Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Receptor Activator of Nuclear factor Kappa-b Ligand (RANKL) is a key regulator of bone metabolism. Anti-citrullinated (cit) protein antibodies (ACPA) have been suggested to cause bone destruction by osteoclast activation. We investigated the relationship between RANKL and ACPA in early-untreated rheumatoid arthritis (RA) patients.

Methods: Patients with newly diagnosed untreated RA (n=183) were analysed at baseline and 3 months after initiating methotrexate (MTX) treatment. Serum RANKL (total RANKL), ACPA (anti-CCP2) and ACPA specificities (anti cit-vimentin, anti cit-enolase and anti cit-fibrinogen) were determined by enzyme-linked immunosorbent assay (ELISA). Synovial RANKL expression was evaluated by immunohistochemistry in a subgroup of patients (N=15). The relationship between anti cit-vim antibodies and bone destruction was further validated in 1116 RA patients included in the EIRA cohort. Pearson’s Chi-Square test, Wilcoxon rank sum test, Wilcoxon signed rank test and linear regression models were used.

Results: Serum RANKL concentration was significantly higher ($p < 0.05$) in ACPA-positive (median: 689 pmol/L, IQR 342-1253) compared with ACPA-negative (median: 159 pmol/L, IQR 96-243) patients and this difference was also seen for synovial RANKL expression. Serum RANKL associated with ACPA and bone erosions in rheumatoid factor (RF) negative patients ($p < 0.05$). Among ACPA specificites, anti-cit-vim was associated with higher RANKL concentration and higher prevalence of bone erosion ($p < 0.05$). Significant reductions in both serum RANKL and ACPA levels were observed after 3 months of MTX treatment ($p < 0.05$).

Conclusion:

RANKL was elevated in ACPA-positive and in anti cit-vimentin positive early untreated RA patients and associated with bone erosions. These findings give further support for an early direct pathogenic link between ACPA and bone destruction in RA.

DAS28-ESR and DAS28-CRP Are Not Exchangeable in Daily Clinical Practice: Data from a Large Outpatient Cohort

Alexander Langer[1], Oliver Wiemann[2], Stephanie G. Werner[2], Felicitas Spiecker[3], Sabine Mettler[3], Gudrun Lind-Albrecht[2] and Hans-Eckhard Langer[4], [1]Department of Computer Science, RWTH Aachen University, Aachen, Germany, [2]RHIO (Rheumatology, Immunology, Osteology), Duesseldorf, Germany, [3]RHIO (Rheumatology, Immunology, Osteology) Duesseldorf, Duesseldorf, Germany, [4]RHIO (Rheumatology, Immunology, and Osteology), Duesseldorf, Germany

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

The original DAS28 is based on the erythrocyte sedimentation rate (ESR). An alternative formulation uses the C-reactive protein (CRP). Previous research[1,2,3] suggests that in comparison the DAS28-CRP underestimates disease activity, and therefore new thresholds[4,5] for levels of disease activity should be used. In this study, we compare the DAS28-ESR and DAS28-CRP data of patients from our outpatient center and derive a formula to convert between the two formulations.

Methods:

A total of 996 patients with RA (n=399, 307 female), PsA (n=356, 235 female) and undifferentiated arthritis (n=242, 176 female) were included in this retrospective study. A sub-cohort with early-arthritis (disease duration ≤ 2 years) includes 248 subjects (206 female) with a definite diagnosis of RA (n=200) or PsA (n=48). For each patient and each visit, the DAS28-ESR and the DAS28-CRP were computed. The mean, standard deviation and skewness were used to obtain a normalization formula to convert the DAS28-CRP scores via

$$\text{DAS28-conv} = 13.1 * (((\text{DAS28-CRP} - 2.53) * 1.15 + 2.91)^{0.2} - 1)$$

For 5254 individual DAS28 records, we computed the number of patients with remission, low, medium and high disease activity for the DAS28-BSG and the converted DAS28-CRP ("DAS28-conv") using the standard DAS28-ESR thresholds, and the number of patients in remission and with low disease activity using the cut-off-points for DAS28-CRP (<2.4, ≤ 2.9) suggested by Fleischmann et al[4].

Results:

The results are summarized in the following table (r/l/m/h = remission/low/medium/high disease activity)

cohort / n. entries	DAS28-ESR	DAS28-CRP	correlation	DAS28-conv	DAS28-ESR r/l/m/h	Fleischmann et al. cut-offs r/l	DAS28-conv r/l/m/h
all patients n=5254	2.91 ± 1.22	2.53 ± 1.06	0.89 p < 0.001	2.91 ± 1.31	2331/995/1652/276	2013/871	2292/813/1848/301
female n=4154	2.99 ± 1.89	2.57 ± 1.04	0.88 p < 0.001	2.97 ± 1.29	1697/819/1419/219	1482/691	1702/661/1559/232
male n=1100	2.58 ± 1.27	2.39 ± 1.10	0.89 p < 0.001	2.70 ±1.35	634/176/233/57	531/180	590/152/289/69
RA n=2285	3.04 ± 1.26	2.62 ± 1.12	0.90 p < 0.001	3.00 ± 1.36	911/453/760/161	830/340	941/328/848/168
PsA n=1467	2.93 ± 1.22	2.61 ± 1.06	0.89 p < 0.001	3.01 ± 1.29	659/270/459/79	531/232	605/223/550/89
undiff. arthritis n=1502	2.69 ± 1.12	2.33 ± 0.92	0.85 p < 0.001	2.67 ± 1.21	761/272/433/36	652/299	746/262/450/44
early arthritis n=3241	2.77 ± 1.14	2.41 ± 0.96	0.87 p < 0.001	2.77 ± 1.14	1560/632/941/108	1356/586	1540/538/1040/123

Conclusion:

Our data confirms earlier findings that the DAS28-CRP underestimates the disease activity. On the other hand, the new DAS28-CRP cut-off points of Fleischmann et al. seem to be too strict with significantly fewer patients in remission and low disease activity.

The data suggests that a normalization formula can be used to convert between the two formulations, resulting in higher classification agreement within our cohort. More research is needed to validate the formula against larger datasets.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The process of patient reported outcome (PRO) validation requires demonstration that the concept being measured and the patient experience of the corresponding symptom or impact are aligned. The NIH Patient Reported Outcomes Measurement Information System (PROMIS) provides standardized measures across the illness continuum of domains of physical, mental, and social health. Whether items contained within PROMIS item banks and short forms (SF) are felt to be relevant to people living with rheumatoid arthritis (RA) has not been previously reported.

Methods: We administered surveys to RA patients (pts) seen for routine care in an academic rheumatology practice. Routine clinical (MD global, joint count, pt global, pain, and fatigue VAS) and demographic data were collected. Surveys included PROMIS SFs for Physical Function (PF) 20a; Pain Interference (PI) 8a, Fatigue 7a and 8a, Ability to Participate in Social Roles and Activities 8a (PSRA), and Depression 8a. Pts also completed the PROMIS Profile 29 v 2.0, which contains 4 item assessments for these domains. For each domain, patients rated the relevance of items within the SF to their disease experience and the importance of the symptom to their disease. We also queried how much patients were able to separate their overall symptom experience from that due to RA (e.g., "How much of your fatigue is due to your RA?"). Mean PROMIS T-scores were calculated.

Results: Fifty two pts (86.5% female, 88.5% Caucasian, 31% HS education or less) were surveyed with a mean (SD) age of 52.5 (13.5) yrs, disease duration of 14.7 (11.4) yrs, and CDAI 9.7 (15). PROMIS T-scores were similar using SF of different lengths, though the magnitude of difference was greatest for the PF measures. RA patients had worse PF, PI, and Fatigue that exceeded 0.4SD from the general population norm of 50 (Table 1). More than 60% of respondents reported that the SF items in a domain completely or mostly reflected their experience due to their RA. For PF and PSRA almost half of patients considered *both* their symptom in general and their symptom due to RA when answering items (55.8 and 48.1%). When answering items on PI, 51.9% were thinking only of their RA. However, most (>88 %) would not have responded differently to the questions if instead asked "due to their RA". Most patients attribute problems with PF and PI to their RA, but not problems with sleep, emotional health, or PSRA. Most patients (>75%) considered all domains very important. Almost all (>85%) did not feel that additional questions needed to be asked regarding these symptoms.

Conclusion: These results provide preliminary evidence of the content validity in terms of importance and relevance of selected PROMIS domains and SF items from the perspective of people living with RA. Additional studies in a broader group of pts are needed.

Table 1. PROMIS short form T-scores for each domain.

Domain/Symptom	Short Form		
Physical Function (PF)	**4a**	**20a**	
	43.9 (10.2)	41.9 (11.5)	
Pain Interference (PI)	**4a**	**8a**	
	56.3 (9.8)	55.9 (9.9)	
Fatigue	**4a**	**7a**	**8a**
	54.1 (13.4)	54.5 (11.3)	54.5 (13.5)
Ability to Participate in Social Roles and Activities (PSRA)	**4a**	**8a**	
	48.9 (10.5)	48.8 (11.1)	
Depression	**4a**	**8a**	
	51.1 (10.7)	50.2 (11.5)	
Anxiety 4a	50.3 (10.5)		
Sleep 4a	51.4 (9.8)		
Legacy PROs	**Mean (SD)**		
Patient Global VAS	34 (29.9)		
Pain VAS	3.8 (3.5)

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

To compare the sensitivity of the EULAR and SDAI50 response measures (RMs) and their impact on future response to treatment in patients with early rheumatoid arthritis (RA).

Methods: Biologic naïve RA patients from the Canadian early ArThritis CoHort (CATCH) who had baseline, 3 and 6 months complete data were evaluated. Kappa statistics & Spearman correlation were used to assess the correlation between the EULAR and SDAI50 RMs. The RMs at 3 months were also compared for their ability to predict low disease state (LDAS) or remission (REM) at 6months.

Results: A total of 419 patients were evaluated. Of those, 198 (47.2%) and 206 (49.1%) patients failed to achieve a EULAR and SDAI50 RMs respectively. A strong correlation was observed between the EULAR and SDAI50 RMs with a Kappa of 0.66 (95% CI 0.58- 0.73) and Spearman coefficient of 0.66 ($p < 0.0001$). Throughout the range of disease activity, the SDAI50 response was shown to be more stringent than the EULAR response. Multivariate linear regression analysis demonstrated that SDAI50 at 3 months had a more significant impact on achieving low disease state or remission at 6 months compare to the EULAR response.

Conclusion: Our results suggest there is a strong overall correlation between the EULAR and SDAI50 RMs however a minority of patients can be identified with discordant RMs at the two ends of disease activity spectrum at baseline. Nevertheless the SDAI response at 3 month was a better predictor of outcomes at 6 months than the EULAR response.

Disease Activity Predicts ABCB1 and ABCG2 Drug-Efflux Transporters Function in Rheumatoid Arthritis (RA) Patients

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: ABCB1 (P-gp) and ABCG2 (BCRP1) are part of the adenine triphosphate (ATP)-binding cassette transporter proteins. These proteins can modulate inflammatory responses and mediate efflux of drugs from cells. Several disease modifying anti-rheumatic drugs are among the substrates of ABC transporters.

The objectives of this study were to compare drug efflux function of ABCB1 and ABCG2 transporters in patients with active and inactive RA and investigate the impact of disease activity and treatment on transporter function.

Methods: Seventeen patients with RA (ACR/EULAR criteria) active (DAS28 ≥3.2 at study inclusion) and 17 with inactive RA (DAS28<2.6) were selected from the Early Arthritis Clinic (Dec 2013-January 2015). Patients were paired according to age, gender and disease duration. All patients had medical evaluation and serum sample at study inclusion. Furthermore, 27 of them had an additional sample and clinical evaluation after six-months.

ABCB1 and ABCG2 functional activity was measured in peripheral mononuclear cells by flow cytometry. The percentage of cells able to extrude substrates for ABCB1 (daunorubicin) and ABCG2 (mitoxantrone) were recorded in the presence or absence of the selective ABCB1 (verapamil) or ABCG2 (KO143) inhibitors. Efflux activity was defined as a percentage greater than the mean in 30 healthy controls plus two standard deviations, i.e. 1.67% (range 0.26% to 1.98%).

The study was approved by our internal review board. All patients signed informed consent.

Statistical analysis. Appropriate tests were used according to variable distribution and linear regression model to establish the association between disease activity and transporter´s function.

Results:

Data from 34 patients (94.1% women) were analyzed. Mean ± SD age: 41.6 ± 11 years, disease duration was 6.3 ± 3.5 years; patients with active disease (DAS28: 4.8 ± 1.3) had significantly higher baseline and cumulative corticosteroids doses than inactive patients (DAS28: 1.2 ± 0.6): 10.1±5 vs. 6.3±2.1 mg/day, p=0.03 and 4041±1849 vs. 2348.5±859.5 mg, p=0.004, respectively. No other remarkable differences were seen.

Active patients had higher ABCB1 activity, median (25-75 IQR): 7.1% (1.4-29.3) vs. 1.6% (0.7-3.5); p=0.02 and ABCG2 activity: 6.2% (1.3-22.4) vs. 1.3% (0.7-2); p=0.007.

The ABCB1 and ABCG2 activity correlated with DAS28: rho=0.45, p=0.008 for ABCB1 and rho=0.52, p=0.002, for ABCG2. No correlation was found with cumulative corticosteroids or other treatment.

Linear regression model applied to the 34 patients at baseline showed DAS28 as the only predictor of both ABCB1 (beta coefficient: 0.50; 95%CI: 1.6-6.7; p=0.002; R2=0.23) and ABCG2 (beta coefficient: 0.48; 95CI%: 1.4-6.8; p=0.004; R2=0.21) function.

Disease activity increased in 14.8% of the patients at 6 month follow-up, while 48.1% remained stable and 37.1% improved. DAS28 changes at this time correlated with shift in ABCB1 (r=0.35, p=0.07) and ABCG2 (r=0.33, p=0.09) function.

Conclusion:

Patients with active RA have a higher efflux function of ABCB1 and ABCG2 compared with those in remission at baseline. ABCB1 and ABCG2 behavior is conditioned by disease activity.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Serum 14-3-3 eta has been described to have diagnostic utility and in established RA an association has been established between the levels of this marker and the degree of joint damage. The η isoform of 14-3-3 is expressed extracellularly in much higher concentration than the ϒ isoform or MMP 1 and 3 levels in the synovial fluid and serum of patients with rheumatoid arthritis compared to the normal population. Rheumatoid factor (RF) is known to be sensitive and anti-CCP highly specific for RA, but a high number of patients remain seronegative .There is a need for a biomarker to prevent underdiagnosis in this subset.

The purpose of the study was to investigate if serum 14-3-3 η enhanced the detection of RA over RF or anti-CCP in RA patients. We also studied the utility of 14-3-3 eta as a diagnostic test by comparing presence of this protein in RA v/s non-RA patients.

Methods:

A retrospective chart review study was conducted in RA patients at an outpatient rheumatology clinic in an inner city population at a community teaching hospital serving a large immigrant population. 90 RA patients were identified who satisfied the 2010 ACR diagnostic criteria and 37 non RA patients seen in the clinic for other rheumatologic conditions were chosen as the control group. Serum 14-3-3η protein was measured by ELISA. The positive threshold range using Quest Diagnostic for RF was 15 International Unit/ml, Anti CCP was 20 Units and for 14-3-3 eta was 0.2 ng/mL. The chi-square goodness-of-fit test was used to analyze the frequency of eta positivity in the RA population while kappa was calculated to compare the RA and non RA patients.

Results:

Of the 90 RA patients, 75.8 % were females and mean age was 58 (range 28- 90) years. The population was predominantly Hispanic (75%). In the non-RA group, 9% had psoriatic arthritis and 14% lupus, 73% were females, 76% Hispanic and the mean age was 54 (range 19-93) years. In the non-RA population, 22 patients were ETA positive, of these 11 patients were also RF positive and 9 were ACPA positive. In the RA population, 1 RF negative patient was ETA positive, while 47 patients were both ETA and RF positive. Further 1 patient was found to be ETA positive with a negative ACPA, while 47 patient's were both ETA and ACPA positive.

Table I: Non-Rheumatoid Arthritis Patients

	ETA Negative		ETA Positive		
Variable	N	%	N	%	Chi-sq test
Gender					
male	5	[18.5]	6	[55]	0.0377
female	22	[81.5]	5	[45]	
Race					
hispanic	21	[77.8]	8	[72.7]	1
not hispanic	6	[22.2]	3	[27.3]	
RF					
0	25	[92.6]	0	[0]	6.48E-008
1	2	[7.41]	11	[100]	
ACPA					
0	24	[88.9]	2	[18.2]	6.09E-005
1	3	[11.1]	9	[81.8]	

Table II: Rheumatoid Arthritis Patients

	ETA Negative		ETA Positive		
Variable	N	%	N	%	Chi-sq test
Gender					
male	6	[14.3]	15	[31.2]	0.0804
female	36	[85.7]	33	[68.8]	
RACE					
hispanic	29	[69]	38	[79.2]	0.336
not hispanic	13	[31]	10	[20.8]	
RF					
0	25	[59.5]	1	[2.08]	4.27E-010
1	17	[40.5]	47	[97.9]	
ACPA					
0	21	[50]	1	[2.08]	0.00E+000
1	21	[50]	47	[97.9]	

Conclusion:

In our population, measurement of 14-3-3η ETA offered limited additional diagnostic value when compared to RF and ACPA. Furthermore, it was found to offer no additional value in differentiating RA from other inflammatory arthropathies where RF can also be found positive.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

The Multidimensional Health Assessment Questionnaire (MDHAQ) was designed to assess quality of life impairment including psychological distress in rheumatoid arthritis (RA) patients. In addition to ten questions addressing the patient's physical activity (Q1-10), MDHAQ also includes the following three questions (4-point scale: 0, 1, 2, and 3), which address the psychological state of the patient: "Get a good night's sleep?"(Q11), "Deal with feelings of anxiety or being nervous?"(Q12), and "Deal with feelings of depression or feeling blue?"(Q13). The utility of these questions has yet to be investigated.

The purpose of the study is to identify RA patients suffering from anxiety and depression using MDHAQ in daily clinical practice

Methods:

A previously validated Japanese version of MDHAQ was used in this study [1]. Hospital Anxiety and Depression Scale (HADS) was used to detect RA patients suffering from anxiety and depression. The validation of MDHAQ (Q11, Q12, and Q13) included test-retest reliability, content validity, and concurrent validity.

