tolerance. However, stimuli that induce extrathymic AIRE expression in DC are unknown. Therefore, we studied whether activation of non-canonical NF-κB signalling induces AIRE expression in DC.

Methods: Monocyte-derived DC were generated by culturing healthy donor monocytes for 6 days with GM-CSF and IL-4. Maturation was induced by addition of LPS or CD40 stimulating antibodies and/or RANKL for 48 hours. *AIRE* and *IDO* expression was quantified by qPCR and cleavage of p100 into p52 (indicative of active non-canonical NF-κB signalling) was analyzed by western blot. Presence of AIRE and IDO protein was also analyzed by western blot and immunofluorescence staining. Additionally, *Aire* and *Ido* gene expression was analyzed in anti-CD40 stimulated murine bone marrow-derived (BM)DC generated from wild type and *Nik*$^{-/-}$ mice.

Results: Both anti-CD40 and RANKL stimulation of DC induced cleavage of p100 into p52, accompanied by upregulation of IDO and AIRE expression. Anti-CD40 stimulation also induced *Ido* and *Aire* expression in murine wildtype BMDC, but not in BMDC from *Nik*-/- mice.

Conclusion: Non-canonical NF-κB signaling is involved in AIRE and IDO expression in DC. This may reflect an imunoregulatory program in these cells. Eventually, this knowledge may be exploited to develop new treatment modalities for patients with autoimmune diseases, including DC-based therapies to modulate immune responses.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Innate Immunity and Rheumatic Disease Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Certain medications are known to induce autoimmune disease in humans, triggering clinical features and autoantibody profiles that mirror idiopathic systemic lupus erythematosus (SLE) and/or ANCA-associated vasculitis (AAV). Neutrophil extracellular traps (NETs) have been implicated in the pathogenesis of both SLE and AAV, and NETs contain the antigenic targets (double-stranded DNA, MPO and PR3) of autoantibodies typically identified in cases of drug-induced autoimmunity. A subset of patients with SLE have impaired NET degradation likely due to presence of DNase I inhibitors or anti-NET antibodies in serum. These findings suggest that impaired regulation of NETosis triggers an autoimmune response against components of NETs and induces autoimmune diseases, including AAV and SLE. This study explored whether medications commonly implicated in cases of drug-induced autoimmunity (hydralazine and procainamide) and medications less commonly implicated in drug-induced autoimmunity, but more strongly associated with agranulocytosis (minocycline and clozapine), induce NET formation.

Methods: Human and murine neutrophils (PMNs) were incubated with medications of interest for one and four hours, respectively, at varying concentrations to mimic physiologic conditions. To address potential induction of impairments in NET degradation, drug-induced NETs were exposed to 10% serum from healthy control patients for 6 hours. NETs were visualized and quantified using fluorescence microscopy. To investigate whether drugs modulate NETosis through canonical pathways, NET inhibition was quantified when PMNs exposed to medications were incubated with Diphenyleneiodonium chloride (DPI; NADPH-oxidase inhibitor), BB-Cl-amidine (peptidylarginine deiminase (PAD) inhibitor) and specific muscarinic receptors antagonists. Release of hydrogen peroxide was measured by Amplex-Red Hydrogen Peroxide/Peroxidase Assay Kit. Whether these drugs stimulate various toll-like receptors (TLRs) was assessed using a human ligand TLR screening platform.

Results: Hydralazine and procainamide induced NETs in human and murine PMNs, while minocycline and clozapine did not. NET degradation was not impaired by these drugs. Hydralazine, but not procainamide, induced significant release of hydrogen peroxide in PMNs and triggered NET formation through canonical pathways (NADPH and PAD4). In addition, induction of NETs by procainamide was inhibited by addition of the muscarinic antagonists atropine, scopolamine, and specific M1/M3 inhibitors. Neither hydralazine nor procainamide stimulated TLRs in PMNs.

Conclusion: Certain medications implicated in drug-induced autoimmunity trigger formation of NETs via different pathways. Induction of NETs by hydralazine is dependent on PADs and NADPH oxidase. Procainamide induces NETs via stimulation of specific muscarinic receptors on PMNs. NETs may play a causal role in drug-induced autoimmunity.

Session Title: Innate Immunity and Rheumatic Disease Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Dysregulation of neutrophil activation and function is important in the pathogenesis of various inflammatory and autoimmune rheumatic diseases (ARDs). Neutrophil dysfunction is well recognised in rheumatoid arthritis (RA), but has also been described in systemic lupus erythematosus (SLE) and antiphospholipid syndrome (APS). Integrin mediated adhesion modulates several aspects of neutrophil activation and function including: cytokine production; generation of reactive oxygen species (ROS); and the release of neutrophil extracellular traps (NETs), which are associated with disease manifestations in certain ARDs. Autoantibodies from patients with ARDs have been shown to bind to and promote the formation of NETs. Therefore, we investigated the effects of purified IgG from patients with ARDs on ROS generation, integrin mediated neutrophil adhesion and NETosis.

Methods:

Neutrophils and IgG were isolated from patients with APS (n=9), SLE (n=5), RA (n=9) or healthy controls (HC) (n=9). ROS production of phorbol 12-myristate 13-acetate (PMA)-stimulated HC and ARD neutrophils, as well as in HC neutrophils preconditioned with ARD or HC IgG, was measured using an enzymatic assay to assess hydrogen peroxide (H_2O_2) generation. Effects of purified IgG upon neutrophil adhesion to immobilised integrin ligands, including fibrinogen (macrophage-1 antigen; Mac-1/$\alpha_M\beta_2$-dependent) and fibronectin (very late antigen-4; VLA-4/$\alpha_4\beta_1$-dependent) were then determined using a fluorescent adhesion assay. NETosis of IgG-treated HC neutrophils was measured using a novel capture ELISA.

Results:

Stimulation of HC and ARD neutrophils with PMA produced similar rates of H_2O_2 generation (n=4, p=0.2286).

However, exposure of HC neutrophils to SLE (n=5; p<0.001) or RA (n=9; p<0.01) IgG increased H_2O_2 production compared to HC (n=9) IgG. Adhesion of PMA-stimulated HC neutrophils to fibrinogen was increased when incubated with RA (n=9; p<0.05) or SLE (n=5; p<0.001) IgG compared to APS (n=9) and HC (n=9) IgG, which was shown to be mediated by $\alpha_M\beta_2$ through the use of a specific blocking antibody. In contrast, APS IgG increased adhesion of PMA-stimulated HC neutrophils (n=9, p<0.05) to fibronectin compared with RA (n=9), SLE (n=5) and HC (n=9) IgG, that was shown to be dependent on β_1 integrins. We also demonstrated differential effects of IgG on NETosis; with APS (n=3) and SLE (n=4) IgG eliciting greater effects than HC (n=7) and RA (n=14) IgG on spontaneous NETosis of HC neutrophils (p<0.05).

Conclusion:

Neutrophils isolated from patients with ARDs did not display different rates of ROS generation compared to controls. We found however, differential activation of neutrophils using patient IgG on HC neutrophils. In particular, RA and SLE IgG increased ROS generation and neutrophil adhesion to fibrinogen in a $\alpha_M\beta_2$-dependent manner, whilst APS IgG increased neutrophil adhesion to fibronectin in a $\alpha_4\beta_1$-dependent manner. Work is currently underway to further evaluate the intrinsic differences between ARD and HC neutrophils, and to dissect the mechanisms underlying these distinctive patterns of IgG mediated neutrophil activation and their relevance to NETosis and disease pathogenesis.

Session Title: Innate Immunity and Rheumatic Disease Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Mononuclear phagocytes depurate apoptotic cells, microparticles (MPs), and immune complexes (IC), leading to a tolerant or inflammatory microenvironment. The MPs, vesicular structures mainly produced during activation and cell death, have a wide spectrum of biological activities in intercellular communication. We propose circulating MPs must be recognized by monocytes affecting their frequency, maturation, migration, and function. This could have an impact on the clinic and activity of this disease. Then, monocytes and MPs were studied in the peripheral blood from SLE patients and healthy controls.

Methods: Venous blood samples from patients with SLE and healthy controls were collected. Monocytes subsets (classical, intermediate and non classical) were defined based on the expression of CD14 and CD16 in HLA-DR+

cells, and several phenotypic markers were assessed by multiparametric flow cytometry. MPs were isolated from platelet-poor plasma by ultra-centrifugation and characterized by multiparametric flow cytometry.

Results: SLE patients had elevated percentages of MPs that forming IC, IgM+, and IgM+IgG+, and, MP HMGB1+ and C1q+. We did not observed differences in the number of MPs, size, or in the content of DNA, RNA and phosphatidylserine externalization compared to healthy controls. To understand the possible pathways by which mononuclear phagocytes interact with MPs, we evaluated putative receptors in monocytes. Monocyte subsets from SLE patients have decreased expression of the scavenger receptor CD36. Non-classical monocytes had increased expression of FcgR CD64, but not in CD16, CD32, and TOSO (FcmR). The protein subunit that forms the complement receptor 3 (CR3), CD11b, was reduced in classical and intermediate monocytes. These data suggest that circulating MPs of SLE patients are probably less recognized by monocytes through CD36 and CR3, allowing the recognition of them through FcgR and FcmR.

Classical and intermediate monocytes of these patients had reduced expression of CCR2 and CX3CR1; and the CCR5 was reduced in classical monocytes. This suggests that mainly circulating classical and intermediate monocytes from SLE patients have reduced ability to interact with the endothelium and to migrate in response to fractalkine, monocyte chemoattractant protein 1, RANTES, and macrophage inflammatory protein 1α and 1β. On the other hand, we observed a reduced percentage of circulating non-classical monocytes in SLE patients. This result, together with their normal expression of CX3CR1, suggests that this monocyte subset may be recruited into inflamed tissue as the kidney, where they have been observed augmented.

Conclusion: All these evidences, suggest that circulating MPs may interact with phagocytes from patients in a different way than with healthy controls; mediating alterations on their activation patterns, migration, contact with the endothelium, and induction of tissue damage in SLE patients. The identification of the modulatory effect of these MPs in monocytes will provide new potential targets to develop alternative treatments.

Session Title: Metabolic and Crystal Arthropathies Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Several studies have suggested that the prevalence of gout has increased over recent years. The majority of this data has been derived from insurance claims databases. However, there are few data available regarding a possible change in the incidence of gout in the United States. We therefore aimed to determine whether

there has been a change in the incidence of gout over the last 20 years, and evaluate possible changes in the clinical presentation of gout.

Methods: The individual medical records of all patients with a potential diagnosis of gout in a defined geographic cohort were reviewed using a resource insuring complete medical record capture. All individuals with a possible diagnosis of incident gout during the time periods January 1st 1989 - December 31st 1992 and January 1st 2009 – December 31st 2010 were identified. Incident cases had to fulfill at least 1 of 3 criteria: the 1977 American College of Rheumatology proposed criteria for gout, the Rome or New York criteria. Demographic and clinical data were abstracted for every incident case. Clinical characteristics were compared between time-periods using chi-square tests. Incidence rates with 95% confidence intervals (CI) were age- and sex-adjusted to the 2010 U.S. white population.

Results: A total of 158 patients with new-onset gout were identified during the 4 year time period between 1989-1992 and 271 patients between the 2 year time period between 2009-2010, translating into age- and sex adjusted incidence rates of 52.1/100 000 (95%CI 43.7-60.5) and 106.9/100 000 (95%CI 94.1-119.8), respectively. The incidence rate ratio for gout of 2.57 (95%CI; 2.11, 3.13) increased significantly over the last 20 years.

Patients diagnosed with gout between 2009-2010 were less likely to present with isolated podagra compared to patients diagnosed 20 years ago (67% versus 80%). Patients with gout incident in the recent period 2009-2010 had higher likelihood of having comorbid conditions compared with 1989-1992, such as hypertension (73% vs. 54%), diabetes (27% vs. 6%), kidney disease (32% vs. 11%), hyperlipidemia (65% vs. 21%), and heart failure (15% vs. 6%), respectively, at the time of their first gout flare. The likelihood of obesity among patient with incident gout increased from 37% to 56% over the last 20 years - with an increase of morbid class III obesity from 3% to 13%.

Conclusion: The incidence of gout has more than doubled in our population-based cohort over the last 20 years. This observation appears to be consistent with the increase in prevalence reported in several studies to date. Patients have become more likely to present with atypical presentations in joint areas other than the 1st MTP joint, which may make the diagnosis more challenging.

The marked increase in various cardiovascular comorbidities and risk factors among patients with incident gout is concerning and emphasizes that gouty arthritis rarely occurs as a stand-alone problem, but rather must be seen as a manifestation of serious systemic metabolic disease.

Session Title: Metabolic and Crystal Arthropathies Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Gout is increasingly becoming recognized as the most common form of inflammatory arthritis worldwide; however, no Canadian general population-based data on the disease burden of gout are available. We estimated the incidence and prevalence of gout in an entire Canadian province (British Columbia, BC) from 1997-2012.

Methods: We utilized Population Data BC, an administrative database spanning the province of BC (approximately 4.5 million individuals) that includes all outpatient visits and hospital admissions from 1990-2012. The primary case definition of gout was at least one recorded diagnosis of gout (ICD-9-CM 274 or ICD-10-CA M10) at either a physician or hospital visit. We additionally explored secondary definitions of gout using available detailed medication dispensation information (obtained from BC PharmaNet), including individuals with at least two recorded diagnoses of gout or at least one recorded diagnosis of gout plus at least one dispensation of anti-gout medication (i.e., allopurinol, febuxostat, probenecid, or colchicine). To ensure incident gout cases, we required all newly diagnosed individuals to have at least five years prior without any record of a gout diagnosis. Annual incidence and prevalence estimates were age-sex-standardized using 2012 as the reference. Annual population estimates were obtained from BC Stats.

Results: Of 4,542,508 individuals in BC in 2012, we identified 173,003 prevalent gout cases (68% male, mean age 63 years) for an overall prevalence of 3.81%. The corresponding prevalence in the same calendar year among males and females was 5.22% and 2.41%, respectively. The prevalence additionally increased according to age group, reaching 11.65% among individuals at least 65 years old. We additionally identified 14,892 incident cases in 2012 for an overall incidence rate of 3.28 per 1,000 person-years. The corresponding incidence rates among men and women in 2012 were 4.32 and 2.25, respectively, per 1,000 person-years. Both the prevalence and incidence of gout increased substantially over the study period **(Figures 1a and 1b)**. All secondary case definitions of gout showed similar levels of this increasing trend.

Conclusion: These findings from BC, representative of the Canadian general population, indicate that the incidence and prevalence of gout are substantial and have increased over the past several decades.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Metabolic and Crystal Arthropathies Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Gout is the most common form of arthritis, and its prevalence is increasing. The identification of monosodium urate (MSU) crystals in synovial fluid (SF) or in an aspirate of a tophus is considered to be the gold standard for the definitive diagnosis of gout (1,2). MSU crystal disappearance from SF depends on the reduction of serum uric acid concentrations and is associated with a decrease of joint inflammatory episodes (3). In addition to diagnostic purposes, SF examination, in particular MSU crystals counting, could be used to evaluate the efficacy of therapy.

Aim of the study is to test an objective method for counting MSU crystals in the SF.

Methods: The SFs of 44 consecutive patients affected by gout diagnosed according to the ACR preliminary criteria were studied. Six of the patients underwent multiple SF aspirations for a total of 52 SFs. SF aspirated was divided into two test tubes, for cytological evaluation and crystal detection, respectively. Cytological evaluation included leukocyte and differential count. For crystal detection, 20 µl of fresh SF were placed on a microscope slide and examined by compensated polarized microscopy (400x). For crystal count, the slide was divided into 4 equal parts drawing a cross with a pencil. The method of count was performed by continued viewing and in each quadrant the crystals were counted up to a maximum of 400 (maximum number of crystals/patient was 1600). Two observers evaluated separately 27 SFs and repeated the count in 21 SFs after 24 hours.

Results: Forty of forty-four patients (90.9%) were men; mean age was 65.2±11.8 yrs. Aspirated joints were the knee (48 SFs), elbow (1 SF), 1st metatarsophalangeal joint (2 SFs), and ankle (1 SF). The volume of SF ranged between 0.1 and 45 ml (median 3 ml). Median leukocyte count was 400 cells/µl (range 50-14.000 cells/µl), median percentage of PMN was 9% (range 0%-98%), median crystal count was 179.5 (range 3-1600). Inter-reader agreement was high, with a weighted k of 0.89 (95% CI 0.85-0.94) for the first examination and 0.86 (95% CI 0.80-0.92) for the second one. Intra-reader concordance was also high with a k of 0.89 (95% CI 0.84-0.93) for the first observer, and of 0.85 (95% CI 0.78-0.93) for the second. The intraclass correlation coefficient for the 4 readings was 0.998 (95% CI 0.996-0.999). Maximum time needed for the count was 30 minutes. Number of crystals in the SF did not correlate with the amount of SF (p=0.15), nor with leukocyte count (p=0.52), percentage of PMN (p=0.69), patients' gender (p=0.46), or age (p=0.89). Interestingly, joints with recent (< 1 week) inflammatory reaction had a higher SF crystal count than the asymptomatic ones (460.5 [range 3-1600] vs. 48.5 [range 4-1600], p=0.03).

Conclusion: MSU crystal count in the SF of gout patients is a feasible and highly reliable technique. It could be used to follow the efficacy of urate lowering treatments within the joint, the location where the noxius effect of MSU crystals is more evident.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Metabolic and Crystal Arthropathies Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Basic calcium phosphate (BCP) crystals frequently deposit in tendons and may cause an acute inflammatory syndrome of calcific tendinitis. Tenocytes are the stromal cells of the tendon and are responsible for maintenance of tendon extracellular matrix. The aim of this study was to determine the effects of BCP crystals on tenocyte function, using an *in vitro* model of calcific tendinitis.

Methods : BCP crystals were synthesized by alkaline hydrolysis of brushite. Primary human tenocytes were prepared by collagenase/dispase digestion from human tendon (biceps, supraspinatus, hamstring) obtained from patients undergoing orthopaedic surgery. BCP crystals (0-50μg/mL) were added to the tenocyte cultures. After 24 hours, cell viability was assessed using the alamarBlue assay and changes in the relative mRNA expression levels of tendon-related genes were analysed using real-time PCR. The effects of cyclo-oxygenase (COX)-1 and COX-2 inhibition on gene expression were analysed by adding 1 μM SC-560 or SC-236 respectively for 45 minutes prior to addition of BCP crystals.

Results: BCP crystals did not alter tenocyte viability or gene expression of tendon extracellular matrix proteins (type 1 collagen, type 10 collagen, and tenomodulin) and inflammatory cytokines (IL-1, IL-6 and TNF-α). In contrast, BCP crystals induced gene expression of matrix metalloprotease (MMP)-1, MMP-3, and a disintegrin and metalloproteinase with thrombospondin motifs (ADAMTS)-4 in a dose dependent manner (Figure). Gene expression of tissue inhibitor of metalloproteinases (TIMP)-1 was also induced (for 50μg/ml BCP, mean (SD) relative expression 2.2 (0.7), ANOVA p for linear trend =0.002), but not TIMP-2 or TIMP-3. COX-1 gene expression was induced (for 50μg/ml BCP, mean (SD) relative expression 2.3 (1.1), ANOVA p for linear trend =0.008), with a similar trend for COX-2 (for 50μg/ml BCP, mean (SD) relative expression 2.6 (1.1), ANOVA p for linear trend =0.08). The COX-2 inhibitor SC-236 suppressed BCP crystal-induced gene expression of MMP-1 (mean change -83%), MMP-3 (-25%), ADAMTS-4 (-51%) and TIMP-1 (-47%). Similar, but generally less pronounced effects were observed with the COX-1 inhibitor SC-560 (mean change MMP-1 -63%, MMP-3 -56%, ADAMTS-4 -31%, TIMP-1 -39%).

Conclusion : BCP crystals induce tenocyte catabolic and anabolic gene expression in a cyclo-oxygenase (1 and 2) dependent manner. These data suggest that BCP crystals interact with tenocytes to influence tendon extracellular matrix integrity.

Figure: Effect of BCP crystals on MMP-1, MMP-3 and ADAMTS-4 gene expression in tenocytes. Data were pooled from four biological repeats and analysed using one-way ANOVA with post hoc Dunnett's tests compared to control (no treatment). *p<0.05, **p<0.01, ***p<0.001.

Session Title: Metabolic and Crystal Arthropathies Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Intra-articular calcium hydroxyapatite (HA) crystals are present in the majority of osteoarthritic (OA) joints. They activate macrophages, synovial fibroblasts and articular chondrocytes, resulting in increased cell proliferation and the production of pro-inflammatory cytokines and matrix metalloproteases. This suggests a pathogenic role in OA by causing extracellular matrix degradation and subchondral bone remodeling. Total joint arthroplasty is performed when conservative therapies have proved unsuccessful in OA. However, particles generated from wear of prosthetic implants also induce pro-inflammatory cytokines, which drive osteoclastogenesis through up-regulation of receptor activator of nuclear factor kappa-B (RANK) ligand, an essential cytokine for the differentiation of osteoclasts. These bone-resorbing cells drive periprosthetic osteolysis through secretion of acid and the proteolytic enzyme cathepsin K and contribute to implant loosening. Both interleukin (IL)-6 and interferon (IFN)-γ exhibit anti-osteoclastogenic activity via activation of the JAK/STAT pathway. Titanium and bone cement wear particles can inhibit this effect, via activation of mitogen-activated protein kinases (MAPK) and induction of suppressor of cytokine signaling (SOCS) proteins. As synthetic HA is used as a biomimetic to coat orthopaedic implants, we sought to **1)** determine whether HA crystals promote osteoclastogenesis, **2)** determine whether HA crystals alter anti-osteoclastogenic signaling by IL-6 and IFN-γ and **3)** elucidate the mechanism by which HA crystals may contribute to periprosthetic osteolysis.

Methods: Murine and human macrophages were stimulated with HA crystals for 3, 6 and 24 hours and expression of RANK ligand and cathepsin K was analysed by quantitative PCR. Human osteoclast precursors were stimulated with HA crystals and MAPK activation was detected by Western blot. Osteoclast precursors were treated with HA crystals for 1 hour prior to IL-6 or IFN-γ stimulation, and phosphorylation of signal transducer and activator of transcription (STAT) 1 and 3 was detected by Western blot. Up-regulation of (SOCS) 1 and 3 was analysed by q-PCR

Results: HA crystals (50μg/ml) up-regulate RANK ligand and cathepsin K in murine and human macrophages by 3 to 5-fold. Stimulation of human osteoclast precursors with HA induces the activation of p38, JNK and ERK MAPK. Pre-treatment of human osteoclast precursors with HA crystals inhibits both IFN-γ and IL-6-induced activation of STAT1 and STAT3 respectively (figs A and B). Furthermore, HA crystals up-regulate the expression of SOCS1 and SOCS3, an effect which is reduced by MAPK inhibition.

Conclusion: Based on these studies we propose that HA crystals could contribute 1) to periprosthetic osteolysis and 2) subchondral bone remodelling in OA through up-regulation of RANK ligand, and inhibition of the anti-osteoclastogenic activity of IL-6 and IFN-γ.

Effects of Monosodium Urate Crystals on Mlo-Y4 Cell Viability; Is There a Role for Osteocytes in Erosive Gout?

Ashika Chhana[1], David Musson[2], Karen E. Callon[3], Dorit Naot[1], Gregory Gamble[3], Geraldine M. McCarthy[4,5], Jillian Cornish[3] and **Nicola Dalbeth**[3], [1]Medicine, University of Auckland, Auckland, New Zealand, [2]University of Auckland, Auckland, New Zealand, [3]Department of Medicine, University of Auckland, Auckland, New Zealand, [4]University College Dublin, Dublin, Ireland, [5]Rheumatology, Mater Misericordiae University Hospital, Dublin 7, Ireland

Session Date: Sunday, November 8, 2015
Session Title: Metabolic and Crystal Arthropathies Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Imaging and histology studies have identified monosodium urate (MSU) crystals present in

subchondral bone in erosive gout, suggesting that these crystals could interact with osteocytes. Osteocytes are the most abundant cell population within bone (>95% of the cellular component of the adult skeleton) and play a central role in regulating bone remodeling. The aim of this study was to investigate the effects of MSU crystals on osteocyte viability.

Methods: MSU crystals were prepared by recrystallization of uric acid. The murine immortalized osteocyte MLO-Y4 cell line was used in these assays; cells were cultured on plastic (2D) or in 3mg/mL type I collagen gels (3D). MSU crystals or soluble urate (0.01-0.5mg/mL) were added to the cells. After 24 hours, cells were washed and MSU crystals or urate completely removed. Cell viability was assessed using MTT and alamarBlue assays. Viability was assessed in the 2D cultures 24 hours after addition of MSU crystals, and both 24 and 48 hours after addition of MSU crystals in the 3D cultures. Different sizes of MSU crystals were prepared by sonication. Basic calcium phosphate, calcium pyrophosphate and aluminum crystals were tested using the same methods in the 3D cultures.

Results: In the 2D cultures at the 24 hour time point, 0.1-0.5mg/mL MSU crystals reduced MLO-Y4 cell viability by ~70% ($P<0.001$ vs. no MSU). In the 3D collagen gel cultures at the 24 hour time point, 0.3-0.5mg/mL (but not lower concentrations) MSU crystals reduced MLO-Y4 cell viability by ~30-40% ($P<0.001$ vs. no MSU) (Figure). In the 3D collagen gel cultures at the 48 hour time point, 0.1mg/mL MSU crystals reduced MLO-Y4 viability ($P<0.01$ vs. no MSU), and culture with the higher MSU crystal concentrations (0.3-0.5mg/mL) resulted in further reduction of MLO-Y4 cell viability by ~60-70% ($P<0.001$ vs. no MSU) (Figure). Different sizes of MSU crystals (5.6-16.2mm) reduced MLO-Y4 cell viability in a similar manner. The effect on cell viability was specific to MSU crystals, as soluble urate and other types of crystals did not reduce MLO-Y4 cell viability.

Conclusion: MSU crystals inhibit osteocyte viability. Direct crystal-cell contact is not necessarily required to induce this effect. These data suggest that osteocytes may play a role in bone erosion in gout.

Figure: MSU crystals reduce the viability of MLO-Y4 osteocyte-like cells in 3D cultures. Viability was assessed using the alamarBlue assay 24 and 48 hours after the addition of MSU crystals. Data are pooled from three biological repeats and are presented as mean (SEM); two-way ANOVA ($P<0.0001$) with *post hoc* Dunnett's test *$p<0.01$, **$p<0.001$ versus control (no MSU crystals) for the relevant time point.

Session Title: Metabolic and Crystal Arthropathies Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Recurrent flares constitute the main clinical burden of gout. The neo-epitope blood-based biomarkers, C1M and C3M, measuring matrix metalloproteinases (MMP)-mediated connective tissue degradation, have previously been shown to be associated with joint inflammation in rheumatoid arthritis and osteoarthritis. The aim of present study was to evaluate the level of C1M and C3M in gout patients compared to matched controls, to investigate the discriminating power of these biomarkers for frequent gout flares.

Methods: Fasting plasma samples from 112 men with gout and 170 age-sex matched controls men without gout (case-control study), and baseline serum samples from 447 community-derived men with gout (RCT) were analysed by ELISA for neo-epitopes from MMP degradation of collagens type I (C1M) and type III (C3M). The log10 of C1M and C3M levels were compared between cases and controls, and between gout patients with three or more gout attacks in the past year (frequent gout flares) and those with two or less attacks, giving the odds ratio (OR[95%-CI) and area under the curve.

Results: The blood levels of the C1M and C3M were significantly associated with gout status in the case-control study: OR=4.1 log10C1M, and OR=82.8 for log10C3M (table). The level of C3M was associated with frequent gout flares; in the case-control participants with an OR=34.4 and in the RCT participants with an OR=5.2 after adjustment for age, BMI and age at first attack (table). C1M was also significantly associated with frequent flares in the RCT participants with OR=2.8. The combination of available clinical variables gives an area under the curve (AUC) of 0.68 and 0.60 for frequent gout attacks in the case-control and RCT groups using a receiver operating characteristic (ROC) analysis. The AUC values increase to 0.74 [0.63-0.84] and 0.66 [0.61-0.71] with the inclusion of log10C1M and log10C3M in the model.

Conclusion: C1M and C3M were strongly associated with gout status in a case-control study in men and with frequent gout flares in two independent groups of men with ongoing gout, suggesting that increased connective tissue turnover predispose to frequent gout flares, and that biomarkers of connective tissue turnover may aid in identifying people at risk of frequent attacks of gout

Table. Association between connective tissue degradation neo-epitopes and gout and frequent gout flares, odds ratios [95% confidence intervals] and p-values are shown for each of the associations tested

Session Title: Metabolic and Crystal Arthropathies Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Gout is a consequence of an innate immune reaction to monosodium urate crystals deposited in joints. Acute gout attacks are commonly triggered by dietary factors, the most common of which have been associated with raised serum urate levels. However, individuals with gout often identify other foods as their gout triggers. The implementation of a hypothesis free diet-wide association study (DWAS) could reveal foodstuffs that have not previously been associated with urate levels. Our aim was to conduct a DWAS with serum urate as outcome.

Methods: 13,782 individuals of European ancestry from the Atherosclerosis Risk In Communities (n=7228), Coronary Artery Risk Development In (Young) Adults (n=1413), Cardiovascular Health (n=2101) and Framingham Heart (n=3040) studies were used to test for association between serum urate ($\mu molL^{-1}$) and 66 different food items (serves/week). All analyses were adjusted for sex, menopause status, age, BMI, average daily calorie intake and the first four eigenvectors from whole genome principal components analysis. Individuals with gout or kidney disease and those taking urate lowering medications or diuretics were excluded from analyses. Three quality control criteria were applied to the food consumption data to ensure reliable information was used.

Results: Six novel associations with a $P < 0.0008$ (Bonferroni multiple testing threshold) were found. Brown bread, peanut butter, eggs, non-citrus fruit and margarine all had urate lowering effects ($\beta = -0.55; -0.93; -1.09; -0.35$ and -0.36 $\mu molL^{-1}$ per extra serve per week respectively), whilst French-fried potatoes had a urate increasing effect ($\beta = 2.30$ $\mu molL^{-1}$ per extra serve per week). Additionally six known urate modifying foods, beer, cheese, shellfish, tea, skim milk and liquor ($\beta = 1.48; -0.67; 5.11; 0.38; -0.92$ and 1.63 $\mu molL^{-1}$ per extra serve per week) had *P*-values below the multiple testing threshold. Eleven other foods had nominally significant association ($0.0008 < P < 0.05$) – wine, soft drink, fish, poultry, tomato and self-reported added sugar were urate-raising, and cake, apple, peach, banana and cold cereal were urate-lowering.

Conclusion: This research represents the first diet-wide association study in serum urate which considers each food item separately. Several of the novel associations may be confounded by correlations with other foodstuffs, or represent differences in overall diet. However this work represents an unbiased and inclusive understanding of dietary factors influencing urate levels.

Session Date: Sunday, November 8, 2015
Session Title: Metabolic and Crystal Arthropathies Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Genetic variants in uric acid transporters that control serum urate levels in Europeans have been identified by genome-wide association studies. However there is no evidence for association with the organic anion transporters (OAT) 2-4 (encoded by *SLC22A6-A8*) and multi-drug resistance protein 4 (MRP4) encoded by *ABCC4*. The Māori and Pacific (Polynesian) population of New Zealand (NZ) has the highest prevalence of gout worldwide and exhibits lower fractional excretion of uric acid (FEUA) than Europeans. Our aim was to identify genetic variants in the Māori and Pacific *SLC22A6-8* and *ABCC4* genes that influence the risk of gout.

Methods: 218 hyperuricaemic and 205 normouricaemic individuals, the majority (93%) of whom self-reported >=3 Māori and Pacific grandparents, were resequenced over a total of 24.3 kb of promoter, exon and 3' and 5' untranslated region DNA within the four genes. Sequencing was done using Illumina chemistry on a HiSeq 2000 on DNA captured using a custom version of the Roche NimbleGen SeqCap kit. The Genome Analysis Toolkit was used to align reads to the human reference genome and generate variant call files. Replication genotyping for *rs4148500*was done by Taqman over 284 Western Polynesian (Samoa, Tonga, Niue, Tokelau) gout cases and 174 controls, and 471 Eastern Polynesian (EP: NZ and Cook Island Māori) gout cases and 450 controls (that included 187 Māori gout cases and 170 Māori controls from the area of the Ngati Porou tribe). All replication individuals had >=3 self-reported Māori and/or Pacific grandparents. Logistic regression association analysis was done adjusting by age and sex.

Results: A total of 39 variants with frequency greater than 0.05 were detected with the majority (n=26) in *ABCC4*. Of these, six variants in *ABCC4* significantly associated with hyperuricaemia. The most significantly associated (*rs4148500*; $OR_{Hyperuricaemia}$=1.76, *P*=1.6x10^{-3}; monomorphic in Europeans) was also associated with gout in the resequenced sample set (OR=1.86, *P*=9x10^{-4}) and was therefore genotyped over the replication sample set. *Rs4148500* was associated with gout in Western Polynesian (OR=1.47, *P*=0.026) but not in Eastern Polynesian (OR=1.09, *P*=0.52) in this sample set. In the combined (resequence plus replication) sample set the minor allele of *rs4148500* was associated with reduced FEUA in the combined Polynesians (beta=-0.50, *P*=3.8x10^{-3}).

Conclusion: We demonstrate for the first time association of *ABCC4* with hyperuricaemia, gout and FEUA, providing further support for the proposition of MRP4 as a unidirectional urinary uric acid efflux pump for uric acid. The variant was monomorphic (for the protective major allele) in Europeans and can be regarded as the first report of a genetic factor contributing to the increased risk of gout that is specific to people of Western Polynesian ancestry.

Session Title: Metabolic and Crystal Arthropathies Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Acute gouty arthritis results from an innate immune response to monosodium urate (MSU) crystals deposited in the joints and soft tissues of hyperuricaemic individuals. Genome-wide association studies (GWAS) have provided insight into the genetic control of urate homeostasis. However there have been very few genetic insights into the pathogenesis of acute gouty arthritis. Key checkpoints are expected to be in MSU crystal formation and immune response. The aim was to conduct a GWAS in gout using the immune-centric Immunochip.

Methods: 456 European patients with gout fulfilling the 1977 ARA gout classification criteria were genotyped with the Immunochip microarray, which contains single nucleotide variants (SNVs) at loci chosen largely on the basis of association with other immune-mediated phenotypes. SNVs out of Hardy Weinberg equilibrium ($P<1x10^{-7}$) and with minor allele frequency <0.01 were discarded with 139,874 SNVs remaining. The genomic inflation factor was 1.06. Allele frequencies were compared by logistic regression using PLINK software to 1,000 European controls sourced from the 1958 British Birth Cohort. Replication was conducted using Taqman genotyping in 1,190 European cases with gout and 960 NZ controls, with additional data from 11,127 publically-available European controls, and Taqman genotyping of 931 Polynesian cases and 964 controls. For replication, logistic regression analyses were adjusted by age, sex and (for Polynesian) number of self-reported Polynesian grandparents. Replication sample sets were combined by meta-analysis using METAL software. Replication was declared at $P<0.01$.

Results: Five SNVs with P between $1x10^{-5}$ and $6x10^{-5}$ from the discovery GWAS were selected for replication (Table). *Rs1466085*, in the enhancer region 11kb upstream of the transferrin receptor (*TFRC*), was the only variant to replicate (OR=1.30, $P=5x10^{-5}$) in a directionally consistent fashion to the discovery GWAS data (OR=1.77, $P=3x10^{-5}$). Combining the discovery and replication sets yielded $P=6.4x10^{-8}$ at *rs1466085.* There was no evidence for association of *rs1466085* with serum urate levels in European controls (beta=0.003, $P=0.18$).

Conclusion: These data, with $P=10^{-5}$ in both discovery and replication phases, convincingly implicate the region immediately upstream of the transferrin receptor in the etiology of gout in an urate-independent manner. It is important that further genetic fine-mapping and molecular expression experiments are done to confirm *TFRC* as the causal gene in the region.

Session Time: 9:00AM-11:00AM

Background/Purpose: Hyperuricaemia and secondary gout are well-recognised complications of diuretic use. Variants in *ABCG2* and *SLC2A9* have been identified as the two major genetic risk factors for gout in genome wide association studies. The aim of this study was to examine the clinical and genetic characteristics of diuretic-associated gout.

Methods: Participants (n=1,365), all fulfilling the 1977 ARA gout classification criteria, were recruited from primary and secondary care. All participants attended a study visit, which included a detailed clinical assessment. Use of diuretic therapy at the time of recruitment was recorded, and was confirmed by electronic dispensing data. The gout-associated *ABCG2 rs2231142* and *SLC2A9 rs11942223* SNPs were genotyped. Clinical and genetic features of diuretic-associated gout were analysed using a case-control study design (diuretics vs. no diuretics). Loop and thiazide diuretics were also analysed separately (participants taking both loop and thiazide diuretics were included in loop diuretic group).

Results: There were 939 participants on no diuretics and 426 participants on at least one diuretic (281 in the loop diuretic group and 145 in the thiazide diuretic group). In the diuretic group, there were more women, later onset of disease, higher rates of cardiac disease, hypertension and type 2 diabetes, higher body mass index, higher serum urate and lower eGFR, compared to those not on diuretics (Table). Gout disease duration, frequency of gout flares and presence of tophi were similar in the two groups (Table). The *ABCG2 rs2231142* minor (risk) allele was present less frequently in the diuretic group (36.1%) than in those not on diuretics (47.6%, p=2.9E-04). *ABCG2 rs2231142* minor (risk) allele positivity was lower in those taking loop diuretics (37.1%) and thiazide diuretics (34.3%). In contrast, there was no significant difference in positivity for the minor (protective) allele for *SLC2A9 rs11942223* between the two groups (p=0.074).

Conclusion: Diuretic-associated gout represents a medically complex condition with frequent comorbid conditions. The observed differences in the *ABCG2* risk allele frequency suggest that some genetic factors play a less dominant role in the etiology of diuretic-associated gout, compared to primary gout.

Table: Clinical and genetic features separated by use of diuretics. Unless specified, data are presented as mean (SD). For genotype analysis, p values were generated by logistic regression adjusting for ancestral group.

	No diuretic (n=939)	**Diuretic (n=426)**	**p**

Session Title: Metabolic and Crystal Arthropathies Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Diagnosis of a patient who comes with acute foot pain is often challenging, because both acute gouty arthritis and cellulitis share common clinical manifestations such as redness, warmth, tenderness and soft tissue swelling, and inflammatory markers do not discriminate between those two entities. When it comes to patients with normouricemia, it is even more challenging. Differentiating acute gouty arthritis from cellulitis is critical for deciding treatment strategies, which will prevent the misuse of antibiotics for gout and prevent a delay of antibiotics treatment for cellulitis.

Delta neutrophil index (DNI) is a difference between leukocyte subfractions which corresponds to the fraction of immature granulocyte. DNI was reported to be associated with infection and sepsis, therefore it is considered to be helpful in differentiating acute gouty arthritis and cellulitis.

In this study, we evaluated the utility of DNI as a predictive marker in differentiating acute gouty arthritis and cellulitis in normouricemic patients.

Methods:

We reviewed medical records of total 212 normouricemic patients who were admitted from January 2011 to April 2015. 74 patients had acute gouty arthritis and 138 patients were diagnosed cellulitis of lower limbs, and all the patients had serum uric acid below 7 mg/dL. DNI was automatically determined by the ADVIA 2120 electronic cell analyzer. Multivariate logistic regression was used to find independent variables for predicting cellulitis among variables which had statistical differences in chai-square test or which had clinical implication. Cutoff for categorizing values were determined by receiver operating characteristic (ROC) curve.

Results:

The cellulitis group showed higher levels of white blood cell counts, CRP and lower levels of uric acid. ESR and procalcitonin had no difference between two groups. Patients in acute gouty arthritis group had significant lower

values of DNI than those in cellulitis group (0.7 ± 0.9 % vs 2.6 ± 3.1 %, p<0.0001). In multivariate logistic regression analysis, DNI was the only significant independent factor for discriminating cellulitis from acute gouty arthritis. When we selected DNI value of 1.7% as the cutoff for cellulitis, patients with DNI 1.7% or higher were found to have higher risk for cellulitis than those with DNI less than 1.7% (Odds ratio 4.780).

Conclusion:

The present study seems to be the first to evaluate DNI in gout investigating its usefulness as a novel serologic marker for differentiating acute gouty arthritis from cellulitis. Our findings demonstrate that DNI measurement is useful for predicting cellulitis superior to ESR, CRP or procalcitonin in normouricemic patients and helpful in making decisions about the treatment.

Table 1. Multivariate analysis for the independent variable to predict cellulitis

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Metabolic and Crystal Arthropathies Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Patients with inflammatory arthritis, including gout, have an increased risk of cardiovascular events and mortality. Increased platelet reactivity is a risk marker for cardiovascular events. The glycoprotein VI (GPVI) receptor is found exclusively on platelets and megakaryocytes and is the predominant platelet receptor for collagen. It remains intact on platelets under resting conditions. The proteolytic cleavage of GPVI occurs only upon specific activation of platelets and is detectable in the plasma as soluble GPVI (sGPVI). Therefore elevated plasma sGPVI represents a potential biomarker for platelet hyperreactivity and hence adverse cardiovascular outcomes

Methods:

The aim of this study was to assess platelet reactivity, as measured by plasma sGPVI levels, in acute gout, chronic gout, and acute calcium pyrophosphate (CPP) arthritis, and to compare these to each other and to healthy controls. Following ethics approval and informed consent, blood samples were taken from patients with gout and CPP arthritis. Healthy control samples were obtained from volunteers. Demographic and clinical data were collected for all participants. Blood samples were processed as double spun platelet poor plasma. sGPVI levels were measured using ELISA. Mann-Whitney U test was used to compare groups. Spearman's Rank Correlation Coefficient was used to assess for associations between sGPVI levels and demographic and clinical markers. GraphPad Prism Version 6.05 and IBM SPSS Statistics Version 20 were used for data analysis.

Results:

One hundred and six patients were included in the study, 16 with acute gout, 5 with acute CPP arthritis, 32 with chronic gout, and 53 healthy controls. There were no significant differences in demographic details between the groups. Median (IQR) sGPVI levels were 7.03 ng/ml (3.80, 9.70) in acute gout, 5.42 ng/ml (3.73, 9.63) in acute CPP arthritis, 4.28 ng/ml (2.10, 6.07) in chronic gout, and 2.05 ng/ml (1.69, 3.31) in healthy controls. sGPVI levels in all 3 disease groups were significantly increased compared to healthy controls ($p<0.05$ for each) (Figure 1). GPVI levels in patients with active gout were significantly increased compared to chronic gout ($p=0.02$). There was moderate correlation between sGPVI levels and CRP ($r=0.42$), VASPain ($r=0.42$), and VASQOL ($r=0.51$), and a weak correlation with ESR ($r=0.35$).

Conclusion:

Patients with crystal-induced arthropathies exhibit platelet hyperactivity as demonstrated by elevated plasma sGPVI levels. This was particularly evident during acute gout. Platelet hyperactivity may contribute to the elevated cardiovascular risk in gout patients and GPVI represents an attractive new target as an antiplatelet reagent in this patient population, for whom no anti-thrombotic guidelines exist.

Silent Monosodium Urate Crystals Deposits in Asymptomatic Hyperuricemia Lead to a Higher Need for Coronary Revascularization

Mariano Andrés[1], María Amparo Quintanilla[2], Francisca Sivera[3], José Sánchez-Payá[4], Juan M Ruiz-Nodar[5], Eliseo Pascual[1,6] and Paloma Vela[1,6], [1]Sección de Reumatología, Hospital General Universitario de Alicante, Alicante, Spain, [2]Sección de Cardiología, Hospital General Universitario de Elda, Alicante, Spain, [3]Reumatología, Hospital General Universitario de Elda, Alicante, Spain, [4]Servicio de Medicina Preventiva, Hospital General Universitario de Alicante, Alicante, Spain, [5]Servicio de Cardiología, Hospital General Universitario de Alicante, Alicante, Spain, [6]Departamento de Medicina Clínica, Universidad Miguel Hernández, Alicante, Spain

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Metabolic and Crystal Arthropathies Poster I

Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Increased cardiovascular (CV) risk in gout relates to crystal-driven inflammation. In a preliminary, cross-sectional study we found that silent deposits of monosodium urate (MSU) crystals in asymptomatic hyperuricemia (AH) associated with a more severe coronary calcification, in comparison to AH alone and normouricemia (NU) [1]. Whether this silent deposit also leads to a poor CV prognosis of AH patients has not been assessed so far. We aimed to compare the incidence of CV events between the study groups in the follow-up period after the admission.

Methods:

Prospective follow up of patients from the previous study [1]; consecutive patients admitted due to an acute coronary event were classified at baseline as NU, AH alone, and AH with crystals after serum uric acid levels, joint ultrasound and polarized microscopy of synovial fluid samples. The date of admission was considered as the index date. Electronic clinical records were reviewed in order to register the occurrence of all-cause death, CV-related death, new ST-elevation (STE) acute coronary event, new non-STE acute coronary event, and need for coronary revascularization during follow-up. Kaplan-Meier curves were plotted for each outcome for between-group comparisons, and a multivariate Cox regression model was built to adjust for CV risk factors.

Results:

140 patients were enrolled, and classified as 66 NU, 61 AH alone, and 13 AH with MSU crystals. Only one patient (from the *AH alone* group) was lost in the follow-up. Median (p25-75) follow-up was 12.0 (8.3-16.0) months. No new STE acute coronary event was registered. No significant differences were found in all-cause or CV-related death. The AH with crystals group showed higher need for new coronary revascularization and higher incidence of new non-STE acute coronary event [Figures A and B, respectively). After adjustment for CV risk factors, a non-sigficant but evident trend towards a higher need for new coronary revascularization was found in the AH with crystals group (aHR 4.5; 95%CI 0.8-24.1, p=0.08); no significant differences in non-STE acute event were found.

Conclusion:

Silent deposits of MSU crystals in AH appear to lead to a higher need for new coronary revascularization. Low patient numbers likely account for the lack of significance. This finding adds more evidence to the detrimental role of MSU crystals on the arteriosclerotic disease of these subjects.

Gout Patients Present Carotid Plaques at Presentation in Spite of Low-Risk Cardiovascular Score

Mariano Andrés[1], Francisca Sivera[2], José Antonio Bernal[1], Neus Quilis[1], Loreto Carmona[3], Paloma Vela[1,4] and Eliseo Pascual[1,4], [1]Sección de Reumatología, Hospital General Universitario de Alicante, Alicante, Spain, [2]Reumatología, Hospital General Universitario de Elda, Alicante, Spain, [3]Instituto de Salud Musculoesquelética, Madrid, Spain, [4]Departamento de Medicina Clínica, Universidad Miguel Hernández, Alicante, Spain

Gout patients present carotid plaques at presentation in spite of low-risk cardiovascular score.

Background/Purpose:

Gout is associated with an increased cardiovascular (CV) risk related to high prevalence of CV risk factors (CVRF) and to persistent, crystal-led inflammation. Beside proper gout-specific treatment, an accurate CV assessment at first presentation appears essential to initiate strategies to control this increased CV risk. We aimed: 1) to describe the CV profile at presentation of gout patients; 2) to estimate the proportion of patients that may be at very high risk by carotid ultrasound (cUS) despite a low Systematic COronary Evaluation (SCORE); and 3) to evaluate the predictability of the SCORE to identify those patients with carotic plaque.

Methods:

We performed an observational, cross-sectional study of all consecutive crystal-proven gout patients newly seen in our unit. All patients underwent a CV structure consultation that included: presence of CV disease or traditional CVRFs, background of CV disease, blood pressure levels, body mass index, and lab tests (glucose, HbA1C, lipids, creatinine). SCORE was calculated in those without prior CV events. CV risk was stratified as low, moderate, high, or very high, according to current European guidelines [1]. Those patients who were not at a very high CV risk underwent carotid ultrasound (cUS) to assess carotid intima-media thickness (cIMT) and presence of atheroma plaques [2]. The prevalence of carotid plaque in cUS was estimated and its predictability by the SCORE tested by receiver operating curves, estimating the area under the curve (AUC).

Results:

A total of 138 patients were recruited, median aged 65.0 years (p25-75 54.8-74.3), 89.1% males. The prevalence of CVRFs was as follows: 65.9% hypertension, 23.2% diabetes, 51.4% dyslipidemia, and 60.1% smoking background. Glomerular filtration rate was under 60mL/min in 23.9% of patients, and 30.4% had a diagnosis of CV disease. Median SCORE was 3% (p25-75 1-5%). CV risk stratification of patients before cUS is shown in the Figure, prevailing very high risks (38.2%). cUS was performed in 86 patients, finding cIMT>0.9mm in 48 patients (55.8%; 95%CI 45-67) and

atheroma plaques in 39 (45.3%; 95%CI 35-56). A 19.8% of patients showed bilateral carotid plaque. Up to 58.1% of the patients who underwent cUS had their CV risk reclassified, mostly to very high risk (Figure). The AUC for SCORE for predicting unilateral and bilateral plaque were 0.732 (95%CI 0.627-0.837).

Conclusion:

A majority of newly attended gout patients may be at very high CV risk indicating the need for initiating optimal prevention strategies at this stage. The SCORE tool appears to underestimate the presence of carotid plaque in gout patients.

Session Date: Sunday, November 8, 2015

Session Title: Metabolic and Crystal Arthropathies Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoarthritis (OA) and gout are each associated with increased cardiovascular disease (CVD), but their relative impacts on CV risk are not known. We compared rates of CVD among patients with OA (OA-only), gout (gout-only), or both (gout+OA).

Methods: We used ICD-9 codes to identify male patients from within our VA health care system with OA-only, gout-only, or gout+OA, and an active medical record between August 2007 and August 2008. For each group, we collected baseline demographics and CVD risk factors. The primary outcome was a composite index (CV4) consisting of any diagnosis of myocardial infarction (MI), angina, coronary bypass surgery (CABG), and/or coronary artery disease (CAD). Secondary outcomes included individual diagnoses within the CV4, congestive heart failure (CHF) and death. Logistic regression was used to compare the associations of OA-only, gout-only, and gout+OA with CV outcomes, adjusting for traditional CV risk factors: age, race, hypertension (HTN), diabetes mellitus, hyperlipidemia (HLD), chronic kidney disease (CKD), and smoking.

Results: 1280 gout subjects met inclusion criteria (983 gout-only, 297 gout+OA), along with 1231 OA-only subjects. Gout subjects, with or without OA, had more CVD risk factors at baseline, including HTN, HLD and CKD vs. OA-only. In an unadjusted model, a diagnosis of gout increased the risk for CV4, CAD, angina, CABG, CHF, and death compared to a diagnosis of OA-only. In a fully adjusted model, gout-only subjects continued to have increased risk for all outcomes except MI and death compared to OA-only subjects, while gout+OA subjects exhibited increased risk for angina and CHF (Table 1). Gout+OA did not impart additional risk over gout-only for any outcome except CABG.

Conclusion: Our data suggest that gout is associated with higher risk of CVD compared with OA, that at least some of this increased risk may be independent of traditional risk factors, and that OA does not impart additive CVD risk to patients who also have gout.

Table 1. Relative cardiovascular disease outcomes among OA-only, Gout-only and Gout+OA subjects, adjusted for age, race, HTN, HL, DM, CKD, and smoking. Data are odds ratios with 95% confidence intervals and p-values.

Impact of Gout on the Risk of Atrial Fibrillation

Chang-Fu Kuo[1], Matthew J. Grainge[2], Weiya Zhang[3] and Michael Doherty[4], [1]Division of Rheumatoplogy, Allergy and Immunology, Chang Gung Memorial Hospital, Tayuan, Taiwan, [2]Division of Epidemiology and Public Health, School of Community Health Sciences, University of Nottingham, Nottingham, United Kingdom, [3]Academic Rheumatology, School of Clinical Sciences, University of Nottingham, Nottingham, United Kingdom, [4]Academic Rheumatology, City Hospital, Nottingham, United Kingdom
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Metabolic and Crystal Arthropathies Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

To examine the risk of atrial fibrillation (AF) at the time of first diagnosis of gout compared to matched controls and to follow incident gout patients and their matched controls after diagnosis to compare their subsequent risk of AF.

Methods:

45,378 incident gout patients and 45,378 age-, sex-, practice-, registration year- and index year-matched controls were identified from the UK Clinical Practice Research Data-link. Index dates were initial diagnosis date for gout patients and their matched controls. The risk of AF at diagnosis (odds ratios [ORs], using conditional logistic regression) and after the diagnosis of gout (hazard ratios [HRs], using Cox proportional models) were estimated, adjusted for body mass index, smoking, alcohol consumption, ischaemic heart disease, heart failure, heart valve disease, hyperthyroidism and other comorbidities and medications.

Results:

The prevalence of AF at index date in gout patients (male, 72.3%; mean age, 62.4 ± 15.1 years) was 7.42% (95% confidence interval [CI], 7.18%–7.66%) and in matched controls 2.83% (95% CI, 2.67%–2.98%). The adjusted OR (95% CI) was 1.45 (1.29–1.62). The cumulative probability of AF at 1, 2, 5 and 10 years after index date was 1.08%, 2.03%, 4.77% and 9.68% in gout patients and 0.43%, 1.08%, 2.95% and 6.33% in controls (log-rank test, $p < 0.001$). The adjusted HRs (95% CIs) was 1.09 (1.03–1.16).

Conclusion:

This population-based study indicates that gout is independently associated with a higher risk of AF at diagnosis and the risk is also higher after the diagnosis.

Session Title: Metabolic and Crystal Arthropathies Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Prior studies suggest an association between osteoporosis, systemic inflammation and pro-inflammatory cytokines such as IL-1 and IL-6. Gout is a common inflammatory arthritis characterized by hyperuricemia leading to crystallization of uric acid in joints. Several observational studies, but not all, report a relationship between hyperuricemia and bone mineral density (BMD). Furthermore, it is unknown whether gout has an impact on BMD and the risk of osteoporotic fracture.

Methods: Using data from a US commercial insurance plan (2004-13), we conducted a cohort study to evaluate the incidence rate (IR) of any non-vertebral fracture (i.e. forearm, wrist, hip and pelvis) and hip fracture in patients with and without gout. Gout patients were identified with ≥2 diagnosis codes and ≥1 dispensing for a gout-related drug. Non-gout patients were free of gout diagnosis and received no gout-related drugs; but, the non-gout group had ≥2 physician visits for any diagnosis and ≥1 dispensing for any prescription drugs. Non-vertebral fracture was defined with a combination of diagnosis and procedure codes for invasive/noninvasive treatment for fracture. The index date was the date of the 1st dispensing of a gout-related drug for the gout group or any drug for the non-gout after ≥1-year continuous enrollment. We excluded patients with prior fracture, malignancy, chemotherapy, ESRD, or renal transplantation. The non-gout group was matched to the gout group on age, sex and the index date with a 3:1 ratio. We calculated the incidence rates (IR) of non-vertebral and hip fracture in both groups. Multivariable Cox proportional hazards models compared separately the risk of non-vertebral and hip fractures in patients with and without gout.

Results: We identified 73,202 gout and 219,606 non-gout patients, matched on age, sex, and the index date. The mean age was 60 years and 82% were men. Among patients with baseline uric acid levels available (n=18,176), the mean (SD) uric acid level (mg/dL) was 7.4 (2.0) in gout and 6.0 (1.4) in non-gout. Over the mean 2-year follow-up, the IR of non-vertebral fracture per 1,000 person-years was 2.92 in gout and 2.66 in non-gout. In both groups, the IR of non-vertebral fracture was 3-fold higher in women than men (**Table**), but no significant interaction between sex and effect of gout on fracture was noted (p=0.4). Multivariable HR adjusted for potential risk factors for osteoporotic fracture in gout patients was 0.98 (95%CI 0.85-1.12) for non-vertebral fracture and 0.83 (95%CI 0.65-1.07) for hip fracture. In the subgroup analysis further adjusted for baseline serum uric acid levels, HR of non-vertebral fracture in gout was 1.20 (95%CI 0.54-2.67).

Conclusion: In this large cohort study, gout does not appear to be associated with an increased risk of non-vertebral or hip fracture. Whether serum uric acid is associated with osteoporotic fracture needs to be further studied.

Session Title: Metabolic and Crystal Arthropathies Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: In patients with gout, maintaining the serum uric acid (SUA) levels too low with ULT is a matter of concern because UA is thought to be neuroprotective. However, the relation between UA and both dementia and cognitive function, in which both vascular mechanisms and oxidative stress are thought to play a role, has been poorly explored.

Methods: We assessed the longitudinal association between SUA levels and the risk of incident dementia (DSM-IV criteria) over 10 years of follow-up in a large cohort of elderly individuals (3C cohort). Additionally, we investigated the relation between SUA levels and change in cognitive function (minimental state examination, Benton and Isaac tests, Trail making tests) and change in brain MRI patterns (total brain volume, white matter lesions volume and infarct-like brain lesions).

Results: The study sample comprised 1,769 individuals (mean age 72.4, male 39.6 %). During the 10,608 person-years of follow-up (median duration: 9.6 years), 134 participants developed dementia (crude incidence rate: 9.2/1000 person-years) with 94 (70.1%) classified as Alzheimer's disease and 9 (6.7%) as vascular dementia. Dementia was associated with older age, depressive symptoms, and APOE-ε4 genotype. Increasing age and BMI, current smoking, renal impairment, hypertension, history of cardiovascular disease, low HDL cholesterol, hypertriglyceridemia, high CRP and IL-6 levels, as well as the use diuretics, or aspirin were associated with hyperuricemia (all P values <0.001). The multivariate HR of dementia among individuals in the highest tertile of SUA levels as compared with those in the lowest tertile was 1.67 (95% CI 1.04 to 2.71); P for trend=0.05). The association was stronger for vascular dementia (HR 6.37 (95% 0.61 to 66.98)) than for Alzheimer's disease HR 1.71 (95% 0.97-3.03). There was no clear association between SUA levels and change in cognitive performance, nor with change in white matter lesions volume or brain structure as assessed with MRI.

Conclusion: These findings suggest that higher SUA levels are associated with an increase risk of dementia, mainly from vascular cause.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Metabolic and Crystal Arthropathies Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Many studies have showed that the serum uric acid (SUA) is an independent predictor of adverse cardiovascular events and all-cause mortality, but some studies have yielded conflicting results. Even more contradicted issue is the relationship between SUA and mortality in acutely hospitalized patients. In this context there is scarce data about SUA as an independent predictor of short-come outcome in the hospitalized older patient. The aim of this study is to determine whether SUA obtained within 48 hours after admission can predict short-term outcome.

Methods: The analysis was conducted in an 850-bed medical center. 860 adult patients were admitted to internal medicine departments between March 1st 2014 and June 30th 2014. We evaluated SUA level drawn within 48 hours after admission as predictor of in-hospital mortality. In addition we collected clinical and epidemiological data.

Results: The mean age of patients was 78±14. The mortality rate was 15.1% (130 patients), and the mean SUA was 6.25 ± 2.70 mg/dl. The most common cause for hospitalization was pulmonary infection (16.8%) followed by congestive heart failure exacerbation (9.3%). The mortality rate was 11% (66 patients out of 562) in the group with SUA ≤ 7.5 in comparison to 27% (64 patients out of 171) in the group with SUA above this level [P < .001]. Moreover, SUA was an independent predictor of mortality in multivariate regression analysis, with odds ratio of 2.71 [confidence interval 1.82- 4.04 *P* < .001].

Table 1: Logistic regression analysis

Variables in the Equation	B	S.E.	Wald (df=1)	Exp(B)	95% C.I.for EXP(B)
Gender	0.01	0.2	0.00	1.01	0.69-1.49
Age	0.02	0.01	4.12*	1.02	1-1.03
creatinine	0.13	0.06	4.70*	1.14	1.01-1.29
Uric Acid	0.18	0.04	26.64***	1.2	1.12-1.29
Constant	-4.55	0.72	39.87	0.01	

*p < .05, *** p< .001

Conclusion: SUA level is a strong independent predictor of short-term outcome in elderly patients admitted to internal medicine departments.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Metabolic and Crystal Arthropathies Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Hyperuricemia induces chronic inflammation and is associated with many diseases such as metabolic syndrome, high blood pressure, chronic kidney disease and cardiovascular diseases. The best known manifestation is gout. Risk for gout flares begins when serum uric acid exceeds 360mmol/l. That is also internationally used as the limit for hyperuricemia.

Because hyperuricemia is connected with many severe health problems, we investigated whether serum uric acid levels associate with survival in a population-based cohort.

Methods:

The data is based on health study with representative nationwide population sample of adults from a Western society. Information about health and living habits was collected by questionnaires and interviews. Everyone went through a physical examination, and a large range of laboratory tests. The mortality analyses were performed separately for men and women. Unadjusted mortality was calculated for each quintile of uric acid levels. Adjusted prognostic capacity of serum uric acid levels was analyzed with Cox regression with the following covariates: age, body mass index (BMI), diagnoses of coronary artery disease, hypertension and diabetes; fasting serum levels of LDL cholesterol and triglycerides and serum gamma-glutamyl transferase. The end-points were all-cause and cardiovascular mortality, separately.

Results:

The dataset consisted of 6691 subjects (3703 or 55.3% were women) aged 30 years or more. Mean age was 54 years with interquartile range (IQR) 51–65 years. Mean BMI was 26.9 (IQR 23.6–29.5). At the baseline, mean uric acid level was 303 mmol/l (IQR 243–353mmol/l). The prevalence of hyperuricemia was 1529 (22.9%), being essentially higher than the prevalence of diagnosed gout with 64 participants (1.0%). During the median follow-up of 72 (IQR 70–73) months, the total number of deaths was 607 and number of cardiovascular deaths was 262.

Unadjusted mortality increased systematically along the elevating uric acid level quintile for women but not for men (Figure). Hyperuricemic women had an adjusted hazard ratio (HR) 1.41 (p=0.010) for mortality in comparison to those without hyperuricemia; for men 0.94 (p=0.650). Similarly, HR for cardiovascular mortality was 1.87 (p=0.002) for women and 1.18 (p=0.408) for men

Conclusion:

Our study shows that elevating serum uric acid levels have significant association with the risk of total and

cardiovascular mortality among women. Remarkably, the increase in mortality took place even before the commonly used level of hyperuricemia was reached. This interesting finding confirms results from earlier studies: uric acid level and at least hyperuricemia is a reason for concern even before flares of gout.

Hyperuricemia, Urate Lowering Therapy and Kidney Function: A Systemic Review and Meta-Analysis

Gaurav Sharma[1], Abhishek Dubey[1] and Jasvinder A. Singh[2], [1]Internal Medicine, Seth GS Medical College and KEM Hospital, Mumbai, India, [2]University of Alabama at Birmingham, Birmingham, AL

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Metabolic and Crystal Arthropathies Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To determine whether hyperuricemia is associated with deterioration of kidney function and to examine whether urate-lowering therapies (ULTs) can improve or maintain kidney function.

Methods: A literature search of various databases was performed. All randomized control trials, controlled clinical trials and observational studies of interest were included. Protocol was registered in PROSPERO database. Duplicate, independent screening of titles and abstracts and data abstraction was done . The primary outcome was renal function (measured by serum creatinine level, changes in GFR, Cystatin C level, progression to chronic kidney disease or end stage renal disease). Meta-analysis for association between increased serum uric acid and renal function (Q1) and for effect of urate lowering therapy on renal function(Q2) was done using RevMan 5.3.

Results: 5817 abstract and titles were screened for uric acid and renal outcomes (Q1) and for urate-lowering therapy and renal outcomes (Q2) questions. 24 studies with 316,391 patients and 5 studies with 522 patients qualified for final analyses, respectively. Mean ages were 20-79 years (Q1) and 35-85 years (Q2). Mean follow-up was 2 to 10 year and 2 months to 2 years, respectively.

We found that individuals with hyperuricemia (defined as serum uric acid ≥ 7 mg/dL in men and ≥ 6 mg/dL in women) had 1.5 times greater odds each of decline of glomerular filtration rate (GFR) by ≥ 3 mL/min/1.73 m^2/year or development of new albuminuria [defined as development of either micro albuminuria :Urine Albumin to Creatinine Ratio(UACR) is 30-300 mg/g or overt proteinuria (UACR > 300 mg/g)] compare to individuals with normal serum uric acid level. Individuals with hyperuricemia developed chronic kidney disease (CKD) about 2 times more frequently than the normourcemic individuals **(Table_1)**.

For Q2, we found 3 studies of Allopurinol (272 patients), 1 for Rasburicase (38 patients) and 1 for Pegloticase (212 patients). Compared to placebo patients treated with standard ULT doses had better glomerular filtration, creatinine clearance and low levels of serum Creatinine and serum Cystatin C **(Table_2);**urine albumin did not differ significantly.

Conclusion: Our systemic review and meta-analysis revealed an important relationship between hyperuricemia and renal function deterioration/renal failure development. Evidence is emerging that ULT use may improve renal function, although more data are needed. These findings indicate that appropriate treatment of hyperuricemia in patients with gout or other hyperuricemic condition may help to preserve kidney function.

Table 1: Comparison of renal functions in Hyperuricemic (serum uric acid ≥ 7 mg/dL in men and ≥ 6 mg/dL in wome) **vs Normouricemic group of individuals.**

Outcome	Odds Ratio [95% CI]	Hazard Ratio [95% CI]	Quality of evidence (Newcastle-Ottawa scale)
Decline in Glomerular Filtration Rate(decline of eGFR ≥ 3mL/min/1.73m2)	**1.48 [1.19, 1.83]**	---- --	Moderate
Albuminuria (defined as both microalbuminuria [Urine Albumin to Creatinine Ratio (UACR) >/= 30 mg/g) and overt is >/= 300 mg/g]	**1.55 [1.16, 2.07]**	---- --	Moderate
Chronic Kidney Disease (GFR </= 60 mL/min/1.73 m2)	**1.12 [1.06, 1.18]**	**1.96 [1.43, 2.70]**	Moderate-high
End Stage Renal Disease (defined as requirement of dialysis or renal transplant)	------	1.12 [0.97, 1.30]	Moderate

Gout Does Not Decrease the Risk of Parkinson's Disease: A Systematic Review and Meta-analysis

Background/Purpose: Uric acid is a potent anti-oxidant and hyperuricemia is well-linked to a lower risk of Parkinson's disease (PD), one of the most common neurodegenerative disorders. However, data on gout, the major complication of hyperuricemia, remain unclear.

Methods: Two investigators independently searched published studies indexed in MEDLINE, EMBASE and the Cochrane database from inception to April 2015 using the terms for gout combined with the terms for Parkinson's disease. A manual search of references of selected articles was also performed. The inclusion criteria were as follows: (1) cohort or case-control study evaluating the risk of PD among patients with gout (2) odds ratio (OR), relative risk (RR) or hazard ratio (HR) or standardized incidence ratio (SIR) with 95% confidence interval (CI) were provided (3) subjects without gout and subjects without PD were used as control group in cohort and case-control study, respectively. Study eligibility was independently determined by the two investigators.

RevMan 5.3 software was used to perform the statistical analysis. Point estimates and standard errors were extracted from individual studies and were combined by random-effect model, generic inverse variance method of DerSimonian and Laird. Statistical heterogeneity was assessed using the Cochran's Q test and I^2 statistics.

Results: Out of 351 potentially relevant articles, three case-control studies and two cohort studies were identified and included in the data analysis. The pooled risk ratio of PD in patients with gout was 0.93 (95% CI, 0.79 to 1.09). The statistical heterogeneity of this meta-analysis was high with an I^2 of 87% (Figure 1). The results were not significantly different between males and females (RR 0.85; 95% CI, 0.68 to 1.06 and RR 0.95; 95% CI, 0.76 to 1.19, respectively).

Conclusion: This study did not support the inverse relationship between gout and risk of PD

Session Title: Metabolic and Crystal Arthropathies Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: How body weight, anthropometric parameters, and their changes are associated with serum urate concentrations and hyperuricemia remains unclear. The CARDIA study has been following young adults for 25 years and has detailed anthropometric data along with serum urate levels at multiple follow-up examinations. The present analysis aims to describe the association of weight and anthropometric variables with serum urate and hyperuricemia in young and middle aged-adults.

Methods: We performed multivariable linear regression analyses to determine if weight and anthropometric variables (body mass index [BMI], excess weight, waist circumference, hip circumference, waist to hip ratio) and their changes were associated with serum urate and serum urate changes. In addition, we analyzed associations between changes in BMI and development of incident hyperuricemia using logistic regression during the first and second 10-year periods of CARDIA follow up. We excluded participants with missing serum urate information or missing covariate data (renal function, serum insulin levels, dietary data, alcohol intake, hypertension) from analyses.

Results: Mean age of the study population at enrollment was 24.8 years. At baseline (n=4976) 46% of the included CARDIA populations were women and 51% were African-Americans. Weight and body mass index were associated with serum urate concentrations with comparable strengths at different points in the overall populations, but on later exams (Years 10 and 20 of follow-up) these associations were stronger for men than for women (Figure). Throughout the study, changes in BMI were associated with a small but significant 9-10% of the variance (partial r^2) in serum urate change. In the first 10 years of follow-up, participants who gained more than 25% BMI had a 7.2 fold increased odds (95% confidence interval 4.8-10.8) of incident hyperuricemia after full multivariable adjustment when compared with participants who kept a stable BMI. Losing more than 5% BMI wasn't negatively associated with hyperuricemia during the same study period. Similar results, but of smaller magnitude, were found for BMI changes during starting at year 10 until year 20 (Table).

Conclusion: Weight and body mass index were associated with serum urate concentrations at similar magnitudes. Although BMI changes seem to explain a small proportion of the variance in serum urate change in young adults, gains in BMI during young adulthood are independently associated, in a dose-response fashion, with significantly increased odds of developing hyperuricemia.

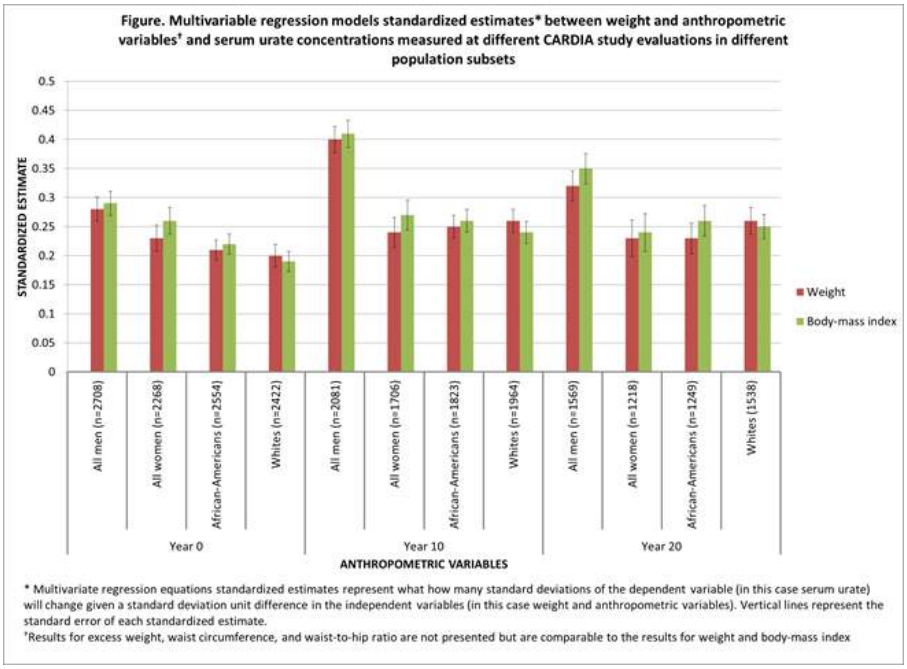

Table. Multivariate odds of incident hyperuricemia associated with changes in body mass index in young adults by the end of 10-year follow-up CARDIA study periods

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Metabolic and Crystal Arthropathies Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Gout typically presents at characteristic sites such as the 1st metatarsophalangeal joint, midfoot or ankle. A potential explanation for this distribution is that tissue stress during biomechanical loading promotes deposition of monosodium urate crystals at certain sites. The aim of this study was to determine whether patterns of high tissue stress during gait are associated with patterns of urate deposition and bone erosion in gout.

Methods: We analysed patterns of foot von Mises stress predicted computationally during gait in 25 volunteers with normal (18-25kg/m^2) body mass index (BMI) and 25 volunteers with high BMI (>25kg/m^2). Von Mises stress is used to evaluate the failure of tissues in bioengineering, and is reported as a single value that accounts for internal stresses in all directions. Von Mises stress patterns within the bones of the feet were compared with patterns of urate deposition and bone erosion in gout using dual energy and conventional computed tomography data.

Results: The highest average and peak von Mises stress during gait was observed at the 3rd metatarsal (MT) head (Figure). In contrast, for both urate deposition (Figure) and bone erosion, the 1st MT head was most frequently affected, with very infrequent involvement of the 3rd MT head. There was no clear relationship between average or peak von Mises stress patterns with patterns of urate deposition or bone erosion ($-0.20 > r < 0.16$ for all comparisons). Although ground reaction forces were higher in those with high BMI ($p<0.0001$), foot contact area was also higher ($p<0.0001$) with similar von Mises stress patterns were observed for the high and low BMI groups ($p>0.29$). Addition of BMI into linear regression models did not alter the findings.

Conclusion: These data do not support the concept that elevated tissue stress during biomechanical loading plays an important role in patterns of monosodium urate crystal deposition or structural damage in gout.

Figure: Foot maps showing the patterns of average tissue stress and peak tissue stress during gait in volunteers and urate deposition in gout. For each map, both the sphere diameter and colour represents the linear range from 0 - maximum value, as shown in the figure keys.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Metabolic and Crystal Arthropathies Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Foot and ankle structures are commonly affected in gout. People with gout experience difficulty walking and report high levels of foot pain, disability and impairment. Despite the importance of lower limb and foot muscle strength requirements in walking, the strength of foot and ankle muscles in gout is unknown. The primary aim of this study was to determine differences in foot and ankle muscle strength for ankle plantarflexion, dorsiflexion, inversion and eversion between people with gout and age- and sex-matched controls. The secondary aim was to examine the relationship between foot and ankle muscle strength, and foot pain and disability.

Methods: Peak isokinetic concentric muscle torque was measured for ankle plantarflexion, dorsiflexion, eversion and inversion in 20 participants with gout and 20 matched controls at two testing velocities (30°/s and 120°/s) using a Biodex dynamometer. Peak torque was calculated and normalised to body weight. Foot pain and disability was measured using the Manchester Foot Pain and Disability Index (MFPDI). Differences in peak torque between gout and control participants were analysed using mixed linear models. Pearson's correlation coefficients were used to determine associations between MFPDI scores and peak torque.

Results: Differences in peak torque between gout participants and controls are displayed in the Table below. At both the 30°/s and 120°/s testing velocities, participants with gout had lower ankle peak plantarflexion, inversion, and eversion torque compared with control participants. No differences between gout and control participants were evinced for peak dorsiflexion torque at either 30°/s or 120°/s testing velocities. Mean MFPDI scores were higher in participants with gout compared to controls (p=0.00001). For participants with gout, MFPDI scores were inversely correlated with peak plantarflexion torque at both 30°/s (r=-0.66, p<0.001) and 120°/s (r=-0.44, p=0.008), peak eversion torque at the 120°/s testing velocity (r=-0.36, p=0.045) and peak inversion torque at both 30°/s (r=-0.49, p=0.005) and 120°/s (r=-0.56, p=0.001) testing velocities.

Conclusion: People with gout have reduced foot and ankle muscle strength and experience greater foot pain and disability compared to controls. Foot and ankle strength reductions are strongly associated with increased foot pain and disability in people with gout.

Table. Mean peak torque and difference between gout and controls, N·m/kg

	Mean (SD) peak torque		Difference (95% CI)	*p*
	Control	Gout		
Plantarflexion 30°/s	0.94 (0.10)	0.65 (0.10)	-0.29 (-0.51, -0.07)	**0.010**
Dorsiflexion 30°/s	0.41 (0.08)	0.37 (0.09)	-0.04 (-0.10, 0.03)	0.280

The Prevalence of Chondrocalcinosis of the Symphysis Pubis on CT Scan and Correlation with Calcium Pyrophosphate Dihydrate Crystal Deposition Disease

Trusha Patel[1], Lawrence Ryan[2], Melissa DuBois[3], Guillermo Carrera[3], Keith Baynes[3], Rajeev Mannem[3] and Jennifer Mulkerin[3], [1]Rheumatology, Medical College of Wisconsin, Milwaukee, WI, [2]Department of Rheumatology, Medical College of Wisconsin, Milwaukee, WI, [3]Radiology, Medical College of Wisconsin, Milwaukee, WI

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Metabolic and Crystal Arthropathies Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Calcium pyrophosphate dihydrate (CPP) crystal deposition in articular cartilage can often be seen radiographically as chondrocalcinosis (CC). CPP crystals preferentially deposit in fibrocartilages such as the knee menisci and symphysis pubis (SP). We sought to determine the prevalence of CC in the SP on computed tomography (CT) of the abdomen and pelvis.

Methods: This retrospective study involved readings on 1070 consecutive CTs of the abdomen and pelvis performed over 3 months in patients over 65 years of age. Medical records of 226 patients found to have CC were reviewed to

determine age, gender, documentation of CPPD on problem lists or in medical histories, and whether radiology readings of the CTs mentioned CC.

Results: SP CC was identified in 21.1% (226/1070) of consecutive CT scans with the mean age of CT+ patients being 78.6. Of the 226 patients with SP CC, the observation of CC was documented in only 5.3% (12/226) of the radiology reports. Of the 12 instances in which the radiology reports mentioned CC, this observation was never (0/12) transmitted to the medical history or problem list.

Conclusion: The prevalence of CC in patients older than 65 was 21.1%. Since CTs of the abdomen are not ordered for evaluation of musculoskeletal conditions, this is likely a true prevalence without selection bias. When CC of the SP was present on images, radiologists routinely overlooked or chose not to report CC. Even in the rare instances when it was reported, that information was not added to the medical history or problem list. There are several clinical situations in which recognizing that a patient has CPP deposition (e.g acute monoarthritis) would be useful. Taking the time to review images may yield clinically important findings that are not mentioned anywhere on the patient chart.

Session Title: Metabolic and Crystal Arthropathies Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: urate intra-articular deposits are seen in ultrasound as double contour sign (DCS), and hyperechogenic aggregates and tophi, but the extent of contribution of any of these findings to synovial inflammation has yet to be determined. Only tophi have been shown to date sensitivity to change during urate-lowering therapy.

Methods: to evaluate the association between DCS and tophi with the presence of synovial inflammation in ultrasound examination, patients with crystal-proven gout were recruited from two cohorts of prospective follow-up, one on active treatment and the other after withdrawal of urate-lowering therapy, were to be consecutively included. They had to be asymptomatic (no flare, no chronic swelling) for at least 4 years, not on colchicine, NSAID, corticosteroids, or IL-blockers. Ultrasonography of the first metatarsophalangeal joint (1st MTP) and of the non-dominant knee was performed by an skilled explorer who was blinded for clinical data. The DCS was predefined as absent or present and in in less or more than 50% of the synovial surface. In the knee joint, the DCS location was also assessed as present in one or both femoral condyles. The presence of tophi was evaluated as hyperechogenic conglomerates of at least 5mm in

maximum diameter, with a hypoechogenic halo associated. Synovial inflammation was evaluated by the measurement of synovial thickening with a semi-quantitative scale (0-3) and Power-Doppler (PD) with a semiquantitative scale (0-3). Bi-variable and multiple regression analysis were performed.

Results: ultrasonopgraphy was proposed to 100 consecutive patients who fulfilled criteria, of which 88 agreed and attended the appointment. All of them were male, with a median age of 57 ± 9 years, 74% with previous involvement of 1st MTP joint and 59% of the examined knee. Thirteen patients were excluded from analysis due to the presence of ultrasonographic chondrocalcinosis in the knee. The frequency of deposits in both cohorts was not different, a pooled analysis therefore being conducted. The descriptive findings are presented in the table:

%	Any deposit	DCS	Synovitis>0	Synovitis>1	Tophus	PD>0	PD>1
1st MTP	64.7	54.8	29.8	48.8	9.4	48.8	21.2
Knee	52.9	48.2	17.6	53.0	1.2	47.1	25.9

Multiple regression analysis showed that the presence of synovitis >0 was only statistically associated in the 1st MTP to tophi (R^2 0.31), and in the knee to the presence of extense or bilateral DCS and tophi (R^2 0.28). The PD>0 signal was only associated in both 1st MTP and in knee to tophi (R^2 0.25 and 0.18, respectively). The more restrictive analysis of synovitis>1 and PD>1 did not show changes in the results, although numbers were small.

Conclusion: ultrasonographic urate deposits, as tophi or extense double contour) are associated to synovitis or active synovitis (intra-articular synovitis with PD signal) as markers of synovial inflammation. The presence of tophi is the main factor associated, so the resolution of the intra-articular tophi seems to be the principal therapeutic goal for urate-lowering therapy.

Session Title: Metabolic and Crystal Arthropathies Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The gold standard of acute gouty arthritis diagnosis has been to verify the presence of monosodium urate (MSU) crystal in the aspirated fluid of the affected joint. Recently, dual energy computed tomography (DECT) has emerged as a non-invasive MSU detecting tool. This study was undertaken to evaluate the diagnostic accuracy of DECT in acute gouty arthritis and to determine the affecting factors.

Methods: Medical charts of patients who underwent both DECT and ultrasound (US) guided aspiration in suspicion of acute gouty arthritis from August 2013 to March 2015 were retrospectively reviewed. Positive ultrasound findings included effusion with snowstorm appearing microtophi or double contour sign or presence of tophi. For statistical analysis, Mann-Whitney U test was used for continuous variables. Chi-Square test was used for categorical variables.

Results:

A total of 74 patients were analyzed. All patients except one were male and mean age was 45.3 years. Mean disease duration was 46 months, mean serum uric acid level 7.4 mg/dL. Fifty six patients had one or more positive findings of DECT or US or MSU presence in aspirated joint fluid. MSU deposition was observed in 28/61 (46.0%) patients. There were 4 patients who had clinically apparent tophi on physical examination, all of which were detected on DECT. Joint fluid was successfully acquired in 40/61 (65.5%) patients and the presence of MSU crystal was confirmed in 28 patients. Positive US findings were observed in 60/61 (98.4%) patients. 26 patients showed positive findings of both DECT and ultrasound, whereas 34 patients had only positive ultrasound findings. Serum uric acid level, symptom duration was significantly greater in DECT(+) positive group. Of note, DECT could not detect MSU crystal in patientswith high BMI. After adjusting age, multivariate logistic regression revealed that DECT may not be appropriate in patients with high BMI and short symptom duration in acute setting.

Conclusion: DECT can detect MSU deposition in acute gout patients without clinical tophi. However, the probability of false negativity rises in patients with high BMI and short symptom duration.