Results:

A total of 348 patients were included in this study. Mean (SD) age and disease duration in the validation study population were 65.2 (12.1) years and 11.4 (10.5) years, respectively.

The proportion of cases with possible anxiety (HADS-Anxiety (HADS-A) ≥8) and probable anxiety (HADS-A ≥11) was 7.9% and 21.4%, respectively, whereas the proportion of cases with possible depression (HADS-Depression (HADS-D) ≥8) and probable depression (HADS-D ≥11) was 7.9% and 24.7%, respectively.

The test-retest reliability of Q11, Q12, and Q13 (50 patients) was 0.730, 0.757, and 0.708 (Spearman's rank correlation coefficient), respectively. The internal reliability of Q11, Q12, and Q13 was 0.930, 0.628, and 0.680 (Chronbach's α), respectively. The correlation between Q11 and 12, Q11 and 13, and Q12 and 13 was 0.503, 0.463, and 0.891 (Spearman's rank correlation coefficient), respectively. The correlation between Q12 and HADS-A, and Q13 and HADS-D was 0.557 and 0.420 (Spearman's rank correlation coefficient), respectively.

In screening for patients with probable anxiety, Q12 ≥1 showed a sensitivity of 82.6 % and a specificity of 40.6% while Q12 ≥2 showed a sensitivity of 21.7% and a specificity of 98.6%. In screening for cases with probable depression, Q13 ≥1 showed a sensitivity of 62.5% and a specificity of 68.7% while Q13 ≥2 showed a sensitivity of 8.3% and a specificity of 97.9%. Among the 7 ACR Core Data Set measures, all 3 patient-reported outcomes (patient global assessment, pain VAS, and HAQ) and tender joint counts were significantly worse in patients with Q13 ≥1 than in patients with Q13=0 but other 3 ACR Core Data Set measures (swollen joint count, physician global assessment, and acute phase reactants) were similar for both groups.

Conclusion:

MDHAQ was found to be suitable for use in daily practice for identifying RA patients with probable anxiety and depression.

Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with chronic inflammatory disorders such as rheumatoid arthritis (RA) or spondyloarthritis (SpA) create personal sets of fears and beliefs related to their disease. These fears and beliefs may influence the patient-physician relationship and potentially treatment adherence. Little is known about these fears and beliefs in the era of biologics.[1] The purpose of this study was to describe the most frequent fears and beliefs in RA and SpA patients.

Methods: These analyses used cross-sectional assessment of unselected patients with a diagnosis of RA (ACR/EULAR criteria) or axial SpA (axSpA)(ASAS criteria) in France in 2014. The study was proposed to all rheumatologists in France and consecutive patients recruited through the first 51 rheumatologists agreeing to participate. A self-reported 44-item questionnaire (25 items on fears, 19 on beliefs) was built and preliminarily validated for this study. Each item was scored 0–10 (10 indicating higher fears/beliefs).[2] The analysis was descriptive for the 5 fears and the 5 beliefs, most frequently scored as ≥7/10, in both RA and axSpA patients.

Results: Overall, 226 patients (161 RA and 65 axSpA; 64.4% female) were analyzed: patients had a mean disease duration of 11.9 vs 13.8 years and mean patient global assessment was 31/100 vs 41/100 for RA vs axSpA patients, respectively. Of 25 fear items, the 6 most frequently-reported fears were: “afraid of suffering again” (66.7% scored this as ≥7/10), “afraid of losing control and autonomy” (61.4%), “afraid of being a burden for relatives” (59.6%), “afraid of losing all joint mobility” (58.9%), “afraid of the spread of the disease to other joints” (58.6%) and “afraid of the consequences of my disease on my professional activity” (58.6%). Of 19 belief items, the 5 most frequently-reported beliefs were: “flares are triggered by fatigue” (41.7%), “physical activity reduces flares” (38.7%), “flares are triggered by changes in the weather” (37.3%), “flares are triggered by physical effort” (37.1%) and “the disease is linked to a genetic cause” (36.9%).

Conclusion: This study highlights the main fears and beliefs from a patient perspective using a novel questionnaire specific for chronic inflammatory arthritis. Consistent work needs to be performed to better document the effect of these fears and beliefs on adherence, disease care and progression.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

The main cause of mortality in patients with rheumatoid arthritis (RA) is atherosclerotic cardiovascular disease (ASCVD). RA patients have a 10-year decrease in life expectancy when compared to healthy controls. Reports of ASCVD outcomes in Hispanic RA patients is scarce. The objective of the present study is to determine the mortality of a Hispanic RA cohort followed for a 10-year period, and its relation to the presence of carotid plaque (CP) after initial carotid ultrasound evaluation.

Methods:

An observational, longitudinal, descriptive study was designed based on a cohort that included 124 Hispanic patients with RA who fulfilled the ACR 1987 classification criteria. A telephonic questionnaire was applied to the subjects or family members to determine ASCVD-related mortality and new onset of comorbidities (hypertension, diabetes, dyslipidemia, acute myocardial infarction, stroke, arrhythmias, heart failure, angina, and chronic kidney disease). A descriptive analysis of current and past comorbidities was carried out. Survival analysis was performed with Kaplan-Meier curves. Log-Rank test was used to compare between patients with and without carotid plaque (CP), considering statistically significant a difference in mortality if a value of $p<.05$ was obtained.

Results:

The original cohort included 124 subjects of which 52 were lost to follow-up. A total of 72 patients were included in the analysis (Table 1). CP was present in 44 (61.11%) of the patients. Of the 72 patients, 11 (15.3%) had died: 7 (9.7%) of them due to ASCVD (4 myocardial infarctions, 2 strokes, 1 heart failure), 2 of non-cardiovascular causes and 2 in traffic accidents. Diabetes mellitus type 2 was diagnosed in 6 (10.6%) of the remaining patients, hypertension in 24 (39.34%) and dyslipidemia in 12 (25%). Only 1 patient had a non-lethal myocardial infarction. In the CP group, 8 (18%) had died against 3 (10.7%) of the patients without CP (Figure 1). The majority of ASCVD-related deaths occurred in patients with CP, although there was no difference in mortality (p=.373).

Conclusion:

ASCVD was the most frequent cause of death in this cohort. In a 10-year period, there was no difference in mortality in RA in relation to the presence of CP. Prospective studies with a greater sample are necessary to corroborate this finding.

Table 1. Demographical data at baseline. Comorbidities at baseline and at follow up

Feminine, n (%)	68 (94.4)

Rheumatologists More Likely to Perform Tobacco Cessation Counselling in Uncontrolled Rheumatoid Arthritis Visits

Andrew Vreede[1], Katya Voelker[2], Joanna Wong[3] and **Christie M. Bartels**[4], [1]Internal Medicine, University of Wisconsin Hospitals and Clinics, Madison, WI, [2]University of Wisconsin School of Medicine and Public Health, Madison, WI, [3]Tufts School of Medicine, Boston, MA, [4]Medicine, Rheumatology, University of Wisconsin School of Medicine and Public Health, Madison, WI

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Tobacco use is a risk factor for developing rheumatoid arthritis (RA) and a predictor of more severe disease and heightened cardiovascular disease (CVD) risk. Despite these known health effects, there is significant variation in rheumatologists performing tobacco cessation counseling. Herein we examine the frequency and predictors of tobacco discussions in RA visits among a cohort of RA patients with at least one additional CVD risk factor. We hypothesized that tobacco cessation counseling would occur more frequently in patients with well-controlled RA due to fewer competing demands for clinical time.

Methods: Electronic health records were used to identify RA patients with either high cholesterol or uncontrolled blood pressure in 3 rheumatology clinics (2004-2011) within an academic center for a prior study. Uncontrolled cholesterol was defined as LDL >100 in individuals with diabetes, CVD or chronic kidney disease or LDL>130 without one of these conditions. Uncontrolled blood pressure was defined according to JNC-7. Trained abstractors reviewed clinic notes using a standardized tool to identify CVD risk discussions including tobacco counselling, and to assess perceived RA control. Perceived RA control was defined as subjectively stated by a rheumatologist in the visit note. We used logistic regression to calculate the odds ratios (OR) and 95% confidence intervals reflecting RA control as a predictor of tobacco cessation counseling after controlling for sociodemographics, comorbidity (ACG score) and clinic.

Results: 3707 RA visits were abstracted, of which 360 visits involved active tobacco users. RA tobacco users had a mean age of 53 years, 73% were female, 79% white and BMI of 29 ± 7 (mean ± SD). Physician-perceived well-controlled RA was present in 31% of

tobacco user visits (42% of non-user). Of the 360 visits, documentation of smoking status occurred in 43% of visit notes. Counseling was only documented in 10% of total visits (n=37). In contrast to our hypothesis, patients with well-controlled RA were less likely to receive tobacco cessation counseling (OR 0.25, 0.09-0.68; Table 1). Obese BMI was an additional negative univariate predictor. Positive univariate predictors of tobacco cessation counseling included CVD, pulmonary disease, hypertension, or anxiety-depression at baseline. In a multivariate model RA control remained significant, as did pulmonary disease, and obesity. Limitations of our study include small size and reliance upon physician documentation for occurrence of counseling events.

Conclusion: Perceived uncontrolled RA predicted more likely tobacco cessation counseling by rheumatologists, but overall rates were low. Given the clear negative health effects of smoking on patient's RA disease severity and CVD risk, systematic efforts are needed to employ evidence based practices for promoting tobacco in rheumatology clinics.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Questionnaires assessing the beliefs of patients with chronic rheumatic diseases mainly focus on medications.[1] A validated questionnaire evaluating patients' fears and beliefs towards their disease and therapeutic strategy could improve specific counseling and educational programs. The purpose of this study was to develop and validate a patient-reported questionnaire to assess the fears and beliefs of patients suffering from rheumatoid arthritis (RA) or spondyloarthritis (SpA).

Methods: Step 1: qualitative research (individual patient interviews: 25 RA, 25 axial SpA [axSpA]).[2] Step 2: all fears and beliefs appearing in more than 10% of interviews rephrased as questions by an expert group including a patient-partner. Each question scored 0–10 (10=higher fears/beliefs). Step 3: preliminary questionnaire tested by cognitive debriefing (5 RA and 5 axSpA patients), and reproducibility through a test-retest procedure among 28 patients (13 RA, 15 axSpA). Step 4: psychometric validation through a cross-sectional study of 226 patients. Internal consistency assessed by Cronbach's alpha, principal components analysis and descending hierarchical classification. Step 5: scoring results: descriptive presentation of the number of patients with scores ≥7/10, for ≥50% of the questions for a given domain, based on the psychometric validation.[3]

Results: Steps 1–3: development and adaptation of a self-reported 44-item questionnaire on a 0–10 scale of fears and beliefs. Step 4: in the study of 226 patients (161 RA, 65 axSpA), mean DAS28 was 2.5/10 (RA patients) and the mean BASDAI was 25.9/100 (axSpA patients). Based on the psychometric validation, the following domains were identified: fears of the disease progression or consequences (18 items), fears about treatment (5), beliefs related to: psychological influence (2), genetic influence (2), physical influence (4), diet influence (4), lifestyle (3) and diverse opinions (4). Step 5: the 3 domains with the highest number of patients with scores ≥7/10, for ≥50% of the questions for a given domain were: fears of the disease progression or consequences (55.3%), beliefs related to psychological influence (48.2%) and fears about treatment (46.9%).

Conclusion: This analysis indicates the internal consistency of the questionnaire developed. The questionnaire and the scoring results by domain should help physicians to better understand their patients' perceptions of their disease, thus improving the patient-physician dialogue and eventually leading to a better adherence to treatment.

Association of Medication Beliefs, Self-Efficacy, and Adherence in a Diverse Cohort of Adults with Rheumatoid Arthritis

Caroline McCulley[1], Patricia P. Katz[2], Laura Trupin[2], Edward H. Yelin[3] and Jennifer Barton[4,5], [1]Internal Medicine, Providence Portland Medical Center, Portland, OR, [2]Rheumatology, UCSF, SF, CA, [3]University of California, San Francisco, San Francisco, CA, [4]Rheumatology, OHSU, Portland, OR, [5]Rheumatology, VA Portland Healthcare System, Portland, OR
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III
Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Adherence to disease-modifying anti-rheumatic drugs (DMARDs) among rheumatoid arthritis (RA) patients ranges from 30% to 107%, leading to potential adverse outcomes. Patient beliefs about medications and self-efficacy have been associated with decision-making and adherence. The aim of this study was to assess the association among medication beliefs, self-efficacy, and adherence to oral DMARDs among diverse populations with RA.

Methods:

Data were derived from RA patients enrolled in a longitudinal observational cohort (Rheumatoid Arthritis Outcomes Study; RAOS). Subjects completed a telephone interview in 2012-2013 in English or Spanish that included measures of self-reported adherence (missing ≥1 dose in past week was considered to be poor adherence) and the Beliefs about Medicine Questionnaire (BMQ). The BMQ consists of two 5-question subscales (specific necessity scale and specific concerns scale), which are scored from 1 to 5 (agree strongly to disagree strongly), summed and averaged. Higher scores indicate greater belief in medication necessity or stronger concerns (e.g., beliefs about potential long-term effects of taking medication). Logistic regression was used to estimate the association of poor adherence with the BMQ subscales, with and without adjustment for depressive symptoms, self-efficacy (Self-Efficacy for Managing Chronic Disease 6-item Scale), demographics (race/ethnicity, age, gender, education) and RA disease activity (global assessment).

Results:

Of 438 patients, 88% were female, 29% Latino, mean age 61±13 years, 32% had high school education or less, 75% reported taking a synthetic DMARD. Only 14% reported poor adherence to oral DMARDs. In terms of medication beliefs, 64% reported that having to take medicines worries them, 81% reported they sometimes worry about long-term effects of medicines, and 47% reported worrying about becoming dependent on their medicines. However 91% agreed with the statement "my health, at present, depends on my medicines" and 92% agreed that "my medicines will protect me from becoming worse." In multivariate analyses, the BMQ necessity score – but not the concerns subscale – was associated with lower odds of poor adherence. Self-efficacy conversely was associated with higher odds of poor adherence (table).

Conclusion:

In a diverse cohort of patients with RA, our data suggest that patients who report stronger beliefs in the necessity of medication are more likely to adhere to their DMARDs. Higher self-efficacy scores were associated with greater odds of poor adherence. Given the often sub-optimal adherence to DMARDs, providers can play an important role in enforcing positive patient beliefs about medications to improve adherence and ultimately health outcomes. Further research is needed to explore how best to inform positive medication beliefs among diverse populations with RA.

Table. Unadjusted and adjusted odds ratios of poor self-reported adherence to oral synthetic DMARDs among a diverse cohort of adults with RA

	Unadjusted OR (95% confidence interval)	Adjusted* OR (95% CI)
BMQ concerns subscale	1.24 (0.96-1.61)	0.96 (0.68-1.35)
BMQ necessity subscale	0.89 (0.65 – 1.23)	**0.68 (0.47-0.99)**
Self-efficacy	1.09 (0.95-1.26)	**1.25 (1.03-1.53)**

*Includes: age, gender, self-efficacy, race, education, depressive symptoms, RA disease activity VAS, mean BMQ subscale as indicated

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Vulnerable populations with rheumatoid arthritis (RA) experience poorer health outcomes despite access to current therapies. These disparities may result from limited health literacy, cultural barriers, or mood disorders leading to negative beliefs and concerns about medications, which are in turn associated with poor medication adherence. RA patients with limited health literacy also report suboptimal patient-provider communication and shared decision making, suggesting missed opportunities to address negative beliefs about medications. Prior research has demonstrated these pathways to disparities in other conditions such as HIV but has not been studied in RA. Our objective was to examine associations between health literacy, ethnicity, communication with physicians, and mood, with beliefs about medicine in a diverse population with RA.

Methods:

Data were derived from RA patients enrolled in a longitudinal observational cohort (Rheumatoid Arthritis Outcomes Study or RA OS). Subjects completed a telephone interview in either English or Spanish that included measures of patient-provider communication, health literacy, depressive symptoms (PHQ), demographics and the Beliefs about Medicine Questionnaire (BMQ). Linear regression was performed to identify correlates of the two subscales of the BMQ – necessity of taking RA medications and concerns about medication use and long-term effects.

Results:

Of 438 patients, 88% were female, 29% were Latino, 32% had high school education or less and 30% had limited health literacy. Mean age was 61 (SD 13) years and mean disease duration was 23 (SD 12) years. Subjects with limited health literacy were more likely than those with adequate literacy to be female, of Latino ethnicity, have high school or less education, and have depressed mood. More than half of subjects with adequate health literacy reported their doctor “always” spent enough time with them (63%) compared to only 48% of those with limited health literacy ($p=0.006$). Subjects with limited health literacy had more concerns about medicines compared to those with adequate literacy ($p<0.001$) as did those who did not report that their doctor always spend enough time with them ($p<0.001$). In multivariate linear regression, limited health literacy, depression, Latino ethnicity, female gender, younger age and reports that the doctor did not “always” spend enough time were associated with stronger concerns about medicines. None of these factors was associated with perceived necessity of medicines.

Conclusion:

Among a diverse cohort of adults with RA, limited health literacy, Latino ethnicity, depressed mood and lower perceived quality of communication with the doctor were independently associated with stronger concerns about medicines. This may in turn be associated with poorer adherence and poorer outcomes in these vulnerable populations who also have significant barriers to communication. Future research should focus on knowledge transfer, including evidence based risk and benefit information, and promotion of patient engagement in shared decision making to reduce disparities.

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

The utility of synovial biopsy has been confirmed as an important research tool in increasing our understanding of the pathogenesis of RA, evaluating new treatments and identifying potential therapeutic targets.[1, 2] However, no scoring system for the assessment of synovitis at knee arthroscopy has been validated against the histological grade of inflammation observed in the synovial biopsies retrieved.

Furthermore, the power that arthroscopy may have in identifying patients with active inflammation despite normal CRPs has not been reported. Finally, we currently understand only 32% of the variance in factors that predict joint destruction,[3] and macroscopic findings at arthroscopy may present an additional opportunity in assessing those most at risk of this disease course.

Aims

To validate synovitis scores at arthroscopy with histology scores, CRP levels and erosive disease on radiographs.

Methods:

141 patients with RA were recruited to undergo arthroscopy, and serum CRP levels were measured at the same time. The most recent set of hands and feet radiographs were assessed for the presence or absence of erosions. A macroscopic score of synovitis, graded at 5 unit intervals between 0-100, was recorded by the operator at each arthroscopy.

Synovitis scores were analysed using Pearson's test for correlation, with categorical data for histology findings (no inflammation, mild inflammation, and moderate-severe inflammation).The same test was used to determine if there was a correlation between synovitis scores and CRP levels.

The Chi-square test was employed to test for a relationship between categorical synovitis scores (4 quartiles), and the presence or absence of erosions.

Results:

A correlation was observed between synovitis scores and histology findings ($p=0.0014$, $r=0.2943$).

There was no correlation with synovitis scores and CRP levels. 49 (34.8%) patients had normal CRP levels (0-5mg/l), with 29 (59.2%) having synovitis scores >50%.

An association was also observed with higher synovitis scores and the presence of erosions ($p=0.0173$).

Conclusion:

Synovitis can be reliably assessed by scores at arthroscopy, which correlate with subsequent histological findings. Arthroscopy has the power to identify patients with synovitis, where CRP levels are normal, favouring the concept that not all RA phenotypes manifest elevated CRP levels during active disease. Furthermore, those with high synovitis scores are more likely to have erosions on radiographs.

Title: Comparison of Arterial Health in Patients with Rheumatoid Arthritis to a Population-based Cohort

Background/Purpose: Patients with rheumatoid arthritis (RA) have increased risk of cardiovascular disease (CVD). Vascular stiffness is associated with increased cardiovascular risk in the general population. We aim to characterize the differences in arterial health, including vascular stiffness and endothelial function between patients with RA and no history of CVD and a population-based cohort of non-RA patients without a known history of CVD or RA.

Methods: A set of arterial health tests were carried out in patients with RA who were seen in our institution's Cardio-Rheumatology Clinic as part of a cardiovascular risk assessment. Assessment included 2-D carotid artery ultrasound, brachial artery reactivity, and arterial tonometry. Data from these patients were compared to normative data from the institution's cardiovascular healthcare clinic. Each patient with RA was matched on age and sex to 10 subjects from the comparison cohort. Diagnosis of RA was made by rheumatologists according to the 2010 American College of Rheumatology/ European League Against Rheumatism criteria. Comparisons between cohorts were performed using conditional logistic regression.

Results: The study cohort included 28 patients with RA (mean age: 58.1 [SD:10.4] years; 82% female) compared to 280 controls (mean age: 58.4 [SD:9.7] years; 82% female). Flow-mediated dilation (FMD) was higher in the patients with RA (8.7±6.3 vs 6.2±4.9, p=0.014; Table) than controls. Hyperemic flow was marginally higher in the patients with RA (458±255 vs 403±169, p=0.067). Among our RA cohort, treatments included methotrexate in 61%, corticosteroids in 39% and biologics in 54% at the time of arterial health studies.

Conclusion:

In subjects without a history of CVD, vascular stiffness is similar in patients with treated RA compared with subjects without RA. Patients with RA show a trend toward decreased augmentation pressure, augmentation index and pulse wave velocity, consistent with increased arterial stiffness. Flow-mediated dilation was increased in patients with RA, suggesting better endothelial function. Hyperemic response was similar in both cohorts. It is possible that endothelial function in this population is affected by RA therapies. These measures of arterial stiffness may also have prognostic values for prediction of risk for CVD and lead to more targeted prevention strategies to reduce this risk in this population that is already at higher risk for CVD.

Table

	Control	RA Patients	p-value
	N=280	N=28	
Augmentation Pressure (mmHg)	14.6 ± 7.5	14.1 ± 7.5	0.65
Aortic Pulse Pressure (mmHg)	43.2 ± 14.3	44.7 ± 16.5	0.59
Augmentation Index (%)	32.5 ± 10.1	30.2 ± 10.6	0.23
Pulse Wave Velocity (m/s)	9.5 ± 2.8	8.7 ± 2.0	0.14
Brachial Artery Diameter (mm)	3.5 ± 0.7	3.4 ± 0.8	0.20
Basal Flow (mL/min)	59.0 ± 62.6	71.4 ± 61.6	0.30
Hyperemic Flow (mL/min)	403.4 ± 169.2	458.3 ± 254.6	0.067
Flow Mediated Dilation (%)	6.2 ± 4.9	8.7 ± 6.3	0.014
Hyperemic flow response	0.15 ± 0.12	0.15 ± 0.08	0.75

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Pain is a commonly reported cause of affliction in RA-patients, also after adequate anti-rheumatic treatment. The objective of this study was to investigate the prevalence of unacceptable pain in early RA-patients with good inflammation control after anti-rheumatic treatment and also how this condition may affect the risk of long-term fatigue, sleeping problems and continuous pain.

Methods: Data was compiled from the population-based case control study Epidemiological Investigation of Rheumatoid Arthritis (EIRA) and linked to the Swedish Rheumatology Quality Register (SRQ). All patients were diagnosed with RA according to the 1987 ACR criteria. Early RA-patients with follow-up data both from diagnosis, 1 year and 3 years after diagnosis were included (N=186; 75% women, median age at diagnosis 56 years). Unacceptable pain in spite of good inflammation control at the 1 year follow-up (in the following named “refractory pain”), was defined using the previously validated definition of unacceptable pain (Patient Acceptable Symptom State (PASS) VAS pain ≥ 40) (1), combined with CRP <10 g/L (depicting good inflammatory control). The associated risk for significant fatigue (VAS ≥40), sleeping problems (defined as quite big/very big problem by the patient) and current pain, minimal pain and maximal pain (VAS ≥40, VAS ≥20 and VAS 75th percentile in the group; respectively) at 3 years follow-up was calculated using logistic regression, adjusted for age and sex.

Results: Although a majority of patients (85%) reached good inflammatory control at the 1 year follow-up, 28% of them had unacceptable pain according to PASS. After 3 years, 17% of all patients had sleeping problems and 26% had significant fatigue. Median VAS pain at 3 years was 11 mm. Refractory pain at 1 year was associated with an increased risk of fatigue OR= 2.80 [95% CI:

1.36-5.78] and sleeping problems OR= 4.64 [95% CI: 1.96-10.98] 3 years after diagnosis. Refractory pain also associated with an increased risk of both current pain at the 3 year follow-up OR= 5.17 [95% CI: 2.33-11.47], as well as minimal pain level OR= 5.32 [95% CI: 2.34-12.11] and maximal pain level OR= 5.38 [95% CI: 2.56-11.31] at the 3 year follow-up.

Conclusion: Approximately a quarter of RA-patients have unacceptable pain despite good inflammation control 1 year after diagnosis. This condition strongly predicts fatigue, sleeping problems and continuous pain 2 years later. These findings highlight the insufficiency of anti-rheumatic treatment to suppress long-term pain and fatigue, and support the importance of early acknowledgement and treatment of pain also in patients with good inflammation control.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Measuring disease activity in rheumatoid arthritis (RA) is important in evaluating efficacy of treatments, but many tests are subjective and lead to discordance in patient and physician assessments. Identifying factors contributing to discordance may allow disease activity to be assessed more accurately from patient-centered assessments.

Methods: In 195 patients with RA, demographic information, measures of disease activity, and use of therapeutic agents were assessed by questionnaire. Patient Global Assessment (PtGA) and Physician Global Assessment (PhGA) were assessed by marking level of disease activity on a standard 100mm line with higher scores reflecting more disease activity (range 0-100). Discordance in global assessment (PtGA-PhGA) was stratified into tertiles. Multiple validated scales for an array of psychosocial comorbidities (depression, chronic life stressors, anxiety/anger, social support, discrimination/hassles) were assessed. Quality of life and fatigue were assessed using SF36 and FACIT scores respectively. Multivariable (MV) linear regression was used to fit models predicting discordance in global assessments.

Results: Tertiles of discordance in global assessment were defined as “Physician Higher than Patient (Ph>Pt)” [PtGA<PhGA -52 to -9 (n=65)], Concordant [PtGA=PhGA -8 to +8 (n=66)], and “Patient Higher than Physician (Pt>Ph)” [PtGA>PhGA +9 to +92 (n=64)]. Compared with the Pt>Ph and concordant groups, the Ph>Pt group had significantly higher DAS28 scores with more swollen/tender joints. In contrast, the Pt>Ph group had higher HAQ and pain/pain catastrophizing scores and was more likely to be on no DMARDs compared with the Concordant group. Also, the Pt>Ph group had significantly higher job stress and fatigue, depression, and anxiety scores and lower SF36 total, physical and mental health scores along with slower walking pace and a trend towards less physical activity. In MV models, male gender, slower walking pace, no DMARD use, job and health stress, higher FACIT and lower SF36 Total scores were associated with more discordance in which the PtGA was higher than the PhGA, and more tender/swollen joints, use of a biologic and higher anger scores were associated with more discordance in which the PhGA was higher than the PtGA. Together, these variables explained 51% of the discordance between patients and physicians. The psychosocial variables made up 9.4% of the explainable variability, and tender/swollen joints and slow walking speed were the largest contributors to discordance.

Conclusion: Psychosocial comorbidities, fatigue, quality of life, tender/swollen joints, functional status and type of therapy may explain some, but not all, of the discordance in patient and physician assessments of disease activity in RA.

Table: Selected RA variables and Psychosocial Comorbidities According to Concordance/Discordance of Patient and Physician Global Assessments

	1- More physician PtGA<PhGA (-52 to -9) n=65	2 - Concordant PtGA=PhGA (-8 to +8) n=66	3 - More Patient PtGA>PhGA (+9 to +92) n=64	1 v. 2 p-value	3 v. 2 p-value	1 v. 3 p-value

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: A great challenge in managing rheumatoid arthritis (RA) is the scenario of patient-physician discordance, in which despite seeming control of inflammation, patients suffer from undifferentiated symptoms of pain, fatigue, psychosocial distress, and functional disability. Our aim was to explicate the etiologic domains underlying patient-physician discordance.

Methods: We identified consecutive patients with RA fulfilling the ACR/EULAR 2010 criteria from our outpatient practice. Patients with ≥25-mm difference between patient and provider global assessments (0-100) of disease activity were identified. We abstracted electronic records for RA disease characteristics and comorbidities. Disease activity was classified according to Clinical Disease Activity Index (CDAI). In a sub-study, 50 discordant and 20 concordant patients (10 each with CDAI ≤10 and >10) completed several validated health status instruments (e.g., pain visual analog scale (VAS), Health Assessment Questionnaire II (HAQ-II), Fibromyalgia Research Survey, and the Patient-Reported Outcome Measures Information System (PROMIS) Pain Interference and Ability to Participate surveys) and underwent grayscale (GS) and power Doppler (PD) ultrasonography of the dominant hand, wrist and foot. Differences between discordant and concordant groups were evaluated using chi-square and rank sum tests.

Results: Patient-physician discordance affected 118 (34%) of 351 consecutive visits. The study cohort included 141 of these patients (mean age 61 years, 73% female), with discordant global assessments in 68 (48%). Of the discordant patients, 63 (93%) rated their disease activity as greater than their provider, with median (range) patient global assessment of 57 (2-87) and provider global assessment of 15 (0-80). Discordance was associated with seronegativity (p=0.008 for rheumatoid factor and p=0.035 for anti-cyclic citrullinated peptide (anti-CCP) antibodies), lack of joint erosions (p=0.013), and the presence of comorbid osteoarthritis (p=0.005), depression (p=0.004), and fibromyalgia (p=0.011). The proportion of patients with CDAI >10 was significantly higher in the discordant than concordant group (50% vs. 33%, p<0.001). While usage of RA therapies was similar between groups, discordant patients had greater usage of opioids (p=0.015), antidepressants (p<0.001), and fibromyalgia medications (p=0.018). In the sub-study, higher values for the pain VAS, HAQ-II disability, Fibromyalgia widespread pain index, PROMIS Pain Interference, and PROMIS Ability to Participate questionnaires distinguished the discordant group. On sonographic examination, the discordant group had 66% GS synovitis ≥2 and 38% PD synovitis ≥1.

Conclusion: Our findings demonstrate that a comprehensive framework for evaluation of patient-physician discordance should include domains of seronegativity, fibromyalgia, depression, comorbid osteoarthritis, and persistent synovitis. Further work is necessary to develop a standardized approach for patient-centered evaluation and shared decision-making to improve outcomes for patients with RA in the setting of patient-physician discordance.

Factors Influencing Treatment Adjustments in RA Patients – Biologic DMARD Treatment Start and Options

Peter C. Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Current recommendations for pharmacologic management of rheumatoid arthritis (RA) advise dose titration or switching treatment if goals of remission or low disease activity are not met.

Our objective is to describe factors causing treatment change and choice of drug from non-biologic DMARD to a biologic DMARD (bDMARD), and subsequent progression in bDMARD therapy, in real-world practice.

Methods: Data were drawn from the Adelphi 2014 RA Disease Specific Programme, a survey of rheumatologists and their RA patients in France, Germany, Italy, Spain and UK. Rheumatologists provided patient demographics, clinical details and treatment history including reasons for switching treatment. In bDMARD-naïve patients physicians provided reasons why they would initiate a bDMARD. Summary statistics were used to describe the decision-process of physicians at varying stages of treatment, and to compare bDMARD vs. non-bDMARD patients who were eligible for bDMARD therapy at initiation of current therapy.

Results: 307 rheumatologists provided data for 2536 patients, 71% female, a mean age of 52.8 years and 72.6 months since diagnosis. 63.5% of patients had never received bDMARD therapy (bDMARD naïve), 36.5% had received bDMARD therapy (33.9% currently receiving, 2.6% on a treatment break or had discontinued). 24.8% of patients had only ever received 1 bDMARD.

The main reasons prompting initiation of a bDMARD in naïve patients were worsening of RA severity as assessed by the physician (60.6%) and failure of non-bDMARD therapy (32.5%). bDMARD patients had been diagnosed longer compared to bDMARD-eligible patients who had not received a bDMARD (103.4 vs. 80.3 months), had a more severe condition at initiation of therapy (% rheumatologist perceived ‘severe': 51.7 vs. 26.5), experienced more pain at initiation (mean score [1=none; 10=worst]: 7.1 vs. 6.4); all $p<0.01$). When selecting which bDMARD therapy to prescribe first, physicians report ‘strong overall efficacy' as the main reason for bDMARD selection (70.8%) followed by ‘convincing efficacy in clinical trials' (54.9%).

The main reasons for switching from previous bDMARD to current bDMARD are physician assessed worsening of condition (45.8%) and loss of response over time (38.4%). The main reasons for second bDMARD choice were similar to first: strong overall efficacy (73.8%), convincing efficacy in clinical trials (50.2%), and in addition ‘inhibits disease progression' (50.2%). Reasons were relatively consistent regardless of bDMARD switched to (TNF inhibitor (TNFi) or non-TNFi).

Conclusion: Worsening severity of RA, rather than high baseline RA activity, is the main reason for treatment escalation regardless of the stage in the treatment pathway, suggesting current treatment approaches are not sustainably maintaining disease control in all patients. Furthermore, there is a need for clinical and laboratory biomarkers that could better inform the selection of first and subsequent bDMARDs. These findings emphasise the importance of early and optimum disease control where feasible, and physicians may therefore benefit from additional guidance and clarity on appropriate sequencing of bDMARD treatments.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Efforts have been made in recent years to standardize the clinical assessment of RA patients with increased focus on objective measures, such as the DAS28.

The objective of the current study was to compare physicians' perceptions of the severity of their patients' RA against the patients' DAS28, treatment, and quality of life.

Methods: Data were drawn from the Adelphi 2014 RA Disease Specific Programme, a survey of rheumatologists and their RA patients in France, Germany, Italy, Spain and UK. Rheumatologists provided patient clinical details including DAS28, physician perceived disease severity (mild/ moderate/ severe) and treatment history. Patients completed the EuroQoL 5-Dimension Health Questionnaire (EQ-5D) and Work Productivity Activity Impairment (WPAI) questionnaire. Three cohorts were created based on the physician's perceived severity of the patient's RA: mild, moderate, severe and were compared across DAS28 (as reported by the physician), treatment history, EQ-5D and WPAI. Appropriate univariate tests were used to compare subgroups statistically.

Results: 307 rheumatologists provided records for 2,536 patients, of whom 68.8% were perceived to have currently mild RA, 27.1% moderate RA and 4.2% severe RA. Comparisons of mean DAS28 scores across groups showed an increase in mean score as severity worsened (DAS28: 2.48, 3.81, 5.45 for mild, moderate and severe, respectively; $p<0.01$). When DAS28 was categorized based on agreed definitions of remission (<2.6), low disease activity (LDA; ≥2.6 and ≤3.2) and active disease (>3.2) the percentage of mild patients in each DAS28 category was 53.2%, 34.5% and 12.3%, respectively; moderate patients: 9.2%, 22.4% and 68.3%; and severe patients: 5.6%, 2.8% and 91.7% ($p<0.01$). 47.2% of patients who are currently severe have been prescribed a biologic DMARD (bDMARD) therapy, which was higher than for patients who are currently moderate (39.1%) or mild (34.9%).

Higher disease activity scores were associated with lower EQ-5D scores indicating worse quality of life (EQ-5D: 0.81, 0.60, 0.21 for mild, moderate and severe, respectively; $p<0.01$), and overall work impairment increased (18.8%, 37.6% and 55.9% for mild, moderate and severe, respectively; $p<0.01$).

Conclusion: Results showed that in general rheumatologists' labels of mild, moderate and severe RA correlate with more objective measures of disease activity (DAS28) and impact on the patient (EQ-5D and WPAI), although the finding that some patients classed as 'mild' have active RA (DAS28 >3.2) implies active disease can still be overlooked and potentially undertreated.