Volumetric Assessment of Tophaceous Gout

Ralf G. Thiele[1], Laura Coates[2] and Darren Tabechian[1], [1]University of Rochester Medical Center, Rochester, NY, [2]Medicine, University of Rochester, Rochester, NY

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Metabolic and Crystal Arthropathies Poster I

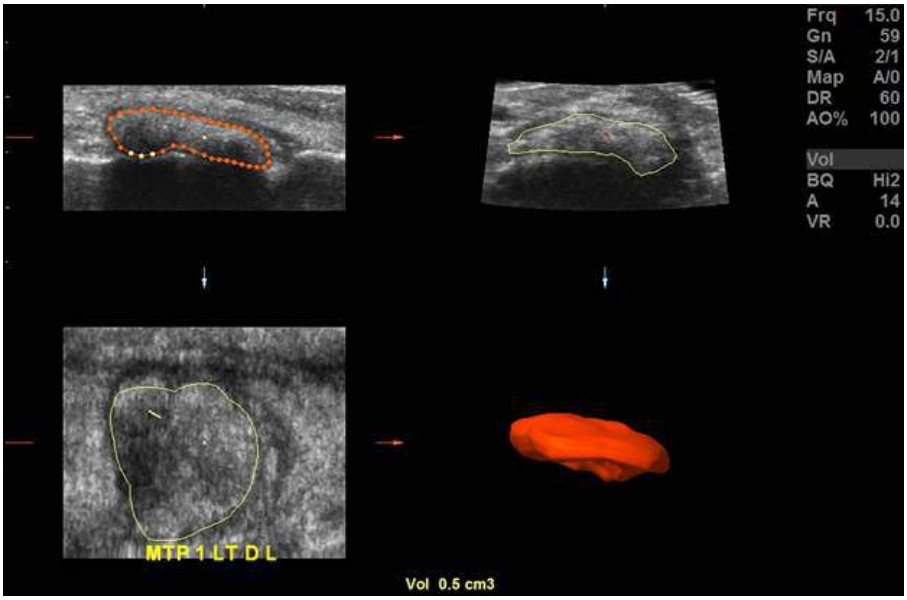
Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Ultrasound (US) can identify monosodium urate (MSU) tophi within joints, tendons, bursae and other soft tissues. The ability to readily, quickly and inexpensively assess volumes of tophi would be an attractive goal. Available 3D ultrasound transducers can scan tophi, and volumes can be re-constructed using commercially available software. The aim of this study was to assess the feasibility, repeatability and reproducibility of US volumetric assessment of MSU tophi.

Methods: 14 consecutive patients (9 male, 5 female, 32-84 years) with a history of gout and previously US identified MSU tophi were enrolled. Eleven were on urate lowering drugs (allopurinol, n=7; febuxostat, n=2; pegloticase, n=1). Joint areas included MTP1 n=8, Achilles tendon, n=1; MCP2, n=1, olecranon, n=1; prepatellar, n=1; wrist, n=1. Only 2 had clinically palpable tophi (prepatellar and olecranon bursae). Medial fullness at MTP 1 was palpable in 4, but could not be distinguished by clinical exam from hallux valgus. A GE Logiq E9 built 2014 unit with a RSP6-16-D 4D linear transducer at 15 MHz was used. After placement the probe performed an internal sweep of 3 seconds to obtain the 3D data set. Volumetric analysis was performed using volume calculation software (VOCAL, GE Ultrasound, Wauwatosa, WI.) Tophi were identified as typical hyperechoic material with an anechoic rim, if present. The 3D image was rotated 6 times at 30 degree intervals. The area of the tophus on each orientation was traced manually on the screen. The software provided the volume of the resulting structure in cm3. For each resulting tophus volume, this process was performed twice by the first reader (RT) to test the intra-observer reliability. For 6 tophi, an additional volume calculation was performed by a second rheumatologist-sonographer to test the inter-observer reliability.

Results: The software-aided volume analysis took on average 6 minutes per assessment. Reader 1 (RT) calculated a mean volume of 0.682cm3 (standard deviation (SD) 0.699, range 0.03 to 2.60) in the first reading and 0.705cm3 (SD 0.705, range 0.03 to 2.60) in the second reading. ICC showed excellent intra-reader reliability for reader 1 (0.995, 95% CI 0.985, 0.998). Reader 2 (DT) scored 6 of the 14 scans and calculated a mean volume of 0.607cm3 (SD 0.595, range 0.05 to 1.40). The ICC showed excellent inter-reader reliability between reader 1 and reader 2 (ICC 0.990, 95% CI 0.928, 0.999 using reader 1's first reading and ICC 0.994, 95% CI 0.958, 0.999 – second reading).



Conclusion: Volumetric assessment of MSU tophi by reconstruction of 3D ultrasound is a feasible, fast, inexpensive method to assess the tophus burden with excellent intra- and inter-reader reliability in this study. Future work should evaluate sensitivity to change and with positive results this method could act as an objective outcome measure for clinical trials of urate lowering therapy.

Inflammatory Syndrome in Polyarticular Gout – Description of a Previously Neglected Entity

Valentin S. Schäfer[1], Andreas Krause[2] and Wolfgang A. Schmidt[2], [1]Immanuel Krankenhaus Berlin, Medical Center for Rheumatology Berlin-Buch, Berlin, Germany, [2]Medical Center for Rheumatology and Clinical Immunology Berlin-Buch, Immanuel Krankenhaus Berlin, Berlin, Germany

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Metabolic and Crystal Arthropathies Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Inflammatory polyarticular gout occurs in clinical practice. However, only very few single case reports have been published as yet. This case series aims at describing this previously poorly defined entity.

Methods: This is a retrospective analysis of all consecutive patients of a single rheumatology center between January 2013 and April 2015. Patients were included with polyarticular gout with at least 5 joint regions involved (1st MTP joints, other MTP joints, ankles, knees, wrists, digits, elbows) and highly elevated inflammatory markers (CRP >80 mg/l and/or ESR > 80mm/h). Joint involvement was considered if clinical examination revealed swelling or tophi, or if imaging (ultrasound, dual energy CT or x-ray) showed features consistent with gout. Demographic, laboratory, imaging, clinical parameters and treatment regimens were recorded.

Results: Of the 22 included patients, 18 were male; mean age 67 years (standard deviation (SD), ±11 years); mean BMI 29 (SD ±6). The diagnosis was confirmed in 19 patients by polarization microscopy. All patients fulfilled the new ACR/EULAR classification criteria for gout. Fourteen (64%) patients were newly diagnosed with gout. The other patients had been diagnosed with gout for a mean of 10 years (SD ±10).

All patients except one were admitted to hospital due to the inflammatory syndrome. The median duration of the acute symptoms before presentation to our institution was 13 days (minimal / maximal, 2-90). A mean of 10 joint regions (minimal / maximal, 5-14) were affected. Of note, only 3 patients (14%) had fever (37.8, 38.1, 39°C, respectively). Mean visual analogue scale (VAS) for pain, disease activity and fatigue was 8.3, 8.1, and 6.7.

The mean CRP was 172 mg/l (SD ±83.6 mg/l); mean ESR, 91 mm/h (SD ±24 mm/h). All patients had anemia (mean hemoglobin, 7.2 mmol/l; SD± 0.9mmol/l). Leukocytosis was found in only 6 patients (27%; mean, 14.8 G/l), thrombocytosis in 7 patients (32%; mean 405 G/l) and neutrophilia in 12 patients (54%; mean, 9.9 Gpt/l). In 12 (55%) of patients serum ferritin was elevated (mean 391 µg/l). Procalcitonin was normal in all 11 patients in whom it had been determined. Mean uric acid levels were 531 µmol/l (8.9 mg/dl). In 8 patients (36%) acute renal failure was observed, defined as >1.5 fold increase of creatinine. Ten patients had a glomerular filtration rate (GFR) of 30-60 ml/min; in 2 patients GFR was <30 ml/min.

Seven patients received NSAID, 13 colchicine, and 2 glucocorticoids (GC) as first-line anti-inflammatory drugs. NSAID were replaced by colchicine in all 7 patients because of inefficacy. Colchicine was replaced by GC in 14 of 20 cases, and canakinumab was administered in 2 patients who had not responded well to GC. CRP values of <20 mg/l were reached by 82% of patients after a mean of 26 days (SD ±23 days) after onset of symptoms.

Conclusion: Patients with inflammatory syndrome in polyarticular gout with CRP >80 mg/l and/or ESR >80 mm/h are severely affected but rarely exhibit fever. Anemia is common. Leucocytosis and thrombocytosis are rare. Procalcitonin is usually normal. Renal failure occurs in

Session Title: Metabolic and Crystal Arthropathies Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Acutely painful flares represent the typical clinical burden of gout. Effective therapy can reduce serum uric acid (sUA) levels; however, epidemiologic evidence for the relationship between sUA and the risk gout flares is thought to be limited. The objective here was to systematically summarize the evidence of the association between sUA levels and the risk of gout flares.

Methods: A systematic review of the published literature (1946 to present) was conducted in April 2015 in Medline, EMBASE, and Cochrane, using a search strategy including terms for gout, sUA, and flares. Two reviewers screened abstracts and extracted data from eligible articles reporting flares according to sUA level. The number and proportion of patients experiencing flares, or mean (standard deviation [SD] or error [SE]) flares per patient, were tabulated according to sUA category; mean sUA levels were also tabulated by mean gout flares. Studies were classified as retrospective (flares occurred prior to sUA measure) or prospective (flares occurred after sUA measure), and according to the treatment status of the cohort.

Results: Of 866 abstracts, 19 articles presented estimates of flares according to sUA, and 17 presented estimates relevant to these analyses. In the seven studies describing flares according to sUA category, the proportion of the cohort experiencing flares increased in a dose-response fashion with higher sUA levels; as did the mean flares per gout patient (Table 1). The proportion experiencing flares was 1.4- to 2.8-fold higher in the highest sUA categories compared to the lowest. Mean flares also generally increased with higher sUA levels (Table 1). Ten studies also presented data on mean flares according to mean sUA level; these also demonstrated a dose-response relationship. As expected, clinical cohorts tended to show this relationship more clearly than administrative cohorts.

Conclusion: Our systematic review of published articles on the risk of gout flares suggested a dose-response relationship, where higher sUA levels were associated with more flares. The selection, assessment methods, and timing

of outcome measures were variable between studies. As little evidence from prospective studies designed to comprehensively evaluate flares was identified, existing risk measures are likely underestimates. Nevertheless, the existing evidence underscores the need to treat to target as recommended by the recent gout care guidelines.

Table 1: n (%) patients with flares, and mean (SD) flares over time, according to sUA level and the treatment status of the cohort

				Patients with flares		Mean flares				
Study	N	sUA level category	Period of flare measure (yrs)	n	%	Per gout patient	SD (range)	Per gout flare patient	SD	Treatment status
*Retrospective assessment of flares**										
Dalbeth, 2012		89 < 6.0 mg/dL	0.25	--	--	1.2	2.3	--	--	Mixed treated

		61 >= 7.0 to < 8.2 mg/dL		13	21.3	--	--	--	--	
		61 >= 8.3 to <9.3 mg/dL		31	50.8	--	--	--	--	
		62 >= 9.3 mg/dL		38	61.3	--	--	--	--	
Sarawate, 2006**		NR < 6.0 mg/dL	5	--	23.0	--	--	--	--	Mixed treated
		NR >= 6.0 to < 8.0 mg/dL		--	33.0	--	--	--	--	and untreated
		NR >= 8.0 mg/dL		--	45.0	--	--	--	--	
Shoji, 2004		NR 5.0 to <6.0 mg/dL		--	12.0	--	--	--	--	Mixed treated
		NR 6.0 to <9.0 mg/dL	2	--	47.7	--	--	--	--	and untreated
		NR >= 9.0 mg/dL		--	89.5	--	--	--	--	
Wu, 2009		633 < 6.0 mg/dL	1	170	26.9	--	--	1.5	0.8	Mixed treated
		1,173 >= 6.0 to < 9.0 mg/dL		509	43.4	--	--	1.6	0.9	and untreated
		432 >= 9.0 mg/dL		235	54.5	--	--	1.7	1.2	

*Retrospective: Flares were assessed prior to sUA measurement; Prospective: Flares were assessed following sUA measurement.
**Perez-Ruiz 2011 also reported mean sUA after urate lowering therapy; but no subsequent flare measures. Sarawate 2006 reported that, among those with flares, mean (SD) sUA was 8.0 (2.0) mg/dL prior to the flare, and 7.7 (2.1) mg/dL after the flare.
***Mean, 56 months follow up
None of the studies with mixed treated and untreated patients stratified both flares and sUA by treatment status

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Metabolic and Crystal Arthropathies Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: While there appears to be consensus that non-pharmacological uric acid lowering therapies (diet and lifestyle modifications) should be initiated in every patient presenting with gout, there is much less agreement as to when urate lowering drugs should be considered. Expert opinion ranges from starting uric acid lowering therapy after the first attack of gouty arthritis through a more cautious approach where therapy is only started in patients with more than 3 attacks per year. We aimed to assemble a population-based cohort of patients with newly diagnosed gout

to determine the risk of additional flares after an initial gout attack and explore the role of various demographic, clinical and laboratory predictors that may aid the clinician in quantifying this risk.

Methods: We examined a population-based incidence cohort of patients with gout, diagnosed according to the New York, Rome or ACR preliminary criteria during two time periods: January 1st 1989 - December 31st 1992 and January 1st 2009 – December 31st 2010. All subjects were followed longitudinally through their complete community medical records, until 5 years after their first gout attack, death, migration or July 1st 2012 – whichever came first. Person-year methods were used to estimate and compare flare rates over time. Frailty models (accounting for multiple flares per subject) were used to explore risk factors of subsequent flares.

Results:

429 patients with incident gout (158 patients in the 1989-1992 time period and 271 patients in the 2009-2010 time period) were followed for a mean of 4.2 years. The majority of patients were male (73%) and the mean age (SD) at gout onset was 59.7 (17.3). Isolated podagra was the most common form of joint involvement at disease onset (64.0%) and the mean (SD) serum uric acid level was 8.1 (1.9) mg/dl. 248 patients developed at least 1 subsequent flare (cumulative incidence of first flare was 61.6% by 5 years in 1989-1992 vs 60.3% by 5 years in 2009-2010; p=0.70), with a total of 582 subsequent flares during the entire follow-up period. The rate of subsequent flares increased significantly from 2.82 per 10 person-years (py) in 1989-1992 to 3.49 per 10 py in 2009-2010 (rate ratio [RR]: 1.23; 95% confidence interval [CI]: 1.04, 1.47). Men were at higher risk for subsequent flares than women (HR 1.51, 95% CI 1.14, 2.00). Other predictors were a high serum uric acid level (>6mg/dL in women and >7mg/dL in men) at baseline (HR 2.20, 95% CI 1.49, 3.27), polyarticular involvement (HR 1.46, 95%CI 1.00, 2.13) and diuretic use (HR 1.30, 95%CI 1.03, 1.65). Age and body mass index were not significant predictors of subsequent flare risk.

Conclusion:

The majority of patients in our population-based cohort did develop at least one subsequent flare after an initial diagnosis of gout. The rate of subsequent flare was higher in patients diagnosed in 2009-2010 compared to those diagnosed in 1989-1992. Male sex, use of diuretics, polyarticular involvement and high uric acid levels at first flare were significant predictors of subsequent flares and should be taken into account when deciding on the timing of initiating uric acid lowering therapy.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Metabolic and Crystal Arthropathies Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Hospitalization of patients with gout may be associated with an increased risk of arthritic flares, due to administration of IV fluids, discontinuation of established uric acid lowering therapies and other medication changes. While previous studies have suggested an association of gouty arthritis and hospitalization, the absolute flare risk has not been identified. We aimed to determine the risk of flares with future hospitalizations and examine potential predictors of in-hospital gout flares.

Methods: We examined a population-based incidence cohort of patients with gout, diagnosed according to the New York, Rome or ACR preliminary criteria during two time periods: 1989 - 1992 and 2009 – 2010. All subjects were followed longitudinally through their complete medical records, until 5 years after their first gout attack, death or migration, whichever came first. Hospitalizations of each subject were recorded and hospital records were evaluated for a possible flare of gouty arthritis. Person-year methods were used to calculate the rate of flares of gouty arthritis during hospitalizations and out-of-hospital. In addition, mixed logistic regression models with random subject effects (accounting for multiple hospitalizations per subject) were used to explore risk factors of in-hospital gout flares.

Results:

429 patients with incident gout were followed for a mean of 4.2 years. The majority of patients were male (73%) and the mean age (SD) at gout onset was 59.7 (17.3). 169 patients had at least 1 hospitalization (cumulative incidence of first hospitalization was 39.1% for patients diagnosed in 1989-1992 compared to 43.1% for patients diagnosed in 2009-2010; p=0.56), with a total of 454 hospitalizations during the entire follow-up period. The rate of hospitalizations increased marginally from 2.26 per 10 person-years (py) in 1989-1992 to 3.49 per 10 py in 2009-2010 (rate ratio [RR]: 1.19; 95% confidence interval [CI]: 0.98, 1.45).

28 hospitalizations were complicated by a flare of gouty arthritis during a total of 3276 hospital days (9.0 total py) compared to 554 out-of hospital flares during 1784 py of follow-up. The rate of in-hospital flares was 85 per 100 py compared to 8.5 per 100 py out-of-hospital. Hospitalization was associated with a significantly increased risk of gout flares (RR: 10.2; 95% CI: 6.8, 14.5). In addition, the rate of in-hospital flares increased marginally over time (6.3 per 10 py in 1989-1992 vs 11.7 per 10 py in 2009-2010; RR: 1.85; 95% CI: 0.89, 4.00).

Various possible predictors of gout flares during hospitalization were evaluated, including discontinuation of established uric acid lowering therapy, administration of IV fluids, ICU admission, use of diuretics and reason for admission, but none were identified as statistically significant predictors of in-hospital flares.

Conclusion:

Hospitalization represents a significant risk factor for flares of gouty arthritis in patients with a prior diagnosis of gout, although the absolute risk is still low. Future studies are needed to clarify which patient subgroups are at particular risk and if inpatient care related measures can help to prevent arthritic flares during hospitalization.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Metabolic and Crystal Arthropathies Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Studies describing seasonal variations in acute gouty arthritis note a seasonal trend, but disagree on timing, with most showing a peak in spring months while others showing peaks later in the year. The peak serum uric acid (SUA) levels however, have been found to be in the summer months. This disparity has led to the hypothesis that the flares might be related to factors other than high SUA levels. Various theories on the effect of weather and immune system changes on the chronobiology of the equilibrium and precipitation of monosodium urate crystals have been proposed. We aimed to shed light on this question by examining the seasonal variation in the incidence of acute gouty arthritis in the US using a large inpatient database.

Methods: We used the Nationwide Inpatient Sample (NIS) database to identify patients aged ≥ 18 years with primary diagnosis of acute gouty arthritis ICD-9-CM code 274.01 from 2009-2011 during hospitalization. We used the Edwards' recognition and estimation of cyclic trend method to study the seasonal variation of the incidence of acute gout and Z-test to compare the seasonal incidences.

Results: A total of 28,172 hospitalizations with primary diagnosis of acute gouty arthritis were reported in during the period. The peak incidence of acute gout was seen in November (peak/low ratio 1.34, 95% CI 1.29-1.38, $p<0.05$) (Figure 1). The highest number of hospitalizations was observed in autumn months while the lowest incidence was observed in spring (28.12% vs. 23.13%, $p<0.001$).

Conclusion: Unlike previous studies, our analysis found the peak incidence of acute gout in the fall with its peak in the month of November. Various environmental (temperature, humidity, diet, physical activity) and biochemical factors (low cortisol levels, high absolute neutrophil counts and plasminogen activator inhibitor-1) have been implicated for the seasonal variation. There have been conflicting data on the correlation of the incidence of acute gouty arthritis with environmental factors such as temperature or humidity. Dehydration during summer months has been postulated to precipitate crystal formation. In contrast, lower temperatures have also been reported to precipitate monosodium urate crystals in vitro, however cooling the joints with ice has been found to improve recovery. Whether our findings are reflective of purine and alcohol intake over the US holidays in November and December is a hypothesis that requires further testing. Further studies are required to verify whether seasonal, hormonal, dietary or immunological changes and acute-phase reactants have a role in the pathogenesis of acute flares. The control of these factors could potentially lead to better management of patients with gout who are at risk of acute attacks and perhaps prevent these attacks.

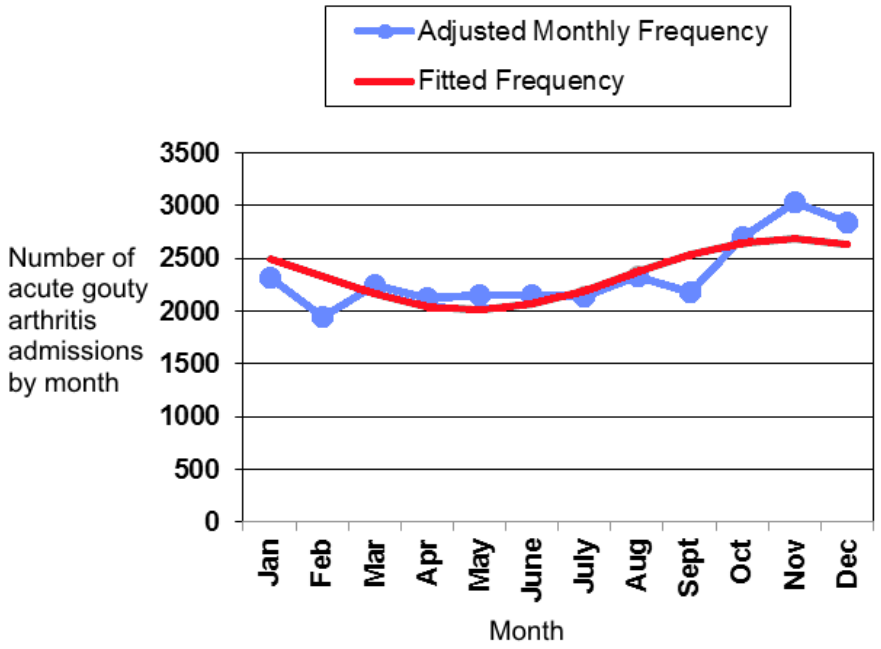

Figure 1. Graph showing seasonal trend for acute gouty arthritis admissions, 2009-2011

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Autoinflammatory diseases (AIDs), aka, periodic fever syndromes include monogenic diseases, such as familial Mediterranean fever (FMF), cryopyrin-associated periodic disease (CAPS), tumor necrosis factor receptor-associated periodic syndrome (TRAPS), and hyper IgD periodic syndrome (HIDS), and polygenic disease like NOD2-associated AID (NAID). A diagnosis of these diseases is clinically challenging in adults, and it often relies on genetic testing. Our aim is to study the disease frequency and report our diagnostic experience.

Methods:

A total of 266 adult patients with clinical phenotypes at presentation were referred due to a concern for AIDs to our Adult AID Clinic at Cleveland Clinic between November 2009 and February 2015. All patients were genotyped for *NOD2*mutations or periodic fever syndrome panel in commercially available genetic testing centers, depending on a clinical suspicion of an individual disease. The case definition included patients of 17 years of age and older and the definite diagnosis of each disease was deemed to be present if both clinical phenotypes and genetic confirmation were met. The patient electronic medical records were examined for demographic, clinical and genetic data. The frequency of positive genetic testing was calculated to estimate the concordance between the clinical diagnosis and genetic confirmation.

Results:

Of 266 patients, 79 (26.4%) were diagnostic of AIDs, including 54 cases of NAID, 13 FMF, 6 TRAPS, 5 CAPS and 1 HIDS. Of the 143 patients at risk for NAID, 37.8% were confirmed to have NAID, with 85% specificity of the *NOD2* genetic testing. Thirteen (44.8%) of 29 patients clinically suspicious for FMF had positive genetic testing. Six (9%) of 66 patients had positive testing for TRAPS. Five (21.7%) of 23 patients had positive testing for CAPS. Only one out of 5 patients was tested positive for HIDS. The demographic and genetic data of these patients with definite AIDs are summarized (Table 1). The frequencies of the genetic tests among these patients were higher (all *P*s <0.001) as compared to the literature controls (Table 2). These data demonstrated that the AIDs diagnosed in our Clinic included NAID, FMF, TRAPS, CAPS and HIDS in a descending order. The concordance between the clinical suspicion and positive genetic testing results was higher for FMF and NAID, but it was extremely low for TRAPS. Since these AIDs share overlapping clinical phenotypes and are indistinguishable frequently, the most commonly encountered diseases, NAID and FMF, should be preferably considered. Given the extreme rarity of TRAPS and HIDS in adults and very low genetic detection rate, we suggest caution be exercised to order the genetic testing for these two disorders.

Conclusion:

Our study demonstrates that NAID and FMF are relatively common in adults. TRAPS and HIDS are extremely rare and the concordance between clinical suspicion and positive genetic testing is very low for both diseases. To be cost-effective, an ordering of genetic testing for AUIDs should highly consider both the disease frequency and stringent phenotypes, and a consultation with experts should be encouraged.

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I

Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Pneumococcal vaccination is recommended for patients requiring treatment with immunosuppressive drugs. The aim of this report is to describe unusually severe adverse reactions to pneumococcal vaccination in each of seven consecutive patients with cryopyrin associated periodic syndromes (CAPS).

Methods: Seven consecutive patients with CAPS were vaccinated with pneumococcal polysaccharide or conjugate vaccines according to current guidelines. Clinical information was collected retrospectively.

Results: Within a few hours after the vaccination, all seven patients developed severe local reactions at the injection site (Table). Two patients had to be hospitalized for systemic reactions including fever. One patient had developed a severe headache associated with neck stiffness and photophobia. A florid red rash was covering much of the arm where the vaccine had been administered. The patient was admitted to her local hospital that evening with a diagnosis of presumed viral meningitis. Lumbar puncture revealed elevated white cells (96 per cubic millimetre, neutrophils 84%), normal glucose 2.3 mmol/L and elevated protein at 0.79 g/L In all patients, the symptoms resolved in a period of 3 to 17 days. The reaction occurred with pneumococcal vaccines from three different manufacturers and in patients with different CAPS phenotypes. Four vaccination reactions occurred in temporal association with concomitant co-injections of canakinumab, two other vaccination reactions were separated by 15 days from last canakinumab dose. In one case, an event was also observed prior to any canakinumab therapy. Some patients had been vaccinated with a variety of other vaccines without complications.

Table. Clinical characteristics of CAPS patients who developed severe inflammation after pneumococcal vaccination

Case Nr. Age, gender	Clinical presen-tation	NLRP3 Mutation	CAPS duration	CAPS treatment	Vaccine/ manufacturer	Days since last canakinumab	Days until onset	Local symptoms	Systemic reaction	Days until resolution	Previous uneventful vaccines
Case 1 43 years, female	MWS	T348M	43 years	Canakinumab 150 mg every 8 weeks	Pneumovax II / Sanofi Pasteur	New canakinumab dose given on day of vaccination (63 days since previous dose)	0	Swelling, rubor, dolor, calor	Fever, nausea, headache, stiff neck	17	Nil
Case 2 20 years, female	NOMID	L632F	20 years	Canakinumab 300 mg every 8 weeks	Pneumovax II/ Sanofi Pasteur	New canakinumab dose given on day of vaccination (56 days since previous dose)	0	Swelling, rubor, dolor, calor	Fever	12	Influenza
Case 3 26 years, female	NOMID	A352T	26 years	Canakinumab 300 mg every 8 weeks	Pneumovax II/ Sanofi Pasteur	New canakinumab dose given on day of vaccination (49 days since previous dose)	0	Swelling, rubor, dolor, calor	Not known	14	Nil
Case 4 43 years, male	MWS	T348M	43 years	Canakinumab 150 mg every 8 weeks	Pneumovax II/ Sanofi Pasteur	New canakinumab dose given on day of vaccination (63 days since previous dose)	0	dolor	None	4	Influenza
Case 5 24 years, female	MWS	E311K	10 years	Canakinumab 150 mg every 8 weeks	Pneumovax 23/ Merck	Canakinumab was given 15 days prior to vaccination	0	Swelling, rubor, dolor, calor	None	3	Influenza, HiB
Case 6 52 years, female	MWS	E 311K	51 years	Canakinumab 300 mg every 8 weeks	Pneumovax 23/ Merck	Canakinumab was given 15 days prior to vaccination	0	Swelling, rubor, dolor, calor	None	10	Influenza
Case 7		No				No prior or		Swelling,			Diphtheria

7 years, female	FCAS	No known mutation	7 years	None	Prevenar 13/ Wyeth	No prior or concomitant canakinumab	0	rubor, dolor, calor	None	4	Diphtheria Polio Tetanus

Conclusion: Pneumococcal vaccines can trigger a severe local and systemic inflammatory reaction in patients with CAPS and possibly patients with other autoinflammatory diseases. TLR triggering by pneumococcal vaccine components with subsequent inflammasome hyperactivation in CAPS patients with NLRP-3 mutations may explain the high incidence rate of this event, its rapid onset, severity, and systemic nature.

Careful consideration is warranted when implicating current EULAR immunization guidelines in this patient population.

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Canakinumab (CAN) is indicated for the treatment of cryopyrin-associated periodic syndrome (CAPS) in patients aged ≥2 years.[1,2] However, the efficacy of CAN has not yet been studied in infants. Here we present the efficacy and safety of CAN in patients with CAPS aged <24 months.

Methods: Patients aged 28 days to 4 years with CAPS received CAN at 2 to 12 mg/kg every 4 or 8 weeks for 56 weeks. Efficacy was evaluated by complete response (clinical response and normal C-reactive protein [CRP] levels) and subsequent relapse. Safety assessments included adverse events (AEs).

Results: Of 17 patients enrolled, 6 were aged <24 months (44 days to 5 months). The phenotypic distribution of patients aged <24 months was: familial cold autoinflammatory syndrome (FCAS, n=1), Muckle–Wells syndrome

(MWS, n=4), and neonatal-onset multisystem inflammatory disease (NOMID, n=1). All 17 patients achieved a clinical response, and 16 achieved a complete response, with 5/6 patients <24 months of age achieving a complete response. One patient aged 1 year with persistently elevated CRP levels did not achieve complete response (Table). Of the patients with a complete response, 4 (2 MWS and 2 NOMID) subsequently relapsed; however, all regained complete response 2 (1 MWS; 1 NOMID) with and 2 (1 MWS; 1 NOMID) without dose escalation. Seven patients required dose escalation to achieve and/or maintain their responses. The proportion of complete responders without a relapse was higher in the <24 months age group (5/5, 88.9%) versus ≥24 months (7/11, 63.6%). The most common AEs were infections, typically involving the upper respiratory tract. Four patients experienced a serious AE (SAE), with no SAE occurring more than once. No patient discontinued due to an AE.

Table. Response assessment

n (%)	**Age <24 months n=6**	**Age ≥24 months n=11**	**Total N=17**
Patients achieving complete response	5 (83.3)	11 (100.0)	16 (94.1)
Patients not achieving complete response	1* (16.7)	0 (0.0)	1 (5.9)
*One-year-old patient with persistently elevated CRP			

Conclusion: Canakinumab is an effective treatment for patients with CAPS aged as young as 44 days. The safety profile of canakinumab was acceptable in younger patients and similar to that observed for older patients.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with autoinflammatory diseases treated with immunosuppressive agents reportedly experience an increased risk of serious infections.[1] Therefore, these patients are likely candidates for vaccinations, such as those against the influenza virus and meningococcal infections. A previous report has shown that treatment with canakinumab (CAN) does not affect antibody production after vaccination in healthy volunteers[2]; however, no data are available in patients with cryopyrin-associated periodic syndrome (CAPS) receiving standard childhood vaccines. Here we assess the presence of protective antibody levels following immunization with inactivated vaccines in patients with CAPS.

Methods: Patients aged 28 days to 4 years received CAN at 2 to 12 mg/kg (based on body weight) every 4 or 8 weeks for 56 weeks. Vaccination response was evaluated using postvaccination antibody titers at 0 to 14 (predose assessment), 28, and 57 days after vaccination. Patients were considered assessable for an antibody response to a specific vaccination if they had a predose and at least one postdose antibody titer measurement. However, for patients with adequate predose antibody titers without any difference at subsequent antibody titer measurements, the specific patient vaccination was deemed non-assessable.

Results: Of 17 patients, 7 (aged 5-60 months) received ≥1 vaccinations against *Corynebacterium diphtheria*, *Bordetella pertussis*, *Neisseria meningitidis*, *Clostridium tetani*, influenza type A, influenza type B, *Haemophilus influenza* B, *Streptococcus pneumoniae*, or hepatitis B. The Table summarizes predose antibody titers and the last measured antibody titer during the study for each patient and corresponding vaccination. Of 31 unique patient vaccination cases, only 18 were assessable for a vaccination response, whereas for the remaining 13, patient-vaccination was not deemed assessable. For all 18 (100%) assessable cases, postvaccination antibody titers increased to protective levels compared to the predose measurement. All the 31 vaccination cases showed protective level antibody titers at the last assessment in the study. No CAPS flares were reported with vaccination.

Table. Summary of vaccination assessments

Vaccination		Patient, age (months)						
		31	14	29	5	60	38	27
C. diphtheria [IU/mL]	predose	0.12	0.4	n/a	n/a			
	postdose	>1	>1	>1	>1			
B. pertussis [U/mL]	predose	54.64	15.18*	n/a	n/a			
	postdose	>150	137.9*	>150	16.29			
*N. meningitidis***	predose		7.39		n/a			
	postdose		14.92		9.53			
C. tetani [IU/mL]	predose	0.59	0.12	n/a	n/a			
	postdose	>5	1.06	>5	1.81			
Influenza type A (H1N1) [mm²]	predose					38.49	33.18	56.75
	postdose					56.75	113.10	103.87
Influenza type A (H3N2) [mm²]	predose					56.75	33.18	7.07
	postdose					70.88	78.54	113.10
Influenza type B [mm²]	predose					23.76	33.18	44.18
	postdose					38.49	70.88	95.03
H. influenza B [µg/mL]	predose	0.83	>4.9		n/a			
	postdose	>4.9	>4.9		>4.9			
S. pneumoniae [U/mL]	predose		>10		n/a			5.67
	postdose		>10		>10			8.01
Hepatitis B [mIU/mL]	predose	<10	>250					
	postdose	209.7	>250					

*Patient initially mounted an antibody response, received a booster vaccination, and maintained protective antibody levels

**The ELISA kit used for *Neisseria meningitidis* assessment was qualitative

n/a = predose titer not available; cursive/grey = vaccination response not assessable

Conclusion: Canakinumab appears to have no effect on antibody production against standard childhood nonlive vaccines.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: ,

We present the case of a family with a new diagnosis of

TRAPs. The father, a 59 year old man with a history of type 2 diabetes mellitus and hypertension had presented to a DGH on numerous occasions since 1990 with recurrent pyrexic episodes associated with rigors, fatigue and arthralgia. This had often been attributed to a lower respiratory tract infection, despite a lack of positive culture results or chest x-ray changes to support this.

He was entirely well between episodes.

He had an extensive travel history over the years but had previously tested negative for malaria and other tropical diseases. His ESR and CRP were elevated with each flare, but had not been checked during asymptomatic periods. He was extensively investigated during each admission, but multiple blood, urine and sputum cultures returned negative.

Methods: ,

He was admitted again in August 2013 with a 4 week history of pyrexia, rigors and elevated inflammatory markers with CRP 150 mg/l and ESR 111 mm/h and a leukocytosis of 11.7x10^9/L. Ferritin was elevated at 1700 ng/ml on this occasion, but he met no other Yamaguchi criteria for Still's disease. Blood and urine cultures were negative as was quantiferon gold testing. HIV and viral serology were negative. His echocardiogram, CT chest, abdomen and pelvis and ultrasound of urinary tracts all found no abnormalities. His ANCA, ANA, ANA to Hep cells, ENA, complement, rheumatoid factor and immunoglobulins were normal. He was also seen by haematology who performed a bone marrow

biopsy which returned morphologically normal with no evidence of malignant cells.

Results: ,

He went on to have a white cell HMPAO whole body scan which showed slight increased uptake in the left side of his manubrium which raised the suspicion of an inflammatory arthropathy, prompting a referral to rheumatology. Bloods were sent to the national amyloid centre on the suspicion of an systemic autoinflammatory syndrome. Results confirmed a new mutation in the region of the TRAPS gene TNFRSF1Aex4-5 C96Wc.375T>G. This is a new mutation not previously reported in the literature.

During this period his son was admitted with pyrexia, abdominal pain and elevated inflammatory markers. CT abdomen revealed no abnormality. Given his father's history of TRAPS, he too was tested and this returned positive for the TRAPS mutation.

Conclusion: ,

Currently he receives prednisolone 0.5-1mg/kg with acute attacks which settle within 5 days. If however he starts to require more than 10 days of treatment or if his annual mean dose of prednisolone is >5mg/day he will require anakinra. His inflammatory markers have remained normal in between attacks to date and he has no evidence of amyloid.

Pyrin (MEFV) Mutations in New York: Revisiting the Mount Sinai Experience with Periodic Fever and Serositis

Daniel Bunker and Mark Matza, Medicine, Mount Sinai Medical Center, New York, NY

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: In 1945, Dr. Sheppard Siegel, a Mount Sinai allergist, described 5 patients with "Benign Paroxysmal Peritonitis," a disorder now recognized as Familial Mediterranean Fever (FMF). By 1964 (Am J Med 36: 893, 1964), he was able to review a cumulative experience with 50 patients affected by this disorder from the New York City area, describing in detail self-limited attacks of intense abdominal pain with accompanying fever, usually found in younger patients of specific ethnicities, including 38 ashkenazi and 4 sephardic jews, and 7 armenians . Possibly affected by the disorder himself, he also identified "progressive nephropathy" as a feared complication, and correctly surmised an underlying genetic cause. Although Dr Siegel was unable to identify an effective treatment, including a search for food allergies, his work overlapped with that of Dr Tsai Fan Yu @ Mount Sinai 1962-86 that established the efficacy of daily colchicine prophylaxis for gout, eventually identified as another autoinflammatory disease. In 1997 FMF was linked to the MEFV gene on chromosome 16 by two groups, and, that year, we established an referral practice for FMF and Amyloidosis at the Mount Sinai Medical center.

Methods: We now report our experience with 51 patients affected by this disease, and /or found to have MEFV mutation over the period 1997-2015.

Results: In our cohort, the most common ethnicity was Sephardic Jewish (17), with varying origins from Morocco (4) to Khazakhstan, and the most common genotype was heterozygous M694V (22%). 9 patients were homozygous, 17 patients were heterozygous, and 10 patients were compound heterozygous. An additional three patients having the typical FMF phenotype (Tel Hashomer criteria) and response to colchicine were wild type, assessed by full DNA sequence analysis. Interestingly, a number of patients with the FMF phenotype and documented MEFV mutations began manifesting symptoms in adulthood; atypical phenotypes seen were periodic fever without serositis, recurrent pleuritis, and recurrent pericarditis. Associated diseases were nonspecific colitis, thalassemia, G6PD deficiency, and one case of primary Sjogren 's syndrome complicated by mesothelioma. Only one patient with typical FMF symptoms eventually developed secondary (AA) amyloidosis. However, one patient homozygous for the M694V mutation had secondary amyloidosis as his initial manifestation of the disease ("phenotype II"), and four additional patients with secondary amyloidosis, and one egyptian man with renal amyloid due to Lect2, were found to have the low penetrance E148Q mutation. Median delay from first attack to diagnosis was 10 years. Treatment modalities included colchicine and anticytokines, notably IL-1 and more recently IL-6 antagonists.

Conclusion:

Availability of genetic testing has allowed analysis of the heterogeneity of genotype-phenotype correlations and distribution frequencies for pyrin mutations in a "melting pot" population from which the initial description of FMF in New York City were made.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Familial mediterranean fever (FMF) is caused by a number of mutations of the *MEFV* gene, coding for a protein named pyrin that acts as a major regulatory component of the inflammasome. It is widely accepted that elevated acute phase proteins such as SAA, CRP and inflammatory cytokines including IL-6, IL-18 are found in active phase of patients with FMF. However serum cytokine profiling of FMF patients still remains to be obscure. The aim of this study was to identify the utility of multiple cytokines measurement for understanding the specific molecular networks in patients with FMF.

Methods: FMF patients in attack or remission were classified by Japan College of Rheumatology-certified rheumatologists through medical records. Serum levels of 45 cytokines were measured by multi-suspension cytokine array from 49 FMF patients, in either attack or remission, and 33 age-matched controls. They gave their informed consent to be subjected to the protocol, which was approved by the Institutional Review Board of Nagasaki University. Multivariate classification algorithms were used to determine discriminating biomarkers.

Results: Twenty-nine out of 45 cytokines were available for further analyses. Serum levels of 8 cytokines (IL-4, IL-6, IL-7, IL-17, IL-18, G-CSF, ICAM-1 and CXCL10) were significantly elevated from FMF in attack than healthy control. Furthermore, eleven cytokines (IL-6, IL-10, IL-12p40, IL-12p70, IFN-alpha, IFN-gamma, GM-CSF, G-CSF, FGF-2, CXCL10 and CX3CL1) were increased from FMF in attack compared to FMF in remission. We performed multivariate classification algorithm and ranked cytokines by their importance (Fig. 1) and found that IL-6, sICAM-1, IL-18 and IL-17 were the best combination to distinguish FMF in attack from healthy control with high accuracy (sensitivity; 92.0%, specificity; 93.9%, accuracy; 93.1%). Among FMF patients, combined measurement of IL-6, G-CSF IL-10 and IL-12p40 discriminated FMF in attack from FMF in remission with high accuracy (sensitivity; 76%, specificity; 90.3%, accuracy; 83.9%).

Conclusion: Our data suggest for the first time that specific molecular interactions are present in patients with FMF based on multiple cytokines measurement. These findings may extend to our further understanding of the activation of inflammasome leading to promote cytokine networks.

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Interleukin-1 (IL-1) is a major mediator of the inflammatory cascade in Familial Mediterranean Fever (FMF) and an established therapeutic target (1). To retrospectively assess the efficacy and safety of the IL-1 inhibitor Canakinumab in adult and adolescent FMF patients.

Methods: Thirteen patients (7 men) with genetically confirmed FMF, fulfilling the Tel Hashomer criteria, aged 37 years (median, range 13-70), with median disease duration of 15 years and active disease despite treatment with colchicine (n=9), anakinra (n=1) or both (n=3), received Canakinumab 150mg subcutaneously every 4 (n=7) or 6 (n=2) or 8 weeks (n=4) for a median of 18 months (range 7-53). Canakinumab was given as monotherapy in 9; 4 patients received concomitant treatment with colchicine and/or corticosteroids. The clinical and laboratory parameters during follow up were recorded.

Results: Ten out of 13 patients (77%) achieved complete clinical remission within a median time of 3.5 months, while normalization of all laboratory parameters associated with inflammation occurred in 85% of patients within a median time of 3 months. The remaining patients achieved partial responses, with persisting, albeit milder, arthralgias, exertional leg pain, abdominal pain, anemia, and lower, but abnormal, C-reactive protein levels. Response was maintained until the last visit in all but one patient who relapsed with fever and arthralgias and re-remitted after reducing the Canakimumab administration interval. Overall, in 3 patients, including the patient who relapsed, the interval between Canakinumab injections was reduced in order to achieve complete remission, whereas in another two patients drug administration intervals could be safely increased without disease exacerbation until the last visit. The concomitant corticosteroid dose was significantly reduced during follow up. The recently proposed FMF50 score for assessing outcome in FMF (2) was achieved by 62% and 85% of patients at one month and 12 months, respectively. Canakinumab was well tolerated; one patient experienced an urinary tract infection, which resolved with antibiotics, and another one a viral gastroenteritis, which required short-term hospitalization.

Conclusion: The rapid and sustained response to Canakinumab in the majority of our patients, together with the favorable safety profile, encourages its further use in FMF.

What Acute Phase Reactants Accurately Identify Patients Who Will Develop Amyloidosis in Familial Mediterranean Fever? a Systematic Review

Burak Erer[1], Erkan Demirkaya[2], Seza Ozen[3,4], Tilmann Kallinich[5] and Loreto Carmona[6], [1]Department of Internal Medicine, Division of Rheumatology, Istanbul University, Istanbul Faculty of Medicine, Istanbul, Turkey, [2]Gulhane Military Medical Faculty, Ankara, Turkey, [3]Pediatric Nephrology and Rheumatology, Hacettepe University, Ankara, Turkey, Ankara, Turkey, [4]Deptartment. of Pediatric Rheumatology, Hacettepe University, Ankara, Turkey, [5]Charite, University Medicine Berlin, Berlin, Germany, [6]Instituto de Salud Musculoesqueletica, Madrid, Spain
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Familial Mediterranean Fever (FMF) is a prototype of autoinflammatory diseases. Inflammation is expressed by attacks of fever and serositis and elevation of acute phase reactants (AFR). The most dreaded complication of FMF is amyloidosis, being the treatment target to prevent it. There is controversy as to what AFR should be monitored in these patients. The objective was to analyze the performance of the various AFR for the prediction of amyloidosis in FMF.

Methods: We performed a systematic review based on a sensitive search in Medline, Embase, and Cochrane Library, with terms related to FMF, to performance and diagnostic studies, and to longitudinal studies. Selection criteria included: 1) FMF any age; 2) measure of Serum amyloid A (SAA), C-RP, proteinuria, or ESR; 3) amyloidosis should be the outcome measure; 4) sensitivity, specificity, predictive value and other performance parameters could be calculated; and 5) designs should be longitudinal preferably. Two fellows screened the registers captured by the search strategy and collected the data in pre-specified tables. Evidence tables and qualitative synthesis were produced.

Results: The search captured 1516 items of which 26 were selected for detailed review, and 12 were finally included in the review. No study actually analyzed the performance by means of sensitivity and specificity to predict, or even detect, proteinuria or amyloidosis. The studies reviewed combine and stratify variables in a descriptive manner and it is very difficult to interpret the true performance of the tests. Each study was designed *ad hoc*, thus, yielding a high heterogeneity in designs, parameters measured, and results, despite being set from research questions similar to ours. Many are described as longitudinal; however, the measures are actually performed cross-sectionally. We were able to calculate the performance from three studies (See Table), although the performance was not tested in the appropriate population (ill versus healthy controls instead of amyloidosis yes/no). The correlation between measures is low.

Table. Calculated performance of tests

Study	test	Gold standard	Se	Sp	LHR+	LHR-	PPV	NPV
Berkun **Y, et al, 2007**	SAA	Symptomatic vs Asymptomatic	79.3	52.5	1.7	0.4	80.4	52.5
Korkmaz **C, et al, 2002**	CRP	FMF attack/Healthy control	100	94.7	19.0	0.00	98.0	94.7
Korkmaz **C, et al, 2002**	ESR	FMF attack/Healthy control	87.8	100	-	0.12	100.0	100.0
Abbreviations: SAA, Serum amyloid A; C-RP, C-reactive protein; ESR, erythrocyte sedimentation rate; Se, sensitivity; Sp, specificity; LHR, likelihood ratio: PPV, positive predictive value; NPV, negative predictive value.								

Conclusion: The evidence supporting the monitoring of FMF with any AFR over the others is limited and of poor quality in general. Well designed longitudinal studies with a mixture of outcomes should be undertaken. Until them, recommending an AFR over other would be based on expert opinion and indirect evidence.

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Familial Mediterranean Fever (FMF) is an autoinflammatory disease characterized by recurrent attacks of fever and serositis. Abdominal pain is the most frequent symptom of these patients and approximately 95% of the FMF patients experience an abdominal attack sometime during their illness. One of the main concerns in FMF is the impaired oral intake and possible weight loss during abdominal attacks. In this study, we aimed to investigate the association of the clinical conditions with attack type, and weight status in patients with abdominal attacks.

Methods: A group of 118 consecutive patients with a diagnosis of FMF seen in a tertiary rheumatology outpatient clinic were included in the study. The demographical, laboratory, genetic and clinical features of the patients were recorded. Body mass indexes were calculated as kg/m^2. Statistical analysis was made with SPSS 22.0.

Results: 18 % (n=21) of the patients were female. The mean age and BMI's of the study group were 29.05±8.69 (17-53) years and 24.28±3.5 (16.5-33.4) kg/m^2, respectively. The mean disease duration of these patients was 12.32±8.8 (0-39) years. 26% (n=31) of patients were smokers. The levels of the inflammatory markers did not differ significantly with predominant attack types. Patients with arthritis attacks had lower BMI's (23.7±3.4 vs 25.0±3.5 kg/m2, p=0.047) compared to non-arthritis patients (Figure 1). Disease duration from the first symptom or attack was significantly associated with serum uric acid measurements (r=0.280, p=0.041)(Figure 2). BMI was significantly associated with

serum uric acid measurements (r=0.263, p=0.036). Patients with an erysipelas-like erythema had lower serum magnesium levels (1.86±0.11 vs 2.06±0.14 mg/dl, p=0.013). Abdominal peritonitis attacks were associated with lower diastolic arterial pressures (69.8±8.4 vs 73.8±5.4, p=0.024). Myositis attacks and febrile myalgia were associated with higher serum creatinine kinase levels (366.4±317.3 vs 108.5±48.5 U/L, p<0.001). The disease duration, genetic mutation and smoking status lacked any significant association with BMI's (p=0.803, 0.269 and 0.512, respectively).

Conclusion: These preliminary findings are needed to be confirmed in larger cohorts. Especially the correlation between serum uric acid levels and higher disease duration may point to higher cardiovascular risks of FMF patients in time.

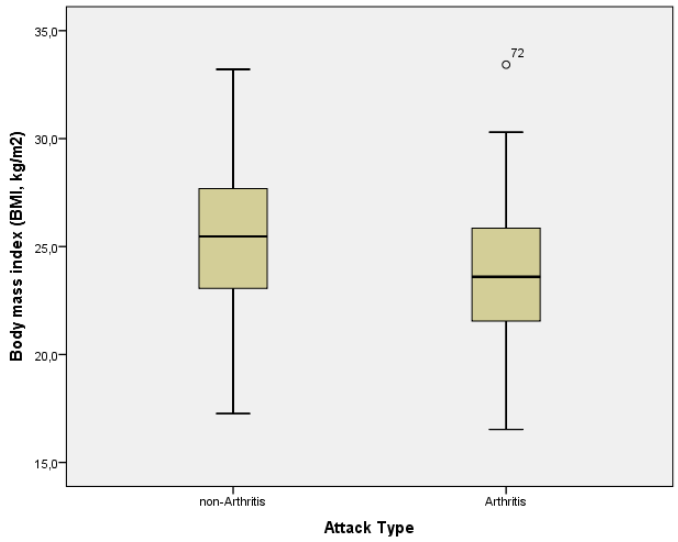

Figure 1. Chart showing the BMI differences of FMF patients in arthritis and non-arthritis attacks (p=0.047).

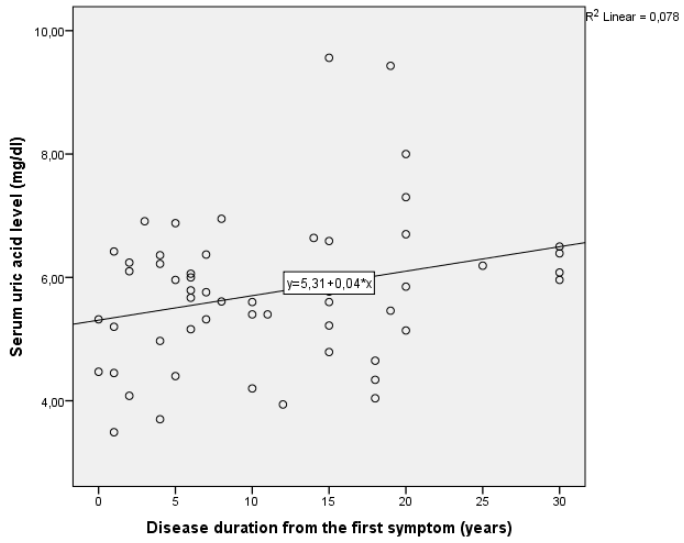

Figure 2. The chart showing the association between serum uric acid levels and disease duration of FMF patients.

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Arterial stiffness represents the viscoelastic properties of the vessel wall. It occurs as a result of known atherosclerotic risk factors such as hypertension, diabetes mellitus, smoking, hypercholesterolemia and aging. It has high cardiovascular risk-predictive value, reproducibility and cost-effectiveness. Familial Mediterranean Fever (FMF) is an autoinflammatory disease characterized by recurrent attacks of fever and serositis. These patients may experience a high risk of cardiovascular events due to the ongoing and recurring inflammatory state. In this study, we aimed to investigate the arterial stiffness and associated factors in patients with FMF.

Methods: A total of 104 subjects were enrolled in the study. 35 of them were healthy controls. 69 patients, of whom 11(16%) were female, were consecutive patients with a diagnosis of FMF examined in a tertiary rheumatology outpatient clinic. The mean ages and BMI's of the patient vs control groups were 27.04±8.0 vs 28.29±4.9 years (p=0.331) and 24.11±3.3 vs 24.48±3.2 kg/m2 (p=0.586). The groups were also matched in terms of gender (p=0.836) and smoking status of the subjects (p=0.058). The demographical, clinical, laboratory and genetic features of the patients were recorded. The predominant attack type was recorded as peritonitis, pleuritis, arthritis, febrile myalgia and erysipelas-like erythema. Tensiomed device (TensoMed Ltd, Budapest, Hungary) was used for arterial stiffness measurements. SPSS 22.0 statistical package was used for statistical analysis.

Results: FMF patients had a significantly higher pulse wave velocity measurements (PWV) (7.73±1.3 vs 7.18±1.1 m/sec; p=0.03), lower brachial and aortic augmentation indexes (-64.6±14.6 vs -54.6±25.9 %, p=0.041 and 4.9±7.4 vs 14.0±11.5 %, p=0.025; respectively) compared to controls. Central aortic pressure and ankle brachial index measurements were statistically similar. 31(45%) of the patients were examined in attack and had significantly higher PWV measurements (8.17±1.6 vs 7.38±0.9 m/sec; p=0.027) compared to symptomless patients. PWV measurements had significant correlations to serum CRP (Figure), WBC, erythrocyte sedimentation rate, fibrinogen, and neutrophil/lymphocyte ratios (r=0.581, 0.251, 0.367, 0.348, 0.337; p<0.001, p=0.049, 0.004, 0.006, 0.007; respectively. The genetic mutation and predominant attack type had no effect on arterial stiffness measurements.

Conclusion: These preliminary results suggest that FMF patients have impaired arterial stiffness measurements, which get worse during attacks, compared to controls. The impaired arterial stiffness measurements seem to be due to the severity of the inflammatory state, rather than attack type and genetic mutations. These data point to higher future cardiovascular risks in FMF patients.

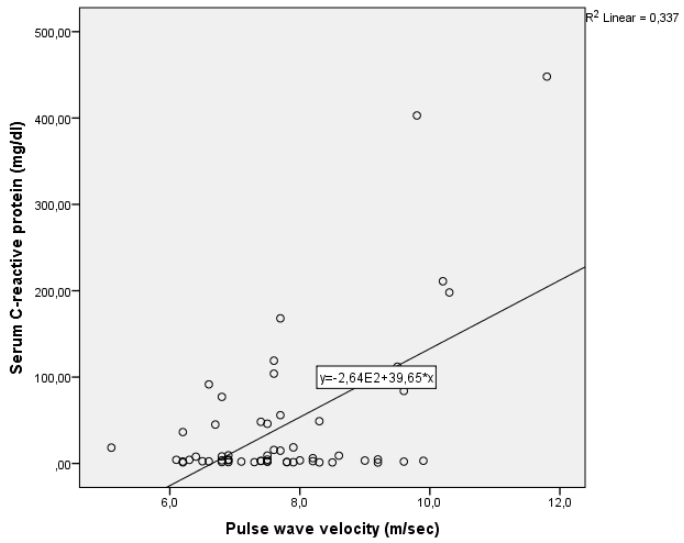

Figure: The association between serum CRP (mg/dl) and PWV (m/sec) in FMF patients.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Introduction: Familial Mediterranean Fever (FMF), the most common form of the hereditary autoinflammatory disorders, is characterized by recurrent attacks of fever along with serosal or synovial inflammation lasting usually 12

to 72 hours. FMF is associated with impaired functional ability, and the persistent disabling features and chronic pain, emotional and physical limitations can have a negative impact on the health-related quality of life (QoL) of the patients.

There is no established treatment available for those resistant or intolerant to standard of care colchicine treatment. Interleukin-1 (IL-1) plays a pivotal role in the pathogenesis of crFMF. Canakinumab, a fully human, selective, anti-IL-1β monoclonal antibody, binds to IL-1β and inactivates its signalling activity. Gul et al. have described the efficacy and safety of canakinumab in adults with colchicine resistant (cr) FMF in a local pivotal phase II trial. Here, we report the effect of canakinumab treatment on QoL measured by SF-36 Questionnaire.

Objectives: This study aimed to show the effects of canakinumab treatment on quality of life by 8 sub-items of SF-36 as well as to see the correlation between the physician global assessments and SF-36 scores.

Methods:

crFMF patients with ≥1 attack/month in the preceding 3-months despite the highest tolerated colchicine dose entered the study. Canakinumab injections were administered at Day 1, Day 29 and Day 57. Changes in the quality of life was recorded in 9 subjects by using SF-36 at Day 1, 8, 29,57, 86,115 and the end of the study.

Results:

In all 8 sub-items (physical functioning, role limitations due to emotional/physical health, energy, emotional-well being, body pain, social functioning and general health) of SF-36 scores improved dramatically with canakinumab treatment, starting from 1st day. However the differences in emotional well-being and role limitations due to emotional problems scores couldn't reach the statistical significance. All scores are showed in tables below. Also there was a strong negative correlation between Physician Global Assessment (PGA) and Physical Component Score(PGS) (R-sq: -0,793). A weaker correlation observed between Mental Component Score(MCS) and Physical Global Assessment (R-sq: -0,540).

Conclusion:

Canakinumab treatment in cr-FMF patients resulted in a rapid improvement in QoL measures. Also these improvements sustained during the withdrawal period. PGA scores seem to be correlating well with SF-36 scores. In addition, Physical Component Score matches with PGA more than Mental Component Score.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To assess the safety and efficacy of anakinra in pregnant FMF patients.

Methods: Six FMF patients, treated with anakinra during pregnancy were monitored for side effects, fetal and maternal outcomes.

Results: We present six FMF patients who were treated with Anakinra 100 mg/d sc during pregnancy due to severe protracted febrile myalgia in 4, thrombocytopenia in 1 and amyloidosis in 1. One of these patients has been previously reported (1). No anakinra-related adverse event was observed either in the mother-to-be or the fetus during pregnancy and delivery. One patient had an incision-site infection after c-section and one of the babies developed thrombocytopenia as his mother, and improved after treatment with IVIG. Four of these six patients gave birth to healthy babies and two are still pregnant . During the anakinra treatment, all patients recieved anakinra together with cholchicine, except one patient with thrombocytopenia was solely on Anakinra throughout pregnancy. No flare was observed in 3 out of 4 patients in whom Anakinra was was stopped after delivery. Pregnancy-related features are listed in Table 1.

Conclusion:

Anakinra promises to be a safe alternative in pregnant FMF patients who have active disease despite colchicine or intolerant and also can be given transiently during pregnancy and successfully stopped after delivery, as in our patients.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

AA amyloidosis is the long-term complication of various chronic inflammatory diseases avoidable by the treatment of the underlying disease but with no established treatment once diagnosed. Recently there are few reports pointing out that tocilizumab (TCZ) may be effective in controlling AA amyloidosis.

We aim to demonstrate our data on the effect of TCZ in patients with AA amyloidosis secondary to FMF.

Methods:

The follow-up data of FMF patients with histologically proven AA amyloidosis, treated with TCZ (8 mg/kg/mo) is evaluated by assessing the changes in creatinine, creatine clearance, 24-hour urine protein, erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) values measured before and throughout the treatment period. Adverse effects of the treatment were closely monitored.

Results:

TCZ was given to 13 patients with AA amyloidosis secondary to FMF who were also on Colchicine (2.28 ± 0.48 mg/day). Two patients had coexisting ankylosing spondylitis, and one each had systemic lupus erythematosus and Crohn's disease. The mean age was 37.46±9.96 years, the mean disease duration of FMF was 24.15±7.65 and of amyloidosis was 5.52±4.98. The mean follow-up period on TCZ treatment was 12.92 ± 8.44 months. The mean creatinine levels decreased from 1.23±0.89 mg/dl to 1.07 ± 0.59 mg/dl ($p < 0.001$), mean creatine clearance increased from 97.66±54.35 ml/min to 108.46±64.17 ml/min ($p < 0.001$). Renal function was impaired in 4 patients which

improved significantly on TCZ therapy (creatinine from a mean of 2.33±0.76 mg/dl to 1.77±0.47 mg/dl, p=0.005; creatinin clearence from a mean of 37.52±4.51ml/min to 50.82±9.84ml/min, p<0.001). The median of 24-hour urinary protein excretion for the whole group was reduced from 3038.5 mg/dl (IQR 1771-6539) to 1710 mg/d (IQR 634-4953) (p=0.007). The mean level of CRP was reduced from 22.36±20.83 mg/dl to 5.71±5.98 mg/dl (p=0.002) as the mean ESR from 52.42±33.27 mm/h to 38.30±37.50 mm/h (p=0.003).

Twelve of the patients did not experience any FMF attack under TCZ treatment. TCZ was terminated in the patient with concommitant diagnosis of SLE and APLS who had ischemic chest pain after the 12th dose, and in another patient because of an increase in the frequency of attacks associated with erysipelas-like erythema and no decrease in proteinuria. Treatment was also stopped in two other patients; one who was an illicit user of synthetic cannabinoid who developed high blood pressure 5 days after a single infusion and the other who experienced diplopia after the 6th dose. Both of these patients' creatinine increased after termination of the therapy (from1,43mg/dl to 2.85mg/dl;from0.8mg/dlto 3.85mg/dl, respectively) leading them to the end stage renal disease. None of the patients developed infusion reactions.

Conclusion:

TCZ improves the acute phase response and the renal function impaired by amyloidosis secondary to FMF. Among this patient group TCZ treatment is well tolerated and not associated with serious side effects. Further studies are warrented to test the efficacy and safety of TCZ in AA amyloidosis secondary to FMF as well as other inflammatory conditions.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To review the patients followed in our center with FMF who received anakinra, an anti IL-1 receptor antagonist, because of insufficient colchicine response.

Methods: FMF patients who were treated with anakinra were retrospectively reviewed with regard to indication, effect on disease activity and acute phase response, adverse events. Patient global assessment was recorded before and after anakinra treatment.

Results:

There were 38FMF patients with FMF who were treated with anakinra for various indications (amyloidosis in 11, colchicine resistant recurrent febrile attacks in 22, colchicine related side effects in 5). Two patients were excluded since they have been on anakinra for less than one month (one with amyloidosis, one pregnant). The mean age of the group was 35.6±11.2 years. The mean duration of the disease was 23.1 ±12,0 years. There were various co-existing pathologies among this study group like multiple sclerosis (1), ankylosing spondylitis (1), SLE (1), Behçet's disease (1), low grade lymphoma (1) and PAN (2). Six patients were pregnant. The mean colchicine dose was 2,09±0,49 mg/d. The mean duration of anakinra treatment was 19.6± 13.2 months. Twenty seven patients reported no attacks after anakinra treatment whereas 5 patients reported at least 50% decrease in the attack frequency. Mean patient global assessment decreased from 8.75±2.1 to 1.72±2.6 under anakinra treatment (p=0.001).

Among the 10 patients with amyloidosis, anakinra was stopped in 2 patients because of increased proteinuria. However, a significant decrease in proteinuria was detected in 5 patients. One patient developed severe injection site reaction and therefore the drug was stopped. Overall, 7 of our patients with amyloidosis are still on Anakinra treatment.

Three patients had a severe allergic reaction (severe disseminated rash in 1 patient and severe injection site reaction in 2 patients) and therefore the drug was stopped. Two patients had infections (one had genital warts and urinary tract infection, the other had sinusitis and folliculitis) and the treatment was terminated. One of our patients reported that her psoriatic lesions got worse on anakinra. Twenty six patients reported no adverse events during the treatment.

Conclusion:

Anakinra was effective in controlling the symptoms in colchicine-resistant FMF cases. It was also effective in FMF related amyloidosis. The major cause of treatment termination was injection site reactions. Anakinra seems to be an effective alternative in patients who have insufficient response to colchicine.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

It has been reported that Canakinumab reduced the frequency of attacks in patients with Familial Mediterranean Fever (FMF) resistant to colchicine with no apparent side effects.

We present our experience with Canakinumab in FMF patients resistant or intolerant to colchicine.

Methods:

The charts of the patients with FMF who were on Canacinumab were evaluated retrospectively with regard to response and safety.

Results:

There were 36 patients with FMF (19 F/17 M) receiving canakinumab for various indications. We report 32 (17 F/15 M) who had at least 3 injections. Six patients had concomitant diseases such as psoriasis (1), AS (4), PAN (1), AS and PAN (1) and vasculitis(1). The indications for canakinumab (150mg/mo) were insufficient response to colchicine in 22 (>1 attack/month), amyloidosis in 6, injection site reaction to anakinra in 6 and adverse effects of colchicine (azoospermia in 1, neuropathy in 1, hepatotoxicity in 1, myopathy in 2 patients). The mean age of the patients was 35,71 ± 12,82 years, the mean duration of FMF was 14,87 ± 9,19 years, the mean injection number was 10,53 ± 7,06 and the mean duration of canakinumab therapy was 16,81 ± 10,46 months. Twenty five of the patients had no attacks after canakinumab, 5 patients' attack frequency was reduced more than %50 while two patient's attack frequency remained more than %50. In 6 cases with FMF amyloidosis, proteinuria decreased in 2 (from 15020mg/dl to 364mg/dl and from 6135mg/dl to 280mg/dl), increased in the other 2 (from 1700mg/dl to 4700mg/dl and from 5001mg/dl to 7061mg/dl), and did not change in the remaining 2. Fourteen patients complaining of severe myalgia and calf pain unresponsive to colchicine treatment improved significantly. According to patient global assessment the mean score decreased from 8,18 ± 2,48 to 1,53 ± 2,43 ($p<0.001$). Canacinumab was stopped because of remission (no attacks at least for 3 months) in 5, for pregnancy demand in 1, for unresponsiveness in 2, for increasing proteinuria in 2, and the treatment was also stopped in the patient with oligospermia after being fertile.

Attacks recurred after 4, 7, 12, 12 months from discontinuation of the therapy in 4 patients, and 3 patients are attack-free for 12, 17 and 17 months till now.

Canakinumab was well tolerated in general. None of the patients had injection site reactions. The patient with psoriasis reported a flare in psoriatic plaques, which responded to local treatment. Therapy was discontinued temporarily in one patient who developed mild leucopenia, which did not reccur on a 2-monthly regimen. One other patient with amyloidosis whose proteinuria was stable, developed lichen planus lesions and the treatment had to be stopped. One patient had pneumonia, also he is attack-free for 15 months untill last dose.

Conclusion:

Canacinumab is effective in controlling the attacks in patients with inadequate response to colchicine and may serve as a treatment alternative with a favorable side effect profile. For better understanding the drug's efficacy and safety in the long term there is a need for controlled trials.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Yamaguchi's criteria for classification of adult-onset Still's disease (AOSD) has been widely applied in clinic despite it was established decades ago. However, hyperferritinemia, which is a hallmark of AOSD, is not included in the criteria. Moreover, the criteria require differential diagnosis of malignancy, infection, etc., which has been challenging. Heme oxygenase (HO)-1 is stress-inducible heme degrading enzyme highly expressed in monocyte/macrophage, serum levels of which has been reported as a promising biomarker for AOSD. We here report preliminary data on serum ferritin and HO-1 levels and AOSD disease activity.

Methods: Under the Hypercytokinemia Study Group collaboration, we collected sera from a total of 111 AOSD cases. Those patients were further divided into active, remission, and relapse groups, based on their clinical status. Other rheumatic diseases such as ANCA-associated vasculitis, and culture-positive sepsis were included as disease controls. Serum ferritin and HO-1 levels were measured in all of the collected samples by means of ELISA. An association among clinical symptoms, serum ferritin, and HO-1 was explored.

Results: Serum ferritin and HO-1 levels were significantly higher in active and relapsed AOSD cases compared to disease controls, and were reduced by the treatment. Although significant correlation between serum ferritin and HO-1 levels were observed, there were some discrepancies. After remission-induction therapy, 72.2% of the patients' serum ferritin levels were normalized, but 61.1% of them had high serum HO-1 levels (>13.8 ng/ml). Moreover, 31% of patients in remission exhibited high HO-1 levels, but high ferritin levels were observed only in 6.9% of the patients (figure).

Conclusion: We confirmed that serum ferritin and HO-1 serve as a biomarker for AOSD. Characterization of serum ferritin and HO-1 levels in AOSD disease status merit further investigation. By enrolling more cases and disease controls, we plan to determine use of ferritin and HO-1 for the diagnosis of AOSD (UMIN000012912).

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Adult-onset Still's disease (AOSD) is a rare inflammatory disorder that has been recently classified as a polygenic autoinflammatory disorder. Patients with Familial Mediterranean Fever (FMF) share clinical features (eg. recurrent fever, skin rash, synovitis and serositis) with the major symptoms of AOSD. FMF is considered to be caused by gain-of-function mutations in the MEFV gene. Although the pathophysiology of AOSD remains unknown, a growing number of studies support the hypothesis that dysregulation of inflammasome activation and subsequent overproduction of interleukin-1β play a pivotal role. The aim of this study was to investigate the allele frequencies of MEFV gene variants and identify clinical phenotypes as well as responses to treatments of AOSD patients with MEFV variants.

Methods:

A retrospective analysis was performed in 50 patients (9 males and 41 females) diagnosed with AOSD based on the diagnostic criteria of Yamaguchi M, et al. and 105 healthy individuals who were enrolled as controls. The study protocol was approved by the institutional review board/ethics committee of Sasebo City General Hospital. Written

informed consent was obtained from each individual for their clinical records to be used in this study. Genetic DNA was extracted from peripheral blood, and exon1, 2, 3 and 10 of the MEFV gene were genotyped by direct sequencing. MEFV mutation frequencies in AOSD patients were compared with controls. Furthermore, clinical features and responses for treatments were examined in patients with or without MEFV variants.

Results:

MEFV variants were identified in 32 AOSD patients (64.0%). No significant difference was found statistically between AOSD patients and healthy subjects in terms of allele frequencies of MEFV exon1 (E84K), exon2 (L110P, E148Q, R202Q, and G304R) and exon3 (P309S and R408Q) variants. However, the carriage rate of exon10 MEFV variants (M694I and G632S) was significantly higher in AOSD patients than that of healthy subjects (6.1% versus 0%, p=0.031). The polycyclic and systemic clinical courses of AOSD disease phenotype were frequently observed in patients with MEFV variants. Biologic agents were administered to 7 patients with MEFV exon2 and/or exon3 variants who were refractory to conventional treatments such as steroid, steroid pulse and immuosuppressants. Six of them were treated with tocilizumab; one was treated with infliximab. All patients except one demonstrated rapid improvement in both clinical and laboratory parameters. The median dosage of prednisolone was reduced. However, one patient treated with tocilizumab developed macrophage activation syndrome.

Conclusion:

Our study provides preliminary evidence that FMF-related MEFV variants may be clinically implicated with the disease phenotype and treatment outcomes of AOSD. Therefore, identification of MEFV variants is beneficial to define clinical phenotypes and predict clinical responses to treatments.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Interleukin (IL)-1 and IL-6 are pivotal cytokines in the pathogenesis of adult-onset Still's disease (AOSD). Our aim was to compare the efficacy and safety of tocilizumab (TCZ) versus anakinra (ANK) given for at least 1 year to AODS patients refractory to conventional treatment.

Methods: Multicenter study (31 hospitals) of 75 patients (TCZ; n=34 and ANK; n 41) with AODS refractory to conventional immunosuppressive drugs and in many cases also to other biological agents.

Results: Comparisons of the group of patients with TCZ and ANK were: a) Average age: 39±16 vs. 34±14 years (p=0.2) b) Percentage of women: 76.5% vs. 63.4% (p=0.2) c) Median disease duration 4.2 [1-9] vs. 2.2 [0.3 to 4.9] years (p=0.14) d) Average dose of prednisone 15±9.9 mg/day vs. 28.3±22 mg/day (p=0.013) e) Median of conventional

immunosuppressants (2 [1-3] vs 1 [1-2] (p=0.05) f) Median of other biological therapies: 1 [0-2] vs. 0 [0-1] (p=0.04). The initial dose of i.v. TCZ were: 8 mg/kg/4 weeks (n=22), 8 mg/kg/2 weeks (n=10) and 4 mg/kg/4 weeks (n=2). ANK dose was 100 mg/day s.c. Both biologic agents were often combined with a conventional immunosuppressive drug (55.9% vs 70.7%; p=0.2). Both biologi agents yielded a quick and sustained improvement of all clinical and laboratory parameters (Table). The improvement in the clinical parameters was similar in both groups. However an earlier improvement of CRP and ESR was observed following TCZ therapy. After a median follow-up of 19 months [12-31] with TCZ and 15.5 months [4.5 to 50] with ANK (p=0.1), the major adverse effects in the TCZ group were: elevation liver enzymes (n=4), mild to

moderate leucopenia (4), upper respiratory tract infection (3), pneumonia (1), pyelonephritis and severe enterocolitis (1) and spondylodiscitis (1). In the group of ANK: skin lesions (n=8), mild leucopenia (3), myopathy (1), respiratory infection by P. aeruginosa and gluteal abscess (1), herpes zoster (1), osteomyelitis (1) and infection of urinary tract (2). While none of the TCZ-treated required discontinuation of the drug due to inefficacy, ANK had to be discontinued for this reason in 11 patients (p=0.001). Adverse effects leading to discontinuation of the drug were observed in 2 patients with TCZ and 4 patients with ANK (p=0.54).

Conclusion: TCZ and ANK are associated with a rapid and sustained clinical improvement in most patients with

refractory AODS. However, TCZ appears to be more effective than ANK.

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Adult onset Still's disease (AOSD) is a rare inflammatory disorder of unknown etiology. Nonsteroidal anti-inflammatory drugs or corticosteroids are first-line drugs for treating AOSD. Immunosuppresants are needed to patients who are refractory to corticosteroids. Recently, it has been reported that biologic agents in AOSD are effective. Although IL-1 targeting therapy is very effective, an anti-interleukin-6 receptor monoclonal antibody may be an effective agent especially in the countries where anti-IL-1 therapy is not easily available. In this study, we reviewed the effect of tocilizumab (TCZ) on AOSD in Korean patients, retrospectively.

Methods: 24 AOSD patients were collected from 7 centers in Korea. The response to TCZ was defined as decreased modified Pouchot's score more than 2 score with decreased acute phase reactants compared to initial treatment of TCZ at least two consecutive months. We used the one-way ANOVA (or Krusal-Wallis test) for continuous variable and chi-square test for trend for categorical variables.

Results:

Patients (18 women/6 men) had a mean age of 44.0 ± 18.4 years and the age of diagnosis was 37.4 ± 20.6 years old. The mean disease duration before TCZ treatment was 48.43 ± 43.7 months. Eleven patients (45.8%) had polycyclic systemic pattern and twelve patients (50.0%) had chronic articular pattern. One patient couldn't be classified due to short disease duration.

Immune modulating agents before TCZ therapy were as follows: methotrexate (n=17), leflunomide (N=6), cyclosporine (n=4) and hydroxychloroquine (n=3). Biologic agents before TCZ therapy were etanercept (N=8), infliximab (n=6), adalimumab (n=4), abatacepts (n=2) and anakinra (n=1). At the time of TCZ treatment, the most frequent clinical manifestation was arthritis (79.2%). Rash (41.7%), fever (41.7%), myalgia (33.3%), and sore throat (20.8%) were accompanied. The baseline laboratory parameters such as leukocytosis, ESR, CRP and serum ferritin showed high level. The mean dosage of TCZ was 6.9 mg/kg (4-8 mg/kg) per 4 weeks and mean duration of TCZ administration was 8.4 ± 6.8 months. The majority of patients showed clinical or laboratory improvement after TCZ therapy. Although the dosage of prednisolone was reduced with clinical improvement at 6th month and 12th month, statistical significance was not showed (Table 1).

In 25.0 % of patients adverse events occurred during TCZ treatment as follows: leukopenia (n=1), gastrointestinal symptoms (n=2), infusion reaction (n=2), and pulmonary tuberculosis (n=1). Four patients (16.7%) relapsed after 5.0±3.6 months of discontinuation of TCZ.

Table 1. Change of clinical manifestations and laboratory parameters before and after TCZ treatment			
	Baseline (N=24)	After 6 months (N=17)	After 12 months (N=11)
Fever*	10(41.7)	1(5.9)	1(9.1)
Sore throat	5(20.8)	1(5.9)	0(0.0)
Rash*	10(41.7)	2(11.8)	1(9.1)
Itching	7(29.2)	2(11.8)	1(9.1)
Myalgia**	8(33.3)	0(0.0)	0(0.0)
Arthralgia/arthritis	19(79.2)	11(64.7)	8(72.7)
Lymphadenopathy	2(8.3)	0(0.0)	0(0.0)
Splenomegaly	2(8.3)	1(5.9)	0(0.0)
Serositis	3(12.5)	0(0.0)	0(0.0)
Modified Pouchot's Score, mean±SD	3.0 ± 1.9	1.3 ± 1.2	1.1 ± 0.7
Leukocytosis, mean±SD	14081.3 ± 6597.3	11810.0 ± 6712.8	12784.6 ± 6741.0
ESR (mm/hour), mean ±SD**	64.7 ± 29.0	14.2 ± 20.0	23.6 ± 29.3
CRP (mg/dL), mean±SD*	5.0 ± 4.2	1.7 ± 2.8	4.6 ± 6.4
Ferritin (ng/mL), mean ±SD	1440.2 ± 2027.3	374.3 ± 857.0	302.6 ± 340.0
Prednisolone dose (mg/day), mean±SD	15.4 ± 10.0	6.8 ± 4.4	7.8 ± 3.0
Values are the number (%), *p < 0.05, **p < 0.005			

Conclusion: TCZ was effective in Korean AOSD patients who were refractory to conventional therapy or other biologic agents. However, larger and prospective study is needed for further investigation.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: CXCL10 is produced in response to interferon-γ, and tumor necrosis factor-α (TNF-α) triggers the accumulation of activated lymphocytes. CXCL13 is constitutively expressed in secondary lymphoid tissues, and the expression is upregulated by TNF-α, via T cell stimulation. It appears that CXCL10 and CXCL13 could play a potential role in the pathogenesis of adult-onset Still's disease (AOSD), therefore, we investigated the associations between CXCL10 and CXCL13 levels and clinical manifestations in patients with active AOSD.

Methods: Blood samples were collected from 39 active AOSD patients and 40 healthy controls (HC). Of the AOSD patients, follow-up samples were collected from 15 9.6 ± 9.2 months later. CXCL10, CXCL13, and CXCR3 expression levels in biopsy specimens obtained from 26 AOSD patients with skin rashes were investigated via immunohistochemistry.

Results: The CXCL10 level of AOSD patients (1,031.3 ± 2,019.6 pg/mL) was higher than that of HC (104.4 ± 47.9 pg/mL, p=0.006). Also, the CXCL13 level of AOSD patients (158.8 ± 151.2 pg/mL) was higher than that of HC (23.5 ± 18.1 pg/mL, p<0.001). Serum CXCL10 levels correlated with ferritin and systemic scores. Serum CXCL13 levels correlated with those of hemoglobin, C-reactive protein, ferritin, and albumin, and systemic scores. In follow-up AOSD patients, the levels of CXCL10 and CXCL13 fell significantly (153.7 ± 130.1 pg/mL, p=0.002, and 89.1 ± 117.4 pg/mL, p=0.001, respectively). On immunohistochemistry, the percentages of inflammatory cells expressing CXCL10 ranged from 1 to 85%, CXCL13 from 1 to 72%, and CXCR3 from 2 to 65%. The percentage of CXCL10-positive inflammatory cells was higher in skin biopsy samples exhibiting mucin deposition than in those that did not (p=0.01). CXCL13 levels were correlated with those of CD4 and CD68.

Conclusion: Serum CXCL10 and CXCL13 levels may serve as clinical markers for assessment of disease activity in AOSD. CXCL10/CXCR3 and CXCL13 may contribute to the inflammatory response, especially skin manifestations thereof, in AOSD.

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: S100A8 and S100A9 are two calcium-binding proteins that belong to the S100 family, and those are expressed by infiltrating monocytes and neutrophils under inflammatory conditions. S100A8/A9 has been suggested as biomarkers of disease activity in patients with systemic juvenile idiopathic arthritis or adult-onset Still's disease (AOSD). We investigated the clinical significance and the pathogenic role of this marker in AOSD.

Methods: Serum samples were prospectively collected from 20 active AOSD patients, 20 rheumatoid arthritis (RA), and 20 healthy controls (HC). S100A8/A9 expression levels in biopsy specimens obtained from 26 AOSD patients with skin rashes and 8 AOSD with lymphadenopathy were investigated via immunohistochemistry. Each marker was recorded as the numbers of positive inflammatory cells divided by the numbers of total inflammatory cells, then expressed as a graded on a scale from 1 to 3: 1,1-33%; 2, 34-66%,; 3, 67-100%. Peripheral blood mononuclear cells (PBMC) from active AOSD and HC were evaluated for interleukin-1β (IL-1β) release, and in vitro study with PBMC and human acute monocytic leukemia (THP-1) cell line was done for cell signal of S100A9 or S100A8/A9.

Results: S100A8/A9 levels of active AOSD (15.43 ± 7.3 μg/mL) were higher than those of RA (4.04 ± 4.18 μg/mL, $p<0.001$) and HC (2.01 ± 1.06 μg/mL, $p<0.001$). The IL-1β and TNF- α levels of AOSD were higher than those of HC. Serum S100A8/A9 levels correlated with IL-1β (r=0.603, p<0.001), TNF- α (r=0.405, p=0.009), ferritin (r=0.698, p<0.001), and CRP (r=0.811, p<0.001). The grade of inflammatory cells expressing S100A8/A9 ranged variably from 1 to 3 in skin and lymph node biopsies of active AOSD. The grading and strength of staining of the positive cells in S100A8/A9 was more intense for karyrrhexis (p=0.028), mucin deposition (p=0.014), and neutrophil infiltration (p=0.006). S100A9 in serum of patients with AOSD was a strong inducer of IL-1β expression in PBMC. S100A9 induced signal transduction pathways, including JNK and p38 in PBMC from AOSD patients and HC.

Conclusion: The data suggest that S100A8/A9 may contribute to the inflammatory response by induction of inflammatory cytokines, and serve as clinicopathologic markers for assessment of disease activity in AOSD.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Widely accepted outcome measures for disease activity and severity at Adult Onset Still's Disease (AOSD) is not developed until now. Predictive factors for worse prognosis, such as response to initial treatment or life-threatening complications are also not clearly defined Yamaguchi criteria is routinely used for AOSD diagnosis which include 4 major and 4 minor criteria, reflecting almost whole essential AOSD features. These essential features might also be associated with disease severity and the objective of this study was to assess the relationship of arithmetic count of Yamaguchi criteria with clinical, laboratory features and treatment choice.

Methods: At 2012, 19 rheumatology centers collected data on clinical features (demographics, fever, rash, arthralgia, arthritis, myalgia, sore-throat, lymphadenopathy, hepatomegaly, splenomegaly, pleuritis, pericarditis and rare findings including macrophage activation syndrome) laboratory features (complete blood count, neutrophil percentage, ferritin, erythrocyte sedimentation rate, C-reactive protein (CRP), AST, ALT, ALP, GGT, LDH, bilirubin, albumin, triglyceride, total cholesterol, HDL-cholesterol, LDL-cholesterol), treatment choices and disease course, retrospectively. Overall 356 patients were enrolled and 269 of 356 patients were available for further analysis. Yamaguchi items were added arithmetically. Total Yamaguchi scores were between 5 to 8. At the end of statistical analysis, a cut-off of 7 or more score is chosen.

Results: Overall, 269 (56.1% female) patients were assessed. Mean age was 38.5 (14.5) years and mean diagnosis age was 34.9 (14.5) years. Total Yamaguchi score ≥ 7 was present in 83 (30.9%) patients. Hepatomegaly and serositis were found more frequently at Yamaguchi score ≥ 7. Essential laboratory activity parameters, such as ferritin and CRP were also related with high Yamaguchi scores. There was a difference at treatment choices that physicians started

higher dosage of corticosteroids with more frequent methotrexate use (Table).