Additionally, the finding that less than half of patients who are currently severe had received a bDMARD therapy suggests a certain population of patients may not receive bDMARD therapy regardless of the severity of their RA, and may benefit from an alternative efficacious treatment option.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

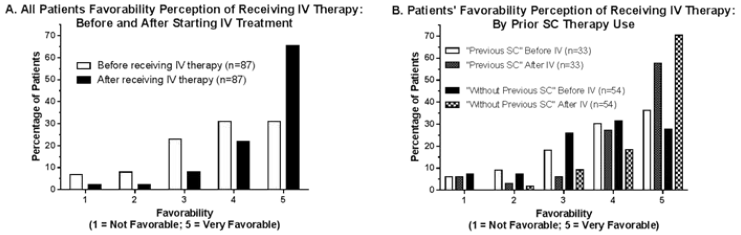
Session Time: 9:00AM-11:00AM

Background/Purpose: Patient-reported outcomes (PRO) are used to assess patient related benefit in clinical trials. Rheumatoid

arthritis (RA) patients are equally receptive to intravenous (IV) or subcutaneous (SC) biologic treatment[1]. The objective of this study was to obtain PRO data to understand characteristics of patients who receive IV biologic agents for RA.

Methods: This was a questionnaire-based study conducted at a single rheumatology practice with extensive clinical trial experience. A total of 100 patients will be enrolled; 87 patients are included in this interim analysis. The inclusion criteria were: a diagnosis of RA with IV biologic use for ≥3 mo; ≥18 yrs age; able to read, write and speak English, willing to complete the questionnaire and a signed informed consent form. IV biologic treatment was per clinical practice; there were no treatment assignments and study drug was not supplied. The questionnaire had 30 questions; patients completed the questionnaire prior to receiving a regularly scheduled dose of IV biologic. Data collected 1-2Q2015.

Results: The mean (±SD) age of patients in this interim analysis was 57.9 (±14.5) yrs with a mean disease duration of 10.6 (±8.5) yrs (range 0.7-45 yrs). Patients were Caucasian (36.8%), African American (28.7%), Latino/Hispanic (20.7%), Asian/Pacific Islander (1.1%) and 12.6% not identified. IV biologics used were infliximab (68%), rituximab (13%), tocilizumab (10%), abatacept (7%), golimumab (1%) and other (1%). The mean duration of current IV therapy was 4.0 (±3.2) yrs (range 0.1 to 16.0 yrs). Patients' favorability (1=Not Favorable, 5=Very favorable) perception of IV therapy BEFORE and AFTER starting IV therapy is shown in Figures A and B. Amongst all patients (A), "Very Favorable" increased ($p<0.05$) from 31% to 65% after receiving IV therapy; the increase in "Very Favorable" was evident in patients with or without previous SC therapy (B).



The favorability scores (mean ±SD) of current IV therapies were: infliximab 4.7 (±0.6), abatacept 4.7 (±0.5), rituximab 4.3 (±1.0), golimumab 5 (n=1) and tocilizumab 3.9 (±1.5). Prior SC biologic users had similar responses to questions identifying advantages or disadvantages associated with receiving IV biologic therapy as those patients who were not previous SC biologic users.

Conclusion: These interim results suggest that among patients receiving IV biologic therapy for treatment of RA, there is a high degree of patient satisfaction, including a similar favorability perception of IV therapy among patients who switched from an SC to an IV biologic. Our results support the concept that when there is a shared decision making discussion with patients regarding biologic treatments, the option of IV therapies should be an essential part of that discussion and that the RA patient's perspective should be given meaningful consideration.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is most prevalent in those who are 60 years of age or older. It has not been clearly established whether pain perception is different according to age in RA patients. We investigated whether there is any difference in pain level to similar synovial inflammation with aging using Modified Disease Activity Score (MDAS), which was shown to have superior correlation with Magnetic Resonance Image (MRI) detected synovitis.

Methods: For RA subjects enrolled in the University of Pittsburgh Rheumatoid Arthritis Comparative Effectiveness Registry (RACER), a cross-sectional analysis was performed for all first visits available. Levels of inflammation were calculated by MDAS28 score (=0.49 x ln(C-reactive protein (CRP)) + 0.15 x Swollen joint count 28 (SJC) + 0.22 x Physician global assessment (PhGA) +1). Spearman's correlations among pain (visual analog scale, VAS), disease characteristics, comorbidities and American College of Rheumatology (ACR) Core Data Set measures were calculated. Univariate and multivariate analyses were performed to investigate association between pain level and age. Age was categorized into 2 groups (younger RA <60, older RA ≥ 60) in regression models. Mann-Whitney U test was used to detect differences between two age groups.

Results: For the 740 subjects analyzed, subject age was 61.2 ±13.7 (median ±SD) years with disease duration of 14.4 ±12.4 years. In multivariate analyses, pain level had significant negative association with age even after adjustment for race, gender, comorbidities, and inflammation. (Table.1) In subjects with moderate inflammation (defined by MDAS28 score above 50 percentile, N=370), older RA subjects (age ≥ 60, N=189) had lower pain level, Tender Joint Count (TJC), Patent Global Assessment (PtGA), PhGA, , Routine Assessment of Patient Index Data 3 (RAPID3), Disease Activity Score (DAS) 28-CRP than younger subjects (age < 60, n=157) but SJC, physical health by 12-Item Short Form Health Survey (SF12) were not different between them. SF12-Mental Health was better in older RA subjects. (Table.2). There were no significant differences between two age groups in subjects with lower levels of inflammation (MDAS ≤ 50 percentile, N=370).

Conclusion: Decreased pain level in older RA patients with a similar degree of joint inflammation as younger RA patients leads to under-estimation of disease activity measured by either patient reported outcome (RAPID3) or composite disease activity index (DAS28-CRP). This suggests that current clinical disease activity measurements may not fully reflect the severity of disease in older RA patients.

Table.1 Multiple regression analyses of the associations of pain level with age adjusted for influences of covariates. Model 1 was adjusted for race, gender, comorbidities, and disease duration. Model 2 was adjusted as model 1 plus MDAS28. Model 3 was adjusted as model 2 plus physical & mental health (β: unstandardized coefficient, SE: Standard Error, MDAS28: Modified Disease Activity Score, 12-Item Short Form Health Survey (SF12)- Physical Health(PCS), Mental Health (MCS))

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Only few studies investigated the prevalence and risk factors of cognitive impairment in patients with rheumatoid arthritis (RA), however, results are controversial. Therefore we performed this study to determine the prevalence and risk factors of cognitive impairment and their association with RA disease activity.

Methods: Patients with RA and osteoarthritis (OA) were recruited from 3 university hospitals and physical, psychosocial, laboratorial, and medication statuses were assessed. Patients under 45 years old or with illiteracy were excluded. The activity and functional status of RA were assessed by Disease activity score (DAS)-ESR and Routine Assessment of Patient Index Data 3 (RAPID 3) score. Cognitive function was evaluated by Korean version of Mini-Mental State Examination (MMSE-K). Cognitive impairment was defined as MMSE-K scores ≤ 23.

Results: A total of 506 RA and 202 OA patients were recruited. Cognitive impairment was observed in 10.5%in RA and 13.4% in OA (*P*=0.272). In subgroup analysis between RA patients with cognitive impairment (n=53) or not (n=453), education level (OR 0.72, 95% CI 0.64-0.80), marriage status (OR 2.12, 95% CI 1.02-4.41), and high disease activity (OR 2.84, 95% CI 1.08-7.48) were independently predicted cognitive impairment after multivariate analysis controlling for age, hypertension, exercise, RAPID 3 score, fatigue, depression, and medication use. In subgroup analysis between RA patients with high disease activity (DAS28-ESR>5.1, n=55) or without (n=448), high disease activity was strongly associated with cognitive impairment (25.5% vs 8.5%, P=0.001). The education level was 63.8±9.96 and 62.1±8.51 (*P*=0.250) and age was 7.9±4.42 and 8.8±3.82 (*P*=0.111). In addition, DAS28-ESR score showed negative correlation with MMSE-K score (ρ=-0.110, *P*<0.05).

Conclusion: High disease activity is strongly associated with cognitive impairment in patients with RA. Thus, controlling disease activity may help preserving cognitive function in RA.

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Sleep problems affect over 60% of RA patients, but little is known about the relationship between sleep and inflammation in RA. Our primary objective was to identify associations between changes in sleep and changes in disease activity among RA subjects starting DMARDs. We also examined differences in these associations among those starting non-biologic vs. biologic DMARDs.

Methods: Individuals with active RA were recruited from 4 academic medical centers and assessed before and 12-weeks after starting a new DMARD. Subjects had to be starting a DMARD due to active disease, meet 2010 ACR criteria for RA, and be taking ≤ 10 mg of prednisone daily. Primary outcomes were changes in the PROMIS computerized adaptive test scores for Sleep-Related Impairment and Sleep Disturbance, reported as T-scores with a general population mean of 50 ± 10 and higher scores indicating worse sleep. The primary predictor was change in the Clinical Disease Activity Index (CDAI). The minimal clinically important improvement in CDAI is 6 for those with moderate baseline disease activity and 12 for those with high baseline disease activity (Curtis 2015). Multivariable linear regression models, adjusted for age, race, gender, RA duration and baseline sleep measures, were used to identify associations between changes in CDAI and changes in sleep. These associations were also examined in subgroup analyses stratified by those starting non-biologic vs. biologic DMARDs.

Results: Of the 58 RA subjects seen to date, 23 (39.7%) started non-biologic DMARDs, and 35 (60.3%) started biologic DMARDs. The mean baseline CDAI was 23.1 ± 14.0. After 12 weeks of DMARD treatment, the mean change in CDAI was -9.6 ± 13.5. Decreases in CDAI were associated with decreases in sleep-related impairment (β = 0.25; *P* = 0.01) but not with changes in sleep disturbance (β = 0.18; *P* = 0.11). In subgroup analyses, subjects who started non-biologic DMARDs had greater, though not statistically significant, decreases in CDAI (-12.9 ± 15.5), sleep disturbance (-3.8 ± 13.4) and sleep-related impairment (-4.5 ± 9.8) than subjects who started biologic DMARDs (CDAI: -7.5 ± 11.8; sleep disturbance: -3.1 ± 7.4; sleep-related impairment: -2.7 ± 10.2) despite similar baseline values. Decreases in CDAI were significantly associated with decreases in sleep disturbance and sleep-related impairment for those who started biologic DMARDs. No associations were observed in those starting non-biologic DMARDs (Table).

Conclusion: The magnitude of association between change in CDAI and change in sleep disturbance and sleep-related impairment differed among those who started non-biologic DMARDs vs. biologic DMARDs. These differences may reflect different mechanisms underlying improvements in sleep. A large, randomized clinical trial, directly comparing different types of DMARDs, is needed to elucidate the link between changes in inflammation and changes in sleep in RA.

Table. Associations between changes in disease activity and changes in sleep over 12 weeks among RA patients starting, switching, or adding a DMARD.

Cohort	Change in Sleep Disturbance		Change in Sleep-Related Impairment	
Primary Predictor	β-coefficient	P-value	β - coefficient	P-value
All DMARD initiators (N = 58)				
Change in CDAI	0.18	0.11	0.25	0.01
Non-Biologic DMARD initiators (N = 23)				
Change in CDAI	-0.14	0.61	0.05	0.79
Biologic DMARD initiators (N = 35)				
Change in CDAI	0.29	0.009	0.45	0.001

All models adjusted for age, race, gender, RA duration, and baseline sleep measures.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The patient global assessment of disease activity (PtGA) is a key variable in assessing RA disease activity and remission (REM). Typically assessed on a 10cm visual analogue scale (VAS), its widely employed wording is: *ÔConsidering all of the ways your arthritis has affected you, how do you feel your arthritis is today?Ô.* This wording may be misinterpreted by patients, not addressing symptoms related to RA in detail. We investigated how different wordings of the question influence results obtained for the PtGA.

Methods: In 4 international centers, RA patients filled in VAS of 6 differently phrased PtGA covering 2 aspects: one set using the traditional phrasing (PtGA_trad; see above), and one using a version including a detailed explanation of RA disease activity *("Active arthritis can cause joint swelling OR stiffness, pain OR discomfort in your joints. WITH ACTIVE ARTHRITIS, You CAN BE tired during the day, even when you've slept well*"; PtGA_expl); each set was divided into 3 questions with different reference periods: *today (TD), last week (LW)* or *last month (LM)*. Questions were on a separate page, and the order of the questions was random. Also, one question on global health was added (PtGA_GH).

To assess agreement of different PtGAs we calculated intra-class correlation (ICC); mean values of different PtGA were compared using paired t-test. The percentage of patients fulfilling Boolean defined REM (SJC²1; TJC²1; EGA²10mm; PtGA²10mm) and CDAI REM (²2.8) was calculated using different PtGA.

Results: 105 randomly selected patients (age 57.7±13.1 years, disease duration 17.9±10.4 years; 84.8% female, 91.4% white, 81% seropositive) participated in the study. Disease specific characteristics at baseline were: swollen joint count 1.5±2.4; tender joint count 1.6±3.9; pain 21.2±22.3 mm; fatigue 26.7±25.3 mm; HAQ 0.44±0.51; evaluator global (EGA) 15.3±15.8 mm. ICC was high across different PtGA (ICC 0.83 to 0.94; p<0.01), with lower ICCs between GH and the other 6 PtGA (0.53 to 0.65; p<0.05). Paired T-test revealed significantly higher mean values for PtGA_expl as compared to PtGA_trad, independent of the reference period (TD: 27.3±23.2 vs. 23.7±21.7; LW: 26.5±22.3 vs. 24.0±20.8; LM: 30.8±25.5 vs. 24.5±21.2; p<0.01 PtGA_expl vs. PtGA_trad respectively). In the total cohort, the percentage fulfilling either CDAI or Boolean REM was lowest when using PtGA_GH (Boolean REM 9.6%; CDAI REM 21.6%). By using PtGA_expl significantly fewer patients fulfilled CDAI and Boolean REM criteria compared to using the traditional phrasing of PtGA (**figure**).

Conclusion: Against our expectations, a more detailed explanation of "disease activity" led to higher ratings on the PtGA scale, and lower REM rates. It appears to increase awareness of and attention to specific symptoms related to RA disease activity, which would otherwise be discounted.

Figure. Percentage of patients fulfilling CDAI REM and Boolean REM using different wording of PtGA

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: It is well established that health related quality of life (HRQoL) is low in patients (pts) with RA and AS. Type C and D behavior patterns negatively influence perceptions on HRQoL, but there is little evidence on the relationship between personality types and clinical outcomes in RA and AS.

Methods: 194 pts from two Rheumatology Departments (104 with RA: 7.7% men, 92.3% women, mean age 59.08 years old, mean duration of disease 12.77 years; 90 with SA: 75.6 men, 22.4 women, mean age 43.63 years old, mean duration of disease 12.7 years) participated in a questionnaire study. HRQoL was evaluated with Medical Outcome Study Short-Term 36 (SF-36v2), analyzing all subscales (Physical function-PF, Social function-SF, Role limitations due to physical problems-RP, Role limitations due to emotional problems-RE, Mental health-MH, Vitality-VT, Bodily Pain-BP and Global Health-GH, including the summary physical component scores-PCS and mental component scores-MCS), personality type A/B with Jenkins Activity Survey (JAS-13), type C with State-Trait Anger Expression Inventory Anger-in Scale (AIS), type D with Type D Personality Scale (DS-14) and disease activity with DAS28 for RA and BASDAI for AS. Pearson's correlation coefficient and independent samples t-tests were used and results were considered statistically significant at $p<0.05$.

Results: In the RA group, type D pts have significant correlations with 7/12 SF36 components, exhibiting limited functional status (higher RP and RE, lower SF), welfare (higher BP, lower VT and MH) and overall decreased GH. These associations are stronger for AS pts, type D personality being linked with deficits in all SF36 subscales, including PCS and MCS. Furthermore, negative affectivity (NA, type D subcomponent) independently influences PF, RP, BP, SF and PCS in AS negatively. Type D is also related with more active disease forms for both RA and AS, not only regarding the total scores in DAS28 and BASDAI, but also with some subcomponents and with other disease activity indicators not included in standard scores, like patient global assessment (PGA), ESR and CRP for AS pts. NA and SI correlate independently with higher DAS28 and BASDAI as well. The same pattern was identified for type C pts. All HRQoL subscales are affected in AS pts, whereas for RA pts, only 7/12 correlations were significant (SF, VT, MH, RP, RE, PCS, MCS). Both RA and AS type C pts have more active disease forms. In the RA group, type A personality did not significantly correlate with HRQoL, but it did positively influence pain visual analog scale (VAS) scores. In AS pts, however, this personality type was found to be linked with better HRQoL (greater VT, better PF, lower RP and RE, overall better PCS and GH) and with less active disease types (lower BASDAI scores, PGA and pain VAS).

Conclusion: Type C and D personality types were found to be strongly correlated with decreased HRQoL and with higher disease activity levels in both RA and AS pts, whereas type A appeared to be linked with less active disease forms in AS pts and with less pain in RA pts. A longitudinal study should be done to establish the causality of these associations, as personality types might be one of the parameters influencing clinical outcomes.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: To evaluate vitality, reduced paid and unpaid work ability, and productivity losses for patients with early rheumatoid arthritis (RA) available for work force at baseline and treated with an add-on 6-month induction infliximab therapy versus a combination of three DMARDs and prednisolone**.**

Methods: In the NEO-RACo trial 99 patients with early, DMARD-na•ve RA were treated with a combination of three DMARDs and prednisolone (FIN-RACo) and randomised to receive either infliximab (FIN-RACo+IFX) or placebo (FIN-RACo+PLA) infusions during the first 6 months. The patients were assessed clinically at weeks 0, 4, 6, 10, 14, 18, 22, 26, and at months 8, 10, 12, and thereafter 3-monthly. Patient-reported SF-36 subscales for vitality (0-100, 100=full vitality) and presenteeism, i.e., decreased work productivity while at work (0-100, 100=full presenteeism, i.e. complete decrease of productivity) were gathered at baseline, and at 8, 12, and 24 months, and the mean values were estimated with an area under the curve (AUC) approach.

Results: During the 24-month follow-up, vitality improved significantly in both groups, with no between-group differences. However, the mean score of presenteeism decreased more from baseline to 8 months in the FIN-RACo+IFX group than in the FIN-RACo+PLA group (-46 vs. -32, p=0.004); by 24 months the difference between the groups had levelled out (Figure 1). A negative curvilinear correlation was found between vitality and presenteeism (Figure 2). A higher body mass index and self-reported depressive symptoms were associated with lower vitality and higher level of presenteeism (Table 1).