Conclusion: Higher Yamaguchi scores may be one of the criteria for higher disease activity and severity in AOSD. We suggest that clinical features, level of acute phase reactant/ferritin and treatment choices are affected from disease load.

Table: Clinical, laboratory and treatment differences according toYamaguchi Score in AOSD

	Yamaguchi < 7 n=186	Yamaguchi ≥ 7 n=83	p
Clinical Differences			
Hepatomegaly (%)	20	46	<0.001
Pleuritis (%)	5	17	0.002
Pericarditis (%)	4	13	0.008
Laboratory Differences			
Ferritin mean (SD)	3882 (8608)	7966 (10193)	0.001
Ferritin > 1500 (%)	54.6	88.9	<0.001
Ferritin > 10.000 (%)	10.3	30.9	<0.001
CRP mg/L mean (SD)	117 (78)	158 (90)	<0.001
ALP mean (SD)	154 (147)	203 (160)	0.028
ALP > UL (%)	35	47	0.002
GGT mean (SD)	78 (91)	146 (142)	<0.001
GGT > UL (%)	45	73	<0.001
LDH mean (SD)	576 (698)	953 (1341)	0.008
LDH > UL (%)	43	72	<0.001
Albumin mean (SD)	3.49 (0.56)	3.13 (0.55)	<0.001
Albumin ≤ 3.0 mg/dl (%)	19	37	0.005
Thrombocytosis	41	27	0.023
Treatment Differences			
Initial treatment with methotrexate (%)	53	68	0.021
Baseline corticosteroid dosage (mg) mean (SD)	43.2 (17.9)	51.6 (16.7)	0.001

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: There is no randomized controlled trial data to guide us for the management of Adult Still's Disease (AOSD) patients refractory to conventional treatments. We herein aimed to analyze retrospectively the treatment results of a series of refractory AOSD patients, who received different biologics.

Methods: We screened our database for patients diagnosed with AOSD between 1987-2015,and reviewed charts of those patients refractory to corticosteroid and DMARD combination and received biologics including TNF, IL-1 and IL-6 inhibitors. Patients were grouped according to their first biologics as TNF-inhibitors (TNF-i) or others (anakinra (ANK) or tocilizumab (TCZ)).We also analyzed the patient responses according to their disease characteristics as polycyclic or chronic patients. Time to remission were analysed by Kaplan-Meier method, and the association of response with first biological treatment was analysed by regression analysis.

Results: Twenty-four patients with refractory AOSD (chronic:9 and polycyclic:15),who received biologic with a mean duration of 41±27 months. The first biological treatment was TNF-i in 14 and other agents in 10 (ANK in 7 and TCZ in 3).Of the patients,50% were switched from TNF-i to ANK or TCZ. Comparison of the patients according to their first biologic therapy is given in Table 1.The patients who received treatment with other biologics were associated with a better response as the first treatment and tended to achieve remission earlier compared with those who received TNF-i as their first biologicals (median time to remission 4 vs.8 months, log-rank p=0.44).

Joint involvement was more common and skin involvement tended to be more common in the chronic course group (100% vs 50%,78% vs 36%, respectively). While the duration of biologic treatment tended to be longer in the chronic course group (51mo vs 28mo,p=0.04), duration of remission was similar between the groups (26mo vs 20mo, p=0.4). The remission rate tended to be higher in the polycyclic group, whereas CRP and ESH tended to be lower in the chronic group.

Complete remission rates under biologics course were as follows: 70% with TCZ 8mg/kg(n=10), 56% with ANK 100-200mg/d(n=16), 25% with etanercept (n=12), and 18% with infliximab (n=11) treatments. Regression analysis showed that selection of TCZ or ANK biologics as the first biologic was associated with a better response independent of the disease course type(estimate 2.5, 95% CI 0.3-4.7, p=0.026).

No serious infection was observed in patients treated with biologics. In two patients severe skin reactions occurred with ANK and infliximab and, in one patient an immune thrombocytopenia developed under TCZ treatment.

Table 1.Comparison of study variables according to the first biologic agents

	TNF inhibitors n=14	Anakinra (n=7) or Tocilizumab (n=3)
Current age (years)	37±13	35±10
Age at diagnosis (years)	26 (20-59)	26 (5-46)
Follow up (months)	72 (18-252)	54 (26-288)
Gender (%males)	31	46
Sore throat (%)	54	73
Skin involvement (%)	54	46
Joint involvement (%)	85	55
Hepatotoxicity (%)	31	46
CRP (mg/L)	115±88	131±78
ESR (mm/h)	101±30	102±32
Ferritin (ng/ml)	1000 (281-29979)	1280 (424-5181)

Conclusion: This case series of AOSD patients suggest that ANK and TCZ seem to be better treatment choices in terms of remission rate and time to remission in patients refractory to conventional treatments.

Investigating an Auto-Inflammatory Component of COPD That Contributes to Progressive Decline in Lung Function Despite Smoking Cessation

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Most Chronic Obstructive Pulmonary Disease (COPD) cases result from amplification of normal inflammatory responses due to noxious stimuli like cigarette smoke. Yet, the mechanism by which COPD lungs continue to deteriorate despite smoking cessation is not well understood. Here, we explore an auto-inflammatory component of COPD via the study of NKG2D (natural-killer group 2, member D) ligands and a cytokine shown to directly activate natural killer (NK) cells, IL-27. Research in COPD murine models has demonstrated high NKG2D

receptor expression on pulmonary NK cells and NK hyper-responsiveness as a result. NK cell activation then leads to destruction of damaged or stressed pulmonary cells and further deteriorates lung parenchyma. We hypothesize that COPD patient serum will show increased expression of soluble NKG2D ligands and IL-27 correlating to a progressive decline in lung function in active but also former smokers.

Methods: COPD patient serum samples were collected from nine hospitals in Spain (1/2004-3/2006). NKG2D ligand and IL27 expression in COPD patients and healthy subjects was compared via sandwich ELISA method and p-values were determined using independent t-test calculations.

Results: When looking at patient groups defined by smoking status, former and active smokers had increased expression on NKG2D ligands (ULBP2, ULBP3 and MICA) and IL-27 compared to controls. ULBP2 expression comparison showed the following: never smokers = 1.03 pg/mL (N=27, SD ±5.35 pg/mL) compared to active smokers= 18.30 pg/mL (N=22, SD ±71.90 pg/mL, $p<0.05$) and former smokers 25.28 pm/mL (N=29, SD ±119.00, $p<0.05$). ULBP3 expression: never smokers = 25.92 pg/mL (N=27, SD ±72.92 pg/mL) compared to active smokers= 77.50 pg/mL (N=23, SD ±267.55 pg/mL, $p<0.05$) and former smokers 79.12 pg/mL (N=29, SD ±362.06, $p<0.05$). MICA expression: never smokers = 290.28 pg/mL (N= 100, SD ±1737.34 pg/mL) compared to active smokers= 887.06 pg/mL (N=162, SD ±3405.86 pg/mL, $p<0.05$) and former smokers 737.27 pg/mL (N=159, SD ±3767.09, $p<0.05$). IL-27 expression: never smokers = 217.50 pg/mL (N=27, SD ±613.41 pg/mL) compared to active smokers= 432.45 pg/mL (N=23, ±SD 745.27 pg/mL, $p<0.05$) and former smokers 367.26 pg/mL (N=29, SD ±1110.82, $p<0.05$).

Conclusion: Our data shows higher mean quantities of soluble NKG2D ligands and IL-27 in COPD patients compared to healthy controls. Within the COPD patients, the ligand and cytokine expression seen in former smokers was comparable to that of active smokers and significantly elevated compared to healthy controls. These findings give us further insight to diagnosis and management of COPD. Diagnostically, ligand levels could help us differentiate COPD subtypes or ligand expression can correlate with varied disease progression. Future plans involve finding a direct correlation between the expression of NKG2D receptors on lung parenchyma and soluble NKG2D ligands in the serum. We can then utilize this insight of the COPD pathophysiology to evaluate if novel treatments for COPD, like biologic agents, could be used to curtail the process by which COPD lungs continue to deteriorate despite smoking cessation.

Are the Autoimmune/Inflammatory Syndrome Induced By Adjuvants (ASIA) and the Undifferentiated Connective Tissue Disease (UCTD) Related to Each Other? a Case-Control Study of Environmental Exposures

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: The Autoimmune/Inflammatory Syndrome induced by adjuvants (ASIA) [1] is an entity that includes different autoimmune conditions observed after exposure to an adjuvant. Patients with Undifferentiated Connective Tissue Disease (UCTD) present many signs and symptoms of "ASIA", alluding to the idea that an exposure to adjuvants can be a trigger also for UCTD. The aim of this control-case study is to investigate prior exposures to adjuvant in 84 patients affected with UCTD and 84 age and sex-matched controls with no family history of autoimmunity.

Methods: An *ad hoc* created questionnaire that lists exposure to the possible triggers of "ASIA", such as vaccinations (HBV vaccine, HAV vaccine, tetanus toxoid vaccine, Haemophilus Influenzae vaccine, Measles-Mumps-Rubella vaccine, Pneumococcal vaccine, HPV vaccine) foreign materials (earrings, piercing, tattoos, silicon breast implants, skin fillers, tooth amalgam, contact lenses, intrauterine device, cardiac valves, artificial joints, metal implants), environmental and occupational exposures (living and/or working near metal or chemical factories, landfills, airports or highways) was administered to both cases and controls. For both groups autoantibodies were analyzed (i.e. antinuclear, anti-ENA, anti-dsDNA, anti-cardiolipin, anti-β2glycoprotein I). Continuous variables were reported as mean and standard deviation, while percentages were reported for categorical variables. T-test was calculated for continuous variables while Chi-square or Fisher's exact tests was used for categorical variables. All statistical tests were two-tailed and only a p value < 0.05 was considered statistically significant.

Results: The Table reports demographic information of the enrolled subjects and those items that were significantly different between cases and controls. As "molecular mimicry" between β2glycoprotein I and tetanus toxoid was described [2], we indeed found that there is a trend toward a higher prevalence of anti-β2glicoprotein I in UCTD who had received a tetanus vaccine in the 10 years before the diagnosis (17/66, 25,7%) in comparison with UCTD patients who did not receive it (3/27, 11,1%) (p=0,10).

Conclusion: As compared with healthy subjects, UCTD patients appeared to have had a greater exposure to adjuvants: HBV and tetanus toxoid vaccinations, metal implants and cigarette smoking. The increased prevalence of allergies proved that UCTD patients have a more reactive immune system, likely on a genetic basis. Thus we can suggest that ASIA and UCTD are two related entities in the "mosaic of autoimmunity": the genetic predisposition and the environmental exposure to adjuvants elicit a common clinical phenotype characterized by signs and symptoms of systemic autoimmunity.

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

In recent years there has been a growing interest in establishing the concept of Undifferentiated CTD (UCTD) and defining its clinical evolution. Remarkable are the *Marta Mosca et al* studies, who have proposed preliminary definition criteria and reported progression to a Defined CTD (DCTD) in 30% of patients after 5-year follow-up. Some studies have pointed out certain clinical, serological and capillaroscopic features as potential predictive factors, with

contrasting results. In our study we aimed to describe the evolution of a cohort of UCTD patients with at least 5-year follow-up and to establish clinical, serological and capillaroscopic features associated with an increased risk of progression to a DCTD.

Methods:

Patients with first nailfold capillaroscopy (NFC) performed between 1999-2008 who met at least 2 of the following baseline criteria: 1) Raynaud's phenomenon (RP), 2) ANA ≥1/80 and/or positive ENA, 3) pathological NFC pattern, were included. Nailfold capillaroscopies were performed by the same observer with a Leica 10x23 10447123 handheld lighted microscope. The association between outcome and the presence of several baseline features (RP, arthralgias, sicca syndrome, skin and esophageal abnormalities, low complement, Ig and hematologic disorders, ANA titre and pattern, ENA, anti-dsDNA and aPL antibodies, RF, and NFC pattern) was analyzed.

Results:

Among 758 patients with first NFC performed in the cited period, 223 fulfilled inclusion criteria. Ninety seven patients who met classification criteria for a DCTD at disease onset (including Prescleroderma (PSSc)) and 28 with less than 5-year follow-up were excluded. Among 98 analyzed, 97 (99%) were women with a baseline mean age of 42 years (s: ± 15.8). After a mean of 10.6 years follow-up (s: ± 3.1), 61 (62%) remained as UCTD, 23 (24%) evolved into remission and 14 (14%) into DCTD: 8 SLE, 4 PSSc, 1 MCTD, and 1 overlap syndrome. NFC pattern progression was observed in 31% of the patients with a second NFC performed 5 years after disease onset (78/98). Significant differences between clinical outcome and presence of cytopenias (p:0.030), ENA (p:0.008) and aPL antibodies (p:0.032), and a pathological NFC pattern (p:0.026) were observed. Homogeneous (29%) and centromere (36%) patterns were more frequent in DCTD group, while in the remission group was the coarse speckled one (41%) (p:0.117). Positive correlation between ANA titre and outcome was demonstrated (rho:0.21, p:0.025). ANA titre ≥1/640 (OR:17 [1.75-165], p:0.015), a pathological NFC pattern (OR:6.48 [1.48-28.3], p:0.013) and NFC pattern progression after 5-year follow-up (OR:7 [1.35-36.3], p:0.021) were associated with an increased risk of evolving into DCTD.

Conclusion:

1. The rate of progression to DCTD in our cohort was similar to that reported in previous studies.
2. Careful monitoring should be recommended in patients with baseline ANA titre ≥ 1/640 and/or pathological NFC pattern, especially those who present capillaroscopic progression during the follow up.
3. Results concerning potential predictive role of baseline IIF pattern, cytopenias, ENA and aPL antibodies, are coherent with previous studies.

Session Date: Sunday, November 8, 2015

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Shrinking lung syndrome (SLS) is a rare a little known complication associated with systemic lupus erythematosus (SLE) and other connective tissue diseases (CTDs). This study describes the clinical features, investigations, management, and outcome of a series of patients with CTDs and SLS.

Methods:

Ambispective study of 9 patients with SLS and CTDs

Results:

All nine patients were women, with a mean age at SLS diagnosis of 42 years (SD: 11; range 30-64). Eight of these patients had SLE and 1 had mixed connective tissue disease (MTCD). The prevalence of SLS in our cohort of SLE patients was 1,8% *(8/429)*. The median time to onset of SLS after SLE/MCTD diagnosis was 7 years (SD: 6.8; range 1.6-25 yrs). Most patients with SLE had a severe disease with concomitant or previous major organ involvement, especially lupus nephritis (75% of cases). All presented progressive exertional dyspnea of variable severity accompanied by pleuritic chest pain in 89% *(8/9)* of cases. Dry cough or fever was more rarely seen (33%). In 56% *(5/9)* of patients, the syndrome was bilateral. Imaging techniques (chest X-Ray and HRCT) at the evolution showed elevated hemidiaphragms without evidence of interstitial lung disease (ILD) in all cases. Pleural thickening/effusions or basal atelectasis were observed in 56% and 89% of patients, respectively. Pulmonary function tests (PFT) were consistent with a restrictive defect (mean baseline FVC: 59%), while the DLCO was decreased in 89% of cases (mean baseline DLCO: 44.95%). In those to whom diaphragmatic function tests were made, a decrease of the minimum inspiratory pressures (MIP) was observed. Treatment included 0.5 to 1 mg/kg/day of oral prednisone (associated with short-term pulses of intravenous methylprednisolone in 2 cases), associated with beta-agonist. Concomitant immunosuppressive agents (azathioprine, mycophenolate, or methotrexate) were used in 5 patients and rituximab in 4. At the end of the follow-up period (median 31.5 months; range, 3-192), 1 patient cured without functional sequelae. The remaining 8 patients had subjective improvement with stabilization or mild to moderate improvement on PFT. One of these patients finally developed ILD (nonspecific interstitial pneumonitis) several years after SLS onset.

Conclusion:

SLS is a rare complication in CTDs which must be suspected in patients with dyspnea and/or pleuritic chest pain, lung volume reduction with no parenchymal abnormalities and a restrictive ventilatory defect on PTF. The frequent presence of pleuritic chest pain and pleural thickening/effusions at the time of evaluation, suggests that pleuritic inflammation may have an important role in the pathogenesis of this complication.

A Comparison of the Clinical Features and Natural History of Autoimmune Interstitial Lung Disease Vs. Idiopathic Pulmonary Fibrosis

Sandra Chartrand[1], Lina Peykova[2], Jeffery J. Swigris[3] and Aryeh Fischer[4], [1]Université de Montréal, Montreal, QC, Canada, [2]Rheumatology, National Jewish Health, Denver, CO, [3]National Jewish Health, Denver, CO, [4]University of Colorado School of Medicine, Aurora, CO

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

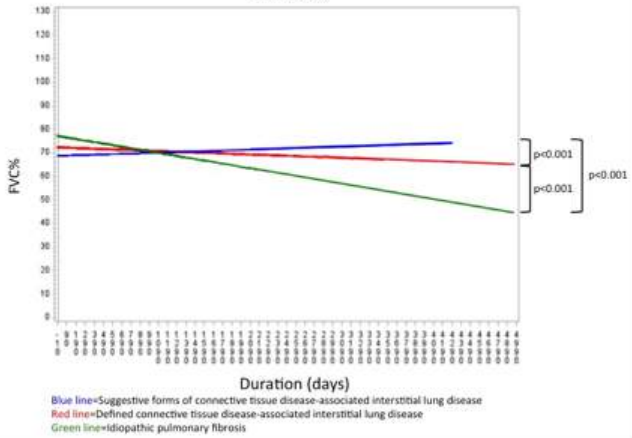
Background/Purpose: We compared clinical features, longitudinal pulmonary physiology, and survival among 3 groups of patients evaluated at our center between February 2008 to August 2014: definite connective tissue disease-associated interstitial lung disease (dCTD-ILD), suggestive CTD-ILD (sCTD-ILD) and idiopathic pulmonary fibrosis (IPF).

Methods : Survival and longitudinal analyses were used to compare survival and changes in percent predicted forced vital capacity (FVC%) over time.

Results : 56 subjects had sCTD-ILD, 191 had dCTD-ILD (99 scleroderma, 42 rheumatoid arthritis, 26 myositis, 14 Sjšgren's syndrome) and 62 had IPF. Compared to IPF (67.9±8.5 years), those with sCTD-ILD (57.5±10.9 years) or dCTD-ILD (54.6±10.3 years) were younger (p<0.001), more likely to be female (16% vs. 67% vs. 71%, respectively), and less likely to be nonsmokers (30.6% vs. 67.9% vs. 52.4%, respectively). Most subjects with sCTD-ILD or dCTD-ILD had a nonspecific interstitial pneumonia pattern on chest HRCT scan (69.2% and 58.1%, respectively). Baseline FVC% was similar between groups (sCTD-ILD: 68.4±16.0% vs. dCTD-ILD: 71.7±15.4% vs. IPF: 73.1±15.9%; p=0.25). Modeled FVC% values are displayed in the Figure.

Figure

Mixed-effects model estimates for percentage of predicted forced vital capacity (FVC%) over time.



During similar follow-up periods (1561±626 vs. 1733±576 vs. 1692±589 days, respectively; p=0.16), there were no deaths in the sCTD-ILD group, 37 (19.4%) in CTD-ILD group and 35 (56.5%) in the IPF group (log-rank p<0.001 for each pairwise comparison).

Conclusion: In this retrospective study, we observed that patients with sCTD-ILD or dCTD-ILD had better FVC% trajectories and survival. The natural history of sCTD-ILD resembled that of dCTD-ILD more than IPF underscoring the importance of differentiating this patient population from idiopathic interstitial pneumonia for purposes of treatment and prognostication.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The question of whether mixed connective tissue disease (MCTD) is a distinct entity still remains controversial. For this reason, we have investigated the long-term outcome in a well characterized cohort of patients with MCTD in order to determine the frequency of evolution toward other connective tissue diseases (CTDs).

Methods: Ambispective study of thirty-four MTCD patients, all of them fulfilling the diagnostic criteria proposed by Alarcon-Segovia *(J Rheumatol 1989;16:328-34)*, with a minimal follow-up after the first clinical presentation of at least 2 yr. The endpoint of patient follow-up was the date of the last clinic visit.

Results: At the end of the follow-up period (median ± SD: 90.5 ± 62.1 months; minimum, maximum: 25-228 months), 41.1% of patients *(14/34)* still satisfied MCTD classification criteria of Alarcon-Segovia; 14.7% *(5/34)* evolved into systemic sclerosis [SSc] (fulfilling the 2013 ACR/EULAR classification criteria for SSc), 26.5% *(9/34)* into systemic lupus erythematosus (fulfilling the 2012 SLICC criteria), 8.8% *(3/34)* into seronegative rheumatoid arthritis (fulfilling 2010 ACR-EULAR classification criteria), and 8.8% *(3/34)* developed an overlap syndrome (2 cases of SSc+SLE and 1 case of SSc+RA).

The mean score in patients that meet the 2013 EULAR/ACR criteria for SSc was 11 (minimum, maximum: 9, 16). The mean score in patients satisfying the 2012 SLICC SLE criteria was 6 (minimum, maximum: 5, 9); only 2 of these patients developed major organ involvement.

Using multiple variable regression analysis, the presence of sclerodactyly (OR 1.1; 95% CI 1.1 – 1.7, P =0.04) was associated with evolution into SSc. No clinical predictors of potential evolution toward SLE were identified.

Conclusion: MCTD is a distinct clinical entity but it is evident that the majority of these patients (59% of the cases)

will evolve into another CTD during disease progression.

Rituximab in Refractory Mixed Connective Tissue Disease: An Observational Study

Maria Pascual[1], Javier Narváez[2], Gloria Albert Espi[3], Mercè López de Recalde[1], Andrea Zacarias[4] and Juan José Alegre[3], [1]Department of Rheumatology, Hospital Universitario de Bellvitge, Barcelona, Spain, [2]Rheumatology, Hospital Universitario de Bellvitge, Barcelona, Spain, [3]Rheumatology Department, Hospital Universitario Doctor Peset, Valencia, Spain, [4]Hospital Universitari de Bellvitge, Barcelona, Spain

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To investigate the safety and preliminary efficacy of rituximab (RTX) in patients with refractory mixed connective tissue disease (MCTD)

Methods: We evaluated 9 patients in this observational cohort study. All received RTX (off label use) in addition to concomitant immunosuppressive agents. RTX treatment consisted of two endovenous infusions of 1 g1 g on days 1 and 15 per treatment cycle separated by a two-week interval. All the patients received premedication to prevent infusion reactions. The endpoint of patient follow-up was the date of the last clinic visit.

Results: All nine patients were women, with a mean age at the time of evaluation of 31 years (SD: 10; range 18-48). The indication for RTX was severe active polyarthritis in 5 cases, progressive nonspecific interstitial pneumonitis (evidence of clinical and functional decline) and inadequate articular response (DAS28 > 3.2) in 2, and autoimmune thrombocytopenia in 1 patient.

The median time to RTX treatment after MCTD diagnosis was 26 months (SD: 34.3; range 5-98 months). Concomitant immunosuppressive agents (azathioprine, mycophenolate, or methotrexate) were used in all patients and hydroxychloroquine in 6. The median follow-up time was 36 months (range, 5 - 80). When data were collected, patients had received a mean of 1.7 cycles (1-5) of RTX, with a dosing interval which ranged from 6 to 15 months.

In general, disease activity declined during therapy. All patients with arthritis achieved clinical remission (DAS28 < 2.6) or low activity (DAS28 ≤ 3.2) by week 16-20, although relapses of disease were frequent with re-treatment being required 6-7 months later. In the 2 patients with NSIP clinical improvement was accompanied by a parallel stabilization or mild improvement in pulmonary function tests (PFT). The autoimmune thrombocytopenia resolved completely after 1 cycle of treatment, without relapses after a follow-up period of 80 months**.**

The concomitant oral steroid dose could be reduced in more than half of the initial dose.

No cases of significant adverse events occurred and none of the patients suffered severe bacterial or opportunistic infections

Conclusion: Our preliminary results suggest that RTX seems to be a safe and useful therapeutic alternative in patients with active MTCD in whom previous treatments have failed, with a steroid-sparing effect.

Mitral Valve Prolapse in Patients with Joint Hypermobility Syndrome

Anand Patel[1], Mark Schwartz[1], Liliana Cohen[2], Daniel Shindler[3], Abel Moreyra[1] and Naomi Schlesinger[4,5], [1]Medicine, Rutgers Robert Wood Johnson Medical school, New Brunswick, NJ, [2]Medicine, Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ, [3]Nedicine, Rutgers Robert wood Johnson Medical school, New Brunswick, NJ, [4]Medicine, Rutgers-Robert Wood Johnson Medical School, New Brunswick, NJ, [5]Rutgers-Robert Wood Johnson Medical School, New Brunswick, NJ

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Joint Hypermobility Syndrome (JHS) may predispose to ligamentous rupture, joint dislocations, fibromyalgia, premature osteoarthritis and non-articular complications include Mitral Valve Prolapse (MVP) (Barron J et al Clin Cardiology 1988;11:401).

MVP is a common cardiac abnormality that affects 2 - 5% of the population. It is defined as the systolic billowing of one or both of the mitral leaflets into the left atrium with or without evidence of mitral regurgitation. The current standardized echocardiography (ECHO) diagnostic criteria for MVP is billowing of any portion of the mitral leaflets >2 mm above the annular plane in a parasternal long axis view.

There are limited published studies concerning JHS and MVP however they are thought to be associated. The incidence of MVP in individuals with JHS has been reported to be 8%- 60% (Mishra B et al Br J Rheumatol 1996;35:861)

This study would be the first to examine MVP in patients with JHS using updated diagnostic ECHO criteria.

Methods:

This is a retrospective study of 127 patients ages ≥ 16, diagnosed with JHS (ICD 9: 728.5), based on the revised Beighton criteria (Grahame R et al J Rheumatol 2000;27:1777), seen by a rheumatologist (NS) between 1/1/2011-10/31/2014. The diagnosis of JHS required presence of 2 Major criteria: Beighton score of ≥4 and arthralgia ≥ three months in ≥ four joints, or 1 major and at least 2 minor criteria. ECHOs were performed and read using the new

MVP criteria by ECHO experts (LC, DS). Past medical history that could increase risk to develop MVP including rheumatic fever, endocarditis, polycystic kidney disease, and family history of MVP was reviewed.

Results:

All patients included in the study had a Beighton score of ≥4 (Major Criterion). Most patients were female n=114 (90%). Mean age: 48 (range 16-87 years). Average Beighton score: 6.6 (range: 4-9). Average BMI: 27.5. 73 (57%) were diagnosed with fibromyalgia (ICD 9:729.1)

Echocardiograms were performed in 45 patients (35%) of which 43 (96%) were female with a mean age of 50.5 (range 22-86 years). Average Beighton score: 6.6 (range: 4-9). Average BMI: 28. None of the patients had underlying rheumatic fever, endocarditis or adult polycystic kidney disease.

None of the patients met the updated echocardiographic criteria for MVP.

Conclusion:

This is the first study examining MVP in patients with JHS using the updated MVP ECHO criteria. We did not find ECHO findings consistent with MVP in our JHS patients. This should be studied in other Rheumatology practices since this observation may be cost saving in patients with JHS, who otherwise would have ECHO studies as part of their routine work up.

Ehlers-Danlos Syndrome Hypermobility Type (Type III) Is Associated with Rheumatological Conditions

Kyla Rodgers[1], Richard Chou[1] and Mary Beth Dinulos[2], [1]Medicine, Geisel School of Medicine at Dartmouth, Lebanon, NH, [2]Pediatrics and Genetics, Geisel School of Medicine at Dartmouth, Lebanon, NH

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Ehlers-Danlos syndrome is a group of inherited conditions caused by genetic mutations in collagen genes, such as COL5A, COL3A, etc, resulting in defects in the structure, production, or processing of collagen or proteins that interact with collagen. The phenotypes of Ehlers-Danlos syndrome vary tremendously among different subtypes or individuals within the same subtype. The present study focuses on retrospective review of subjects who were diagnosed with Ehlers-Danlos syndrome type III, the hypermobility joint syndrome. Individuals of hypermobility joint syndrome often present with hyperextensible joints, chronic back pain, joint pain, among other phenotypic changes. Since hypermobility joint syndrome is also a result of genetic mutations resulting in multiple defects with collagen synthesis

or function, it is conceivable that individuals with this syndrome are more likely to present with rheumatological disorder. The central hypothesis of the present study is that hypermobility joint syndrome increases the prevalence of rheumatological conditions.

Methods: A chart review of electronic medical records at Dartmouth-Hitchcock Medical Center between July 2009 and June 2015 was performed. Once the subjects were identified, detailed chart review was performed to confirm a diagnosis of Ehlers-Danlos syndrome hypermobility type. Pertinent information obtained includes age of diagnosis of hypermobility joint syndrome, gender, any rheumatological conditions such as autoimmune diseases, non-autoimmune conditions (i.e. fibromyalgia), or structural defects, serological workup, and laboratory findings. Subjects were further sorted into the categories of "no rheumatological workup" (ie physical exam only), "limited workup" (ie only ANA and RF), or "complete workup" (all serological markers, HLA B27, ESR, and CRP, etc).

Results: A total of 158 subjects have been identified so far. Of these, 12 subjects were male (age range 8-46) and 146 were female (age range 13-74), with average age at diagnosis of 28.9 years and 36.2 years, respectively. Among the 103 subjects without workup, 5 (4.85%) also had a rheumatological diagnosis (psoriasis or preexisting seronegative RA). Among the 23 subjects with limited workup, 5 (21.74%) presented with a rheumatological disease (psoriasis, RA, PMR). Of the 32 subjects with complete workup, 16 (50%) also had a rheumatological disease (psoriasis, PsA, SS, RP, uveitis, enthesopathy, uSpA, autoimmune thyroiditis, AS, scoliosis, Scheurmann's disease, primary hypogammabulemia, pernicious anemia, fibromyalgia, RA).

Conclusion:

We found that Ehlers-Danlos type III is highly associated with rheumatological conditions, including RA, psoriasis, PsA, fibromyalgia, etc. Based on the finding that these conditions were more prevalent in subjects with complete workup (50%) versus limited (21.74%) or no workup (4.85%), we conclude that rigorous serological studies are necessary to generate a complete clinical understanding and improve symptomatic control in this patient population.

The Fascia Is a Target Organ of Inflammation in Autoimmune Diseases

Kentaro Noda, Ken Yoshida, Taro Ukichi, Kazuhiro Furuya, Kenichiro Hirai, Isamu Kingetsu and Daitaro Kurosaka, Division of Rheumatology, Department of Internal Medicine, Jikei University School of Medicine, Tokyo, Japan

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Muscle Biology, Myositis and Myopathies Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: We previously reported that inflammation occurred early in the fascia of patients with dermatomyositis. We often encounter patients with autoimmune diseases who present with muscle symptoms, such as pain and weakness and biopsies of the affected muscle areas do not show inflammatory cell infiltration among the muscle fibers, thereby leaving the cause of these symptoms unclear. To date, the work-up for autoimmune disease patients presenting with muscle symptoms has focused on the presence or absence of muscle fiber inflammation, and not on the presence or absence of fasciitis. Therefore,we thoroughly investigated the lesions of fasciae and muscles in

patients with muscle symptoms and elevated muscle enzyme levels.

Methods: This study included patients with autoimmune diseases who presented with myalgia, muscle weakness, or elevated serum levels of muscle enzymes (CK and aldolase), and were admitted to the Division of Rheumatology of Jikei University School of Medicine Hospital between April 2007 and December 2013. They underwent magnetic resonance imaging (MRI) and *en bloc* biopsy.

Results: Sixty-three patients presented with myalgia, muscle weakness, and elevated levels of muscle enzymes (CK and aldolase), and consisted of 26 with dermatomyositis (DM), 19 with polymyositis (PM), 9 with clinically amyopathic dermatomyositis (CADM), 7 with systemic lupus erythematosus (SLE), and 2 with adult-onset Still's disease (AOSD). MRI was performed in all sixty-three patients. Fascia involvement was observed in 45 (71.43%) of patients : in 23 (88.46%) out of 26 with DM, 7 (36.84%) out of 19 with PM, 6 (66.67%) out of 9 with CADM, all 7 with SLE, and all 2 with AOSD. Histopathological examination was performed in thirty-five patients. Fasciitis was observed in 23 (65.71%) of patients : in 15 (83.33%) out of 18 with DM, 2 (25%) out of 8 with PM, 3 (50%) out of 6 with CADM, and 3 (100%) out of 3 with SLE. Many patients with fasciitis also had myalgia. However, myositis was not associated with myalgia. Muscle weakness was not associated with fasciitis. A high percentage of patients with normal serum CK levels and elevated serum aldolase levels, developed fasciitis.

Conclusion: Fasciitis occurred in patients with various autoimmune diseases. Patients with myalgia may have fasciitis in autoimmune diseases.

Table. MRI and histopathological findings of fasciae and muscles

	DM	PM	CADM	SLE	AOSD	Total
MRI						
Fascia involvement	23(88.46)	7(36.84)	6(66.67)	7(100)	2(100)	45(71.43)

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Muscle Biology, Myositis and Myopathies Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Idiopathic inflammatory myopathies (IIM), such as dermatomyositis (DM), polymyositis (PM) and inclusion body myositis (IBM), are chronic multi-systemic inflammatory conditions. Substantial studies on health related quality of life (HRQOL) in IIM patients are lacking.

The objective of this study was to document the degree of HRQOL impairment in IIM patients.

Methods: Between December 2010 and July 2012, 1,715 patients who met probable Bohan and Peter criteria for myositis residing in the US and Canada registered for the MYOVISION registry study with The Myositis Association. HRQOL was ascertained via the SF-12v2® Health Survey questionnaire. The SF12v2®is a 12-item 4-week recall questionnaire that features two summary measures – the physical component summary [PCS] and the mental component summary [MCS].

This was an exploratory, cross-sectional descriptive study that examined the variation in HRQOL scores in relation to different patient and disease characteristics, and compared the scores of IIM patients to age-and-gender-matched normative U.S. general population and rheumatoid arthritis (RA) patients.

Bivariate analysis was conducted via t-tests to assess the difference in summary scores for each independent variable and a multiple linear regression analysis was performed using a backward elimination model.

Results: There were 702 DM, 481 PM, 465 IBM, as well as 59 adults with juvenile DM (JDM) and eight with juvenile PM (JPM) included in the study (70% females, 87% Caucasian). The median age at diagnosis and duration of disease were 49.9 and 9.2 years, respectively.

The mean summary scores of the SF-12v2®were significantly lower (indicating reduced HRQOL) among the myositis population compared to the age-and-gender-matched normative population and the RA population (Table 1).

In a multiple linear regression (Table 2), older age, effect of disease on work, presence of another autoimmune disease, lung disease, joint involvement and use of multiple medications were all associated with lower PCS scores. Patients treated primarily by rheumatologists had a higher PCS score. The MCS score was lower with joint involvement and a negative effect of myositis on work.

Conclusion: In this largest study of patient reported outcomes in IIM to date, HRQOL was lower among IIM patients compared to the normal population and to RA patients. An association was found between multiple disease parameters and reduced HRQOL, mostly in the physical domain.

Table 1: HRQOL summary scores relative to an age- and gender-matched U.S. normative population and RA patients

	Myositis Patients			U.S Normative Population						RA Patients					
Scale	N	Mean	SE	N	Mean	SE	F	p	ES	N	Mean	SE	F	p	ES

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Muscle Biology, Myositis and Myopathies Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: We have previously demonstrated that fasciitis is a common lesion of dermatomyositis (DM) detectable early after disease onset. Furthermore, *en bloc* biopsy showed that the fascial microvasculature, rather than intramascular microvasculature, is one of the primary sites for inflammatory cell infiltration (Arthritis Rheum. 2010;62:3751-9). We also showed that fasciitis was detectable by Power Doppler ultrasonography in patients with DM. In the current study, we examined whether angiogenesis was observed in fasciitis associated with DM, and which angiogenesis-related factors were expressed.

Methods: We analyzed 12 patients consisting of 6 newly diagnosed with DM and 6 newly diagnosed with polymiositis (PM) in the Division of Rheumatology at Jikei University Hospital. In the current study, all patients underwent *en bloc*

biopsy before treatment. All samples were fixed in 10% neutral-buffered formalin and embedded in paraffin. Total vascular inflammation score (TVIS) was defined as the total number of aggregates of ≥50 perivascular inflammatory cells per 4-mm^2area of the fascia in the 3 fields with the most remarkable perivascular infiltrates in order to evaluate the severity of fasciitis. Immunohistochemical staining was performed on paraffin-embedded sections by using anti-CD31 antibodies to evaluate angiogenesis, and anti-VEGF, anti-IL-6, and anti-TNF-α antibodies to evaluate the expression of angiogenesis-related factors in the fascia. Angiogenesis score (AS) was defined as the total number of CD31-positive blood vessels in the 3 high-power fields (200×) that showed the most remarkable proliferation of the vessels in the fascia. The numbers of VEGF, IL-6, and TNF-α positive cells were counted in the 3 high-power fields (400×) that showed the largest accumulation of these positive cells.

Results: Significant fasciitis, histologically defined as TVIS of ≥3, was detected in all patients with DM. Although mild inflammation of the fascia (TVIS 1) was observed in 1/6 patients with PM, significant fasciitis was not detected in any patients with PM. TVIS and AS in the fascia were significantly higher in patients with DM compared with PM. AS was positively correlated with TVIS in DM-associated fasciitis. The numbers of VEGF and TNF-α positive cells were both significantly higher in the fascia of patients with DM compared with PM. IL-6 positive cells were barely present in the fascia among patients with DM and PM.

Conclusion: Angiogenesis was predominantly observed in the fascia with severe inflammation among patients with DM. Our data suggest that VEGF and TNF-α are involved in DM-associated fasciitis with angiogenesis. Inhibiting VEGF and TNF-α may be a useful therapeutic option to treat inflammatory myopathy, especially DM.

Session Title: Muscle Biology, Myositis and Myopathies Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Polymyositis (PM) and dermatomyositis (DM) are chronic autoimmune diseases, characterized by muscle fatigue. Despite conventional immunosuppressive treatment including high doses of glucocorticoids, only a few patients completely recover muscle function. Our group has recently discovered that immunosuppressive treatment has

significant effects on skeletal muscle gene expression related to lipid and fatty acid (FA) metabolism that may contribute to the persistent muscle weakness in myositis patients. Previous studies have described important effects of FAs on skeletal muscle growth, performance and inflammation. Nevertheless, the involvement of lipids and FA in the pathogenesis of PM and DM has not been elucidated. The aim of the study was to study lipid and FA profiles in sera from patients with PM or DM in comparison to healthy individuals and in relation to immunosuppressive treatment.

Methods:

Serum samples were obtained from 14 patients with established PM or DM with persisting muscle weakness and 12 age and sex matched healthy controls (HC). In a second cohort, serum samples were obtained from 8 new onset PM or DM patients before and after 6 months of conventional immunosuppressive treatment including glucocorticoids. Serum lipids were extracted by using liquid-liquid extraction. FA composition of total lipids was determined by gas chromatography flame ionization detector (GC-FID). FA composition of several lipid classes e.g., triacylglycerols, phospholipids, sphingolipids and lysophospholipids was analyzed by using liquid chromatography tandem mass spectrometry (LC-MS/MS).

Results:

Our preliminary results show that FA composition of total serum lipids was altered in myositis patients compared to HC; the levels of palmitic16:0 acid was significantly higher ($p<0.05$) in myositis patients whereas the levels of arachidonic 20:4(n-6) acid was significantly lower ($p<0.05$). Immunosuppressive treatment affected the FA profiles in total lipids and in lipid classes in the serum from myositis patients. The levels of eicosadienoic acid 20:2(n-6) and eicosapentaenoic 20:5(n-3) acids in myositis patients were significantly higher after treatment compared to before treatment ($p<0.05$). Moreover, the levels of phosphatidylcholine (PC) (32:1), phosphatidylethanolamine (PE) (36:5) and lysophosphatidylcholine (LPC) (16:1) were all significantly higher ($p<0.05$) in myositis patients after treatment compared to before.

Conclusion:

FA composition of total serum lipids was altered in myositis compared to HC. This could be explained by given immunosuppressive treatment as FA composition of serum PC, PE and LPC was altered after 6 months of treatment compared to before treatment. These data suggest that FA metabolism might be deregulated in PM and DM patients and this may contribute to impaired muscle performance and representing a potential therapeutic target in PM and DM.

Session Title: Muscle Biology, Myositis and Myopathies Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Patient-reported outcomes (PROs) assess disease symptoms and impact from the patient's perspective. This research aimed to establish the validity, reliability, and responsiveness of the sporadic Inclusion Body Myositis (sIBM) Physical Functioning Assessment (sIFA) for measuring physical functioning in sIBM patients.

Methods: The development and psychometric evaluation of the sIFA followed the Food and Drug Administration's PRO guidance. Data were collected from three small, non-interventional, observational studies of sIBM patients in the United States, with a subset of 31 patients followed longitudinally for 1 year. Patients completed the sIFA either electronically or using paper forms. The Improved Health Assessment Questionnaire (IHAQ), as well as objective measures of physical functioning, such as the 6 Minute Walk Distance (6MWD) and Short Physical Performance Battery, were included to evaluate construct validity. Measures of reliability (Cronbach's alpha, test-retest intraclass correlations), construct validity (correlations, analyses of variance), and responsiveness (effect size estimates) were computed.

Results: Cronbach's alpha (range: 0.86–0.91) and test-retest reliability (0.91) were highly satisfactory. Correlations with the IHAQ and 6MWD supported convergent validity; for example, the correlations between the sIFA and IHAQ activities scores were strong (range: 0.73–0.85), but the correlations between the sIFA and IHAQ pain scores were weak (range: 0.19–0.29). The sIFA also correlated strongly with the 6MWD (range: -0.59 to -0.60). sIBM patients who were able to walk without assistive devices scored significantly better ($p<0.01$) on the sIFA (range: 36.0–47.1) than those requiring power mobility or wheelchairs (range: 54.9–71.5) and patients who walked >400 meters on the 6MWD scored significantly better ($p<0.01$) on the sIFA (range: 30.0–31.9) than those who walked <300 meters on the 6MWD (range: 56.3–59.5), demonstrating the discriminating ability of the sIFA. Although estimates of responsiveness were small, indicating slow progression of functional impairment, preliminary evidence suggests that the sIFA can be used to detect functional change in sIBM patients.

Conclusion: The psychometric analysis of the sIFA strongly supports its reliability, validity, and responsiveness for assessing the impact of sIBM on patient-reported physical function. The sIFA has the potential to facilitate a more comprehensive evaluation of treatment benefit in sIBM patients.

Tobacco Smoking in Different Racial Groups Is Differentially Associated with the Development of Myositis Autoantibodies and Interstitial Lung

Disease in the Idiopathic Inflammatory Myopathies

Adam Schiffenbauer[1], Natalie Smith[2], Lisa G Rider[1] and Frederick W. Miller[3], [1]Environmental Autoimmunity Group, NIEHS, NIH, Bethesda, MD, [2]Statistics, Purdue University, Allison Park, PA, [3]Clinical Research Branch / Environmental Autoimmunity Group, NIH, Bethesda, MD

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Muscle Biology, Myositis and Myopathies Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Smoking has been found to be a risk or protective factor in certain autoimmune diseases. Yet, its role in the idiopathic inflammatory myopathies (IIM) has not been fully explored. Thus, we assessed the role of smoking in adult IIM and selected phenotypes among different racial groups.

Methods: Patients with probable or definite dermatomyositis (DM, n=186) and polymyositis (PM, n=250) by Bohan and Peter criteria enrolled in NIH studies for whom smoking history could be obtained from their records were studied. Patients were defined as smokers if they had smoked at least 100 cigarettes in their lifetime. Racial background was self-reported, and included 307 Caucasians, 96 African Americans (AA), and 33 patients of other races. The presence of interstitial lung disease (ILD) was based on physician review of chest-x-ray, chest CT, lung biopsy, and/or pulmonary function tests. Autoantibodies (Abs) were assessed in three composite groups -- anti-synthetase autoantibodies (ASA) (directed against Jo-1, PL-12, PL-7, EJ, KS, OJ antigens), myositis-specific autoantibodies (all ASA and those directed against Mi-2, MJ, TIF-1, SRP antigens), and myositis-associated autoantibodies (directed against Ku, MAS, PM-ScL, tRNA, and U1RNP antigens) -- as well as each autoantibody individually. Categorical comparisons were done using chi-squared analysis or Fisher's exact test. Adjustments for age, race, and gender were done using logistic regression.

Results: There was a significant difference in the frequency of ILD across the 3 racial groups with 60% of AA having ILD compared to 75% of Caucasians and 55% of Other races (p=0.002). In Caucasians and Other races, smoking was positively associated with ILD (OR 1.79, 95% CI 1.07-2.98, p=0.025 and OR 6.53, 95% CI 1.2-35.57, p=0.023 respectively). In AA, no significant association between ILD and smoking was observed (OR 0.82, 95% CI 0.32-2.02).

In Caucasian DM/PM patients, smoking was positively associated with any ASA (OR 2.24, 95% CI 1.28-3.92, p=0.004) and anti-Jo-1 Abs (OR 2.4, 95% CI 1.31-4.4, p=0.004). In Caucasians there was a negative association between smoking and anti-TIF-1 (OR 0.14, 95% CI 0.02-0.93, p=0.018), as well as anti-Mi-2 (p=0.045) and anti-MJ (p=0.025) Abs. In AA, there was no association between smoking status and ASA as a group (Chi-square=0.7, p=0.391), anti-Jo-1 (Chi-square=0.0006, p=0.980), or anti-Mi-2 Abs (Chi-square=0.0265, p=0.871), and there was a negative association between U1RNP Abs and smoking (Chi-square=3.9, p=0.049). Although the number of patients in the Other race category was small, there was a positive association between smoking and ASA (p=0.013), as well as with anti-Jo-1 Abs (p=0.034).

Conclusion: These data suggest that in Caucasians smoking is a risk factor for developing ILD, as well as anti-Jo-1 Abs and ASA, but is protective for anti-TIF-1, -Mi-2, and -MJ Abs. In contrast, in AA, smoking appears to have no impact on the development of ILD, anti-Jo-1 Abs, or ASA. Thus, smoking may differentially modulate the clinical and serologic expression of myositis across racial groups.

Session Title: Muscle Biology, Myositis and Myopathies Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Interleukin-35 (IL-35) is a newly described heterodimeric cytokine that belongs to the IL-12 family and consists of p35 (IL-12a) and EBI3 (IL-27b) subunits. IL-35 exerts immunomodulatory activities in several human autoimmune inflammatory diseases. Our objective was to assess IL-35 expression in muscle tissue and serum levels of IL-35 in myositis patients compared to healthy controls and characterise its potential association with myositis disease activity.

Methods: The expression of IL-35 was studied by primary rabbit anti-human EBI3 polyclonal antibody and mouse anti-human p35 monoclonal antibody in a series of 19 muscle biopsy samples of idiopathic inflammatory myopathies (9 dermatomyositis/DM, 10 polymyositis/PM) and 10 cases of non-inflammatory myopathies and 10 control muscles biopsies. Serum levels of IL-35 were determined in 28 DM, 26 PM and 17 cancer associated myositis patients as well as in 40 healthy controls. Disease activity was evaluated by the score of the Myositis Disease Activity Assessment Tool (MYOACT), including both extramuscular, muscular and the physician's score of overall disease activity.

Results: Both IL-35 subunits were found in immune cells of the inflammatory infiltrates in idiopathic inflammatory myopathies, but not in muscle cells. No immunoreactivity was observed in muscle tissue of healthy controls and in non-inflammatory myopathies. IL-35 serum levels were increased in all myositis patients compared to healthy controls ($p< 0.001$). There were no differences in IL-35 serum levels among myositis subgroups. In patients with PM, but not DM, serum IL-35 levels correlated with MYOACT score ($r=0.548$, $p=0.023$), lactate dehydrogenase ($r=0.621$, $p=0.024$), CRP ($r=0.632$, $p=0.009$) and physician's score ($r=0.514$, $p=0.042$).

Conclusion:

IL-35 subunits are overexpressed in inflamed muscle tissue and elevated circulating IL-35 levels are associated with several disease activity parameters in polymyositis patients. These data suggest potential role of IL-35 in the

pathogenesis of inflammatory myopathies.

Session Date: Sunday, November 8, 2015

Session Title: Muscle Biology, Myositis and Myopathies Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Interstitial lung disease (ILD) frequently complicates Polymyositis (PM) and Dermatomyositis (DM) and accounts for significant morbidity and mortality in affected patients. Patients with Myositis associated Interstitial Lung Disease (MA-ILD) are often refractory to conventional treatment which commonly includes the use of glucocorticoids with or without azathioprine, methotrexate or mycophenolate. In recent years, tacrolimus has shown favorable outcomes in refractory MA-ILD. Little is known about clinical variables that are associated with a response to treatment. The aim of this study is to evaluate clinical predictors of response to conventional treatment and tacrolimus.

Methods:

This is a retrospective study of 54 patients with MA-ILD seen in Rheumatology and Pulmonology clinics at The University of Chicago. Myositis was diagnosed based on Bohan and Peter criteria and ILD was diagnosed based on abnormalities on CT scan of chest. Chart review was performed and clinical variables were compared between the groups who responded versus failed to conventional treatment. All patients received glucocorticoids with at least one disease modifying agent (DMARDs such as azathioprine, methotrexate, mycophenolate mofetil) as conventional treatment for MA-ILD. In those who failed conventional treatment, and were challenged with tacrolimus, clinical predictors to treatment were again evaluated. We strictly defined improvement in myositis (serial CK and objective muscle weakness) and ILD (serial pulmonary function tests and symptoms including cough and dyspnea). The response to tacrolimus was measured by observing the improvement in myositis, ILD and changes in the doses of glucocorticoids.

Results:

Our study included 30 patients with PM, 20 with DM, and 4 patients with clinically amyopathic dermatomyositis (CADM). The mean age was 44.8 years (14.8 SD), and 48% of patients were African Americans. 23 out of 54 patients failed to respond to conventional treatment. Patients who had PM were more likely to respond to conventional treatment as compared to DM (p=0.017). There were 20 patients who received tacrolimus for treatment of refractory MA-ILD. There was an improvement in ILD in 94% of patients and improvement in myositis in 75% of patients after the addition of tacrolimus.

The mean dose of prednisone at the time of initiation of tacrolimus was 33.6 +/- 4.3 mg. After 3-6 months the mean dose of prednisone was 11.9 +/- 1.8 mg, $p < 0.0001$ (65% decrease) and was 7.32 +/- 1.7 mg, $p < 0.0001$ (78% decrease) by the end of 1 year. The mean dose of azathioprine at the time of initiation of tacrolimus was 88.15 +/- 16.7 mg. By the end of 1 year the mean dose of azathioprine was 48.6 +/- 15.3 mg (p=0.003, 45% decrease).

Conclusion:

PM/DM/CADM is a group of rare, heterogeneous diseases and predicting their response to treatment remains challenging. Patients with PM associated ILD were more likely to respond to conventional treatment than patients with DM associated ILD. Tacrolimus is a favorable option in patients with refractory MA-ILD and was successful in decreasing the dose of baseline glucocorticoids and other DMARDS.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Muscle Biology, Myositis and Myopathies Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Because of the extremely variable incidence and outcome of interstitial lung disease (ILD) in polymyositis/dermatomyositis (PM/DM), explorationand validation of biomarkers for diagnosis, prognosis, and response to treatment is mandatory. Lung epithelium-derived proteins such as Krebs von den Lungen-6 (KL-6) and surfactant protein-D (SP-D) are widely used as serum biomarkers for ILD. However, their usefulness in patients with PM/DM is not fully established. We aimed to evaluate the usefulness of KL-6 as a biomarker of ILD with PM/DM, including in the short time course after treatment.

Methods: A total of 42 patients with active PM/DM who were admitted to our hospital from April 2010 through March 2015 were included: 22 with PM, 14 with classical DM, and 6 with clinically amyopathic dermatomyositis (CADM). PM/DM and CADM were diagnosed according to Bohan and Peter's criteria and Sontheimer's criteria, respectively.

Overlap patients with other collagen tissue diseases were excluded to avoid potential confounding. ILD was defined as presence of a diffuse parenchymal lung disease on high-resolution CT such as reticular opacities, ground-glass opacities, and honeycombing. Clinical, radiological, and laboratory data were retrospectively collected from the medical records and statistically analyzed.

Results: Of the 42 study subjects, 30 patients had ILD on high-resolution CT: 24 with PM and classical DM, and 6 with CADM. There was no significant difference in age, sex, or disease duration between patients with and without ILD. Because most of the patients had short disease duration at study entry, % vital capacity (%VC) on admission (pre treatment) was not significantly different between patients with and without ILD ($p = 0.19$). However, serum KL-6 and SP-D levels were significantly higher ($p < 0.01$ and $p = 0.01$, respectively), and % diffusing capacity for carbon monoxide (%DLCO) was significantly lower ($p = 0.049$) in patients with ILD than those without. Levels of serum KL-6 were significantly correlated with %VC, %DLCO, and levels of serum SP-D ($p < 0.01$ in all comparisons) but not with alveolar-arterial oxygen difference ($p = 0.39$). All the patients with ILD were treated with prednisolone. In addition, cyclosporine, tacrolimus, and intravenous cyclophosphamide were administered simultaneously in 19, 6, and 8 patients, respectively. Although most of the patients showed some clinical and/or radiological improvement in 4 weeks, levels of serum KL-6 were not significantly different between those at pre treatment and at 2 or 4 weeks post treatment ($p = 0.59$ and 0.58, respectively).

Conclusion: The present study validated that serum KL-6 is a useful biomarker for the diagnosis of ILD associated with PM/DM. However, the levels of serum KL-6 did not respond immediately by treatment even in the cases with clinical improvement. Serum KL-6 should be used as a biomarker for ILD with PM/DM knowing its strengths and limitations.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Muscle Biology, Myositis and Myopathies Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Twenty percent of inflammatory myopathy are associated with a synchronous cancer occurring ±3 years around the diagnosis. Malignancy is a major cause of mortality in inflammatory myopathy. The association is mainly reported in dermatomyositis (DM) patients. It has been clarified that DM patients positive for either anti-TIF1γ or anti-NXP2 myositis specific anti-bodies have increased risk of cancer. Some reports showed that malignancy could also occur in patients with necrotizing myopathies (NAM).

We aim to analyse the incidence of cancer in a large cohort of NAM with or without the myositis specific anti-single recognition particle (SRP) or anti-3-hydroxy-3-methylglutaryl-coenzyme A reductase (HMGCR) auto-antibodies.

Methods: One hundred fifteen NAM patients were analysed: 48 SRP patients, 52 HMGCR patients and 15 seronegative NAM. NAM was defined based on pathological criteria.

Results: Malignancy occurred in 28.5% of seronegative NAM patients and in 17.3% of HMGCR patients compared to 6.1% in SRP patients (p=0.04). The median time between the diagnostic of malignancy and the myopathy was 4.9±21 months in seronegative NAM patients, 25.1±58 months in HMGCR patients and 80.1±76.2 months in SRP patients. Synchronous malignancy (±3 years) was diagnosed in 21.4% of seronegative NAM patients, 11.5% of HMGCR patients and 4% of SRP patients (p=0.03). No specific types of cancer was predominant. Compare to the French cancer registry increase incidence of cancer occurs in seronegative NAM and HMGCR NAM with standard incidence ratios of 8.35 [1.7-24.4] and 2.79 [1.02-6.07] respectively. Survival analysis showed that patients suffering from a synchronous cancer had a poor out-come with a median survival of 57.2 years (p<0.0001).

Conclusion: Seronegative NAM and anti-HMGCR patients have an increased risk of malignancy. The presence of cancer is associated with a poor survival. Cancer screening is necessary in seronegative and in anti-HMGCR NAM patients.

Correlations Between Muscle-MRI, Muscle Strength and Creatine Kinase Levels in the Anti-Synthetase Syndrome; A Comparative, Cross-Sectional Study

Helena Andersson[1], Eva Kirkhus[2], Else Merckoll[2], Ragnhild Walle-Hansen[3] and Øyvind Molberg[1], [1]Department of Rheumatology, Institute of Clinical Medicine, Oslo University Hospital, Oslo, Norway, [2]Department of Radiology, Oslo University Hospital, Oslo, Norway, [3]Department of Orthopaedic Surgery, Oslo University Hospital, Oslo, Norway

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Muscle Biology, Myositis and Myopathies Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Muscle MRI is used to describe the myositis component of the anti-synthetase syndrome (ASS), but the value of the examination is limited by lack of reference data from non-myositis populations. The primary aim of this study was therefore to compare the MRI findings in ASS with healthy age- and gender matched controls.

Methods:

In September 2011, 68/70 ASS patients in the Oslo University Hospital ASS cohort were included in a comparative, cross-sectional study that included muscle MRI, manual muscle testing of 24 muscles (MMT24) and plasma CK. Sex and age-matched healthy controls were randomly collected from the National People Register of Norway in a 1:1 proportion (N=67). MRI was using a 1.5 T scanner with coronal and axial T1-weighted spin echo and short T1 inversion recovery (STIR) sequences of thigh muscles. The images were analyzed by two radiologists blinded for the participant's status. Edema in muscles or fascia was evaluated as present/not present. Fatty infiltration was scored according to the Guttalier grading (0-4) and considered pathological if > 2 [1]. Elevated CK was defined as > 2x upper limit of normal (ULN). The MMT24 score (0-140) was performed by two experienced physiotherapists. Chi-Square and Mann Whitney U-test were used to evaluate statistical significance ($p<0.05$). Pearson's correlation was used to detect correlations.

Results:

Median disease duration for the ASS patients was 71 months and 76% had previously been diagnosed with myositis. Abnormal MRI findings were found in 63% of the patients compared to 18 % in the controls with significant differences in the proportion of muscle and fascia edema, as well as fatty infiltration (Table 1). The MRI findings in the control group were to some extent asymmetric. Median MMT24 scores were lower in ASS than controls, but CK levels did not differ between the groups (Table 1). In ASS patients no correlation was seen between muscle-edema and elevated CK or between MMT24 and elevated CK. MRI abnormalities were detected in 35/52 ASS patients with myositis and in 7/15 cases with no previous myositis signs. There was no difference in MMT24 or CK values between the two ASS subsets. Of the 12 controls with abnormal MRI findings, only one had elevated CK and three had MMT24 score ≤ 137.

Table 1; MRI findings, MMT24 and CK levels in ASS patients and matched controls

	ASS N=68	Controls N=67	p-value
MRI findings n/N (%)			
A Edema in muscles	26/67 (39)	7/66 (11)	<0.001
B Edema in fascia	19/67 (28)	5/66 (8)	<0.003
C Fatty infiltration	25/67 (37)	3/66 (5)	<0.001
A, B and/or C	42/67 (63)	12/66 (18)	<0.001
Other muscle parameters			
Median CK, U/ml (range)	95 (24-1344)	98 (35-839)	<0.676
CK> 2x ULN, n/N (%)	4/67 (6)	1/65 (2)	<0.366
Median MMT24 score (range)	139 (114-140)	140 (130-140)	<0.001

Conclusion:

This comparative study reports significant differences in myositis-related MRI findings between ASS patients and matched controls. Muscle-edema was present in 37% of ASS patients with normal CK but only in 10% of the controls. The study shows that MRI has potential as a complementary tool to assess myositis in ASS, and highlights the need for MRI scoring systems that differentiate patients from controls.

Session Title: Muscle Biology, Myositis and Myopathies Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Polymyositis (PM) and Dermatomyositis (DM) are inflammatory conditions characterized by persistent inflammation of muscle tissue (and for DM also skin). Myositis has been shown to be associated with upregulationof MMP expression and activity in muscle.

Neoepitope biomarkers are peptide biomarkers that are the product of pathology specific post-translational modification, e.g. MMP-mediated proteolytic cleavage. Several such biomarkers have shown to be modulated during inflammatory conditions such as rheumatoid arthritis and synovitis in osteoarthritis, as well as in tissue fibrosis. Thus, we hypothesized that they likewise be differentially modeulatedduring DM or PM, individually or together. **Methods:**

In a previously described clinical trial comprised of 61 myositis patients (28 DM, 23 PM) and 30 age and gender-matched controls, we measured the serum biomarkers MMP-cleaved collagens 1, 3, and 6 (C1M, C3M, C6M), Propeptides of collagens 1 and 3 (P1NP and PRO-C3), MMP-cleaved CPR (CRPM), MMP-cleaved titin (TIM), and caspase-cleaved Myosin light chain 3 (MYL-C3). First we analyzed biomarker levels across PM, DM and controls using one-way ANOVA. Second, we analyzed the ability of the biomarkers to separate PM and DM from healthy controls through logistic regression and Receiver-operator characteristic analysis. Third, we examined the relationship between the biomarkers and the MMT8 score (a manual measurement score of muscle function across 8 muscles),

through multivariate regression analysis. **Results:**

We found that C1M, C3M, CRPM, PINP and PRO-C3 were differentially modulated in PM and DM relative to controls (Figure 1), in the form of downregulation of CRPM and PINP relative to controls and upregulationof PRO-C3 in PM and in C1M and C3M in DM.

Next, we found that biomarkers panels could separate DM, PM and DM+PM from controls with 90%+ sensitivity and specificity (area under the curve for corresponding ROC curves of 0,997, 0.973 and 0,996, Figure 2).

Last, we report that biomarker panels can effectively predict MMT8 scores in PM (best model included C6M, $p<0.0001$), DM (best model included C6M and CRPM, $p<0.0001$) and DM+PM (best model included C6M, CRPM and PRO-C3, $p=0.0001$) **Conclusion:**

First, we can report that neoepitope biomarkers differentially produced in myositis patients relative to healthy controls. Second, we found that neoepitope biomarker panels can discriminate between healthy controls and DM, PM or DM/PM combined with extremely high sensitivity and specificity. Third, we report that biomarker panels, particularly C6M, closely followmuscle function.

Session Title: Muscle Biology, Myositis and Myopathies Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Many data suggest that advanced glycation endproducts (AGEs) play an important role the development of atherosclerosis and cardiovascular (CV) disease. AGEs are produced and may accumulate during chronic inflammation, and may impact on patients with idiopathic inflammatory myositis (IIM). The aims of this study was to evaluate whether AGEs are increased in patients with IIM and to explore whether AGE accumulation is related to clinical data, disease activity and measures of subclinical atherosclerosis assessed by ultrasonography sampling of carotid artery.

Methods: Twenty-seven IIM patients (F/M 19/8; mean age 56.7±12.3; mean disease duration 8.8±7 years, 13 polymyositis and 14 dermatomyositis) fulfilling the Bohan and Peter criteria were prospectively enrolled and compared with 29 healthy subjects (HS) matched for age, sex and classical cardiovascular risk factors (smoking habits, diabetes mellitus, hypertension, family history of CV disease, body mass index). AGEs were determined by skin autofluorescence at level of left forearm.

AGEs levels were correlated with demographic data, disease activity parameters (physician and patient's activity using visual analogic scale, manual muscle test 8, muscular enzyme levels, health quality assessment questionnaire), disease duration, cumulative corticosteroids dose. We also collected markers of subclinical atherosclerosis including Intima-Media-Thickness (IMT), mean arterial diameter (mAD) and distensibility coefficient (DC) measured on B-mode ultrasound image sequences of right common carotid artery, 1 cm beneath the bifurcation.

Results:

IIM patients presented higher subcutaneous AGEs than healthy subjects. (mean 2.83 ± 0.6360 DS vs 2.176 ±0.5773 DS) $p<0.001$.

In the IIM group, AGEs are significantly correlated with age ($p=0.011$), and with IMT ($p<0.001$) and mAD ($p=0.035$), while no correlation was found with DC. In healthy subjects, AGEs were significantly correlated with age ($p<0.001$), but no correlations were found between AGEs and IMT, mAD and DC.

In addition, in myositis patients, no correlations were observed between AGEs and gender, classic cardiovascular risk factors, disease duration, cumulative corticosteroid dose, disease activity parameters and laboratory data.

Conclusion:

Our data have shown that IIM patients presented higher AGEs than healthy subjects; a correlation between AGEs and age at the evaluation, and between AGEs and signs of premature atherosclerosis were found. These observations may suggest that, in myositis patients, AGEs may be an early marker of subclinical CV. Further data are necessary to confirm our observation.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Muscle Biology, Myositis and Myopathies Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Interstitial lung disease (ILD) is a leading cause of mortality in myositis. Clinical trials in myositis-associated ILD (MA-ILD) are lacking due to the absence of validated outcome measures. Serial pulmonary function tests (PFTs) predict outcome in ILD; however, the degree of change in PFT variables that predict survival has not been studied in MA-ILD. We investigated PFT variable changes over 1 year that predict disease outcome for use in future clinical trials.

Methods: MA-ILD patients were identified from a prospective myositis database (1985-2014). Myositis was defined using the Bohan and Peter classification criteria (probable or definite) *or* anti-synthetase syndrome. The latter was defined by the presence of an anti-synthetase antibody and at least one associated clinical feature. ILD was defined by radiographic fibrosis consistent with ILD. Clinical variables and relative and absolute % change in FVC, FEV-1 and DLCO over 1 year were analyzed for prediction of survival and event-free survival. Relative percent change was defined as [(baseline Ð follow-up)/baseline] x 100, and absolute change was defined as baseline Ð follow-up. Independent variables (relative and absolute % decline in FVC, FEV-1, DLCO by 5/7.5/10/15% over 1 year) were used to predict survival and event-free survival. Event was defined as death or lung transplant. The same independent PFT predictors were evaluated after controlling for baseline PFT values, age, gender and ethnicity. Kaplan Meier and Cox Proportional Hazard model were used for analysis.

Results: 121 MA-ILD patients were identified; 63% (76/121) were female and 87% (101/116) Caucasian with a mean (SD) age at ILD diagnosis of 48 (13.2) years. 104 patients met criteria for anti-synthetase syndrome and 106 (88%) possessed at least one myositis specific antibody. There were 29 events (25 death/9 transplant) with a median (IQR) follow up time of 6.0 (5.2) years from first visit. A relative decline in FVC of 15%, 10% and 7.5%, an absolute decline in FVC of 7.5%, and a relative decline in FEV-1 of 10% predicted survival with HR of 9.2, 8.8, 6.8, 8.9, and 3.5 respectively ($p<0.01$), after controlling for baseline FVC or FEV-1, age at first visit, gender and race (Figure 1). A relative decline in FVC of 15% and 10%, an absolute decline in FVC of 7.5%, and a relative decline in FEV-1 of 10% predicted event-free survival with similar results as above. Relative or absolute declines in %DLCO were not predictive of survival or event- free survival.

Conclusion: Relative declines of 15% and 10% in FVC over 1 year are the best candidates for predicting survival and event-free survival in MA-ILD. Clinical trials for MA-ILD should be done using outcome criteria of 10-15% change in FVC over 1 year.

Figure 1. Kaplan Meier curve for survival outcome in patients with FVC ³10% decline in 1 year of follow up.

Session Title: Muscle Biology, Myositis and Myopathies Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Previous studies have shown that skin lesions in dermatomyositis (DM) are best assessed using the Cutaneous Dermatomyositis Disease Area and Severity Index (CDASI). Although the CDASI has been validated for use by dermatologists, it has not yet been validated for use by other specialists such as rheumatologists and neurologists, who also manage DM patients and evaluate their skin in clinical trials. The purpose of this study is to assess the inter-rater and intra-rater reliability of the CDASI and extend the validation of the CDASI to rheumatologists and neurologists.

Methods: Five dermatologists, five rheumatologists, and five neurologists specializing in neuromuscular medicine individually assessed 15 patients with cutaneous DM using the CDASI and the Physician's Global Assessment (PGA). All physicians received a 30-minute training session on the CDASI and PGA prior to evaluating patients. Each physician also re-rated three patients. Intraclass correlation (ICC) scores <0.5 were considered poor, 0.50 to 0.70 moderate and minimally acceptable, 0.70 to 0.81 good, and >0.81 excellent.

Results: Inter-rater reliability yielded an ICC for CDASI activity that was good for dermatologists and rheumatologists (0.73 and 0.74, respectively) and moderate for neurologists (0.56). The ICC for CDASI damage was excellent for all physicians (dermatologists 0.83, rheumatologists 0.82, neurologists 0.85). For PGA activity, the ICC was moderate for dermatologists (0.61) and rheumatologists (0.69) but poor for neurologists (0.44). The ICC for PGA damage was excellent for neurologists (0.85), good for rheumatologists (0.75), and moderate for dermatologists (0.58) (Table 1).

Intra-rater (test-retest) reliability for CDASI activity was excellent for all physicians (dermatologists 0.94, rheumatologists 0.88, neurologists 0.82). For CDASI damage the scores were excellent for dermatologist and rheumatologists (0.92 and 0.91, respectively) and moderate for neurologists (0.66). For the PGA activity and damage the intra-rater reliability was excellent for dermatologists (0.89 and 0.91, respectively) and good for rheumatologists (0.75 and 0.75, respectively). For neurologists, the PGA activity was good (0.74) but the PGA damage was poor (0.39) (Table 2).

Conclusion: Our data confirm the reliability of the CDASI when used by dermatologists and support the CDASI as a reliable instrument for use by rheumatologists. The data was not as robust for its use by neurologists.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Muscle Biology, Myositis and Myopathies Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: MRI is often used to evaluate muscle inflammation in myositis. Muscle edema on fat-suppressed (short tau inversion recovery, STIR) sequences is thought to represent active inflammation. Dermatomyositis (DM) and polymyositis (PM) affect very often thigh muscles. However, it is unclear whether DM and PM differ in the respective

involvement of the various thigh muscle groups. In this study, we aimed to assess which thigh muscle groups are preferentially inflamed in DM and PM, respectively, using MRI fat-suppressed sequences.

Methods: We analysed 72 patients from 2 Rheumatology centers (Reggio Emilia & Bari, Italy), 31 with DM and 41 with PM diagnosed according to Bohan and Peter criteria. MRI edema (1= present, 0= absent) was assessed bilaterally on STIR sequences in 17 thigh/pelvic floor muscles. An MRI composite edema score (0-17) was calculated by adding the separate scores bilaterally and dividing them by two as described in Clin Exp Rheumatol 2012; 30:570. The (single measures) intraclass correlation coefficient (ICC) between the Radiologists involved was 0.78. Fisher's exact test was used for comparison of binomial data.

Results: Age (years, mean±SD) was similar in patients with DM (53 ± 16) and PM (56 ± 16). The F:M ratio was similar in DM (23/8) and PM (32/9). Disease duration (months, mean±SD) was shorter (20±31) in DM than in PM (52±68) (p=0.02). The Table shows the frequency (n° and %) of all thigh muscle groups involved in DM and PM.

TABLE	Compartment	DM (n=31)	PM (n=41)	p value
Gluteus maximus	axial	17 (55%)	13 (32%)	0.06
Quadratus femoris	axial	9 (29%)	1 (2%)	0.002
Vastus lateralis	anterior	15 (48%)	11 (27%)	0.08
Ileopsoas	axial	8 (26%)	3 (7%)	0.046
Vastus medialis	anterior	14 (45%)	10 (24%)	0.08
Tensor fasciae latae	anterior	12 (39%)	4 (10%)	0.005
Rectus femoris	anterior	16 (52%)	10 (24%)	0.03
Sartorius	anterior	13 (42%)	11 (27%)	0.2
Gracilis	medial	15 (48%)	8 (20%)	0.01
Pectineus	medial	8 (26%)	2 (5%)	0.02
Adductor longus	medial	9 (29%)	6 (15%)	0.16
Adductor brevis	medial	12 (39%)	5 (12%)	0.01
Adductor magnus	medial	10 (32%)	10 (24%)	0.6
Short head biceps femoris	posterior	10 (32%)	6 (15%)	0.09
Long head biceps femoris	posterior	12 (39%)	12 (29%)	0.5
Semimembranous	posterior	10 (32%)	8 (20%)	0.3
Semitendineous	posterior	14 (45%)	10 (24%)	0.08

Conclusion: Compared with PM, DM affects more frequently some muscle groups. Posterior muscle groups discriminate poorly between DM and PM. These findings may be useful for differential diagnostic purposes in patients with histological DM without the typical skin rash as well as to target physiotherapy at more frequently affected muscles.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Muscle Biology, Myositis and Myopathies Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: MRI is commonly used to assess muscle inflammation in myositis. Muscle edema on fat-suppressed sequences is thought to reflect active inflammation. However, it is unclear how useful MRI is in monitoring patients with myositis, in particular which is its sensitivity to change after treatment onset or intensification. In this study, we aimed to assess changes in the edema of the thigh muscles in a cohort of patients with myositis at their first presentation to our centers (T0) and at follow-up after onset/intensification of immunosuppressive therapy (T1). Ancillary aims were to correlate the extent of muscle edema on MRI with serum creakine kinase (CK) and muscle strength .

Methods: We enrolled in 2 Rheumatology centers 36 patients, 17 with dermatomyositis (DM) and 19 with polymyositis (PM) diagnosed according to Bohan and Peter criteria. The diagnosis of PM was confirmed by histology in all cases. In all patients, CK was measured, manual muscle test (MMT) was performed, and MRI fat-suppressed sequences were acquired within a week. MRI edema (1= present, 0= absent) was assessed bilaterally in 17 thigh and pelvic floor muscles. An MRI composite edema score (0-17) was calculated by adding the separate scores bilaterally and dividing them by two as described in Clin Exp Rheumatol 2012; 30:570-3. The CK upper limit of normal was 190 U/l. The (single measures) intraclass correlation coefficient (ICC) between the Radiologists involved was 0.78. Muscle strength was measured by MMT and graded according to the Medical Research Council extended scale (0-5). The ICC between the 2 physicians performing the MMT was 0.8. Analysis was performed by Wilcoxon sum rank and Spearman's tests, as appropriate

Results: Mean age (years±SD) was 54±15. The ratio F:M was 31:5. MRI was positive (edema score equal to, or greater than 1) in 26 (72%) patients at T0 and in 18 (50%) at T1. Mean MRI edema score was 5±5.2 (mean±SD) at T0 and 2.4±4.5 at T1 (p=0.002). Median and interquartile range (IQR) of MRI edema score were 3.5 (8) at T0 and 0.5 (4.5) at T1. CK was elevated in 22 (61%) patients at T0 and 10 (28%) at T1. CK was 1,816±3,560 at T0 and 531±1,536 at T1 (p=0.002). MMT score was 4.4±0.44 at T0 and 4.6±0.40 at T1 (p=0.02). MRI edema score did not correlate with CK or MMT scores neither at T0 nor T1. Eleven patients had a normal CK but a positive MRI at T0. In 5 of these patients, MRI became negative at T1. In the 11 patients with a normal CK but positive MRI at baseline, MRI edema score decreased from 6.7±5.3 at T0 to 2.4±2.7 at T1 (significance not calculated because of the small sample size).

Conclusion: MRI is a useful tool to monitor patients with myositis, and might particularly have a role in monitoring disease activity in patients with a normal serum CK at baseline. Larger studies are required to confirm our findings.

Investigating the Pathogenic Role of ER Stress Pathway Activation in the Idiopathic Inflammatory Myopathies (IIM): Skeletal Muscle Cells As a Source of Cytokines (Myokines)

Adam P. Lightfoot[1], Katarzyna Goljanek-Whysall[2], Kate E. Earl[2], Caroline V. Cotton[2], Anne McArdle[1] and Robert G. Cooper[3], [1]Musculoskeletal Biology, University of Liverpool, Liverpool, United Kingdom, [2]University of Liverpool, Liverpool, United Kingdom, [3]Rheumatic Diseaes Center, Salford Royal Foundation Trust, University of Manchester, Salford, United Kingdom

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Muscle Biology, Myositis and Myopathies Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The idiopathic inflammatory myopathies (IIM) are a collection of autoimmune disorders, characterised by the development of debilitating symmetrical skeletal muscle weakness. IIM Patients also have elevated creatine kinase levels with an array of circulating myositis-specific autoantibodies. Upregulation of major histocompatibility complex (MHC) I molecules *in vitro* and *in vivo*is also a characteristic histological finding, and associated with activation of the Endoplasmic Reticulum (ER) stress response (Nagaraju et al. 2005). Pharmacological activation of the ER stress response is known to cause increased expression of pro-inflammatory muscle-derived cytokines, or myokines (Welc et al. 2013). Based on recent research demonstrating that skeletal muscle acts as a source for many and diverse cytokines, we investigated whether induced MHC I overexpression in myotubes would result in ER stress pathway activation, and release of cytokines.**Methods:** Murine C2C12 myotubes were transfected with a vector to overexpressing MHC I (H2-k^b) using Lipofectamine2000^{TM} transfection reagent with, or without the presence of salubrinal, an ER stress blocking agent. Successful transfection of the MHC I (H2-k^b) vector was confirmed using qPCR. Cellular cytokine gene expression and release was examined using qPCR and Luminex multiplex analysis respectively. ER stress pathway activation was confirmed using qPCR and SDS-PAGE/western blotting. **Results:** The results show that overexpression of MHC I within C2C12 myotubes results in activation of the ER stress pathway, evidenced by upregulation of the ER stress genes, Grp78, ATF6, PERK, IRE1 and XBP-1. ER stress pathway blocking by salubrinal was confirmed by elevated levels of phosphorylated eif2-alpha. Overexpression of MHC I in C2C12 myotubes also resulted in increased gene expression and release of the potentially chemotactic cytokines IL-6, CCL2, CCL4, CCL5 and CXCL-1. This cytokine expression/release was significantly reduced when transfection occurred in the presence of salubrinal. **Conclusion:** Our data builds on previous published findings demonstrating that MHC-1 overexpression in skeletal muscle causes ER stress pathway activation. Our results also demonstrate that muscle is potentially a source of various cytokines, a process mediated here via ER stress pathway activation. These findings suggest that muscle cells may exhibit chemotactic capability, so attracting immune cells. Such myokines release suggests muscle may exert paracrine signals on neighbouring fibres, which could contribute to muscle dysfunction in the absence of immune cells. Skeletal muscle may thus act as a source of cytokines in the IIM. Targeted therapies towards myokine production may thus be worthy of further investigation, to further understand muscle dysfunction in IIM.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Muscle Biology, Myositis and Myopathies Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Myositis specific antibodies are known to be associated with specific phenotypes. The unusual presentation of subcutaneous edema, distal weakness and dysphagia was seen in several successive patients who were found to be positive for the NXP2 antibody. Further analysis was done to determine if this association was more common with this antibody.

Methods:

A retrospective chart review was completed on patients seen in the Johns Hopkins Myositis Center during the period of 2002-2015. Patients were included in our analysis if they met Bohan and Peter criteria for definite or probable dermatomyositis, Sontheimer's criteria for amyopathic dermatomyositis, or dermatomyositis by muscle biopsy using ENMC criteria, with known antibody status and available clinical data. Patients who had confirmed autoantibody testing at a CLIA certified lab were included in this study. One hundred and twenty two patients met the criteria and were included for analysis, with 40 patients being NXP2 positive. Subcutaneous edema was defined as pitting or non-pitting edema of one or more extremity that accompanied the active phase of the disease. Muscle strength was graded for 16 muscle groups using the Medical Research Council (MRC) scale. Dysphagia was determined clinically by patient report. Parametric analysis was used to determine the difference between these variables in patients positive for the NXP2 antibody and those with antibodies other than NXP2.

Results:

The edematous phenotype was seen more commonly in the NXP2 + patients than in the NXP2- patients (45% vs. 10%, $p<0.001$). Overall, NXP2 + patients had statistically significant weakness in distal muscle groups (finger extensors, ankle flexors and ankle extensors) as compared to NXP2- patients. NXP2 is also associated with dysphagia (68% in NXP2+ vs 31% in NXP2-, $p<0.001$). In NXP2+ patients with edema, there was an associated increase in weakness (significant at the deltoids, triceps, wrist extensors and ankle extensors). There was also a trend to have more dysphagia than in those without edema (82% in those with edema vs 57% in those without it, $p=0.1$).

Conclusion:

A specific phenotype of subcutaneous edema associated with more severe muscle weakness, distal involvement and dysphagia is associated with the NXP2 antibody.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Muscle Biology, Myositis and Myopathies Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with significantly elevated creatine kinase (CK) levels are commonly referred to rheumatologists to evaluate for the presence of an idiopathic inflammatory myopathy (IIM). However, no studies have evaluated the frequency with which IIMs are encountered in this clinical scenario. The purpose of this study was to define the causes of elevated CK levels in patients referred for rheumatology consultation with a CK greater than 1,000 IU/L and to examine the clinical characteristics of these patients to determine if any distinguishing factors could be discerned.

Methods: The Vanderbilt Synthetic Derivative, a de-identified copy of over 2 million patient charts, was searched to identify patients with a CK greater than 1,000 IU/L. Other inclusion criteria were age greater than 18 and containing a document with the word rheumatology. Patients were excluded if rheumatology involvement was unrelated to the elevated CK or if there was inadequate follow-up. These criteria identified 192 patients who were assigned a diagnosis using a pre-defined algorithm. Patients determined to have an IIM were classified using the Bohan and Peter criteria for dermatomyositis (DM) and polymyositis (PM), the Griggs criteria for inclusion body myositis (IBM), or by clinical diagnosis for patients with an overlap syndrome, necrotizing myopathy, or DM/PM not meeting the above criteria. To ensure diagnostic consistency and accuracy, 10% of the charts were examined by an independent reviewer. Each chart was reviewed for pertinent demographic data and clinical characteristics.

Results: A total of 105 (55%) patients were diagnosed with an IIM. The majority of the IIM patients met Bohan and Peter criteria for DM (n=24, 13%), PM (n=41, 21%), or were diagnosed clinically with an overlap syndrome (n=28, 15%). The rest of the IIM patients were diagnosed with a necrotizing myopathy (n=2, 1%), IBM (n=1, <1%), or an IIM not meeting criteria (n=9, 5%). The non-IIM causes were drug or toxin exposure (n=16, 8%), infection (n=12, 6%), trauma (n=10, 5%), myocardial injury (n=5, 3%), hypothyroidism (n=4, 2%), muscular dystrophy (n=4, 2%), neuropsychiatric disorder (n=3, 2%), glycogen storage disorder (n=1, <1%), mitochondrial myopathy (n=1, <1%), idiopathic CK elevation (n=11, 6%), and other diagnoses (n=20, 10%). Several characteristics were found to be significantly different between IIM and non-IIM cases. Patients with an IIM were more likely to be younger (average age 48 vs. 53, p=0.04), female (71% vs. 40%, p<0.001), seen in clinic and not as an inpatient (78% vs. 44%, p<0.001),

have symptoms longer than 6 months (55% vs. 29%, p<0.001), have an ANA greater than or equal to 1:40 (54% vs. 24%, p<0.001), and have a positive Jo-1 antibody (11% vs. 0%, p=0.001). Patients without an IIM had more cardiac and renal comorbidities (61% vs. 31%, p<0.001 and 16% vs. 3%, p=0.002 respectively). There was no significant difference between the CK levels of patients with IIM vs. non-IIM.

Conclusion: More than half of patients referred for rheumatology consultation with a CK greater than 1,000 IU/L were diagnosed with an IIM. Given the importance of prompt diagnosis and treatment, rapid assessment by the consulting rheumatologist for these patients is recommended.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Muscle Biology, Myositis and Myopathies Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Sporadic inclusion body myositis (sIBM) is a rare & debilitating muscle disease characterized by the slow progressive asymmetric weakness, atrophy of proximal & distal muscle, with symptoms generally developing ≥ 50 years of age. This study aimed to describe demographics & clinical profile of sIBM patients, to evaluate their healthcare resource utilization & economic cost compared to a matched general population cohort.

Methods: Using administrative claims data from the Truven MarketScan Commercial & Medicare supplemental database, the sIBM patient cohort included patients (≥50 years) with ≥2 outpatient diagnoses of sIBM ≥7 days apart or with ≥ 1 inpatient sIBM diagnosis identified between January 1, 2010 & December 31, 2012. The date of the first observed diagnosis of sIBM was defined as the index date; patients with ≥1 year continuous enrollment in medical insurance plans pre- & post-index were included. The control cohort was selected from patients without sIBM with ≥ 1 healthcare encounter between January 1, 2010 & December 31, 2012. Patients with diagnoses of congenital hereditary muscular dystrophy/ hereditary progressive muscular dystrophy were excluded. Control patients were matched to sIBM patients by age, gender, region, continuous enrollment of medical benefits in 1: 5 ratio & were assigned the same index date as the paired sIBM patients. Generalized Estimating Equation models with appropriate link functions & two parts models were conducted controlling for matching structure, to assess health care utilization & costs of sIBM patients in the follow up period compared to the control group, adjusting for baseline characteristics and healthcare resource utilization.

Results: 333 sIBM patients & 1,665 matched controls (66% male) with a mean age of 69 years (SD: 9.6) were included in the analysis. Charlson comorbidity index score was significantly higher (P<0.0001) in sIBM patients

(Mean: 2.0 SD: 2.4) compared to controls (Mean: 1.2, SD: 1.9). 11.1% of sIBM patients reported pneumonia compared to 3.2% of the controls, while 22.5% of sIBM patients reported dsyphagia compared to 2.0% of the controls (P<0.0000). Falls requiring medical visit were reported by 8.1% of sIBM patients compared to 1.1% of the controls (P<0.0000). 26% of sIBM patients had an all-cause hospitalizations, 42% had an ER visits & 99% had an office visit compared to the control patients of 12%, 22%, and 95% (P<0.0002), respectively. Number of office visits were significantly higher in sIBM patients compared to control (mean [SD]): 11.4 [7.2] vs. 7.0 [6.3], P<0.0001). Adjusting for baseline characteristics, sIBM patients had higher risk of all-cause hospitalization, (OR: 1.89; 95% CI: 1.34–2.67), all-cause ER visits (OR: 1.94; 95% CI: 1.46–2.58), office visits (OR: 3.03; 95% CI: 0.88–10.49), & had higher healthcare cost (Mean difference: $19,389; 95% CI: 12,855–26,763) compared to the control group.

Conclusion: sIBM imposes a considerable economic burden in terms of increased healthcare resource used & associated costs compared to the matched general population. The major cost driver was outpatient costs.

Session Title: Muscle Biology, Myositis and Myopathies Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Sporadic Inclusion Body Myositis (sIBM) is a progressive, idiopathic inflammatory myopathy characterized by dysphagia, weakness of proximal and distal muscles and atrophy. This cross-sectional study aims to characterize the socioeconomic burden of sIBM patients in the United States (US).

Methods: sIBM patients registered for The Myositis Association 2013 and 2014 annual patient conferences completed the Skeletal Muscle Activity and Resource Tool for sIBM (SMART-sIBM). The SMART-sIBM is a measure of self-reported resource utilization developed with extensive sIBM patient input and cognitively tested (sIBM patient interviews) to ensure its relevance to the sIBM patient population. The SMART-sIBM is designed to characterize direct and out-of-pocket expenses including items not reimbursed by US third-party payers. Patients completed the SMART-sIBM either electronically or using paper forms.

Results: Of 102 unique sIBM patients who participated, 31 were assessed both years. For the overall sample, mean age was 67.2 years (range 49–88), and the majority were male (62%), Caucasian (96%). Mean (±SD) number of years since diagnosis was 5.3 (±4.3) and years since first symptoms was 11.3 (±6.4). Approximately 36% of participants were ambulatory without use of an assistive device, 36% used an aid/brace, 17% used power mobility for long distances, 7% used power mobility most of the time, and 4% were not able to walk or stand. The average number of falls in the past month was <1 (range: 0–4) and the average number of healthcare visits due to falls in the past 12 months was 0.71 (±1.8, range: 0–12). In the past 6 months 62% of participants reported visiting specialists for their sIBM and 39% visited a general practitioner. A large majority of sIBM patients (68.4%) reported that they had to make non-reimbursed modifications to their house, apartment, or car because of their sIBM, and 76.5% reported non-reimbursed purchases of special equipment, devices, or aids since diagnosis with sIBM. Paid help for household tasks was required by 37% of participants, 60% relied on unpaid caregivers (87.5% spouse), and 42% reported a change in job status due to sIBM-related functional limitations.

Conclusion:

This study provides resource utilization data for the first time in a US sample of patients with sIBM. sIBM patients experience considerable financial burden, including important out-of-pocket expenses, due to their physical disability and loss of independence.

Session Title: Muscle Biology, Myositis and Myopathies Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Our CureJM JDM Registry/Repository contains sequential samples of peripheral blood mononuclear cells (PBMCs) and sera obtained every 6 months from over 467 children with definite juvenile dermatomyositis (JDM). Recent international genome-wide association studies confirmed that the highest genetic association with JDM is the ancestral HLA locus on chromosome 6, shared with other autoimmune disease, but did not identify novel pathways with genome-wide significance. In our cohort, 7.9% of JDM patients have another autoimmune disease; psoriasis is the most prevalent with 9 cases (2.2%). The purpose of this study was to assay PBMC samples using RNA-Seq to find biomarkers of disease activity for JDM as well as psoriasis.

Methods: After informed consent, PBMCs were obtained from 4 M and 5 F JDM patients (mean age <7), along with 2 M and 2 F controls (mean age 13.5). Of the JDM, 4 had JDM alone, 5 had JDM initially and later in their disease course developed psoriasis; all were tested versus the 4 controls. We utilized 18 total samples from the 9 JDM patients and 4 controls for RNA extraction and stranded RNA-Seq. We aligned the data to GRCh38 with STAR and analyzed differential expression using different strategies, including cuffdiff2, DESeq2, and edgeRun.

Results: Both the JDM-only and JDM pre-psoriasis samples show increased fold-changes (FC) compared to control samples for both *CD69* (FC $\geq$ 3.5) which may be a signal of T cell proliferation and *CD83* (FC $\geq$ 6), a marker enriched on mature dendritic cells. In the pre-psoriatic samples the significant changes included increases in the transcription factors *ATF3* (FC $\geq$ 9) and *NR4A1* (FC $\geq$ 4), as well as *IL1B* (FC $\geq$ 10) and Fos ligand (*FOSL1*; FC $\geq$ 20), in addition to genes associated with TNFα and NFκB signaling as determined by Gene Ontology, Corum, and KEGG annotations. At the time of psoriatic symptoms, the expression of *CD69* had normalized in some patients with previous JDM. The post-psoriatic samples were similar to controls and the majority of the JDM inflammatory signatures had resolved.

Conclusion: 1) Upregulation of *CD69*, *CD83*, along with increased TNFα and NFκB signaling, are components of the pathophysiology of JDM which may resolve as the disease subsides; 2) In the pre-psoriasis state, upregulation of transcription factors *ATF3* and *NR4A1*, as well as *IL1B* and *FOSL1*were documented.

Speculation: These gene expression patterns could represent biomarkers for the evolution of phases of JDM clinical activity, but increased sample size is needed to fully differentiate the JDM and psoriatic signatures.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Muscle Biology, Myositis and Myopathies Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Interstitial lung disease (ILD) is common in classic dermatomyositis (DM) and clinically amyopathic dermatomyositis (CADM), in which rash is present without weakness. Previous studies have shown increased mortality from ILD in CADM vs. DM due to increased rates of acute-onset lung disease. This study aimed to 1) identify the frequency of abnormal pulmonary function tests (PFTs) in patients with DM and CADM and 2) assess frequency of ILD and changes in PFTs in patients with abnormal PFTs.

Methods: Medical records of patients in an established single-center outpatient dermatology cohort were screened to identify patients with possible, probable, or definite DM based on Bohan and Peter criteria or CADM based on Sontheimer criteria, excluding overlap connective tissue disease. Charts of patients with any abnormal PFTs (FVC, TLC, or DLCO < 80% predicted) were reviewed in detail. A radiologist blinded to clinical characteristics reviewed chest CTs obtained within 1 year of the first available abnormal PFTs to identify evidence of ILD. Follow-up PFTs were recorded, with significant change defined as a 15% change in DLCO or 10% change in FVC or TLC compared to the first abnormal PFTs.

Results: 128 patients met inclusion criteria, 76 with DM and 52 with CADM. 69 (91%) patients with DM and 47 (90%) with CADM had PFTs available. Abnormal PFTs were present in 34 (46%) patients with DM and 20 (38%) with CADM ($p = 0.48$). Characteristics of these patients are shown (Table 1). A CT was available for review in 39/54 (72%) of patients with abnormal PFTs. Among those with an available CT, ILD was present in 9/23 (39%) patients with DM vs. 6/16 (38%) with CADM ($p = 0.92$). Follow-up PFTs were available for review in 38/39 (97%) patients with median follow-up of 3 years (range 0.5 to 9.5). 32/38 (84%) of patients received immunosuppression during follow-up. At last follow-up, PFTs declined significantly in 4/15 (27%) of patients with ILD and 7/23 (30%) of patients without ILD. Among those with ILD, patients with a history of acute-onset ILD but not CADM were more likely to have a decline in PFTs (Table 2). Anti-Jo-1 antibodies and inflammatory arthritis were more common in patients with PFT decline although differences were not statistically significant.

Conclusion: PFT abnormalities are common and present at similar rates in patients with DM and CADM. In patients with abnormal PFTs, CT evidence of ILD is found at baseline in less than half of patients with either DM or CADM. History of acute-onset ILD is associated with increased frequency of PFT decline. Patients with CADM are not more likely than patients with DM to have a decline in PFTs.

Table 1: Characteristics of patients with classic DM vs CADM with abnormal pulmonary function tests			
	Classic DM (n = 34)	**CADM (n = 20)**	**p-value**

The “Sleeve Sign” in Dermatomyositis

Arash Lahoutiharahdashti[1], Julie J. Paik[2], Jemima Albayda[1], Andrew Mammen[3,4] and Lisa Christopher-Stine[5], [1]Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD, [2]Division of Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD, [3]Center Tower Ste 5300, Johns Hopkins University School of Medicine, Baltimore, MD, [4]NIAMS, NIH, Bethesda, MD, [5]Ste 4100 Rm 409, Johns Hopkins University School of Medicine, Baltimore, MD
First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Muscle Biology, Myositis and Myopathies Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Dermatomyositis (DM) is a subset of idiopathic inflammatory myopathies, characterized by proximal skeletal muscle weakness and skin manifestations. Several skin eruptions have been described in DM patients including Gottron's papules, Gottron's sign, heliotrope rash, facial erythema, periungual erythema, shawl sign, V-neck sign, and holster sign. We describe a new skin eruption we have termed the "sleeve sign" observed in 27 patients with DM. To our knowledge, this typical skin finding has not been described before.

Methods:

Two hundred sixty-two patients with a Bohan and Peter diagnosis of definite, probable, or possible DM or a diagnosis of amyopathic DM by Sontheimer's criteria were evaluated in a systematic fashion including a detailed skin examination with distribution and location of cutaneous findings. All patients underwent clinical evaluation between 2004 and 2015. Demographic and clinical information were retrieved by chart review. Patients' sera were tested for myositis-specific antibodies using previously validated immunoprecipitation methods.

Results:

Twenty-seven patients (10.3%) had a history of an erythematous to violaceous macule or patch confined to the lateral aspect of the upper arm detected on physical examination. The location was compatible with the contour of the sleeves. Thus, it was labeled the "sleeve sign" (Figure 1).

Twenty-five patients (92.6 %) had dermatomyositis (44.4 % definite, 29.6 % probable, and 18.5 % possible) and 2 patients (7.4%) had amyopathic dermatomyositis. The sera from 22 patients (81.5%) were tested for all DM-specific (anti-TIF-1γ, anti-NXP2, and anti-MDA5) and anti-synthetase autoantibodies (anti-Jo1, anti-PL7/PL12, and anti-EJ/OJ). Table 1 summarizes the demographics, clinical manifestations, and myositis-specific autoantibody profile of the study population.

Conclusion:

A macular erythematous to violaceous rash (sleeve sign) may affect the lateral aspect of the upper arms. Although in our study, the sleeve sign was frequently present with other characteristic DM skin findings, the presence of this rash should raise the suspicion of dermatomyositis in the clinically appropriate setting.

Table 1- Demographic, clinical manifestations, and myositis-specific autoantibody profile of patients with sleeve sign	
Age, mean (SD)	44.5 (14.3)
Female, number (frequency)	23 (85.2%)
Race, number (frequency) Caucasian African-American Other	 22 (81.5%) 3 (11.1%) 2 (7.4)
Proximal weakness	21 (77.8%)
The frequency of the skin findings at the same visit the patient presented with sleeve sign	
Heliotrope rash	12 (44.4%)
Malar rash	14 (51.9%)
Gottron's sign	23 (85.2%)
V Sign	16 (59.3%)
Shawl Sign	15 (55.6%)
Nail-bed erythema	17 (63.0%)
Dilated capillary loops	14 (51.9%)
Holster sign	7 (25.9%)
Mechanic's hand	6 (22.2%)
Calcinosis	5 (18.5%)
Raynaud's	3 (11.1%)
Myositis-specific antibodies	
Anti-jo1	2 (10.5%)
Anti-nxp2	4 (22.2%)
Anti-TIF-1γ	13 (65.0%)
DM-specific or anti-synthetase autoantibody negative	4 (18.2%)

Investigating the Pathogenic Role of ER Stress Pathways in the Idiopathic Inflammatory Myopathies (IIM): Interrogating the Role of Micro-RNA 133a As an Important Regulator of ER Stress Activation

Adam P. Lightfoot[1], Katarzyna Goljanek-Whysall[2], Anne McArdle[1] and Robert G. Cooper[3,4], [1]Musculoskeletal Biology, University of Liverpool, Liverpool, United Kingdom, [2]University of Liverpool, Liverpool, United Kingdom, [3]Rheumatic Diseaes Center, Salford Royal Foundation Trust, University of Manchester, Salford, United Kingdom, [4]MRC/ARUK Institute of Ageing and Chronic Disease, University of Liverpool, Liverpool, United Kingdom

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Muscle Biology, Myositis and Myopathies Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The Idiopathic Inflammatory Myopathies (IIM) is a heterogeneous group of acquired autoimmune disorders, characterised by symmetrical muscle weakness. Whilst immune cells clearly play a role in muscle weakness induction in IIM, the correlation between inflammatory cell loads and the degree of muscle weakness is poor, while muscle weakness is detectable prior to inflammatory cell infiltrations. It is thus accepted that non-immune mechanisms, such as ER stress induction, are also key contributors to muscle weakness induction in IIM (Lightfoot et al. 2015). However, the mechanisms which regulate ER stress pathway activation here are poorly understood. MicroRNAs are short, non-coding RNAs whose primary role is to post-transcriptionally regulate gene expression. MicroRNAs have been described to regulate a plethora of biological processes, and dysregulation of microRNA expression has been reported in several diseases (Goljanek-Whysall et al. 2012). A study examining various myopathies reported that the expression of multiple microRNAs was dysregulated (Eisenberg et al. 2007). More recently a study examining miRNA expression in the muscle of PM, DM and IBM patients identified that expression of micro-RNA 133a was significantly downregulated in all subtypes of IIM (Georgantas et al. 2007). However, the mechanistic implication of microRNA regulation in the context of IIM remains unelucidated. Micro-RNA 133a is a muscle-specific microRNA, or "myomiR" and is predicted to regulate several genes associated with ER stress pathways. We hypothesise that, given the importance of ER stress pathway activation in IIM and the dysregulation of miR-133a in the muscle of IIM patients, microRNAs may play an important pathogenic role in IIM. Specifically, miR-133a may contribute to chronic ER stress pathway activation here, and thus represent a potential future therapeutic target to minimise non-immune cell mediated muscle weakness. **Methods:** C57Bl6 mice (6-10 months) were treated with a miR-133a mimic, a miR-133a inhibitor or a scrambled miR-133a control. The *anterior tibialis* was excised and RNA isolated and purified using standard TRizol extraction. qPCR and SDS-PAGE was used to examine changes in miR-133a and ER stress pathway gene expressions. C2C12 myotubes overexpressing MHC I was used as an experimental model of ER stress pathway activation to validate our miR-133a findings. **Results:** Our data demonstrate that downregulation of a muscle specific microRNA, i.e miR-133a, resulted in the activation of a specific arm of the ER stress pathway, as demonstrated by upregulation of expression of the ER stress receptor IRE1, and activation of the downstream transcription factor X-box binding protein 1 (XBP-1). Additionally, inhibition of miR-133a resulted in downregulation of the ER stress chaperone Grp78. **Conclusion:** These data suggest that miR-133a may be a key regulator of ER stress pathway activation in skeletal muscle, and which may have implications in the chronic ER stress pathway activation demonstrable in IIM patients.

Session Title: Muscle Biology, Myositis and Myopathies Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Pulmonary hypertension (PH) is a feared complication of the anti-synthetase syndrome (ASS) and has previously been reported to occur in 8% of the patients [1]. Prognosis is currently poor, but may be improved by earlier referral to diagnostic right heart catheterization (RHC) and therapeutic interventions. Data on non-invasive screening approaches for PH in ASS are limited. Here, the aim was to test the utility of four different and complementary PH screening approaches.

Methods:

In September 2011, 68/70 living ASS patients from the Oslo University Hospital ASS cohort were included in a cross-sectional study where pulmonary function tests (PFT), Echocardiography (Echo) and HRCT of the lungs were performed. In addition, medical reports from six dead patients with confirmed PH by RHC were analyzed. Arbitrary cut-off values for PH suspicion were defined as follows; (1) DLCO < 50 % of expected value, (2) a ratio between FVC% and DLCO% >1.6, (3) Arteria pulmonalis (A Pulm) diameter ≥ 30 mm on lung CT, (4) estimated mean pulmonary arterial pressure (mPAP) ≥ 45 mmHg by Echo. HRCT and Echo analysts were blinded to the participant's clinical status. Chi-Square test was used to evaluate statistical significance, $p<0.05$.

Results:

Median disease duration for the 68 patients was 71 months (6-362) and 97 % of the patients had been diagnosed with interstitial lung disease. Median DLCO% was 62% (range12-87), median FVC /DLCO ratio was 1.33 (0.53-3.03) and the median estimated mPAP and pulmonary artery diameters were 23 mmHg (0-98) and 29 mm (20-45), respectively. Altogether, 16/74 patients had performed RHC, confirming PH in 11/16 patients.

Values below the arbitrary PH suspicion cut-offs were frequent, most frequent was increased diameter of A Pulm, seen in 30/72 (42%) patients. Values suspicious of PH in DLCO, FVC/DLCO ratio, and estimated mPAP were seen in 34%, 28% and 17%, respectively. The correlations between the four variables and confirmed/not confirmed PH are seen in Table 1; Significant correlations were seen between all four variables and confirmed PH, most with the diameter of A Pulm.

Table 1;Correlations between different parameters and Pulmonary Artery Pressure

Parameters	Not confirmed PH	Confirmed PH	p-value
A Pulm < 30 mm, n/N(%)	42/62 (68)	0/10 (0)	<0.001
A Pulm > 30 mm, n/N(%)	20/62 (32)	10/10 (100)	
mPAP <45mmHg,n/N(%)	58/62 (94)	2/10 (20)	<0.001
mPAP >45mmHg,n/N(%)	4/62 (6)	8/10 (80)	
DLCO ≥ 50%, n/N (%)	45/60 (75)	1/10 (10)	<0.001
DLCO ≤ 50%, n/N (%)	15/60 (25)	9/10 (90)	
FVC/DLCO <1.6 n/N (%)	46/60 (77)	4/10 (40)	<0.027
FVC/DLCO >1.6 n/N(%)	14/60 (23)	6/10 (60)	

Conclusion:

Although a small number of patients with confirmed PH, this study shows significant correlation between all tested screening-tools for PH and confirmed PH. All patients (N=10) with confirmed PH had a diameter of A Pulm > 30 mm, and 8/10 had a mPAP of > 45mmHg, indicating these two methods as possible screeningtest for PH. Further studies on PH and it's predictors are most warranted.

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Muscle Biology, Myositis and Myopathies Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Nailfold capillaroscopy (NC) has been demonstrated to be an important tool in the treatment of patients with juvenile dermatomyositis (JDM) and systemic sclerosis. However, NC has been scarcely studied in adult patients with DM. Therefore we analyzed NC specifically in adult patients with early onset-DM and also evaluated the possible correlation between NC abnormalities and clinical and activity parameters of DM.

Methods: The present cross-sectional single-center study included 39 consecutive adult patients with early onset-DM (Bohan & Peter, 1975) followed in our Rheumatology outpatient clinic. The early onset was defined as DM diagnosis up to 24 months. We excluded patients with diabetes mellitus, malignancy associated-DM, amyopathic DM or other autoimmune diseases. The NC was performed using Olympus®stereomicroscope. A semiquantitative rating scale was used to score capillaroscopy changes. Myositis disease activity assessment tools were used to assess disease activity [Manual Muscle Testing (MMT), Myositis Disease Activity Assessment Visual Analogue Scales (MYOACT), Health Assessment Questionnaire (HAQ), physician's VAS, patient's VAS, serum muscle enzymes levels].

Results: The median age of patients was 42.0 (interquartile range: 36.0-55.0) years, with 69.2% Caucasian and 71.8% female gender. The median time of DM diagnosis was 1.0 (0.0-1.0) year, whereas the time duration between symptoms onset and DM diagnosis was 4.0 (3.0-12.0) months. The results presented median value of 75 (62-80) for MMT, 1.00 (0.13-2.41) for HAQ, 4.5 (3.0-5.8) cm for physician's VAS, 5.0 (2.0-6.0) cm for patient's VAS, 11 (6-21) for MYOACT, 174 (95-598) U/L for creatine kinase and 6.0 (3.8-12.0) U/L for aldolase. Concerning treatment, 92.3% were using prednisone 40 (10-60) mg/day and 76.2% at least one immunosuppressive drug. Thirty-two (82.1%) patients had scleroderma capillary (SD)-like pattern in the NC [density of 6.2 (4.0-7.6) capillaries/mm; 43.6% with severe avascular areas; 15.4% with high degree of micro-hemorrhages; 87.2% with bushy capillaries; 87.2% with dilated capillaries; 61.5% with giant capillaries, 89.7% with neoangiogenesis). The SD-like pattern correlated positively with HAQ, patient's and physician's VAS. The capillary density correlated positively with "shawl" sign, patient's and physician's VAS, whereas the neoangiogenesis correlated positively with patient's VAS, MMT, HAQ and serum creatine kinase levels (P<0.05). The micro-hemorrhages correlated negatively with pulmonary involvement, while dose of prednisone correlated negatively with SD-like pattern (P<0.05). No significant correlations between NC and other demographic, clinical and laboratory parameters were observed.

Conclusion: Similarly to JDM, the NC may provide helpful information about patients with early onset-DM by: (a) contributing to an early diagnosis and (b) correlating with disease activity parameters. Additional investigations with larger series of patients and prospective studies may be useful to reinforce our data.

Session Title: Muscle Biology, Myositis and Myopathies Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Heat shock proteins (Hsps) are chaperones playing important roles in skeletal muscle physiology, adaptation to exercise or stress, and in activation of inflammatory cells. Hsp90 expression was shown to be increased in regenerating and atrophic muscle fibers, and in macrophages and cytotoxic T-cells actively invading nonnecrotic muscle fibers in polymyositis. The aim of our study was to assess plasma Hsp90 in patients with idiopathic inflammatory myopathies (IIM) and to characterize its association with IIM-related features.

Methods: A total of 277 patients with IIM (198 females, 79 males; mean age 54.8; disease duration 4.1 years; dermatomyositis (DM, 104)/polymyositis (PM, 104)/cancer associated myositis (CAM, 42)/ necrotizing myopathy (IMNM, 27)) and 100 age-/sex-matched healthy individuals were included. Patients with PM/DM fulfilled Bohan and Peter diagnostic criteria and CAM was defined as cancer occurring within 3 years of the diagnosis of myositis. Plasma Hsp90 levels were measured by ELISA (eBioscience, Vienna, Austria). Clinical disease circumstances were evaluated by Myositis Disease Activity Assessment (MYOACT), Myositis Intention to Treat Index (MITAX), Myositis Damage Index (MDI), physician and patient global activity using visual analogue scales (VAS) and manual muscle testing (MMT8). Levels of CK, LD, ALT, *AST*and CRP were analyzed by routine laboratory techniques and IIM-associated autoantibodies by immunoprecipitation. Data are presented as median (IQR).

Results: Plasma Hsp90 levels were increased in IIM patients compared to healthy controls (20.2 (14.3-40.1) vs. 9.2 (7.2-12.6) ng/ml, $p < 0.0001$), and between individual subgroups of IIM and healthy controls (PM: 19.4 (14.5-40.4), DM: 22.4 (14.3-43.5), CAM: 19.1 (12.3-29.8), IMNM: 19.6 (15.7-50.0) ng/ml, $p < 0.0001$ for all). Hsp90 levels in all patients positively correlated with LD and AST ($r=0.551$, $p < 0.0001$; $r=0.372$, $p < 0.0001$, respectively), and there was a trend towards correlation with CK ($r=0.111$, $p=0.068$). Increased Hsp90 was associated with decreased MMT8 values ($r=-0.136$, $p=0.029$), in particular with proximal muscles. Hsp90 positively correlated with patient and doctor disease activity ($r=0.222$, $p=0.0004$; $r=0.217$, $p=0.0005$, respectively), pulmonary and muscle disease activity ($r=0.201$, $p=0.001$; $r=0.146$, $p=0.018$, respectively), MITAX and MYOACT ($r=0.175$, $p=0.005$; $r=0.159$, $p=0.012$, respectively), and with MDI extent/severity ($r=0.215$, $p=0.003$; $r=0.120$, $p=0.041$, respectively). Higher Hsp90 was found in patients with IIM-associated interstitial lung disease, cardiac involvement and dysphagia (25.4 vs. 18.9, $p=0.004$; 27.5 vs. 19.3, $p=0.004$; 25.0 vs. 18.2, $p=0.018$, respectively). Increased Hsp90 was associated with higher prednisone equivalent dose ($r=0.180$, $p=0.007$) and treatment with DMARDs (22.0 vs. 18.9, $p=0.013$).

Conclusion: We demonstrate increased Hsp90 plasma levels in IIM patients that are associated with disease activity and damage, and with the involvement of proximal skeletal muscles, the heart and lungs. Hsp90 might become a useful biomarker of disease activity and muscle involvement in IIM.

Hyaluronic Acid Injections in Knee Osteoarthritis Patients Are Associated with Delay to Knee Arthroplasty

Kevin Ong[1], Allen Anderson[2], Edmund Lau[3], Faizan Niazi[4], Anke Fierlinger[4], Steven Kurtz[1] and **Roy Altman**[5], [1]Exponent, Inc., Philadelphia, PA, [2]Tennessee Orthopaedic Alliance, Powderly, KY, [3]Exponent, Inc., Menlo Park, CA, [4]Ferring Pharmaceuticals, Inc., Parsippany, NJ, [5]David Geffen School of Medicine, UCLA, Los Angeles, CA

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Osteoarthritis - Clinical Aspects Poster I: Treatments and Metabolic Risk Factors
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Although only few nonoperative treatment options for knee osteoarthritis (OA) are available, there continues to be debate about the effectiveness of hyaluronic acid (HA) injections, particularly in light of recent clinical practice guidelines by AAOS and recommendations by OARSI, ACR, and recent systematic reviews. Thus, we investigated whether the formulation of HA may be contributing to some of the reported variation in clinical outcomes. This study evaluated whether the use of HA injections is associated with a delay to knee arthroplasty (KA) and whether there was a difference in effect size by formulation of HA injections. **Methods:** A retrospective, observational study design based on the 5% sample of Part B Medicare data from 2007 to 2012 was used to identify knee OA patients who underwent KA. The time to KA was compared between patients who were coded with HA injection use ("HA") and those who were not ("no HA"), using quantile regression with propensity score adjustment. These were further stratified by HA formulation between bioengineered HA (high molecular weight (HMW) and medium MW (MMW) Bio-HA) and non-bioengineered HA (high MW (HMW) and low MW (LMW) non-Bio-HA).

Results: A total of 23,008 knee OA patients (n=17,007 "no HA"; n=6,001 "HA") subsequently underwent KA and were included in the study. After adjusting for potential confounding patient factors and propensity scores, the "HA" cohort was found to be associated with a delay to KA of 7.1 months (95% CI: 6.6 to 7.5 months; $p<0.001$) compared to the "no HA" cohort. When compared to the "no HA" cohort, patients who were treated with HMW Bio-HA were found to have the longest time to KA over patients treated with other HA formulations (Figure 1 and Table 1). However, when comparing between HA formulations, LMW non-Bio-HA was found to have the shortest time to KA, while the remaining three formulations had similarly longer time to KA (Table 1).

Conclusion: Our analysis of elderly knee OA patients showed a significantly longer delay to KA for those who were treated with HA. The delay may provide additional time for patients to better control pre-existing conditions prior to KA, which could aid in reducing postoperative morbidity. Furthermore, there appears to be some differences in the effect of HA formulation, in particular molecular weight, on the delay to KA.

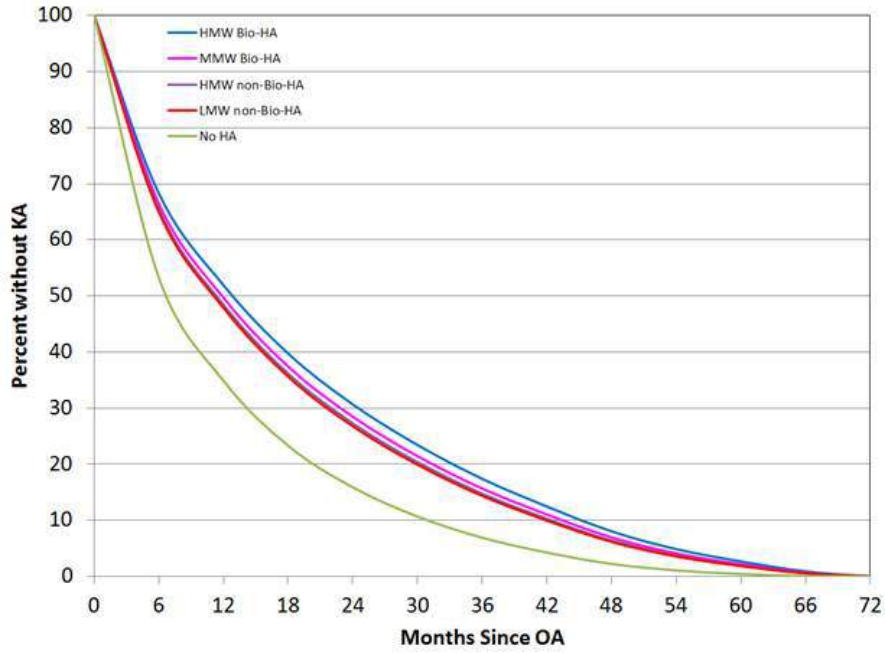

Figure 1: Survivorship curves (KA as the endpoint) for "no HA" and "HA" cohorts. **Table 1.** Difference in time to KA (in months) between patient cohorts with propensity score adjustment (*positive means more delay, negative means less delay)

Vs. no HA	**Difference in time to KA***
HMW non-Bio-HA	+6.8 mos. (p<0.001)
LMW non-Bio-HA	+7.6 mos. (p<0.001)
MMW Bio-HA	+7.5 mos. (p<0.001)
HMW Bio-HA	+8.6 mos. (p<0.001)
Vs. HMW Bio-HA	**Difference in time to KA***
HMW non-Bio-HA	+0.5 mos. (p=0.387)
LMW non-Bio-HA	-2.9 mos. (p<0.001)
MMW Bio-HA	-0.8 mos. (p=0.175)

Comparison Between Intra Articular Ozone and Placebo in the Treatment of Knee Osteoarthritis: A Multicentric, Comparative, Randomized and Double-Blinded Clinical Trial

Carlos Jesus[1], Virginia Trevisani[2,3] and Fânia Santos[4], [1]Health Evidence Based, Escola Paulista de Medicina - Universidade Federal de São Paulo, São Paulo, Brazil, [2]Health Evidence Based, Universidade Federal de São Paulo, Sâo Paulo, Brazil, [3]Health Evidence Based, Universidade Federal de São Paulo, São Paulo, Brazil, [4]Geriatrics and Gerontology Departament, Escola Paulista de Medicina - Universidade Federal de São Paulo, São Paulo, Brazil
First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Osteoarthritis - Clinical Aspects Poster I: Treatments and Metabolic Risk Factors
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoarthritis (OA) is a common, progressive condition, which is associated with severe pain, functional disability and impairment of health related quality of life, causing a significant social and economic burden. There are no currently approved OA treatments capable of slowing OA-related structural progression or delaying the need for total knee replacement. Ozone (O3) is a triatomic variety of oxygen, applied to the human organism with therapeutic aims, mainly in chronic diseases that have little benefit with allopathic medicine, like the rheumatic disease osteoarthritis. However, there are only a few articles about the use of intra articular ozone in the treatment of knee osteoarthritis and they are just case reports. ***Objective:*** To determine if knee osteoarthritis treatment with intra articular ozone is more effective than knee osteoarthritis treatment with intra articular placebo in relation to pain reduction, joint functional improvement and quality of life. ***Methods:*** Randomized, double-blinded, placebo controlled clinical trial. Ozone was generated by using an Ozone & Life O&L 3.0RM generator. Patients from treatment group received an injection of ozone 20µg/ml 10ml. Patients from placebo group received an injection of air 10 ml. Both groups were treated once a week during 8 consecutive weeks. We evaluated Visual Analogic Scale (VAS), Lequesne's Index, Timed Up and Go Test (TUG Test), SF-36 questionnaire, Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) and Geriatric Pain Measure (GPM) after allocation, after 4^{th} and 8^{th} injections and 8 weeks after the last injection. Normally distributed variables were analyzed using parametric methods and those with asymmetric distribution with nonparametric statics. It was performed an intention-to-treat analysis. ***Results:*** 98 subjects, 63 from ozone group and 35 from placebo group completed the study. Groups were similar in relation to sociodemographic data. TUG presented no significant difference between the groups. In relation to Lequesne's Index, there was a significantly statistical difference from 4^{th} week on ($p<0.001$) and that was maintained until 16^{th} week ($p<0.001$), favorable to ozone group. Similar results were observed in relation to VAS ($p<0.000$) and to GPM ($p<0.001$), showing a pain reduction and improvement in daily activities in ozone group soon after the beginning of the intervention and during the treatment. From the second evaluation on, according to SF36, there was sensible improvement in all levels of quality of life, showing that ozone had a remarkable effect on the treatment group patients' lives. ***Conclusion:*** Our study showed the efficacy of intra articular treatment of knee osteoarthritis with ozone in relation to pain reduction and improvement of joint function and life quality.

Session Title: Osteoarthritis - Clinical Aspects Poster I: Treatments and Metabolic Risk Factors

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Knee osteoarthritis (OA) is characterized by the destruction of articular cartilage, subchrondral bone alterations and varying degrees of synovitis. Current OA treatments are limited to relieving pain as there are no drug therapies approved which treat the underlying cause of the disease. The Wnt signaling pathway is known to play a central role in the formation of joint tissues and altered Wnt signaling has been associated with cartilage loss in preclinical and clinical studies.[1] SM04690 is a small molecule inhibitor of the Wnt pathway which is administered via intra-articular (IA) injection. This report provides interim safety, efficacy and biomarker data from an ongoing phase I randomized, double-blind, placebo-controlled, dose-escalation clinical trial of SM04690 in knee OA subjects.

Methods: Subjects with symptomatic, radiographic knee OA were randomized to receive a single IA injection in the target knee with either 0.03, 0.07, 0.23 mg SM04690 or placebo (volume 2mLs) in a 4:1 SM04690 (N=16):placebo (N=4) ratio. Safety, pharmacokinetics (PK), efficacy (WOMAC Total, Function, Pain subscales), and biomarker data (P1NP, β-CTXI and COMP) were collected at baseline prior to injection and during the 24-week follow-up period. Exploratory analyses of efficacy outcomes were conducted using a baseline-adjusted repeated measures analysis of covariance (ANCOVA).

Results: 61 subjects (average age 62.6 [±5.7] years, female N=41 [67%], average BMI 30.4 [±4.7] kg/m^2) were enrolled. At time of abstract submission, 41 subjects had completed the 24-week trial: Cohort 1: 0.03 mg (N=17), Cohort 2: 0.07 mg (N=16) and placebo (N=8). Cohort 3 (subjects treated with 0.23 mg [N=16] and placebo [N=4]) are ongoing and data not reported. Serum levels of SM04690 in both 0.03 and 0.07 mg groups were below limits of detection at all time points. No DLTs or SAEs were reported in the 0.03 mg cohort. 2 DLTs, paroxysmal tachycardia, (also an SAE), and increased pain were reported in 0.07 mg cohort: Both were deemed unrelated to SM04690 by safety review adjudication. 35 AEs were reported; 5 (14%) considered possibly or probably related to study drug (4 increased knee pain, 1 acne). At Week 24, improvements were seen in both 0.03 mg and 0.07 mg cohorts (respective change from baseline: WOMAC Total, -23.1 and -22.8; WOMAC Function, -16.7 and -16.2; WOMAC Pain, -4.9 and -4.5; all P<0.001) (Table). Biomarker data showed significant reduction in COMP in the 0.07 mg group at Weeks 12 (-130.13 ng/mL, P=0.001) and 24 (-127.93 ng/mL, P=0.002) (Table). There were no significant changes in COMP in the 0.03 mg group, or in β-CTX or P1NP in either 0.03 mg or 0.07 mg groups.

Conclusion: These interim data from an ongoing phase 1 trial suggest that one intra-articular injection with a novel Wnt inhibitor SM04690 into the knee in OA subjects appears safe and may be effective in reducing pain and improving

function.

Session Date: Sunday, November 8, 2015
Session Title: Osteoarthritis - Clinical Aspects Poster I: Treatments and Metabolic Risk Factors
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Knee osteoarthritis (OA) is characterized by the destruction of articular cartilage, subchrondral bone alterations and varying degrees of synovitis. Current OA treatments are limited to relieving pain as there are no drug therapies approved which treat the underlying cause of the disease. The Wnt signaling pathway is known to play a central role in the formation of joint tissues and altered Wnt signaling has been associated with cartilage loss in preclinical and clinical studies.[1] SM04690 is a small molecule inhibitor of the Wnt pathway which is administered via intra-articular (IA) injection. This report provides interim magnetic resonance imaging (MRI) data from an ongoing phase I randomized, double-blind, placebo-controlled, dose-escalation clinical trial of SM04690 in knee OA subjects.

Methods: Subjects with symptomatic, radiographic knee OA were randomized to receive a single IA injection in the target knee with either 0.03, 0.07, 0.23 mg SM04690 or placebo (volume 2mLs) in a 4:1 SM04690 (N=16):placebo (N=4) ratio. Knee MRIs were obtained with a 16 channel knee coil on a 3.0T MRI machine using a standard diagnostic protocol, and were collected at baseline visit (which could occur ≤28 days prior to study injection), Week 12 and 24. Average cartilage thickness over covered subchondral bone was reported for medial and lateral femoral condyles as well as medial and lateral tibial plateaus. Also, the average of the lowest 1% of cartilage thickness was reported for all 4 compartments. The total for both average thickness and lowest thickness were derived by summing each of the 4 compartments' observations. An exploratory analysis of change in imaging outcomes was conducted using repeated measures analysis of covariance (ANCOVA) adjusting for baseline.

Results: 61 subjects (average age 62.6 [±5.7] years, female N=41 [67%], average BMI 30.4 [±4.7] kg/m^2) were enrolled. At time of abstract submission, 41 subjects had completed the 24-week trial: Cohort 1: 0.03 mg (N=17), Cohort 2: 0.07 mg (N=16) and placebo (N=8). Cohort 2 24-week imaging data are under review and Cohort 3 (subjects treated with 0.23 mg [N=16] and placebo [N=4]) is ongoing; these data are not reported at this time. At Week 12, total average cartilage thickness decreased 0.07 mm and 0.02 mm for 0.03 mg and 0.07 mg, respectively, adjusting for the baseline value (Table). However, total average thickness of the lowest 1% increased 0.10 mm and 0.08 mm for 0.03 mg and 0.07 mg, respectively, adjusting for baseline value. Moreover, total average cartilage thickness increased 0.02 mm and total average thickness of the lowest 1% increased 0.12 mm in the 0.03 mg group at Week 24.

Conclusion: Preliminary data from this interim, exploratory analysis of MRI outcomes from an ongoing Phase 1 trial suggest that SM04690 may maintain or increase cartilage thickness, both at the site of maximal cartilage degradation as well as overall.

Session Title: Osteoarthritis - Clinical Aspects Poster I: Treatments and Metabolic Risk Factors

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Fasitibant (FAS) is a competitive, potent and selective antagonist of the bradykinin B2 receptor administered IA for SOAK. In response to positive outcomes in a previous exploratory RCT, a phase 2 double blind RCT to evaluate FAS, given as single IA injection at three different doses *versus* placebo, was conducted at 25 clinical sites in Europe and US.

Methods:

Patients with moderate to severe symptomatic knee OA were randomized (1:1:1:1) to single IA injections of either FAS (1 mg, 2.5 mg or 5 mg) or Placebo (saline) given as 1 ml solution. IA administration was performed by clinical investigators experienced with the use of the IA injection route.

The efficacy variable of primary interest was the change in pain intensity evaluated as change of WOMAC VA 3.1 A (total pain) subscore (A1-5, VAS 0-500 mm) from baseline over 2 weeks post treatment. Secondary measures included WOMAC Index, WOMAC stiffness (B) and functional impairment (C) subscores, pain at rest, pain after 15 meters walk (100 mm VAS) and patient global assessment (PGA) scores.

Safety was assessed by monitoring of lab tests, vital signs, ECG, physical examinations including the target knee, adverse events and concomitant medications.

Results:

All randomized patients (Intention-to-Treat-ITT, n=431) were allocated to the study treatment; with FAS 1mg (n=108), FAS 2.5 mg (n=108), FAS 5mg (n=107) and Placebo (n=108), with balanced demographic and baseline characteristics across treatment arms. Single IA injections of fasitibant did not significantly discriminate for WOMAC A pain over Placebo, with all treatments showing a decrease at week 1 and at week 2 post administration (Table 1). The time to first use of rescue medication (secondary endpoint) discriminated significant from placebo in the fasitibant 5 mg dose group (Kaplan-Meyer analysis; $p< 0.0154$). Fasitibant was well tolerated. There were no related SAEs. The majority of TESSs were mild or moderate. Severe TESSs occurred only in 12 patients (2.8%). Only 29 TESSs were considered related, most of them in placebo group (n=13). Lab tests, ECGs and vital signs were in general unremarkable and similar between treatments.

Conclusion:

The primary efficacy analysis has not shown any statistical significant evidence of superiority of fasitibant at any dose *over*Placebo on pain reduction from baseline over 2 weeks after randomisation; however fasitibant 5 mg treated patients used statistically significant less rescue medication, which might be considered as an indirect evidence of its efficacy. The very high placebo response as well as the long duration of OA-symptoms (8.5±7.06 years) in all treatment groups may have contributed to the lack of efficacy as reported for other RCT in patients with symptomatic knee OA. Fasitibant was in general safe and local tolerability at the target knee was good.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Osteoarthritis - Clinical Aspects Poster I: Treatments and Metabolic Risk Factors

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

A randomized, double-blind, placebo-controlled phase 1b clinical trial of sprifermin (rhFGF18) in knee OA assessed central medial tibio-femoral compartment cartilage thickness on quantitative MRI (qMRI) as structural primary endpoint and reported no statistically significant response (Lohmander et al. Arthritis Rheumatol 2014;66:1820-31). However, the drug was associated with dose-dependent effects in the lateral tibio-femoral compartment.

Methods:

Sprifermin was administered in 2 cycles of 3 weekly intra-articular injections at 10, 30, and 100 µg. MRIs were assessed semi-quantitatively (sq) by expert radiologists. The post-hoc analysis focused on structural changes in the 100 µg subgroup (n=57) and matching placebo subgroup (n=18) evaluating changes from baseline (BL) up to 12 months. Assessed were cartilage morphology (lesions), bone marrow lesions (BMLs), meniscal damage and extrusion, Hoffa- and effusion-synovitis using the semiquantitative WORMS scoring system. Analyses included multi-dimensional assessment: Delta subregional [DSR] approach (including number of subregions [SRs] showing worsening (>0), no change (0) and improvement (<0), negative values indicating improvement and positive values indicating worsening) and Delta-sum [DSM] approach (including total sum of grades for SRs showing worsening, no change and improvement). Analyses were performed on a whole knee level and separately for medial and lateral tibio-femoral joints (MTFJ, LTFJ), and patello-femoral joint (PFJ). Mann−Whitney−Wilcoxon tests assessed differences between treatment groups. P-values were not adjusted for multiple testing.

Results:

At BL, no significant differences were observed between placebo and treatment groups for all sqMRI parameters, except for whole knee cartilage morphology (29.97 ± [standard deviation] 16.00 for treatment vs 21.11 ± 14.76 vs placebo, p=0.040). For change in cartilage morphology, statistically significant differences were seen from BL to 12 months using DSR approach, with lower values on sprifermin (corresponding to less worsening) vs placebo for the PFJ (0.22 ± 0.55 vs treatment 0.02 ± 0.23, p=0.046), with similar results observed using the DSM approach. Although not statistically significant, less worsening vs placebo was observed in the LTFJ (DSR, 0.11 ± 0.32 vs treatment 0.05 ± 0.48). For change in BMLs, statistically significant changes from 6 to 12 months were observed for the whole knee, with negative values indicating improvement and positive values worsening (placebo 0.44 ± 1.20 vs treatment −0.14 ± 1.24, p=0.042), and borderline for LTFJ (0.22 ± 0.65 vs treatment -0.05 ± 0.80 p=0.064) using the DSR approach. No notable changes from BL were observed for remaining analyzed parameters.

Conclusion:

Cartilage morphology showed less worsening from BL to 12 months and BMLs showed improvement after 100 ug Sprifermin treatment from 6 to 12 months compared to placebo. The potential effect of Sprifermin on subchondral bone (BMLs) is a novel finding that warrants further exploration. This finding may be explained by altered loading as a result of cartilage surface restoration or by direct effects on bone.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Osteoarthritis - Clinical Aspects Poster I: Treatments and Metabolic Risk Factors
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: To examine the effect of vitamin D supplementation on synovial inflammation in patients with knee osteoarthritis (OA) and low vitamin D levels over 24 months.

Methods: In a multi-center, parallel, randomized, placebo-controlled and double-blind trial, symptomatic knee OA patients with a low 25-(OH)D level (12.5 to 60 nmol/l) were recruited. 413 patients (age 63.2±7.0 years, 208 females) were allocated monthly to a 50,000IU vitamin D_3 capsule (n=209) or placebo (n=204) for 24 months. In this post-hoc analysis, the primary outcome was change in total knee effusion-synovitis volume assessed using magnetic resonance imaging (MRI). Secondary outcomes included change in regional effusion-synovitis volume, change in semi-quantitative effusion-synovitis score and dichotomized minimal clinical important improvement in effusion-synovitis volume. Generalized linear regression models were used to compare differences between groups in both intention-to-treat and per protocol analyzes.

Results: Serum 25-(OH)D level increased markedly in the vitamin D group (40.6 nmol/l) compared with placebo (6.7 nmol/l) over 24 months. Overall total effusion-synovitis volume significantly increased in all patients (baseline: 8.0 ± 8.5 ml, follow-up: 9.0 ± 10.5 ml), but the increase was less in the vitamin D group than controls (0.26 ml (16% p.a.) versus 2.20 ml (60% p.a.), $p = 0.02$). This effect was evident in suprapatellar pouch (0.04 ml (19% p.a.) versus 2.53 ml (148% p.a.), $p = 0.03$), but not in central region (0.12 ml (10% p.a.) versus 0.40 ml (39% p.a.), $p = 0.12$). The likelihood of achieving a minimal clinical important improvement in total (relative risk: 1.22 p.a.; $p = 0.05$) and suprapatellar (relative risk: 1.27 p.a.; $p = 0.03$) effusion-synovitis were significantly higher in vitamin D group compared to placebo. Additionally, change in 25-(OH)D levels was negatively associated with change in total effusion-synovitis volume in whole sample ($p = 0.09$). Adverse events were similar.

Conclusion: Supplementation of vitamin D in knee OA patients over 24 months can reduce the worsening of knee joint effusion-synovitis, especially in suprapatellar pouch.

Relation of Incident Bisphosphonate Use to Trajectory of Joint-Space

Width

Session Date: Sunday, November 8, 2015
Session Title: Osteoarthritis - Clinical Aspects Poster I: Treatments and Metabolic Risk Factors
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Trials regarding bisphosphonate (Bisph) effects in knee osteoarthritis (OA) have been conflicting, and are unable to provide insights into long-term effects. While Bisph may have beneficial articular cartilage effects, there are theoretical concerns about their long-term effects on bone due to decreased bone turnover, which could have consequences for bone's biomechanical properties. We therefore sought to evaluate the effects of incident Bisph use (to avoid prevalent user bias) on joint-space width (JSW) among knees with OA over a 4-year period.

Methods: OAI participants had bilateral fixed-flexion knee x-rays and clinical factors assessed at 0, 12, 24, 36, and 48 mo. We limited our sample to females with tibiofemoral radiographic OA (TFROA) at baseline, and defined incident Bisph users as those that did not report using a Bisph at baseline, but subsequently did so. Quantitative radiographic JSW was assessed with software that delineated the margins of the femoral condyle and tibial plateau and measured JSW at fixed locations with respect to an anatomical coordinate system. We focused on medial JSW at x=0.250 (ICC >0.99) among all knees, and stratified by baseline radiographic OA (ROA) status. To be included, JSW measurements had to occur in ≥2 visits, with appropriate film quality, beam angle, and tibial plateau-rim distance. We agnostically categorized knees into distinct groups of JSW loss using a group-based semiparametric mixture model to identify these trajectories (SAS macro proc traj). This method does not force data to fit a particular model, and improves precision by using several measurements. Follow-up time for the trajectory determination started at the visit at which incident Bisph use was identified, or at the 12-mo visit for non-users. The number of distinct trajectories was determined by optimal model fit statistics (BIC), and we required trajectory differences of ≥10%. We then examined the relation of incident Bisph use to JSW trajectory groups using logistic regression, adjusting for age, BMI, knee injury, education, prior fracture, and baseline KL grade.

Results: There were a total of 1303 female subjects who had TFROA at baseline and the necessary JSW readings, with 65 incident users. Three distinct trajectory groups were identified (**Figure**), with rates of JSW loss being 0.23 mm/yr for group 1 (21.4% of the sample), 0.11 mm/yr for group 2 (53.9%), and 0.06 mm/yr for group 3 (24.7%). Incident Bisph users were less likely to be in group 1 (worst group) than group 3 (best group) compared with non-users, though this was not statistically significant (adj. OR 0.60, 95% CI 0.26-1.04). Similar results were found for incident Bisph users in group 2 vs. group 3 (adj. OR 0.65, 95% CI 0.34-1.24).

Conclusion: Incident Bisph use may be associated with a lower rate of JSW loss, but we lack sufficient precision to definitively assess this relation.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Osteoarthritis - Clinical Aspects Poster I: Treatments and Metabolic Risk Factors

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: ABT-981 is a novel human Dual-Variable Domain Immunoglobulin (DVD-Ig™) that inhibits interleukin (IL)-1α and IL-1β. The purpose of this study is to evaluate IL-1α and IL-1β protein levels in serum, and IL-1α, IL-1β, and IL-1Ra (IL-1 receptor antagonist) mRNA levels in peripheral blood leukocytes (PBLs) in patients with knee osteoarthritis (OA).

Methods: In a randomized, double-blind, placebo (PBO)-controlled, multiple dose study (NCT01668511), 27 knee OA patients received ABT-981 (0.3, 1, or 3 mg/kg; n=7 each group) or PBO (n=6) subcutaneously every 2 wks (4 doses total). Serum samples were collected on days 1 (predose), 5, 15, 19, 29, 33, 43, 47, 57, and 113. Peripheral blood was collected on days 1, 5, 57, and 113. Imperacer® Immuno-PCR assays (Chimera Biotec) were used to detect free protein concentration of IL-1α/IL-1β in serum. Total RNA isolated from PBLs was converted to cDNA for quantitative PCR detection of IL-1a, IL-1b, and IL-1Ra mRNAs. Changes in biomarkers in ABT-981 groups were compared with baseline (BL) and PBO. Repeated measures analysis was performed using SAS 9.2. Adjusted *P* values were calculated using Bonferroni method.

Results: Mean BL serum IL-1α level was 7.1 pg/mL. In all ABT-981 groups serum IL-1α levels significantly (P<.001) decreased from day 5 to 57 (2 wks after last dose), a decrease of 75-95% from BL. Decreases were maintained until day 113 in 1 (-69.8%, P<.001) and 3 mg/kg groups (-58.3%, P=.005). IL-1α level in 0.3 mg/kg group recovered to near BL level on day 113. Compared with PBO, serum IL-1α levels in all ABT-981 groups were significantly decreased from day 5 to 113 (P<.001). Mean BL serum IL-1β level was 0.46 pg/mL. In the 1 and 3 mg/kg groups serum IL-1β levels significantly decreased 48.7-87.1% from BL (P≤.01) throughout the study. Compared with PBO, serum IL-1β levels were significantly decreased in the 1 and 3 mg/kg groups (P<.001), and a downward trend was observed in 0.3 mg/kg group (P=.034). PBL IL-1a mRNA was undetectable in all dose groups and at all time points. At day 5, IL-1b mRNA expression significantly decreased in 3 mg/kg group (P<.001) and a downward trend in 1 mg/kg group (P=.092). IL-1Ra mRNA expression levels in PBLs did not show dose dependent changes in the treatment groups.

Conclusion: Simultaneous robust inhibition serum of IL-1α and IL-1β with ABT-981 was observed in this study in a dose-dependent manner. The prolonged inhibition of IL-1α and IL-1β in the 1 and 3 mg/kg groups indicates a long lasting biological effect of ABT-981 even after the drug has been ~97% cleared from the system (day 113). The dose-dependent decrease of IL-1b mRNA expression in PBLs on day 5 coincides with decrease in serum IL-1β protein. However, transient decrease in PBL IL-1b mRNA, despite persistent decreases in serum IL-1a and IL-1b levels, suggest that other cytokines also play a role in regulating IL-1b transcription in these cells. In conclusion, serum levels of IL-1a and IL-1b proteins and PBL IL-1b mRNA are dose-dependently inhibited in knee OA subjects dosed with ABT-981 and represent candidate measurements of target engagement.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Osteoarthritis - Clinical Aspects Poster I: Treatments and Metabolic Risk Factors

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Interleukin (IL)-1 is a catabolic cytokine that plays an important role in pathogenesis and progression of osteoarthritis (OA). Two phase 1 clinical trials investigated the use of a novel human dual-variable domain–immunoglobulin (DVD-Ig™) simultaneously targeting IL-1α and IL-1β (ABT-981).

Methods: ABT-981 was evaluated in a randomized, double-blind, placebo (PBO)-controlled single ascending dose (SAD) trial and a multiple ascending dose (MAD) trial (NCT01668511). In the SAD trial, 56 healthy subjects were divided into 7 cohorts. Each cohort received single intravenous (IV) or subcutaneous (SC) dose of ABT-981 (0.3, 1, 3, 10 mg/kg IV or 0.3, 1, 3 mg/kg SC) or PBO in a 6:2 ratio. In the MAD trial, 36 patients with mild/moderate knee OA

were divided into 4 cohorts. Cohorts 1–3 received ABT-981 (0.3, 1, 3 mg/kg) or PBO in a 7:2 ratio every 2 weeks (EOW) for total of 4 SC injections; cohort 4 received ABT-981 (3 mg/kg) or PBO in 7:2 ratio every 4 weeks for total of 3 SC injections. Safety, tolerability, pharmacokinetics (PK), and anti-drug antibodies (ADAs)were assessed in both trials. In addition, a panel of serum/urine biomarkers of target engagement, inflammation and joint degradation were evaluated in the MAD trial.

Results: The incidence of adverse events (AEs) was similar with single-dose ABT-981 vs PBO via IV (66.7% vs 50.0%) or SC (55.6% vs 66.7%) routes and multiple SC doses of ABT-981 vs PBO (53.6% vs 62.5%). The most common AEs with ABT-981 vs PBO was diarrhea (IV: 20.8% vs 12.5%) and headache (SC: 22.2% vs 0%) in the first trial, and injection-site reaction (17.9% vs 0%) in the second trial. In MAD trial, absolute neutrophil count (ANC) decreased dose-dependently, starting at 48 hours and reaching nadir by 14 days; lowest ANC values observed with 3 mg/kg. One patient had a transient grade 2 neutropenia after 1 dose in 3 mg/kg EOW group, along with serious AE of grade 3 bronchitis/viral syndrome both considered possibly study-drug related.

In MAD trial, ABT-981 at all 3 doses significantly reduced serum levels of high-sensitivity C-reactive protein (hsCRP; $P<0.05$), matrix metalloproteinase (MMP)-degraded type 1 collagen (C1M; $P<0.05$ at 1 and 3 mg/kg), IL-1α ($P<0.001$), and IL-1β ($P<0.001$). Serum concentrations of MMP-degraded type 3 collagen (C3M; 1 and 3 mg/kg) and MMP-degraded CRP (CRPM; 3 mg/kg) demonstrated decreasing trends ($0.05<P<0.1$) with ABT-981 treatment but did not reach statistical significance.

Conclusion: The results of these phase 1 trials demonstrate that ABT-981 was well tolerated and had dose-proportional PK in healthy subjects and patients with knee OA. The similar safety profiles between ABT-981 and PBO support phase 2 investigation of ABT-981 in patients with OA. Through simultaneous inhibition of IL-1α and IL-1β in patients with OA, ABT-981 significantly reduced serum hsCRP levels, indicating a reduction in systemic inflammation, and C1M levels, indicating a dampening of inflammation-mediated joint destruction. Additionally, the observed serum C1M, C3M and CRPM decreases suggest that ABT-981 may ameliorate inflammation-mediated tissue destruction and chronic tissue inflammation in patients with inflammation-driven OA.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Osteoarthritis - Clinical Aspects Poster I: Treatments and Metabolic Risk Factors
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoarthritis (OA) is highly prevalent in the elderly, with the knee being the most commonly

affected joint in this population. Knee braces are often used to prevent common problems in knees during daily activities. The purpose of these devices is to decrease pain and improve functionality. In the literature some studies have tested the effectiveness of unloader brace for valgus or varus. However, the braces most used in our clinical setting and the less costly ones have not been evaluated in quality studies in the literature. There are no studies that compared the effectiveness between the knee brace with metal hinges (no alignment) and knee brace without metal hinges (neoprene sleeve). The purpose is to evaluate the effectiveness of knee braces on pain, function and quality of life in the elderly with knee OA.

Methods: Elderly with knee OA, both genders, with pain scale between 3-7cm on a 10cm pain numeric scale were included. Of the 222 patients screened, 120 met the eligibility criteria and were randomized to the groups: neoprene sleeve (without metal hinges); brace (with metal hinges - no alignment) or control group (CG). The groups neoprene sleeve (NSG) and brace (BG) received knee brace and were instructed to use it in daily activities, every day, during three months. Assessment for pain (NPS), function (WOMAC and Knee Lequesne), quality of life (SF-36) and performance tests (6MWT, TUGT and FTSS) were done at baseline and after 45, 90 and 180 days by a blinded assessor.

Results: Forty patients were randomly assigned to the each group. At baseline the groups were homogeneous for all measures, except for gender where the CG had more women and the pain domain of SF-36 where pain was higher in the CG. The analysis between the groups using ANOVA for repeated measures for pain (NPS), show statistically significant difference between groups over time (p=0,049), with the BG showing better results. Statistically significant differences were found between groups over time for: function - WOMAC questionnaire (global, p=0,005; pain, p=0,004 and function, p<0,001) and Knee Lequesne (p= 0,009) and quality of life - functional capacity domain the SF-36 (0,046) with better results to BG.

Conclusion: The knee brace was effective in improving pain, function and some aspects of quality of life in elderly with knee OA.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Osteoarthritis - Clinical Aspects Poster I: Treatments and Metabolic Risk Factors

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Osteoarthritis (OA) remains a debilitating burden for patients and a challenge to their physicians, as there is no known cure. Obesity has been linked to OA progression and is a possible modifiable risk factor. Consequently patients undergoing bariatric surgery may help elucidate the complex relationship of massive weight loss in patients with OA. This is the first randomized, controlled study that will evaluate the effects of massive weight loss through bariatric surgery on long-term quality of life for obese patients with OA.

Methods:

Medical records of the 150 subjects in the STAMPEDE trial were individually reviewed for documented evidence of OA. STAMPEDE is a randomized, controlled trial that evaluated the efficacy of medical therapy alone (n=50) versus medical therapy in combination with bariatric surgery (n=100) in 150 obese patients with uncontrolled Type II diabetes. The criteria used for OA diagnosis for each patient included one or more of the following: American College of Rheumatology criteria for knee or hip OA (26.9%); radiographic evidence of degenerative change in the hip, knee, ankle, foot or spine (37.3%); or physician documented OA (35.8%). A total of 67 OA patients were included: 18 in the medical group and 49 in the surgical. Demographics at baseline were similar between both groups with no significant differences in patient characteristics (mean age 51, female 44/67, mean BMI 36.6). Linear mixed effect models were used to compare changes in SF-36 scale scores at 1 and 3 years between surgical and medical groups and were adjusted for baseline scores. Analyses were performed using SAS software (version 9.3; Cary, NC).

Results:

At 1 year following intervention, patients who received bariatric surgery when compared to those treated with medical management alone demonstrated statistically significant improvements in the following SF-36 domains: physical functioning, general health, and energy/fatigue. Improvement in the overall physical component score was also statistically significant. At 3 years post-intervention, although improvements were preserved in these domains, only the general health category sustained statistical significance. (See Table 1)

Conclusion:

These results demonstrate that massive weight loss following bariatric surgery has the potential to greatly improve the quality of life for patients suffering from osteoarthritis. Although statistical significance was not preserved for all SF 36

domains at 3 year follow-up, statistical trends in these domains at 3 years reflect similar improvements from 1 year. Further study elucidating factors such as activity level, maintenance of weight loss, and metabolic cytokines, may need to be performed to understand how we can preserve the impacts of bariatric surgery.

Session Title: Osteoarthritis - Clinical Aspects Poster I: Treatments and Metabolic Risk Factors

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Medical treatment for knee osteoarthritis (KOA) can be limited and risk morbidity. Weight loss

reduces the arthritis burden and may preclude aggressive treatment. Bariatric surgery trumps diet/exercise for sustainable weight loss; studies suggest improvement in KOA pain long after surgery. We prospectively evaluate the prevalence of painful KOA in obesity and track the effect of bariatrics on knee pain and function. Our hypothesis is that successful weight loss surgery decreases the need for KOA management.

Methods: We screened patients prior to bariatric surgery, targeting knee pain for ≥1 month and a visual analog scale pain ≥30mm. We excluded those with lupus, inflammatory arthritis, psoriasis, or bilateral total knee replacements. Pre-op assessments included BMI, Radiographic severity by Kellgren-Lawrence (KL) grade, questionnaires for knee pain/function (i.e. Knee Injury and Osteoarthritis Outcome Score), and an inventory of KOA treatment – including visits to musculoskeletal subspecialists, medication (oral/topical/intraarticular) and physical therapy. We reassessed patients at 1, 3, 6 and 12 months post surgery, also calculating percent excess weight loss (%EWL).

Results: Of 536 patients considering bariatric surgery, we found 308 with knee pain and enrolled 176 (91.5% female; mean BMI 43.6 kg/m^2±7, range 32-61; mean age 42 ±11, range 18-73). Radiographic severity was well distributed (KL0-KL4). Higher KL grade and BMI correlated with worse pre-op symptoms (data not shown). Patients with worse baseline KL scores visited specialists more often (KL0=33% vs KL3-4=72%, p=0.001) and were more likely to use at least one prescribed treatment (KL0=19% vs KL3-4=57%, p=0.001).

For the 150 patients who completed bariatric surgery, average knee pain and function improved at each post-operative interval, correlating with %EWL sustained over time (data not shown). We found a marked decrease in treatment used at the intervals, including the 6 month followup. The percent of patients using over the counter analgesics dropped from 87.5% to 47.2% (p<0.0001), visits to specialists fell from 55.7% to 24.7% (p<0.0001), and patients needing the various prescribed treatments decreased from 40.3% to 12.4% (p<0.0001).

While the attenuated need for KOA treatment trended with %EWL, those with post-op BMI >40 had an increased need for knee specialists - up from 33.3% to 71.4% (post-op month 1 to 12) with a pre-op baseline 53.8%. Conversely, specialist visits for patients with a BMI <40 only rose from 26.8% to 28.6% with a pre-op baseline of 58.6%. Prescription KOA treatment in the post-op BMI>40 group also rose from 11.1% to 43% (post-op month 1 to 12) from pre-op baseline 38.7%, while those patients remaining under a BMI of 40 saw their use of prescription KOA treatment fall from 17.1% to 14.3% with pre-op baseline 42.9%.

Conclusion: The improvement in KOA symptoms from bariatric weight loss is reflected by a significantly decreased need for treatment. This reduction is sustained over time except in the patients whose BMI remains above 40. While radiographic severity correlates with patients' treatment patterns at baseline, it does not appear to limit their ability to decrease knee treatment with successful weight loss surgery.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Osteoarthritis - Clinical Aspects Poster I: Treatments and Metabolic Risk Factors

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Total knee and hip arthroplasty (TKA and THA) are very common surgeries performed in patients who suffer from pain and functional limitation due to symptomatic arthritis, when medical management has failed. These surgeries are usually elective, and are associated with excellent outcomes including significant improvement in function, quality of life and reduction in pain severity. Smoking is a modifiable risk factor for patients failing to improve dramatically after a Total Hip Arthroplasty or Total Knee Arthroplasty surgeries. Our objective was to assess the benefits and harms of perioperative smoking cessation interventions on outcomes and complications after knee or hip replacement.

Methods: An expert librarian searched six databases for any clinical trials of relevance, including the Cochrane Central Register of Controlled Trials (CENTRAL), OVID MEDLINE, CINAHL, EMBASE, Science Citation Index and Current Controlled Trials databases. Studies were included if they used perioperative smoking cessation as an intervention in patients undergoing TKA/THA, were randomized or quasi-randomized and provided clinical outcomes. Two review authors independently reviewed all titles and abstracts, selected appropriate studies for full review and reviewed the full-text articles for the final selection of included studies. For each study, they independently abstracted study characteristics, safety and efficacy data and performed risk of bias assessment. Disagreements were resolved by consensus. The primary outcomes of interest were wound complications, revision or reoperation rate, any postoperative complication within 30-days of the surgery, venous thromboembolism, death, function: as assessed by validated outcome and pain.

Results: Three RCTs with 311 participants were included that had the data for the outcomes comparing Counselling/Nicotine replacement versus No counselling/Smoking cessation program. The outcomes of interest found to be statistically significantly associated with Smoking cessation interventions were postoperative complications within 30 days of arthroplasty(OR= 0.23) and smoking cessation after surgery (4 weeks,OR= 9.06; 1 year,OR= 6.5; after 1 year, OR= 0.15). Detailed data results are shown in Table. 1

Conclusion: With an overall high grade of evidence, Perioperative smoking cessation therapy is significantly more efficacious than placebo in preventing incidence of complications after knee or hip replacement. Long-term surveillance studies are needed for safety assessment.

Session Title: Osteoarthritis - Clinical Aspects Poster I: Treatments and Metabolic Risk Factors

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Historically, persons with knee OA considered for total knee replacement (TKR) have had severe pain, as reflected in high WOMAC scores, in addition to extensive structural changes and limited mobility. The WOMAC Pain scale captures basic mobility domains, including pain at rest (sitting or lying down), standing, walking, and using stairs. More recently, patients undergoing TKR have had lower WOMAC Pain scores, raising questions about

the appropriateness of TKR in these patients. We hypothesized that pain in TKR patients with low WOMAC pain scores is provoked by more demanding activities such as kneeling, twisting, and squatting. Difficulty with these activities may compromise their quality of life and lead to TKR. We sought to evaluate the degree of difficulty with more rigorous recreational activities in persons undergoing TKR with low, medium, and high levels of WOMAC Pain.

Methods: We used baseline data from the Study of Physical Activity Rewards after Knee Surgery (SPARKS). Participants completed baseline questionnaires within 8 weeks prior to TKR, which included the WOMAC Pain and Knee Injury and Osteoarthritis Outcomes Score (KOOS) Sports and Recreational Activity scales. We stratified subjects into three groups according to WOMAC Pain scores (0–100, 100 worst): Low (<25), Medium (26–40), and High (>40). Within each pain group we assessed the difficulty subjects reported with going up and down stairs, twisting or pivoting, kneeling, squatting, and running.

Results: The sample consisted of 140 persons scheduled to undergo TKR, with an average age of 66 (SD 8) years. The mean WOMAC Pain score was 42 (SD 20). 22% of study participants were in the Low Pain group, 31% in the Medium Pain group, and 47% in the High Pain group. Those with lower WOMAC Pain scores tended to be older: mean age 68 years for those in Low Pain compared to 63 years for those in High Pain. 42% of patients in the Low Pain group reported at least moderate pain using stairs, compared to 91% and 100% of those in the Medium and High Pain groups (Figure). About half of patients in the Low Pain group reported severe or extreme difficulty with squatting, kneeling, or running, while an additional 30% reported moderate difficulty with those same tasks.

Conclusion: Persons with low or medium WOMAC Pain undergoing TKR seldom report pain with basic mobility yet frequently report substantial difficulty with more demanding daily activities, such as using stairs, kneeling, and squatting. TKR is likely to allow these patients to regain the ability to perform these activities that are fundamental to their quality of life. Determining the effectiveness of TKR based on improvements in WOMAC Pain may be limited in patients with low preoperative WOMAC pain scores. Assessment of TKR effectiveness should consider improvement in the ability to perform more demanding but important daily activities such as kneeling, squatting and using stairs.

Figure. Proportion of patients reporting difficulty performing basic mobility tasks measured by the WOMAC and more demanding activities measured by the KOOS in patients scheduled for TKR, stratified by level of WOMAC Pain

Session Title: Osteoarthritis - Clinical Aspects Poster I: Treatments and Metabolic Risk Factors

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Accelerated knee osteoarthritis (AKOA) may be a unique subset of knee osteoarthritis (KOA) that is associated with a knee injury and greater age, body mass index (BMI), and knee pain. There are several definitions of AKOA, making it challenging to understand this phenotype. It is important to compare the performance of these AKOA definitions. Therefore, we evaluated agreement among several definitions of AKOA and construct validity by comparing their individual associations with injury, age, obesity, and knee pain.

Methods: We selected knees from the Osteoarthritis Initiative (OAI) that had no radiographic KOA (Kellgren-Lawrence [KL]=0 or 1) at baseline and had quantitative medial joint space width (JSW) measures on high-quality radiographs at >2 consecutive visits (n=1,061 knees, 738 participants). Quantitative medial JSW was based on a semi-automated method and location specific (x=0.25). We compared a KL-based definition of AKOA, which accounts for changes throughout a knee, to 4 JSW-based definitions that are derived from previous latent class analyses: 1) stringent JSW (averaged): average JSW loss >1.05 mm/year over 4 years, 2) stringent JSW (consistent): JSW loss >1.05 mm/year for >2 years, 3) lenient JSW (averaged): average JSW loss >0.25 mm/year over 4 years, and 4) lenient JSW (consistent): JSW loss >0.25 mm/year for >2 years. We also defined AKOA as progression from no radiographic KOA to end-stage KOA (KL=3 or 4) within 4 years. We calculated kappa statistics between the JSW-based definitions and KL-based definition of AKOA. We then examined how the different definitions influenced the effect size of group differences (AKOA or no AKOA) of an injury during the first four years of the OAI, baseline age, baseline BMI, and average WOMAC pain score from baseline and the first four annual visits as a form of construct validity.

Results: Over 4 years the incidence rate of AKOA was 0.7%, 1.2%, 18.1%, 24.7%, and 11.2% based on the stringent JSW (averaged and consistent), lenient JSW (averaged and consistent), and KL-based definitions. Everyone meeting the stringent JSW definition also met the KL-based definition. There was fair-moderate agreement between the lenient JSW (averaged) and KL-based definitions. KL-based definition led to larger effect sizes for injury, age, BMI, and average pain.

Conclusion: A KL-based definition of AKOA may be ideal because it offers greater effect estimates for known risk factors for the condition. The performance of the KL-based definition may be related to the broader definition of joint deterioration compared with those focused on just joint space alone.

Table 1. Low level of agreement between the JSW-based definition of accelerated knee osteoarthritis (KOA) and KL-based definition of accelerated KOA.

	Average JSW Loss >1.05 mm/year		2+ Years with JSW Loss > 1.05 mm		Average JSW Loss >0.25 mm/year		2+ Years with JSW Loss > 0.25 mm

Session Title: Osteoarthritis - Clinical Aspects Poster I: Treatments and Metabolic Risk Factors

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Accelerated knee osteoarthritis (AKOA) may be a unique subset of knee osteoarthritis (KOA). AKOA is more common among those who are older, overweight, or had a recent knee injury. These three risk factors interact to exacerbate an individual's risk for AKOA. Identifying which subset of individuals are at most risk for AKOA will help clinicians recognize patients that need more frequent follow-up visits to ensure early detection of AKOA. Therefore, we explored age and body mass index (BMI) to identify a subset of individuals who are at high risk for AKOA compared with common KOA.

Methods: In the Osteoarthritis Initiative we studied participants without KOA on their baseline radiographs (Kellgren-Lawrence [KL] < 2). We compared 2 groups: 1) AKOA: > 1 knee progressed to end-stage KOA (KL Grade 3 or 4) within 48 months and 2) common KOA: > 1 knee increased in radiographic scoring within 48 months (excluding those with AKOA). Age and BMI were collected at the baseline visit. A recent knee injury was a self-reported injury within a year prior to a knee meeting the definition of AKOA or common KOA. We reviewed 3-dimensional surface and contour graphs with age, BMI, and probability of AKOA versus KOA on the axes to identify groups that have the highest probability of AKOA compared with common KOA (see Figure). After we identified two possible subsets as high risk we conducted a logistic regression with AKOA as the outcome and age-BMI groups as the predictor

(adjusting for sex and recent knee injury). We also explored stratified analyses among those with and without a recent knee injury.

Results: Among 1,637 participants, 52 (3.2%) individuals had AKOA and 184 (11.2%) had common KOA. We identified two high-risk sets of individuals (Figure 1B): 1) individuals > 65 years of age with BMI < 35kg/m^2 (n = 64, 27%) and 2) individuals < 65 years of age with BMI > 32.5 kg/m^2 (n = 43, 18%). We defined all other participants as low risk. Overall, older individuals with a BMI < 35kg/m^2 were 3.5 times more likely to develop AKOA instead of common KOA than individuals at low risk (see Table). In contrast, younger individuals with a BMI > 32.5 kg/m^{2}were not statistically more likely to develop AKOA instead of common KOA. These findings were consistent among those with and without a recent knee injury (see Table).

Conclusion: While older age and greater BMI are associated with AKOA we found that older individuals with a BMI < 35kg/m^{2}were more likely to develop AKOA than common KOA. Individuals with these characteristics who also report knee pain should be carefully monitored to detect early signs of AKOA.

Figure 1. Probability of Accelerated Knee Osteoarthritis (AKOA) Compared with Common Knee Osteoarthritis (KOA) by Age and Body Mass Index.
A. Surface plot of the probability of AKOA (vertical axis) by age and body mass index as continuous variables.
B. Surface plot of the probability of AKOA (vertical axis) by age and body mass index categorized by World Health Organization criteria. Red boxes highlight high-risk subsets of interest (> 65 years with BMI < 35 kg/m^2, <65 years with BMI ≥32.5 kg/m^2)

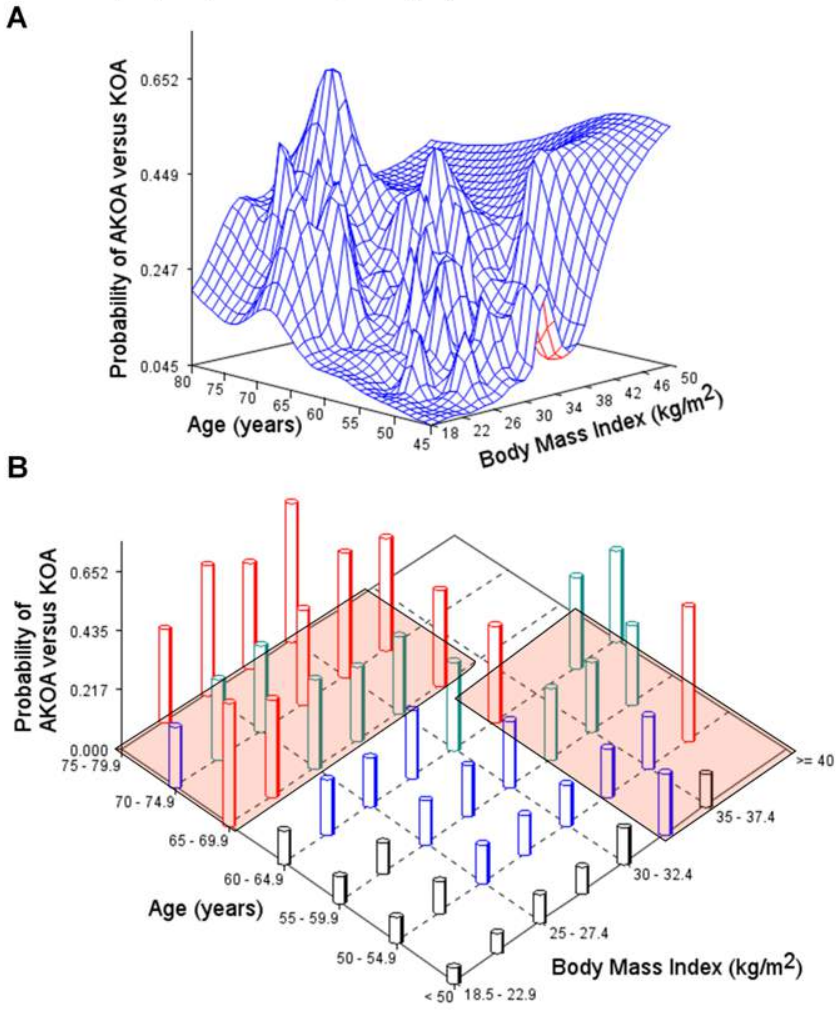

Table. Interaction Between Age, Body Mass Index Influences the Risk of Accelerated Knee Osteoarthritis (KOA)

	Common KOA	Accelerated KOA	Adjusted Odds Ratio (95% Confidence Interval)
	(REF)		Accelerated KOA
All Participants	*(n = 184)*	*(n = 52)*	
Low Risk Group (n = 129)	110 (60%)	19 (37%)	REFERENCE
Older with BMI < 35 kg/m^2 (n = 64)	40 (22%)	24 (46%)	**3.47 (1.70, 7.10)**
Younger with BMI ≥ 32.5 kg/m^2 (n = 43)	34 (18%)	9 (17%)	1.43 (0.58, 3.53)

Session Title: Osteoarthritis - Clinical Aspects Poster I: Treatments and Metabolic Risk Factors

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Vitamin K is an essential cofactor in bone and cartilage mineralization. Low serum vitamin K has been associated with increased prevalence of hand and knee osteoarthritis (OA), higher risk of developing knee OA and cartilage lesions, and, in one study, worsening of meniscal lesions; however, incidence of meniscal damage was not assessed. Meniscal damage is a potent risk factor for knee OA, and severe knee OA is associated with meniscal

damage. We therefore sought to identify whether vitamin K status was associated with the prevalence and incidence of meniscal pathology on MRI.

Methods: The Multicenter Osteoarthritis (MOST) Study is a NIH-funded longitudinal cohort study of adults with or at high risk for developing knee OA. Participants had knee x-rays and 1.0T MRIs at 0 and 30 months. MRI evidence of meniscal pathology was evaluated using WORMS. Meniscal integrity was graded on a 0-4 scale in 3 subregions of the medial and lateral menisci, respectively, and medial and lateral meniscal extrusion were graded on a 0-2 scale. We defined meniscal pathology as any abnormality of meniscal integrity (score ≥1 in any subregion) or meniscal extrusion (medial or lateral score ≥1). Vitamin K status was determined by plasma phylloquinone levels at baseline, and categorized as insufficient (<1.0nM) or sufficient (≥1.0nM); there were too few to analyze true deficiency (<0.5nM). We excluded baseline coumadin users. We examined the relation of vitamin K status to knee-specific baseline presence of meniscal pathology in the whole sample, and to development of meniscal pathology at 30 months among subjects without meniscal pathology at baseline using binary regression with robust variance estimation to obtain prevalence ratios (PR) and risk ratios (RR), respectively. We used GEE to account for correlations between two knees within a person. All analyses were adjusted for age, sex, BMI, vitamin D, smoking status, race, and prior knee injury. Analyses were also stratified by radiographic OA status.

Results: 1457 knees from 1048 subjects (mean age 62.0±7.9 years, BMI 29.9±4.9 kg/m^2, 62.4% female, 34.0% with insufficient vitamin K levels) were included in the cross-sectional analysis. Of these, 535 knees did not have meniscal pathology at baseline and were used in the longitudinal analysis. The prevalence of meniscal pathology was high. Vitamin K status was not significantly associated with either the prevalence or incidence of meniscal pathology (**Table**). Effects were similar when stratified by radiographic OA status.

Conclusion: Plasma vitamin K insufficiency was not associated with prevalence or incidence of meniscal pathology over 30 months. Given the high prevalence of meniscal pathology at baseline, we may need to examine the effects of vitamin K on meniscal pathology at an earlier age, or in a cohort not specifically selected for OA risk to avoid the possibility of depletion of susceptibles.

Table: Relation of vitamin K to meniscal pathology

Cross-sectional analysis (N= 1457 knees, 1048 subjects)		
Baseline Vitamin K status (Prevalence)	Prevalence of meniscal pathology (knee-based) (%)	Adjusted* Prevalence Ratio (95% CI), p-value
Insufficient (<1nM) (n=494 (34%) knees)	293 (59.3)	0.98 (0.90-1.08), p=0.7
Sufficient (≥1nM) (n=963 (66%) knees)	586 (60.9)	1.00 (reference)
Longitudinal analysis (N=535 knees, 448 subjects)		
	Incidence of meniscal pathology over 30 months (knee-based) (%)	Adjusted* Risk Ratio (95% CI), p-value
Insufficient (<1nM) (n= 191 (36%) knees)	21 (11.0)	0.96 (0.79-1.16), p=0.7
Sufficient (≥1nM) (n= 344 (64%) knees)	44 (12.8)	1.0 (reference)
*Adjusted for: age, sex, BMI, vitamin D level, smoking status, race, prior knee injury

Session Title: Osteoarthritis - Clinical Aspects Poster I: Treatments and Metabolic Risk Factors

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: We examined the effects of fat deposition on radiographic osteoarthritis (OA) to determine the role of obesity in the pathology of radiographic OA.

Methods: Data were taken from the Dong-gu cohort, a cross-sectional study of 2,367 subjects. Baseline characteristics, waist circumference (WC), fat mass, and fat percentage were collected, along with X-rays of the knees and hands. Waist-to-hip ratio (WHR) was defined as the ratio of waist and hip circumferences. Diabetes mellitus was defined as fasting glucose > 126 mg/dL or the use of hypoglycemic medication. Hypertension was defined as systolic blood pressure ≥ 140 mmHg, diastolic blood pressure ≥ 90 mmHg, or use of antihypertensive medication. Total knee and hand radiographic OA scores were summed using a semi-quantitative grading system, and then stratified by gender using a multiple linear regression model.