Conclusion : Vitality (antithesis of fatigue) manifests itself in better work productivity while at work. BMI and depressive symptoms at baseline were found to be the significant determinants of decreased vitality and increased presenteeism.

Leirisalo-Repo et al. Ann Rheum Dis 2013

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Adherence to disease modifying anti-rheumatic drug (DMARD) therapy is suboptimal in patients with rheumatoid arthritis (RA). Efficient, low-cost measures are required for optimal monitoring of medication adherence in the rheumatology clinic. Self-report tools are the most efficient and cost-effective measures available. Recently, a 5-item version of the Compliance Questionnaire Rheumatology (CQR5) was developed from the original 19-item version to reduce patient burden[1]. Reliability of CQR5 over time has not been evaluated, nor has its association with other factors that can impact medication taking. In a sample of RA patients, we investigated 1) test-retest reliability of CQR5 and 2) correlation of CQR5 with psychosocial and physical factors known to influence adherence.

Methods: RA patients (disease duration ≥ 1 yr) taking at least one DMARD were randomly selected from a rheumatology clinic database. Patients were assessed at baseline and 2 weeks. Demographic data were collected at baseline. At each visit, medication adherence was assessed with CQR5. Each item on the CQR5 was scored on a 4-point Likert scale (1 = strongly disagree, 4 = strongly agree). Scores for each item were summed into a total score which varied between 0 and 20. Higher scores indicated greater adherence. Psychosocial measures were evaluated using 1) Beliefs about Medicines Questionnaire (BMQ)[2], which examines beliefs around necessity of and concern with taking medications (high scores reflect strong beliefs) and 2) RA Self-Efficacy Questionnaire (RASE)[3] (high scores reflect high self-efficacy). Physical factors were assessed using 1) multi-dimensional HAQ (MDHAQ)[4] (high numbers indicate poor general health and worse symptoms) and 2) disease activity measured by the Composite Disease Activity Index (CDAI)[5](high scores indicate high disease activity). Intraclass correlation coefficients (ICC) were used to evaluate test-retest reliability of CQR5 scores measured at baseline and 2 weeks. Bivariate correlations (Pearson's r) were performed to determine relationships between psychosocial factors and medication adherence measured by CQR5 at baseline.

Results: 100 RA patients, [age, mean (SD) = 60.75(12.67) yrs], were recruited. In this sample, the CQR5 demonstrated excellent test-retest reliability (ICC=0.78). Adherence measured by CQR5 had a strong positive correlation with BMQ necessity scores ($r = 0.64$, $p<0.001$) and a weak negative correlation with BMQ concerns scores ($r = -0.22$, $p<0.05$). Correlations between the CQR5 and RASE, MDHAQ, and CDAI were negligible ($r<0.17$, $p>0.05$).

Conclusion: The CQR5 demonstrates excellent reliability over time. Adherence measured by the CQR5 is associated with beliefs about medicines, especially around the necessity of taking medications. A more in-depth investigation of the CQR5, including its validation against a gold standard for measuring medication adherence, is currently underway.

Impact of Patient Education on the Satisfaction of Rheumatoid Arthritis Patient : A Randomized Trial of Nurse-Led Vs. Physician-Led Education

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Early, more aggressive treatment of rheumatoid arthritis (RA) has resulted in greatly improved outcomes compared to past decades. However, because of heterogeneity and complexity of RA disease course and potential toxicity of therapies, shared decision-making (SDM) between physician and patient is central to patient safety and outcomes. Patient education (PE) is a useful tool for patient empowerment, since patients should aware of their disease course, treatment target, medications and their adverse effects. However, it is uncertain that how we can measure the clinical benefits of PE and who should be responsible for educating patients. This study aims to examine the impact of PE on the patients' satisfaction in RA patients and to compare the nurse-led education with physician-led education for RA patients.

Methods: Patients were enrolled by categorizing in three according to their clinical characteristics: early RA patient (<2 years of disease duration) with conventional DMARDs (Group I), established RA patients (≥ 2 years of disease duration) with conventional DMARDs (Group II), and RA patients treated with biologic DMARDs (Group III). After constructing two groups of nurse-led and physician-led education, stratified randomization was performed by randomly assigning the two education groups separately within each group by characteristics. Patient education materials were composed of the characteristics and outcomes of RA, T2T, treatment options with side effects, and comorbidities. Two times of face-to-face education was performed and changes in patient satisfaction before and after PE were assessed using visual analogue scale (VAS, 0-100mm) and Leeds Satisfaction Questionnaire (LSQ) score. Changes of patients' outcomes were measured using DAS28-ESR, HAQ-DI, and EQ-5D scores. Changes of patients' satisfaction and disease outcomes between before and after PE were compared using paired t-test, and the comparison between nurse-led and physician-led education was analyzed using independent t-test.

Results: A total of 120 RA patients, 40 patients from each groups, were randomized to receive either nurse-led or physician-led education. Among them, 113 patients completely received twice face-to-face education and final assessment with 1 or 2 month interval: 38, 36, and 39 patients in group I, II, and III, respectively. In total patients, patients' satisfaction by PE was significantly increased from 87.8 (± 13.1) to 92.3(± 8.8) in VAS ($p<0.01$), and from 3.7 (± 0.4) to 4.0 (± 0.4) in LSQ score ($p<0.01$). The improvement of patients' satisfaction measured with LSQ was highest in group I (0.45 ± 0.45) and followed by group II (0.22 ± 0.34) and group III (0.19 ± 0.38). However, there was no improvement in DAS28-ESR, HAQ, or quality of life after PE. Improvement of patients' satisfaction by LSQ after nurse-led education was 0.37 ± 0.37 and it was higher than 0.27±0.45 after physician-led education, but it was not statistically different (P =0.25).

Conclusion: Patient education in outpatient clinic for RA patients improved patients' satisfaction, especially in patients with early stage. Nurse-led education showed comparable improvement in patients' satisfaction with physician-led education.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Testing for anti-citrullinated peptide antibodies (ACPA) is included in the 2010 ACR classification criteria for RA. ACPA concentration, beyond ACPA positivity, is indicative of more aggressive radiographic progression. Biologic (b)DMARDs such as abatacept have been shown to reduce ACPA levels in clinical trials; however, there are limited data on the impact of DMARDs on ACPA in clinical practice. **Methods:** Data were analyzed from patients (pts) enrolled in a large, US RA registry established in 2003. The registry comprises pts with established RA who were evaluated annually for multiple clinical and laboratory measures, and semi-annually for multiple pt-reported outcomes and resource utilization parameters. The current analysis is based on pts enrolled in the registry with ACPA values at the time of initiating DMARDs (baseline ACPA levels). Baseline and follow-up ACPA levels were measured using a validated ELISA (Inova Diagnostics) until its discontinuation in 2011; the Euro-Diagnostica assay (distributed by IBL-America, Minneapolis, MN), which supplied the 'capture' antibody for the original Inova Diagnostics ELISA, has been used since (correlation between the two assays: 0.984). Mean ACPA level and mean change from baseline to Year (Yr) 1 and Yr 2 were compared between conventional (c)DMARDs, TNF-inhibitors (TNF-Is) and abatacept. To control for baseline differences in clinical and laboratory measures, additional ACPA comparisons between groups were conducted based on a 1:1 matched cohort of TNF-I and abatacept pts. **Results:** Overall, 1316 (98%) registry pts with ACPA levels at therapy initiation were included in the analysis; 45, 49 and 6% of pts were initiated on cDMARDs, TNF-Is or abatacept, respectively. The mean (SD) age (yrs) was 58.7 (14.1), 54.7 (13.6) and 59.3 (11.4) for cDMARD, TNF-Is and abatacept cohorts, respectively. The average (SD) disease duration (yrs) in the abatacept cohort was 20.5 (12.0) (vs 12.5 [12.6] for cDMARDs and 14.2 [11.4] for TNF-Is). The abatacept group also had higher mean (SD) disease activity (24.3 [15.7] vs 19.9 [15.5] in cDMARDs and 20.1 [17.3] in TNF-Is). ACPA values at baseline, Yr 1 and Yr 2 by treatment group are shown in Table 1. The pt characteristics of the matched abatacept and TNF-I groups, and ACPA values in Yr 1 and Yr 2 are shown in Table 2. Pts treated with abatacept showed a lowering of the ACPA values during follow-up, while similar reductions in ACPA values were not seen in pts treated with TNF-Is or cDMARDs.

Conclusion:

These results from a real-world clinical setting support observations from clinical trials that abatacept treatment leads to a reduction of ACPA levels, which is not seen with TNF inhibitors.

Table 1. Baseline and follow-up ACPA levels (U/mL) in pts treated with cDMARDs, TNF-Is and abatacept				
	N	**Mean (SD)**	**Change from baseline**

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Many studies have shown disparity between clinical and ultrasound (US) findings in rheumatoid arthritis (RA). US appears to detect subclinical synovitis in patients in clinical remission. The aim of the present study was to compare clinical and US activity in patients with RA in clinical remission, applying different US definitions of an active joint, and to evaluate whether replacing clinical by US assessment would change patients' disease activity state.

Methods: We included consecutive patients with RA according to 2010 ACR/EULAR criteria in clinical remission by DAS28 (<2.6). US examinations were performed by the same rheumatologist, using a MyLab 70 machine equipped with 6-18 MHz broad band multi-frequency linear transducer. The following 20 joints of both hands were assessed: wrist, first to fifth MCP joints and second to fifth proximal PIP joints. Power Doppler (PD) US signal was evaluated on a semi-quantitative scale from 0 to 3 (0= no PD signal; 1= a single PD signal; 2= confluent PD signal in less than 50% of intra-articular area; 3= PD signal in more than 50% of intra-articular area). Three different US DAS28 (US DAS28) were constructed, replacing the clinical swollen joint count by the PD US joint count (clinical examination was used for joints not included in US assessment) using PD grade ≥ 1, ≥ 2 or ≥ 3, respectively.

Results: Eighty six patients were included. Sixty-five (75.5%) were female; mean age (SD) was 58.5 (13.8) years; and mean disease duration (SD) was 7.2 (7.9) years. Mean DAS28 (SD) was 2.1 (0.37). Twenty-three (26.7%) patients had at least one joint with abnormal vascularization by PD US (PD ≥ 1). Among these, 14 (60.8%) had only one joint with abnormal vascularization by PD ≥ 1; 6 (26.1%) had two; 2 (8.7%) had three and 1 (4.3%) had four. Mean (SD) US DAS28 were 2.18 (0.47); 2.16 (0.45) and 2.1 (0.4) using the number of joints with PD grade ≥ 1; ≥2 and ≥3, respectively. Thirteen out of 86 (15%) patients were reclassified to low disease activity using US DAS28 with PD ≥ 1. Using US DAS28 with PD ≥ 2, only nine (10.5%) patients were reclassified to low disease activity, and US DAS28 with PD ≥ 3 did not reclassify any patient. No patients were reclassified into moderate or high disease activity using any of PD grades (Table). Correlation between clinical DAS28 and US DAS28 was excellent (Spearman's rho: 0.8271; 0.8470 and 0.8701 for US DAS28 using PDUS grade ≥ 1; ≥ 2 and ≥3, respectively).

Table. Clinical and US DAS28 scores in patients with at least one joint with PD signal.

	Clinical DAS28	Number of joints with PD Grade 1	Number of joints with PD Grade 2	Number of joints with PD Grade 3	US DAS28 with PD grade ≥ 1	US DAS28 with PD grade ≥ 2	US DAS28 with PD grade ≥ 3

20	2,08	0	1	0	2,36	2,36	2,08
21	2,06	0	1	0	2,34	2,34	2,06
22	0,4	1	1	0	0,4	0,28	0,0
23	2,5	0	1	0	**2,78**	**2,78**	2,5

PGA: patient global assessment; **ESR**: erythrosedimentation rate.

Conclusion: Although around one quarter of patients with RA in clinical remission showed PD US features indicating residual activity, a low percentage of these patients were reclassified to a DAS28 low disease activity state, and none to either moderate or high disease activity, using PD US assessment. There was a very good correlation between clinical and US assessment.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

In patients with tender and swollen finger joints, the differential diagnosis between rheumatoid arthritis (RA) and osteoarthritis (OA) of

the hands can be initially difficult. In a previous pilot study we have shown that the positive response to a 3-day-course of 20 mg prednisolone (the 'pred-test') differentiates between RA and OA of the hands. An subjective percentage of improvement of 40% was found to discriminate best. The objective is to study the diagnostic value of the pred-test in patients with possible RA.

Methods:

Consecutive patients with hand pain referred because of suspected RA (n=100) were included in the study. Clinical examination by one experienced rheumatologist, laboratory tests, and magnetic resonance imaging (MRI) were regularly performed. All patients received 1g paracetamol/day for 5 days. On days 3-5 a morning dose of 20 mg of prednisolone was added. Hand pain was quantified on a numerical rating scale (NRS 0–10) and the subjective percentage of improvement recorded. The predefined cut-off of 40% improvement was applied to differentiate between responders and non-responders. Diagnoses were made by the expert who was unaware of the treatment result. Patients were reexamined at week 12 to confirm the diagnosis.

Results:

There were 95 patients with complete data (Tab.1). RA was diagnosed in about half of the patients. RA patients had more swollen joints, higher CRP levels and a comparable HAQ (Tab.1). The pred test was positive in 42.1% of the patients (40/95). The median percentage of improvement after 3 days of 20 mg of prednisolone was higher in RA than in OA: 50% (IQR 30%-60%) vs. 20% (IQR 10%-30%), $p<0.001$. The sensitivity and specificity of the pred-test was 65.9% (31/47) and 81.2% (39/48), and the positive and negative predictive value was 0.77 and 0.70, respectively.

Table 1: Clinical characteristics of patients with RA and OA (mean±SD)

	RA (n=47)	OA (n=48)
mean age	57.6±12.2	54.5±9.2
sex (female)	85%	68%
pain	6.1±1.6	5.8±1.6
HAQ	1.15±0.5	1.13±0.4
Swollen joint count (66/68)	2.3±2.4	1.4±2.3
Tender joint count (68/68)	13.0±8.5	13.9±10.5
CRP (mg/dl)	0.5±0.6	0.2±0.3

Conclusion:

This is the first evaluation of the widely used pred-test that has ever been performed. We found that this test has a moderate sensitivity and good specificity. We propose that rheumatologists use this test in uncertain clinical situations to be able to better differentiate between inflammatory arthritis and osteoarthritis. Finally, we hope that a negative test result will prevent patients to receive unnecessary glucocorticoid treatment, while a positive test will help to identify patients with inflammatory arthritis who can then receive proper treatment.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The ACR/EULAR Boolean definition of remission is expected to be used as an outcome measure in randomized clinical trials for rheumatoid arthritis (RA). Boolean defined remission requires satisfaction of all of the following: (TJC≤1, SJC≤1, CRP≤1 mg/dl and patient global assessment (PGA) ≤1 (0-10 scale) (1).The extent to which PGA may be driven by the presence and the duration of morning stiffness and thus the ability to meet Boolean based remission criteria has not been investigated.

Methods: Patients enrolled in the Corrona RA registry were analyzed. Data from the most recent visit for the components of Boolean remission criteria were used. The percentage of patients in Boolean based remission was calculated. Morning stiffness data (presence or not, and duration) as reported by the patient at each registry visit were utilized. We investigated the prevalence and the duration of morning stiffness in RA patients in remission and for those not meeting the remission criteria due to PGA>1 while all other components (TJC, SJC, CRP) were ≤1.

Results: Out of 24,170 patients, Boolean defined remission was met in 4,856 (20.09%) patients at the most recent visit. Boolean remission was not met in 19,314 (79.91%) patients and 4,371 (18.08%) patients did not meet remission criteria due to PGA>1. Morning stiffness was present in 39.4% of patients in remission (and PGA≤1) while it was reported in 78.4% of patients not in remission because PGA>1 ($p<0.001$). The median duration of stiffness at most recent visit was 0.33(IQR: 0.17-0.5) hours for patients in remission while it was 0.75(0.33-1.5) hours for patients not in remission because of PGA>1($p<0.001$). 8.9% of patients had morning stiffness >1 hour in the former group while 26.3% of patients reported a similar duration in the latter group ($p<0.001$).

Conclusion: PGA may be affected by several factors and may not allow patient to meet remission criteria based on the Boolean definition. In this analysis, 18.08% of patients did not meet remission criteria because PGA>1. Morning stiffness duration was longer in these patients compared to patients in remission. This finding suggests that morning stiffness is an important contributor to the PGA and likely plays a role in patients' inability to meet the remission criteria.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: A reference point for clinically important worsening (CIW) of RA disease activity requiring retreatment or escalation is needed for randomized trials of treatment withdrawal. These studies are usually performed in patients (pt) in states of low disease activity (LDA) or remission (REM). Restarting RA therapy needs a Pt-MD concordant assessment of worsening ("flare") to maximize adherence. Here we examine the construct and convergent validity of a combined Pt-MD concordant report of flare that indicates CIW in pts who are in LDA/REM.

Methods: CATCH (Canadian early ArThritis CoHort) Pts were eligible for study if they were in DAS28 REM or LDA at first (V1) of 2 sequential visits (3 or 6 months apart). RA flare was assessed at the 2nd visit (V2). Pts reported if their RA was flaring (yes/no) and if yes the severity and duration. Concurrently, MDs classify them as flaring (yes/no). Changes in disease activity and treatment, OMERACT core flare domains, MD measures, inflammatory markers, and DAS28 were assessed in pts reporting flare, MDs classifying flare, and when Pt-MDs were concordant in identifying flare**.**

Results: Of 849 RA pts who completed OMERACT flare questions twice between 11/2011-10/2014, 360 (42%) were in LDA or REM at the 1st of paired visits. Pts most often reported a flare duration lasted >14 days in Pt-MD concordant flares with mean (SD) severity rating of 5.0 (2.3)(Table 1). DAS28 worsening was less in MD-report of flare DAS28 0.9 (1.3) vs 1.8 (1.2) in Pt-MD concordant flare. Prior treatment reduction/withdrawal was observed in 36% of Pt-MD flares with subsequent treatment addition in 61% at/after the 2nd "Flare". Mean differences in measures of RA disease activity, (PROs, clinical, and laboratory assessments), were significant in pt-reported flare, and of greater magnitude with concordant Pt-MD flare. This was notable for all measures in the existing RA core set for monitoring disease activity and the expanded OMERACT Flare Core Set (Table 2).