Results: After adjusting for confounders, weight was the only factor significantly associated with knee radiographic OA, regardless of gender ($p = 0.027$ and $p < 0.001$, for males and females, respectively). Regarding the hand, fat percentage had the largest effect on radiographic OA in males (Eta = 0.007, $p = 0.008$), while WHR was the most significant factor in females (Eta = 0.009, $p = 0.001$). For the knee, fat mass was the most important factor for radiographic OA in males (Eta = 0.012, $p = 0.001$), while in females, body mass index (BMI) was the most important factor (Eta = 0.059, $p < 0.001$). Among the variables, only fat percentage was significantly related to both hand and knee radiographic OA in both genders (all $p < 0.01$).

Conclusion: Regardless of gender, mechanical stress was significantly associated with knee radiographic OA. Otherwise, fat deposition correlated with hand and knee radiographic OA in both genders, while the distribution of fat tissue was significantly associated with hand and knee radiographic OA only in females, with the largest effect on hand and knee radiographic OA.

Serum Leptin and Risk of Knee Pain and Osteoarthritis: Multicenter Osteoarthritis Study

D. Misra, J. Niu, D.T. Felson, M. Nevitt, J. Torner, C.E. Lewis, A. Hu, S. Jinno, T. Neogi

Background/Purpose: Obesity is a major risk factor for knee osteoarthritis (OA). Leptin, a proinflammatory adipose tissue product that is highly correlated with adiposity, has been associated with risk of knee OA. Given that leptin is proinflammatory, it could contribute to synovial inflammation. Since synovial inflammation leads to pain in knee OA, it is particularly relevant to study the association of leptin with pain and symptomatic knee OA. Thus, we evaluated the longitudinal association of serum leptin with risk of incident knee pain, incident radiographic and symptomatic knee OA in community-dwelling older men and women.

Methods: We included participants from Multicenter Osteoarthritis (MOST) study, a NIH-funded, longitudinal, observational study of individuals with or at high risk for knee OA, who had serum leptin measured at baseline and knee radiographs at baseline and follow up visits (30-, 60- and 84-month visits). We limited our study sample to those without radiographic OA (KL grade < 2 and no patellofemoral OA) in either knee at baseline. Serum leptin was not normally distributed and highly correlated with body mass index (BMI); thus, we first created BMI residuals of the log of serum leptin and then created tertiles. Incident radiographic knee OA was defined by development of Kellgren-Lawrence grade≥2 or patellofemoral OA by the 84-month visit. Incident symptomatic knee OA was defined by presence of knee pain (both at the telephone screen and clinic visit) in addition to incident radiographic OA changes in the knee by the 84-months. The association of leptin tertiles with incident knee pain, incident radiographic and incident symptomatic OA was assessed using logistic regression with GEE to calculate Odds Ratios (OR), adjusting for age, BMI, race, site, knee injury, knee surgery and CES-D score. All analyses were sex-specific since leptin levels and potentially its effects may be sex-specific.

Results: Among 690 subjects (mean age 60.6 yrs, mean BMI 29.1 kg/m^2 and 62.5% women), mean serum leptin level at baseline was 37022.5 pg/ml in women and 15099.1 pg/ml in men. At the 84 month visit, there were 80, 226 and 64 knees with incident pain, incident radiographic and incident symptomatic OA, respectively. We found a significant increase in the risk of incident knee pain in women (p for trend =0.003) but not in men (**Table 1**). Although the results

did not reach statistical significance, there was a slight increase in the risk of symptomatic OA but not in radiographic OA, in women and men (**Table 1**).

Conclusion: Serum leptin is associated with incident knee pain in women and may be associated with symptomatic OA in men and women but not with radiographic OA. Larger studies are needed to confirm the findings and evaluate leptin as a target for treatment of pain in knee OA.

Table 1: Association of baseline serum leptin tertiles with risk of incident knee pain and osteoarthritis

Calf Muscle Adiposity Is Associated with Impaired Physical Performance in Knee OA

Michael Davison[1], Monica R. Maly[2], Jonathan D. Adachi[3] and Karen A. Beattie[4], [1]School of Medicine, McMaster University, Hamilton, ON, Canada, [2]School of Rehabilitation Science, McMaster University, Hamilton, ON, Canada, [3]Division of Rheumatology, McMaster University, Hamilton, ON, Canada, [4]Medicine, McMaster University, Hamilton, ON, Canada

Session Title: Osteoarthritis - Clinical Aspects Poster I: Treatments and Metabolic Risk Factors

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Knee osteoarthritis (OA) is a degenerative disease associated with significant muscle weakness and disability. Ectopic fat in the thigh, including intramuscular fat (intraMF; fat within a muscle belly) and intermuscular fat (IMF; fat within the deep fascia and between muscles bellies), is associated with impaired strength and physical performance in knee OA. Despite the role of calf muscles in creating power for gait and mobility, there has been little investigation of calf muscle composition in knee OA. We investigated the relationships between calf muscle adiposity, IMF and intraMF volume with physical performance in women with knee OA.

Methods: Women (n=20) with radiographic knee OA had the calf of their most symptomatic knee imaged using 3.0T magnetic resonance imaging (MRI). The iterative decomposition of water and fat with echo asymmetry and least-squares estimation (IDEAL) sequence obtained 10 fat-separated axial images (3 mm slice thickness). Images were analyzed using SliceOmatic® software with region-growing to quantify IMF, intraMF and lean muscle volumes (cm^3) (Figure 1). Muscle adiposity was calculated as the percent of total muscle volume consisting of intramuscular fat; this was calculated for the whole calf and individually for the medial gastrocnemius (MG), lateral gastrocnemius (LG), soleus (SOL), and tibialis anterior (TA). Participants performed five physical performance tests, and rated their knee pain using a numeric pain rating scale. Linear regression analyses were performed.

Results: Mean sample characteristics (±SD): age 65±5 y; BMI 30±5 kg/m^2. After adjusting for knee pain, whole calf muscle adiposity, but not IMF or intraMF volume, was associated with poor performance on the timed up-and-go (TUG), stair ascent/descent test (SADT), and 6 minute walk test (6WT) (Table 1). Furthermore, MG adiposity, but not LG, SOL or TA adiposity, was associated with poor performance on the TUG, SADT, 6WT, and 40 meter fast-paced walk test (40FPWT) (Table 2).

Conclusion: Whole calf, and particularly medial gastrocnemius adiposity, are associated with poor physical performance in women with knee OA. The medial gastrocnemius may be important in mobility disability in OA. Further investigation of longitudinal changes in calf muscle composition in knee OA are required.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Osteoarthritis - Clinical Aspects Poster I: Treatments and Metabolic Risk Factors
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Aging, trauma and obesity are the 3 main risk factors for knee, hip and hand osteoarthritis (OA).

It is noteworthy that risk factors for shoulder OA (SOA) have been much less studied. SOA is divided into 2 anatomical subtypes: i) primary SOA (i.e., centered SOA) and ii) rotator cuff-related OA (i.e., non-centered SOA). We hypothesized that metabolic factors are preferentially associated with the primary SOA than the mechanical-induced rotator cuff-related SOA.

Methods: This 2004-2012 retrospective multicentric study included patients with SOA at the time of joint surgery from 1 rheumatology and 2 orthopedic departments specialized in upper limb surgery. Clinical characteristics, especially hypertension, dyslipidemia, obesity (defined as body mass index >30), type 2 diabetes mellitus, current/past smoking, cardiovascular diseases and dysthyroidism were collected using medical files and phone calls to the patients for missing data. Primary SOA and rotator cuff-related SOA were defined by rheumatologists or surgeons using the standard radiographs. Exclusion criteria were history of a high-energy trauma on the shoulder, chronic inflammatory arthritis, avascular necrosis of the humeral head and age below 30 years-old. We first compared primary SOA and rotator cuff-related SOA using the chi-2 or Student t-test for all characteristics. Then a multivariate analysis using logistic regression was performed to determine specific factors associated with primary SOA.

Results: We included 147 patients (mean ± SD age 75.8 ±10 years-old) including 101 women (68.7%). Primary SOA involved 99 patients and the other 48 had rotator cuff-related SOA. The comparison between the 2 groups indicated that primary SOA patients were older (primary SOA *versus* rotator cuff arthropathy: 77.5 ±9 *vs* 72.4 ±11 years-old; p=0.004) and had more dysthyroidism (15% *vs* 4%; p=0.05) without difference in each cardio-metabolic disturbance (body mass index: 27.2 ±5.1 *vs* 27.3 ±4.5; type 2 diabetes: 13% *vs* 15%; hypertension: 64% *vs* 66%; dyslipidemia: 36% *vs* 31% p=non-significant) or in their accumulation between the 2 groups.

Multivariate analysis indicated that older age was independently associated with primary SOA (odds ratio 95% confidence interval): 1.06 (1.02-1.1) p=0.004), while cardiovascular event diseases was more less associated with this subtype (OR (95%IC): 0.27 (0.089-0.824); p=0.02). Dysthyroidism tended to be also associated with primary SOA (OR (95%IC): 3.47 (0.67-18.9); p=0.14).

Conclusion: Conversely to what expected, metabolic disturbances were not more prevalent in the primary SOA compared to the rotator cuff-related SOA. Surprisingly, whereas the primary OA population was older, CV diseases were more frequent in the rotator cuff-related SOA.

Session Title: Osteoarthritis - Clinical Aspects Poster I: Treatments and Metabolic Risk Factors

Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Osteoarthritis is a chronic, inflammatory, multifactorial disease. The metabolic syndrome (MS) has been linked to this disease; adipokines levels have been associated in the pathogenesis of OA, several studies have described this association in patients with late OA, however few studies had described the behavior in patients with early OA.

Objectives:

To assess the levels of adipokines and inflammatory cytokines in three groups: 1. Healthy people, 2. Early OA with MS and 3. Early OA without MS.

Methods:

A cross-sectional study was realized, which included patients with early knee OA who met the inclusion criteria: patients with osteoarthritis according ACR criteria, early knee OA (Kellgren and Lawrence classification ≤ 2), overweight or obesity. Patients included were divided divided into two groups, with and without metabolic syndrome (MS) and were compared with a group of control patients. Demographic data were collected and serum adipokines and inflammatory cytokines were evaluated by ELISA (R & D Systems®). Descriptive statistics and bivariate applied using nonparametric tests, with 13® STATA software.

Results:

164 patients with OA and 42 healthy controls were studied. The mean age was 49.6 ± 6.0 in the osteoarthritis group with metabolic syndrome (OAMS), 46.55 ± 6.98 and 46.92 ± 6.7 for groups of osteoarthritis without metabolic syndrome (OAnMS) and healthy controls respectively. There were 83.3% women in the group of OA with metabolic syndrome, 89.1% OA without metabolic syndrome group and 95.2 % in the control. The mean BMI was 31.32 ± 4.04 OAMS group, 27.60 ±12.62 OAnMS and 26.48 ± 4.83 for the control group.

We evaluted the serum levels of cytokines: NGF, IL-6, IL-8, HGF, MPC-1, TNF-α, IL-β and PAI-1 and we found stadistical differences between groups. Most of the cytokines were higher in patients with OAMS group "NGF (nerve growth factor), HGF (hepatocyte growth factor), MCP-1 (macrophage chemoattractant protein-1), TNF-α (tumor necrosis factor-α) and PAI-1 (plasminogen activator inhibitor-1)" and the levels of IL-β were the same in all groups and other cytokines like IL-6 and IL-8 were increased in the healthy control group. Regarding the adipokines, as it shows in table 1, adiponectin was found higher in patients with OAnMS, and like the resistin and leptin were significantly in the OAMS group.

Conclusion:

We found a significant difference between the levels of cytokines and adipokines, this supports that in the early stages of OA, adipokines levels are elevated, it is likely that in the future, we can be study patients with OA phenotypes according to the serum levels of adipokines. It is noteworthy that our entire population was overweight, including the control group. A possible confounding factor is that the three groups studied were overweight, which can influence the levels of adipokines.

Table 1. Serum adipokines found in the different study groups and the statistical significance

Adipokines Mediana (Range)	OAMS group	OAnMS group	Healthy control group	p value
Leptin	866 (126.7- 5173)	308.06 (15.48- 7034)	401 (21.1-1436)	<0.003

Session Title: Osteoarthritis - Clinical Aspects Poster I: Treatments and Metabolic Risk Factors
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Relations between smoking and osteoarthritis remains discussed. The protective effect found in previous epidemiological studies has not been confirmed by recent studies and meta analyses. This study aims to investigate the effect of smoking on pain, function and structural evolution in hip and knee symptomatic osteoarthritis.

Methods:

The subjects studied were enrolled in the KHOALA cohort (Knee and Hip OsteoArthritis Long-term Assessment) which has been described in detail elsewhere. Briefly, it is a population-based cohort of 878 subjects aged from 40 to 75 years with symptomatic lower limb OA (knee and/or hip). Data were collected at baseline and after three years during an outpatient visit, and each year with self-administered questionnaires. The data collected included demographic characteristics, and annual data for pain (0-100), function (Harris Hip Score and Womac), smoking information (duration, amount and ongoing). Standard radiographs of both hips were obtained at baseline and at three years. The progression of hip and or knee osteoarthritis was evaluated according to the radiological Kellgren-Lawrence score (KL), osteophytes scores (0-3) per location and swelling. Univariate and multivariate statistical analysis were performed adjusted on age, BMI, sex and diabetes. the subjects were divided into smokers, non-smokers and former smokers.

Results:

873 subjects have been included, 119 smokers, 215 former smokers et 539 non-smokers, 64% of smokers and 31 % of former smokers have smoked during over 20 years. 40% of smokers have smoked 20 pack years. 20 subjects were not taken into account due to lack of data. Baseline characteristics are presented in table with comparisons between baseline and 3 years

At 3 years, no difference has been shown between different groups about function, pain and structural evolution for the hip (0.16) and knee (p=0.9) as for the laying prosthesis (p=0.4 and p=0.5). But smokers (OR=0.33 [0.11-1.09]) and former smokers (OR=0.30[0.1-0.85]) developed fewer osteophytes only in the knee either in medial and lateral condyles (p=0.037 and 0.07). The dose of intoxication (p = 0.026 (OR = 0.98 [0.97-1]) and the duration of intoxication (p = 0.0005 (OR = 0.98 [0.97-0.99]) were significantly associated with the development of these osteophytes. No difference is found for other structural parameters.

Conclusion:

Our results shows that smoking does not influence function and pain but smokers and ancient smokers seems to develop less osteophytesat femoral level. As a possible explanation, recent experimental studies have shown that nicotine upregulated collagen synthesis, chondrocytes proliferation and influences TGFβ synthesis which is involved in the formation of osteophytes.these results needs to be confirmed.

Session Title: Osteoarthritis - Clinical Aspects Poster I: Treatments and Metabolic Risk Factors

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Osteoarthritis (OA) affects 27 million adults in the United States. Symptomatic hand osteoarthritis (SHOA) is a common condition that affects hand strength and function. Lifetime risk, defined as the probability of developing a condition over the course of a lifetime, has been used to convey person-level risk of other chronic conditions including breast cancer, and more recently estimates of symptomatic knee and hip OA have been published. To better understand the overall burden of SHOA, as well as to guide targeted interventions, we estimated the lifetime risk of SHOA and whether the risk is different by potential risk factors.

Methods:

We analyzed data from the Johnston County Osteoarthritis Project, an on-going population-based prospective cohort study in residents of Johnston County, North Carolina. Data were collected among 2,218 adults ≥ 45 years at the first (1999-2004) and second (2005-2010) time period. The presence of SHOA at each time period was defined by self-reported symptoms (pain, aching, and stiffness) and radiographic OA (ROA) in the same hand. ROA was defined as a Kellgren-Lawrence grade ≥2 in at least 3 total joints out of the 15 joints in each hand, and at least one of them being the distal interphalangeal joint (361 participants met this criteria in at least one time period). Lifetime risk, defined as the proportion of the population who will develop SHOA in at least one hand by age 85, was estimated using the predicted marginal probability from generalized estimating equations logistic regression, accounting for clustered variance from the stratified random sampling design and multiple measurements within participant. Additionally, sampling weights were applied in analyses to make appropriate population-based statistical inferences. The overall and stratified lifetime risk by sex, race and obesity (BMI≥30 kg/m²) are presented.

Results:

The lifetime risk of SHOA was 39% (95% confidence intervals [CIs] 34-45%) overall. Nearly one of two women (48%; CIs 41-55%) developed SHOA by age 85 compared with one of four men (25%; CIs 19-31%). Lifetime risk of SHOA was 47% (CIs 38-57%) among the obese participants, higher than that among those who were not obese (36%; CIs 29-42%). Race-specific estimates were 40% (CIs 34-47%) among whites and 32% (CIs 21-44%) among African-American adults.

Conclusion:

Almost 40% of people will develop SHOA by age 85. The risk is particularly high among women and obese adults. SHOA has substantial public health implications considering its high lifetime risk, and its impact on functional impairment of the hands and quality of life.

These findings underscore the need for increased use of public health and clinical interventions to address the impact of SHOA on individuals and society. Earlier diagnosis can allow earlier use of the same standard interventions used for other types of OA. These include self-management education, losing weight if overweight/obese, physical/occupational therapy, thermal modalities, joint protection techniques, provision of assistive devices, and acetaminophen/NSAID use, which may contribute to maintaining better function and fewer symptoms.

Session Title: Osteoarthritis - Clinical Aspects Poster I: Treatments and Metabolic Risk Factors

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Farming activity is burdened work with excessive use of hands. Thus, farmers are expected to have high prevalence of hand osteoarthritis (HOA). However, there is a lack of studies investigating prevalence and characteristics of HOA in Korean farmers. Therefore, we conducted this study to investigate the prevalence of HOA and to identify factors that influence hand pain among farmers in rural areas of Korea.

Methods: The study was conducted from June 2013 to Dec 2014 with 700 farmers in Gyeong-nam Province of Korea. Clinical evaluation for hand joints was performed and the plain radiographs of both hands were taken. The Australian/Canadian Osteoarthritis Hand Index (AUSCAN) was used to assess pain severity of hand joints. Radiographic HOA was defined as Kellgren–Lawrence (KL) grade≥2 on plain radiographs and symptomatic HOA as KL grade≥2 with pain/aching/stiffness at the same joints. Severe HOA was defined KL grade≥3. Presence of HOA at individual level was defined as ≥1 affected joint. Depressive symptoms were assessed using the Patient Health Questionnaire (PHQ-2).

Results: Participants comprised of 53% women and 47% men with mean age of 59.7±8.6 years. The mean farming duration was 30.0±14.3 years. The overall prevalence of radiographic and symptomatic HOA was 59.1%, and 13.9%, respectively. The prevalence of radiographic and symptomatic HOA was higher in women (62.3%, 14.8%) than in men (55.6%, 12.8%). Among participants with radiographic HOA, AUSCAN pain scores were also higher in women (99.9±106.8) than men (68.0±99.9, p=0.002). Linear regression analysis showed that women and depressive symptoms were associated with AUSCAN pain score after adjustment for radiographic severity of HOA, total numbers of affected joints, and frequently repetitive hand use or and pinch grip working during harvest.

Conclusion: The prevalence of HOA and AUSCAN pain scores were higher in women compared to men. And AUSCAN pain scores were associated with female gender and depressive symptoms. Therefore, our results show the need for depression care management in female farmers to reduce hand pain.

Lack of Uniform Diagnostic Criteria for Erosive OA: A Systematic Review

Supraja Yeturi[1], Payal Patel[2], Gazeley David[2] and Ann K. Rosenthal[3], [1]Rheuamtology, Medical college of Wisconsin, Milwaukee, WI, [2]Medical College of Wisconsin, Milwaukee, WI, [3]Div of Rheumatology, Medical College of WI, Milwaukee, WI

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Osteoarthritis - Clinical Aspects Poster I: Treatments and Metabolic Risk Factors

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Erosive osteoarthritis (EOA) is a potentially important subtype of osteoarthritis initially described in the 1960s. Since that time, EOA has been the focus of substantial literature describing its clinical presentation, epidemiology, genetics, and response to therapy. We set out to review clinical studies of EOA in order to determine if there was general agreement about diagnostic criteria.

Methods:

Ovid, Pubmed, and Google Scholar were searched using the phrase "erosive osteoarthritis" from the years 1962-2015. References that were not pertaining to EOA, were exclusively animal studies, or were not in English were eliminated from review.

Results:

After reviewing all 180 papers, we identified 50 papers which described the inclusion and exclusion criteria utilized in the study and included more than 3 patients. The numbers of patients varied between 9 and 355. A synopsis of the inclusion/exclusion criteria is shown in Table 1. Six of the 50 studies used no clinical inclusion criteria, which we defined as features obtained by history or physical examination. In the remaining 44 studies, ACR criteria for hand OA were the most commonly used clinical inclusion criteria (33/44). Radiographic inclusion criteria were cited in all 50 studies but varied widely. Eighteen studies required only a single involved joint. The Verbruggen-Veys scale was designed to stage hand osteoarthritis and was used in 7/50 papers. In the majority of studies (35/50) the authors designed their own radiographic definitions. Sixteen of the 50 studies described no exclusion criteria. The most frequently employed exclusion criteria were an alternative diagnosis (31/50), a positive rheumatoid factor or anti- CCP antibody (8/50), or a family history of psoriasis (7/50). There were no clear trends with time in the choice of diagnostic criteria.

Table 1. The number of published studies of EOA utilizing various types of diagnostic criteria out of a total of 50 studies. *

Clinical Inclusion Criteria			Radiographic Inclusion Criteria				Exclusion Criteria		
ACR hand OA	Misc	None	Joints involved	V-V scale	Kelgren - Lawrence scale	Kalman scale	Alternative Diagnosis	Labs	Family history
33	11	6	≥1 18 ≥2 10 ≥3 2	7	5	3	31	8	7

V-V is Verbruggen-Veys

Conclusion:

The considerable heterogeneity in the definition of EOA renders this literature difficult to interpret. Despite a heavy reliance on radiographic findings, there is little agreement about even a radiographic definition of this disease. Progress in understanding and treating patients with EOA will require the development of clear classification criteria.

Session Date: Sunday, November 8, 2015

Session Title: Osteoarthritis - Clinical Aspects Poster I: Treatments and Metabolic Risk Factors

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

The Outcome Measures in Rheumatology (OMERACT) working group on hand osteoarthritis (OA) has endorsed a preliminary set of core domains for outcome measures in clinical trials. One domain is joint activity, reflecting the underlying osteoarthritic process, such as inflammation and/or subchondral bone activity, leading to pain and destruction.

The Doyle Index (DI), a measurement of joint tenderness, is proposed as an instrument to assess joint activity, however validity and its added value over other domains like self-reported pain is unknown. Therefore, construct validity of the DI is investigated.

Methods:

Data were used of two cohorts with primary hand OA patients: HOSTAS (n=507, mean (SD) age 61 (9) years, 86% women) and ECHO (n=56, age 62 (9) years, 86% women). Self-reported pain was assessed by Australian/Canadian Hand OA Index (AUSCAN, Likert scale, 0-20) and Visual Analogue Scale (VAS) 1-100. Tenderness on palpation (0-3) was assessed in24 joint units: all DIP, PIP, 1^{st} IP, 1^{st} MCP and 1^{st} CMC joints individually and 2^{nd}-5^{th} MCP joints as one joint group. In each patient the DI was the summated score of the 24 joint units (max. 72).

Contrast-enhanced MRI of the right DIP and PIP joints (8 joint units) were performed in a subgroup of HOSTAS (n=93) and images were scored for synovitis and bone marrow lesions (BMLs), both 0-3, following standardized methods. Ultrasound (US) was performed in the ECHO study and all hand joints (the same 24 joint units as in DI) were scored for grey scale (GS) synovitis and power Doppler signal (PDS), both 0-3, following standardized methods.

MRI or US scores were summated scores of synovitis and BMLs or GS synovitis and PDS, respectively, of all imaged joint units.

To assess construct validity, first, non-parametric correlation coefficients between DI and self-reported pain or US or MRI scores were calculated. Subsequently, quartiles of DI (lowest vs highest) of MRI and US scores were compared with Mann-Whitney U test.

Results:

Baseline data and non-parametric correlations are depicted in table 1. DI varied from 0 to 48 and correlated moderately to self-reported pain in both studies.

Correlations for DI and US and MRI scores were low. Median DI differed between lowest quartile and highest quartile scores (figure 1) for the US score (p=0.050) and MRI score (p=0.066).

Conclusion:

Doyle Index seems a promising instrument to assess joint activity in clinical trials in hand OA. Further work on metric properties, including sensitivity-to-change, is needed in hand OA and its subgroups.

Table 1: Baseline data and non -parametric correlations in the ECHO and HOSTAS studies, cohorts with primary hand osteoarthritis patients.

Variable, median (range)	ECHO study	HOSTAS study	
	all joint units	Total, all joint units	MRI-subgroup, right DIP and PIP joints
Doyle Index	9.5 (0 to 32)	4 (0 to 48)	1 (0 to 10)
AUSCAN pain	10 (0 to 19)	10 (0 to 20)^	na
VAS pain	49 (0 to 99)	35.5 (0 to 93.5) *	na
MRI score	na	na	6 (0 to 27)
US score	11.5 (0 to 38)	na	na
Non-parametric correlations , Spearman's rho			
DI-AUSCAN	0.46 ($p < 0.01$)	0.38 ($p < 0.01$)	na
DI-VAS	0.38 ($p < 0.01$)	0.41($p < 0.01$)	na
DI-US score	0.29 ($p < 0.05$)	na	na
DI-MRI score	na	na	0.25 ($p < 0.05$)

*n=364, ^n=503.

Abbreviations: na = not applicable, DI = Doyle Index, VAS = Visual Analogue Scale, US = ultrasound

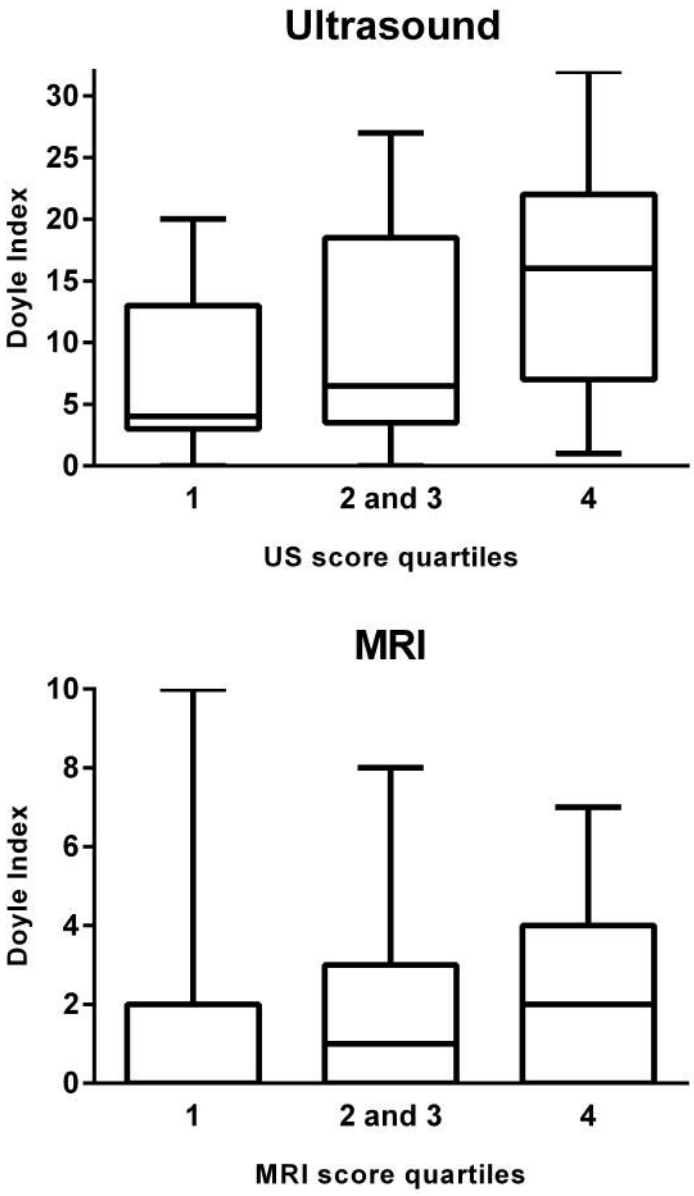

Figure 1: boxplots of median Doyle Index in percentile groups of US or MRI score with 25th and 75th percentile, minimum and maximum.
Doyle was calculated for US score in 24 joint units: all DIP, PIP, IP, 1st MCP and 1st CMC joints individually and 2nd-5th MCP joints as one joint group. For MRI it was calculated in the right DIP and PIP joints (8 joint units).

Session Date: Sunday, November 8, 2015

Session Title: Osteoarthritis - Clinical Aspects Poster I: Treatments and Metabolic Risk Factors

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Smoking has been shown to have a potential protective effect on radiographic knee osteoarthritis (OA), possibly mediated through lower body weight in smokers. A recent animal study showed an association between chronic alcohol consumption and OA-like pathological changes, whereas no studies have explored this potential association in humans. By studying the relationship between harmful health behavior and OA in the hands, we avoid mediation by body weight. Hence, our aim was to explore whether smoking and alcohol use are associated with hand OA features.

Methods: We included 530 persons from the Musculoskeletal pain in Ullensaker study (MUST), Norway (mean (SD) age 65 (8.0) years and 71% females) with radiographic hand OA in 1 or more joints and no inflammatory joint diseases. The participants were grouped into three categories based on their self-reported smoking status; Current (daily), former (quit > 6 months ago) and never smokers. Persons reporting to consume alcohol daily, weekly or monthly were categorized as drinkers. Conventional hand radiographs were obtained, and the number of finger joints with radiographic OA (Kellgren-Lawrence grade 2 or more) was calculated (0-30 scale). Participants having one or more joint(s) with ultrasound-detected grey-scale synovitis were classified as having inflammatory OA. We studied the associations between smoking and alcohol (as the independent variables) and the severity of radiographic OA, AUSCAN pain and presence of inflammatory OA (as the dependent variables), using linear and logistic regression analyses. Separate models were performed for smoking and alcohol. Analyses were adjusted for age, sex and education status.

Results: Current smoking was significantly associated with fewer joints with radiographic OA independent of age, sex and education status (Table 1). There was also a trend that former smoking was related to less radiographic hand OA, but the association was not statistically significant in the adjusted analyses. Being a drinker was significantly associated with inflammatory OA in the adjusted analyses (Table 1). Neither smoking nor alcohol use were associated with increased hand pain (data not shown). Additional adjustment for alcohol use and smoking in respective sensitivity analyses did not attenuate the results.

Table 1. The associations between smoking and alcohol exposure and structural and inflammatory hand OA features.					
	N (%) persons	**Number of joints with radiographic hand OA**		**Presence of inflammatory hand OA**	
		Crude B (95% CI)	Adjusted B (95% CI) *	Crude OR (95% CI)	Adjusted OR (95% CI) *
Smoking					
Never smoker	256 (48.3%)	0.00 (ref.)	0.00 (ref.)	1.00 (ref.)	1.00 (ref.)
Former smoker	203 (38.3%)	**-1.10 (-2.18 to -0.01)**	-0.77 (-1.81 to 0.27)	0.94 (0.64 to 1.40)	1.02 (0.67 to 1.53)
Current smoker	71 (13.3%)	**-3.07 (-4.38 to -1.76)**	**-1.77 (-3.07 to -0.48)**	**0.53 (0.28 to 0.99)**	0.57 (0.30 to 1.12)
Alcohol					
Abstinence	82 (15.5%)	0.00 (ref.)	0.00 (ref.)	1.00 (ref.)	1.00 (ref.)
Drinker	448 (84.5%)	-0.11 (-1.51 to 1.29)	0.57 (-0.68 to 1.81)	1.41 (0.83 to 2.37)	**2.06 (1.16 to 3.66)**
* Adjusted for age, sex and education status.					

Conclusion: Our results suggest a protective effect of smoking on radiographic hand OA whereas alcohol consumption may increase the risk of joint inflammation in hand OA. Future longitudinal studies are needed to explore the causal associations.

Session Title: Osteoarthritis - Clinical Aspects Poster I: Treatments and Metabolic Risk Factors

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Hand osteoarthritis (HOA) causes considerable pain and disability. Radiographic HOA features show only a modest association with symptoms in HOA. Ultrasound is an easy non-invasive procedure, which is able to visualize synovial inflammation and joint effusion. HOA is a heterogeneous group of disorders with two main subsets including non-erosive disease and erosive, sometimes referred to as inflammatory, HOA. Few studies demonstrated inflammatory ultrasound changes and more severe clinical symptoms in patients with erosive compared with non-erosive disease, however the results are inconclusive.

Methods: The aim of the study was to compare pain, stiffness, physical impairment and ultrasound features between patients with erosive and non-erosive HOA in a cross-sectional study. Consecutive patients with symptomatic HOA fulfilling the American College of Rheumatology (ACR) criteria were included in this study. Joint pain and swelling were assessed. Patients reported joint pain on 100 mm visual analogue scale (VAS). Pain, joint stiffness and disability were assessed by the Australian/Canadian OA hand index (AUSCAN). Radiographs of both hands were examined and erosive disease was defined by at least one erosive interphalangeal joint. Synovial hypertrophy and power Doppler signal (PDS) were scored with ultrasound. Synovitis was graded on a scale of 0–3 and osteophytes were defined as cortical protrusions seen in two planes.

Results: Altogether, 134 patients (13 male) with symptomatic nodal HOA were included in this study between April 2012 and January 2015. Out of these patients, 72 had erosive disease. Patient's characteristics are given in table 1. The disease duration ($p<0.01$), duration of morning stiffness ($p<0.01$) and number of clinically swollen joints ($p<0.05$) were significantly higher in patients with erosive compared with non-erosive disease. According to the AUSCAN, patients with erosive compared with non-erosive disease had more pain ($p<0.05$) and stiffness ($p<0.01$). US-detected pathologies such as gray-scale synovitis total score ($p<0.001$), intensity of PDS ($p<0.01$) and number of osteophytes ($p<0.01$) were significantly higher in patients with erosive compared with non-erosive disease (table 1). There were no significant differences in consumption of non-steroidal anti-inflammatory drugs (NSAIDs), analgesics and symptomatic slow-acting drugs (SYSADOA) for OA between both groups.

Table 1.

	All patients	Non-erosive HOA	Erosive HOA	P
Age, years (mean ± SD)	65.98 ± 8.16	64.25 ± 7.61	67.48 ± 8.33	NS
Female, no. (%)	121 (90.29%)	55 (88.70%)	66 (91.66%)	NS
Disease duration (years)	8.54 ± 7.14	7.52 ± 7.02	9.42 ± 7.13	<0.01 *
BMI, kg/m2	27.53 ± 4.33	27.50 ± 4.12	27.55 ± 4.49	NS
AUSCAN, total	21.60 ± 10.44	20.05 ± 9.98	22.93 ± 10.65	<0.05 *
AUSCAN A, pain	8.16 ± 4.26	7.73 ± 4.18	8.53 ± 4.29	<0.05 *
AUSCAN B, function	1.96 ± 0.87	2.02 ± 0.98	1.90 ± 0.77	NS
AUSCAN C, stiffness	11.34 ± 6.27	10.16 ± 5.78	12.36 ± 6.48	<0.01 *
VAS, pain (mm)	43.91 ± 21.42	41.85 ± 21.49	45.69 ± 21.19	NS
Morning stiffness (min)	21.12± 37.84	18.55± 29.06	23.34± 43.89	<0.01 *
Tender joints, no.	7.66 ± 3.34	7.32 ± 3.41	7.96 ± 3.25	NS
Swollen joints, no.	3.69 ± 4.42	3.45 ± 3.86	3.89 ± 4.78	<0.05 *
Ultrasound				
Synovial hypertrophy	6.72 ± 8.06	4.47 ± 6.09	8.67 ± 8.99	<0.001*
Power Doppler signal	1.99 ± 2.72	1.61 ± 2.07	2.31 ± 3.14	<0.01*
Osteophytes, no.	11.95 ± 5.31	10.6 ± 5.59	13.11 ± 4.76	<0.01*

* Significantly higher in patients with erosive HOA

Conclusion: In general, this study shows that patients with erosive HOA have more severe pain and stiffness associated with US-detected synovial hypertrophy, inflammatory signs and osteophyte formation than patients with non-erosive disease.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Osteoarthritis - Clinical Aspects Poster I: Treatments and Metabolic Risk Factors

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To evaluate the role of oblique view images in the radiographic assessment of hand osteoarthritis (HOA).

Methods: 159 patients of our HOA cohort were included. X-ray images were analyzed according to the interphalangeal osteoarthritis radiographic simplified (iOARS) score (pa views) or examined with regard to radiographic alterations that could not be detected in pa images (oblique views). Spearman's correlation was applied to examine the relationship of dorsal osteophytes (dOP) and radiographic features/severity of joint damage. Differences between groups were determined by Student's t test.

Results: A total of 4770 joints were examined. Oblique views showed additional information in 12.98% oft the analyzed joints. dOPs seem to be the most important radiographic changes found in oblique view images and occured with a prevalence of 12.4% (n=158) in DIP, 8.2% (n=26) in CMC-I and 7.2% (n=92) in PIP joints. Further calcualtions revealed a subgroup of patients displaying dOP in the oblique views without any radiographic changes in the plain images (DIP: 10.1%, CMC-I: 8.2% and PIP: 7.2%).

Conclusion: Prevalence data on dOP in HOA are provided. Oblique view images allow us to detect a subgroup of patients with HOA displaying dOP without any radiographic alterations in plain view images.

Session Date: Sunday, November 8, 2015

Session Title: Osteoarthritis - Clinical Aspects Poster I: Treatments and Metabolic Risk Factors

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The OMERACT HOA working group recently proposed ‘hand mobility' as an outcome measure in HOA trials, although no disease specific instruments are available yet. We aimed to investigate the construct validity of four hand mobility tests, validated in other rheumatic diseases, in HOA and its subsets.

Methods: 207 participants from the Genetics ARthrosis and Progression study with symptomatic HOA following ACR criteria completed standardized questionnaires. Hand mobility was examined by trained assessors with the Hand Mobility in Scleroderma test (HAMIS, scale 0-27, higher worse), fingertip to palm distance (FPD, millimetres, higher worse), modified Kapandji index (MKI, 0-50, higher better), and number of hand joints with limited mobility (0-30, higher worse). Subscores for thumb base and finger HOA subsets were calculated for HAMIS (thumb abduction and pincer grip (0-6), versus finger flexion, extension and abduction (0-9)) and MKI (thumb opposition (0-10), versus finger flexion and extension (0-40)). Radiographs were scored using OARSI atlas. With multivariable linear regression the capability to measure unique concepts was investigated. Complete and (thumb/finger) subscores were compared in cumulative probability plots, exploring whether scores differed between participants with complaints at different sites (carpometacarpal joint (CMCJ) only, interphalangeal joint (IPJ) only and both sites). Data were analysed in SPSS V20.0.

Results: Participants displayed large variation in mobility scores (table, figure). Strongest correlations were with OARSI osteophyte score (r_s 0.43-0.52), number of joints with bony swellings (r_s 0.46-0.58) AUSCAN function (r_s 0.27-0.36), grip strength (r_s 0.08-0.33) and AUSCAN pain (r_s 0.25-0.34). All tests showed similar correlations with these outcomes, and in multivariable models 35-46% of the scores were explained by a combination of structural damage, disability and strength; pain and joint activity did not contribute substantially. Probability plots demonstrated that FPD and MKI measure finger more than thumb mobility (figure). Additional plots showed that subscores differ per HOA subset. Only HAMIS-derived thumb subscores distinguished the CMC subset.

Conclusion: The tests show similar and acceptable levels of construct validity. Despite a large variation in scores, they appear to measure in part a unique domain. HAMIS, FPD and MKI perform similarly for finger mobility, although only HAMIS can measure thumb mobility specifically. Other metric properties and the potential of separate thumb- and finger-tests need to be studied.

Table 1. Characteristics of included participants (n=207)*	
Age, mean (SD)	64.7 (6.9)

Women, N (%)	178 (86.0%)
Symptomatic HOA subsets	
CMCJ OA only , N (%)	7 (3.4%)
IPJ OA only, N (%)	74 (35.7%)
Symptoms at both sites, N (%)	126 (60.9%)
Number of self-reported painful joints (0-30)	8 (0-30)
AUSCAN pain subscale (0-20)	8 (0-20)
AUSCAN function subscale (0-36)	16 (0-36)
Grip strength, kg	19.5 (3.5-49)
Number of joints with bony swelling (0-30)	14 (2-26)
Total OARSI osteophyte score (0-88)	10 (0-51)
Total OARSI JSN score (0-88)	18 (0-49)
Hand mobility tests	
HAMIS (0-27)	3.5 (0-20.5)
Finger palm distance, mm	7 (0-191)
Modified Kapandji Index (0-50)	48 (27-50)
Number of joints with limited mobility (0-30)	2 (0-30)

*median (range) unless otherwise stated

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Osteoarthritis - Clinical Aspects Poster I: Treatments and Metabolic Risk Factors

Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose : It is debated whether erosive hand osteoarthritis (OA) is a separate inflammatory subset of hand OA, or just a severe form of the same disease. Cross-sectional studies on ESR and CRP are limited in numbers, performed on small cohorts, and have show conflicting results, with higher as well as lower serum levels in erosive OA compared to non-erosive OA.[1-4] With a large OA cohort, we have the opportunity to explore this further, and hereby compare the serum levels of inflammatory biomarkers in erosive and non-erosive hand OA.

Methods: We included subjects with radiographic hand OA (i.e. Kellgren-Lawrence grade ≥ 2 in one or more finger joint(s)) from a community-based OA cohort, and measured their plasma levels of erythrocyte sedimentation rate (ESR) and C-reactive protein (using a high-sensitivity assay; hsCRP). Erosive status was defined as having one or more interphalangeal joint(s) with radiographic central erosions, and rheumatic inflammatory comorbidities were excluded. In crude linear regression analyses, we explored whether erosive hand status was associated with higher levels of ESR and hsCRP (log-transformed) as compared to non-erosive hand OA. In adjusted analyses, age, sex and body mass index (BMI) were added to the model. To explore the association between OA-related joint inflammation and systemic inflammatory markers, we performed additional analyses, in which the sum scores of ultrasound-detected synovitis in the hands (range 0-90) and the knees (range 0-6) were included in the model. Significance level was set at $p<0.05$.

Results: Non-erosive and erosive hand OA were present in 373 (76%) and 119 (24%) subjects, respectively (Table).

In crude analyses, there were significant associations between erosive hand OA status and higher log-transformed ESR (ß = 0.23, 95% CI 0.05,0.41) as well as hsCRP (ß = 0.22, 95% CI –0.1,0.45). After adjusting for age, sex and BMI, the associations were not longer significant for neither ESR (ß =, 95% CI) nor hsCRP (ß = 0.11, 95% CI –0.12,0.35). Ultrasound-detected synovitis sum scores for the hands and knees were not related to higher systemic inflammatory markers with ß = 0.02 (95% CI –0.01,0.04) and ß = –0.02 (95% CI –0.10,0.05) for ESR and ß = 0.02 (95% CI –0.01,0.04) and ß = –0.01 (95% CI –0.11,0.09) for hsCRP, respectively.

Conclusion: Persons with erosive hand OA have higher ESR and hsCRP as compared to non-erosive hand OA. However, the higher levels of systemic inflammatory markers are explained by age, sex and BMI, rather than local joint inflammation. Both erosive and non-erosive hand OA is associated with local joint inflammation with no effect on systemic inflammatory markers.

Table:

	Non-erosive hand OA (n=373)	Erosive hand OA (n=119)	p-value
Age, mean (SD)	64.5 (8.3)	68.1 (6.6)	0.38
Sex, n(%) women	67%	76%	0.09
Body mass index, mean (SD)	28.3 (5.0)	28.5 (4.2)	0.44
hsCRP, median (IQR)	1.39 (0.61–3.23)	1.57 (0.90–2.80)	0.14
ESR, median (IQR)	11.0 (6.0–17.0)	14.0 (8.0–22.0)	0.006
Grey scale synovitis sum score in hands, median (IQR)	1 (0–4)	5 (1–9)	<0.001
Grey-scale synovitis sum scores in knees, median (IQR)	0 (0–1)	0 (0–1)	0.14

Session Title: Osteoporosis and Metabolic Bone Disease - Clinical Aspects and Pathogenesis Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Odanacatib (ODN), a selective oral inhibitor of cathepsin K, is in development for the treatment of osteoporosis. In the Phase 3, Long-Term Odanacatib Fracture Trial (LOFT; NCT00529373) of postmenopausal women with osteoporosis, ODN significantly reduced fracture risk and led to progressive increases in BMD at the lumbar spine (LS) and total hip (TH) vs. placebo. The incidence of AEs and serious AEs has been previously presented. Major cardiovascular events overall were generally balanced but there were numerically more adjudicated strokes in the ODN group. Final blinded, independent adjudication of all major cardiovascular events is ongoing. Pre-specified analyses evaluated the efficacy of ODN in different patient subgroups.

Methods: Women aged ≥65 years without a baseline radiographic vertebral fracture (VFx) and a TH or femoral neck (FN) BMD T-score between -2.5 and -4.0 or with a prior VFx and a TH or FN T-score between -1.5 and -4.0 were randomized (1:1) to ODN 50 mg/week or placebo. All patients received vitamin D3 (5600 IU/week) and calcium as required to achieve ~1200 mg/day. Treatment effects on primary endpoints (new and worsening morphometric vertebral, incident hip, non-VFx) were investigated in patient subgroups, including baseline age, race, bisphosphonate intolerance, prior radiographic VFx, and baseline BMD.

Results: 16,713 women were randomized (16,071 included in analyses) at 387 centers in 40 countries. Baseline mean age was 72.8 years, 57% Caucasian, 46.5% with prior VFx. Mean BMD T-scores were: LS -2.7, TH -2.4, and FN -2.7. The risk reduction of ODN vs. placebo for primary fracture endpoints was generally consistent across all subgroups.

For morphometric VFx, the relative risk reductions (RRR) for participants with or without prior VFx were 51% and 60%, respectively; for age groups <70 and ≥70 years, the RRRs were 57% and 53%, respectively (Table). RRR for morphometric VFx based on baseline LS BMD T-score tertiles (≥-2.22; -3.25< to <-2.22; ≤-3.25) were 54%, 47% and 58%, respectively. In bisphosphonate-intolerant patients, the RRR for morphometric VFx, hip and non-VFx were 52%, 48% and 17% respectively consistent with the overall study population.

Conclusion: In postmenopausal women with osteoporosis, the effect of ODN vs. placebo was generally consistent among various predefined subgroups in reducing the risk of new and worsening morphometric vertebral, hip and non-VFx.

Table. Interval-censored analysis of time to first morphometric vertebral fracture and time to first adjudicated osteoporotic fracture (hip and non-vertebral): subgroup analyses (Full-Analysis-Set population; base study)

Session Date: Sunday, November 8, 2015
Session Title: Osteoporosis and Metabolic Bone Disease - Clinical Aspects and Pathogenesis Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Romosozumab is a sclerostin inhibitor that rapidly increases bone mineral density (BMD) through a dual effect on bone, causing increased bone formation and decreased bone resorption, as shown in a global phase 2 study in postmenopausal women with low bone mass (McClung et al *NEJM* 2014). Here we report the key results of a phase 2 dose-ranging study to assess the efficacy and safety of romosozumab in a Japanese population (NCT01992159).

Methods: This randomized, double-blind, placebo-controlled study enrolled Japanese postmenopausal women aged 55–85 years with a lumbar spine (LS), total hip (TH), or femoral neck (FN) DXA T score ≤ –2.5. Women were randomized to receive placebo or 1 of 3 doses of subcutaneous romosozumab (70 mg, 140 mg, or 210 mg) once monthly (QM) for 12 months. The primary endpoint was percentage change from baseline in LS BMD at month 12. Secondary endpoints included percentage change from baseline in LS BMD at month 6, TH and FN BMD at months 6 and 12, and percentage change from baseline in serum bone turnover markers.

Results: Women enrolled in the study (N = 252) had a mean (standard deviation) age of 68 (6.4) years and mean LS, TH, and FN T-scores of –2.7, –1.9, and –2.3, respectively. All romosozumab doses significantly increased BMD compared with placebo at each of the three skeletal sites at month 12 ($P < 0.01$). The largest improvements were observed with romosozumab 210 mg QM, which resulted in BMD gains from baseline of 16.9% and 4.7% at the LS and TH, respectively (Fig.), and 3.8% at the FN, at month 12. All doses of romosozumab increased P1NP and reduced CTX vs placebo by week 1 ($P < 0.0001$). In the 210 mg QM group, P1NP levels peaked at month 1 (median increase 101.1%) and fell below placebo levels by month 12; CTX levels were lowest at week 1 (median decline 45.6%) and were still below placebo at month 12. Subject incidences of adverse events and serious adverse events were generally comparable between treatment groups. Numerical differences were observed between the total romosozumab vs placebo groups for subject incidence of mild to moderate osteoarthritis adverse events (6.9% vs 0%) and mild injection-site reactions (3.7% vs 1.6%).

Conclusion: In this study of Japanese women with postmenopausal osteoporosis, romosozumab treatment resulted in rapid, large, and significant gains in BMD compared with placebo and baseline, and the 210 mg QM dose showed the

greatest efficacy. Romosozumab was generally well tolerated in this population. Global phase 3 studies evaluating the 210 mg QM dose for the treatment of osteoporosis are underway.

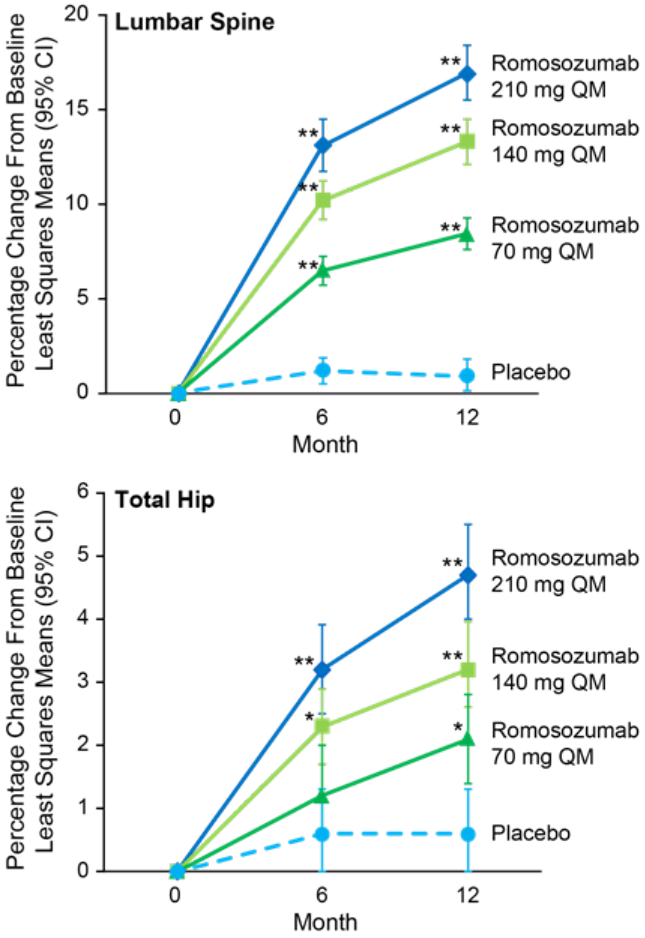

Fig. Percentage change in BMD from baseline in women receiving placebo or romosozumab (70 mg, 140 mg, or 210 mg) QM for 12 months. Estimated least squares means for the changes by linear models are presented. *BMD*, bone mineral density; *QM*, every month.
*$P < 0.01$ vs placebo; **$P < 0.0001$ vs placebo.

Session Title: Osteoporosis and Metabolic Bone Disease - Clinical Aspects and Pathogenesis Poster

Session Type: ACR Poster Session A

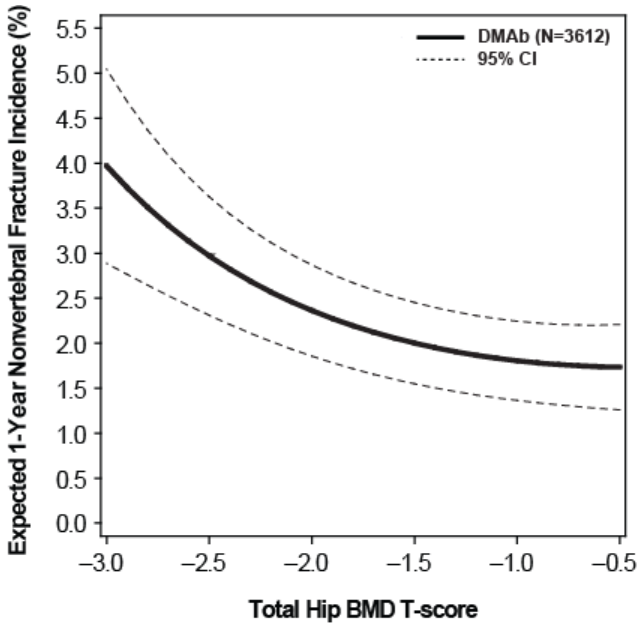
Session Time: 9:00AM-11:00AM

Background/Purpose: The relationship between BMD T-score and fracture risk has not been established in patients on therapy. We previously reported that denosumab (DMAb) treatment over 8 years enabled a substantial proportion of women with osteoporosis to achieve non-osteoporotic BMD T-scores (Ferrari, ASBMR 2014). Further improvement in T-score would only be meaningful if it were associated with fracture reductions; thus, we investigated the relationship between total hip BMD T-score and the incidence of nonvertebral fracture through 8 years of DMAb therapy.

Methods: For these analyses, women received DMAb for 3 years during the FREEDOM trial (N=3902). A large subset of these women enrolled in the Extension and received DMAb for up to an additional 5 years, for a total of up to 8 years of continued treatment (N=2343). A repeated-measures model was first used to estimate each subject's BMD T-scores during the entire follow-up, specifically at each unique nonvertebral fracture time among all subjects at risk at the time of each fracture. Cox's proportional-hazards model was then fitted with time to nonvertebral fracture as the response and total hip BMD T-score time course as a time-dependent covariate.

Results: The incidence of nonvertebral fracture was lower with higher total hip BMD T-score throughout a wide and clinically relevant T-score interval (Figure). For example, total hip BMD T-scores of –2.5 and –1.5 were associated with 1-year nonvertebral fracture incidences of about 3.0% and 2.0%, respectively. The relationship flattened at a T-score somewhere between –2.0 and –1.0, similar to what is known to occur in untreated subjects. This inverse relationship between total hip BMD T-score and nonvertebral fracture incidence was maintained regardless of age or prior fracture (data not shown).

Conclusion: Higher total hip BMD T-scores during DMAb treatment were associated with a lower incidence of nonvertebral fracture, which is similar to the relationship previously established in treatment-naïve patients. Improvements of similar magnitude in BMD would result in different reductions in fracture risk depending on the baseline BMD value. Our findings highlight the importance of BMD measurement in patients on osteoporosis treatment as a predictor of fracture risk and support the concept that a specific T-score should be further evaluated as a practical goal for therapy.



N=number of subjects randomized to DMAb in FREEDOM who had an observed total hip BMD T-score at FREEDOM baseline and ≥ 1 observed total hip BMD T-score during FREEDOM or the Extension.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Osteoporosis and Metabolic Bone Disease - Clinical Aspects and Pathogenesis Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Axial spondyloarthritis (axSpA) is associated with osteoporosis. However the underlying causes are incompletely understood. Osteoprotegerin (OPG) is a bone protective protein that acts as a decoy receptor for RANK-L and inhibits osteoclastogenesis. Previous work has suggested that antibodies to OPG (OPG-Ab) occur more commonly in patients with autoimmune disease and may be associated with increased bone turnover. The aim of this study was to determine whether OPG-Ab are associated with bone health in axSpA.

Methods: Patients with a clinical diagnosis of axSpA were recruited from routine outpatient clinics at two centres in the United Kingdom between 2011-2015. Patient demographics and disease characteristics and fracture history were recorded. All had BMD assessment using anteroposterior dual-energy X-ray absorptiometry (AP-DEXA). Serum levels of OPG-Ab were measured from each patient in triplicate using an in-house ELISA (intra-assay coefficient of variation 10.4%). Patients were considered to be positive for OPG-Ab if values were ≥13units (3 standard deviations above the mean in 100 healthy controls). Associations between OPG-Ab and disease characteristics were assessed by univariate logistic regression. Association with BMD and fractures were assessed by linear and logistic regression, respectively (adjusted for age, gender, duration since diagnosis, BMI and study centre).

Results: We studied 134 patients of whom 75% were male. The mean age was 47 (SD±15) years, and 71% were HLA-B27 positive. 16 patients tested positive for OPG-Ab (11.9%). Presence of OPG-Ab was not associated with patient demographics, axSpA disease characteristics/activity, but was associated with increasing years of disease duration (OR 1.04; 95%CI 1.00, 1.07; P=0.045). OPG-Ab positive patients had reduced hip (but not spinal) BMD and increased history of fracture (Table 1). OPG-Ab positivity was associated with reduced t-score at the hip (ß=-0.83; 95%CI -1.47,-0.18; P=0.012) and increased odds of any fracture (OR_{adj}4.63; 95%CI 1.36, 15.8; P=0.014).

Conclusion: This cross-sectional study demonstrates that the prevalence of OPG-Ab is much higher in axSpA than the healthy population (population prevalence 1%, P<0.001). In axSpA presence of OPG-Ab was strongly and independently associated with hip BMD and history of fractures. This raises the possibility that OPG-Ab may contribute to the bone loss and increased fracture risk observed in axSpA. Spinal BMD is not accurately assessed by AP-DEXA due to presence of syndesmophytes, and it is likely that vertebral BMD will be reduced to a similar extent at the spine. Future studies should utilize lateral spinal DEXAs. OPG-Ab positive axSpA patients may warrant more rigorous bone protection and BMD monitoring.

Table 1 Difference in bone mineral density (BMD) between OPGa positive and negative patients.

	Total	Positive (n=16)	Negative (n=118)	P-value

Session Title: Osteoporosis and Metabolic Bone Disease - Clinical Aspects and Pathogenesis Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Denosumab (DMAb) is approved for the treatment of postmenopausal women with osteoporosis at increased risk for fracture. In the pivotal 3-year FREEDOM trial comparing placebo (Pbo) and DMAb, questions arose regarding imbalances of low-frequency adverse events and some common adverse reactions. Here, we examined the incidences of these events in women who originally received Pbo during FREEDOM and then received DMAb for 3 years during the FREEDOM Extension (cross-over group). This provided a unique opportunity for comparison with the original 3-year Pbo and DMAb FREEDOM observations.

Methods: In FREEDOM, postmenopausal women with osteoporosis received Pbo or DMAb for 3 years. Women were eligible for the Extension if they completed the 3-year FREEDOM visit, missed no more than 1 dose of investigational product (IP) during FREEDOM, and agreed to enroll. During the Extension, all women received DMAb. Three-year cumulative incidences of selected adverse events of interest observed during FREEDOM for the Pbo and DMAb groups were also determined for the first 3 years of DMAb exposure during the Extension for the cross-over group. For each of these 3 groups, the safety analyses included women who received ≥ 1 dose of IP during the respective 3-year periods (FREEDOM Pbo, N=3883; FREEDOM DMAb, N=3879; Extension cross-over DMAb, N=2206). Selected safety events of interest included malignancy, pancreatitis, endocarditis, delayed fracture healing, serious infections, serious opportunistic infections, and serious cellulitis or erysipelas, in addition to the top 5 most frequent adverse events in the US prescribing information (USPI; back pain, pain in extremity, musculoskeletal pain, hypercholesterolemia, and cystitis).

Results: The incidences of these adverse events in the cross-over DMAb group during the first 3 years of the Extension were similar to or lower than the incidences reported in FREEDOM and did not show a trend for increasing risk of any of these events (Table). For example, the incidence of serious adverse events of cellulitis or erysipelas observed in FREEDOM DMAb subjects (0.31%) was not observed in the FREEDOM Pbo subjects who crossed over to DMAb (0.05%) in the Extension.

Conclusion: Analyses of 3-year safety data from FREEDOM (Pbo and DMAb groups) and 3-year safety data from the Extension (cross-over DMAb group) did not show an increasing trend regarding the imbalances of low-frequency events and some common adverse reactions observed in FREEDOM.

Table. Incidences of Events of Interest

	FREEDOM (3 years)		Extension (3 years)
Event of Interest, n (%)	Placebo N = 3883	Denosumab N = 3879	Cross-over Denosumab N = 2206
Adverse Events			
Malignancy[a]	167 (4.30)	187 (4.82)	108 (4.90)
Pancreatitis[b]	3 (0.08)	7 (0.18)	2 (0.09)
Endocarditis	0 (0.00)	3[f] (0.08)	0 (0.00)
Delayed fracture healing[c]	5 (0.13)	2 (0.05)	NA
Delayed fracture healing[d]	1 (0.03)	0 (0.00)	1 (0.05)
Serious Adverse Events			
Infections	134 (3.45)	160 (4.12)	81 (3.67)
Opportunistic infections[e]	3 (0.08)	4 (0.10)	2 (0.09)
Cellulitis or erysipelas	1 (0.03)	12 (0.31)	1 (0.05)
Top 5 Most Frequent Events in USPI			
Back pain	1343 (34.59)	1344 (34.65)	318 (14.42)
Pain in extremity	432 (11.13)	451 (11.63)	171 (7.75)
Musculoskeletal pain	291 (7.49)	297 (7.66)	118 (5.35)
Hypercholesterolemia	236 (6.08)	280 (7.22)	145 (6.57)
Cystitis	225 (5.79)	228 (5.88)	125 (5.67)

Treatment groups are the original randomized assignments in FREEDOM. Seven placebo subjects who received 1 dose of denosumab in FREEDOM were analyzed in the denosumab column in US PI.
N = Number of subjects who received ≥ 1 dose of investigational product.
Includes only treatment-emergent adverse events; based on MedDRA version 13.0.
[a] Based on neoplasms benign, malignant and unspecified (including cysts and polyps) system organ class excluding benign events used in the FREEDOM Extension
[b] Based on acute pancreatitis event of interest search strategy
[c] Based on delayed fracture healing response collected on Clinical Fracture Summary CRF II in FREEDOM
[d] Based on AE reporting of delayed fracture-healing events and subsequently selected by search strategy
[e] Includes aspergillosis, herpes zoster, pulmonary tuberculosis, and tuberculosis
[f] No causative pathogen was identified in any of the 3 cases reported as endocarditis. One subject was hospitalized for treatment with antibiotics. One had endocarditis listed as a consideration in a fatal event of multi-organ failure due to sepsis; however, no treatment details from the case were available. The third case was listed as "non-serious," and the patient did well without long-term antibiotic therapy. Further information is not available.

Session Title: Osteoporosis and Metabolic Bone Disease - Clinical Aspects and Pathogenesis Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Although a higher risk of osteonecrosis of the jaw (ONJ) has been associated with antiresportive treatment based on spontaneous reports and observational studies, no study has systematically assessed the ONJ risk associated with Prolia (denosumab 60 mg). This study estimates the incidence rate (IR) of ONJ in users of Prolia or BP for postmenopausal osteoporosis (PMO) in administrative databases.

Methods: Using administrative data from US Medicare, Optum and Scandinavian national medical registries (Denmark, Norway and Sweden), postmenopausal women with a diagnosis of osteoporosis or osteoporotic fracture, or osteoporosis medications were identified from May 2010 to Dec 2011 (Medicare and Scandinavian national registries) or Mar 2013 (Optum). Women were followed for incident event of potential ONJ defined by ICD codes. Prolia and BP (oral and IV) exposure was updated in a time-varying manner and characterized “as treated”, with and without a 1-year extension following the on-treatment period defined as the days supplied + 60 days. The age-standardized IR of ONJ was computed for each exposure cohort.

Results: A total of 2,561,119 women with PMO were identified from Medicare (1,995,915), Optum (193,003), Denmark (106,691), Norway (95,628) and Sweden (169,882). The IR (95% CI) per 100,000 person-years of ONJ in women with PMO was 40 (38–42) in Medicare, 27 (20–34) in Optum, 37 (27–50) in Denmark, 17 (11–26) in Norway and 25 (17–38) in Sweden. In Medicare, when exposure cohorts were classified only by the on-treatment period, the IR (95% CI) was 70 (28–145) in the Prolia only cohort and 90 (11–328) in the Prolia + BP cohort, and ranged from 45 (41–49) to 77 (7–310) in cohorts exposed to BP only (Table 1). When exposure cohorts were classified by on-treatment plus 1-year post-treatment period, the IR (95% CI) was numerically lower in the Prolia only cohort [59 (11–180)] and the Prolia + BP cohort [76 (30–160)], and remained similar in cohorts exposed to BP only [ranging from 45 (42–48) to 84 (53–125)] relative to the corresponding on-treatment only cohorts (Table 2). The number of ONJ cases in the other data systems was too low (0–2) in Prolia users to allow a robust estimation of the IR.

Conclusion: The descriptive analysis based on Medicare suggested the IR of potential ONJ was low in the PMO population and did not differ substantially by treatment. The number of cases in other data systems was low and precluded meaningful interpretation of the ONJ IR, especially in Prolia recipients. To confirm these results, further analysis based on medically confirmed cases and adjustment for confounders is warranted.

Session Title: Osteoporosis and Metabolic Bone Disease - Clinical Aspects and Pathogenesis Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: In 2014, the Japanese Society for Bone and Mineral Research (JSBMR) updated their guidelines for the management and treatment of glucocorticoid-induced osteoporosis (GIO) and incorporated a new scoring method that does not use the Fracture Risk Assessment Tool (FRAX®). In this study, using the JSBMR guidelines [1] and the American College of Rheumatology (ACR) 2010 recommendations for the prevention and treatment of GIO, we compared our evaluations of Japanese patients with rheumatoid arthritis (RA) who were treated with glucocorticoids.

Methods: The Institute of Rheumatology Rheumatoid Arthritis (IORRA) study, which began in 2000, was a prospective cohort study of RA patients conducted at the Institute of Rheumatology, Tokyo Women's Medical University (Tokyo, Japan). Applying ACR recommendations and JSBMR guidelines, we evaluated 1,752 of these Japanese patients who were over the age of 50 years (mean age 63 years) and had been treated with glucocorticoids. The ACR recommendation is to prescribe osteoporosis treatments for patients treated with ≥ 7.5 mg/day prednisolone or whose 10-year risk of major osteoporotic fractures is > 10%. The Japanese GIO guidelines identify age, glucocorticoid dose, lumbar bone mineral density, and prior fragility fractures as factors predictive of bone fracture, and the fracture risk for an individual can be calculated as the sum of the scores for each risk factor with a score of 3 representing the optimal cut-off score for pharmacological intervention.

Results: Among the female RA patients older than 50 years who were treated with glucocorticoids (n = 1,438), in accordance with the ACR recommendations and the Japanese guidelines, 1,183 (82%) and 1,119 (78%) patients, respectively, should have received osteoporosis treatments (Table). Among the male RA patients older than 50 years who were treated with glucocorticoids (n = 314), the ACR recommendations and the Japanese guidelines propose that 217 (69%) and 267 (85%) patients, respectively, should have received osteoporosis treatments (Table). Among the male patients, the Japanese guidelines would recommend significantly more patients receive osteoporosis treatments compared with the ACR recommendations ($P < 0.0001$).

Table: Japanese patients older than 50 years and treated with glucocorticoids for RA for whom osteoporosis treatments were recommended*

Recommendations/guidelines	Female (n = 1,438)	Male (n = 314)
ACR	182 (12.7%)	3 (1.0%)
JSBMR	118 (8.2%)	53 (16.9%)
ACR and JSBMR	1001 (69.6%)	214 (68.2%)
None	137 (9.5%)	44 (14.0%)

* Data are n (%).

Conclusion: The updated Japanese GIO guideline appears to be a simple and useful tool to use when treating Japanese RA patients with glucocorticoids. The ACR recommendations may have underestimated the need for osteoporosis treatment in male patients with RA compared with the Japanese guideline, although prospective studies are necessary to conclude.

Session Title: Osteoporosis and Metabolic Bone Disease - Clinical Aspects and Pathogenesis Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) are diagnosed with osteoporosis earlier than and those without RA, and are therefore exposed to Bisphosphonates (BPs) for longer. The long-term BPs treatment is one of the suggested predisposing factors for atypical femur fracture (AFF). Thus the aims of the present study were to examine the incidence and clinical characteristics of BPs-associated AFF and to identify predictors of AFF in patients with RA.

Methods: An age- and sex- matched nested case-control study was conducted based on 7 years of data collected at Seoul St. Mary's Hospital, a tertiary rheumatology center. All patients treated with BPs met the 2010 RA classification criteria. AFFs were defined as atraumatic or low-trauma fractures of the subtrochanteric or femoral shaft (Figure 1A). Ten cases of AFF were identified by reviewing surgical procedures and radiographs of the low extremities. The study included 40 age- and sex-matched controls with RA but without AFF. The femorotibial angle (FTA) was measured on radiographs taken with the patient standing to examine alignment of the lower limb under weight-bearing conditions (Figure 1B).

Results: All patients with AFF were female (age, 66.3±8.7 years) and 90% of cases involved fracture of the proximal femur. The mean length of BPs exposure for patients with AFF was 7.4±3.2 years. Patients with AFF had longer exposure to BPs and a smaller FTA ($P < 0.001$ and 0.010, respectively, Table 1). There were no differences in RA duration, medications taken during the previous 6 months, and bone mineral density in the femur and lumbar spine between patients with and without AFF. Multivariate logistic analyses identified BPs exposure (odds ratio [OR], 2.145; 95% confidence interval [CI], 1.175–4.283) and interestingly a FTA < 175°Æ (OR, 114.796; 95% CI, 2.263–5821.991) as being associated with an increased risk of AFF.

Conclusion: RA patients with a valgus deformity and receiving long-term BPs are at higher risk of AFF than matched RA control subjects. These patients should be carefully followed up with X-rays or dual energy bone densiometry.

Figure 1(A) Anteroposterior radiopraph shows right atypical subtrochanteric fracture and a cortical thickness at the left lateral cortex (arrow) (B) Measurement of femorotibial angle (FTA) on a radiograph. The FTA is the lateral angle between the axis of the femoral shaft and that of the tibial shaft

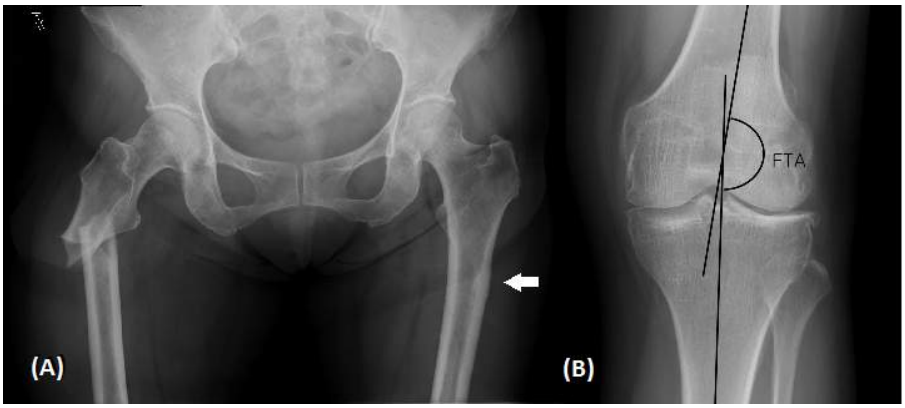

Table 1. Clinical characteristics of rheumatoid arthritis patients ever exposed bisphosphonates according to experience atypical femur fracture

Session Title: Osteoporosis and Metabolic Bone Disease - Clinical Aspects and Pathogenesis Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Patients with chronic obstructive pulmonary disease (COPD) have a high risk of osteoporosis and fractures. In a cohort of male patients with COPD we reported 33% of vertebral fractures, with 27% of fractures in patients with normal bone mineral density (BMD)[1]. Trabecular Bone Score (TBS) has been described as an index of bone microarquitecture, and could be a new assessment tool to detect bone quality impairment in these patients.

Analysis of TBS in a sub-cohort of male patients with COPD and its possible association with BMD, corticoid use, COPD severity or vertebral fractures.

[1]Casado E, et al. JBMR 2007; 22 (S1): S202.

Methods:

Male patients, older than 50 years, with COPD defined according to ATS/ERS classification (FEV_1/FVC<70%) were included. Exclusion criteria: Other concomitant pulmonary disease, rheumatologic and/or vertebral disease that may lead to missinterpretation of BMD by DXA. BMD was determined by dual-energy X-ray absorptiometry (DXA) at lumbar spine and proximal femur. Vertebral fractures were assessed by thoracic and lumbar X-ray. Corticosteroid use in the previous five years and number of hospitalizations were recorded in all patients.

Results:

We included 98 patients. Mean age 67.8±7.5 years. 38% patients had a mild pulmonar disease, 39% moderate and 23% had a severe disease ((FEV_1/FVC<30%). 29 patients (30%) had morphometric vertebral fractures. Mean BMD T-score at lumbar spine -1.67±1.55, at femoral neck -1.81±1.04, and al total hip -1.31±1.14. Mean TBS was 1.035±0,135 (T-score -2.85±1.18). TBS was lower in fractured patients (T -2.59±1.16 vs -2.34±1.22; p=NS). According to COPD severity TBS was lower in patients with modereate disease (T-2.57±1.34) and severe disease (T -2.54±1.34) than in patients with mild disease (T -2.19±1.32), although without reaching significant differences. We didn't find any significant assotiation between TBS and corticosteroid use.

Conclusion:

TBS is severely affected in male patients with chronic obstructive pulmonary disease, especially in patients with moderate and severe pulmonar disease. Low TBS seems to be associated with vertebral fractures in this population.

Session Title: Osteoporosis and Metabolic Bone Disease - Clinical Aspects and Pathogenesis Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

There is an evidence vacuum concerning the mechanisms underlying the high atherosclerotic cardiovascular disease (ASCVD) burden in patients with psoriatic arthritis (PsA). In the general population, osteoporosis and low bone mineral density (BMD) are risk factors for ASCVD. However, this has not been established for patients with PsA. The T-score represents a patient's BMD compared to the BMD of a healthy 30-year old and is the most commonly used measure when screening for osteoporosis. The aim of the present study was to evaluate if low BMD, measured by T-score, is correlated with ASCVD in patients with PsA.

Methods:

In this cross-sectional study, patients with PsA, recruited from an outpatient clinic, underwent a thorough clinical rheumatology examination, carotid ultrasound, laboratory tests and BMD measurements by dual-energy X-ray absorptiometry (DXA) scans. Established ASCVD was defined as a previous ASCVD event (acute myocardial infarction, coronary interventions, transient ischemic attack [TIA] and ischemic stroke), established peripheral artery disease or atherosclerotic carotid artery plaque(s). Unadjusted and adjusted analyses of variance (ANOVA) were applied to compare the T-score between patients with and without ASCVD. In addition, we performed logistic regression analyses with ASCVD as the dependent variable, both unadjusted and adjusted (age, gender and BMI) and evaluated the Nagelkerke R^2 as a proxy for the degree of correlation between ASCVD and T-score, traditional CVD risk factors, inflammatory biomarkers and PsA disease activity variables.

Results:

In the cohort of 137 PsA patients, 51 (37%) had ACSVD, 70 (51%) were male and the median (IQR) age and disease duration was 53.0 (44.5, 59.5) and 7.8 (3.2, 12.5) years, respectively. The T-score was significantly lower in patients with ACVD compared to those without (p=0.001) (Table). This finding was largely robust to adjustments for demographic data (p=0.04), traditional CVD risk factors (p=0.03-0.06), inflammatory biomarkers (p<0.05), PsA disease activity (p=0.03-0.10) and common rheumatology drugs (p=0.02-0.04). In logistic regression analyses with ASCVD as the dependent variable, the Nagelkerke R^2 value for T-score (unadjusted: 0.11, adjusted: 0.27) was higher than for ACVD risk factors (unadjusted: 0.003-0.04, adjusted: 0.23-0.25), inflammatory biomarkers (unadjusted: 0.005-0.05, adjusted: 0.24) and PsA disease activity variables (unadjusted: <0.001-0.04, adjusted: 0.23-0.26).

Conclusion:

Our study provides the first evidence of an association between ACVD and low BMD in PsA patients, which was robust to adjustments. In addition, ACVD was more strongly correlated with the T-score than with traditional CVD risk factors, inflammatory biomarkers or PsA disease activity. Our results suggest that there may be indication for CVD risk evaluation including carotid ultrasound in PsA patients with low BMD.

T-score in patients with and without established atherosclerosis.

Session Title: Osteoporosis and Metabolic Bone Disease - Clinical Aspects and Pathogenesis Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Although weekly teriparatide (56.5ug, wTPTD) and denosmab (DMAB) have been developed as potent anti-osteoporotic agents, effects of these agents on prevention of osteoporotic fractures in glucocorticoid-induced osteoporosis (GIO) have not yet well demonstrated. We conducted a cohort study to clarify effects of wTPTD and DMAB when compared with bisphosphonates (BIS) on osteoporotic vertebral fractures in GIO.

Methods: A one-year cohort study recruiting 223 patients (196 women) with connective tissue diseases was conducted in Tokyo, Japan. Means of age, disease duration, total prednisolone (PSL) dosages, and daily PSL dosages (dPSL) of subjects were 65+/-15 (yo, +/-SD), 11+/-11 (y), 25+/-29 (g) and 6.4+/-5.7 (mg/day), respectively. Vertebral fractures were defined from X-ray films with the semi-quantitated method (SQ; Genant, 1993). Lumbar bone mineral densities (BMD) were measured with Lunar 3030 (GE). Prevalent vertebral fractures were seen in 103 (46%) patients. Bisphosphonates, wTPTD, and DMAB were used in 149, 53, and 21 patients, respectively.

Results: 1) The BMD at the base line was 0.916 +/- 0.181, and showed no difference between treatment groups. The daily PSL was significantly increased ($p<0.03$) in the group of wTPTD than in BIS and DMAB (10.5, 6.0, and 6.0, respectively). 2) Incident vertebral fractures were observed in 24 (16%), 2 (4%), and 2 (10%) in BIS, DMAB, and wTPTD, respectively. 3) A multivariate logistic regression analysis revealed that statistically significant factors for incident fractures were BMD (per 0.1 decrease, OR; 1.40, 95%CI; 1.02–1.91), dPSL (per 5mg increase, 1.95, 1.29–2.95), prevalent fractures (5.16, 1.85–14.4), DMAB (vs BIS, 0.01, 0.001-0.05), wTPTD (vs BIS, 0.12, 0.03-0.88). 4) There were no significant differences in severe adverse effects between the treatment groups.

Conclusion: These results suggested that wTPTD and DMAB might be more effective than bisphosphonates for prevention of osteoporotic vertebral fractures in patients treated with glucocorticoids.

Session Title: Osteoporosis and Metabolic Bone Disease - Clinical Aspects and Pathogenesis Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Ankylosing spondylitis (AS) is a chronic inflammatory rheumatological disease of unknown origin that primarily affects the axial skeleton, including the sacroiliac joints and spine, but also the peripheral joints and entheses.

This study aimed to evaluate the relationship between physical function, disease activity, spinal mobility and bone parameters in ankylosing spondylitis (AS)

Methods:). Fifty patients were examined: 27 men and 23 women. None of the patients exhibited evidence of a fracture in any of the visualized vertebrae. The clinical assessment included Bath AS Disease Activity Index (BASDAI), AS Disease Activity Score (ASDAS-CRP), Bath AS Functional Index (BASFI), Bath AS Metrology Index (BASMI). Lumbar spine and femoral neck bone mineral density (BMD), spinal trabecular bone score (TBS) and the TBS T-score were calculated by dual-energy X-ray absorptiometry (DXA).

Results: Using the WHO categorization scheme, 50% of the patients were deemed to have normal lumbar BMD, 36% were osteopaenic, and 14% were osteoporotic. This compares with normal TBS in 50% of the patients, with partially-degraded and fully-degraded micro-architecture seen in 34% and 16%, respectively. We found moderately strong inverse correlations between TBS and BASMI (r=-0.34; p=0.02), between the TBS T-score and BASMI (r=-0.35; p=0.01) and between femoral BMD and BASMI (r= -0.395; p=0.004). The correlation coefficient for the relationship between the TBS T-score and age was -0.29 (p=0.045), suggesting a weak inverse association, while TBS only exhibited a borderline inverse correlation with age (r=-0.27; p=0.06). Femoral BMD was moderately inversely correlated with age (r=-0.44; p=0.001). In addition, the lumbar spine TBS and TBS T-score were moderately to strongly correlated with BMI (both r=-0.65; p<0.001). No significant correlations were observed between bone parameters and other markers of disease activity, physical function, or applied therapy administered for AS. Subject`s age was independently associated with a femoral neck BMD < -1.00 (OR = 1.08, 95% CI 1.01 to 1.15, p=0.03).

Conclusion:

In summary, spine BMD can be erroneously influenced by osteoproliferation, unlike the TBS and TBS T-score. The limitations in spinal mobility predicted abnormal results for these two TBS parameters. The TBS may be a better indicator of bone health than BMD in AS.

Session Title: Osteoporosis and Metabolic Bone Disease - Clinical Aspects and Pathogenesis Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Different from infantile forms, adult forms of hypophosphatasia have less severe manifestations and may go unrecognized. Low serum levels of alkaline phosphatase (ALP), the enzyme encoded by the ALPL gene, are a hallmark of hypophosphatasia. However, the clinical significance and the underlying genetics of low ALP in unselected populations are unclear.

Methods:

In order to clarify this issue, we performed a clinical and biochemical study of subjects with reduced serum ALP activity. The screening of the coding sequences and intron/exon boundaries of ALPL gene was performed by direct sequencing using the BrightDye Terminator cycle kit.

Results:

Forty two adult individuals with unexplained persistently low serum ALP were studied. There was a 3:1 female:male ratio. Age range was 20-77 yr. Although many subjects experienced minor complains, such as mild musculoskeletal pain (60%), none had major health problems. ALPL mutations were found in 21 out of 42 subjects (50%). Twenty patients carried heterozygous mutations; whereas 1 had a homozygous mutation. Eight mutations were novel and had not been previously described. Eighteen of the 21 patients with mutations (86%) had a missense mutation; in 1 case the mutation caused a splice change and there were 2 frameshift mutations. Most mutations were located in exons 5 and 6 (12 aminoacid positions were mutated in 17 patients) and were predicted to have a damaging effect on the protein

activity, both according to the structure-based Polyphen webtool (13 mutations) and the evolutionary criteria proposed by Silvent (14 mutations). The presence of a mutated allele was associated with premature tooth loss (48% versus 12%; p=0.04), slightly lower levels of serum AP (30±6 vs 25±6 u/l; p=0.002) and higher levels of enzyme substrates, such as serum pyridoxal phosphate (p<0.0001) and urine phosphoetanolamine (p<0.0001), as well as mildly increased serum phosphate (p=0.03). Ten patients had pyridoxal phosphate levels above the normal range, a test frequently used when hypophosphatasia is suspected. All carried a gene mutation; predicted to be deleterious in 9 cases and of doubtful significance in one.

Conclusion: One half of adults with persistently low levels of total alkaline phosphatase had a mutated allele of the ALPL gene. Although clinical manifestations are usually mild, in about 50% of them enzyme activity is low enough to cause substrate accumulation and may predispose to disorders of the teeth and other calcified tissues.

Session Date: Sunday, November 8, 2015

Session Title: Osteoporosis and Metabolic Bone Disease - Clinical Aspects and Pathogenesis Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

In patients with rheumatic diseases (RD), pro-inflammatory cytokines induce receptor activator of nuclear factor kappa-B ligand (RANKL), which plays a crucial role in inducing osteoclasts differentiation and consequent osteoporosis and bone erosion. Glucocorticoid (GC) is often used to treat RD, while strongly inhibits bone formation and increases fracture risk. Denosumab (DMAb) is an anti-RANKL antibody which strongly inhibits bone resorption, while its effect in RD (especially in GC-induced osteoporosis) remains unknown.