Conclusion: A concordant Pt-MD report of flare can provide a feasible assessment of CIW of RA disease activity associated with worsening in ACR RA core set measures and domains in the expanded OMERACT Flare core set. This anchor for CIW is often associated with stopping or reducing treatment and with subsequent increases in therapy. These data provide a rationale for using this Pt-MD anchoring construct to identify CIW for existing and new RA disease activity measures.

Table 1: Patient and MD Reported Flare Characteristics, DAS28 worsening, and changes in treatment.			
Patients Previously in DAS28 LDAS or REM (N=360)	**Patient Flare (Yes)**	**MD Flare**	**Patient Flare Yes/ MD Flare**
	N=58 (16%)	N=71 (20%)	N=28 (8%)
Flare severity (0-10) (mean SD)	4.4 (2.1)	4.5 (2.6)	5.0 (2.3)
Duration of flare			
1-3 days	12 (21%)	5 (18%)	5 (18%)
4-7 days	6 (10%)	4 (14%)	4 (14%)
8-14 days	12 (21%)	6 (21%)	6 (21%)
>14 days	28 (48%)	13 (46%)	13 (46%)
Change in DAS28:			
DAS28 at time of flare	3.2 (1.4)	3.0 (1.4)	3.9 (1.4)
DAS28 at previous visit	2.1 (0.7)	2.1 (0.6)	2.1 (0.7)
Worsening of DAS28	1.1 (1.4)	0.9 (1.3)	1.8 (1.2)
Treatment Reduced/Stopped Before Flare Assessment

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Patient reported outcomes such as morning stiffness are reported frequently in rheumatoid arthritis (RA) patients. But little has been reported about the presence and the treatment of it in patients who have achieved low disease activity (LDA) (1). The CAPRA-2 study demonstrated previously absolute and relative reductions in morning stiffness in RA patients on DMARDs and concomitantly treated with low dose delayed-release (DR-) prednisone as compared to placebo/DMARDs over 12 weeks (2). Herein we report the relative and absolute changes in morning stiffness from the CAPRA-2 study in patients who achieved, and did not achieve, LDA.

Methods: RA patients with moderate disease on non-biologic DMARDs previously randomized to receive DR-prednisone or placebo were evaluated at baseline, 2, 6, and 12 weeks for relative and absolute changes in morning stiffness and LDA status (DAS28 $\leq$3.2).

Results: Patients who attained LDA at 12 weeks had similar demographics at the beginning of the trial to those who did not achieve LDA. By week 12, patients who received DR-prednisone and attained LDA (N=62) had significantly higher absolute ($p<0.05$) and relative reductions ($p<0.001$) in morning stiffness as compared to patients who received DR-prednisone and did not reach LDA (N=153). There were no differences in the placebo treated LDA (N=17) and non-LDA (N=90) groups. Of the patients attaining LDA status the DR-prednisone group had longer duration of disease, greater severity of morning stiffness and greater pain upon awakening, but similar DAS scores, at baseline compared to the placebo group. Despite this, there were significant differences from baseline found in both absolute ($p<0.0001$) and relative reductions ($p<0.0001$) in morning stiffness in those treated with DR-prednisone (n=62) which was not observed with placebo patients reaching LDA (n=16). (Figure 1)

Conclusion: Attainment of LDA is not accompanied by decreasing morning stiffness in patients on DMARD monotherapy but is with DR prednisone/DMARDs, indicating the potential lack of construct validity between the two outcomes in the absence of glucocorticoid therapy. Glucocorticoid/DMARD treatment had a profound suppressing effect (-95%) on morning stiffness in patients who reached low disease activity. It is unknown whether this construct validity exists with other commonly used therapies in RA.

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The utilization of a swollen (SJC) to tender joint count (TJC) ratio (STR = (SJC/TJC)) has been proposed in the past to identify a phenotype of rheumatoid arthritis (RA) patients that may have somatic complaints that do not reflect active RA. The influence of comorbidities such as depression and anxiety concomitant with RA, may influence the tender joint count and may be an important factor moderating the STR. To evaluate the influence of anxiety and depression on the distributions of TJC, SJC and the STR within the Veterans' Affairs Rheumatoid Arthritis cohort (VARA),

Methods: Four mutually exclusive RA patient groups were identified: 1) RA without anxiety or depression; 2) RA and depression only; 3) RA and anxiety only; 4) RA and Anxiety and Depression. We used Kolmogorov-Smirnov test to determine differences in the distribution of the STR by patient group.

Results: There were 2,170 RA patients within VARA. Mean age was 63 ± SD 10.9, 90% were men with an overall STR median (IQR) = 0.55 (0-1.30). The median (IQR) of the STR for the RA only group was 0.57 (0-1.4); RA + depression 0.55 (0-1.3), RA + anxiety 0.25 (0-1.0) and RA + anxiety + depression 0.54 (0-1.0). When comparing the actual distribution of the STR only RA + Anxiety compared to RA only was significantly different (p-value = 0.029). There was no difference between the RA + Depression group or the RA + Depression and Anxiety when compared to the RA only group (p-value = 0.17, 0.13, respectively) (Figure). The proportion of patients with STR ratio <0.5 was 43% (RA only), 54%, (RA+Anxiety), 45% (RA+Depression), and 43% (RA+both), p<0.038.

Conclusion: The distribution of the swollen to tender joint count ratio (STR) appears to be influenced by different comorbidities. While the tender joint count is part of many disease activity metrics, our study suggest that the tender to swollen joint count ratio may identify a phenotype of RA patients with less active disease with somatic complaints. Typical RA disease activity metrics may be overestimated in such patients.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Treat to target (T2T) trials in RA to date have focused on the effect of T2T on articular disease without directly addressing cardiovascular risk. The aim of this study was to examine if a T2T strategy is associated with improved cardiometabolic risk factors in patients with newly diagnosed RA.

Methods: Patients were participants in TACARRA (TArgeting CArdiometabolic Risk in Rheumatoid Arthritis) and had RA based on 2010 ACR criteria with symptoms <2 years, were DMARD- and biologic-naïve (except hydroxychloroquine), took corticosteroid equivalent of prednisone ≤10 mg daily, had clinical disease activity index (CDAI) >10 and did not have known diabetes. The patients were treated according to a predetermined structured protocol that mandated treatment escalation for CDAI >10. The primary outcome was insulin resistance as assessed primarily by the homeostatic model assessment 2 for insulin resistance (HOMA2-IR) and secondarily by the 2 hour glucose tolerance test (GTT). Secondary outcomes were lipid levels and body composition measurements by dual energy xray absorptiometry (Hologic). Differences between outcome data at 52 weeks and baseline was tested using the Wilcoxon

signed rank test. Differences of the change between 52 weeks and baseline in patients with low (CDAI ≤10) and higher (CDAI >10) disease activity at 52 weeks were compared using exact Wilcoxon tests.

Results: Of the 25 patients who entered the study, the 16 completing 52 week follow-up were included in the analysis. 44% were female with median age 55 years. 75% were RF and 62.5% ACPA positive respectively, with median body mass index (BMI) 29 kg/m^2. Patient characteristics and outcome measures at baseline and week 52 are shown in Table. At week 52, 10 patients had low and 6 patients had higher disease activity. Median change in HOMA2-IR levels was -0.43 (-0.65, 0.02) vs.1.45 (0.78, 2.18), p=0.06, and median change in HDL was 2.5 (0.0, 12.0) vs. -11.5 (-19.0, -6.0), p< 0.01 in the low and higher disease activity groups respectively. The low disease activity patients at 52 weeks were more likely to be on hydroxychloroquine and had a smaller increase in BMI between 52 weeks and baseline. Change in HOMA2-IR according to disease activity at 52 weeks is shown in Figure.

Conclusion: Newly diagnosed RA patients who reach low disease activity (CDAI ≤10) by 1 year of treatment have higher HDL and a trend to lower insulin resistance than patients with higher disease activity. Although our findings need confirmation in larger trials, they provide evidence that T2T is associated with decreased cardiometabolic risk factors in RA.

Table. Patient characteristic of RA patients at baseline and week 52 (n=16)

	Baseline	52 Week	Week 52 - Baseline Difference Median (IQR)	Baseline to 52 Week Difference P-value

Poor Correlation Between Vectra DA and DAS28 Scores in Patients with Rheumatoid Arthritis

Marcia S. Genta[1], Amnon Sonnenberg[2] and Robert M. Genta[3], [1]Dallas Arthritis Center, Dallas, TX, [2]Medicine - Gastroenterology, Portland VAMC - Oregon Health & Science University, Portland, OR, [3]Laboratory, Dallas Arthritis Center, Dallas, TX

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

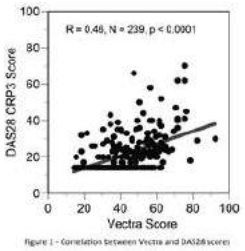
Session Time: 9:00AM-11:00AM

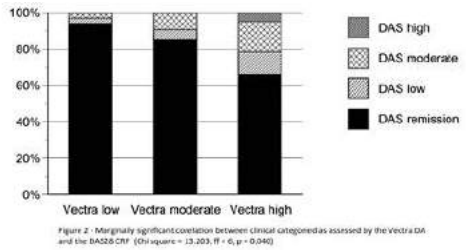
Background/Purpose: Vectra DA, a blood test that integrates the blood levels of 12 biomarkers into a single score (1-100), is claimed to provide an objective measurement of disease activity in RA patients. There is considerable controversy on whether it adds actionable information to that provided by joint examination, CRP, and ESR, and the resulting DAS scores. The purpose of this investigator-initiated non-sponsored study was to evaluate the correlation between Vectra DA and DAS28 CRP scores in RA patients followed in a solo practice.

Methods: Patients with an established diagnosis of RA underwent the Vectra DA test; the DAS28 CRP activity score was calculated at the time of the examination, when Vectra DA scores were unknown. Scores from each test were analyzed by multivariate linear regression. Levels of disease activity associated with the scores for each test were compared by the chi-square test.

Results: Vectra DA and DAS28 CRP scores were available for 239 unique patients (mean age 63.4 years, SD 13.2; 79% women; 40% African American, 36% Hispanic, and 25% White). RF was positive in 159 patients (67%) and CCP in 125 (52%); 129 patients were on DMARDs only (54%); 19 (8%) had only biologics; 72 (30%) were on combinations of DMARDs and biologics; and 19 (8%) had prednisone only or no therapy. There was a significant but weak correlation between Vectra DA score and the DAS28 CRP score (r^2 = 0.2102 or r = 0.4584; Figure 1), which was unaffected by age, sex, or ethnicity. In a multivariate linear regression analysis that included the type of therapy, the correlation improved slightly (r^2 = 0.321). In concordance with this weak correlation, the relationship between the 3 Vectra DA and the 4 DAS categories (Figure 2) also yielded a marginally significant chi-square (chi-square = 13.203, df = 6, p = 0.040). However, only 6 of 120 patients in a high Vectra clinical category were also in a high DAS category (concordance =

5%); of the 204 patients with a DAS in remission or low, only 32 were in the low Vectra category (concordance = 16%).





Conclusion: In a previous validation study Vectra DA scores showed a significant correlation with DAS28 scores. While our study confirmed a statistically significant but weak correlation, it also showed that when clinical categories rather than raw scores were used, the concordance between the two tests was minimal. Since therapeutic decisions based on a test that may not accurately reflect a patient's clinical status would be inappropriate, cost effectiveness and benefits of this expensive test should be reevaluated.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The 14-3-3 family of conserved regulatory proteins consists of seven isoforms: α/β, γ, δ/ζ, ε, η, θ/τ and σ. These proteins exist as intracellular adapters that interact with more than 200 intracellular proteins to modulate their activities. Extracellular 14-3-3η at concentrations found in patient serum activates key signalling cascades and induces factors associated with Rheumatoid Arthritis (RA) pathogenesis.[1] The purpose of this study was to determine if 14-3-3η serum levels are additive to available RA-associated autoantibodies to identify RA patients in a cohort of recent-onset polyarthritis cohort (EPA).

Methods: Using the manufacturer's (Augurex 14-3-3η) ELISA, serum 14-3-3η levels were measured at baseline in 331 patients with EPA from the Sherbrooke EUPA cohort. All 331 had completed a follow up of at least 5 years. Patients were rapidly and intensively treated with DMARDs and/or biologics to achieve clinical remission defined as 0 swollen joint among 66. The manufacturer's reported diagnostic cut-off of ≥0.19 ng/ml was used. Anti-CCP2 (EuroImmun and Inova Diagnostics) and IgM RF (RapiTex, Dade-Behring) were determined using commercial assays and Anti-Sa/citrullinated vimentin (Sa), using an in-house assay previously described.[2]

Results: Median age was 60 y.o. and 62% were female; median time of symptom duration was 4 months. Up to 92% were treated with DMARDs between baseline and the 18-month follow up; 23 also received biologic agents over that period. 14-3-3η was positive at baseline in 153 (46%) of patients and RF, anti-CCP2 and anti-Sa were positive respectively in 146 (44%), 132 (39.9%) and 73 (22%). When 14-3-3η protein was combined with antibodies, the proportion of patients with at least one positive test increased to 54.8% (RF or 14-3-3η), 55% (anti-CCP2 or 14-3-3η) and 49.7% (anti-Sa or 14-3-3η), corresponding to an incremental benefit in sensitivity of 25%, 38% and 126%, respectively. When combining 14-3-3η with all 3 antibodies, the number (proportion) of positive patients for at

least one marker increased from 164 (51.0%) to 194 (58.6%).

Conclusion: Serum 14-3-3η positive status in recent-onset polyarthritis adds significant sensitivity to currently available RA-associated antibodies. Since higher 14-3-3η titres are associated with an increased risk of joint damage progression, our data support measuring it in early inflammatory polyarthritis to assist with patient stratification.

Assessing Information Needs for Chronic Disease Management in Rheumatoid Arthritis

Marylou Cardenas-Turanzas[1], Elsa Gonzalez[2], Maithili Shethia[1], Maria A. Lopez-Olivo[3], Pratibha Nayak[4] and **Maria E. Suarez-Almazor**[3], [1]Department of General Internal Medicine, The University of Texas, MD Anderson Cancer Center, Houston, TX, [2]Higher Education Administration, Texas A&M University, Corpus Christi, TX, [3]General Internal Medicine, The University of Texas, MD Anderson Cancer Center, Houston, TX, [4]National Institutes of Health, Atlanta, GA

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with chronic disease are increasingly using social networking to share experiences about their disease, and receive peer support. As part of an educational intervention we conducted a qualitative needs assessment to evaluate the information needs of patients with RA and to determine the acceptability of the Internet, and specifically social networking tools such as Facebook (FB), as a source of information and interaction among peers.

Methods: We conducted 20 semi-structured cognitive interviews with adult participants with RA who were diagnosed by a rheumatologist, had ongoing or prior treatment with disease-modifying anti-rheumatic drugs or biologic agents, disease duration <=10 years, and had internet access. Themes explored included: (1) health information needs, (2) use of self-management health behaviors, (3) use of internet resources for disease management, (4) role of peer support in health self-management, and (5) use of social networking sites (SNS) such as FB in disease management. Data was organized, sorted and interpreted from the participant's verbatim responses using *Dedoose*, a web application to analyze qualitative data.

Results: Participants included 85% females. The majority were White (65%) and 50% were 51-65 years old. Categories identified by the themes mentioned above were (see table): (1) important aspects that patients' needs to know, source of information, useful information but difficult to get, advice giving to others; (2) self-management health condition and practices, dealing with ongoing health needs and stress, managing medication regularly, support from family and friends; (3) definition of uses of internet such as getting familiar/getting started, frequency of use, familiar or not with internet, self-management/use of internet, daily use, self-management/useful information, preferred learning vehicles; (4) forms of online communication, type of social networking site, purpose and frequency of use, information on, and support from SNS.

Conclusion: Although the dominant theme was RA information needs, the rest of the themes contribute in supporting the robust emergence of Internet media in informing patients about their health. In searching for useful information to manage their condition including activities as exploration of internet sites and interest for FB as support tool, participants are authenticating their need for accurate information on RA to help them managing their condition. The interpretation of these findings will inform the choices and format of educational and self-management materials to be considered for online educational, self-management and social networking tools.

Validation of the Quickdash in the Assessment of Rheumatoid Arthritis Disease Activity

Cassandra Craig[1] and Matthew Carroll[2], [1]Internal Medicine, Keesler Medical Center, Keesler AFB, MS, [2]Rheumatology, Keesler Medical Center, Keesler AFB, MS

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid Arthritis (RA) is a chronic inflammatory arthritis associated with substantial morbidity and mortality. Measuring disease activity in RA is important as it facilitates a treat-to-target approach. The purpose of this study was to determine whether the modified version of the Disabilities of Arm, Shoulder, and Hand (DASH), the QuickDASH, was valid in measuring disease activity in RA. Validity was assessed by correlation with the Routine Assessment of Patient Index Data 3 (RAPID3).

Methods: This prospective cohort study gathered commenced July 2014 at a single academic facility Rheumatology Clinic. Subjects with a diagnosis of RA based on 1987 or 2010 American College of Rheumatology (ACR) Classification Criteria, depending on year diagnosed, were enrolled. When seronegative, subjects with polyarticular symptoms and synovitis or erosions on MRI established diagnosis. Primary endpoint was establishing validity of QuickDASH in routine clinical assessment of RA disease activity through correlation with RAPID3.

Results: From a cohort of 98 subjects, 89 had at least 2 data points available for analysis and 178 data points were used in paired analysis. The average patient age was 62.3 ± 13.7 years old. Slightly more than 70% of study participants were women and alomst 75% were Caucasian. Seropositivity was 72.4% and 74.5% had erosive disease.

Test-retest reliability of the QuickDASH was excellent with an intraclass correlation coefficient (ICC) of 0.915 (95% Confidence Interval (CI): 0.871, 0.945). Assessed by the Pearson correlation coefficient, the strength of the relationship between the QuickDASH and RAPID3 questionnaire was high ($r = 0.834$, $p < 0.0001$). The interclass reliability of the QuickDASH to correlate with the RAPID3 was moderate with an ICC of 0.627 (95% CI: 0.498, 0.722).