Methods:

DMAb was introduced in 181 RD patients (160 female, 61.6 years old, 127 RA, 31 SLE, 5 dermatomyositis, 4 sarcoidosis, 14 other diseases, 77.2% taking prednisolone (PSL) with average dose 4.3mg/day, 21.4% taking biologics, lumbar spine (LS) T-score -1.7, femoral neck (FN) T-score -2.2, total hip (TH) T-score -1.9, prior treatment; bisphosphonate (BP) 63.4%, teriparatide (TPTD) 18.6%, naïve 16.6%) and followed up for 12 months by

monitoring bone mineral density (BMD) and bone turnover markers.

Results:

Baseline FN T-score showed negative correlation with baseline serum CRP levels (r=-0.24, P<0.01) and bone resorption marker Isoform 5b of tartrate-resistant acid phosphatase (TRACP-5b; r=-0.44, P<0.001）, suggesting high inflammation levels and increased bone resorption is associated with low bone mass in RD patients. BMD increase from baseline→6→12 months was as follows. LS; 0→2.8→4.7%, TH; 0→1.5→2.9%, FN; 0→1.7→2.7%. There was no significant difference in BMD increase between the difference of prior osteoporosis treatment (BP, TPTD, and naïve) or the presence or absence of combined oral GC [without PSL (n=41); LS 0→3.2→4.4%; FN 0→2.2→2.5%, with PSL (5.6mg/day; n=140); LS 0→2.9→4.8%; FN 0→1.7→2.9%] or the dose of combined PSL [PSL<5mg/day (n=108); LS 0→3.4→4.9%; FN 0→2.3→2.9%, with PSL≧5mg/day (n=73); LS 0→2.3→4.6%; FN 0→1.2→2.4%]. In addition, there was no significant difference in baseline levels of bone turnover markers, which converged to constant levels regardless of the presence or absence of combined oral GC [TRACP-5b; without PSL; 267→238→126 mU/dl, with PSL; 298→151→113 mU/dl] . On the other hand, patients with high dose of combined oral GC (PSL≧5mg/day; n=73), compared to low dose users (PSL<5mg/day; n=108), was associated with lower TRACP-5b (94 vs 133 mU/dl; P<0.01) and undercarboxylated osteocalcin (ucOC; 0.9 vs 1.5 ng/ml; P<0.05) levels, but not with bone formation marker Type I collagen N-terminal propeptide (P1NP; 18.2 vs 18.2 ug/l) at 12 months. BMD increase (%) of LS at 12 months was positively correlated with baseline value of bone turnover markers〔TRACP-5b（r=0.34, P<0.001）, ucOC（r=0.29, P<0.01）〕and their decreasing rate at 6 months [TRACP-5b（r=0.31, P<0.01）, ucOC（r=0.30, P<0.01）].

Conclusion:

Our findings indicate that DMAb increased BMD regardless of prior osteoporosis treatment and combined oral GC dose. High dose of combined oral GC (PSL≧5mg/day) significantly decreased serum TRACP-5b and ucOC levels, while sustained serum P1NP levels compared to that of low dose GC users (PSL<5mg/day). Sustained bone formation and greater bone resorption inhibition induced by DMAb in high dose GC users may contribute to sustained BMD increase.

Session Date: Sunday, November 8, 2015

Session Title: Osteoporosis and Metabolic Bone Disease - Clinical Aspects and Pathogenesis Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Although glucocorticoid-induced osteoporosis is the most common cause of secondary osteoporosis, providing effective treatment remains a challenge. Bisphosphonates are currently recommended for treatment and prevention of glucocorticoid-induced osteoporosis in several international guidelines. However, some people cannot tolerate any of the available bisphosphonate therapy because of their adverse effects. Moreover, bone resorption is inhibited with bisphosphonates, while the primary action of glucocorticoids is to decrease bone formation. On the other hand, human parathyroid hormone (hPTH) stimulates bone formation. As a result, hPTH may have significant advantages for treatment and prevention of glucocorticoid-induced osteoporosis. To the best of our knowledge, this topic has not yet been systematically reviewed. We therefore examine the benefit and harm of hPTH in the prevention and treatment of glucocorticoid-induced osteoporosis.

Methods: We searched three different databases (Cochrane Central Register of Controlled Trials (CENTRAL), MEDLINE and EMBASE) as well as reference lists of retrieved studies and review articles published between January 1966 and October 2014. All relevant randomized controlled trials that assess the efficacy of hPTH for the prevention or treatment of glucocorticoid-induced osteoporosis were included. All papers meeting strict inclusion criteria were scrutinized for data on population size, participants characteristics, vertebral fracture, non-vertebral fractures, bone mineral density (BMD) at the lumber spine, withdrawals due to adverse events, serious adverse events.

Results: A total of 1,784 articles were initially identified and 414 of these articles were duplicates and therefore excluded. After the initial screening, 20 full-length articles were selected for detailed analysis on the basis of title or abstract. Eventually, four studies (17 articles) met all the inclusion criteria. Two studies compared hPTH with bisphosphonate while the other studies assessed the efficacy of hPTH comparing with placebo or no treatment. A total of 595 patients were covered by these studies, with women accounting for a median of 52.7 percent and the median of the mean age was 56.7 years. We could not pool data on the vertebral fracture or non-vertebral fracture because there were no fractures in one study that compared hPTH with bisphosphonate, while the other showed fewer vertebral fractures in hPTH than in bisphosphonate (P =0.004) whereas the incidence of non-vertebral fractures was similar (P = 0.36). Patients in hPTH had an greater increase in change from baseline in BMD at lumber spine than patients in bisphosphonate (pooled percentage change: 3.77: 95% confidence interval: 1.99-5.56).The pooled analysis showed fewer withdrawals due to adverse events in hPTH than bisphosphonate (odds ratio (OR): 0.45, 95% confidence interval: 0.24-0.86) while that for serious adverse events was similar (OR: 0.80, 95% confidence interval: 0.32-2.00).

Conclusion: hPTH seems to be more effective than bisphosphonate.

Session Title: Osteoporosis and Metabolic Bone Disease - Clinical Aspects and Pathogenesis Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Gouty arthritis is a common inflammatory joint disorder and hyperuricemia (HU) is known to be the main risk factor. Beside clinical signs of inflammation such as pain and swelling, gout is associated with local bone loss. Higher serum uric acid concentrations correspond with higher bone mineral density (BMD), a lower prevalence of non-vertebral fractures and a lower bone turnover. Other inflammatory joint disorders such as rheumatoid arthritis (RA) and psoriatic arthritis (PsA) are associated with low BMD, altered bone microstructure and consequently secondary osteoporosis. To date there is no information about the influence of HU on bone microstructure. The objectives were to investigate trabecular and cortical bone microstructure, volumetric BMD (vBMD), bone turnover markers in female and male subjects with HU without signs and symptoms of arthritis and respective controls with low serum uric acid.

Methods:

Otherwise healthy male and female subjects with HU (uric acid>7.5 mg/dl) and respective controls with low serum uric acid (CO, uric acid<6.0 mg/dl) were included. Patients with known gouty arthritis, inflammatory disorders, osteoporosis, liver or kidney diseases were excluded.

Microstructure and vBMD were assessed by HR-pQCT (XtremeCT, SCANCO Medical, Brüttisellen, Switzerland) at the ultra-distal radius (standard non weight bearing bone site) in all subjects.

Total vBMD (Tot.BMD, mgHA/cm^3), trabecular vBMD (Trab.BMD, mgHA/cm^3) and cortical vBMD (Ct.BMD, mgHA/cm^3) were evaluated. Microstructure analyses included the trabecular bone volume fraction (BV/TV), trabecular number (Tb.N, 1/mm), inhomogeneity of the trabecular network (Tb.1/N.SD, mm), trabecular thickness (Tb.Th, mm) and cortical thickness (Ct.Th, mm). Bone turnover markers including Cross Laps (CTX), reflecting osteoclast activity, Procollagen type 1 Amino-terminal Propeptide (P1NP), reflecting osteoblast activity, intact parathyroid hormone (iPTH), 25-hydroxyvitaminD(25-OH vitamin D), calcium and phosphate were measured.

Results:

29 subjects with HU (57.4±10.1 years) and 15 CO (57.7±11.3) were analyzed. Serum uric acid was 8.9±1.4 mg/dl in HU and 4.4±1.0 mg/dl in CO. Body Mass Index (BMI, 30.0±6.4 vs. 26.9±6.1) was non-significantly different between HU and CO.

Similar results were found for Tot.BMD (p=0.590) and Ct.BMD (p=0.566). Trab.BMD differed by trend in HU (p=0.068) but not BV/TV (p=0.201), Tb.N, (p=0.071), inhomogeneity of trabecular network (p=0.227), Tb.Th (p=0.614) as well as Ct.Th (p=0.271).

Vitamin D levels, CTX, P1NP, calcium or phosphate were similar and within normal range in the two groups. iPTH levels were higher by trend in HU when compared to CO (p=0.053).

Conclusion:

Our results suggest similar volumetric bone mineral density and bone microstructure in subjects with HU and subjects with low serum uric acid levels. Despite the well-known negative effects of uric acid on local bone loss, HU does not seem to be a predictive factor for systemic bone loss. This is in contrast to other inflammatory joint diseases such as RA and PsA where systemic bone loss and changes in microarchitecture start before the onset of clinical disease.

Diminished Health-Related Quality of Life As Measured By the Short Form-10 in Children with Hypophosphatasia

Thomas J. Weber[1], Eileen K. Sawyer[2], Scott Moseley[2] and Priya S. Kishnani[1], [1]Duke University Medical Center, Durham, NC, [2]Alexion Pharmaceuticals, Cheshire, CT

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Osteoporosis and Metabolic Bone Disease - Clinical Aspects and Pathogenesis Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Hypophosphatasia is a rare metabolic disease caused by loss-of-function mutation(s) in the gene encoding the tissue non-specific alkaline phosphatase (ALP). In children, low tissue non-specific ALP activity leads to deficient skeletal mineralization and complications that may include poor growth, proximal muscle weakness, pain, and compromised physical function. The impact of these symptoms on health-related quality of life is not known.

Methods: The Short Form-10 (a short version of the Child Health Questionnaire) was administered as part of the internet-based Hypophosphatasia Impact Patient Survey (HIPS) developed to characterize the burden of disease in patients with hypophosphatasia. Outreach from 2009-2011 by patient advocacy groups provided awareness of the survey to patients or caregivers and invited participation. Summary statistics were calculated for the norm-based Physical Health and Psychosocial Summary scores (healthy population mean=50, standard deviation [SD]=10) and for each individual question.

Results: Forty-four children (50% male, 80% via caregiver respondents) participated in the Hypophosphatasia Impact Patient Survey, of which 39 completed the Short Form-10. Mean (SD) age at the time of the survey was 6.8 (4.8) years; age at onset of hypophosphatasia symptoms was 0.9 (1.0) years. The majority of children reported pain (82%, 38/44), including in the joints (61%, 27/44) and bones (52%, 23/44), and muscle weakness (66%, 29/44). Thirty-six percent (16/44) reported fractures. The mean Physical Health score (23.7, 95% confidence interval [CI]: 17.2-30.3, n=39) was >2 SD below normal. The mean Psychosocial Summary score (45.6, 95% CI: 41.9-49.3, n=39) revealed a small decrease relative to population norms. The majority of children reported limitations in high energy activities such as riding a bike or skating (79%, 31/39); basic activities such as bending, lifting, and stooping (64%, 25/39); and school work or activities with friends (62%, 24/39) due to physical health problems. Eighty-two percent (32/39) reported experiencing pain in the past 4 weeks. Behavioral and emotional problems limited school or social activities in 33% (13/39) of children, and behavior was rated by the respondent as “Good” or higher for 90% (35/39) of the children.

Conclusion: As reported by caregivers/patients and consistent with the reported burden of symptoms, hypophosphatasia has a high physical impact on children which reduces their ability to keep up with peers and participate in normal childhood activities, including both high energy and daily living activities, substantially diminishing health-related quality of life. The lower impact of hypophosphatasia on psychosocial health reported herein may reflect higher resilience to disease in children compared with adults, or the influence of parental report. An understanding of the impact of hypophosphatasia on health-related quality of life is important for evaluating future treatment options. Further

studies are needed to characterize health-related quality of life longitudinally in these patients.

Massive Elimination of Multinucleated Osteoclasts By Eupatilin Is Due to Dual Inhibition of Transcription and Cytoskeletal Rearrangement

Session Title: Osteoporosis and Metabolic Bone Disease - Clinical Aspects and Pathogenesis Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoporosis is an ageing-associated diseases requiring better therapeutic modality. Eupatilin is a major flavonoid from Artemisia. We aimed to evaluate the effects of eupatilin on RANKL-induced osteoclast differentiation and its mechanism of action.

Methods: ICR mice were divided into 4 groups: saline-treated (Control), only LPS-treated, only eupatilin-treated, and LPS and eupatilin-treated groups. Eupatilin or PBS was administered orally 1 day before LPS injection. Eupatilin or PBS was administered orally every other day for 8 days. LPS was injected intraperitoneally on days 1 and 4. The mice were sacrificed after 8 days, and the left femurs were analyzed by high-resolution micro-computed tomography. To confirm the therapeutic effect of eupatilin on LPS-induced bone loss in vivo, ICR mice were divided into 6 groups : PBS-treated, LPS-treated, and LPS plus eupatilin-treated groups. Eupatilin or PBS was administered orally every day from 4, 6, or 8 days. LPS was injected intraperitoneally on days 1 and 4. Mice were sacrificed after 10 days, and the left femurs were analyzed by high-resolution micro-CT. We further assessed the effect of eupatilin on OVX-induced bone loss. Eight-week-old female C57BL/6 mice were either 6 sham-operated mice or 12 OVX mice. OVX mice were divided into two groups: OVX controland eupatilin groups. After, eupatilin was administrated orally for 4 weeks. Femur metaphysic regions were scanned using a high-resolution micro-CT.

Results: Upon stimulation prior to RANKL treatment or poststimulation of BMCs in the presence of RANKL with eupatilin complete blockade of RANK-dependent osteoclastogenesis was accomplished. This blockade was accompanied by inhibition of rapid phosphorylation of *Akt, GSK3b*, *ERK* and *IkB* as well as downregulation of c-Fos and NFATc1 at protein levels, suggesting that transcriptional suppression is a key acting mechanism on the anti-osteoclastogenesis. Transient reporter assays or gain of function assays confirmed that eupatilin was, indeed, a potent transcriptional inhibitor in osteoclasts (OC). Surprisingly, when multinucleated osteoclasts (MNCs) were cultured on

bone scaffolds in the presence of eupatilin bone resorption activity was also completely blocked by dismantling actin ring, suggesting that another major acting site of eupatilin is cytoskeletal rearrangement. The eupatilin-treated MNCs revealed a shrunk cytoplasm and accumulation of multi-nuclei, eventually becoming fibroblast-like cells. No apoptosis occurred. Inhibition of phosphorylation of *cofilin* by eupatilin suggests that actin may play an important role in the catastrophic morphological change of MNCs. Human OC were similarly responded to eupatilin. When eupatilin was administered to LPS-induced osteoporotic mice after manifestation of osteoporosis, it was capable of preventing bone loss. The ovariectomized (OVX) mice remarkably exhibited bone protection effects.

Conclusion: Taken together, eupatilin is an effective versatile therapeutic intervention for osteoporosis as dual blockaders; 1) transcriptional suppression of c-Fos and NFATc1 of differentiating OC and 2) inhibition of actin rearrangement of pathogenic MNCs.

Session Title: Osteoporosis and Metabolic Bone Disease - Clinical Aspects and Pathogenesis Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The relationship of sodium intake to bone mineral density (BMD) in postmenopausal women has not been established, and no study to date has examined its relationship with fracture risk. The purpose of this study was to examine whether sodium intake is associated with changes in BMD at the lumbar spine, total hip, femoral neck and total body and with incident fractures and whether this relationship is modified by potassium and/or calcium intake among women in the Women's Health Initiative (WHI).

Methods: Data from 69,735 postmenopausal women in the WHI were included in this report. Linear regression models and Cox proportional hazard models were used to estimate the relationships between calibrated sodium intake, changes in BMD, and incident fractures that occurred during WHI follow-up, and to ascertain whether calibrated potassium or calcium intake modified these relationships. Models were adjusted for demographics, clinical factors and

medication use.

Results: The median calibrated sodium intake was 2891.6 mg/day (range: 1234.5-7574.9mg/day). There was no association between whether or not sodium intake was above the median and changes in BMD at the total hip, femoral neck or lumbar spine from baseline to three ($p>0.24$) or six years ($p>0.16$) or with all fractures, osteoporotic fracture sites other than the spine and hip (other fractures) and spine fractures ($p> 0.13$). Sodium intakes above the median were associated with significant increases in BMD at the total body from baseline to three years ($p=0.02$), though changes from baseline to six years were not significant ($p=0.36$). Sodium intake above the median was also associated with fewer hip fractures ($p=0.03$). Levels of sodium intake above or below currently recommended guidelines for cardiovascular disease (2300 mg /day) were not associated with changes in BMD at any skeletal site from baseline to three ($p> 0.66$) or six years ($p> 0.74$) or with incident fractures ($p\geq0.70$). There was no association of sodium intake with incident fractures after adjusting for potassium intake ($p\geq0.30$). Calcium intake did not modify the association between sodium intake and changes in BMD or risk of incident fracture ($p\geq0.20$).

Conclusion: Adherence to current population-based recommended intakes for sodium intake is unlikely to significantly impact osteoporosis. The surprising association of higher sodium intakes with fewer hip fractures merits further study.

Session Title: Osteoporosis and Metabolic Bone Disease - Clinical Aspects and Pathogenesis Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Bone is a dynamic tissue, and its formation and resorption are continuous processes that promote changes throughout the life of the organism, and changes in bone microstructure contribute to fracture risk. High-Resolution peripheral Quantitative Computed Tomography (HR-pQCT) can assess microstructural and biomechanical properties of human distal end. Faced with so multitude of applications and perspectives of HR-pQCT, it is necessary to establish normal standard curves. The aim of this cross-sectional study is to establish normal values related to age, weight and height using HR-pQCT regarding volumetric bone mineral density (vBMD), microstructure, cortical porosity and estimated bone strength at the distal radius and tibia from a women population aged 20 to 85 years.

Methods: References curves were calculated in 450 healthy women (> 50 women per decade). The HR-pQCT acquisitions (XtremeCT, Scanco Medical) were performed using the standard scanning protocol. Statistical analysis including linear regression models were developed to predict the values of the twenty normal curves measured according to age, weight and height. The outcome variables used in our analyses included the following: **Volumetric bone density parameters** (mg HA/ccm): trabecular bone density (Tb.vBMD), cortical bone density (Ct.vBMD); **Bone structure parameters:** number of trabeculae (Tb.N, 1/mm), trabecular thickness (Tb.Th, mm), trabecular separation (Tb.Sp, mm), cortical thickness (Ct.Th, mm); **Cortical porosity parameters:** cortical porosity (Ct.Po, 1), mean cortical pore diameter (Ct.Po.Dm, mm); **Finite element analysis (FEA):** stiffness (S, kN/mm), estimated failure load (F.Load, N).

Results: Evaluation of the distal radius by HR-pQCT: All parameters showed linear curves with age, except for Ct.Po, S and F.Load. Positive correlations were observed between stiffnewomenss and Tb.vBMD (r: 0.644, $p < 0.001$), Ct.vBMD (r: 0.521, $p < 0.001$), Tb.N (r: 0.245, $p < 0.001$), Tb.Th (r: 0.616, $p < 0.001$), Ct.Th (r: 0.619, $p < 0.001$), Ct.Po.Dm (r: 0.140, $p < 0.001$) and F.Load (r: 0.995, $p < 0.001$). In contrast, weak negative correlations were detected between S and Tb.Sp (r: -0.312, $p < 0.001$) and Ct.Po (r: -0.162, $p= 0.015$). **Evaluation of the tibia by HR-pQCT:** All obtained curves were linear, except for Ct.vBMD, Ct.Th and Ct.Po. The cortical density and thickness showed a plateau until about 50 years of age, following by a decreasing curve. Positive correlations were observed between stiffness and Tb.vBMD (r: 0.571, $p < 0.001$), Ct.vBMD (r: 0.316, $p < 0.001$), Tb.N (r: 0.298, $p < 0.001$), Tb.Th (0.355, $p < 0.001$), Ct.Th (r: 0.392, $p < 0.001$) and F.Load (r: 0.955, $p < 0.001$). Moreover, negative correlations were found between S and Tb.Sp (r: -0.354, $p < 0.001$) and Ct.Po (r: -0.273, $p < 0.001$).

Conclusion: This study established a set of reference data for HR-pQCT parameters in a heathy women population, which will be useful for interpreting clinical data from patients in clinical practice and in future studies.

Determination of the Osteoporotic Vertebral Fractures By a New Quantitative Approach: Intervertebral Volume Index

Omer Kuru[1], Yasemin Ulus[2], Halil Sen[2], Bunyamin Sahin[3] and Ayhan Bilgici[2], [1]Physical Medicine And Rehabilitation Division of Rheumatology, Ondokuz Mayis University School of Medicine, Samsun, Turkey, [2]Physical Medicine and Rehabilitation Division of Rheumatology, Ondokuz Mayis University School of Medicine, Samsun, Turkey, [3]Anatomy, Ondokuz Mayis University School of Medicine, Samsun, Turkey

Session Date: Sunday, November 8, 2015

Session Title: Osteoporosis and Metabolic Bone Disease - Clinical Aspects and Pathogenesis Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Vertebral fractures caused by osteoporosis are quite common and have a negative effect on quality of the life. But they may not be clinically detectable. Computed tomography (CT) is an appropriate method in examining and evaluating the vertebral fractures because it shows bone details accurately, clearly and quickly.

Stereology is a science which is used to obtain quantitative data about the structure using two-dimensional section from the three dimensional structures. In this study, we aimed to describe a new method that demonstrates objectively the decrease percentage of the volume of the fractured vertebral body according to the average volume of the neighboring vertebrae using the volume intervertebral volume index (IVF).

Methods: Forty women, who admitted to the Ondokuz Mayis University, Department of Physical Medicine and Rehabilitation and who were diagnosed with osteoporosis by bone mineral density (BMD) and osteoporotic vertebral compression fracture by routine thoracolumbar radiographs, were included in the study. CT images of the patients were taken with 3 mm thickness in axial plane were converted to the sagittal orientation. Vertebrae volumes were calculated using the Cavalieri principle, which is one of the stereological methods in ImageJ software. Reduction in the volume of the fractured vertebra was calculated as percentages based on above and below vertebral volumes.

Results: It was determined that the measured volume of the fractured vertebra at each fracture level decreased by 67.70% compared to the expected vertebral volume that was calculated according to volumes of the above and below vertebrae of the fractured vertebra. In all patients, significant differences were determined between the average detected volume and the expected volume of the fractured vertebrae ($p < 0.001$).

Conclusion: In this study, the method that we used may be cheap, safe and quick way for determining osteoporotic vertebral fracture volume as unbiased and the most accurate. This method, which allows obtaining objective data in the detection of vertebral fracture, does not require an additional procedure or equipment because of it is obtained from CT images which is routinely used in all radiology centers. Therefore, it can be suggested that this method may be used routinely.

Session Title: Osteoporosis and Metabolic Bone Disease - Clinical Aspects and Pathogenesis Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: To evaluate the incidence of fragility fractures associated with high-dose glucocorticoid therapy in patients with systemic rheumatic disease.

Methods: A retrospective study of patients who were treated with high-dose prednisolone (more than 0.8 mg/kg) for systemic rheumatic disease at Kobe University Hospital from April 1988 to March 2012. The primary outcome was a major osteoporotic fracture (defined as a clinical vertebral, hip, forearm, or proximal humerus fracture) after high-dose

glucocorticoid therapy. For postmenopausal women and men over 40 of age, the patient's fracture risk at the beginning of high-dose glucocorticoid therapy was assessed by the World Health Organization's Fracture Risk Assessment Tool (FRAX).

Results: Of 229 patients (median age: 49 years), 57 suffered a fragility fracture during the observation period (median observation period: 1558 days). Of 84 premenopausal patients, 5 suffered a fracture. In contrast, of 86 postmenopausal female, 36 suffered a fracture. Fragility fractures were far more frequent than predicted by the FRAX score. Bisphosphonate use did not reduce the risk of fragility fractures. Patients with FRAX scores over 8.3% had a particularly high risk of fracture.

Conclusion: Fragility fractures associated with high-dose glucocorticoid therapy are common among postmenopausal women. Bisphosphonate does not prevent fragility fractures in patients undergoing high-dose glucocorticoid therapy. Alternative drugs should be considered as a first-line prophylactic measure.

Session Title: Osteoporosis and Metabolic Bone Disease - Clinical Aspects and Pathogenesis Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Bone turnover markers (BTMs) respond faster than bone mineral density as an indicator of response to therapy in osteoporotic patients; however, it remains unclear when and how best to evaluate treatment

response using BTMs. Denosumab (DMAb) has a dynamic BTM profile over the 6-month dosing period (ie, reduction in turnover with release of inhibition at the end of the dosing interval). This analysis assessed the use of potential target values for serum C-telopeptide of type 1 collagen (CTX) and serum procollagen type 1 N-terminal propeptide (P1NP) to explore guidance to clinicians for monitoring postmenopausal women with osteoporosis (PMO) during treatment.

Methods: BTMs measured at baseline in treatment-naïve PMO entering FREEDOM, a large randomized, placebo-controlled study of DMAb (Cummings et al *NEJM* 2009), were used to derive threshold values at the 5th percentiles of the observed distributions. The relevant values for serum CTX (N = 7594) and P1NP (N = 1023) were 0.2 ng/mL and 25.8 ng/mL, respectively. These BTM target values were applied to the study populations of DECIDE (Brown et al *JBMR* 2009) and STAND (Kendler et al *JBMR* 2010) enabling evaluation of a population-based assessment of BTM target values. DECIDE (N = 1189) and STAND (N = 504) were phase 3, randomized, double-blind, double-dummy studies to compare the efficacy and safety of DMAb (60 mg subcutaneously every 6 months) with alendronate (ALN; 70 mg weekly oral tablet) in treatment-naïve PMO or PMO already receiving ALN, respectively. The percentage of subjects in each treatment group with BTMs below the predefined target values was evaluated midcycle at month 3 after the 1st dose of DMAb, which also enabled trough values for ALN, and then re-evaluated at month 9. Subjects with BTM values below the predefined targets at baseline were excluded from the analysis.

Results: A total of 1112 (93.5%) women in DECIDE and 155 (30.8%) women in STAND had CTX values ≥ 0.2 ng/mL and P1NP values ≥ 25.8 ng/mL at baseline. Table 1 reports the percentage of subjects with CTX and P1NP values below the respective targets at months 3 and 9. The predefined target values were almost universally achieved at 3 and 9 months on DMAb, whereas the target for CTX, for example, on ALN was only achieved in 49.1% and 19.0% of treatment-naïve and ALN-pretreated PMO, respectively, at month 3.

Conclusion: In this population-based analysis, in both treatment-naïve and pretreated PMO, BTMs have utility in determining response, and awareness of failure to reach a treatment target may help improve clinical management.

Table 1 Percentage of Subjects With CTX < 0.2 ng/mL or P1NP < 25.8 ng/mL at Follow-up

		CTX < 0.2 ng/mL		P1NP < 25.8 ng/mL	
		Alendronate (N = 544)	Denosumab (N = 568)	Alendronate (N = 544)	Denosumab (N = 568)
DECIDE	Month 3	49.1	95.1*	65.6	98.0*
	Month 9	66.5	96.4*	80.7	97.0*
		CTX < 0.2 ng/mL		P1NP < 25.8 ng/mL

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Osteoporosis and Metabolic Bone Disease - Clinical Aspects and Pathogenesis Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

The aim of the present study was to identify the FRAX®Port (FRAX® validated for Portugal) ten-year major and hip osteoporotic fracture probabilities, above which pharmacologic interventions become cost effective in the Portuguese context.

Methods:

A previously developed and validated state transition Markov cohort model was populated with epidemiologic, economic and quality-of-life fracture data from Portugal. Cost-effective FRAX-based intervention thresholds for generic alendronate, zoledronic acid, denosumab and teriparatide when compared to “no intervention” were calculated assuming a willingness to pay of €32,000 (2 times national Gross Domestic Product per capita) per QALY (Quality-Adjusted Life Years).

Results:

In the Portuguese epidemiological and economic context, treatment with generic alendronate is cost-effective for people aged 50+, presenting 10-year probabilities (FRAX®Port) at or above 8.8% for major osteoporotic fractures and 2.5% for hip fractures. These values increase to 20.4% and 10.1% for zoledronic acid, 34.9% and 10.1% for denosumab and to 77.8% and 62.6% to teriparatide for major osteoporotic and hip fractures respectively. A tool is provided to perform the calculation of cost-effective intervention thresholds for different medications, according to age group and diverse levels of willingness to pay (WTP).

Conclusion:

Cost-effective intervention thresholds, for different medications, age-groups and WTP, based on 10-year probabilities of major and hip fracture probabilities calculated with FRAX®Port are provided.

Session Title: Osteoporosis and Metabolic Bone Disease - Clinical Aspects and Pathogenesis Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The main goal of our study was to evaluate the efficacy and safety of bisphosphonates and/or general preventive strategies in the prevention and treatment of post-transplant bone loss.

Methods: We conducted a comprehensive search in electronic databases until September 2014. We retrieved articles describing patients with bone loss or fractures who received hematopoietic stem cell transplantation (HSCT). Study selection, data collection and quality assessment were independently performed by two pairs of investigators. Studies were included if they were controlled trials, with a follow-up period of at least 12 months. Our primary outcome was change in BMD. Secondary outcomes included fracture, and bone turnover markers levels. Meta-analyses were performed when there were two or more studies with similar outcomes.

Results: Eleven publications were included (8 studies randomized trials (12 publications) and 3 studies non-randomized trials with a control group (4 publications)). 565 participants underwent HSCT for hematological diseases or malignancies: 85.7% underwent allogeneic HSCT, 1.4% underwent autologous HSCT, and 12.9% did not report the type of HSCT. Participant's age varied from 15 to 70 years. Seven comparisons were evaluated: (i) Zolendronic acid + Calcium + Vitamin D versus Calcium + Vitamin D; (ii) Pamidronate + Calcium +Vitamin D + hormone replacement therapy (HRT) versus Calcium + Vitamin D + HRT; (iii) Risedronate + Calcium +Vitamin D versus Calcium + Vitamin D; (iv) Zolendronic acid + Calcium versus Calcium alone; (v) Calcium +Vitamin D +HRT versus Calcium + Vitamin D; (vi) Calcium + Calcitonin versus no intervention; (vii) Calcium alone versus no intervention. Percent change in BMD in lumbar spine was higher when comparing any bisphosphonate groups compared with non-bisphosphonate groups at 12-24 months (see Table). The risk of fractures or x-ray findings of subclinical vertebral fractures was not increased in any of the comparison groups during the study period. A greater reduction in various bone turnover and resorption marker levels was observed in the bisphosphonate groups compared to patients in the control groups at 1-12 months, including: bone alkaline phosphatase, urinary hydroxyproline excretion, serum type 1 procollagen amino-terminal propeptide, urinary- type 1 collagen amino-terminal telopeptide, serum type 1 collagen cross-linked carboxy-terminal telopeptide beta, serum type 1 collagen carboxy-terminal telopeptide, and tartrate resistant acid phosphatase 5b. Flu-like symptoms were higher in Zolendronic acid treated patients.

Conclusion: Bisphosphonates are promising in the prevention and treatment of bone loss following HSCT. However bisphosphonates should be used with caution since they are not free of adverse effects.

The Effects of Monitoring on a Quality Indicator for Glucocorticoid–Induced Osteoporosis and Trends of the Drug Variation in a Japanese Hospital

Masei Suda[1], Masato Okada[1], Yasuhiro Suyama[2], Mitsumasa Kishimoto[1] and Tokutaro Tsuda[1], [1]Immuno-Rheumatology Center, St. Luke's International Hospital, Tokyo, Japan, [2]Rheumatology, JR Tokyo General Hospital, Tokyo, Japan

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Osteoporosis and Metabolic Bone Disease - Clinical Aspects and Pathogenesis Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Glucocorticoid-induced osteoporosis (GIOP) is one of the most clinically significant side effects of glucocorticoid use, and the prevention of GIOP has become more important in these days. The American College of Rheumatology (ACR) published the recommendations for the prevention and treatment of GIOP in 2010, and it recommended patients on prednisolone as low as 7.5 mg daily or its equivalent for more than 3 months to take anti-osteoporosis drugs. Quality indicators (QI) has been received an increasing attention in rheumatology field. However, few studies have reported the clinical use of QI in the GIOP care. Herein, we repot the efficacy of monitoring for the QI for GIOP. Besides, It is well known that the adherence to bisphosphonate relate with the risk reduction of fracture, and monthly bisphosphonate greatly improves patient's adherence. Therefore, we analyzed the prescription trend of monthly bisphosphonate as well.

Methods: We studied all patients who were prescribed prednisolone as low as 7.5 mg daily or its equivalent for more than 3 months in our institution. We divided patients into 3 groups based on gender and age; male as group A, female younger than 50 year-old as group B, and female older than 50 year-old as group C. Group A and B were recommended to take vitamin D analogue, and group C was recommended to take bisphosphonates with vitamin D analogue following the ACR 2010 guideline for GIOP. Since 2011, we started monitoring of QI for GIOP and shared the result with other department in the seasonal QI meeting. Moreover, we informed the need of GIOP treatment to each attending physician if his/her patient was a candidate for the GIOP prophylaxis, by writing the recommended regimen to patients' chart. Clinical data from 2010 to 2013 were collected to compare the adherence rate in each group (A-C) before and after the investigation. We also measured an adherence rate of each department as a subanalysis. Furthermore, we searched for the trend of drug variation other than vitamin D, especially prescription rate of daily, weekly, monthly bisphosphonates.

Results: After implementation of monitoring, the adherence to the QI standards had elevated year by year until 2013 (69.0% in maximum). In the subanalysis, there were substantial gap in the adherence rate between each department.There was increasing trend in prescription rate of monthly bisphosphonates from 2011. The trend was most prominently seen in rheumatology department. In other departments, the mainstay of osteoporosis treatment was daily or weekly bisphosphonates.

Conclusion: Implementation of monitoring on a QI for GIOP significantly improved adherence to the QI standards, which followed the 2010 ACR GIOP guidelines.Despite institution-wide announcements of QI goals, a substantial information gap may exist between the various clinical subspecialties involved in GIOP patient care.

Incidence of Fragility Hip Fractures over 10 Years (2004-13) in Three UK Centres with Reference to Local Fracture Prevention ('fracture liaison') Service Activity

Gavin Clunie[1] and Jonathan Belsey[2], [1]Rheumatology, Cambridge University Hospital NHS Foundation Trust, Cambridge, United Kingdom, [2]JB Medical, Sudbury, United Kingdom
First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Osteoporosis and Metabolic Bone Disease - Clinical Aspects and Pathogenesis Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Fracture Liaison Services systematically identify patients with fragility fracture and screen patients for osteoporosis and associated conditions and instigate evidence-based 'secondary' fracture prevention management. The success of such a service is thus demonstrated by its effect on reducing secondary fractures, particularly hip fractures, which are most important in terms of causing morbidity and their cost. There is a need for Fracture Liaison Services to demonstrate a direct and specific effect on fracture prevention.

Methods: A Fracture Liaison Service was implemented at The Ipswich Hospital in 2003. Expected hip fracture incidence 2004-13 for the hospital was estimated by applying age and sex specific hip fracture rates, derived from UK Hospital Episode Statistics (2007-8) to changes in the demographic profile of the local population (2001 and 2011 population census) and applied to the 2009 estimates of the Hospital catchment population (Public Health England). Hip fracture (codes ICD10 S72.0-3) rate ratios were then calculated comparing observed (local derived) versus expected hip fractures. SDs and CIs for the rate ratios were estimated using the Poisson function. **Results** were compared with data derived similarly from Norwich, an area with no Fracture Liaison Service and Cambridge, where a Hospital-based service has been in place since 2006.

Results: Over a 10y period 2004-13: annual hip fracture incidence varied 355-511 (Ipswich), 684-798 (Norwich) and 448-706 (Cambridge). There was no change in hip fracture incidence 2004-13 (versus expected) in Norwich, where there had been no service activity (rate ratio mean 0.97 [CIs 0.9-1.04]). For the hospitals where a service had been active, non-parametric trend analysis showed a significant reduction in hip fractures 2004-13 (all ages >55y) in Cambridge ($p<0.05$) and at Ipswich (service from 2003) mean hip fracture rate ratio decreased 15% (1.1[CI ±0.26] to 0.93[CI ±0.22]; NS) for subsequent 5y periods (2004-8 and 2009-13) at ages <75y (though no significant trend for hip fracture reduction for all ages >55y).

Conclusion: Overall, these analyses, based on low event numbers, fairly wide fracture rate ratio CIs (±0.1) and the need to derive accurate population demographic and expected hip fracture data, illustrate the challenges in linking changes in hip fracture incidence to local Fracture Liaison Service activity. There is, however, some evidence to suggest hip fracture reduction in areas where a Fracture Liaison Service had been active, but no evidence of a change in hip fractures (versus expected) even in the non-elderly, in an area with no historic service activity.

Impact of Didactic Lecture on Osteoporosis Screening and Fracture Risk Assessment Among House Staff

Meghan Greenfield[1], Jordan Brodsky[2] and Erin Patton[3], [1]Rheumatology, University Of Washington, Seattle, WA, [2]Medicine, Albert Einstein College of Medicine, Bronx, NY, [3]Medicine/Rheumatology, Mount Sinai Beth Israel, New York, NY

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Osteoporosis and Metabolic Bone Disease - Clinical Aspects and Pathogenesis Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: It has been estimated that 12 million Americans over the age of 50 have osteoporosis. Of those, only 30% of eligible women age 65 and older have had a bone density test. Previous studies of academic hospitals with resident outpatient primary care providers have concluded that residents are following the current guidelines for screening for osteoporosis with DEXA scans. However, the use of The Fracture Risk Assessment Tool (FRAX) score for the identification of patients at high-risk for fracture is highly underutilized. Further education of residents in the form of a didactic lecture may improve the osteoporosis screening practices among house staff.

Methods: Resident outpatient primary care providers in the Internal Medicine Department at one academic medical center were given a didactic lecture on the principles of osteoporosis screening, including current guidelines and utilization of the FRAX score. The electronic medical record system at two outpatient care centers was reviewed for one week prior to and one week after the didactic lecture. Patients with the following screening criteria were identified: women over age 65 or men over age 70, and postmenopausal women with at least one documented risk factor, including previous fracture, parent with a fractured hip, current smoking, glucocorticoid use, rheumatoid arthritis, secondary osteoporosis, and alcohol use (three or more drinks/day). Each chart was evaluated for osteoporosis risk assessment by house staff.

Results: Eleven Internal Medicine residents were present for the didactic lecture. Five residents were PGY1 level, three residents were PGY2 level, and three residents were PGY3 level. 73% were male and 27% were female. A total of 59 patients met the criteria for chart review during the one week prior to the didactic lecture. Of those 59 patients, 13 (22.0%) had osteoporosis risk addressed during that visit. A total of 79 patients met the criteria for chart review during the one week after the didactic lecture. Of those 79 patients, 32 (40.5%) had osteoporosis risk addressed during that visit.

Conclusion: A didactic lecture improved osteoporosis screening from 22.0% to 40.5%. This results in a relative increase in screening by 54.3%. After the lecture, residents achieved a higher screening rate than is nationally achieved at this time1. It is imperative that house staff be further educated on current osteoporosis screening tools, such as the FRAX score, to better prevent future fracture among those at risk. An expanded study should include a longer time period of chart review, in order to further evaluate the impact of didactic lecture on current practices in the resident-led outpatient setting.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Osteoporosis and Metabolic Bone Disease - Clinical Aspects and Pathogenesis Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: We previously reported the results of a randomized participant and outcome assessor blinded controlled trial that found no beneficial effect of vertebroplasty (VP) over placebo for people with acute osteoporotic fractures up to 24 months and no between-group differences in incident clinical vertebral fractures. A secondary aim was to determine the effect of VP on the risk of further radiologically apparent vertebral fracture at 12 and 24 months.

Methods: The trial was registered (ACTRN012605000079640), and conducted between April 2004 and October 2010. Eligible participants had one or two acute osteoporotic vertebral compression fractures of at least grade 1, confirmed by history, radiograph and the presence of bone oedema. They were randomly assigned to VP (n=38) or placebo (n=40). Cement volume and leakage were recorded for the VP group during the cement injection and on imaging post-procedure.

Plain thoracolumbar radiographs were taken at baseline, 12 and 24 months. Two independent radiologists assessed these for new and progressed fractures at the same, adjacent and non-adjacent levels. Discrepancies were resolved by consensus at the completion of the review process.

A total sample of 164 participants (82/group) was needed to show a three-fold increase in the risk of further vertebral fractures at 24 months assuming a 10% event rate in the placebo group. Recruitment difficulties led to trial enrolment being terminated early after reaching sufficient numbers to address the primary efficacy outcomes but insufficient to assess the safety outcomes.

Results: Baseline characteristics were similar between the two groups (31 females in each group, mean (SD) age, median (interquartile range) duration of symptoms and one or more prior vertebral fractures was 74.2 (14.0), 9.0 (3.8 to 13.0) and 18 (47%) in the VP group, and 78.9 (9.5), 9.5 (3.0 to 17.0) and 21 (52%) in the placebo group).

At 12 and 24 months, radiographs were available for 45 (58%) and 47 (60%) participants respectively. There were no between-group differences for new or progressed fractures: 32 and 40 in the VP group after 12 and 24 months compared with 21 and 33 in the placebo group (hazard ratio (HR) 1.80, 95% confidence interval (CI) 0.08 to 3.94). Similar results were seen when considering only adjacent (HR (95% CI): 2.30 (0.57 to 9.29)), and non-adjacent (HR (95% CI): 1.45 (0.55 to 3.81) levels. In all comparisons there was a consistent trend towards higher risk of any type of fracture in the group undergoing VP.

Within the VP group, fracture risk was unrelated to total cement volume (HR (95% CI): 0.91 (0.71 to 1.17)), relative cement volume (HR (95% CI): 1.31 (0.15 to 11.48)), cement leakage (HR (95% CI): 1.20 (0.63 to 2.31)), age, sex, site of treated level, use of bisphosphonates at baseline or current bisphosphonate use, glucocorticoid use or duration of use, previous vertebral fracture or bone mineral density.

Conclusion: While our results indicate a possible increase in risk of radiologically apparent vertebral fractures

following VP, we did not have sufficient power to draw definitive conclusions. Further adequately powered studies are needed to address this question.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Osteoporosis and Metabolic Bone Disease - Clinical Aspects and Pathogenesis Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Actually, Biphosphonates are considered the first line treatment for osteoporosis. One of the side effects of the continuous treatment with these drugs is the development of atypical fractures. These are generally subtrochanteric, although they can appear anywhere in the femoral diaphysis, with a low prevalence (1.1% of all the femur fractures). Their incidence grows with the time to exposure to bisphosphonates.

To determine the prevalence of atypical fractures according to the American Society of Mineral and Bone Research (ASMBR) criteria between 2011 and 2014 in the Universitary Hosptial of Donostia (Guipúzcoa, Spain) and describe the demographic and sanitary features in these patients.

Methods:

Retrospective research of clinical data of patients operated of hip fracture and/or femur fractures between November 2011 and December 2014 Variables included were: age, sex, race, clinical features, treatment received, and presence or absence of diseases and pharmacological treatments that participate in the bone remodeling.

Results:

921 patients operated of hip fracture and 76 of diaphyseal fracture. 6 patients met the clinical and radiologic criteria of the ASMBR for an atypical fracture, 100% of these had received a long term treatment with biphosphonates and ment the 6,57% of the diaphyseal fractures, the 0,12% of the hip fractures and the 0,6% of the total of the fractures studied. The most used biphosphonate was Alendronate, being in the 66,6% of the patients the first treatment used for osteoporosis. The median time of exposure to biphosphonates was 8,5 years (IQR=3).

In the 83,3% of the patients the fracture was situated in the medial third of the femoral diaphisis.

	DEMOGRAPHIC		TREATMENT FOR OSTEOPOROSIS		FRACTURE	COMORBIDITIES	
ID	SEX	AGE	MEDICATION	TIME	LOCATION	DISEASES	OTHER DRUGS (Heparin, Steroids, Anticonvulsants, others)
1	Female	42	1.- Alendronate	1.- 10 years	Diaphyseal femur (1/3 medium)	No	No
			2.- Teriparatide	2.- 2 years			
			3.- Ibandronate	3.- 2 years			
			4.- Denosumab + Strontium ranelate	4.- 1 year			
2	Female	63	1.- Alendronate	1.- 10 years	Diaphyseal femur (1/3 medium)	Hipothyroidism	No
3	Female	73	1.- Alendronate	1.- 6 years	Subtrochanteric	Diabetes mellitus	No
			2.- Denosumab	2.- 6 months			
4	Female	77	1.- Alendronate	1.- 8 years	Diaphyseal femur (1/3 medium)	Hipothyroidism	No
5	Female	83	1.- Risedronate	1.- 6 years	Diaphyseal femur (1/3 medium)	No	No
			2.- Alendronate	2.- 3 years			
6	Female	88	1.- Risedronate	1.- 5 years	Diaphyseal femur (1/3 medium,)	Hipothyroidism	No
			2.- Alendronate	2.- 2 years			

Conclusion:

- In our study the prevalence of atypical fractures with biphosphonates was low, a 0,6% of all of the fractures studied.

- No alternative cause was found, nor clinical nor pharmacological, to the take of biphosphonates that explained the atypical fractures.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Osteoporosis and Metabolic Bone Disease - Clinical Aspects and Pathogenesis Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: It is widely believed that use of glucocorticoids (GC) increase risk of fracture through reduction in bone quality as well as reduction in bone mineral density (BMD). Data supporting the 'bone quality hypothesis' come from a post-hoc analysis of two trials with limited numbers of fractures (van Staa). In a preliminary unadjusted analysis from a large cross-sectional study we surprisingly found that patients on GC had a lower prevalence of fractures.(Bukhari et al) We now report the effect of GC on fracture in the same population, adjusting for BMD and

other risk factors including treatments at presentation.

Methods: We used data from patients referred by their general practitioner or secondary care doctor for first BMD estimation by Dual X-Ray absorptiometry (DEXA) in the North West of England. Patients details recorded at time of scan included age, Body Mass Index (BMI), and the presence of risk factors: smoking, alcohol, family history of osteoporosis, history of clinical fragility fracture, rheumatoid arthritis and drug treatment, specifically GC and antiresorptive agents (mostly bisphosphonates). DEXA assessed BMD in the spine (mean of L1-L4 vertebrae) and femoral neck. Two subpopulations were identified at the extremes: patients on current GC and those with no prior exposure to GC. The prevalence of BMD fractures in each group was compared by chi-square test. A logistic model was fitted to adjust for possible confounding by imbalances in risk factors and BMD.

Results: 20210 subjects were included in the analysis, mean age was 63.2 years (SD 13.0 years), 82% were female. 32% had as history of fracture and 3772 (19%) were on GC at referral. Patients on GC vs unexposed were of similar age: 63.1 vs 62.8 years (p=0.21); As previously reported GC patients had higher bone mass at both sites 1.09 vs 1.04 g/cm2 at lumbar spine (p<0.001) and 0.9 vs 0.90 g/cm2 in the femoral neck (p<0.01). Less GC patients had a history of fracture: (13% vs 22%; OR 0.53 95%CI 0.49,0.58 p<0.001). 19.5% of GC patients were on antiresorptive agents vs 7.2 % of controls (P<0.01) . Modelling steroids as a dependent variable adjusting first for BMD at hip and then BMD at spine and for all the risk factors, gave an odds ratio of fracture 0.56(95%CI 0.52; 0.61) and 0.55(95%CI 0.51,061) repsectively. Restricting the analysis to patients who were not on antiresorptive treatment at the time of scanning (n=18,226 in the spine and 17,490 in the hip) yielded similar results: spine OR of fracture 0.54 (95%CI 0.49; 0.60); hip OR of fracture 0.54 (95%CI 0.49; 0.60).

Conclusion: The surprising, apparently protective effects of GC on bone quality from this large cross-sectional study cannot be explained by known confounding factors. These results are likely subject to unmeasured confounding and need to be interpreted with caution. The finding could be due to confounding by indication for DEXA .However, they suggest that current GC use is associated with less prevalent fractures at the same bone mass level, directly contradicting commonly held views about the detrimental effect of GC on bone. It will be worth exploring in a large longitudinal cohort.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Osteoporosis and Metabolic Bone Disease - Clinical Aspects and Pathogenesis Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Overall survival of primary necrotizing vasculitides, including ANCA-associated vasculitis (AAV) and polyarteritis nodosa (PAN), has greatly improved over the last 50 years. Because of a longer survival and prolonged treatment, long-term sequelae and comorbidities have now become a major concern. Studies assessing the prevalence of osteoporosis, fractures and their determinants, in these patients are lacking. The aim of this study is to assess the prevalence of osteoporosis and fractures in patients with vasculitides and to identify variables associated with their presence.

Methods:

Patients with AAV and PAN seen in our department were prospectively included in an ongoing cross-sectional study assessing bone complications and other sequelae (OSTEOVAS cohort). Lumbar spine and hip bone mineral density (BMD), body composition (lean and fat masses) and abdominal fat masses (visceral and subcutaneous) were measured by Dual X-ray Absorptiometry (DXA). Vertebral fractures were assessed using the Vertebral Fracture Assessment (VFA) measured by DXA.

Results:

One hundred and twenty consecutive patients were analyzed (66 females and 54 males, mean age 53±18 years, with a median disease duration of 54 months). Diagnoses were granulomatosis with polyangiitis in 61 patients, eosinophilic granulomatosis with polyangiitis in 30, PAN in 14, microscopic polyangiitis in 13, and cryoglobulinemia vasculitis in 2 cases. The median daily dose of glucocorticoids was 8.5 mg/day (0-80), with an estimated total cumulative dose of 15000±10000 mg of glucocorticoids. Osteoporosis was observed in 36 patients (30%) and low trauma fractures in 33 patients (27.5%). Overall, osteoporosis and/or previous fractures were observed in 54 patients (45%). Among them, only 18 (33%) received an antiosteoporotic treatments, and 20 (37%) and 34 (63%) had calcium and vitamin D supplementation.

Variables significantly associated with bone disease in multivariate analysis were an increased visceral adipose tissue (VAT) and subcutaneous adipose tissue (SAT) ratio [OR 1.03 (1.01-1.05); P=0.005], decreased calcium intakes [OR 0.998 (0.997-1.00); P=0.02] and decreased grip strength [OR 0.22 (0.08-0,60), P=0.003]. Variables significantly associated with fractures in multivariate analysis were an increased age [OR 1.05 (1.01-1.08); P=0.006], decreased calcium intakes [OR 0.998 (0.996-1.00); P=0.046] and increased Vascular Damage Index (VDI) evaluating sequelae related to vasculitis and/or treatments [OR 1.28 (1.02-1,60), P=0.03]. Finally, using multiple linear regression analysis, femoral neck BMD was independently associated with age (P=0.0003), skeletal muscle mass (P<0.0001), VDI (P=0.008), and grip strength (P=0.03).

Conclusion: Osteoporosis and fractures are observed in nearly half of patients with primary necrotizing vasculitides and only 33% received an antiosteoporotic treatment. Increase in abdominal adiposity and decrease in muscular function are strongly associated with bone complications. Bone complications assessment, cardiovascular risk and muscular function should be assessed and managed in clinical practice in patients with primary necrotizing vasculitides.

Session Title: Osteoporosis and Metabolic Bone Disease - Clinical Aspects and Pathogenesis Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Osteoporosis (OP) is a common disease and is increasingly being recognized in males. A number of underlying diseases including rheumatoid arthritis (RA) have been associated with it and this relationship has been well proven in females but remains unclear in males with RA. This study was done to evaluate the association between RA and OP in male population. We analyzed male cohort at UMMC, followed by a PubMed literature review.

Methods:

585 men who underwent DEXA scan performed at UMC from 2005-2012 were included in the analysis of retrospective cohort with documented RA. A PubMed literature search was performed using keywords- Male, OP and RA yielding 775 articles (limiting data to English and publication year > 1960), 663 articles were excluded with abstract review, 112 underwent full text review with 7 having relevant data. Only 4 studies had sufficient data to be included in the pooled analysis, while other 3 studies had to be analyzed individually. Data looking at mean male bone mineral density (from the National Health and Nutritional and Examination Survey (NHANES) compiled by the CDC) was matched by age and used for control. Z-scores were calculated using age adjusted Standard Deviation values from the NHANES database.

Results:

UMC Retrospective Cohort. RA patients	Normal DEXA	Osteoporosis	P-value
RA N=38/291	10.81% (16/148)	15.38% (22/143)	NS

Study	Age	#patients	Study Mean Lumbar BMD	Control Mean Lumbar BMD	Z-score
Haugeberg et al, 2000	59.9±11.3	91	0.907 gm/cm2	0.803 gm/cm2	0.811
Oelzner, 2008	57.9±11.8	108	0.623 gm/cm2	0.821 gm/cm2	-1.589
Nolla et al, 2006	60.34±13.0	187	0.739 gm/cm2	0.823 gm/cm2	-0.656
Loddler et al, 2004	53.8±11.9	87	0.803 gm/cm2	0.858 gm/cm2	-0.433

Total patients	Overall Mean Lumbar BMD	Overall Mean Z-score	Association
473	0.768 gm/cm2	-0.467	Unclear

Conclusion:

This analysis suggests that relationship of RA and OP in male patients remains unclear and confusing. Although no firm conclusions can be drawn, the results of our cohort analysis and review of literature suggest that RA diagnosis and disease activity may not add any increase in the risk of developing OP in men. The association of RA and risk fracture was also not clear in this analysis. Sub-analysis done in the studies suggested; “age” as a factor conferring the risk of OP in RA. Furthermore, the literature search revealed that limited data is available looking at this association, and more studies are needed to clarify the association between RA and male OP.

Session Title: Osteoporosis and Metabolic Bone Disease - Clinical Aspects and Pathogenesis Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The relationship between osteoarthritis (OA) and osteoporosis has exhibited contradictory features over the past four decades. We evaluated this relationship using separate analysis of the radiographic features of OA whether various radiographic features of OA were associated differently with bone mineral density (BMD) in the Korean elderly.

Methods: Data were derived from the Dong-gu cohort; 2,377 subjects were enrolled in the present cross-sectional study. Baseline characteristics, the BMDs of the lumbar spine and femoral neck, and X-rays of knees and hands, were collected. A semi-quantitative grading system was used to estimate the severities of individual radiographic features. We adjusted for confounders using multiple linear regression modeling to analyze the relationships.

Results: After adjustment for confounders, knee and hand OA total scores were negatively associated with the BMDs of the lumbar spine and femoral neck ($p < 0.001$, both), except for the total knee OA score and lumbar spine BMD. In detail, hand osteophytes and sclerosis exhibited positive relationships with the BMDs of the lumbar spine and femoral neck ($p < 0.001$ for all). On the contrary, however, knee joint space narrowing (JSN), hand JSN, and hand subchondral cysts were negatively associated with the BMD of the lumbar spine and femoral neck ($p< 0.001$ for all). Knee JSN and hand subchondral cysts exerted the greatest effects on BMD.

Conclusion: Separate analysis of the radiographic features of OA better reveals associations of OA with the BMD of the lumbar spine and femoral neck.

Session Title: Osteoporosis and Metabolic Bone Disease - Clinical Aspects and Pathogenesis Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Skin thickening and hand joint involvement induce bone loss and contribute to functional disability in patients with dcSSc. The high-resolution peripheral quantitative CT (HR-pQCT) can analyze the microarchitecture and bone mass at distal radius and allow the better understanding of bone impairment in dcSSc. The objetive is to analyze the volumetric BMD (vBMD) and bone microarchiteture by HR-pQCT in dcSSc patients, and correlates with the disease clinical variables.**Methods:** 38 dcSSc patients and 76 healthy controls (HC) were selected. HR-pQCT were performed in distal radius using X-Treme CT (Scanco). The SSc clinical and HR-pQCT parameters were correlated. **Results:** The density, structure and mechanical characteristics were significantly impaired in dcSSc compared to HC, with decrease of trabecular BMD [Tb.BMD], cortical BMD [Ct.BMD], trabecular number [TbN], trabecular thickness [TbTh], cortical thickness [CtTh], stiffness [S] ($p<0.05$). Clinical and HR-pQCT parameters were correlated: **BMI** with Tb.BMD ($r=+0.67$, $p<0.001$), Tb.N ($r=+0.55$, $p<0.0001$), Tb.Th ($r=+0.47$, 0.003); Tb.Sp ($r=-0.45$, $p=0.004$); Ct.Th ($r=+0.45$, $p=0.04$). Right/left **Range of motion** with Tb.BMD ($r=+0.41$, $p=0.01$; $r=+0.39$, $p=0.02$), Ct.BMD ($r=+0.46$, $p=0.03$; $r=+0.49$, $p=0.001$), Tb.N ($r=+0.05$, $p=0.005$; $r=+0.44$, $p=0.006$), Tb.Sp ($r=-0.43$, $p=0.008$; $r=-0.4$, $p=0.01$), Ct.Th ($r=+0.39$, $p=0.01$; $r=+0.420$, $p=008$). **Grip Strength (HAQ)** with Tb.N ($r=-0.33$; $p=0.04$), Tb.Sp ($r=+0.37$, $p=0.02$). The following clinical manifestations were associated with worse HR-pQCT parameters: **Esophageal dismotility** with Tb.BMD (109.23±45.53 vs 147.17±35.71, $p=0.01$), Tb.N (1.5±0.44 vs 1.88±0.27, $p=0.006$), Tb.Sp (0.69±0.34 vs 0.47±0.1, $p=0.02$); **Intersticial lung Disease** with Tb.BMD (113.81±40.89 vs 158.46±47.66, $p=0.01$), Tb.N (1.49±0.44 vs 1.87±0.31, $p=0.006$), Tb.Sp (0.7 ±0.35 vs 0.48±0.12, $p=0.02$), Tb.Th (0.06±0.01 vs 0.07±0.01, $p=0.02$), Ct.Th (0.52±0.15 vs 0.7±025, $p=0.007$); **Acroosteolysis** with Tb.BMD (103.61±36.6 vs 153.27±42.37, $p<0.001$), Tb.N (1.5±0.44 vs 1.88±0.27, $p=0.006$), Tb.Sp (0.69±0.34 vs 0.47±0.1, $p=0.02$), **Scl-70** with Tb.Th (0.06±0.008 vs 0.07±0.01, p=0,03), Ct.Th (0.52±0.18 vs 0.66±0.22, $p=0.03$); **Late capillaroscopy pattern** with Ct.BMD (803.79±112.91 vs 873.07±69.75, $p=0.03$) Tb.Th (0.07±0.01 vs 0.06±0.008, p=0,03), Ct.Th (0.66±0.22 vs 0.52±0.18, $p=0.03$). No correlation was observed with age, menopausal age, digital ulcers, Modified Rodnan skin score, Medsger Disease Severity Index. **Conclusion:** dcSSc patients had lower bone quality and bone mass at distal radius compared to HC. Quality of life and clinical parameters showed a significant correlation suggesting that the SSc clinical profile should indicate patients at increased risk of bone disease.

Osteoporotic Fragility Tibia/Fibula Fractures Are Not Asociated with a Low Body Mass Index: An Observational Study

Vishnu Kammath[1] and Marwan Bukhari[2], [1]Faculty of Health and Medicine, Lancaster University, Lancaster, United Kingdom, [2]Rheumatology, Royal Lancaster Infirmary, Consultant and Honorary Senior Lecturer, Lancaster, United Kingdom

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Osteoporosis and Metabolic Bone Disease - Clinical Aspects and Pathogenesis Poster
Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Tibia/Fibula (Tib/Fib) fractures are one of osteoporotic fragility fractures. They have been suggested to be more likely to occur secondary to osteoporosis (OP) than any other fracture (1). Furthermore, as they are more likely to be open fractures, are more prone to infections and other co-morbidities. It is known that body mass index (BMI) is a protective factor in fragility fractures whilst low Bone Mineral Density (BMD) is known to be predictor of fragility fractures. However the specific predisposing factors for Tib/Fib fragility fractures are not known. Furthermore risk of factues is determined using the femoral neck in the FRAX (tm) tool. Use of lumbar spine BMD has not been examined as a specific predictor. We aimed to use a Case-Control approach to examine these predictors for Tib/Fib fractures.

Methods: A cohort of patients referred after a Tib/Fib fragillity fracture for a DEXA scan in the North West of England between 2004 and 2011 were identified, and were age and sex matched with scanned controls that had no indications for a scan. Students T-Test and Chi 2 test were used to test for any differences between the groups in terms of continuous and categorical variables respectively. Logistic models were fitted examining the contribution of risk factors to tib/fib using BMD in the femoral neck and the lumbar spine.

Results: 797 patients were matched to 797 controls, 679 (85%) were female. Mean age in both cases and controls was 64.3years (SD11.3). Surprisingly, mean BMI was higher in the fracture group 28.3 kg/m2 vs 26.7 kg/m2 ($p<0.01$). This was mostly due to the fracture group being heavier (74.6kg vs 69.7 kg $p<0.01$) Univariate analysis showed an unadjusted odds ratio of 1.06 (95%CI 1.04,1.08) , after adjustment for the lumbar spine BMD , the difference persisted (OR 1.06 95%CI 1.04,1.08) and after adjusting for femoral neck BMD this also persisted (OR 1.05 95%CI 1.02,1.09). This would suggest that that BMI does not influence the risk of developing Tib/Fib fragility fractures. This is contrary to what is stated in literature in relation to fragility fractures.

Conclusion: This study would seem to indicate that people with higher BMI values tend to get Tib/Fib fragility fractures compared to a control population. this persisted after adjusting for BMD, an obvious confounder. This suggests that other factors are involved in increasing the risk of Tib/Fib fractures. Further work is therefore needed to assess other predictors for Tib/Fib fractures.

Session Title: Osteoporosis and Metabolic Bone Disease - Clinical Aspects and Pathogenesis Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Calcium supplements are prescribed for prevention of osteoporotic fractures, but excess intake has been associated with cardiovascular events. The most adequate tools for estimating dietary calcium intake are time-consuming, while an accurate estimation is a prerequisite to be able to prescribe the adequate amount of supplementation. The aim of this study is to validate a Short Calcium Intake List (SCaIL) that is feasible in daily clinical practice, with an extensive dietary history (DH) as reference method.

Methods: Based on the Dutch food groups which contribute most to daily dietary calcium intake and on portion sizes determined in our earlier validation study, a new three-item, one minute SCaIL was designed. As a reference method, an extensive DH with specific focus on calcium products and extra attention for portion sizes was performed. Beforehand, a difference of ≥250 mg calcium between both methods was considered clinically relevant.

Results: Sixty-six patients with either primary (n=40) or secondary (n=26) osteoporosis were included. The SCaIL showed a very small and clinically non-relevant difference with the DH: mean 24 ± 350 mg calcium per day (1146 ± 440 vs 1170 ± 485, respectively; p=0.568). Sensitivity and specificity of the SCaIL, compared to the DH, were 73% and 80%, respectively. However, in 50% of the individuals, a clinically relevant difference was observed between both methods, while in 17% a difference of ≥500 mg was observed.

Conclusion: The SCaIL is a quick and easy questionnaire to estimate dietary calcium intake at a group level, but is not sufficiently reliable for use in individual patients. Remarkably, mean dietary calcium intake via the DH is 1170 mg per day, which indicates that a large proportion of osteoporosis patients might not even need calcium supplementation.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Osteoporosis and Metabolic Bone Disease - Clinical Aspects and Pathogenesis Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Glucocorticoids are effective at treating rheumatologic diseases but are known to increase fracture risk. In 2010, the ACR developed recommendations for the prevention and treatment of glucocorticoid induced osteoporosis (GIOP) based on risk factors, FRAX score, and prednisone dose. The purpose of this study is to evaluate compliance with the ACR GIOP recommendations in a large teaching institution.

Methods: Men and women seen at the fellows' general rheumatology clinic at Montefiore Medical Center (Bronx, NY) who were ≥50y with history of rheumatoid arthritis between 1/2015 and 2/2015 were included. Charts were reviewed for DEXA Screening within 2 years of visit and appropriate bisphosphonate usage based on the risk stratification proposed by the ACR.

Results: 52 patients were evaluated. 92.3% were women with a mean age of 66.5 years. In this cohort, 13.5% were Black. Only 67% of the patients were appropriately screened with an up to date DEXA (Figure 1). Patients that were not screened tended to be younger (62.6 v 67.2, p=0.08). Also male patients were less likely to be screened (6.6% v 14.3%). There was no statistically significant difference in screening in women or by race. Out of the 35 patients that were appropriately screened, 32% were not appropriately treated (figure 2). 6 of these 11 patients were candidates for treatment due to being medium risk and on prednisone. 3 of 11 were candidates for treatment due to their osteoporotic T-score. One patient was low risk but was on prednisone 7.5mg and warranted treatment. Another patient was low risk on prednisone 5mg daily but was inappropriately on a bisphosphonate.

Conclusion: Overall, 53% of the patients in our academic institution were not appropriately screened or treated for GIOP. Although not statistically significant, RA patients that were not effectively screened tended to be patients of younger age and male. This study concludes that rheumatologists underutilize osteoporosis screening and preventative treatment, which is prudent toward preventing debilitating fractures and its subsequent impact on diminished quality of life. Provider education on screening and treatment of GIOP may be an area for quality improvement for both primary care and rheumatology.

Session Title: Osteoporosis and Metabolic Bone Disease - Clinical Aspects and Pathogenesis Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Vitamin D deficiency is highly prevalence, especially in adults and elderly population. There is controversy about its relationship with increased cardiovascular risk, osteoporosis and bone fractures.

To describe the vitamin D levels in a population evaluated with suspected osteoporosis in a Bone Metabolism Unit and its relationship to other diseases.

Methods:

We selected the patients attended in the Bone Metabolism Unit of the Hospital of Mérida between June 2013 and June 2014 that have at least one determination of 25-OH-cholecalciferol, bone densitometry and complete clinical history.

Results:

We included 171 patients between 34 and 75 years (mean 64.5, SD 11.75), 11 men and 160 postmenopausal women. The detected levels of 25-OH-cholecalciferol were normal (>30ng/ml) in 75 and deficient in 96 patients (56.14%). Deficiency was severe (<10ng/ml) in 11, moderate (10 to 20ng/ml) in 48 and mild (between 20 and 30ng/ml) in 37 patients. We didn´t find any correlation (Pearson coefficient) between the levels of 25-OH-cholecalciferol and age (-0.17), lumbar spine T-score (0.1) and hip T-score (-0.004), major and hip fracture risk using FRAX without BMD (0.13 for both) and with BMD (-0.017 and -0.063, respectively). Neither we didn´t find any association between levels of 25-OH-cholecalciferol and the existence of comorbidities and cardiovascular risk. Patients with severe deficiency (<10ng/ml) of 25-OH-cholecalciferol had higher rates of presence of cardiovascular risk factors (RR 5.87, 95%CI 1.16, 1.87) and bone fractures (OR 3.76 95%CI 1.75, 13.18).

Conclusion:

Severe deficiency of 25-OH-cholecalciferol was significantly associated with the presence of bone fractures, irrespective of BMD values and FRAX risk. Levels below 10ng/ml of 25-OH-cholecalciferol were more frequent in patients who had at least one cardiovascular risk factor. No association between vitamin D deficiency and the presence of comorbidities was found.

Twelve Months after Osteoporosis Associated Fracture – Has Adequate Therapy Been Initiated?

Christoph Hemmeler[1], Sabrina Morell[2], Paul Hasler[1] and Thomas Gross[2], [1]Rheumatology, Kantonsspital Aarau, Aarau, Switzerland, [2]Traumatology, Kantonsspital Aarau, Aarau, Switzerland
First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Osteoporosis and Metabolic Bone Disease - Clinical Aspects and Pathogenesis Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Evidence shows that of ten patients taking medication against osteoporosis one will avoid subsequent fractures, decreasing the risk by > 50 %. On the other hand, epidemiologic studies indicate that merely 15 – 30 % of the affected cases are initiated on adequate therapy.

Methods: All cases over fifty years of age admitted to the traumatology department with a fracture were investigated with osteodensitometry and standard of care laboratory parameters. A questionnaire was provided to gather data in a quality assurance program. Therapy was recommended according to the FRAX validated for Switzerland. One year after the fracture, the patients and their family physicians were invited to answer a questionnaire targeted at evaluating compliance with the recommendation provided after discharge from the hospital.

Results: 101 of 127 patients that we were able to contact answered the query (79%; median 72 years, 80% females; 83% low-energy trauma). 54% stated that they regularly took a specific medication against osteoporosis. 66 % were supplemented with vitamin D and 67 % with calcium. 30 % were on all three medications. Reasons given by 41 % of the patients for not taking medication were lack of prescription by the treating physician, 17 % considered the treatment unnecessary, 4 % indicated a lack of interest. Financial reasons, drug intolerance, old age and illness were each given as reasons by 2 %. Other reasons were given in 22 %.

Family physicians stated that in 87 % and 75 % prescriptions were given for vitamin D and calcium supplementation, respectively, for specific therapy in 58 % and a combination of all three in 42 %. Reasons for failure to prescribe medications were lack of interest in 18 %, insufficient confidence in the therapeutic recommendation therapy in 10 %, insufficient information about the therapy in 12 % and other reasons including intolerance or morbidity (20 % of other reasons). There was significant divergence between the reasons given by patients and treating physicians ($p<0.001$).

Conclusion: One year after an osteoporotic fracture at most half of the patients were taking adequate medication against osteoporosis. Though this result is higher than those reported in the literature, the indicated lack of information and the discrepancy between the reasons given by the patients and their family physicians provide the scope for optimization with improvements in communication and information.

Stiffness Index Study in Ehler Danlos Syndrome

Chandralekha Ashangari, Henykumar Patel, Neelesh Gupta and Amer Suleman, DEPARTMENT OF CARDIOLOGY, THE HEARTBEATCLINIC, DALLAS, TX
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Osteoporosis and Metabolic Bone Disease - Clinical Aspects and Pathogenesis Poster
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Ehlers-Danlos syndrome is a group of inherited disorders that affects connective tissues primarily skin, joints and blood vessel walls. Ehlers-Danlos syndromes usually have overly flexible joints and stretchy, fragile skin. The purpose of this research is to measure the Stiffness index(T Score and Z score) by Achilles express. Achilles express Ultrasonometry provides a measurement of physical properties of bone. Two of the most commonly used ultrasound measures are Speed Of Sound (SOS, in m/sec) and Frequency Attenuation (Broadband Ultrasound Attenuation; BUA in dB/MH2) of a sound wave as it travels through bone.

Methods: 38 EDS patients and 23 non EDS controls are randomly selected from our clinic and Stiffness index is calculated by Achilles express. To express the ultrasound results, the Achilles combines the SOS and BUA values to calculate a clinical measure called the Stiffness Index (SI).Measurement of SOS in the heel involves accurate determination of the transit time of a sound wave as it passes through the heel. This is compared to the time required for a signal to pass through the water bath alone. Stiffness Index combines BUA and SOS into single clinical measure that has a lower precision error than either variable alone. SI= [0.67*BUA + 0.28*SOS] – 420.T score higher than -1.0 indicates low risk,score between -1.0 and -2.5 indicates intermediate risk,score lower than -2.5 indicates high risk.ANOVA analysis is performed

Results: Out of 61 subjects, 98% are females (n=60, age 31.49±11.53) , 2% are males (n=2, age 17),Mean age of 38 EDS patients (31.31±11.10) ,Mean age of 23 non EDS controls (30.79±11.02) , ANOVA:Stiffness index (Mean ± Standard deviation) in 38 EDS patients 92.73±16.65, In 23 non EDS controls 103.43±15.50 (Stiffness index EDS vs non EDS, P=0.01), T Score EDS vs Non EDS controls (-0.5±1.09 Vs 0.23±0.96 ,P =0.01), Z score EDS vs Non EDS controls (-0.3±1.12 Vs 0.33±0.86 ,P =0.02).

Conclusion: Patients with EDS appear to have low stiffness index at a young age. They may be predisposed to osteopenia or osteoporosis. Further research is needed to develop a proper strategy to avoid future complications.

Dental Treatments, Tooth Extraction, and Osteonecrosis at Jaw in Japanese Patients with Rheumatoid Arthritis; Results from the IORRA Cohort Study

Takefumi Furuya, Shigeki Momohara, Atsuo Taniguchi and Hisashi Yamanaka, Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Osteoporosis and Metabolic Bone Disease - Clinical Aspects and Pathogenesis Poster

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Oral health is an important issue for the patients with rheumatoid arthritis (RA) because many RA patients were treated with bisphosphonates and bisphosphate use appears to be associated with osteonecrosis at Jaw (ONJ), and periodontitis is a potential risk factor for RA. Limited data exist in the literature concerning the dental treatment, tooth extraction, and ONJ in Japanese patients with RA. This study aimed to evaluate the dental treatments, tooth extraction, and ONJ in our Institute of Rheumatology Rheumatoid Arthritis (IORRA) cohort.

Methods: The IORRA cohort was established in 2000 as a single institute-based large cohort of Japanese RA patients conducted at the Institute of Rheumatology, Tokyo Women's Medical University (Tokyo, Japan). More than 100 publications have described various characteristics of Japanese RA patients using this cohort. Patients with RA enrolled in IORRA cohort completed self-administered questionnaires as part of the April IORRA surveys of 2014, which included their dental treatment, tooth extraction at dentists during the past 6 months from October 2013 to March 2014, and past history of ONJ. The past histories of ONJ were validated with the patients' medical records. Logistic regression was used to determine the association variables and tooth extraction.

Results: Among 5,779 Japanese patients with RA (median age 65 years old, female 85%), 2,323 patients (40.2%) and 378 (6.5%) reported to have dental treatment and extracted tooth at dentist during the past 6 months, respectively. Among 1,257 patients with RA treated with oral bisphosphonate and denosmab, 533 patients (42.4%) and 83 (6.6%) reported to have dental treatment and extracted tooth during the 6 months, respectively. Among the patients who had tooth extraction and took bisphosphonate during the 6 months (n = 34), 22 (64.7%) were advised to stop bisphosphonates before the tooth extraction by physicians and dentists. In multivariate model, advanced age (P = 0.0060) and current smoking (P = 0.0072) were associated with tooth extraction. Among the patients, 25 patients reported to have a history of ONJ. Among them, we confirmed ONJ with their medical records in 6 patients during the past 36 months (Table). Among the 6 patients with ONJ, they were all female aged over 65 years old, 5 and 4 were treated with oral bisphosphonates and prednisolone, respectively, at the diagnosis of ONJ, 1 had a history of oral bisphosphonate treatment, and 2 were complicated with diabetes. The incidence rate of ONJ was 0.35/1,000 person-years in all RA patents, 0.93/1,000 person-years in female RA patients over 65 years.

Table. Clinical characteristics of 6 Japanese RA patients with ONJ

Age at the diagnosis of ONJ	Gender	Oral bisphosphonate use	Prednisolone use
80	Female	7 years	5 mg/day
66	Female	10 years	6 mg/day
77	Female	5 years	5 mg/day
79	Female	Until 1 year ago	none
77	Female	5 years	1 mg/day
66	Female	10 years	none

Conclusion: In Japanese patients with RA, many patients have dental treatment and tooth extraction at dentists. Japanese physicians should consult dentists before and after prescribing bisphosphonates and denosmab especially for elderly female RA patients taking prednisolone.

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Lupus, Scleroderma, JDMS

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

MicroRNAs (miRNAs) are single-stranded RNAs involved in the regulation of host genome expression at the post-transcriptional level. The objective of this study was to investigate whether select urinary cell-free microRNA's may serve as biomarkers in children with active lupus nephritis (LN) and to assess their relationship to the recently identified combinatorial urine biomarkers, a.k.a. the LN-Panel (neutrophil gelatinase associated lipocalin, monocyte chemotactic protein 1, transferrin, and beta-trace protein).

Methods:

In this prospective longitudinal cohort study, miRNAs (125a, 127, 146a, 150 and 155) were measured using real-time polymerase chain reaction in the urine pellet (PEL) and supernatant (SUP) in 14 patients with active LN, 10 patients with active extra-renal SLE, and 10 controls (five juvenile idiopathic arthritis and five fibromyalgia patients). The concentrations of the LN-Panel biomarkers were also assayed. Traditional LN-measures (complement levels of C3 and C4, anti-dsDNA antibodies, protein to creatinine ratio) and the renal and extra-renal disease activity were measured using renal and extra-renal domain scores of the Systemic Lupus Erythematosus Disease Activity Index (SLEDAI), respectively.

Results:

SUP levels of miR-125a, miR-150, and miR-155 were at least weak to strongly associated with most of the LN-Panel biomarkers (Pearson correlation coefficients; $0.3 < r < 0.9$; $p<0.05$), but generally no more than weakly with the renal domain of the SLEDAI or traditional LN-measures (r-<0.5)(table). In the PEL, miRNA levels did not correlate with any of the LN-measure (LN-Panel, traditional LN-measures, renal-SLEDAI).

Conclusion:

Levels of cell-free miR-125a, miR-150, and miR-155 in the urine supernatant but not the sediment are differentially excreted with active LN and may complement, but are unlikely superior to the LN-Panel for estimating concurrent LN activity.

Table:Associations of MiRNA levels in the urine supernatant vs. traditional measures **Values are Pearson correlation coefficients of log-transformed urine concentrations the miRNAs listed with miR, micro RNA ; BTP, beta trace protein ; NGAL, neutrophil gelatinase associated lipocalin ; MCP, monocyte chemotactic protein 1; WBC, white blood count ; DSDNA, anti-double stranded DNA titer ;

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Lupus, Scleroderma, JDMS

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Acute articular involvement is an important feature of childhood systemic lupus erythematosus (cSLE) and adult-onset (aSLE) patients, and it has been described in up to 70% of children and 90% of adults. In

contrast, evaluation of chronic arthritis (CA) has been restricted to case reports or small series in cSLE and aSLE patients. Moreover, comparison of clinical and laboratorial parameters in both SLE groups with CA is lacking in the literature. Therefore, the objective of the present study was to determine the overall prevalence of CA, and to compare clinical/laboratorial features and treatment in a large population of children and adult lupus patients.

Methods: This retrospective study evaluated medical charts of 336 cSLE and 1,830 aSLE patients (ACR criteria) followed in the same tertiary hospital. Demographic data, arthritis characteristics, clinical features, disease activity (SLEDAI-2K) and treatment were recorded. CA was defined as synovitis with least 6 weeks duration. Rhupus syndrome was characterized as the association of SLE and juvenile idiopathic arthritis/rheumatoid arthritis with erosion. Jaccoud's arthropathy was defined as a non-erosive subluxation leading to severe deformity of the hands and feet, mild aching and little or no evidence of synovitis.

Results: Frequencies of CA were similar in cSLE and aSLE patients (2.3% vs. 3.7%,p=0.261). Hands (62% vs. 58%,p=1.000), wrists (62% vs. 48%,p=0.480) and knees (50% vs. 17%,p=0.053) were the most frequently involved joints in both groups. Ankles were significantly more involved in cSLE (100% vs. 16%,p<0.001). The median of disease duration until CA diagnosis was shorter in cSLE (0 vs. 10 years,p<0.001). Children presented more polyarthritis than adults (75% vs. 32%,p=0.024), as well as median number of joints with arthritis [8.5(1-18) vs. 3(1-9),p=0.017] and number of joints with limitation on motion [1.5(0- 24) vs. 0(0-4),p=0.004]. Further analysis of cSLE and aSLE patients at CA diagnosis revealed higher frequencies of hepatomegaly (25% vs. 0,p=0.009), splenomegaly (25% vs. 0,p=0.009), alopecia (37% vs. 1.4%,p=0.002), pericarditis (25% vs. 0, p=0.009), nephritis (37% vs. 3%,p=0.006), hematuria (37% vs. 1.4%,p=0.002), lupus anticoagulant (40% vs. 1.6%, p=0.012) and anticardiolipin IgM (40% vs. 1.5%,p=0.012) and higher median of SLEDAI-2K [10.5(1-20) vs. 6(4-16),p=0.029] in the former group. Frequencies of rhupus syndrome (12% vs. 17%,p=1.0) and concomitant Jaccoud's arthropathy (0 vs. 17%,p=0.343) were similar in cSLE and aSLE patients at CA diagnosis. The frequencies of glucocorticoid, antimalarials and methotrexate use were similar in both groups (p>0.05).

Conclusion: We identified that chronic arthritis in SLE has distinct features in children with very early onset, polyarticular involvement and often associated with active disease. We further demonstrated that rhupus is not a relevant cause of CA in cSLE and aSLE patients, suggesting that CA represents a distinct manifestation of lupus.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Lupus, Scleroderma, JDMS
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Previous retrospective evaluations suggested that age at diagnosis may influence disease expression in terms of initial clinical presentation, pattern of organ involvement and serological findings in childhood systemic lupus erythematosus (cSLE) patients. However, the small sample size of previous studies, particularly regarding the early-onset cSLE patients (<6 years), precludes a definitive conclusion about their findings. In addition, no data is available regarding the relevance of age in Latin-American c-SLE population. Therefore, the main objective of the present large multicenter study was to compare demographic data, clinical and laboratory findings at disease diagnosis in three different age-related cSLE groups.

Methods: A retrospective multicenter study was performed in 847 cSLE patients from 10 Pediatric Rheumatology services of São Paulo state, Brazil. Patients were divided in three age-related cSLE groups: A - early-onset (<6 years), B - school age (≥6 and <12 years) and C - adolescent (≥12 and < 18 years). An investigator meeting was held to define the protocol, to harmonize clinical parameters definition and disease activity tool scoring. Demographic data, clinical and laboratorial features, and disease activity (SLEDAI-2K) were evaluated.

Results:

Groups of cSLE patients were divided: A 39 (4%), B 395 (47%) and C 413 (49%). Of 39 cSLE patients of group A, 3 (8%) were infants, 4 (10%) toddlers and 32 (82%) preschool. Complete C1q deficiency was observed in 3/74 (4%) cSLE patients, all of them of group A. Groups were similar regarding frequencies of nephritis (47% vs. 51% vs. 49%, p=0.742), neuropsychiatric involvement (37% vs. 25% vs. 24%, p=0.348), autoimmune hemolytic anemia (19% vs. 23% vs. 19%, p=0.237), thrombocytopenia (11% vs. 18% vs. 14%, p=0.264) and median of SLEDAI-2K at disease diagnosis [15(5-41) vs. 15(0-58) vs. 14(0-49) p=0.831). Frequencies of female gender, autoantibodies profile, acute phase proteins and low complement levels were also comparable in these three groups (p>0.05). Of note, frequencies of fever (78% vs. 61% vs. 47%, p<0.0001), hepatomegaly (42% vs. 29% vs. 14%, p<0.0001), splenomegaly (28% vs. 12% vs. 4%, p<0.0001) and discoid lupus (13% vs. 4% vs. 4%, p<0.020) were significantly higher in the group A compared to groups B and C. In contrast, the frequencies of weight loss >2kg (19% vs. 28% vs. 36%, p<0.017), photosensitivity (34% vs. 41% vs. 51%, p<0.006), leukopenia<4,000/mm^3 (14% vs. 25% vs. 30%, p<0.048) and lymphopenia<1,500/mm^3 (22% vs. 41% vs. 47%, p=0.011) were significantly lower in the group A.

Conclusion:

Our large multicenter study identified that the initial presentation of cSLE is characterized by comparable high frequencies of internal organ involvements and some distinct clinical and laboratorial features in early-onset and adolescent groups.

Pain, Fatigue and the Psychological Impact on Health-Related Quality of Life in Childhood-Onset Lupus

Jordan T. Jones[1], Natoshia Cunningham[2], Catherine Donnelly[3], Susmita Kashikar-Zuck[4] and Hermine I. Brunner[5], [1]Division of Rheumatology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Behavioral Medicine & Clinical Psychology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [3]Internal Medicine, University of Cincinnati, Cincinnati, OH, [4]Behavioral Medicine and Clinical Psychology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [5]Pediatric Rheumatology Collaborative Study Group, Cincinnati Children's Hospital Medical Center, Cincinnati, OH

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Lupus, Scleroderma, JDMS

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Childhood-onset lupus (cSLE) is a chronic autoimmune disease that has negative impact on health-related quality of life (HRQoL), especially when increased disease activity and damage exist, however, even with well controlled disease, HRQoL with cSLE remains lower compared to healthy populations. Chronic disease and related symptoms (pain, fatigue and poor sleep) as well as psychological factors (depression, anxiety and difficulty coping) can impair participation in developmentally appropriate activities. However, the impact of these potentially modifiable factors in relation to HRQoL in youth with cSLE is unknown. O*bjectives* of this study were to evaluate pain, fatigue and psychological functioning of cSLE patients and examine how these factors impact HRQoL.

Methods: As part of an ongoing study, cSLE patients (n= 65; 8 – 20 years) followed at Cincinnati Children's Hospital, were asked to complete measures of *pain* (Pain visual analog scale), *fatigue* (PedsQL Multidimensional Fatigue Scale), *depression* (Children's Depression Inventory I), *anxiety* (Screen for Child Anxiety Related Disorders), *pain coping* (Pain Coping questionnaire, Pain Catastrophizing scale), *sleep* (Adolescent Sleep Wake Scale), and *HRQoL* (PedsQL Generic Core scale and Rheumatology Module, Functional Disability Inventory). Measures of disease activity (Systemic Lupus Erythematosus Disease Activity Index, and physician completed visual analog scale of cSLE disease activity [0-10; 0=inactive]) were also obtained.

Results: Subjects were 83% female with mean age of 16.1 years (SD 2.6) and mean SLEDAI score of 5.6 (SD 5.6). Fatigue was present in 63% of the patients; clinically relevant pain (Pain-VAS > 3), anxiety (SCARED ≥ 25) and depressive symptoms (CDI-I > 12) were observed in 38%, 38% and 31% of the patients, respectively; 60% had moderate catastrophizing (PCS ≥ 15). On average, the PedsQL-GC/RM for cSLE were lower than those observed in healthy populations (Table 1). Reduced PedsQL-GC/RM scores were highly correlated with greater levels of fatigue, anxiety, and depressive symptoms (Pearson r > 0.65), but had weak correlation with disease activity (Pearson r < 0.25). Regression analysis demonstrated HRQoL was most impacted by fatigue, and pain when evaluating all factors concurrently ($p < 0.001$; Table 2).

Conclusion: cSLE is associated with decreased HRQoL, psychological aspects of health are prevalent and markedly contribute to low HRQoL. Fatigue, pain, and anxiety symptoms are present in a large subgroup of patients and need to be addressed to achieve optimal health outcomes.

Table 1. Health-related quality of life (HRQoL) and modifiable factors

Measures	Normative population mean (SD)	cSLE mean (SD)	Frequency, n (%) above cutoff value†	p-value

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Lupus, Scleroderma, JDMS

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To assess clinical and serological differences between patients with juvenile-onset systemic lupus erythematosus (jSLE) and adult-onset (aSLE) from a National database.**Methods:** Data included in the transverse phase of the National Register of lupus of the Spanish Society of Rheumatology (RELESSER –T) were analysed, which includes retrospective data from SLE patients. Inclusion criteria: patients with SLE with > or = 4 ACR criteria for SLE who were divided into 2 groups: disease date onset < 18 years and > 18. Sociodemographic, clinical, serological, activity, treatment and cumulative damage and chronicity data were collected. Associative descriptive statistical analysis was performed.**Results:** we reviewed 3.428 aSLE (89.6 % women) and 484 jSLE (89.8 % girls), 93.1 % Caucasian in both groups; age at diagnosis: 38.1±14 and 16.6 ± 6.3 years, respectively; average delay in diagnosis 24.7±47.4 and 39.9±5 months, respectively; mean age at followup: 48.8 ± 14.3, 31.5 ± 30 years, respectively. Table 1 shows all significant differences ($p < 0.05$). In aSLE 68.7 % had positive anti-DNA Ab vs. 82.9 % of jSLE ($p < 0.001$). Table 1

Treatment and Outcomes in Pediatric SLE Patients in South Africa

Laura Lewandowski[1], Christiaan Scott[2], Laura Schanberg[3] and Nathan Thielman[4], [1]Pediatric Rheumatology, Duke University Medical Center, Durham, NC, [2]Rheumatology, Red Cross War Memorial Children's Hospital, Cape Town, South Africa, [3]Duke University, Durham, NC, [4]Duke Hubert Yeargan Center for Global Health, Durham, NC
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Lupus, Scleroderma, JDMS
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Although African children with SLE may be at high risk for poor outcomes based on race, socioeconomic status, and

age, little research has investigated this population. We have initiated the first registry of this high risk pediatric SLE (pSLE) population in South Africa (SA). Here, we present the first comparison of treatment and outcomes between a South African pSLE cohort (PULSE) and a North American pSLE cohort (Childhood Arthritis and Rheumatology Research Alliance (CARRA) Registry).

Methods:

We conducted a cross sectional analysis (retrospective chart review) of pSLE patients in Cape Town, SA from 1988-2014 meeting ACR criteria for pSLE. Patient age, gender, race, presenting features, clinical and serologic disease markers, and treatment were recorded and compared to an established North American pSLE cohort.

Results:

The SA cohort includes 72 patients; mean age 11.5 years, 83% female. The SA cohort had increased rates and severity of lupus nephritis and high disease activity at enrollment (**Table 1**) SA patients had increased use of cyclophosphamide (942% vs 29%), methotrexate (30% vs 19%), and azathioprine (61% vs 16%). PSLE patients in the CARRA cohort had increased use of antimalarials and mycophenolate mofetil (**Table 2**). The PULSE cohort had high rates of end organ damage with 63% having a SLICC-DI score >0. Within the SA cohort, 13% went on to develop ESRD, of which 9% required transplant, strikingly higher than North American peers. (**Table 3**)

Conclusion:

The PULSE cohort is the largest registry of pSLE patients in Africa to date. Children in SA receive different therapy and demonstrate a striking increase in poor renal outcomes, end stage renal disease, and irreversible organ damage compared to North American peers. These differences may be due to treatment, health care access, racial predisposition, or a combination of factors. Further prospective research is required to determine the burden of pSLE in South Africa, and identify risk factors for poorer outcome in this high risk population.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Lupus, Scleroderma, JDMS

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Depression and anxiety are common in adolescents with SLE. Barriers to mental health intervention in pediatric rheumatology care are unclear. We aimed to determine current provider practices and

perceived barriers to mental health care for adolescents with SLE.

Methods: We conducted a web-based survey from May-June 2015 among members of the Childhood Arthritis and Rheumatology Research Alliance (CARRA). Inclusion criteria were providers caring for adolescents with SLE, with an available email address. The survey assessed provider demographics, current practices and barriers for mental health care of adolescents with SLE. Participants rated potential barriers on a 4-point Likert scale as: "never=0", "sometimes=1", "often=2" or "very often=3". We defined significant barriers as those rated "often" or "very often", and ranked them by frequency. We used multivariable negative binomial regression to examine associations of demographics with the number of significant barriers to mental health care. Provider covariates included: type (attending or trainee MD/DO, NP, PA); sex; years in practice; mental health training. Practice covariates included: setting; location; size; upper age limit of patients treated; SLE population size and insurance composition; presence of a specialized SLE clinic; involvement in SLE research.

Results: Of 375 eligible CARRA members, 120 (32%) responded. After exclusions (13 incomplete, 6 not in clinical care), 101 were analyzed. Eighty percent of respondents were attending physicians, 43% had >10 years in practice, 95% were university-affiliated and 72% were female. Fifty-four percent said identification of depression/anxiety in adolescents with SLE was currently inadequate and 47% said treatment was inadequate. Routine screening for depression and anxiety was supported by 84% and 71%, respectively, and 89% thought screening should occur in outpatient rheumatology. Although 54% reported practicing routine informal mental health screening, only 9% used a standardized screening tool. The most frequent barriers to routine screening in rheumatology were limited time and staff resources (Table 1). The most frequent barriers to treatment were limited availability and long waiting lists for mental health providers. Mental health training beyond medical school (IRR=0.34, 95% CI 0.16-0.73, $p<0.01$) and experience treating adults with SLE (IRR=0.36, 95% CI 0.20-0.64, $p<0.01$) were associated with fewer barriers. Interest in receiving training for mental health evaluation was endorsed by 90% and prescribing mental health medications by 60% of respondents.

Conclusion: Significant barriers exist to addressing the need perceived by rheumatologists for improved mental health care of adolescents with SLE. On-site resources and enhanced mental health training for pediatric rheumatologists may help overcome these barriers.

Table 1: Significant Barriers to Mental Health Care for Adolescents with SLE as Perceived by Respondents (N=101)		
Perceived Barriers to Routine Mental Health Screening*	**Rank**	**N (%) of Respondents**
Limited time during the encounter	1	77 (76)
Lack of staff resources to screen	2	74 (73)
Limited availability of mental health providers	3	66 (65)
Lack of staff resources to follow up results	4	65 (64)
Lack of institutional support	5	55 (54)
Limited space	6	45 (44)
Provider lack of mental health knowledge	7	29 (28)
Patient willingness to be screened	8	28 (27)
Parent willingness to have child screened	9	24 (23)
Language barriers	10	13 (12)
Provider discomfort with results	11	15 (14)
Confidentiality concerns	12	10 (9)
Perceived Barriers to Mental Health Treatment*	**Rank**	**N (%) of Respondents**
Limited availability of locations of mental health providers	1	76 (75)
Long waiting lists for mental health providers	2	76 (75)
Parent/patient uncertainty about where to obtain services	3	63 (62)
Time burden for patients/families	4	61 (60)
Insurance concerns	5	59 (58)
Cost to patients/families	6	53 (52)
Patient perceived lack of usefulness of mental health services	7	49 (48)
Transportation problems	8	49 (48)
Provider lack of knowledge of available mental health providers	9	41 (40)
Patient/parent concerns about what others will think	10	41 (40)
Parent perceived lack of usefulness of mental health services	11	39 (38)
Patient/parent distrust of mental health providers	12	34 (33)
Communication barriers between medical & mental health providers	13	29 (28)
Language barriers	14	21 (20)
Confidentiality concerns	15	13 (12)
* Potential barriers in survey were based on known correlates of unmet need for mental health services from the Methods for the Epidemiology of Child and Adolescent Mental Disorders Study (Flisher et al. *Psychol Med* 1997, 27(5):1145-1154), and known factors affecting integrated mental health care in primary care settings (Gunn et al. *Journal of clinical psychology* 2009, 65(3):235-252).

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Lupus, Scleroderma, JDMS
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Outcomes of patients with cSLE over time and into adulthood are poorly understood. There has been no information about the longitudinal trajectory of organ damage in cSLE patients. We undertook this study to: 1) determine the longitudinal damage trajectory– as measured by the American College of Rheumatology (ACR)/ SLE International Collaborating Clinics (SLICC) SLE damage index (SDI)– in patients with cSLE. 2) identify both baseline and disease course (time-varying) predictors of damage trajectory.

Methods: Single centre, retrospective, inception cohort. We included 473 patients who were diagnosed and followed, from 1st January 1985 to 30th September 2011. To be included, patients had to be <18 years at diagnosis, have satisfied the ACR classification criteria for SLE, were treated for <3 months with steroids or an immunosuppressant for any other disease, and have had at least 3 visits. Longitudinal pediatric-age data was obtained from our research database while adult-age data was obtained from either a research database or patients' charts. Clinical information at every visit was collected: for SLE disease activity index 2000 (SLEDAI2K), the SDI, laboratory results, and medications. Longitudinal trajectory of damage fit best with a 2nd order fractional polynomial (0.5,1). Predictors were identified using a weighted generalized estimating equation (WGEE). Time-varying predictors: disease activity, individual items of SLEDAI2K, corticosteroid, immunosuppressant and antimalarial exposures, were lagged by 6, 12, 18 and 24 months in different models.

Results: 67/473 (14%) patients were lost to follow-up. There were 14097 visits, totaling 3290 patient-years. The median follow-up duration was 5.5 years. The median age at diagnosis was 14.1 years and median age at last visit was19.5 years (range 6.0–41.9 years). 65% of patients were >18 years old at last follow-up. The predicted average population damage was 0.7 at 5 years, 1.3 at 10 years, 1.9 at 15 years, 2.3 at 20 years and 2.7 at 25 years. Cataract (14%) was the most common item of damage, followed by avascular necrosis (10%) and osteoporosis (5%). Only 2 patients had myocardial infarctions. Life-threatening major organ manifestations predicted higher initial damage but the accrual of damage slowed down over time. Higher prednisone dose (12, 24 months before) and the use of

cyclophosphamide (6, 12,18, 24 months before) predicted an increased damage trajectory at current visit. Antimalarial exposure (6 months before), mucosal ulcers (6,12,18,24 months before) and pericarditis (6 months before) were protective against an increase in damage trajectory.

Conclusion: Patients with cSLE accrue damage steadily throughout their disease course into adulthood. We identified the baseline factors that predict higher initial damage and influence damage trajectory. Over time, SLE clinical features and therapeutic exposures during the course of disease, predicted a change in damage trajectory.

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Lupus, Scleroderma, JDMS

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Although SLE patients are thought to follow different patterns of disease courses, no information is available about the longitudinal disease activity or the number of possible different disease courses. This study sought to: 1) determine the longitudinal disease activity trajectory in childhood-onset SLE (cSLE) patients; 2) determine the number of latent classes of disease activity trajectories and 3) identify factors predictive of membership in different disease trajectories.

Methods: Single centre longitudinal inception cohort of cSLE patients (onset <18 years) diagnosed and followed from Jan 1985 to Sep 2011. Clinical data from childhood to adulthood was obtained: pediatric data from our institutional cSLE database, adult data from the Toronto Lupus database or extracted from clinical charts from rheumatologists' offices. Longitudinal disease trajectory was constructed using data from every clinic visit in the 1st 10 years after diagnosis. Longitudinal SLE activity is a latent construct that is imperfectly measured with SLE disease activity index 2000 (SLEDAI2K) and prednisone exposure. Longitudinal mean population trajectories of SLEDAI2K and prednisone use were first fitted with the mixed effects model. SLEDAI2K and prednisone use were then jointly modeled in a Bayesian growth mixture model (GMM).

Results: 473 patients were included. 82% were females, median age of diagnosis was 14.1 years. There were 11992

visits, 2666 patient years. By the end of 10 years, 67% of the population had transferred to adult care. Mean population SLEDAI2K and prednisone trajectories of cSLE patients showed rapid decline to low activity levels within 2 years after diagnosis. However, joint GMM showed 5 latent classes were present in this cohort of cSLE patients in the following distributions: 30(6%), 57 (12%), 79 (17%), 92(19%), 215 (45%). Class1 patients have chronic moderate-high disease activity, class 2 had moderate initial disease activity and continued moderate long-term prednisone use, class 3 had initial high disease activity but achieved long-term remission, class 4 had high initial disease activity but relapsed later, class 5 had chronic low-grade disease activity. Across all classes, there was chronic use of prednisone (at least 5-10 mg/day) among cSLE patients in the first 10 years after diagnosis. Baseline major organ involvement, ethnicity, age at diagnosis and the number of baseline ACR criteria predicted membership in different classes.

Conclusion: cSLE patients could be subclassified into 5 distinct classes of disease activity trajectories. Baseline organ involvement and personal demographic factors could predict membership in the distinct disease activity trajectory classes.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Lupus, Scleroderma, JDMS

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Lupus nephritis (LN) is the major findings in systemic lupus erythematosus (SLE). LN with some pathologic findings in the kidney but had normal urine were called as silent LN (sLN); renal biopsy revealed that 70% of sLN patients were in Class I/II and 20% in Class III/IV in adult survey. However, there were few studies to examine sLN in juvenile SLE (JSLE). Therefore, clinical and renal pathologic findings in children with sLN were examined.

Methods: JSLE patients whose onset was before 16 years old, referred to our hospital from 2000 to 2011, were recruited in the study. Patients were divided into two groups according to urinary findings at the first examination; sLN and overt LN (oLN). Clinical findings such as gender, age at onset, ISN/RPS pathologic classification, general analysis of whole blood, and urinary findings after 3 years of therapy were retrospectively examined and compared between the two groups by using the Mann-Whitney *U*-test or the Fisher exact test.

Results: A total of 31 JSLE patients were involved in the study. Of the 31 patients, 18 (58%) were sLN and 13 (42%) were oLN. As to gender, the incidence of male was significantly higher in sLN group (33%) than oLN group (0%) (P =

0.028). Pathologic findings of ISN/RPS classification in sLN patients were Class I in 3, Class II in 12, and Class III in 3. In oLN patients, those were Class II in 3, Class III in 6, Class IV in 2, Class V in 1, and Class III + V in 1. Complement C3 level showed no statistical difference between the two groups. However, in sLN group, complement C3 levels in Class II (56 ± 23 mg/dL) and Class III (37 ± 19 mg/dL) were significantly lower than that observed in Class I (96 ± 26 mg/dL) (P = 0.02 and 0.04, respectively). Anti-dsDNA antibody titer showed no statistical difference between the two groups. On the other hand, anti-Sm antibody titer was significantly higher in sLN group (67 ± 54 U/mL) compared to oLN group (30 ± 49 U/mL) (P = 0.015). Urinary findings were still normal in 17/18 (94%) of sLN patients after 3 years of therapy.

Conclusion: In conclusion, these results suggest that complement C3 level and anti-Sm antibody may be a useful tool for predicting the severity and associated with the pathogenesis of sLN in JSLE, respectively. Though the all of the male patients were in sLN group, more than 90% of sLN patients maintained normal urinary findings at 3 years after initiating therapy. Considering the general concept that the prognosis of JSLE in male is more severe than that of female's, the present study may indicate that the early therapeutic intervention from sLN stage is essential to prevent the progression of renal damage.

Session Date: Sunday, November 8, 2015

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Lupus, Scleroderma, JDMS

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Neuropsychiatric syndromes are prevalent in childhood-onset systemic lupus erythematosus (cSLE), but the long-term risk of depression in adults with cSLE is unknown. We compared the prevalence of depression among adults with cSLE to those with adult-onset SLE (aSLE) using the UCSF Lupus Outcomes Study (LOS).

Methods:

Data derive from the 2002-2012 cycles of the LOS, an annual longitudinal telephone survey of diverse English-speaking individuals with confirmed SLE. Participants aged 18-45 years (N=520) were included. Respondents were classified as childhood-onset if age at diagnosis was <18 years (N=112). Mental health was assessed with the Center for Epidemiological Studies Depression Scale (CESD), the ACR Committee on Neuropsychiatric Lupus' suggested

measure of depression in SLE, using validated cutoff values. Outcome variables included CESD≥24 (indicative of major depression) and CESD≥20 (indicative of a mood disorder). We performed repeated measures analysis using generalized estimating equations to compare cSLE and aSLE with and without adjustment for other characteristics that could affect depression risk. Age, gender, non-white ethnicity, marital status, poverty, education attained, obesity, self-reported disease activity according to the Systemic Lupus Activity Questionnaire (SLAQ) score, and physical disability according to the SF-36 Scale of Physical Function (SF36-PF) were included as covariates.

Results:

Respondents with cSLE were younger at baseline (26±7 v. 35±6), more likely to be male (13% v. 5%), and more likely to be ethnic minorities (60% v. 46%), all $p<0.01$. Mean age at diagnosis was 14±3 for respondents with cSLE as compared to 27±6 for those with aSLE. Mean disease duration at baseline was 13±7 years in the cSLE group and 8±6 years in the aSLE group. Mean baseline SLAQ score was 12±8 for all respondents. Prevalence of depressed mood at baseline was slightly higher among respondents with aSLE, though not statistically significant (23% vs. 29% for major depression and 31% vs. 35% for all mood disorders). Respondents with aSLE were more likely to have ever taken medication to treat depression (59% vs. 43%, $p=0.01$). In multivariate analysis, the odds of major depression among participants with cSLE was increased as compared to those with aSLE (OR=1.7, 95% CI 1.1-2.6) after adjustment for covariates (Table 1).

Conclusion:

Onset of SLE in childhood may be an independent risk factor for the development of major depression in early adulthood, with other important predictors including older age, lower educational attainment, increased disease activity and decreased physical function. Appropriate screening and treatment for depression is important to maximize long-term quality of life and functional outcomes in patients with cSLE.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Lupus, Scleroderma, JDMS
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

The Patient Reported Outcomes Measurement Information System (PROMIS®), developed by the National Institutes of Health, seeks to create standardized instruments to measure patient reported health-related quality of life (HRQoL) across diverse domains, both within and *between* disease processes. Our objective was to use PROMIS pediatric short form responses to conduct a comparison of HRQoL between childhood-onset systemic lupus erythematosus (cSLE), juvenile idiopathic arthritis (JIA), and widespread chronic musculoskeletal pain (CMP)

Methods:

We compared cross-sectional data from a cohort of 100 children diagnosed with cSLE to a cohort of 121 patients diagnosed with JIA, and 66 patients diagnosed with widespread chronic musculoskeletal pain (CMP). Specifically we compared mean PROMIS pediatric short form T scores across conditions using ANOVA and post-hoc Tukey honest significant difference testing. We also compared mean pediatric quality of life inventory (Peds QL) general core (GC) total scores for cSLE and JIA via T-test.

Results:

Compared both to patients with cSLE and JIA, CMP had significantly worse PROMIS T-scores in every category aside from Peer Relationships (see table 2). cSLE and JIA patients' PROMIS T-scores did not differ significantly, except for lower mobility reported by patients with JIA ($p = 0.026$). Comparison of cSLE and JIA via mean Peds QL GC total scores showed cSLE fared significantly worse. The level of difference in PROMIS scores observed between CMP patients and cSLE/JIA was marked, with large F scores (17 or greater, in context of a critical difference of 2).

Conclusion:

We showed significantly poorer HRQoL in children with widespread chronic musculoskeletal pain compared to JIA and SLE patients (who did not differ significantly from each other). This result emphasizes the importance of HRQoL to children with rheumatologic and pain conditions, in addition to more objectively demonstrable physical pathology. Assessment of patient reported outcomes helps to identify areas for intervention to improve HRQoL. Further, given the significant difference between cSLE and JIA seen on the PEDS QL GC measures (but not PROMIS) additional validation of the PROMIS short forms is required to ensure that they address all quality of life domains relevant for SLE

Table 1. Demographics and Mean Scores

Values are mean (SD) unless stated otherwise	cSLE	JIA	CMP	
Total N	100	121	66

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Lupus, Scleroderma, JDMS

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Childhood-onset Lupus (cSLE) is associated with decreased Health-related Quality of Life (HRQoL), and disease activity measures are often unrelated to overall perception of health. The patient's perspective is necessary to further understand disease effect as cSLE is a chronic, episodic health condition impacting critical points in a child's psychosocial development. The objective of this study is to assess disease experience trends in patients with cSLE by evaluating patients' reports of psychological factors (fatigue, depression, anxiety, sleep), and their potential effect on HRQoL.

Methods: As part of an ongoing, longitudinal study, twenty cSLE patients (age 8-20 years) were assessed at two separate clinic visits approximately 6 months apart. Patients completed validated measures of fatigue (PedsQL Multidimensional Fatigue Scale), depressive symptoms (Children's Depression Inventory; CDI-1), anxiety (Screen for Child Anxiety Related Disorders; SCARED), sleep (Adolescent Sleep Wake Scale; ASWS), and HRQoL (PedsQL Generic Core scale and Rheumatology module). Physician assessments were completed for disease activity (Systemic Lupus Erythematosus Disease Activity Index-2K), damage (SLICC/ACR Damage Index), and visual analog scales of disease activity.

Results: Patients were 90% female, mean age 16.5 years (SD 2.8), 40% African American, and 55% Caucasian. cSLE was well controlled at visit 1 and 2 with mean SLEDAI ≤ 5 in 70% and damage was absent in 75%. Fatigue was reported by 65% of patients at both visits. Clinically relevant anxiety (SCARED$\geq$25) was reported in 40% and 35% at visit 1 and 2, respectively, which is higher than prior reported prevalence rates in cSLE patients. Clinically significant depressive symptoms (CDI-1>12) were reported in 25% and 30% at visit 1 and 2, respectively, which is similar to previous reported prevalence rates in cSLE patients. Of the five sleep quality ASWS subscales, cSLE patients have most difficulty 'going to bed' and 'returning to wakefulness', however reported similar overall mean scores to normative US teens surveyed. HRQoL measures remained lower compared to healthy populations over time (Table 1).

Conclusion: Lower HRQoL was observed over the 6 month study period, concomitant with ongoing difficulties with fatigue, anxiety and depression in many patients, despite stable disease activity and no increased damage. These findings suggest a persistent disease burden that is not being addressed by current management practices which focus on preventing tissue damage. A routine assessment of fatigue and psychological factors as part of standard of care is necessary in order to determine the need for potential behavioral interventions that could improve HRQoL for patients with cSLE. Further investigation into sleep behaviors and potential effect on sleep quality is needed.

Table 1. Paired T-tests for Comparison of Visit 1 and 2 Measures

Measures	Normative Population mean (SD)	cSLE mean (SD) VISIT 1	cSLE mean (SD) VISIT 2	t	p
HRQoL Measures					
PedsQL Generic Core Scale	83.9 (12.5)	74.7 (20.7)	76.7 (20.6)	-0.767	0.453
PedsQL Rheumatology Module	84.4 (18.0)	74.7 (18.6)	79.9 (19.7)	-2.081	0.051
Psychological Factors					
Fatigue (PedsQL-FS)	80.5 (13.3)	58.5 (22.3)	61.8 (25.7)	-1.354	0.192
Depression (CDI-1)	9.09 (7.0)	8.4 (8.3)	8.5 (9.4)	-0.101	0.921
Anxiety (SCARED)	17.4 (12.1)	22.0 (16.4)	18.8 (17.4)	1.775	0.092
Sleep (ASWS)* Total		4.09 (0.79)	4.21 (0.74)	-1.177	0.253
Go to Bed		4.05 (1.29)	3.8 (1.27)	0.954	0.352
Fall Asleep		4.05 (1.14)	4.23 (0.94)	-1.190	0.248
Maintain Sleep		4.26 (1.05)	4.50 (0.99)	-1.609	0.123
Reinitiate Sleep		4.62 (0.62)	4.94 (0.72)	-2.188	0.041
Return to Wake		3.47 (1.25)	3.54 (1.21)	-0.428	0.673
Disease Measures					
SLEDAI-2K		4.8 (4.9)	4.5 (3.6)	0.304	0.764
Physician Global		1.5 (1.4)	1.4 (1.3)	0.438	0.666
SLICC/ACR Damage Index		0.4 (0.82)	0.4 (0.82)		

PedsQL Generic Core and Peds QL Rheumatology module higher scores represent better quality of life.

PedsQL-FS higher scores represent less fatigue.

CDI-1 higher scores indicate higher level of depressive symptoms; score >12 reflects clinically significant depressive symptoms.

SCARED higher scores represent more anxiety; score ≥25 reflects clinically relevant anxiety.

*ASWS higher scores represent better sleep quality. No established normative or cutoff value; range 1-6 with higher values representing better sleep.

SLEDAI-2K higher scores represent increased disease activity.

Physician Global higher scores represent higher disease activity.

SLICC/ACR Damage Index higher scores represent increased disease damage.

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Lupus, Scleroderma, JDMS

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Several studies have shown the relationship between anti-SSA-Ro/SSB-La antibodies and Systemic Lupus Erythematosus (SLE), Sjögren Syndrome (SS) and other autoimmune diseases in adult population. However, the expression of these autoantibodies and clinical correlation in juvenile patients is poorly described. To characterize the clinical and serological profile and primary rheumatic diseases in pediatric patients with positive anti-SSA-Ro and/or anti-SSB-La antibodies.

Methods: The data was obtained from a long term prospective cohort of patients under age 18 diagnosed with rheumatic diseases in a tertiary hospital in Spain. Demographic, clinical, and laboratory data were collected from 1986 to 2010. Patients were divided into 2 groups: anti-SSA-Ro/SSB-La positive and anti-SSA-Ro/SSB-La negative.

Results: A total of 187 patients were tested for anti Extractable Nuclear Antigens (ENA), with a following mean time of 11 years. Mean age at disease onset was 12.6 years and 77% were female. Fifty-four (28.9%) anti-SSA-Ro/SSB-La positive subjects were compared against 133 (71.1%) anti-SSA-Ro/SSB-La negative subjects. Among positive cases, 13 (24.1%) patients were double-positive for anti-SSA-Ro and anti-SSB-La, 51 (94.4%) were positive for anti-SSA-Ro and 3 (5.5%) were single-positive for anti-SSB-La. The anti-SSA-Ro/SSB-La antibodies were found less frequently ($p=0.003$) in the overlapping syndromes, and more frequently in SLE ($p=0.007$). In addition rheumatoid factor ($p<0.001$), anti-Sm ($p<0.001$) and anti-RNP ($p<0.001$) were frequently co-expressed with anti-SSA-Ro/SSB-La antibodies. Finally the anti-SSA-Ro/SSB-La positive group presented more hematological and skin manifestations than the negative group ($p<0.05$).

CLINICAL AND SEROLOGICAL PROFILE OF CHILDREN WITH POSITIVE SSA-RO/SSB-LA ANTIBODIES			
FEATURES	Anti-SSA-Ro/SSB-La (+) N=54 (%)	Anti-SSA-Ro/SSB-La (-) N=133 (%)	p
Age at Disease Onset (Sd, Range)	12.6 (4.4, 1-17)	12.4 (4.4, 1-17)	0.76

CLINICAL FEATURES			
Inflammatory Fever	18 (33)	34 (25.6)	0.28
Arthralgias	39 (72.2)	98 (73.7)	0.84
Arthritis	33 (61.1)	71 (53.4)	0.33
Malar Rash	25 (46.3)	39 (29.3)	0.02
Photosensibility	23 (42.6)	36 (27.1)	0.03
Pleurisy	9 (16.7)	19 (14.3)	0.68
Pericarditis	8 (14.8)	15 (11.3)	0.50
Cardiac Arrhythmias	3 (5.6)	3 (2.3)	0.25
Renal Manifestations	23 (42.6)	44 (33.1)	0.22
Hematologic Manifestations	40 (74.1)	73 (54.9)	0.01

Conclusion: Similarly to adults, we observed a relationship between anti-SSA-Ro/SSB-La antibodies and SLE in pediatric patients. However a low proportion of childhood primary SS exists in our anti-SSA-Ro/SSB-La positive cases. This could be explained by underdiagnoses related to the atypical clinical presentation of SS in pediatric population. Single-positive anti-SSB-La patients are uncommon, the clinical significance of this serological result remains uncertain in children.

Management of Lupus Anticoagulant Hypoprothrombinemia Syndrome in Juvenile Systemic Lupus Erythematosus – Single Center Experience

J. Brian Shirley[1], Patricia Rosillo[1], Andrea Ramirez[1] and Anna Carmela Sagcal-Gironella[2], [1]Allergy, Immunology and Rheumatology, Baylor College of Medicine/Texas Children's Hospital, Houston, TX, [2]Pediatrics, Baylor College of Medicine, Texas Children's Hospital, Houston, TX

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Lupus, Scleroderma, JDMS

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Lupus anticoagulant hypoprothrombinemia syndrome (LAHS) is a rare phenomenon that leads to concomitant thrombosis and hemorrhage thus presenting a therapeutic dilemma. In children, this acquired prothrombin deficiency may be associated with infection or autoimmunity, specifically systemic lupus erythematosus (SLE). LAHS in juvenile SLE (jSLE) has a protracted course requiring long-term immunosuppressive therapy. Due to the rarity of this syndrome and paucity of reported cases, there is lack of standardized management. We describe a case series of jSLE patients with LAHS managed with an aggressive combination therapy.

Methods: We retrospectively reviewed the medical records of 3 jSLE patients at our institution from 2007 to 2015. All patients fulfilled at least 4 of the ACR classification criteria for SLE. Literature review was also performed to compare our cohort with reported cases of LAHS in jSLE.

Results:

Patient 1 is an 8 y.o. Caucasian female who presented with ascites, pleural and pericardial effusions, hepatosplenomegaly and pancytopenia. She had epistaxis and pulmonary hemorrhage. Labs notable for positive lupus anticoagulant (LAC) and strongly positive IgG and IgM prothrombin antibodies (PTabs). Initial therapy included plasmapheresis, IV rituximab, IV cyclophosphamide, pulse IV methylprednisolone, and prothrombin complex; subsequent therapy with IVIG, tapering course of oral prednisone and mycophenolate mofetil (MMF).

Patient 2 is a 17 y.o. Hispanic female who presented with hemorrhagic shock from severe coagulopathy and excessive menorrhagia, epistaxis, pulmonary hemorrhage, pancytopenia and fever. Labs notable for almost undetectable Factor 2 (2%; ref range 50-100%), strongly positive IgG and IgM PTabs, and positive LAC. Initial therapy included IV rituximab, IV cyclophosphamide, pulse IV methylprednisolone and prothrombin complex; subsequent therapy with IVIG, tapering course of oral prednisone and azathioprine.

Patient 3 is an 18 y.o. Hispanic male with prolonged history of recurrent epistaxis and bruising. Earlier therapy for presumed infection associated LAHS included prolonged IV and oral steroid and oral methotrexate. He then presented acutely with fever, abdominal pain, thrombocytopenia, serositis, adrenal hemorrhage and microthrombic skin lesions. Labs strongly positive for IgG PTabs and LAC. Initial therapy included IV rituximab and pulse IV methylprednisolone; subsequent therapy with IVIG, repeat rituximab, tapering course of oral prednisone and azathioprine. Patients 1 & 2's PTabs normalized within 4 months from disease onset. Presently, all patients are on minimal oral prednisone (1, 2.5, and 5mg daily). At 1 year from initial aggressive immunotherapy, all patients have achieved clinical remission.

Conclusion: LAHS presents a challenge in management considering the dichotomous manifestation of thrombosis and hemorrhage. While no consensus exists for optimal therapy, we report 2 patients achieving normalization of PTabs and all patient with clinical remission within a year of presentation while currently on minimal therapy. Perhaps early aggressive combination immunosuppressive therapy may have more favorable outcomes.

Disease Activity and Health Care Utilization Among Young Adults with Childhood-Onset Lupus Transitioning to Adult Care: Data from the Pediatric Lupus Outcomes Study

Erica F. Lawson[1] and Aimee O. Hersh[2], [1]Pediatrics/Rheumatology, UC San Francisco, San Francisco, CA, [2]Pediatrics/Rheumatology, University of Utah, Salt Lake City, UT

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Lupus, Scleroderma, JDMS

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Individuals with childhood-onset systemic lupus erythematosus (cSLE) must transfer from pediatric- to adult-oriented health care as they enter adulthood. However, few studies have assessed outcomes of the transition from pediatric to adult care in cSLE. The goal of this study is to examine disease activity and health care utilization among young adults with cSLE who are undergoing or have recently completed the transition to adult care.

Methods:

Data derive from the baseline interview of the Pediatric Lupus Outcomes Study, an annual longitudinal telephone survey of 91 diverse English- and Spanish-speaking participants age 18-30 with confirmed cSLE (age of onset <18 years). Subjects were recruited from pediatric and adult rheumatology clinics; diagnosis of cSLE was confirmed by chart review. To define a cohort undergoing transition from pediatric to adult care, we included respondents who received care from a pediatric rheumatologist currently or in the past (N=85). We assessed disease activity according to the Systemic Lupus Activity Questionnaire (SLAQ), self-reported SLE flare in the past 3 months, current immunosuppressive medication use (any steroid, DMARD or biologic medication), current health insurance coverage, and health care utilization over the past year. Bivariate analyses were used to compare individuals cared for by adult rheumatologists to those who continue in pediatric care.

Results:

Mean baseline age was 21±3 years, and mean age at diagnosis was 13±3 years. Ethnicities included White (48%), Black (5%), Asian (20%), Latino (24%), multi-ethnic (5%) and other (6%). 38 respondents (45%) had transferred care out of pediatric rheumatology (Table 1). Most respondents were currently insured (93%), however those who had transferred were more likely to report difficulty obtaining insurance (34% v. 11%, p=0.008). 32% had visited an emergency department and 27% had received inpatient care in the past year, with similar rates in adult and pediatric care groups. There was no difference in disease activity (SLAQ score 9 v. 11) or likelihood of self-reported flare over the last 3 months (31% vs. 26%) among those who had transferred to adult rheumatology vs. those who had not. Those who remained in pediatric care were significantly more likely to have seen a rheumatologist in the past year (94% v. 68%, p=0.002) and more likely to be taking immunosuppressive medications (89% v. 34%, p<0.001).

Conclusion:

Many individuals in this cohort of young adults with cSLE continue with active lupus. In spite of similar disease activity among those who had left pediatric care and those who had not, young adults who had transferred to adult care were significantly less likely to access routine rheumatology care or take immunosuppressive medication, and more likely to encounter difficulty obtaining health insurance coverage. Improving access to adult rheumatology care may be important to prevent poor health outcomes in cSLE.

Racial and Ethnic Disparities in Depression Diagnosis and Treatment for Adolescents with SLE: Analysis of a National Medicaid Sample

Andrea Knight[1], Ming Xie[2] and David Mandell[3], [1]Pediatrics/Rheumatology, Children's Hospital of Philadelphia, Philadelphia, PA, [2]University of Pennsylvania, Center for Mental Health Policy and Services Research, Philadelphia, PA, [3]Psychiatry and Pediatrics, University of Pennsylvania, Center for Mental Health Policy and Services Research, Philadelphia, PA

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Lupus, Scleroderma, JDMS

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Adolescents with systemic lupus erythematosus (SLE) are at high risk for depression. Racial/ethnic minorities are disproportionately affected by SLE, and previous studies suggest a higher risk of untreated depression in these groups. We aimed to compare the prevalence of diagnosed depression and treatment between racial/ethnic groups of adolescents with SLE.

Methods: We conducted a cross-sectional study using claims data from the Centers for Medicare and Medicaid Services Medicaid Analytic Extract data files from 49 states and the District of Columbia. We included adolescents aged 10 to 18 years, with continuous enrollment from January 1, 2006 to December 31, 2007, and a diagnosis of SLE, defined as having >=3 outpatient visit claims with an ICD-9 primary diagnosis code for SLE of 710.0, each recorded at least 30 days apart. We categorized race/ethnicity as: white, African-American, Latino and other. We conducted unadjusted and adjusted logistic regression analyses to compare the following between racial/ethnic groups: 1) depression diagnoses and 2) antidepressant use. Covariates included: age, sex, urban vs. rural location, presence of SLE nephritis and central nervous system (CNS) disease, defined as seizures or stroke.

Results: We identified 970 adolescents with SLE; 15% were white, 42% African American, 27% Latino and 16% of other races/ethnicities. The mean age was 14.7 (SD=2.0), 83% were female and 85% were of urban location. Nephritis was present in 36% and CNS disease in 16%. Seventeen percent of the sample had depression diagnosis and 21% used an antidepressant. In adjusted analyses, African-Americans were less likely than whites to have a depression diagnosis (OR=0.5, 95%CI 0.3-0.8, $p<0.01$) or use an antidepressant (OR=0.5, 95%CI 0.3-0.8, $p<0.05$) (Figure 1). Older adolescents were more likely to be diagnosed with depression (OR=1.1, 95% CI 1.0-1.2, $p<0.01$) and use an antidepressant (OR=1.2, 95% CI 1.1-1.3, $p<0.001$), as were those with CNS disease (OR=2.9, 95% CI 2.0-4.3, $p<0.001$).

Conclusion: In the context of other studies showing under-treatment of depression in African-American adolescents, our results suggest that African-Americans with SLE may be at higher risk for under-diagnosis and under-treatment than adolescents with SLE of other race/ethnicity. Interventional strategies for depression in adolescents with SLE should address disparities in mental health care.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Lupus, Scleroderma, JDMS

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Mycophenolate mofetil (MMF) is an immunosuppressive drug used off-label for the treatment of childhood-onset systemic lupus erythematosus (cSLE). Therapeutic drug monitoring (TDM) of MMF's active metabolite, Mycophenolic acid (MPA), has been increasingly used in order to achieve a target area under the curve (AUC) and improve cSLE patient outcomes. However, multiple timed blood samples are required to estimate AUC. We applied a population pharmacokinetics (PK) approach to derive a prediction model of MMF AUC in cSLE patients, so that we could test validity of limited sampling strategies

Methods: Our retrospective analysis included cSLE patients (≥ 4/11 ACR classification criteria) followed at the Hospital for Sick Children, Toronto. Patients were on stable dose of MMF for at least 6 weeks with no concomitant calcineurin inhibitors. Blood samples at baseline (trough levels), 1 h, 2h and 6 h were used for AUC estimation. A population pharmacokinetics (popPK) model describing MPA plasma concentration was developed using nonlinear mixed effects modeling (NONMEM) software. A Bayesian estimator based on the population pharmacokinetic model was used to predict the MPA AUC_{0-12}. The final model was examined using goodness of fit, bootstrap method and visual predictive check. The individual MPA AUC_{0-12} predicted by a Bayesian estimator was compared to the individual MPA AUC_{0-12}calculated by a limited sampling strategy formula (1) to evaluate validity of the model.

Results: We included 648 samples from 90 cSLE patients to build the popPK model. 128 samples with time window +/- 10 minutes from 32 patients were included to compare the AUC predicted by popPK model with the AUC calculated by the formula. All patients had normal liver/kidney function. The median age was 16 years (range: 6-19). Mean MMF dose was 626 mg/m^2 (SD: 19) and the mean formula-derived AUC was 67.2mg- h/L (SD:4.5). The MPA PK was best described by a 2-compartment model with lag time and first order absorption. The popPK model-derived MPA AUC_{0-12} was closely correlated to the observed AUC calculated by the formula (r^2=0.93, P<0.01) (Fig. 1). However, correlation between Ctrough and the model-predicted AUC was poor (r^2=0.47). Also, none of the other MPA concentrations at single time point (1h, 2h and 6h post-dose) showed significant correlation with the model-derived AUC. The covariate analysis identified body weight as individual factor influencing the apparent oral clearance and volume distribution. Different steroid dosage, concomitant use of proton-pump inhibitors or ethnicity did not influence in observed and predicted AUC.

Conclusion: MPA trough levels, or levels based on a single post-dose time point (such as 1h, 2h or 6h) are not a reliable predictor for MPA AUC_{0-12}.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Lupus, Scleroderma, JDMS
Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

The time to recovery from proteinuria in patients with lupus nephritis (LN) receiving standard treatment has been described in adult, but not in children. In adult, 52% recovered from proteinuria within 2 years and 3/4 within 5 years. We aim to determine the time to recovery from proteinuria and to identify factors predicting time to improvement.

Methods:

Twenty-four childhood-onset lupus nephritis (cLN) patients receiving standard treatment, were identified from our lupus registry followed from Jan 1, 2009 to May 31, 2015. Indication for biopsy includes persistent proteinuria ≥ 0.5 gm/day or spot protein/creatinine ratio > 0.2. Demographic, clinical, laboratory, disease activity indices and histological data were collected. Time to recovery from proteinuria was assessed by Kaplan-Meier analysis. Risk factors associated with proteinuria resolution were evaluated using cox-regression models.

Results:

Twenty-four cLN patients (66.7% females) were recruited. Majority were Chinese (54.2%), followed by Malays (29.2%). No Indian patients had LN. 83.3% cLN patients presented at diagnosis. Median time to protein clearance was 5.8 months (Fig 1). About 90% recovered from proteinuria within 18 months. Higher SLEDAI-2K scores at diagnosis was associated with shorter time to protein clearance. (HR 1.155, 95% CI 1.046-1.275, p=0.004). Older age, higher chronicity index and nephrotic at baseline were associated with longer time to protein clearance while gender, race, activity index and low complement were not significant risk factors. (Table 2)

Nephrotic†	5.713	0.012	1.458-22.389
Activity Index††	1.222	0.103	0.960-1.554
Chronicity Index††	0.503	0.008	0.303-0.836
Low C3	9.189	0.068	0.847-99.704

‡ at baseline
† nephrotic syndrome is defined as proteinuria exceeding 40 $ml/m^2/hr$
†† based on National Institute of Health (NIH) Activity and Chronicity Index

Conclusion:

Faster urinary protein clearance was demonstrated in our cLN cohort receiving standard treatment compared to that of adults (5.8 months vs 2 years) and 90% achieved in 18 months. Patients with higher disease activity at baseline seem to respond better to treatment with shorter time to protein clearance. Consistent with adult findings, patients with higher level of proteinuria at baseline needed longer time to achieve protein clearance.

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Lupus, Scleroderma, JDMS

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Macrophage activation syndrome (MAS) is a life-threatening inflammatory complication of childhood-onset systemic lupus erythematosus (cSLE). There are few reports of long-term outcomes of MAS complicating cSLE. Our aim is to compare long-term outcomes between MAS and non-MAS patients with cSLE seen at a single tertiary centre.

Methods: Our retrospective review included all patients followed at the Hospital for Sick Children, Toronto, diagnosed with cSLE (≥ 4/11 ACR classification criteria and/or ≥ 4/11 SLICC classification criteria) between January 2002 and December 2012. Within this cohort we identified cSLE patients also diagnosed with MAS (as per Pediatric Rheumatologist's expert opinion). We analyzed prospectively collected data including: 1) demographics: gender, age of diagnoses; 2) SLE major organ involvement (proliferative and membranous lupus nephritis and CNS involvement); 3) immunosuppressive drugs; 4) average daily dose of corticosteroids and 5) SLICC damage index at last visit. Continuous variables were compared using Student's t test and categorical variables were compared using Fisher's test as appropriate.

Results: 402 patients with cSLE were identified. Of those, 34 (8.4 %) patients were also diagnosed with MAS. The majority (76%) of patients with MAS developed it concomitantly with their SLE diagnosis. There was no statistically significant difference in the proportion of patients with major organ involvement between MAS and non-MAS patients (Table). A larger proportion of MAS patients received calcineurin inhibitors and IVIG as compared with non-MAS patients ($p < 0.01$). Azathioprine was used more frequently in non-MAS patients than in patients with MAS ($p = 0.01$). There was no difference in the average daily dose of steroids, frequency of cyclophosphamide or biologic therapy use throughout follow-up. The proportion of patients who sustained damage (SLICC ≥ 1) at last visit was similar between the groups.

Conclusion: We observed that MAS was most likely to be diagnosed concomitantly with cSLE diagnosis. Despite the life-threatening nature of MAS complicating cSLE, we observed comparable rates of major organ involvement, average dose of steroids, use of cytotoxic drugs and disease associated damage between those cSLE patients with MAS and those non-MAS patients throughout their follow-up. As expected, calcineurin inhibitors and IVIG were more commonly used among those with MAS.

Table. Characteristics of MAS and non-MAS cSLE patients.

Demographics	MAS n=34	non-MAS n=368	p-value
Female, n (%)	26 (76)	305 (82)	0.34
Age at diagnosis, mean (SD)	13 (2.8)	13 (3.2)	0.58
Follow-up in years, mean (SD)	3.5 (1.6)	4 (2.4)	0.19
Major organ involvement, n (%)			
Lupus Nephritis	14 (41)	111 (30)	0.24
CNS involvement	9 (26)	87 (23)	0.67
Medications[1], n (%)			
MMF[2] or Mycophenolate sodium	17 (58)	119 (49)	0.43
Azathioprine	11 (38)	149 (62)	0.01
Cyclophosphamide IV	10 (34)	66 (27)	0.51
Methotrexate	3 (10)	49 (20)	0.31
Calcineurin inhibitors[3]	12 (41)	21 (9)	<0.01
IVIG[4]	9 (31)	26 (10)	< 0.01
Rituximab	0	28 (12)	0.05
Average daily dose of steroids[5], mean (SD)	18 (7.4)	18 (18.6)	1.0
Damage (SLICC ≥ 1) at last visit[6], n (%)	6 (18)	57 (19)	1.0

1. Nonsteroidal medication validated in 29 MAS and 240 non-MAS patients; 2. Mycophenolate mofetil; 3. Tacrolimus or Cyclosporine; 4. Intravenous immunoglobulin; 5. Steroids reported as mg/day of prednisone equivalents; 6. SLICC scores at final visit validated in 32 MAS and 297 non-MAS patients.

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Lupus, Scleroderma, JDMS

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Anti-C1q antibodies (AC1q) were shown to strongly correlate with the occurrence and activity of lupus nephritis in adult SLE. Data of the antibodies in jSLE are rare. We aim to explore AC1q role as a diagnostic biomarker and to assess their validity in monitoring jSLE global disease activity in our Southeast Asian jSLE cohort.

Methods:

Eighty two jSLE patients were recruited and 72 patients with 517 patient-visits with complete clinical data/blood samples were studied. Disease activity indices including mS-2K (SLEDAI without lab), SLAM and BILAG were recorded. Anti-dsDNA, antinucleosome Abs (ANu, H1-stripped) and aC1q were measured by ELISA. Patients were evaluated at 1-3 mo intervals depending on their disease severity. Patients were grouped into 3 disease activity groups: no activity (ID), minimal activity (MD) = mild activity with no therapeutic intervention or activity with improvement from previous visit and active disease activity (AD) = new case or flare or persistent activity/refractory to treatment. 94 JIA, 10 JDM, 12 MCTD/UCTD, 13 vasculitides, 13 ANA-positive and 30 other inflammatory conditions made up 172 controls (median age (IQR) 14.6 (11.4-17.6) years). Descriptive statistics were used to describe data. Mann-Whitney/Kruskal-Wallis tests were used to compare data, Spearman's rho for correlation and Kaplan-Meier test for time-to-flare studies.

Results:

72 cSLE (81% female) with median age of 16.5 (14.6-19.0) yrs and median disease duration of 53.1 (26.2-82.4) mo were included. Chinese (48%) and Malay (28%) were majority. Hematologic disease (96%), arthritis (56%), malar rash (45%) and renal disease (39%) were among most common manifestations. All patients had ANA positivity at onset. Fig 1 shows significant differences in AC1q levels between controls vs. jSLE and among disease activity groups ($p < 0.001$). Table 1 reveals strong diagnostic properties of AC1q. The presence of nephritis associated with AC1q ($p=0.036$). Correlation analysis showed fair to moderate correlations with ESR, C3, C4, anti-dsDNA and ANu but weak against clinical indices. AC1q levels increase at median of 4.8 mo (0-12.83) prior to global disease flare in 64% of visits.

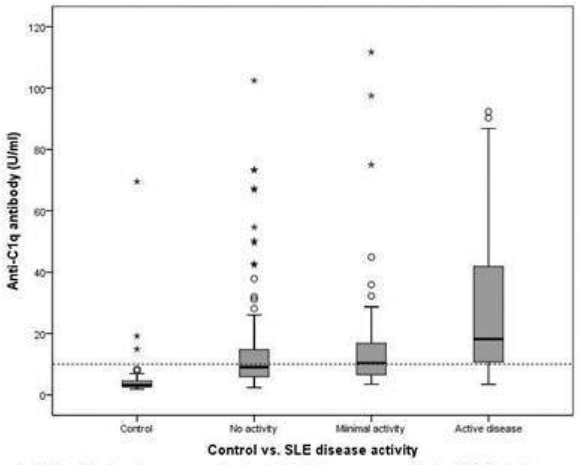

Figure 1 **Anti-C1q Abs levels among control and SLE disease group,** Median (IQR, U/ml)
Control (n=172) 3.16 (2.61-4.54)
No activity (n=125) 9.03 (5.85-14.92); Minimal activity (n=58) 10.41 (6.52-17.15); Active disease (n=54) 18.21 (10.63-42.08)
All pairs antibody level comparison are significantly different (p<0.001), Minimal vs. active disease (p=0.002) except no activity vs. minimal disease (p=0.21)

	rho	p-value	*rho*	p-value
ESR	0.36	<0.001	0.33	<0.001
C3	-0.34	<0.001	-0.57	<0.001
C4	-0.46	<0.001	-0.51	<0.001
Anti-dsDNA	0.33	<0.001		
Anti-nucleosome Ab	0.42	<0.001	0.84	<0.001
Anti C1q Ab			0.59	<0.001
mS-2K	0.18	0.005	0.19	<0.001
SLAM	0.28	<0.001	0.29	<0.001
BILAG	0.20	0.002	0.20	<0.001
*Controls n=172, cSLE n=72 (35 active disease + 13 newly diagnosed) $^{\delta}$patient-visits				

Conclusion:

Our initial findings showed strong diagnostic properties of AC1q in our cSLE cohort. The presence of AC1q was associated with lupus nephritis and its levels seem to fluctuate with global, if not only renal disease activity. The rise in the levels may signal a flare in two-third of the jSLE pts. A longer, prospective study is needed to validate these initial findings in our region.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Lupus, Scleroderma, JDMS

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

In children with SLE, 80% have renal involvement, which is a major prognostic factor for both morbidity and mortality. Few studies have focused on long-term outcomes of this underserved population, who are at increased risk for high disease severity. This project evaluates high risk children with biopsy confirmed lupus nephritis (LN) to assess clinical and demographic factors that may be related to ESRD and/or death.

Methods:

We conducted a retrospective chart review of patients with LN from 1997-2011 at the Children's Hospital at Montefiore. Patients were less than 20 years old at time of biopsy and followed up to 5 years post biopsy or onset of renal failure/death. We compared nonESRD patients (NonE) to those with ESRD and/or death (ESRD) at baseline and looked at: creatinine, pyuria, hematuria, renal histology, protein to creatinine ratio (uP/C), albumin, hemoglobin, age, gender, race, insurance and medications.

Results:

A total of 36 patients were evaluated. 86% lived in the Bronx and more than 60% were from low-income/high poverty areas. The mean age was 14.4 + 2.5 years and 69.4% were female. 92.0% were African American, Hispanic or multiracial. Histology revealed 14% Mesangial LN (Class II,5/36), 56% Proliferative LN (Class III or Class IV, 20/36) 31% Membranous LN (Class V, 11/36). 61% were Medicaid insured (n=22) vs 39% privately insured (n=14). In the ESRD group 100% (n=9) were Medicaid vs 48% (n=13/27) in the NonE.

Development of ESRD was not associated with creatinine, pyuria, hematuria, histology, uP/C, albumin, hemoglobin, age, gender, race and medications at the time of biopsy. However, having private insurance was significantly protective where 100% of those with Medicaid developed ESRD ($P = 0.006$).

Conclusion:

In our cohort, 25% of children went on to develop ESRD. The only factor that was significant for this was being Medicaid insured. This suggests the type of access to healthcare and associated non-genetic factors may play a role in progressive disease among this group.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Lupus, Scleroderma, JDMS
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

The gold standard for diagnosis and classification of lupus nephritis (LN) is according to the renal histology. The inter-observer reliability between histologists is variable. The aim of this study was to assess the inter-observer reliability of the 2003 International Society of Nephrology/Royal Pathology Society (ISN/RPS) histological classification criteria in children with LN.

Methods:

Four expert nephropathologists independently reviewed the renal histology slides from children with using electronic software. Diagnostic consistency was quantified using the kappa statistic for nominal categories (Class 1 – 6) and intra-class correlation (ICC) for numeric scores of histological activity (max 24), chronicity (max 12) or tubulointerstitial markers of disease (max 21). The level of agreement (strength of the kappa coefficient or ICC) was interpreted as: 0.01-0.20 slight; 0.21-0.40 fair; 0.41-0.60 moderate; 0.61-0.80 good; 0.81-1.00 excellent. As Class III or IV LN typically result in change of treatment, sub-analysis assessed whether there was agreement between these classes (Class I/II termed ‘no treatment change’, and Class III/IV termed as ‘treatment change’).

Results:

The majority of the biopsies (n=55) were graded as Class IV LN (42%) and the median activity score was 4 (0-7), chronicity score 2 (1-3) and tubulointerstitial score 4 (3-6). Nephropathologists showed moderate agreement in assigning LN Classes (kappa score 0.33+0.10; good is >0.6). There was significant variation in the level of agreement between the centres (0.07-0.60). Histological activity had excellent agreement (all ICC >0.75, $p<0.001$), whereas raters had variable agreement in assigning chronicity and tubulointerstitial scoring (ICC range 0.20-0.82 and -0.13-0.66 respectively). With regards to treatment changes, 14 biopsies would not have resulted in treatment change and 29 may have altered treatment and the level of agreement remained poor (kappa 0.24+0.11).

Conclusion:

Internationally agreed classification criteria for LN histology, guide the management of LN. Clinicians and researchers should be aware of the variable level of agreement in their interpretation of LN findings and that is similar in children as it is reported in adults. Histological features of activity have the most consistent agreement. Additional consensus criteria may be necessary to improve the inter-rater variability in the other features.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Lupus, Scleroderma, JDMS

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Acquired angioedema, defined as non-hereditary angioedema without associated urticaria, is an uncommon but potentially life-threatening feature among adults with systemic lupus erythematosus (SLE). Although autoantibodies to C1 esterase inhibitor have been identified as a potential mechanism for non-histaminergic acquired angioedema in SLE, the exact pathophysiologic mechanisms remain unclear. The incidence and prevalence of angioedema in pediatric SLE (pSLE) is unknown. In this study, we sought to define and characterize acquired angioedema in pediatric systemic lupus erythematosus in a single pediatric rheumatology center.

Methods: We conducted a chart review pSLE patients seen in a single center between 2000 and 2014. Data included family history and clinical presentation of angioedema.

Results: A total of 160 pSLE patients were included. Nine (6%) had history of acquired angioedema, 8 were females, 7 were African American, 2 were Hispanics. Median age at diagnosis was 14 years, and with a mean follow up of 47 mos. No patient had family history of angioedema. Most common ACR SLE criteria met were hematologic (89%), arthritis (67%), renal (5 or 56%). All 5 patients with renal disease had proliferative lupus nephritis, 2 of whom with Class IV lupus nephritis. Two patients has neurologic involvement. Immunoserologic features include antibodies to DAT (100%), dsDNA (89%), Sm (55%), RNP (6/9%), SSA (5/9%) and phospholipid (44%); significantly low C3 and C4 (100%) were noted in all patients. C1 esterase function and nonfunction assays were normal or elevated. Antibodies to C1 esterase were not noted in 4 patients in which the test was done. Angioedema was present within 6 weeks of SLE diagnosis for 6 (67%) patients; head and neck were the most common sites (8/9), with torso and extremity involvement in 4/9 patients. No patient developed respiratory symptomatology. Resolution of the angioedema was noted in all patients following initiation of corticosteroids treatment. Angioedema was recurrent and feature of clinical disease flare in 2 patients (22%).

Conclusion: Acquired angioedema in a single center cohort of pSLE was described as disease manifestation. Future research needs to address its underlying pathophysiologic mechanisms and its clinical significance in treatment and course of pSLE.

Table 1 Clinical Presentation of Acquired Angioedema in 9 pSLE patients

Patient	Age(yr)/Gender	Ethnicity	Time of angioedema to SLE Diagnosis	Angioedema Site
Pt 1	14 F	Hispanic	28 wks	Face (eyes, lips)
Pt 2	12 F	African American	4 wks	Face (eyes, lips), tongue, UEs, torso
Pt 3	15 F	African American	4-12 wks	Face (eyes, lips) UEs
Pt 4	15 F	African American	28 wks	Face, neck, UEs
Pt 5	17 F	African American	4 weeks	UEs, LEs
Pt 6	12 F	African American	28 wks	Face (eyes, lips)
Pt 7	6 F	African American	2-4 wks	Face (lips) tongue
Pt 8	12 M	African American	3-4 wks	Face (lips)
Pt 9	14 F	Hispanic	12-24 wks	Face (lips and eyes)

Disease Activity, Disease Damage and Predictive Factors in Juvenile Onset Mixed Connective Tissue Disease – a Norwegian Nationwide Study

Siri Opsahl Hetlevik[1], Berit Flatø[1,2], Marite Rygg[3,4], Ellen Berit Nordal[5] and Vibke Lilleby[6], [1]Department of Rheumatology, Oslo University Hospital, Rikshospitalet, Oslo, Norway, [2]Department of Rheumatology, Oslo University Hospital, Institute for Clinical Medicine, University of Oslo, Oslo, Norway, [3]Department of Pediatrics, St Olav University Hospital, Trondheim, Norway, [4]Department of Laboratory Medicine, Children's and Women's health, Norwegian University of Science and Technology, Trondheim, Norway, [5]Department of Pediatrics, University Hospital of North Norway, Tromsø, Norway, [6]Rheumatology, Oslo University Hospital, Oslo, Norway
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Lupus, Scleroderma, JDMS
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Mixed Connective Tissue Disease (MCTD) is a rare rheumatic disease with overlapping features from Systemic Lupus Erythematosus (SLE), Systemic Sclerosis (SSc) and Polymyositis. Juvenile onset MCTD (JMCTD) accounts for approximately 25% of all cases, but knowledge about disease activity and possible organ damage after long-term disease is limited. The purpose of this study is to describe disease activity- and damage in JMCTD after long-term follow-up, and identify possible predictive factors for unfavourable outcome.

Methods:

A cohort of 48 patients with JMCTD from all regions of Norway was examined in a cross-sectional study. Inclusion criteria were fulfilment of the Kasukawa- or Alarcon-Segovia criteria and symptom-onset before 18 years. All patients were clinically examined after mean disease duration of 16.4 (SD 9.9) years. Data from the time of diagnosis were obtained by chart reviews in 45 patients.

As there are no validated criteria for disease activity and damage in MCTD, the following disease activity- and damage scores attributable to SLE, SSc and Juvenile Idiopathic Arthritis (JIA) were used: Systemic Lupus Erythematosus Disease Activity Index (SLEDAI), Rodnan skin score, Systemic Lupus International Collaborating Clinics/ACR Damage Index (SLICC/ACR DI) and Juvenile Arthritis Damage Index (JADI). Remission was defined as fulfilment of the Wallace criteria for remission in JIA, plus the absence of leucopoenia, myositis, progressive lung- or esophageal manifestations and progressive sclerodactyly. Active disease was defined as absence of remission.

Results:

At 16 year follow-up, 31 patients (65%) were considered to have active disease, and 17 (35%) were in remission on or off medication (table 1).

Table 1

Variables at examination after mean 16 year disease duration	Total N = 48	Inactive disease (n = 17)	Active disease (n = 31)	*p* value
RF positive, n (%)	18 (38)	2 (13)	15 (50)	0.01
Anti-RNP titer (median, range)	158 (0-240)	99 (0-240)	222 (0-240)	0.09
Anti-RNP ≥ 240	18 (38)	3 (18)	15 (48)	0.04
ESR (median, range)	9.0 (2-54)	7.0 (3-16)	11,0 (2-54)	0.32
CRP (median, range)	0.7 (<0.6-15)	0.7 (<0.6-3.3)	0.7 (<0,6-15)	0.73
Physicians Global Assessment VAS (Median, range)	15.5 (1-58)	4.0 (1-29)	22.0 (4-58)	0.0
Fatigue VAS (median, range)	47.0 (1-98)	18.0 (1-98)	51.5 (1-96)	0.11
Raynaud VAS (median, range)	32.0 (1-87)	19.0 (1-77)	49 (1-87)	0.02
SLEDAI (mean, SD)	0.5 (1.2)	0.12 (0.3)	0.71 (1.5)	0.03
Rodnan skin score n = 40 (mean, SD)	0.9 (2.2)	0.2 (0.8)	1.2 (2.5)	0.08
SLICC/ACR DI (mean, SD)	0.7 (0.7)	0.71 (0.85)	0.74 (0.68)	0.88
SLICC/ACR DI ≥ 1 (n, %)	21 (44)	12 (39)	9 (53)	0.58
Active joints (mean, SD)	1.1 (2.3)	0	1.1 (2.7)	0.04
Joints with limited range of motion (mean, SD)	5.2 (8.5)	3.5 (8.1)	6.1 (8.6)	0.31
JADI (mean, SD)	1.9 (5.1)	0.94 (1.8)	2.5 (6.2)	0.22

The patients with active disease had more frequently high levels of anti-RNP and positive Rheumatoid Factor (RF) than

those in remission. Twenty one patients (44%) had a SLICC score of 1 or more. The main reason for the high score was the large proportion with signs of pulmonary fibrosis (21 patients, 44%), where 21 (44%) had reduced diffusion capacity or vital capacity, and 12 patients (25%) had CT-verified pulmonal fibrosis.

Disease duration, positive RF at diagnosis and number of months treated with prednisolone were associated with persistently active disease after 16 years, but only the presence of positive RF at diagnosis was identified as a predictor in the multivariate analysis at follow-up (OR 6.84, 95% CI 1.6-29.8).

Conclusion:

In this Norwegian cohort of juvenile onset MCTD, we found that after 16 years of disease duration, 65% had ongoing active disease, and these patients had more frequently high levels of anti-RNP and positive RF. A large proportion of the patients had signs of disease damage with a score of ≥1 assessed with SLICC/ACR DI.

Presence of positive RF at time of diagnosis predicted ongoing active disease.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Lupus, Scleroderma, JDMS

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a rare multisystem autoimmune disease characterized by vasculopathy and organ fibrosis. We present baseline data on the North American observational juvenile systemic sclerosis (jSSc) cohort from the CARRA registry.

Methods: Descriptive statistics were used for demographic, clinical, and laboratory features.

Results: For the 64 children with SSc in the database, baseline CARRA visit occurred a median of 3.6 yrs after disease onset. The median age of onset was 10.3 yr. Median age at first pediatric rheumatology (PRH) evaluation was 11.8 yr, with 23% having a $\geq$ 2 yr delay to PRH. Demographics and clinical manifestations are detailed in Table 1. Overlap with juvenile dermatomyositis was identified in 3 individuals, with mixed connective tissue disease in 1. Of those with documented testing for specific antibodies, 80% were ANA positive, 46% anti-Scl70 and 15% ACA. Three of 15 patients tested for anti-PM-Scl antibodies were positive.

The most prevalent organ manifestations were dermatologic (93%) and vascular (92%), with Raynaud phenomenon as the most common feature. Multiple organ systems were affected in 93%. Reported prior or current medications included use of DMARDs in 87%, steroids in 53%, and biologics in 10%.

While the median Physician Global Disease Activity (PGA) score was 2, patient reported measures reflected the presence of functional impairment and perceived deficiencies in overall well-being (Table 2). ACR functional class was > class I for 36% of individuals at baseline and for 74% individuals at worst function.

Conclusion: Within the CARRA registry, most jSSc patients were female and Caucasian with a median age of onset of 10.3 years. From limited comparison, baseline clinical data from this cohort are similar to the jSSc cohort described by Martini et al in 2006 except the inclusion of overlap patients. While ANA positivity is similar or lower than other cohorts, ACA positivity is higher which may reflect factors aside from disease, such as changes in commercially available ANA testing. Overlap syndrome, present in 29-37% of patients in 2 other cohorts, may be under recognized. This identifies a potential gap in serologic testing, such as anti-PM-Scl, and identification of jSSc subtypes.

Significant morbidity is seen in this cohort, with the majority of individuals having multisystem involvement. Even with low disease activity scores, patients and providers reported impacts on function, pain, and quality of life. This identifies the need for development of accurate serologic identification and clinical measurement indices of damage, activity, and severity for jSSc.

Table 1. Patient Characteristics

Demographics	**n (%)**
Gender	
Female	54 (84%)
Race, Ethnicity	
Caucasian	50 (78%)
African American	12 (19%)
Asian	2 (3%)
Non-Hispanic	55 (86%)

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Lupus, Scleroderma, JDMS

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Patient reported outcomes (PROs) are becoming increasingly important in the care of patients with chronic disease. Involving patients in their own care significantly improves health care outcomes, health care utilization and patient satisfaction. Robust PROs have not been well defined for patients with juvenile dermatomyositis (JDM). We sought to assess the importance of different PROs to patients with JDM and their families to help guide development of these measures and care discussions.

Methods: A survey was developed by members of the Childhood Arthritis and Rheumatology Research Alliance JDM Quality Measures Workgroup through a consensus process and was distributed to approximately 2100 email addresses of families of patients with JDM through the Cure JM foundation. Data were abstracted in a standardized database for analysis, including demographics, myositis characteristics, functional disability, and rating of importance of a variety of common PROs.

Results: Overall, 194 relatives of patients with inflammatory myositis responded to the survey. Nearly all patients (187, or 97.4%) were diagnosed with JDM, while 5 (2.6%) were diagnosed with juvenile polymyositis. Of the respondents, 168 (93%) were parents and the remainder were grandparents and other relatives. The majority of patients were female (140, or 73%). There was a wide range of age at diagnosis (1 to 16 years), with average time to diagnosis 6.7 months (range 1 to over 40). Most patients (166, or 86%) were Caucasian/white, 21 (11%) were Hispanic and 15 (8%) were African American.

The PROs that families of patients with JDM rated as having the highest importance (weighted average over 4.5 out of 5) included overall quality of life (173, or 89% reporting this among the most important factors), timely diagnosis (171, or 89%), access to a rheumatologist (166, or 86%), normal function and strength (155, or 80.3%), ability to perform self-care (146, or 75%), resolution of pain (145, or 75%), discontinuation of steroids (143, or 74%), resolution of fatigue (135, or 70%), and medication tolerance (135, or 70%). Conversely, access to a dermatologist and physical therapy, work attendance, minimizing hospital visits, medication counseling and monitoring of medication toxicity, discontinuation of medications, normalization of labs, resolution of rash, and school attendance were not rated as highly (**Figure 1**).

Families of patients diagnosed within the past 2 years tended to rate all of the PROs as more important compared to those with diagnoses over 2 years ago, as did families of patients with high current functional impact from the disease, compared to those with low current functional impact.

Conclusion: Patients and their families with JDM find certain PROs more meaningful and relevant than others, which should be taken into account when establishing quality metrics and caring for patients with JDM.

Figure 1: The relative importance of a variety of PROs to patients with JDM, reported from highest to lowest weighted average impact factor.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Lupus, Scleroderma, JDMS
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Juvenile systemic sclerosis (jSSc) is an orphan autoimmune disease. Currently just retrospective data exist regarding evolvement of organ involvement. In the previous retrospective studies assessment of the organ involvement was not standardized. Our project is the first one, where data of jSSc patientes were collected prospectively and with a standardized assessment.

Methods: Patients with jSSc were recruited worldwide and were prospectively assessed, using the proposed standardized patient assessment protocol. Data of the juvenile systemic sclerosis inception cohort have been contributed to the DeSScipher project which was funded by a grant of the European Community's Framework Programme 7 under grant agreement N° 305495."

Results:

24 centers from 16 countries agreed to participate on the project. The assent and consent forms were translated into the local native languages. Until now 50 patients have been enrolled with a mean disease duration of 6.1 years. Thirtyseven (74%) of the 50 patients were females. The mean age of the onset of Raynaud´s phenomenon was 9.2 years (2-16 years), the youngest 2 years old. The mean age at the onset of the non-Raynaud presentation of jSSc was 9.7 years (2.3-16.00 years). 34 (68%) of the 50 have diffuse subtype. 5 in the diffuse (14.7%) and 3 in the limited subtype (19%) had an overlap feature.

At the time of the inclusion the mean modified Rodnan Skin Score was 16.7. 32/48 (67%) had already capillary changes and 25/48 (52%) already had history of ulcerations, 12/48 (25%) had active ulcerations at the time of the inclusion. 35/50 (70%) had cardiopulmonary involvement, 18/50 (36%) had signs of interstitial lung disease. 5 (10%) patients had pulmonary hypertension. Four (8%) had renal involvement, but no renal crisis. 20/50 (40%) had gastrointestinal involvement and 15 (30%) of them esophageal involvement. 38/49 (77.5%) had musculoskeletal involvement. ANA positivity occurred in 36/47 (77%) and 15/40 (37.5%) of them were anti-Scl 70 positive. 2/29 (7%) had anticentromere positivity.

Conclusion: We present the data on the first 50 patients with jSSc included in our cohort. The current recruitment data confirms that pediatric patients are different from the adult patients, with a higher proportion of diffuse subset patients with 68% and 16% of patients with overlap features. Anti-centromere antibodies occuring only in 7% of patients.

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Lupus, Scleroderma, JDMS

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Juvenile systemic sclerosis (jSSc) is an orphan autoimmune disease. Several publications in adults looked at the differences between limited and diffuse subtypes. There is rarity of data regarding this topic in pediatric jSSc. The juvenile scleroderma inception cohort (www.juvenile-scleroderma.com) is a prospective standardized register for patients with jSSc.

Methods:

Patients with jSSc were included worldwide into the juvenile scleroderma inception cohort. We compared the demographics and clinical features of the ljSSc and djSSc. Data of the juvenile systemic sclerosis inception cohort have been contributed to the DeSScipher project which was funded by a grant of theEuropean Community's Framework Programme 7 under grant agreement N° 305495.

Results:

Up till now 50 patients were enrolled, 34 (68%) with djSSc and 16 (32%) with ljSSc. 5 in the diffuse (15%) and 3 in the limited subtype (19%) had an overlap feature. The mean follow up of the patients in the cohort was 6.4 years in the djSSc and 5.5 years in ljSSc. 74% in the djSSc and 75% in the ljSSc group were female. The mean age at the onset of Raynaud´s Phenomenon was 8.4 years in the jdSSc and 10.8 years in ljSSc group (p=0.061) while the mean age at the onset of the first non-Raynaud presentation was 8.8 years in djSSc and 11.6 years ljSSc (p=0.010). At the time of the inclusion the mean modified Rodnan Skin Score was 20.4 in the djSSc and 8.9 in ljSSc (p=0.002). 72% in jdSSc and 56% in the ljSSc of patients (p=0.35) had already capillary changes, but 64% in djSSc and only 26% in ljSSc (p=0.015) had already history of ulcerations and 33% presented with active ulceration in the djSSc and 6% in the ljSSc (p=0.074). 71% of djSSc and 68 % of ljSSc had cardiopulmonary involvement. Four patients had pulmonary hypertension. 3 of them had djSSc. 44% in djSSc and 19% in ljSSc group (p=0.117) showed signs of interstitial lung disease on imaging. Four patients had renal involvement, 3 of them had djSSc, no renal crisis was reported. 47% in the djSSc and 25% in the ljSSc (p=0.216) had gastrointestinal involvement. Around 76% in djSSc and 81% in ljSSc had musculoskeletal involvement. Anti-Scl 70 positivity was found in 10/27 (37%) of djSSc and 5/13 (38%) in ljSSc. Only 2 patients and only in the djSSc group had anticentromere antibody.

Conclusion:

We present the data on the first 50 patients with jSSc included in our cohort. Patients with djSSc and ljSSc differ in several characteristics. Patients with djSSc were younger at onset, had more often capillary changes and active ulcerations, pulmonary hypertension and renal involvement. The characteristics of the pediatric subtypes differs from adults with SSc.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Lupus, Scleroderma, JDMS
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

The new adult classifiction criteria (1) for Systemic Sclerosis (SSc) were recently published and the pediatric criteria were published in 2007 (2). None of these criteria were validated in a pediatric cohort of patients.

Methods:

We validated the adult SSc criteria in the juvenile SSc inception cohort stratified by the disease duration of the patients. We performed a latent class analysis on the adult SSc criteria for investigating the pattern of presentation of juvenile patients adjusted for disease duration.

Results:

All pediatric patients in the cohort fulfilled the adult classification criteria of proximal skin sclerosis from MCP joint. It is the main criteria of the pediatric classification system and it already gives sufficient points to be classified as SSc. Raynauds' phenomena (73%) and nail fold changes (57%) were the most common items fulfilled by the juveniles. The pediatric patients had a mean score of 15.3 at <6 months (n=16), 15.5 at <12 months (n=31), 16.5 at < 24 months (n=62) and 17.1 at <48 months (n=86). The latent class analysis on the adult SSc criteria resulted in 3 groups of juvenile SSc patients (table 1). All patients in the first severely affected group had proximal skin sclerosis, fingertip pitting scars, nail fold changes and raynauds' phenomena. In the mild third group (n=33), the item skin sclerosis was

most important, the other criteria played a minor role in that group.

Table 1. Results of the latent class analysis on the adult SSc criteria in the inception cohort of juvenile systemic sclerosis.

	Class I n=16 %	Class II n=37 %	Class III n=33 %
Proximal skin sclerosis	100.0	100.0	100.0
Puffy Fingers	0.0	0.0	0.0
Sclerodactyly	100.0	100.0	100.0
Digital tip ulcers	81.3	0.0	0.0
Fingertip pitting scars	100.0	44.4	36.4
Telangiectasia	0.0	0.0	0.0
Nailfold changes	100.0	78.4	12.1
PH	12.5	13.5	0.0
ISL	81.3	29.7	39.4
Raynauds	100.0	94.6	36.4
SSc AB	18.8	74.3	3.2

Conclusion:

All pediatric patients fulfilled the adult classification criteria. The cumulative score increased continuously with an increasing disease duration. The latent class analysis revealed 3 groups of jSSc patients regarding the performance of adult SSc criteria. An adaption of jSSc criteria, that patients without skin involvement can be included, would be important, to increase the number of patients with early diagnosis.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Lupus, Scleroderma, JDMS
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Juvenile systemic sclerosis (jSSc) is an orphan disease. We have currently new promising effective medication to treat systemic sclerosis, but no valid outcome measures to assess the activity of the disease. In the frame of the juvenile scleroderma working group of Paediatric Rheumatology European Society (PRES JSWG), we developed a provisional response index for jSSc.

Methods:

The facilitating committee designed a 3-round Delphi-exercise to obtain a core set of disease activity measures in jSSc. The members of the international paediatric rheumatology email board, the PRES juvenile scleroderma working group and the active participants of the juvenile scleroderma inception cohort project were invited to participate in our online surveys. In Round 1, they were asked to add unique items in 21 preleminary domains. Round 2 judged the items' applicability and importance using a 1-10 scale. Previous respondents were asked to re-rate uncertain (score 4-7) items in Round 3. The aforementioned were followed by a face-to-face Nominal Group discussion to decide final items and domain structure.

Results:

52 participants of Round 1 suggested a total of 131 items for the 21 domains. In round 2, 56 responders rated the significance of the items. Most of the participating experts took part in the 3rd Round by assessing the uncertain items. The Nominal Group accepted 11 main domains for further validation (global disease activity, biomarkers, Rayneud phenomenon, digital ulcers, skin, pulmonary, cardiac, gastrointestinal and renal involvement, 'health related qualaity of life and function') containing 41 items (see table 1). We have also felt essential to collect data regarding the development of the children.

table 1:

Global disease activity
- Global disease activity according to physician by visual analogue scale (VAS)
- Global disease activity according to patient / parent by VAS
- Scleroderma-related condition rating by physician as in the last 3 months
- Scleroderma-related condition rating by patient / parent as in the last 3 months

Biomarkers
- ESR
- CRP
- Hemoglobin

Raynaud phenomenon
- Raynaud activity score
- Raynaud severity due to patient by VAS

Digital ulcers
- Number of digital ulcers
- Newly occured digital ulcers
- Digital ulcer severity due to patient by VAS

Skin
- Modified Rodnan skin score (mRSS)
- Newly occured calcinosis
- Newly occured teleangiectasia
- Presence of scleroderma-related edema

Pulmonary
- Forced vital capacity (FVC)
- Diffusion capacity (DLCO)
- 6 minute walk test
- Borg index

Cardiac
- Left Ventricular ejection fraction (EF) by echocardiography
- Right Ventricular ejection fraction (EF) by echocardiography
- Newly occured carditis
- Newly occured arrythmia
- Pro-BNP level
- New onset or worsening of pulmory arterial hypertension (PAH)

Gastrointestinal
- New onset of swallowing difficulties
- Change in stool frequency
- New sign of reflux

Renal
- Newly occured hypertension
- Newly occured renal crisis
- Proteinuria (by spot urine)
- Creatinine clearence (in severe muscle loss, EDTA claerance should be measured)
- Change in glomerular filtration rate (GFR)

Health related quality of life and function
- PEDSQL between 8-16 years or SF-36 over 16 years of age

Childhood health assessment questionnaire (CHAQ)
Pain assessment by VAS as in CHAQ
Fatigue assessment by VAS

(Essential paediatric data to collect)
Weight
Height
Growth velocity
Tanner stage

Conclusion:

We reached consensus and developed a Response Index, which should help to conduct clinical trials in jSSc. The validation of the JSSRI is planned on the patients of the Juvenile Scleroderma Inception Cohort.

Prospective, Standardized, Longitudinal Assessment Reveals Higher Prevalence of Extracutaneous Manifestations in a Pediatric Localized Scleroderma Cohort

Kaveh Ardalan, Christina Kelsey and Kathryn S. Torok, Pediatric Rheumatology, Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Lupus, Scleroderma, JDMS

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Localized scleroderma (LS) is an autoimmune condition whose hallmarks are progressive skin fibrosis and atrophy. However, LS is unique among skin diseases for its wide range of reported extracutaneous manifestations (ECMs), including joint contractures, limb-length discrepancies, hemifacial atrophy, uveitis, neurologic sequelae, reflux, and dysphagia. Prior studies reported ECMs in 15-22% of LS patients, but were limited by retrospective, cross-sectional designs. This study aims to describe a standardized, comprehensive list of ECMs, captured prospectively, in a large pediatric LS cohort.

Methods: We extracted demographic and clinical data from the National Registry for Childhood Onset Scleroderma (NRCOS) database as part of an ongoing study on quality of life in LS. Patients included were between 4-16 years old, enrolled in NRCOS from 2002-2013, and had at least one completed Children's Dermatology Life Quality Index (i.e. CDLQI, a dermatologic quality of life measure). Patients in NRCOS were assessed for a comprehensive, standardized list of ECMs, prospectively at all clinic visits.

Data was examined to determine if patients had ECMs attributable to LS (per physician judgment), the type of ECM and organ/system involved, the total number of ECMs ever experienced by patients (throughout follow-up in clinic), and proportion of patients with ECMs by organ system.

Results: Eighty subjects were included in analysis. The majority were female (73%) and Caucasian (92%). At initial visit, subjects were a median 10.4 years old (IQR = 8.0-13.2 years old). LS subtypes were representative of pediatric onset disease (e.g. 33.8% linear limb/trunk, 17.5% linear head/face, 13.8% generalized morphea, 15% circumscribed morphea, 20% mixed subtype). Subjects had a median of 29.5 months of follow-up (IQR: 14.0 to 50.3 months).

Sixty-six percent (n=53) of patients experienced at least one ECM over a median follow-up period of 29.5 months per patient. The mean number of ECMs experienced by patients was 2 (median 1.5, IQR = 0-3). Forty-nine percent of patients had at least one musculoskeletal ECM (n=39), 23% orofacial (n=18; all also having hemifacial atrophy), 19% neurologic (n=15), 8% ocular (n=6), 4% gastroenterologic (n=3), and 5% vascular (i.e. Raynaud's phenomenon; n=4). Table 1 shows specific ECMs by organ system.