Linear regression analysis yielded the equation QuickDASH score = (2.801* RAPID3 score) + 3.542. Using the established disease activity ranges for the RAPID3 questionnaire, we developed similar ranges for the QuickDASH, as noted in the Table:

TABLE

	RAPID3 (raw score)	QuickDASH
Remission	0 – 3.0	0 - 12.0
Low Disease Activity	3.1 – 6.0	12.1 – 20.0
Moderate Disease Activity	6.1 – 12.0	20.1 – 37.0
High Disease Activity	≥ 12.1	≥ 37.1

For the 4 categorical measurements of QuickDASH and RAPID3 as defined in the Table, reliability of testing yielded an average Inter-Item Correlation of 0.786 ($p < 0.001$). Cronbach's α was 0.879 (95% CI: 0.838, 0.910, $p < 0.001$). The measurement of agreement assessed by Kappa testing showed moderate agreement with a Kappa of 0.481 ($p < 0.001$) for the QuickDASH ranges established.

Conclusion: This study demonstrated that the QuickDASH was very reliable and internally consistent in the measurement of RA disease activity. The QuickDASH moderately correlates with established ranges of RA disease activity established by the RAPID3 and could potentially be used as a surrogate for the RAPID3 in clinical practice.

Evaluation of Anti-Cyclic Citrullinated Peptide Autoantibody Levels in Clinical Practice and Its Association with Disease Activity

E Alemao[1], KK Gandhi[1], C Iannaccone[2], M Frits[2], JS Coblyn[2], N Shadick[2] and Michael Weinblatt[2], [1]Bristol-Myers Squibb, Princeton, NJ, [2]Brigham and Women's Hospital, Boston, MA

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

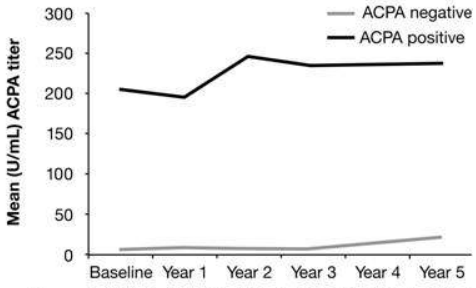
Background/Purpose: Testing for anti-citrullinated peptide antibodies (ACPA) is included in the 2010 ACR classification criteria for RA. ACPA concentration, beyond ACPA positivity, is indicative of more aggressive radiographic progression. However, there is limited information on ACPA levels in clinical practice settings and its association with disease activity measures. **Methods:** Data were analyzed from patients (pts) enrolled in a large, US RA registry established in 2003. The registry mostly comprises pts with established RA who were evaluated semi-annually for multiple clinical PROs and resource utilization parameters. The current analysis is based on pts enrolled in the registry with ACPA values at the time of baseline visit. Baseline and follow-up ACPA levels were based on a well-documented and validated ELISA from Inova Diagnostics until its discontinuation in 2011; the Euro-Diagnostica assay (distributed by IBL-America, Minneapolis, MN), which supplied the 'capture' antibody for the original Inova Diagnostics ELISA, has been used since. In assessments, the correlation between the two assays was 0.984. Mean changes from baseline over the first 5 years (yrs) of enrolling into the registry were calculated. Four categories of ACPA change from baseline were created based on quartiles of the distribution of ACPA change to Yr 1. Multivariate regression analyses controlling for baseline covariates were conducted to evaluate associations between ACPA change from baseline quartiles and disease activity measures defined by CDAI, SDAI, DAS28 (CRP) and joint counts.

Results: Overall, 1309 (97%) registry pts were included in the current analysis. The mean (SD) age of the cohort was 56.01 (14.04) yrs and 83.2% were females. Figure 1 represents the mean of ACPA levels up to Yr 5. The mean (SD) change in ACPA in ACPA+ pts was –0.5 (71.3) U/ml, 50.8 (93.9) U/ml, 33.1 (123.1) U/ml, 33.9 (132.0) U/ml, 40.6 (122.4) for Yr 1 through Yr 5, respectively. The ACPA mean change to Yr 1 quartiles had the following cut-off values: Q1 >–488.1 to ≤–13.6 U/ml; Q2 >–13.6 to ≤0.0 U/ml; Q3 >0 to ≤8.8 U/ml; Q4 >8.8 U/ml. The mean reductions in disease activity based on CDAI, SDAI and joint counts were greatest for Q1 (Figure 2). Similar patterns of change in disease activity were observed after controlling for baseline covariates in multivariate analysis.

Conclusion:

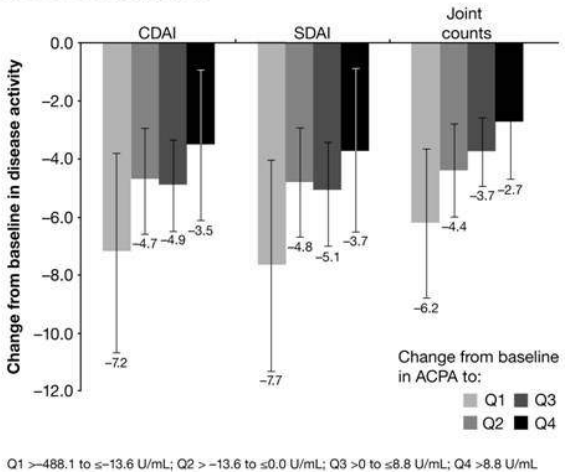
We observed that ACPA titers change over time and ACPA increase is primarily observed in ACPA+ pts with higher ACPA values at baseline. Pts with reduction in ACPA show a numerically greater reduction in disease activity levels.

Figure 1. Mean ACP titer over time



ACPA positive, n	803	530	467	388	295	342
ACPA negative, n	506	307	252	208	141	156

Figure 2. Association between change from baseline in ACPA levels and change in disease activity levels



Q1 >−488.1 to ≤−13.6 U/mL; Q2 > −13.6 to ≤0.0 U/mL; Q3 >0 to ≤8.8 U/mL; Q4 >8.8 U/mL

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: RA patients are at risk for disease worsening (flare) after joint surgery, as medication is withdrawn to mitigate infection risk. We aimed to describe rates and characteristics of RA flare within 6 weeks of total hip (THA) and total knee arthroplasty (TKA).

Methods : RA patients undergoing TKA/THA were queried every week about any change in RA status including pain and function (MDHAQ, HOOS/KOOS ADL). Baseline (BL) characteristics, BL and 6 week DAS-28, were collected. RA Flare was defined by Patient Report (yes/no, “Are you in a flare?”). Flare classification was determined by concordance between patient report of flare and MD assessment of flare, by chart review including joint counts, excluding the surgical joint. Medication use was standard of care: biologic DMARDs stopped; steroids and MTX continued.

Results : Of 37 RA pts recruited, most were female, white and had undergone THA **(Table 1)**. Mean (SD) time to flare was 2.9(2.0) wks in 23/37 (62%) patients, with a self-rated flare severity of 6.3(2.4), duration >4 days in 74%. All but 6 stopping biologics flared. Numerically, more flarers took steroids, MTX and biologics. Disease activity at baseline and 6 weeks remained moderate for both groups **(Table 2)**. Though numerically higher in flares disease activity and function at BL and change over 6 weeks was similar. At 6 weeks, patients reporting flare had significantly higher tender joint counts [RADAI 14.5(8.3) vs. 7.6(6.1), p=0.02], rescored to remove the surgical joint [RADAI 13.3(7.7) vs. 6.5(6.1), p=0.02]. Worse MDHAQ [4.0(1.7) vs. 2.9(1.2), p=0.07] and RAPID3 [13.8(5.3) vs.

14.7(8.2), p=0.09] approached significance.

Conclusion: Post-op flares are frequently reported, and rated as severe in RA patients undergoing THA/TKA. Numerically, flares are more frequent in patients stopping biologics. Increased RA related worsening joint pain and function seen in those whose RA worsens after surgery may contribute to poor long-term outcomes for RA patients undergoing THA/TKA. Further studies of post-op flare are needed.

This study was supported by the Clinical Translational Science Center (CTSC) (UL1-TR000457-06)

Improved Flare/ Remission Pattern in Rheumatoid Arthritis over the Recent Decades

Elena Myasoedova[1], Sherine E. Gabriel[2], Eric L. Matteson[3], John M. Davis III[4] and Cynthia S. Crowson[5], [1]Internal Medicine and Rheumatology, Mayo Clinic, Rochester, MN, [2]Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ, [3]Rheumatology, Mayo Clinic, Rochester, MN, [4]Division of Rheumatology, Mayo Clinic, Rochester, MN, [5]Health Sciences Research, Mayo Clinic, Rochester, MN

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Flare or episodic worsening of disease activity is an important aspect of the disease experience for patients with rheumatoid arthritis (RA), with significant impact on quality of life, well-being, joint damage and comorbidity. Improving trends towards lower RA disease activity have been suggested in recent years as compared to previous decades. However, long-term data on flare and remission rates in RA over calendar time are lacking. We aimed to assess trends in the occurrence of flares and remission in RA over the last decades.

Methods: In a population-based cohort of patients with RA (age≥30 years; 1987 ACR criteria met in 1988-2007) we performed a retrospective medical records review of each clinical visit to estimate flare and remission status. RA flare was defined as any worsening of RA activity leading to initiation/change/increase of therapy (OMERACT 9). Remission was defined as the absence of disease activity (i.e. tender joint count [TJC] = 0 + swollen joint count [SJC] = 0 + ESR ≤ 10 mm/hr) (OMERACT 7). All subjects were followed until death, migration or July 1, 2012. Flare and remission rates were calculated as the percentage of visits in flare or remission in each calendar year. Time spent in flare was calculated as days in flare divided by days of follow-up in each calendar year.

Results: The study included 525 RA patients (mean age 54.5 years; 71% female) with mean follow up of 10.1 years. Flare/ remission status was collected for a total of 15,649 clinical visits. Patients were flaring in 2829 (18%) visits and were in remission in 1545 (10%) visits. The median duration of flare was 2.4 months (Q1 1, Q3 5.4 months). The figure shows trends in flare and remission occurrence in RA patients over time.

There has been a statistically significant decline in the RA flare rate over calendar time, from 32% of visits per year in 1990 to 15% of visits per year in 2010 ($p<0.001$). In contrast, remission rates went up from 0.6% of visits per year in 1990 to 13.1% of visits per year in 2010 ($p<0.001$). During the study period, there has been a statistically significant annual decline in the percentage of time spent in flare (3.6% per year, $p<0.001$), while the percentage of time spent in remission has been increasing by 3.0% per year ($p<0.001$).

Conclusion: Our findings show significant decline in flare occurrence and concurrent increase in remission rates in patients with RA over the last two decades, likely reflecting improved control of RA activity and possibly milder RA disease course in the recent time. Concordantly, there has been a decrease in time spent in RA flare accompanied by an increase in remission time over the years. These positive trends are highly relevant to patients with RA and rheumatology health care providers and have potentially important impact on health care organization and management of RA. The implications of this improved trend on outcomes and mortality in RA require further study.

Figure. Occurrence of flares (upper panel) and remissions (lower panel) in patients with RA over calendar time

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Patient-reported outcomes are recognized as important for evaluating the disease status of rheumatoid arthritis

(RA). The EuroQol 5-dimensional descriptive system (EQ-5D) has been used to assess health-related quality of life (HR-QOL) in clinical research and pharmacoeconomical studies. RA is a chronic disease associated with pain, fatigue, disability, and functional loss, which can markedly decrease a patients' quality of life (QOL). Treatment strategies for RA have changed greatly since the introduction of biological DMARDs (bDMARDs). The QOL of RA patients can be evaluated using EQ-5D in daily practice.

We analyzed a clinical database of a large prospective observational cohort of patients with RA. Subclasses with distinct patterns were identified in the Japanese version of EQ-5D in RA patients who received biologics. The clinical features of patients whose QOL improved after use of biologics in daily practice was then examined.

Methods: Since October 2000, we have established a large observational cohort of RA patients in our institute, the Institute Of Rheumatology, Rheumatoid Arthritis (IORRA). Essentially, all RA patients who attend our clinic are asked every 6 months to answer questionnaires including the EQ-5D, disease activity score 28 (DAS28), and Japanese version of the health assessment questionnaire (J-HAQ). More than 5,000 RA patients are included in the cohort, with 813 patients who received bDMARDs being enrolled in this study. The EQ-5D scores of these 813 patients were recorded biannually for 2.5 years and the latent classes of time trends in EQ-5D score based on posterior probability examined after initiation of bDMARDs. The clinical characteristics of each latent class were then compared.

Results: The 813 patients were classified into 4 classes based on time-related changes in EQ-5D score: Class 1, patients with persistent high score of around 0.9 (n=301); Class 2, patients whose score improved from about 0.7 to 0.9 after use of bDMARDs (n=73); Class 3, patients with a persistent moderate score of around 0.7 (n=348); and Class 4, patients with a persistent low score of under 0.6 in spite of use of bDMARDs (n=166). The patients in Class 2 were younger and had a shorter disease duration (p<0.05), higher DAS28 (p<0.001), lower J-HAQ (p<0.05) and more frequent use of non-steroidal agents (p<0.05) than the patients in Class 3.

Conclusion: This study suggests that QOL is less likely to improve in patients with RA whose disability and deterioration of QOL has already become established despite the use of bDMARDs. We also determined the clinical features of RA patients whose QOL improved after daily use of biologics.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Despite an increasing armamentarium of efficacious treatments for Rheumatoid Arthritis (RA), sustained remission remains an unrealistic expectation for many patients, with most experiencing ongoing disease activity and flares of varying frequency. The aim of the current study is to describe the patients who are inadequately controlled (DAS28>3.2) on their current therapy

and identify common features associated with this population.

Methods: Data were drawn from the Adelphi 2014 RA Disease Specific Programme, a survey of rheumatologists and their RA patients in France, Germany, Italy, Spain and UK. Rheumatologists provided patient demographics, comorbidities, satisfaction with RA control and clinical details including current DAS28. Patients reported their satisfaction, and completed the EuroQOL 5-Dimension Health Questionnaire (EQ-5D) and Work Productivity and Activity Impairment (WPAI) Questionnaire. Of the patients who had been on their current therapy for at least 3 months, two patient cohorts were created based on the physician-reported DAS28: adequately and inadequately controlled (DAS28 ≤3.2 and >3.2 respectively). Univariate tests were performed to compare the cohorts.

Results: A total of 1147 patients had been on current therapy for at least 3 months and had DAS28 scores reported, 74% were female, with a mean age of 52 years, and mean time since RA diagnosis of 84 months. The table demonstrates that compared with the adequately controlled cohort, inadequately controlled patients were more affected clinically, had higher rates of depression, worse quality of life and greater work and activity impairment. There were also lower satisfaction rates among the patients and their physicians.

	Adequately controlled	Inadequately controlled*
n:	839 (73%)	308 (27%)
Rheumatologist reported clinical profile		
Perceived severity: ‘mild' (%)	87.4	31.2
Perceived severity: ‘moderate' (%)	11.9	58.1
Perceived severity: ‘severe' (%)	0.7	10.7
RA currently ‘improving' (%)	31.1	22.1
RA currently ‘stable' (%)	65.3	38.3
RA currently ‘unstable / deteriorating' (%)	3.6	39.6
Physician reports patient is currently ‘in remission' (%)	68.2	13.6
Current level of pain (mean, 1 none – 10 worst)	2.3	4.6
Patient ever experiences flares: yes (%)	41.4	67.3
Comorbidities (%):		
Depression	5.4	15.6
No comorbidities	56.9	34.7
BMI (mean)	24.9	25.8
Treatment		
Months receiving current therapy (mean)	25.9	24.8^
Ever received a bDMARD (%)	44.0	51.0
Status of bDMARD (% of patients prescribed a bDMARD):		
Currently receiving 1st bDMARD therapy	68.0	52.9
Impact on the patient		
Quality of life: EQ-5D score (mean)	0.77	0.53
Employment: Full time employed (%)	46.0	29.2
WPAI: % Overall work impairment (mean)	18.4	33.5@
WPAI: % Presenteeism (mean)	16.5	32.2
WPAI: % Activity impairment (mean)	26.7	48.2
Satisfaction with RA control (%)		
Physician ‘satisfied'	88.4	31.2
Patient ‘satisfied'	84.6	55.1

*: Variables significantly different from ‘adequately controlled' cohort, $p<0.01$ unless indicated by @: $p=0.0146$, or ^: not significant

Conclusion: Results show that almost a third of RA patients are insufficiently controlled despite current therapy. Even though these patients are more affected clinically, more impacted in their daily lives and less satisfied overall, the data indicated that in some cases physicians may perceive these patients to be ‘mild', or ‘in remission'. The discordance between physicians' perceptions and the objective DAS28 in some patients may result in less than optimal therapeutic management, the result of which may be sustained periods of unnecessary active disease. Furthermore, over half of patients who are not adequately controlled report being satisfied with the control their RA therapy provides, suggesting they too may be accepting sub-optimal outcomes and not look to change treatment.