Table 1: Prevalence of Extracutaneous Manifestations by Organ System

	n	%
Musculoskeletal		
Arthralgia	27	39
Joint Contracture	21	26
Limb Circumference Discrepancy	18	23
Limb Length Discrepancy	6	8
Myalgia	5	6
Arthritis	4	5
Gait Abnormality	4	5
Myositis	2	3
Muscle Weakness	2	3
Cramping	1	1
Orofacial		
Hemifacial Atrophy	18	23
Dental Problems (e.g. malocclusion, abnormal eruption, gum recession)	10	13
Tongue Atrophy	3	4
TMJ	1	1
Tongue Spasm	1	1
Ocular		
Dry Eye	4	5
Episcleritis/Scleritis	2	3
Pseudopapilledema with Optic Nerve Thickening	1	1
Gastroenterologic		
Dysphagia or Esophageal Dysmotility	3	4
Constipation	1	1
Abdominal Pain	1	1
Neurological		
Headache	12	15
Peripheral Neuropathy	3	4
MRI Brain Abnormalities	3	4
Bell's Palsy	1	1
Ataxia	1	1
Dysarthria	1	1
Cognitive Dysfunction	1	1
Intention Tremor	1	1
Vascular		
Raynaud's Phenomenon	4	5
Other		
Dry Mouth	2	3
Fatigue	2	3
Nephritis	1	1
Pressure Sores Due to Contracture	1	1

Erythema Nodosum	1	1

Conclusion: The present study suggests that rates of ECMs in pediatric LS patients may be significantly higher than previously reported. Musculoskeletal ECMs were most prevalent, followed by orofacial, neurologic and ophthalmologic ECMs, with lower but still notable rates of gastroenterologic ECMs and Raynaud's phenomenon. These findings suggest that LS should not be primarily construed as a skin disease, but rather a systemic illness with potentially wide ranging and serious sequelae unfolding over many years.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Lupus, Scleroderma, JDMS
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Localized scleroderma (LS) is an autoimmune disease of the skin and underlying tissue that leads to progressive fibrosis and disability in growing children. Pediatric LS is known to affect females more frequently than males, but differences by gender are not well characterized. We examined the LS cohort enrolled in the Childhood Arthritis and Rheumatology Research Alliance (CARRA) registry for gender differences.

Methods: Descriptive statistics for demographic, clinical, and patient-reported data were performed. Statistical differences between genders were assessed using t-test or Wilcoxon rank sum test and Chi-square or Fisher exact test depending on the variable type and distribution.

Results: A total of 369 participants were included in the analysis. The majority of participants were white (n = 333; 90%) and female (n = 279; 76%). Median age at onset was 7.7 years old (IQR: 4.5-11.2), median age at first rheumatologist visit was 10.0 years old (IQR: 6.8-12.9), and median time to rheumatologist was 0.9 years (IQR: 0.4-2.4). The majority of the population had linear subtype of either trunk/limb or head (n = 195; 52%). A total of 53 (14%) patients were diagnosed with circumscribed subtype, 33 (9%) with generalized morphea, with other subtypes present in smaller proportions. Patients with mixed subtype comprised 21% of the cohort.

Females were older at disease onset than males (median: 8.3 years old vs. 6.3 years old, p = 0.01). Females also were

older at time of first rheumatologist visit than males (median: 10.4 years vs. 8.8 years, p = 0.01), but time from onset to first rheumatologist visit was not significantly different by gender. Males were more likely than females to have muscle atrophy (35% vs. 20%, p = 0.009) and abnormal CK levels (16% vs. 7%, p = 0.035). Males were also more likely to experience hemifacial atrophy than females, with this trend approaching significance (15% vs. 7.5%, p = 0.056). Median global well-being score for the overall group was 1 (IQR: 0-3) on a 0-10 scale with lower scores indicating better well-being. However, a higher proportion of females than males reported worse global well-being than the median (48.5% vs. 30.3%, p = 0.003). When pain scale was dichotomized (0 = no pain vs. > 0 = pain reported), a trend was noted towards a higher proportion of females reporting the presence of pain (44% vs. 33%, p = 0.091). No other gender differences for demographic, clinical, or patient-reported outcomes were demonstrated.

Conclusion: In this analysis of a large multicenter sample of LS patients, males more frequently showed evidence of muscle involvement and hemifacial atrophy despite comparable frequency of LS subtypes. Although these clinical differences suggest males might have more severe disease features, female patients reported worse overall well-being and more frequently reported pain. Further study is warranted to better characterize gender differences in LS clinical features and patient-reported outcomes and to examine underlying reasons for such differences.

Relationship of Race, Ethnicity, and Outcomes in Pediatric Localized Scleroderma: Possible Differences in Disease Activity

Kaveh Ardalan[1], Nicole Hershey[1], Jonathan Yabes[2], Kathryn S. Torok[1] and The CARRA Registry Investigators, [1]Pediatric Rheumatology, Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA, [2]Department of Medicine, University of Pittsburgh, Pittsburgh, PA

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Lupus, Scleroderma, JDMS

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Pediatric localized scleroderma (LS) is an autoimmune skin and soft tissue disease that causes morbidity via progressive skin fibrosis and extracutaneous manifestations (ECMs), such as arthritis or uveitis. Studies in other pediatric rheumatic disease populations have shown racial/ethnic differences in outcomes, but such differences have not received significant attention in LS. We examined racial/ethnic differences in the LS cohort enrolled in the Childhood Arthritis and Rheumatology Research Alliance (CARRA) registry.

Methods: Participants with a sole diagnosis of LS (i.e. no other rheumatic diseases) and complete data for gender and race/ethnicity were included for analysis. Participants who were both white (race) and non-Hispanic (ethnicity) were included in the non-Hispanic white (NHW) group. All other participants (i.e. nonwhite race, multiracial, and/or Hispanic ethnicity) were in the racial/ethnic minority (REM) group.

Depending on the variable type and distribution, t-test or Wilcoxon rank sum test and Chi-square or Fisher exact test

were used to assess differences in outcomes and baseline visit variables between NHW and REM group.

Results: A total of 369 participants were included, with 301 (82%) in the NHW group and 68 (18%) in the REM group. Most participants were white (n = 333; 90%) and 42 (11%) were Hispanic. The majority of participants were female (n = 279; 76%). Median age at onset was 7.7 years old (IQR: 4.5-11.2) and at first rheumatologist visit was 10.0 years old (IQR: 6.8-12.9). The study sample was representative of the major LS subtypes, with linear trunk/limb subtype most common (n = 126; 34.1%). The REM group showed trends toward lower rates of linear trunk/limb subtype (23.5% vs. 36.5%; $p = 0.057$) and higher rates of linear face/scalp subtype (26.5% vs. 16.9%; $p = 0.099$). REM participants were significantly more likely to report under $50,000 in annual household income (45.8% vs. 28.2%; $p = 0.025$).

Participants in the REM group were significantly more likely to have active disease (i.e. PGA > 0 in 80% vs. 58%; $p = 0.002$). Median PGA was also significantly higher in the REM group than in the NHW group (2 [IQR: 1-3] vs. 1 [IQR: 0-3]; $p = 0.015$). No differences were noted for patient-reported outcomes (pain scale, global well-being scale, quality of life, Childhood Health Assessment Questionnaire). No differences were noted in other potential confounders of PGA, including: age at onset and first rheumatologist visit; time from onset to first rheumatology visit; lesion location; ECMs; laboratory tests (i.e. ANA, creatine kinase, aldolase); present/past systemic immunosuppressive treatment; or hemifacial atrophy.

Conclusion: REM group LS patients enrolled in this large, multicenter cohort were more likely than NHW to have active disease. Differences in rates of disease subtypes (linear trunk/limb vs. face/scalp) and socioeconomic status (e.g. annual household income) were also noted and their possible contribution to the relationship of race/ethnicity and disease activity warrants further investigation. Future studies should collect detailed sociodemographic data, examining both clinical and social determinants of outcomes in LS.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Lupus, Scleroderma, JDMS
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Evaluation of the level of disease activity is a fundamental component of the clinical assessment of children with JDM. The global tools that are currently available for the assessment of the overall disease activity in JDM are centered on physician's evaluation, neglecting parent's or child's perception. Furthermore, these instruments are lengthy and complex. There remains the need for a concise and easily administered tool that provides an absolute measure of disease activity for use in future trials in JDM. Aim of the study was to develop and test a new composite disease activity score for JDM, named the Juvenile Dermatomyositis Activity Index (JDMAI)

Methods: The JDMAI includes 4 measures: 1) physician global assessment of disease activity on a 0-10 VAS, 2) parent/patient global assessment of well-being on a 0-10 VAS, 3) muscle strength assessment, and 4) cutaneous disease activity. Validation analyses were conducted on 140 patients included in a multinational study and were based on evaluation of construct validity, responsiveness to change, and discriminant validity. Four versions of the JDMAI were tested, which differed items 3) and 4). Three versions included the hybrid MMT/CMAS (hMC), reversed and divided by 10, as measure of muscle strength (range 0-10), and the cutaneous domain of the DAS (range 0-9) (JDMAI-1), a cutaneous VAS (range 0-10) (JDMAI-2), or the skin involvement type and distribution items of the DAS (range 0-7) (JDMAI-3) as measures of skin activity. A fourth version of the score (JDMAI-4) included the 3 CMAS items of the hMC (head lift; sits up, floor rise) (range 0-20) for muscle strength and the skin involvement and distribution items of the DAS for skin activity.

Results:

Construct validity: Spearman's correlations of all JDMAI versions were: strong ($r > 0.7$) with total DAS (0.80 0.90), parents' disease activity VAS (0.73 to 0.80), and CHAQ (0.72 to 0.80); moderate (r 0.4-0.7) with CMAS (-0.63 to 0.65, -0.80 for JDMAI-4), pain VAS (0.55 to 0.60), fatigue VAS (0.62 to 0.70); poor ($r < 0.4$) with LDH (0.27 to 0.32), and ESR (0.35 to 0.38). Correlation of all JDMAI versions with the Myositis Damage Index and CPK was not significant.

Responsiveness to change between 2 consecutive visits : SRM ranged from 0.72 (JDMAI-1) to 0.78 (JDMAI-4).

Discriminant validity: all JDMAI versions discriminated between patients rated in remission, continued active disease, and flare by the physician ($p < 0.001$) and by the parent ($p < 0.001$), and between patients with high, moderate, or low disease activity according to the physician ($p < 0.001$).

Conclusion: All JDMAI versions showed good construct validity and responsiveness to change, and excellent discriminant validity. We have shown that the JDMAI is a valid instrument for the assessment of disease activity in JDM and is, therefore, potentially applicable in standard clinical care, observational studies, and clinical trials.

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Lupus, Scleroderma, JDMS

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Localized scleroderma (LS) is a chronic inflammatory and fibrosing skin disease. We present baseline data on the juvenile LS (jLS) cohort from the Childhood Arthritis and Rheumatology Research Alliance (CARRA) registry, a multicenter observational pediatric rheumatic disease registry.

Methods: Descriptive statistics were used for demographic, clinical and laboratory features. Data analysis included the two-sample t-test, chi-square test, Fisher's exact test, logistic regression, and analysis of variance as appropriate.

Results: Of 386 children in the database, 76% were female and 80% were Caucasian. Mean age at onset was 8.2 yr (± 4.2). Mean age at first pediatric rheumatology (PRH) evaluation was 9.6 yr (± 4.1), yet 18% had ≥ 2 yr delay from onset to first PRH visit. Linear scleroderma (LiS) was the most common subtype (54%), followed by circumscribed morphea (CM) (16%), generalized morphea (GM) (9%), eosinophilic fasciitis (1%), and pansclerotic morphea (1%). 19% of children had mixed subtype, and LiS-CM was the most frequent combination (61%). Among LiS patients with face-scalp localization (34%), neurologic and ocular diseases were reported in 11% and 4%, respectively.

ANA positivity was found in 48% tested and was not associated with disease subtype or age at onset. ANA positivity, however, was associated with features of non-cutaneous disease damage, specifically joint contracture ($p=0.04$), muscle atrophy ($p=0.01$), and extremity shortening ($p<0.01$). Other laboratory findings included elevated aldolase was associated with joint contracture ($p=0.01$), and elevated CK was associated with muscle atrophy ($p=0.04$) and extremity shortening ($p=0.02$).

Children with any functional limitation (baseline worst ever ACR functional class II, III, and IV) (30%) had earlier first PRH visit (mean 0.98 yr ± 1.52) compared to those without limitation (class I) (mean 1.6yr ± 2.2, $p=0.01$). Poorer function also correlated with presence of arthritis, muscle atrophy, joint contracture, and extremity shortening (all $p<0.001$). Medications were similar to the 259 subjects prior analyzed (CARRA 2014 abstract) with subcutaneous or oral methotrexate (97%) and pulse or long term daily corticosteroids (68%) being the most commonly used, followed by mycophenolate mofetil (16%). The only significant difference in treatment according to subtype was the use of topical therapy instead of systemic in superficial morphea.

Conclusion: In the CARRA registry, jLS occurred more frequently in females and Caucasians. LiS was the most common subtype. Almost 1/5 of children had a ≥ 2 yr delay from symptom onset to PRH referral. Children without limitations are referred later, highlighting the insidious onset and need for educating referring providers. There is significant morbidity, with 30% of children reporting functional limitations. Poorer function correlated with presence of arthritis, muscle atrophy, joint contracture, and limb shortening. An elevated CK or aldolase was associated with presence of muscle atrophy, joint contracture, and/or limb shortening, suggesting they may be possible predictors of muscle involvement.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Lupus, Scleroderma, JDMS

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Juvenile dermatomyositis (JDM) is the most common idiopathic inflammatory myositis in children. It is a heterogeneous disease and clinical manifestations range from a relatively mild disease, to that causing significant morbidity and mortality. Especially, JDM that associated interstitial lung disease (ILD) may vary from asymptomatic to severe, rapidly leading causes of fatal outcome. The aim of this study is to determine the clinical and laboratory features of JDM complicated with ILD.

Methods: During March 1984 and May 2015, we retrospectively reviewed the clinical and laboratory features of twenty nine patients who were diagnosed as definite and probable JDM.

Results: Eight cases (27.6%) were complicated with ILD. The mean age was 6.3 years (2-13 years), and 75% of the patients were female. Cutaneous manifestations including Gottron's rash in 6, malar rash in 3, heliotrope rash in 1, skin ulcers in 2 each. The common systemic manifestations were myalgias in 5, arthralgia in 7, fever 6. Five cases had proximal muscle weakness. Anti-Jo-1 antibodies was positive in 2, anti-MDA-5 in 2. The testing for serum KL-6 was elevated in all cases. Respiratory symptoms were initially noticed in three cases. These two of three cases that were found to contain anti-MDA5 antibodies had rapid-progressive ILD (RPILD). One patient with anti-Jo-1 antibodies had ILD and polyarthritis was diagnosed as antisynthetase syndrome. All 8 patients were treated with glucocorticoids; 4 required pulse steroids therapy, 6 required immunosuppressive agents (methotrexate, Cyclosporin A, intravenous cyclophosphamide, mycophenolate mofetil (MMF),

intravenous immunoglobulin, Adalimumab. 3 patients with RPILD died of respiratory failure. Five (62.5%) patients showed no featured of myositis after a follow up of 3 years to 12 years. 5 patients had a normal CK levels.

Conclusion:

ILD is one of the most serious complications with JDM, especially positive for anti-MDA5 antibodies.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Lupus, Scleroderma, JDMS
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: While mood disorder, most commonly manifesting as depression and anxiety symptoms, is often reported in pediatric lupus patients, prevalence rates vary widely. Many published studies did not use validated tools to systematically screen cohorts. Furthermore, although mood disorders occur more frequently in urban, minority, low-income individuals, little is known about the prevalence of mood disorder in pediatric SLE patients from these populations.

Methods: We screened patients for mood disorder who were between the ages of 10-21 and enrolled in the Einstein

Lupus Cohort. Patients met the ACR 1997 revised SLE criteria or SLICC 2012 SLE criteria, and were recruited from pediatric rheumatology clinics in Bronx, NY. To screen for mood disorder we used the Patient Health Qustionaire-9 (PHQ-9) and the Generalized Anxiety Disorder 7-item scale (GAD-7), validated screening tools for depressive symptoms and anxiety symptoms, respectively, in patients ≥10 years of age.

Results: Forty-two patients were screened over a 9 month period with follow up screens on 24 patients (57%) at subsequent visits. The cohort was 83% female, 52% Hispanic, and 40% black. The median age of patients at their baseline screens was 18.4 (IQR 15.3, 19.7). Medicaid-covered patients comprised 79% of the cohort. The median SLEDAI score at baseline was 4 (IQR 2, 8) and 17% of patients had a previous history of neuropsychiatric SLE (NPSLE). The median baseline PHQ-9 score was 5 (IQR 3, 8) and the median baseline GAD-7 score was 3 (IQR 1, 7). Twenty-one percent of patients screened positive for depression at baseline, including 7% who had suicidal ideation or thoughts of self-harm, while 19% screened positive for anxiety. The most commonly endorsed depressive symptoms on baseline and follow-up screens were fatigue (79% of screens), difficulty sleeping (69%), anhedonia (63%), and changes in appetite (55%). The most commonly endorsed anxiety symptoms were irritability (70%) and excessive worrying (67%). Neither PHQ-9 nor GAD-7 scores correlated with SLEDAI or age of patient. From baseline to first follow-up visit, 54% of patients had worsening PHQ-9 scores; whereas 65% of patients had improved or stable GAD-7 scores from baseline to the next screens (Table 1). No significant differences were seen between scores based on sex, race/ethnicity, or history of NPSLE.

Conclusion: Depressive and anxiety symptoms are prevalent in a pediatric SLE cohort with high disease activity from an urban, primarily minority, and low-income cohort. Suicidal ideation and thoughts of self-harm were also not uncommon. Mood disorder symptoms did not correlate with disease activity, and were not associated with a NPSLE history. The high prevalence of mood disorder in this pediatric SLE cohort, if corroborated in other cohorts, may indicate that systematic screening for mood disorder in pediatric lupus patients should become standard of care.

Table 1: Mood disorder screening in pediatric patients of the Einstein Lupus Cohort	
Patient characteristics	**N (patients) = 42**
Sex	
Female	35 (83%)
Male	7 (17%)
Race/ethnicity	
Black	16 (40%)
Hispanic	22 (52%)
Other	4 (10%)
Age (median, IQR)	18.4 (15.3, 19.7)
Medicaid	33 (79%)
SLEDAI (baseline, median, IQR)	4 (2, 10)
PHQ-9 (baseline, median, IQR)	5 (3, 8)
Positive screens (PHQ-9 ≥10 or suicidal ideation)	9 (21%)
PHQ-9 ≥10	8 (19%)
Suicidal ideation	3 (7%)
GAD-7 (baseline, median, IQR)	3 (0, 7)
Positive screens (GAD-7 ≥10)	7/37 (19%)
Patients with follow-up screens	24 (57%)
Patients with 2 visits	15 (36%)
Patients with 3 visits	3 (7%)
Patients with 4 visits	3 (7%)
	N (screens) = 84
PHQ-9 (median, IQR)	5 (2, 8)
Positive screens (PHQ-9 ≥10 or suicidal ideation)	20/84 (24%)
PHQ-9 ≥10	16/84 (19%)
Suicidal ideation	9/84 (11%)
Increase from baseline to first follow-up	13/24 (54%)
GAD-7 (median, IQR)	3 (1, 7)
Positive screens (GAD-7 ≥10)	14/79 (18%)
Increase from baseline to first follow-up	7/20 (35%)

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Lupus, Scleroderma, JDMS

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Early hospital readmission is emerging as an indicator of care quality. The reported 30-day hospital readmission (30-DHR) rate for pediatric patients is 6.5%. However, Childhood SLE (cSLE) has a wide spectrum of health care complexity and disease course. There is limited data describing cSLE rehospitalizations patterns and its impact on the health care system. In this study we sought to describe patient- and hospital-level characteristics for cSLE 30-DHR.

Methods: The Pediatric Health Information System (PHIS) database was used to query cSLE for 5 years (2009-2013). Data collection included patient characteristics, hospital characteristics (also collected from American Hospital Association), length of stay (LOS), day of discharge, payer type and hospital charges. Primary outcome measures analyzed was 30-DHR after prior discharge. Multilevel models were used to accommodate dependence between observations. Patient characteristics (such as gender & race) were nested in patients and hospital characteristics (such as total beds & total 30-DHR) were nested in hospitals. Independent observations were analyzed within the encounter.

Results: There were 1,755 unique cSLE patients and 3,751 admissions with total hospital charges of $191M USD. Among that sample, there were more female (81%) than male (19%) patients. The overall cSLE 30-DHR rate was 28 per 100 admissions (ranged from 0-58); 79 (5%), 35 (2%), and 95 (5%) patients experienced 2, 3, and ≥4 30-DHR respectively. Thirty-day all-cause hospital readmissions for cSLE patients in PHIS hospitals cost the health care system $7M USD annually. There was a 3-fold variation in hospital service costs (between upper and lower quartile) with median admission's adjusted hospital charges of $13,904**. Patients with 30-DHR had lower median LOS (2 vs 4 days) and were more likely discharge on weekend (Sat & Sun)**. Weekend discharges also seemed to have lower LOS of 2 days**. Patients with more diagnosis count and chronic conditions during index admission were less likely to be readmitted**. Total 30-DHR per hospital was associated with total admissions but not hospital size (represented as total beds) or service area (represented as outpatient visits). There was institutional and regional variation in 30-DHR**. Age and race/ethnicity were not statistically significant for 30-DHR. **($P < 0.01$).

Conclusion: 30-DHR is high among admitted cSLE patients. Most hospitalizations in cSLE are for the treatment of disease manifestations, infections or associated medical co-morbidities. There is a variation between hospitals that may be due to patient population or practice differences. Our study highlights the need for additional research to understand these differences and to identify the most cost-effective strategies for managing cSLE across the continuum of care.

Magnetic Resonance and Echocardiographic Strain Rate Imaging for the Early Detection of Cardiac Involvement in Juvenile Systemic Sclerosis

Francesco Zulian[1], Marta Balzarin[1] and Elena Reffo, Biagio Castaldi, Giorgia Martini, Alessandra Meneghel, Ornella Milanesi, [1]Department of Pediatrics, University of Padua, Padua, Italy

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Lupus, Scleroderma, JDMS

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Cardiac involvement is one of the worst prognostic factors in JSSc. The diagnosis is usually based on clinical symptoms, EKG and conventional echocardiography, but histological studies proved that the prevalence of cardiac involvement is higher than expected. Some studies on adults demonstrated that cardiac Magnetic Resonance Imaging and Strain Rate imaging (SR) identify early cardiac involvement in SSc but little is known about their use in juvenile SSc. In this study, we investigated whether subclinical cardiac involvement can be detected by using cardiac MRI and echocardiographic SR imaging in a cohort of JSSc patients.

Methods: Consecutive patients with JSSc, according to the PRES/EULAR/ACR criteria (1), evaluated from January to May 2015, were enrolled in this observational cross sectional study. Demographic and clinical features were collected from the clinical reports. Disease severity was evaluated by the J4S score (2). Each patient underwent EKG, conventional echocardiography, speckle tracking SR and cardiac contrast enhanced MRI. Normal standard for age and body surface area-matched values validated for pediatric age were used as reference (3,4).

Results: Twelve patients, 8 females, mean age 12.8 years, mean disease duration 5.0 years entered the study. Ten had a diffuse form of disease, 2 limited. Three patients (25%) had previously had symptomatic cardiac involvement: 1 cardiac arrest during sustained ventricular tachycardia, 1 not sustained ventricular tachycardia, 1 pericarditis. Conventional echocardiography showed normal left ventricular ejection fraction and diastolic function in all patients, except for the one with previous episode of ventricular fibrillation. Also EKG was abnormal only in this patient. SR imaging (mean -17,9%) was abnormal in 4 patients (33,3%), all with the diffuse SSc; two of them never had cardiac symptoms and their EKG and echocardiography were normal. Cardiac MRI was altered in 2 (16,6%) patients: fibrosis and dyskynesias were found in a symptomatic patient with abnormal EKG, conventional echocardiography and SR; another asymptomatic patient showed dilated ventricles but no fibrosis. No correlation with J4S score was found.

Conclusion: Cardiac MRI and SR imaging allowed to detect early cardiac abnormalities in 3 patients (25%) with neither cardiac symptoms nor abnormal EKG and echocardiography, so they could be considered as valid, non invasive tools for the assessment of early cardiac involvement in JSsc. Prospective multicentric studies are needed to confirm these data.

Session Date: Sunday, November 8, 2015
Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Lupus, Scleroderma, JDMS
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Biopsy specimens of cutaneous neonatal lupus (cNL) lesions usually show interface dermatitis. Hydroxychloroquine (HCQ) is an effective treatment for interface dermatitis seen in connective tissue diseases. It may also be of benefit for cNL. Due to the transplacental passage of HCQ, fetuses of treated mothers are exposed to HCQ. Neonates are not continued on HCQ after delivery, therefore HCQ levels are expected to decline after birth. The aim of this study was to asses if in utero exposure to HCQ delayed the onset of cNL.

Methods: A multicenter retrospective cohort was assembled that included all cases of cNL found in 3 data sources. Inclusion criteria were: infant born to a woman positive for anti-Ro ± anti-La antibodies, infant diagnosed with cNL, known age of onset of cNL and documentation of maternal medications during pregnancy. Kaplan-Meier survival analysis was used to assess if HCQ delayed the onset of cNL. Proportions of infants developing cNL within distinct time frames were compared between those HCQ exposed and non exposed.

Results: A total of 327 cases of cNL were included: N=190 from the Research Registry for Neonatal Lupus, N=107 from the SickKids Neonatal Lupus cohort and N=30 from the French Registry of Neonatal Lupus. Twenty-eight (8.6%) infants were exposed to HCQ. Infants exposed to HCQ had overall similar baseline characteristics to those not exposed (Table 1). Survival analysis showed no statistically significant difference in the median number of weeks to cNL onset: HCQ exposed 6.0 (95% CI: 5.7-6.3) vs non exposed 4.4 (95% CI: 3.8-5.0) weeks; p=0.452 (Figure 1). Although no statistically significant difference was seen, the survival curves showed a delayed onset of rash during the first postnatal month in infants exposed to HCQ in utero. The frequency of infants developing cNL within specific time

frames did not significantly segregate by HCQ exposure (Table 2).

Conclusion: Although in utero HCQ exposure did not significantly delay the time of onset of cNL, survival curves suggest later onset of cNL in those exposed to HCQ perhaps due to protection conferred by HCQ when neonatal HCQ blood levels still remain within a detectable range.

The Risk of Hospitalized Infection Following Initiation of Biologic Agents Versus Methotrexate in the Treatment of Juvenile Idiopathic Arthritis

Timothy Beukelman[1], Fenglong Xie[2], John Baddley[3], Lang Chen[4], Melissa L. Mannion[5], Kenneth G. Saag[4], Jie Zhang[6] and Jeffrey R. Curtis[4], [1]Rheumatology, University of Alabama at Birmingham, Birmingham, AL, [2]Rheumatology & Immunology, University of Alabama at Birmingham, Birmingham, AL, [3]Medicine, University of Alabama at Birmingham, Birmingham, AL, [4]University of Alabama at Birmingham, Birmingham, AL, [5]Pediatrics, University of Alabama at Birmingham, Birmingham, AL, [6]Epidemilogy, University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION
Session Date: Sunday, November 8, 2015

Session Title: Pediatric Rheumatology – Clinical and Therapeutic Aspects Poster I: Lupus, Scleroderma, JDMS
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Biologic agents are highly effective for the treatment of juvenile idiopathic arthritis (JIA) but have the potential risk of increased serious infections. Using observational administrative claims data, we compared the rate of hospitalized infections among patients with JIA newly starting biologic agents versus newly starting methotrexate (MTX) without concurrent biologic use.

Methods:

We used national U.S. Medicaid analytic eXtract (MAX) administrative claims files from 2000 – 2010 inclusive. New users of the 5 available tumor necrosis factor inhibitors (TNFi), the interleukin 1 inhibitor anakinra (ANA), and MTX (without concurrent biologic use) were defined by a 6 month clean period of non-use ("baseline"). Patients with a physician diagnosis code for JIA before age 16 years and prior to new use were included. Follow-up began on the day of the first prescription fill and medication exposures were extended for 90 days beyond the days supplied by each fill. The outcome was hospitalization with any infection as the primary discharge diagnosis. Cox proportional hazards models were used to generate hazard ratios adjusted (aHR) for age, sex, race, comorbidities, baseline mean daily oral systemic glucocorticoid (GC) dose, and infections during baseline. Among biologic users, concurrent MTX use during follow-up was treated as a time-varying covariate. Sensitivity analyses included shortening the medication exposure risk window and including all hospital discharge diagnoses in the outcome assessment.

Because nearly all patients who were new users of ANA were expected to have systemic JIA (sJIA) and there is no reliable physician diagnosis code to identify sJIA patients in the MTX comparator cohort, we attempted to identify patients with a high likelihood of having sJIA based upon any physician diagnoses for macrophage activation syndrome or any use of relatively sJIA-specific medications (cyclosporine or tacrolimus in the absence of uveitis, anakinra, canakinumab, rilonacept, thalidomide, lenalidomide) at any time.

Results:

We identified 3075 new MTX users (204 with sJIA), 3471 new TNFi users (60% etanercept, 28% adalimumab, 11% infliximab), and 247 new ANA users. Crude infection rates per 100 person-years were: MTX 1.46 (39/2668); TNFi 1.70 (66/3887); ANA 8.41 (19/226); MTX with sJIA 2.64 (3/114). The aHR for TNFi vs MTX was 1.11 [0.69-1.79]. Among TNFi users, concurrent MTX use suggested an increased risk of infection that was not statistically significant (aHR 1.44 [0.89-2.34]). The aHR for ANA vs MTX was 2.92 [1.77-7.71] and was 2.91 [0.62-13.5] vs MTX users with sJIA. Among all patients in the study, baseline high dose oral GC (>10mg/day) was associated with increased infection risk compared to no GC use (aHR 1.86 [1.16-2.97]). The results were robust to sensitivity analyses.

Conclusion:

There was no significant increased risk of hospitalized infection among new TNFi users compared to new MTX users. New ANA users had an increased risk of infection compared to MTX, even when restricted to MTX users who likely had sJIA. High dose oral GC was associated with a significantly increased risk of infection among all children with JIA. Further investigation about the risk of infection in children with sJIA is needed.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with Rheumatoid Arthritis (RA) who don't respond to conventional synthetic disease modifying anti-rheumatic drugs (csDMARDs) should be treated with biologic agents(1). The objective of this analysis was to evaluate the impact of initiating a biologic agent early (after failure to 1 csDMARD) versus later (after failure to 2 csDMARDs).

Methods: RA patients starting their first biologic agent after enrollment in Corrona between May 2002 and July 2014 and with at least 1 year of follow-up in the registry were included in the analysis. Baseline characteristics of patients initiating a biologic agent after therapy with 1 vs 2 csDMARDs were compared. The second csDMARD could be added to the first csDMARD or substitute therapy with the first csDMARD. The two cohorts were matched using propensity score (PS). Disease activity and functionality outcomes were assessed at 1 year post biologic initiation among the matched groups. The rate of biologic drug changes in the first year after biologic initiation were evaluated among the matched groups. Time to initiation of biologic and time spent in moderate/high disease activity prior to biologic initiation were evaluated. Mixed logistics and mixed linear regression models were used to evaluate binary and continuous outcomes.

Results: A total of 1612 patients initiated their first biologic after therapy with 1 csDMARD (group 1) and 288 patients after therapy with 2 csDMARDs (group 2). Baseline characteristics at the time of the biologic initiation for group 1 (vs group 2) were: 75.4% females (vs 78.5%), age (mean ±SD) of 57.4±13.2 years (vs 57.5±12.3), Caucasian race 89.1% (vs 93.8%), disease duration 6.3± 8.4 (vs 6.9±7.3), baseline CDAI 19.9±14.0 (vs 19.4±13.2) seropositivity 81.8% (vs 78%). After PS matching 288 patients remained in each group. Similar improvements in disease activity occurred in both groups after 1 year of follow up: 53.4% in group 1 vs. 49.3% in group 2 achieved LDA (p=0.4), mean (SD) CDAI change was 8.4 (13.2) in group 1 vs 7.1 (13.5) in group 2 (p=0.2) and mean (SD) HAQ change was 0.08 (0.36) in group 1 vs 0.06 (0.41) in group 2 (p=0.5). Switching to an alternate biologic occurred in 7.6% and 15.3% of patients in group 1 and 2, respectively, while 14.2% and 15.3% discontinued biologic therapy at 1 year (p=0.01). The time since initiation of the first csDMARD to initiation of the first biologic was 13.3 ±15.9 months for biologic initiators in group 1 vs 20.7±19.7 in group 2 (p<0.01). Time spent in moderate or high disease prior to initiation of the biologic agent was 8.1±10.8 months in group 1 vs 13.7±14.9 months in group 2.

Conclusion: Earlier initiation of a biologic agent was associated with a shorter period of time spent in moderate/high RA disease activity and a higher likelihood of remaining on the same biologic at 1 year after initiation.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The order of use of biologic agents after failing a TNF inhibitor is still a question for debate. Phase III trial data in TNF-IR patients show comparable efficacy results across biologic agents and limited head-to-head studies have been published. Prospective registries offer a unique opportunity to observe the effectiveness (combined evaluation of efficacy and safety profile over time) of these agents in a real world clinical setting where all patients with a specific diagnosis and treated in the center are included. We report here a sixth year follow-up analysis. Our aim is to evaluate if patients with rheumatoid arthritis (RA) treated with rituximab (RIT) after failing a first or a second anti-TNF agents (TNF-IR) have different six-year retention rate than patients similarly prescribed anti-TNF agents (pooled adalimumab, etanercept or infliximab) and compare the treatment strategies of using RIT as second or third biologic treatment .

Methods: Data from TNF-IR RA patients prescribed adalimumab (ADA), etanercept (ETA), infliximab (INF) or rituximab (RIT) as second or third biologic agents on or after January 1st2007 was extracted and subjects taking either ADA, ETA or INF were pooled to form the anti-TNF cohort. Baseline demographics included age, disease duration, HAQ-DI, fatigue and pain visual analog scale evaluations (VAS), TJC, SJC, DAS 28 ESR and SDAI. Six-year drug retention rates were estimated and compared using Kaplan-Meier survival estimates. Statistical analysis was performed using SAS version 9.3. RHUMADATA® is a clinical database and registry used in daily clinical practice at the IRRM and CORQ. All patients with RA are followed over time irrespective of their treatment.

Results: The data from 231 RA patients were extracted, 155 and 76 having respectively failed a first and a second anti-TNF agent. No clinically significant differences in baseline variables were observed between treatment groups in second and third intention. The 6 year retention rates of second line RIT and anti-TNF use were 80.1% and 19.1% respectively (Log-rank p< 0.0001). In patients having failed two anti-TNF, subsequent use of RIT and anti-TNF agents respectively demonstrated 6 year retention rates of 53.6% and 37.2% (Log-rank p=0.0473). Second versus third line use was numerically (80.1% vs 53.6%) and statistically superior (Log-rank p=0.0029).

Conclusion:

As second and third line agent, in TNF-IR RA patients, RIT demonstrates a better 6 year retention rate than anti-TNF agents. Second line use demonstrated a statistically better retention rate than third line use. This suggest that using rituximab as a second agent after failing a first anti-TNF agent is a better strategy than waiting to use it after two different anti-TNF failure.

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Treatment choices in early rheumatoid arthritis need to balance benefits, risks, and other considerations such as dosing and monitoring. The objective of this study was to determine the preferences of patients with early rheumatoid arthritis (RA) for these competing issues.

Methods: We assessed patients' preferences using a discrete-choice experiment. Consecutive adult patients with early RA (<2 years since diagnosis) in 2 Canadian centres were presented 13 different sets of three treatment options described by 8 attributes (clinical trial outcomes, risks, monitoring and dosing regimens) and asked to choose one. We

estimated the value that patients placed on each attribute level using a main-effects multinomial logit model, and explored preference heterogeneity through latent-class analysis.

Results: 152 patients completed the survey (86% response rate): mean age 52, 63% female, disease duration 7.8 months. Fourteen (9%) were DMARD naïve, and 44% had changed DMARD treatment within 3 months. Treatment benefits (increasing the chance of a major symptom improvement (ACR50 response) and reducing the chance of serious joint damage) were most important. Of potential adverse events, a 'small risk of serious infections/possible increased risk of cancer' was the most important. Patients were willing to accept this risk for an increase of 15% in the chance of a major symptom improvement (Table 1). Patients had an aversion to intravenous therapy, but were relatively indifferent to other dosing regimens. Alcohol restriction and the need to have regular eye exams to screen for eye toxicity were unimportant. Through latent-class analysis, we identified two patient groups – 46% who were highly benefit-driven, and others who were more risk averse, particularly to the possible risk of cancer/infection (Table 1).

Conclusion: Patients with early RA were generally risk-tolerant and preferred oral and subcutaneous based treatments that provided the greatest chance of benefit, but clinicians need to be aware of important preference differences and tailor treatment approaches appropriately.

Table 1: Relative importance of undesirable treatment characteristics

Treatment characteristic	Absolute increase in probability of major symptom improvement (ACR50 response) required to accept characteristic		
	Overall analysis (all patients)	Latent class analysis	
		Benefit-driven subgroup (46% of patients)	Risk-averse subgroup (54% of patients)
Trial outcomes			
Chance of serious joint damage increased from 2% to 30%	31% (26 to 35)	27% (23 to 32)	47% (34 to 65)
Chance of stopping due to a side effect increased from 2% to 20%	9.5% (6.3 to 13)	6.8% (4.1 to 9.6)	18% (8.7 to 30)
Rare risks and monitoring			
Possible increased risk of cancer and small risk of serious infection	15% (13 to 18)	3.6% (2.1 to 5.2)	48% (38 to 64)
Rare risk of lung/liver reaction (need regular bloodwork)	7.6% (5.6 to 9.7)	2.2% (0.60 to 3.8)	25% (18 to 35)
Need to restrict alcohol	3.1% (1.2 to 5.0)	0.95% (-0.58 to 2.5)	9.9% (4.3 to 17)
Need regular eye exams (to watch for build up in back of eye)	1.3% (-0.59 to 3.2)	0.68% (-0.88 to 2.2)	3.8% (-1.6 to 9.7)
Dosing regime			
Weekly injections instead of weekly pills	0.39% (-4.5 to 5.4)	-1.6% (-5.5 to 2.4)	9.6% (-4.2 to 25)
3 meds (weekly + 6 daily pills) instead of weekly pills	2.8% (-2.3 to 8.0)	-1.2% (-5.4 to 2.9)	17% (2.6 to 34)
IV infusions every 8 weeks instead of injections every 2 weeks	14% (9.2 to 20)	8.4% (4.3 to 13)	26% (11 to 45)

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: The approach of setting disease activity targets and adjusting therapy appropriately to achieve the target has been proven to optimize outcomes in Rheumatoid Arthritis (RA). Target setting is not yet universal and targets may evolve with rheumatologists' increasing understanding of the patient's RA and their response to treatment over time.

Methods: Data were drawn from the Adelphi 2014 Rheumatology Disease Specific Programme, a survey of rheumatologists and their RA patients in France, Germany, Italy, Spain and the UK. Rheumatologists provided patient demographics, details of treat to target (T2T) approach (if any), satisfaction with RA control and time since RA diagnosis. Patients were allocated to one of two cohorts based on time since RA diagnosis: <2 years, ≥2 years. The cohorts were compared on the T2T approach the treating rheumatologist had reported: aspirational (T2T goal stated as remission), pragmatic (T2T goal stated as something other than remission), T2T approach not adopted for the patient. The level of physician satisfaction with RA control was compared across the T2T approaches within each cohort. Appropriate univariate tests were performed to assess for statistically significant associations, nominal p values were reported.

Results: 307 rheumatologists provided data for 2,536 patients, of whom 2,381 had a time since diagnosis reported (mean age: 52.5; 71% female). 24.3% (579 patients) of patients had been diagnosed with RA <2 years ago and the remaining 75.7% (1,802 patients) diagnosed ≥ 2 years ago. Physicians had a T2T approach with no target, pragmatic target and aspirational target in 48.0%, 16.6% and 35.4% respectively.

Patients with a shorter time since diagnosis (<2 years) were more likely than patients with a longer time since diagnosis to have no target (57.9% vs. 44.9% respectively; p<0.0001) and less likely to have a pragmatic target (7.8% vs. 19.4%; p<0.0001). Levels of aspirational targets were similar regardless of the duration since diagnosis (34.4% vs. 35.7%).

Physician satisfaction with RA control was lower in patients with a shorter time since diagnosis (65.1% vs. 77.0%; p<0.0001). In these patients with a shorter time since diagnosis, satisfaction by T2T approach was 56.3%, 64.4%, 70.4%, for aspirational, pragmatic and no target respectively. In patients with a longer diagnosis, satisfaction by T2T approach was 82.4%, 62.9%, 78.7%, for aspirational, pragmatic and no target respectively (p<0.0001).

Conclusion: This research shows that a T2T approach is not used for almost half RA patients, although use of T2T is more common among those who have been diagnosed ≥2 years ago. The satisfaction level with disease control is also higher in these patients. However, the higher use of pragmatic T2T approaches in patients with longer disease duration suggests that current treatment options may not comprehensively succeed in meeting the early aspirations of remission for RA patients.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: To compare physicians' opinion on and adherence to treatment study protocols targeted at either Disease Activity Score (DAS) ≤2.4 or <1.6.

Methods: The BeSt study compared 4 treatment strategies in 508 early rheumatoid arthritis (RA, 1987 criteria) patients, targeted at DAS ≤2.4, at 3 monthly evaluations. Seven years later, in roughly the same rheumatology clinics, the IMPROVED study started with methotrexate and prednisone in 479 early RA (2010 criteria) and 122 undifferentiated arthritis (UA) patients, followed by 2 randomization arms targeted at DAS remission (<1.6), at 4 monthly evaluations. We evaluated physicians' adherence to the protocols and assessed associated opinions and conditions during 4 year follow up by Generalized Linear Mixed Models (GLMM).

Results: Protocol adherence (PA) over 4 years was higher in BeSt than in IMPROVED (mean over time 88% and 69%, respectively). PA decreased during follow up in both studies from 100% to 77% (BeSt) and to 55% (IMPROVED). Protocol violations (PV) occurred in IMPROVED in (mean over time) 23% and in BeSt in 12%. In IMPROVED, more PV were against required treatment intensification/restart (64%), compared to 33% against required drug tapering/discontinuation, whereas in BeSt this was almost similar (47% and 42%, respectively). Where the physician incorrectly didn't taper/stop, the measured DAS was (median 0.6 (IQR -0.9;-0.3)) lower than the target DAS <1.6 (IMPROVED) and (0.7 (-1.2;-0.3)) lower than target DAS≤2.4 (BeSt). Where they incorrectly didn't intensify/restart, the measured DAS was (0.5 (0.2;0.8)) above the DAS target <1.6 (IMPROVED), and (0.7 (0.3;1.3)) above target DAS≤2.4 (BeSt). In BeSt the odds for PV were higher if physicians were not satisfied with the current treatment effect, disagreed with the DAS, or with the next treatment step (table 1). In IMPROVED the odds for PV were higher if physicians disagreed with the DAS or with the next treatment step, but disagreement with the current treatment effect

was associated with fewer PV. We formulated conditions where objective and subjective measures of disease activity differed, and might therefore induce a higher risk for PV. In table 1 the odds for PV associated with these conditions in the BeSt and IMPROVED are shown.

Conclusion: Physicians mostly followed both DAS steered treatment study protocols but over 4 years follow up PA decreased in both studies and more in the IMPROVED. Where the protocol was not followed, the difference between measured and target DAS appeared smaller in the IMPROVED than in the BeSt. A DAS slightly over target (>1.6) requiring drug intensification resulted in more PV than a DAS under the target requiring drug tapering in the IMPROVED. These results may indicate that physicians intend to follow a DAS <1.6 steered protocol but especially reluctant to increase therapy when elements of a DAS >1.6 may not represent true disease activity.

Table 1 GLMM analysis with protocol violation as outcome variable.

	BeSt			IMPROVED		
Opinions	**OR**	**95% CI**	**p-value**	**OR**	**95% CI**	**p-value**

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The latest recommendations for the treatment of rheumatoid arthritis (RA) focus on the achievement of clinical remission. However, joints with subclinical positive power Doppler (PD) signals in ultrasonography (US) might be exposed to the risk of joint damage progression even after the achievement of clinical remission. The aim of this study was to assess subclinical synovitis by US and evaluate the effects of additional intensive treatment for preventing joint damage among RA patients in clinical remission.

Methods:

This study was based on the SCRUM (suppress the joint destruction in clinical remission patients who have active synovitis of ultrasonographic assessment by increasing the dose of methotrexate) study, an open-label, randomized trial. US examination was performed consecutively for 134 patients with RA in clinical remission defined as DAS (Disease activity score) 28<2.6. US assessment was performed at 34 synovial sites in 30 joints. The gray scale (GS) and PD signals were scored in each joint using a semi-quantitative scale from 0 to 3. According to the results of US assessment, the patients with PD positive synovitis (PD³1 in at least one joint) were randomly assigned to two groups; the patients increased the dose of MTX (intensive treatment group) or the patients continue their current treatment (coutinuous treatment group). The patients without active synovitis continued their current treatment (PD negative group). Standard radiographs of hands and forefeet were obtained at baseline, week 24 and 52. Radiological joint damage was assessed according to the modified total Sharp score (mTSS). The primary endpoint of the study was a change of mTSS after 52 weeks compared to the baseline.

Results:

Of 134 patients with clinical remission, PD positive synovitis was found in 101 patients (75.4%) at baseline. After the randomization, 51 patients were assigned to intensive treatment group and 50 patients to coutinuous treatment group. Thirty-seven patients in intensive treatment group (72.5%), 42 patients in coutinuous treatment group (84%) and 20 patients in PD negative group (60.6%) completed this study until week 52. Total PD score was significantly decreased inintensive treatment group comparing to coutinuous treatment group (-3.9 vs -2.0, p=0.019). The progression of mTSS was significantly suppressed in intensive treatment group compared to coutinuous treatment group at both week 24 (0.27 and 1.02, p=0.007) and week 52 (1.03 and 2.02, p=0.038). Especially, the progression of mTSS in patients treated with biologics in intensive treatment group (n=16) was suppressed as same as PD negative group (0.75 and 0.80, respectively) at week 52.

Conclusion:

In conclusion, clinical remission according to composite indexes allowed the presence of subclinical active synovitis that might induce structural joint damages. Subclinical active synovitis should be controlled by additional treatment and this results in the prevention of the joint damage progression. Evaluation of subclinical active synovitis by using high resolution US should be important even in patients achieving clinical remission and it should be treated more intensively.

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: A majority of RA patients who switch from a tumor necrosis factor inhibitor (TNFi) to another biologic disease-modifying anti-rheumatic drug (DMARD) are TNFi cyclers (Bonafede M et al. Adv Ther 2012;29:664-74). The objective of this study was to examine subsequent biologic switching among RA patients in a large US managed care population after they switched between two TNFi ("TNFi cyclers"), between a TNFi and a non-TNFi, or between two non-TNFi.

Methods: Index claims from January 2010 to June 2014 were analyzed from the Truven Health MarketScan® Commercial database. The "index claim" was the first claim for a biologic DMARD or tofacitinib. Patients were required to be ages 18-64 years at index with ≥12 months of continuous medical and pharmacy enrollment pre- and post-index, ≥1 claim for RA (ICD-9-CM 714.0x) at baseline (pre-index) or within 30 days post-index, ≥1 claim for a different biologic at baseline, no claim for the index agent at baseline, and no claim for any other autoimmune condition. Patients who switched therapy again within 6 months or within 12 months after the index date were categorized based on baseline and index therapy.

Results: Of the 7304 patients who met the selection criteria, 82.1% were female. Mean age was 50.1 years (SD=9.5) and mean Deyo Charlson Comorbidity Index Score was 1.4 (SD=0.9). A total of 4764 (65.2%) patients were TNFi cyclers, 1826 (25.0%) switched from a baseline TNFi to an index non-TNFi, 418 (5.7%) switched from a baseline non-TNFi to an index TNFi, and 296 (4.1%) switched from a baseline non-TNFi to an index non-TNFi. Mean age at index was similar across cohorts (49.5 to 51.9 years); 80.9% to 84.5% of patients in each cohort were female. The table summarizes the proportion of patients who switched therapy again in the first 6 or 12 months post-index. For patients who switched from a baseline TNFi to an index non-TNFi, compared with TNFi cyclers, the odds ratio for switching therapy again was 0.619 (95% CI: 0.53, 0.72; $p<0.01$) within 6 months and 0.824 (95% CI: 0.73, 0.93; $p<0.01$) within 12 months.

Conclusion: RA patients who switch biologic therapy frequently switch again within 12 months. Compared with patients who switch between two TNFi (TNFi cyclers), patients who switch from a TNFi to a non-TNFi are less likely to switch therapy again within 6 or 12 months.

Table. Proportion of Patients Who Switched Therapy Again After the Index Date.

Baseline and Index Therapy	Switched Again Within 6 Months, n (%)	Switched Again Within 12 Months, n (%)
TNFi to TNFi ("TNFi cyclers") (N=4764)	910 (19.1)	1,616 (33.9)
TNFi to non-TNFi (N=1826)	233 (12.8)*	543 (29.7)*
Non-TNFi to TNFi (N=418)	75 (17.9)	134 (32.1)
Non-TNFi to non-TNFi (N=296)	34 (11.5)*	73 (24.7)*

*$p < 0.01$ compared with TNFi cyclers.

Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Several sets of remission criteria have been developed. The ACR/EULAR criteria were validated against their potential to predict prognosis of rheumatoid arthritis (RA) [1]. Duration of remission was not studied, but is likely to be an even better predictor of RA prognosis. We investigated whether remission at one point in time and sustained remission during 26, 52 and 78 weeks of treatment are predictive of RA prognosis in early RA patients after 104 weeks of treatment.

Methods: In the COBRA-light trial [2,3], patients were assessed for remission according to Boolean, SDAI, CDAI, RAPID, DAS44 and DAS28 criteria at 26, 52, 78 and 104 weeks of treatment. ‘Sustained' was defined as remission present at 1) 26 and 52 weeks, and 2) at 26, 52 and 78 weeks. Following the methodology of the ACR/EULAR remission committee [1] good outcome was defined as 1) DHAQ≤0 and HAQ consistently ≤0.5 and 2) DSHS≤0, between 52 and 104 weeks. Logistic regression analyses studied the potential of the above remission criteria to predict good outcome: both at one point in time and according to the two defined periods of sustained remission. Patients with missing data of remission criteria at ≥1 visits (n=64) were excluded from these preliminary analyses.

Results: Hundred early RA patients (66% women, mean age 53 years) were included. Remission percentages at 26, 52, 78 and 104 weeks after treatment are shown in Figure 1. The proportion of patients in sustained remission during

26-52 and 26-52-78 weeks respectively were: Boolean: 10%, 8%; RAPID: 13%, 12%; SDAI:19%, 16%; CDAI: 19%, 17%; DAS44: 36%, 30%; and DAS28: 44%, 38%. Low, stable HAQ scores were seen in 40% of the patients, and lack of radiological progression in 81%. All remission criteria were predictive of low, stable HAQ scores between 52 and 104 weeks of follow-up, both at single points in time, as well as during periods of sustained remission, except for sustained Boolean remission. Sustained remission periods resulted in higher odds ratio's for a low, stable HAQ compared to remission at one point in time, except for DAS28 remission at 52 weeks. None of the criteria were predictive of lack of radiological progression, neither at one point in time nor during periods of sustained remission, except for RAPID remission at 52 weeks.

Conclusion: Early RA patients that reach remission according to any of the available criteria during short or sustained periods are likely to retain a good physical function in the subsequent months, in which sustained periods of remission might be a stronger predictor than remission at one point in time. In contrast, radiological damage progression does not seem to be associated as strongly with (sustained) remission, probably as a consequence of the low radiological damage progression overall.

Impact of Sarilumab on Fatigue, Pain, Morning Stiffness, Productivity, and Health Related Quality of Life (HRQoL) in Patients with Active Rheumatoid Arthritis Who Were Inadequate Responders or Intolerant of Anti-TNF-Î± Therapy: Results from a Phase 3 Study (RCT)

Vibeke Strand[1], Mark Kosinski[2], Neil Graham[3], Chieh-I Chen[3], George J. Joseph[4], Deborah Bauer[5], Yong Lin[5], Cesar Pacheco-Tena[6] and Roy Fleischmann[7], [1]Biopharmaceutical Consultant, Portola Valley, CA, [2]QualityMetric Inc, Lincoln, RI, [3]Regeneron Pharmaceuticals, Inc., Tarrytown, NY, [4]Global Health Economics & Outcomes Research (HEOR), Sanofi, Bridgewater, NJ, [5]Sanofi, Bridgewater, NJ, [6]Universidad Autónoma de Chihuahua, Chihuahua, Mexico, [7]University of Texas Southwestern Medical Center, Dallas, TX

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose : Sarilumab, a human monoclonal antibody directed against the IL-6 receptor, in combination with non-biologic DMARDs, demonstrated efficacy in the TARGET RCT (NCT01709578). TEAEs and SAEs were more frequent in the sarilumab-treated groups. Laboratory findings were consistent with IL-6 blockade and observations from the MOBILITY study. From an RA patient perspective, fatigue, morning stiffness, pain, ability to participate in family/leisure activities, and work are important outcomes to assess treatment effectiveness. These analyses present the effects of sarilumab+DMARD on the pre-defined secondary endpoints of fatigue, AM stiffness, pain, work within and outside the home and participation in family/leisure activities, and HRQoL at Week 24, as well as change in patient global assessment of disease activity (PtGA) and physical function by Health Assessment Questionnaire (HAQ).

Methods : The intent-to-treat population included 546 patients randomized 1:1:1 to placebo, sarilumab 150 mg every 2 weeks (q2w) or 200 mg q2w + background DMARDs. Patient-reported outcomes (PRO) included Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F), AM stiffness, Pain VAS, Work Productivity Survey (WPS),Rheumatoid Arthritis Impact of Disease (RAID), and Short Form-36 (SF-36) assessed at baseline, Weeks 2 (FACIT, RAID, Pain and AM stiffness only), 4, 12, and 24. PRO changes from baseline to week 24 were analyzed using mixed-model repeated measures using region, number of prior TNFis, visit, treatment, and treatment by visit interaction as fixed effects and baseline PRO scores as covariates.

Results: Baseline SF-36 Physical (PCS) and Mental Component Summary (MCS) scores were >2 and >1 standard deviation below normative values, respectively, indicating significant disease burden. Statistically significant ($p<0.025$, simple Bonferroni adjustment) improvements versus placebo+DMARD in FACIT-F, AM stiffness, pain, WPS and RAID were reported by patients receiving sarilumab 150 mg+DMARD and similarly for sarilumab 200 mg+DMARD. SF-36 PCS significantly improved for both doses with no worsening of SF-36 MCS. Significant improvements were seen for 5/8 SF-36 domain scores for sarilumab 150mg + DMARD and 7/8 domain scores for sarilumab 200mg + DMARD. PtGA and HAQ, included in the primary analysis, were statistically significantly improved with both doses of sarilumab. With few exceptions, statistically significant improvements between sarilumab treatment groups and placebo exceeded the minimum clinically important difference (MCID) for those PROs with established MCIDs.

Conclusion: In this Phase 3 RCT, TNF-IR RA patients receiving either dose of sarilumab+DMARD reported statistically significant and clinically meaningful changes from baseline in fatigue, AM stiffness, pain, productivity and participation, RA impact scores and HRQoL at Week 24.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: At the present time remission is the target for treatment of rheumatoid arthritis (RA). Various composite indices are available that can be used to define remission. Although the new ACR/EULAR Boolean criteria is more stringent than others, it is difficult to achieve and even more difficult to sustain this Boolean remission. In this study we aimed to determine the difference of the ultrasonographically (US) assessed actual disease activity of the patients with Boolean remission compared to patients in remission according to other remission criteria.

Methods: RA patients in clinical remission (DAS28-ESR<2.6) for at least 3 months were included to this cross-sectional study. All patients' remission status according to DAS28-ESR-3, DAS28-CRP, SDAI, CDAI and Boolean based definitions were assessed. A standard gray scale (GS) and power Doppler (PD) US examination of 28 joints (included in DAS28) for the presence of synovitis was performed by an experienced sonographer (NI) blinded to clinical data. US synovitis GS and PD signals were semiquantitatively graded from 0 to 3. Total PD and GS synovitis scores of all sites are recorded as sum scores of PD and GS, respectively.

Results: A total of 55 out of 302 RA patients (18.2%) in DAS28 remission were enrolled (F/M=35/20, mean age 52.2±12.0, disease duration 11.0±6.5 years, biologic treatment 43.6%, RF or Anti-CCP positivity 76.4%). Of those 55 patients, 41 (74.5%), 36 (65.5%), 31 (56.4%) and 25 (45.5%) fulfilled the DAS28-ESR-3, SDAI, CDAI and Boolean remission criteria, respectively. SDAI and Boolean remission had the highest percentage of patients with PD signals ≤1, which has shown to be associated with erosion development and worse functional outcome. However despite that, those differences in US disease activity parameters (both PD and GS synovitis sum scores and percentages of patients without PD and GS signals [with both omitting and including grade 1 signals]) in remission patients according to different criteria were not statistically significant. US disease activity parameters of clinical remission group according to different criteria were similar as well, compared to their counterpart nonremission group.

Conclusion: US verified joint inflammation is the lowest in RA patients who are in remission according to Boolean and SDAI criteria. The clinical significance of this statistically nonsignificant inflammatory activity compared to other clinical remission criteria should be assessed in prospective studies. Till then, in clinical practice if Boolean remission could not be achieved, SDAI and also other clinical remission criteria could also be preferred as the remission target.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: About 30% of patients receiving biologic therapy do not have concomitant conventional synthetic DMARDs (csDMARDs). Little is known about the role of different mode of actions when switching biologic therapy. The objective of the present study was to evaluate the impact of anti-TNF and other modes of action on drug adherence in RA patients switching monotherapy.

Methods: All RA patients registered in a regional biologic DMARD (bDMARD) database as initiating bDMARD as monotherapy, i.e. without concomitant csDMARDs, from 1st of January 2006 through 31st of December 2012, were eligible for inclusion. After initiation of the first dose of biologic monotherapy, drug adherence for biologic naïve patients receiving anti-TNF and for patients switching to 2nd course of anti-TNF or a different bDMARD was estimated using life-table technique.

Results: A total of 531 patients with RA were included (80% women, disease duration: mean 12.6 [SD 11.5]), age: mean 56.7 years [SD 14.1], no. of previous DMARDs: median 3.0 [IQR 2.0 to 5.0], EQ-5D: median 0.52 [IQR 0.16 to 0.66], and DAS28: mean 5.0 [SD 1.3]). There was a statistically significant difference in drug adherence when comparing anti-TNF switchers (n=166) to those switching to other modes of action (OMA switchers) (n=83) (p=0.02) (see Figure). There was no statistically significant difference between anti-TNF naïve patients (n=282) and OMA switchers (p=0.30) (see Figure).

Conclusion: When switching to other modes of action biologics after anti-TNF failure, drug adherence was as good as when treated with an anti-TNF as 1st course. However, switching to a 2nd anti-TNF showed significantly inferior drug adherence rates compared to bDMARDs with other modes of action. This suggest that bDMARDs with other modes of action should be considered as the first choice for patients not tolerating csDMARDs and who have had an inadequate response to their first anti-TNF agent.

Figure: Drug adherence of anti-TNF and other modes of action on drug adherence in RA patients switching monotherapy.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I

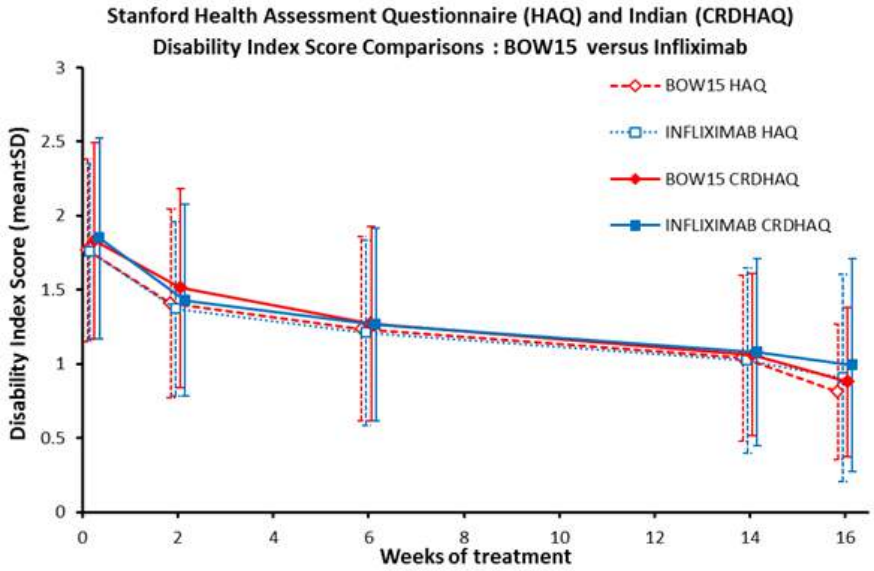
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: The Stanford Health Assessment Questionnaire (HAQ) includes several questions that are more relevant to rheumatoid arthritis (RA) patients in Western countries than to those in India. The Center for Rheumatic Diseases (CRD) Pune developed a modified version of the HAQ (CRDHAQ) to reflect daily activities unique to India and other Asian countries, such as arising from sitting cross-legged on the floor, which may be more difficult to perform than corresponding activities in Western countries. We compared the performance of both questionnaires in a clinical trial conducted in India.

Methods: Indian patients with RA for ≥2 years were randomized in a 54-week clinical trial comparing biosimilar infliximab (IFX) BOW15 to reference IFX (rIFX), which included an initial 16-week double-blind phase followed by an open-label extension in which responders received BOW015. All subjects completed both HAQ and CRDHAQ at weeks 0 (baseline), 2, 6, 14 and 16. Disability index (DI) scores from baseline for both instruments were compared in the ITT population by analysis of covariance within and between treatments.

Results: 189 subjects were, randomized to receive BOW015 (n=127) or rIFX (n=62), of whom 181 subjects (120 receiving BOW015 and 61 receiving rIFX) completed the blinded phase of the study. Baseline HAQ-DI scores were 1.77±0.61 and 1.76±0.60 and baseline CRDHAQ-DI scores were 1.83±0.66 and 1.85±0.67, respectively (mean±SD). The baseline CRDHAQ-DI scores were significantly higher than HAQ-DI scores for each treatment (P<0.05). Data for all time points are shown in Figure 1.

Figure 1.



There were no statistically significant differences between HAQ-DI and CRDHAQ-DI scores from baseline between treatments across each assessment period. Improvements from baseline in each score were statistically significant from week 2 through week 16 for both treatments and both HAQ and CRDHAQ (P<0.001). These decreases in DI by treatment corresponded to comparable increases in %ACR20 responders observed at the time points.

Conclusion: CRDHAQ and HAQ, yielded comparable results when administered to Indian RA patients, and reflected significant functional improvement at week 2. Thus, either the Stanford HAQ or CRDHAQ can be used to assess functional improvement in clinical trials conducted in this patient population with daily activities different from those of Western RA patients.

Progression of Radiographic Joint Destruction in Patients with Rheumatoid Arthritis Treated with a Biologic Agent in Combination with Methotrexate Versus a Biologic Alone: A Systematic Review and Meta-Analysis of Randomized Trials

Tanja Schjødt Jørgensen[1], Simon Tarp[1], Daniel E. Furst[2], Anna Døssing[1], Peter C. SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose : One of the frequently claimed advantages of biologic agents is their potential to arrest radiographic progression. The ability of disease-modifying antirheumatic drugs (DMARDs; typically methotrexate, MTX) is less well defined because the effect of DMARDs when added to biologic agents (bDMARDs) on radiographic progression has only sporadically been investigated in randomized trials. The objective of the present study was to review the evidence on radiographic joint destruction in patients with RA between therapies combining MTX with a bDMARD and bDMARD in monotherapy.

Methods: A systematic review and meta-analysis of randomized trials was performed to identify trials relating treatment of RA with MTX in combination with bDMARD, compared to a bDMARD in monotherapy. According to the protocol a major outcome was radiographic joint progression assessed by total sharp score (TSS). A random-effects model was applied for meta-analysis with standardized mean difference and 95% confidence intervals (SMD, 95%CI) and inconsistency (I^2, %) estimated using Review Manager. The protocol is available from PROSPERO: CRD42014014633.

Results: From the 14 trials that were eligible for inclusion (1), only 7 trials assessed radiographic joint progression (Trial duration ranging from 24 to 104 weeks). The use of the Intention to treat population was frequently ‘unclear/inadequate', reducing our confidence in the estimates. The overall analysis of changes in radiographic joint progression showed an SMD of 0.16 [0.09 to 0.23, P<.0001] – apparently with no heterogeneity (P= .58) and inconsistency (0%). Using an SD of 20 TSS unit, this effect size corresponds to a difference between the groups of 3.2

TSS units in favor of concomitant use of MTX when treating with a biologic (after approximately 52 weeks; see Figure). We found no reason to suspect that the added value of MTX varied with the choice of bDMARD (Test for subgroup differences P= .66).

Conclusion: This study provides moderate quality evidence that combining the prescribed bDMARD with concomitant use of MTX is significantly more efficacious in preventing structural joint destruction compared to patients taking biologics as monotherapy.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Biologic agents are highly effective for rheumatoid arthritis (RA); however, not all cases achieve health assessment questionnaire (HAQ) remission. Although previous studies have reported the prognostic factors, there is no report on predictive factors for HAQ remission. To study predictive factors for HAQ remission, which is one of the treatment goals in RA, after using biologic agents for 6 months.

Methods:

The subjects were 333 RA patients treated with biologic agents for 6 months. The following patient's characteristics were investigated: age, gender, the number of previous drugs, disease duration, the type of biologic agents, baseline steroid dosage, MTX dosage, serum RF, MMP-3, ACPA, TNF-α, and IL-6. For evaluation we used SDAI for RA disease activity, HAQ for ADL, Short Form (SF)-36 for QOL, and Hamilton Depression Rating Scale (HAM-D) or Self-rating depression scale (SDS) for depression status. HAQ remission was defined by HAQ≦0.5 after 6 months of treatment. The subjects were divided into two groups: patients with HAQ≦0.5 and patients with HAQ>0.5 at 6 months, and a retrospective study was conducted. 101 patients were excluded from the study due to loss to 6-month follow-up, and a total of 232 patients were analyzed.

Results: Compared with a group of RA patients without HAQ remission (n=68), a group of patients with HAQ remission (n=164) had younger age (54.8 ± 15.2 vs. 61.8 ± 13.3, p=0.0011), lower baseline steroid dosage (3.4 ± 3.7mg vs. 4.5 ± 3.5mg, p=0.037), lower serum MMP-3 (196 ± 234 ng/ml vs. 321 ± 551, p=0.047), lower SDAI (22.5 ± 13.4 vs. 32.1 ± 12.9, p<0.001), lower HAQ (0.39 ± 0.51 vs. 1.08 ± 0.54, p<0.001), higher SF-36 (p<0.05 in all categories), lower SDS (40.4 ± 9.9 vs. 43.5 ± 9.2, p=0.033), and lower HAM-D (5.0 ± 4.3 vs. 8.4 ± 5.0≦Ap<0.001)

were detected based on univariate analysis. On the other hand, only in lower HAQ score (p=0.0001) and “mental health” item of the SF-36 (p=0.0189) were detected based on logistic regression analysis.

Conclusion:

It was suggested that RA patients with lower HAQ and lower depression scores at baseline are more likely to achieve HAQ remission with biologic treatment.

Ultrasound Assessment of Early Response to Certolizumab Pegol Can Predict Future Response in Patients with Rheumatoid Arthritis

Takanori Fujimura, Takashi Fujimoto, Ryota Hara, Naoki Shimmyo, Yasunori Kobata, Akira Kido, Yasuhiro Akai and Yasuhito Tanaka, The Center for Rheumatic Diseases, Nara Medical University, Kashihara, Japan

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Certolizumab pegol (CZP) is a PEGylated Fab’ fragment of a humanized anti-TNF antibody with high affinity to TNF. It brings rapid improvement of the signs and symptoms of RA and it has been shown that attainment of clinical response at first 12 week predict better longterm outcomes. Musculoskeletal ultrasound (US) has been proved to be useful at assessing synovitis precisely in patients with RA. There are few reports, however, that verify the early response to CZP in RA patients by US and whether early US assessment of synovitis can predict future clinical response is unclear. In the present study we describe the early response to CZP in RA patients by US examination and ascertain whether US is useful for predicting future clinical response.

Methods: Seventeen patients with RA were treated with CZP. Patients were treated with subcutaneous CZP 400 mg at weeks 0, 2, 4 followed by 400mg every 4 weeks or 200mg every 2 weeks. The mean age of patients was 52.2 years old and the mean disease duration was 6.0 years. The mean disease activity at baseline (week 0) was 4.67 and 23.2 for 28-joint disease activity score (DAS28) and simplified disease activity index (SDAI), respectively. The mean modified health assessment questionnaire (mHAQ) was 0.49. Twelve patients (71%) were naïve to biologic agents. Fifteen (88%) and 7 (41%) patients were treated with methotrexate and glucocorticoids concurrently. At baseline and weeks 2, 4 and 12, US examination was performed at bilateral MCP, PIP, IP, and wrist joints. Gray-scale (GS) and pulse Doppler (PD) signal was recorded in each joint using semi-quantitative score (0 to 3). The sum of these scores obtained from each joint was used as GSUS and PDUS score.

Results: At weeks 0, 2, 4, and 12, mean GSUS score was 23.5, 20.1, 16.4 and 15.5, respectively. Mean PDUS score at weeks 0, 2, 4, and 12 was 14.4, 10.5, 10.7 and 9.8, respectively. Both GSUS and PDUS score were improved significantly as early as 2 weeks after treatment (p=0.0428 and 0.0119) and gradually reduced during study period. At week 12, both of DAS28 and SDAI were significantly improved than those at baseline (3.42 and 11.6, p=0.0029 and

0.0007, respectively). Clinical response was evaluated as achievement of DAS remission (DAS<2.6), and we classified 4 patients (24%) in whom DAS remission was achieved at week 12 as "responders". The US assessment at week 2 was compared between CZP-treated patients (responders vs non-responders at week 12). At week 2, three patients out of responders (75%) showed marked reduction of PDUS score to less than 50% of baseline (PDUS 50 response). By contrast, in the 13 patients of non-responders at week 12, only one patient (7.7%) attained PDUS 50 response. Thus, in responders at week 12, the proportion of early US responders (PDUS 50 response at week 2) was significantly higher than that in non-responders (75% vs 7.7%, p=0.0223).

Conclusion: Early response to CZP in patients with RA were confirmed by US examination. Early US assessment of synovitis can predict future clinical response in CZP treatment.

Abstract Number: 442

Use of Adjunctive Neuroregulatory Medication to Improve Etanercept Treatment Response for Patients with Inflammatory Arthritis: A Pilot Study

Andrew Holman[1] and Edmund Ng[2], [1]Inmedix, Normandy Park, WA, [2]Statistical Thinking, Seattle, WA
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: As a proposed inflammatory biomarker for autoimmune disease[1,2], the autonomic nervous system (ANS) has been assessed as a predictor of anti-TNF treatment outcome[3] and as an adjunctive therapeutic target[4-6] to elevate a stagnant remission rate in rheumatoid arthritis which has languished at 27% by ACR70 response[7] for many years.

Methods: This retrospective, community-based study assessed consecutive patients initiating biologic treatment of inflammatory arthritis. In an effort to improve outcome by 28-joint count (swollen and tender), neuroregulatory medications, many of which reduce ANS sympathetic tone, were added to etanercept for patients exhibiting an incomplete therapeutic response to traditional immunosuppression (etanercept combined with DMARDs, prednisone and/or NSAID). Statistical analysis included t-test and logistic regression.

Results: Sixty-six patients (70% female, mean age of 50.8±13.0 years, mean duration of disease 9.7±6.4 years, mean prior DMARD use 2.3±1.4, mean ESR 26.6±27.8) initiated etanercept at 25mg BIW for treatment of their inflammatory joint disease (39 seropositive rheumatoid, 13 seronegative rheumatoid, 14 psoriatic arthritis by ACR criteria). All but five continued etanercept for a mean 20.7±7.7 months for an etanercept retention rate of 92%. Three subjects discontinued for personal reasons, one died of unrelated issues and one was lost to follow-up. Overall, initial joint count decreased after addition of etanercept from 11.6 to 1.3 with 79% achieving >=70% reduction in joint count by LOCF (74% by BOCF).

Baseline doses of prednisone and methotrexate were 6.7 mg/d (n=42) and 19.14 mg/wk (n=32), respectively. Ultimately, prednisone was discontinued in 62% (26 of 42); methotrexate was discontinued in 75% (24 of 32); other DMARDs were discontinued in 79% (22 of 28); and NSAIDs were discontinued in 48% (14 of 29). Neuroregulatory medications were used by 36 subjects (55%), including lorazepam 1-2 mg po qhs (18%), clonazepam 1-2 mg po qhs (15%), pramipexole 0.5-4.5 mg po qhs (29%), trazodone 50-100 mg po qhs (21%), other antidepressants (14%), and anti-epileptics (1%). Regression analysis was unable to identify any factor beyond the frequent use of neuroregulatory medications able to reconcile the clinical treatment response to etanercept seen in this cohort relative to historical etanercept treatment outcomes.

Conclusion: Pure ANS therapies, such as vagal nerve stimulation, are already in human RA trials. Although uncontrolled, this data continues to suggest the relevance of further inquiry into the potential benefit of employing an adjunctive neuroregulatory ANS strategy to improve outcomes with immunosuppressive therapies.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

To evaluate long-term efficacy and safety of biological disease modifying antirheumatic drug (bDMARD) in real-life practice and identify risk factors related to remission and drug discontinuation in rheumatoid arthritis (RA) patients.

Methods:

Two hundred and fifty-six patients fulfilling 1987 ACR or 2010 ACR/EULAR classification criteria for RA and starting bDMARD between December 2009 and October 2014 were selected from the RDPA register. Baseline demographic and clinical data were retrieved. The cumulative probability of bDMARDs discontinuation over 5 years of follow-up and factors associated with remission and bDMARDs withdrawals was analyzed.

Results:

Almost half (46%) of patients were initially treated with rituximab (RTX), followed by etanercept (ETN) 33% and infliximab (IFX) 21%. Less than 10% of patients were subsequently switched to a second bDMARD (ETN to RTX 62.5%, IFX to RTX 33.3% and RTX to IFX 4.2%). In patients who continued using the first bDMARDs, remission had been achieved in 7.2% and 21.5% at 1 year and 5 years, respectively. In multivariate analysis, the factor predicting remission from first bDMARD was male gender with hazard ratio (HR) 1.9 (95%CI 1.05-3.45). At 3 years follow-up, the drug survival rates were 67%, 44%, and 37% for RTX, ETN, and IFX, respectively. The probability of bDMARD continuation during 5 year of follow-up is shown in figure. In multivariate analysis, RTX was significantly associated with highest drug survival. Hazard ratio for drug discontinuation were 2.60 (95%CI 1.53-4.42) for IFX and 2.15 (95%CI 1.36-3.42) for ETN compared to RTX.

Thirty-nine percent of patients stopped treatments, due to inadequate response (42%), serious adverse event (SAE) (22%), non-adherence (14%), and remission/low disease activity (13%). SAE comprised of non-mycobacterium infection (32%), mycobacterium infection (24%) and malignancy (12%). There were 5 deaths (4/5 in RTX group) because of lung cancer, community-acquired pneumonia, aspiration pneumonia, hepatitis B virus infection, and sudden cardiac arrest.

Conclusion:

During 5 years of follow-up, 61% of patients continued using the first bDMARD. The leading cause of drug discontinuation was inadequate response. Non-mycobacterium infection was the most common SAE.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I

Session Type: ACR Poster Session A

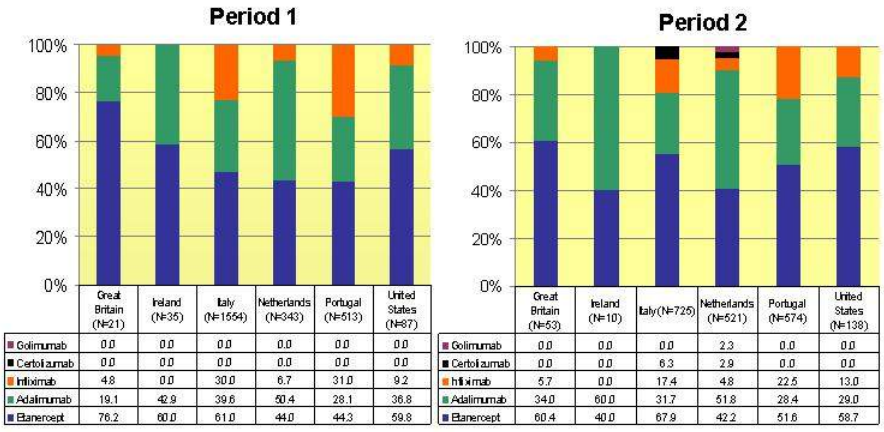
Session Time: 9:00AM-11:00AM

Background/Purpose: Biologic agents are effective treatment for rheumatoid arthritis (RA), but factors exist that may influence the prescription of these drugs in different countries. We compared the prescription of TNF inhibitors (TNFi) among RA patients during two time periods by rheumatologists in Great Britain, Ireland, Italy, the Netherlands, Portugal, and the US who used the METEOR database. We hypothesized that the relative distribution of TNFi prescriptions for RA may vary among countries with different healthcare systems.

Methods: The international online Measurement of Efficacy of Treatment in the Era of Outcome in Rheumatology (METEOR) database is used at 124 hospitals in 38 countries and contains demographic and clinical data about >32,000 RA patients. This database was queried to compare use of TNFi (infliximab, etanercept, adalimumab, certolizumab pegol, and golimumab) during two one-year periods: July 2009-June 2010 (Period 1) and July 2011-June 2012 (Period 2). Data were extracted for 2553 patients in Period 1 and 2021 patients in Period 2. We compared TNFi use across the five countries separately for each time period. For each country, we also compared TNFi use during Period 1 to that during Period 2. A chi-square test was used to calculate significance, Fisher's exact test was used to analyze cell size <5 and SAS 9.3 was used for all analyses.

Results: Relative use of each TNFi differed significantly across all countries within each time period ($p<0.0001$). Comparing TNFi use at US sites to sites in EU countries combined, infliximab was prescribed significantly less at US sites (9.2% vs. 25.7%, $p<0.0001$) for Period 1. Use of other TNFi did not differ significantly for either time period between US sites and all EU sites combined. When TNFi use was compared across the two time periods, use of infliximab and adalimumab was significantly lower (17.3% vs. 29.9%, $p<0.0001$, and 31.7% vs. 39.5%, $p=0.0003$, respectively) and use of etanercept was significantly higher (67.8% vs.61.0%, $p=0.0015$) in Italy during Period 2, compared to Period 1. In Portugal, infliximab use was significantly lower (22.4% vs. 30.9%, $p=0.0015$) and etanercept use was significantly higher (51.5% vs. 44.2%, $p = 0.0159$) during Period 2, compared to Period 1. Otherwise, relative prescription of individual TNFi did not differ significantly across the two time periods in any other countries.

<>Image/graph:



Conclusion: The relative prescription of various TNFi, as recorded in the METEOR database, differed significantly across several EU countries and the US during two distinct time periods. Infliximab was prescribed significantly more often than other TNFi at sites in those EU countries examined compared to the US sites in period 1. In Italy and Portugal, etanercept was prescribed significantly more than other TNFi in period 2, compared to period 1. Further study is warranted to identify factors that drive the different TNFi prescribing patterns in these countries.

Persistence with Biologic Monotherapy in Comparison with Combination Therapy with Disease-Modifying Antirheumatic Drugs in Patients with Rheumatoid Arthritis; Results from a Rheumatoid Arthritis Cohort

Arthur Lau[1], Mohammad Movahedi[2,3], Mark Tatangelo[4], Claire Bombardier[3,5,6] and OBRI investigators, [1]Division of Rheumatology, McMaster University, Hamilton, ON, Canada, [2]JSS Medical Research, St-Laurent, QC, Canada, [3]Toronto General Hospital Research Institute, University Health Network, Toronto, ON, Canada, [4]Clinical Decision Making and Health Care, Toronto General Hospital Research Institute, University Health Network, Toronto, ON, Canada, [5]University of Toronto, Department of Medicine (DOM) and Institute of Health Policy Management, and Evaluation (IHPME), Toronto, ON, Canada, [6]Division of Rheumatology, Mount Sinai Hospital, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Clinical evidence suggests concomitant treatment with a biologic Disease-Modifying Antirheumatic Drug (bDMARD) and a conventional synthetic DMARD (csDMARD), especially with methotrexate (MTX) has greater efficacy than treatment with a bDMARD as monotheapy in patients with rheumatoid arthritis (RA). However, not all patients are able to tolerate a csDMARD. Our objective was to compare the persistence of a bDMARD used as monotherapy, versus combination therapy in patients with active RA.

Methods:

Physician data were collected from the Ontario Best Practices Research Initiative Rheumatoid Arthritis Registry (OBRI- RA), a clinical registry of RA patients followed in routine care. Inclusion criteria comprised of patients over age 18 years, active RA (defined as ³1 swollen joint) and started on their 1st bDMARD within 30 days before registry enrolment, or started after enrolment. Combination therapy was defined as treatment with a bDMARD plus at least one csDMARD, while monotherapy was defined as treatment with only a bDMARD.

The primary outcome was persistence with 1st bDMARD therapy, which was defined as the length of time the patients continued to receive their first bDMARD therapy. Persistence treatment was examined using Kaplan-Meier survival analysis. Patients were censored at date of 1st bDMARD stop, switch to another bDMARD or at date of last follow-up, whichever came first.

Results:

Among 2591 RA patients, 701 patients started their 1st bDMARD within 30 days before cohort enrolment or after

enrolment with the mean (standard deviation) of follow-up 1.9 (1.6) person-years. A total of 598 (85.3%) patients were on combination therapy, and 103 (14.7%) patients were on monotherapy. At baseline, there was a similar mean age, proportion of females between the two groups. A TNFα inhibitor was the biologic used in 22.6% and 14.5% of the monotherapy and combination group respectively.

The mean time to failure of 1st bDMARD was 4.3 years (95%CI: 3.7-4.9) and 4.6 years (95%CI: 4.3-4.8) in the monotherapy and combination group respectively. At 12 months follow-up, 74% (95%CI: 64-81) in the monotherapy group and 81% (95%CI: 77 -84) in the combination group remained on their first bDMARD (table 1).

Conclusion:

Our study demonstrates that a higher proportion of patients on monotherapy failed therapy at 12 months, and the mean time to treatment failure was shorter with monotherapy, but these results were not statistically significant. Although combination therapy is recommended, these real-world results suggest that patients who are unable/unwilling to continue on a csDMARD, bDMARD monotherapy can still provide an efficacious option.

Table 1: Survival function (95% CI) for patients stopping their initial bDMARD therapy by year of follow-up for the monotherapy versus combination group in patients with active rheumatoid arthritis

Time (year)	Whole cohort N=701	Monotherapy N=103	Combination therapy N=598
1	0.80 (0.76-0.83)	0.74 (0.64-0.81)	0.81 (0.77-0.84)
2	0.72 (0.69-0.76)	0.67 (0.56-0.76)	0.73 (0.69-0.77)
3	0.69 (0.65-0.73)	0.67 (0.56-0.76)	0.70 (0.65-0.74)
4	0.65 (0.61-0.70)	0.64 (0.52-0.74)	0.66 (0.60-0.70)
5	0.60 (0.53-0.65)	0.55 (0.38-0.69)	0.61 (0.54-0.67)

Figure 1: Time to failure of 1st bDMARD therapy in monotherapy group versus combination group in patients with active rheumatoid arthritis.