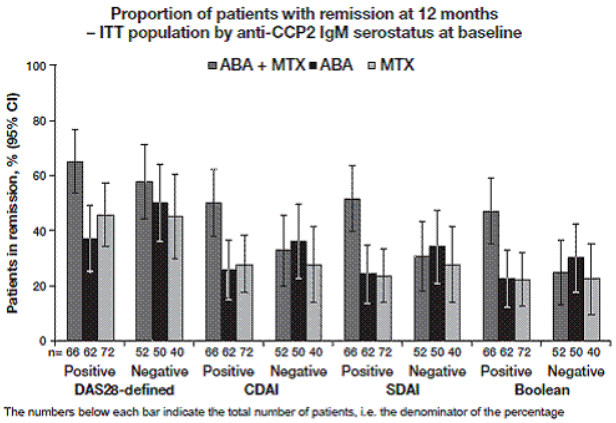
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-citrullinated protein antibodies (ACPA) are a marker of RA, and the presence of the immunoglobulin M (IgM) isotype indicates an ongoing immune response involving the recruitment of naïve B cells.[1] Abatacept (ABA) modulates T-cell co-stimulation and has been shown to impact ACPA maturation, including seroconversion of IgM, in the AVERT (Assessing Very Early Rheumatoid arthritis Treatment) trial.[2] The objective of this analysis was to assess the efficacy of treatment with ABA+MTX, ABA monotherapy or MTX alone in patients (pts) from the AVERT trial based on their anti-cyclic citrullinated peptide 2 (CCP2; a surrogate for ACPA) IgM serostatus at baseline (BL), and seroconversion (anti-CCP2 IgM positive to negative) through 1 year. **Methods:** The AVERT trial has been described previously.[3] In this *post hoc* analysis, pt samples were analysed by ELISA to determine anti-CCP2 IgM serostatus. Efficacy outcomes analyzed by BL anti-CCP2 IgM serostatus included remission rate at 12 mths (CDAI, SDAI, Boolean and DAS28 [CRP] <2.6-defined remission), and adjusted mean change in DAS28 (CRP) and HAQ-DI over time (samples taken every 28 days up to Mth 12 and analyzed with a longitudinal repeated-measures model). Boolean remission was analyzed in pts who seroconverted. **Results:** In the ABA+MTX treatment arm, a higher proportion of pts who were anti-CCP2 IgM positive at BL achieved remission by all indices compared with pts who were BL IgM negative (Figure). This trend was most clearly observed in the stringent indices of CDAI, SDAI and Boolean remission, compared with DAS28 (CRP)-defined remission. This trend was not observed in either the ABA monotherapy or MTX alone arms. Mean improvement in DAS28 (CRP) and HAQ-DI over time was also greatest in BL anti-CCP2 IgM-positive pts treated with ABA+MTX. A numerically higher proportion of pts who seroconverted from anti-CCP2 IgM positive at BL to negative at Mth 12 achieved Boolean remission versus pts who remained seropositive in the ABA+MTX and ABA



The numbers below each bar indicate the total number of patients, i.e. the denominator of the percentage

	Proportion of BL anti-CCP2 IgM-positive pts who achieved Boolean remission, by serostatus at Mth 12	
Treatment group	BL positive to Mth 12 negative	BL positive to Mth 12 positive
ABA+MTX	61.5% (16/26)	41.2% (14/34)
ABA	44.4% (4/9)	23.8% (10/42)
MTX	28.6% (4/14)	27.9% (12/43)

Proportion of pts is expressed as: % (number of pts with remission/total number of pts)

monotherapy arms (Table).

Conclusion: Abatacept in combination with MTX had greater clinical efficacy in pts who were anti-CCP2 IgM positive at BL than in those who were anti-CCP2 IgM negative at BL, and in those who seroconverted over time than those who did not, suggesting that the impact on ACPA is associated with clinical benefit.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: AM stiffness is a common yet under-appreciated symptom in RA. The longitudinal impact of AM stiffness has not been previously investigated. This study evaluated persistency of AM stiffness over time and prevalence of improvement based on decreases in stiffness duration following initiation of new DMARD therapy in the Corrona RA Registry.

Methods: Adult patients enrolled as of December 31, 2014 who initiated new biologic or synthetic DMARDs and maintained treatment for ≥90 days were analyzed and followed until last visit. The proportion and frequency of patients who reported none or decreased duration of AM stiffness were compared with those with persistent or increased duration at last visit. Among patients with AM stiffness at treatment initiation, baseline characteristics and categorical improvement in stiffness duration were evaluated. Patients reporting <1hr of AM stiffness were considered improved if they had no stiffness; those reporting 1-<2hrs were improved if <0.5 hours and those with 2-<3 and ≥3hrs improved if <1hr by last visit.

Results: Of 9377 total patients, 4972 (53%) continued stiffness free or reported decreased duration and 4405 (47%) had persistent or worsened duration of stiffness at last visit (Table 1). 644 (42.2%) with no stiffness at treatment initiation reported stiffness by last visit. Among 7851 with AM stiffness at treatment initiation, a large majority were biologic DMARD naïve (56.5%) and initiated combination therapy (56.4%) (Table 2). When categorical improvement in stiffness duration criteria were analyzed, 5432 (69.2%) among patients reporting AM stiffness at treatment initiation reported no improvement at last visit.

Conclusion: In this analysis, longitudinal and categorical change data demonstrate that AM stiffness is a recurring symptom which persists as an unmet need in a large majority of RA patients despite initiation of new DMARD therapy. Further research is needed to evaluate clinically meaningful metrics from the patients' perspective for improvement in AM stiffness duration. Clinical factors associated with improved responses should be evaluated to address persistency of AM stiffness that continues to affect a large number of RA patients.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Numbers of composite scores are available to assess disease activity in rheumatoid arthritis (RA), the most widely used being the Disease-Activity-Score in 28 joints (DAS28), the Simplified-Disease-Activity-Index (SDAI), and the Clinical-Disease-Activity-Score (CDAI). Baker et al. have recently developed a modified version of these scores (M-DAS28, M-CDAI, M-SDAI) based on widely available clinical measures (swollen joint count [SJC] evaluator global assessment of disease activity [EvGA] and CRP level). (1) These scores demonstrated superior correlation with MRI detection of synovitis and more accurately predicted radiographic progression after 1 year than DAS28 and SDAI.The objective of the study was to evaluate the performance of new composite disease activity scores (M-DAS28, M-SDAI and M-CDAI]) compared to conventional measures (DAS28, SDAI and CDAI)

to predict radiographic progression in rheumatoid arthritis patients from the ESPOIR cohort.

Methods: The French multicentric ESPOIR cohort included a total of 664 patients with early (< 6 months) unclassified arthritis. This study was conducted on the patients fulfilling the ACR/EULAR 2010 classification criteria for RA. The M-DAS28, M-SDAI, and M-CDAI were respectively compared to the DAS28, CDAI and SDAI for predicting radiographic progression (estimated after 1 year by The Sharp/van der Heidje [SHS] scoring system).

Results: A total of 590 RA patients (women 78%, age 48.8 years, symptoms duration 16 weeks, SJC 8, tender joint count 9, ESR 29 mm at the first hour, CRP level 22 mg/L, DAS28-ESR 5.2, DAS28-CRP 5.0, SDAI 30.4, CDAI 28.3) were included.

Ability to predict radiographic progression after 1 year was the same between baseline M-DAS28-ESR and DAS28-ESR (Area under the curve [AUC]: 0.53 [0.49–0.58] *vs* 0.53 [0.48–0.58] respectively), M-DAS28-CRP and DAS28-CRP (AUC : 0.54 [0.49–0.59] *vs* 0.52 [0.47–0.57] respectively), M-SDAI and SDAI (AUC : 0.52 [0.47–0.57] *vs* 0.51 [0.46–0.56] respectively), M-CDAI and CDAI (AUC: 0.51 [0.47–0.56] *vs.* 0.50 [0.45–0.55] respectively).

Conclusion: In conclusion, modified disease activity scores (M-DAS28-ESR, M-DAS28-CRP, M-CDAI and M-SDAI), based on clinical measures of disease activity, did not prove superiority to original disease activity scores on ability to predict structural progression in patients with RA.

Male Gender and Higher Hemoglobin Predict Response to Methotrexate in Rheumatoid Arthritis

Abhijeet Danve[1], Harlan Sayles[2], Ted R. Mikuls[3] and James R. O'Dell[2], [1]Internal Medicine - Rheumatology, University of Nebraska Medical Center, Omaha, NE, [2]University of Nebraska Medical Center, Omaha, NE, [3]Internal Medicine, University of Nebraska Medical Center, Omaha, NE

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Methotrexate (MTX) is routinely used as the first-line drug for rheumatoid arthritis (RA). About 1 in 3 RA patients achieve excellent RA control with MTX monotherapy. Identifying predictors of MTX response could allow treatment optimization, avoid drug toxicities and treatment delays while saving costs.

Methods:

Potential baseline clinical predictors were studied in two cohorts: Rheumatology & Arthritis Investigational Network (RAIN) Early Predictors Study and Treatment of Early Aggressive Rheumatoid Arthritis (TEAR) trial. RAIN is a 16-week, open-label study where RA patients are started on weekly po MTX 15mg and escalated to 20 mg at 8 weeks if not in remission (DAS-28 ESR< 2.6). Clinical and laboratory parameters are collected at baseline, 8, and 16 weeks. TEAR was a randomized, double-blind study using 4 treatment arms: two arms with immediate combination therapy and two step-up arms. We analyzed patients from TEAR step-up arms who initially were on po MTX monotherapy. Primary outcome was absolute change in DAS-28 (baseline to 16 weeks for RAIN and baseline to 12 weeks for TEAR) adjusted for the baseline. Low disease activity (LDA; DAS28 <3.2) was a secondary outcome. Data were analyzed using ordinary least squares and logistic regression.

Results:

Eighty-three patients (75% female, 89% white) completed the 16-week RAIN trial. Mean (SD) change in DAS-28 from baseline to 16 weeks was -1.90 (1.50) with LDA achieved by 51%. Male gender (p=0.015), white race (p=0.019) and lower baseline neutrophil (BNC) count (p=0.011) were associated with significant improvement in DAS-28ESR (Table). Male gender, higher hemoglobin and lower BNC were significantly associated with achieving LDA (not shown).

Patients (n=297) who received MTX monotherapy during TEAR were also analyzed (70% female, 81% white). Mean (SD) change in DAS-28 from baseline to 12 weeks was -1.28 (1.19) with LDA achieved by 20%. Male gender (p=0.016), lower baseline tender joint counts (p=0.037) and lower baseline aspartate transaminase (p=0.020) were associated with primary outcome (Table). Lower BNC showed a non-significant trend towards DAS28 improvement. Male gender, lower swollen joint count and higher hemoglobin were associated with LDA (not shown).

Conclusion:

In both cohorts, male gender and white race were associated with significant improvement in DAS28ESR with MTX monotherapy; higher baseline hemoglobin was also associated with achieving LDA. Lower BNC was associated with good response (absolute change and LDA) to MTX in RAIN cohort, but only showed a trend in the TEAR cohort. Larger studies with a focus on pharmaco-genetics may be required to identify the RA patients who are ideal candidates for MTX monotherapy.

Table - DAS28ESR Change from 0 to 16 Weeks (RAIN) or 12 Weeks (TEAR) Controlling for Baseline DAS28ESR

	RAIN N=83			TEAR N=297		
Characteristic	**Coefficient**	**SE**	**p value**	**Coefficient**	**SE**	**p value**

Determinants of Patient- Physician Discordance in Assessment of Global Disease Activity in Latinos with Rheumatoid Arthritis in the United States

George A. Karpouzas[1], Taylor Draper[2], Elizabeth Hernandez[1] and Sarah Ormseth[1], [1]Rheumatology, Harbor-UCLA Medical Center, Torrance, CA, [2]Psychology, Loma Linda University, Loma Linda, CA

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients and physicians often differ in their perceptions of disease activity in Rheumatoid arthritis (RA) as described by patients' and evaluators' global assessments (PGA and EGA respectively), mostly assessed in Caucasians. We evaluated determinants of PGA and EGA and their proportionate contributions in Latinos with RA in the US. We further explored predictors of discrepancies between PGA and EGA, and interrogated the frequencies of concordant and discordant assessments of changes in PGA and EGA longitudinally.

Methods: We assessed 333 Latinos with RA and follow up in a single center. EGA and PGA were captured on a 0-10 cm visual analogue scale; discordance was defined as difference >2 cm between the 2 assessments. Linear regression models evaluated predictors of PGA and EGA, and relative importance weights were calculated for their proportionate contribution to PGA and EGA variance. Logistic regression models interrogated predictors of both patient and physician higher ratings respectively.

Results: Our models explained 66% of variability in PGA and 83% of the variability in EGA. Main, multivariate determinants for PGA were fatigue (23.7%), pain (21.2%), depression (18%), and sedimentation rate- ESR (3.2%). EGA was mainly predicted by swollen joint counts (44.4%), tender joint counts (30.2%), ESR (5.2%) and fatigue (3.5%). Concordance was observed in 142 (43%), higher patient ratings in 147 (44%), and higher physician ratings in 44 (13%). Fatigue and pain predicted higher patient ratings, while swollen joints, tender joints, and prednisone use predicted higher physician ratings (table 1). At follow up, EGA improved in 31.7%, remained unchanged in 50.9% and worsened in 17.4%. Respective trends for PGA were 28.6%, 44.1% and 27.3%. The lowest concordance was seen for worsening disease, where PGA showed only 27% concordance with the EGA, compared to 59% and 52% for unchanged or improved disease respectively.

Conclusion: Highly divergent parameters shape patients' and physicians' perceptions of disease activity in Latinos with RA in the US; fatigue and pain contribute mainly to higher patient assessments, while swollen and tender joint counts predict higher physician assessments. Patient education of what determines long-term disability, and a better physician grasp of the patient perspective will likely foster shared decision-making and compliance with treat to target initiative.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Depression is highly prevalent in RA. In trials, depression has been found to be associated with higher disease activity and impaired treatment response. However data are limited and subject to methodological limitations such as being derived from highly selected trial populations. Our aim was to examine the long-term association between depression and RA disease outcomes in routine care.

Methods:

Data were collected using electronic records from an inner city hospital in London, UK. The presence of depression/anxiety was identified using PHQ9 and GAD7 respectively. Patients were included in this analysis if they had completed a PHQ9/GAD7 on at least 2 occasions. The first ever PHQ9/GAD7 record was taken as the baseline visit. Follow up included all visit information over the subsequent 12-months. The relationship between anxiety/depression and DAS outcome was analysed using two approaches: 1) we calculated the likelihood of an individual achieving remission during follow up using Cox proportional hazards, adjusted for age, gender, disease duration and disease activity; 2) we modelled DAS trajectory using generalised estimating equations (GEE).

Results:

From a total cohort of 1,375, 385 patients were eligible for analysis. The mean age was 59 (SD 15), with 81% female (see table). At baseline, depression/anxiety were associated with higher disease activity and disability. The presence of depression/anxiety at baseline was associated with significantly higher disease activity throughout follow-up (b= 0.92, SE= 0.15, p<0.001, 95%CI: 0.53 to 1.21), after adjusting for age, gender and disease duration. Using a GEE model DAS was significantly higher for patients with anxiety or depression (b=.85; 95% CI:.54 to 1.16), but reduced slightly over time (b/year=-.11 95% CI: -.21 to -.01). This change may reflect more aggressive treatment of patients with anxiety or depression that have higher DAS, the correlation between a change in DAS and anxiety or depression status of r=.28. Patients with baseline anxiety or depression were less likely to attain a state of remission (adjusted hazard ratio: 0.51, 95%CI: 0.35 to 0.75).

Conclusion:

Our data reveal a high prevalence of psychological comorbidity in RA. The presence of depression/anxiety associated with larger differences in patient reported components of outcomes (tender joint count, patient global, HAQ) than objective measures. Patients with baseline anxiety/depression had higher disease activity that remained high during follow up. Comparing change in DAS over time revealed no material difference in the DAS trajectory in patients with or without anxiety or depression. It is clear that psychological factors are linked to the clinical outcome measures used in rheumatology. However, how depression/anxiety influence prognosis is unclear.

Table

		No anxiety/ depression	Probable anxiety/ depression	p-value*

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Patient global assessment (PtGA) is included in all the current remission definitions for RA despite the fact that PtGA is not exclusively related to disease activity and may be influenced by noninflammatory or psychological processess. In this study in order to objectively identify whether patient's assessment is better than physician's (Ph) or not, we compared disease activities assessed with ultrasound (US) of Boolean remission patients with PtGA and Boolean remission patients with PhGA but not PtGA.

Methods: RA patients in clinical remission (DAS28-ESR<2.6) for at least 3 months were included. Boolean based remission definition and modified versions by substitution of PtGA with PhGA and by omitting PtGA were determined. A standard gray scale (GS) and power Doppler (PD) US examination of 28 joints (included in DAS28) for the presence of synovitis was performed by an experienced sonographer (NI) blinded to clinical data. US synovitis GS and PD signals were semiquantitatively graded from 0 to 3 and were recorded as sum scores of PD and GS, respectively.

Results: A total of 55 out of 302 RA patients (18.2%) in DAS28 remission were enrolled (F/M=35/20, mean age 52.2±12.0, disease duration 11.011.0±6.5 years, bDMARDs 43.6%, RF/Anti-CCP positivity 76.4%). Of 55 patients, 25 (45.5%) fulfilled the Boolean criteria. When PtGA was substituted with PhGA, remission rate increased to 72.7% (n=40) and when PtGA was omitted remission rate increased to 89.1% (n=49) (P<0.001 for both). Regarding US disease activity no PD, no GS and no PD+GS signals were observed in 9 (36%) vs 12 (30%), 7 (28%) vs 8 (20%) and 6 (24%) vs 7 (17.5%) patients in Boolean remission with PtGA and PhGA, respectively (P>0.05 for all). When PD and GS signals ≥ grade 2 were taken into account, % of patients without PD, GS or both signals were also similar (respectively, 16 [64%] vs 25 [62.5%], 12 [48%] vs 18 [45%] and 12 [48%] vs 17 [42.5%]). US disease activity parameters of Boolean PtGA remission and nonremission patients were compared as well, no significant difference was observed. On the other hand patients in Boolean PhGA remission had significantly lower PD scores (without grade 1) compared to Boolean PhGA nonremission (Table 1). In comparison of US disease activity of patients in Boolean PtGA remission and in Boolean remission with PhGA but not PtGA, the median PD and GS synovitis sum scores and the % of patients with no PD or GS signals were not statistically different.

Conclusion: RA patients in Boolean remission with PhGA do not have higher disease activity that is verified by US, compared to patients in Boolean remission with PtGA. Furthermore Boolean remission with PhGA better differentiates patients with US evinced inflammation. These data suggest that PtGA might be substituted with PhGA in Boolean criteria. Prospective follow up and recruitment of more patients will clarify the consistency of these results over time and impact of this substitution on functionality.

Table 1. US disease activity parameters of remission and nonremission patients according to Boolean based criteria with PtGA and PhGA*

	Boolean remission with PtGA (n=25)	Boolean non-remission with PtGA (n=30)	*P* value	Boolean remission with PhGA (n=40)	Boolean non-remission with PhGA (n=15)	*P* value

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) management paradigms have changed over the last two decades. Evidence now supports aggressive immunosuppression with early use of combination disease modifying anti rheumatic drugs (DMARDs) and biologics when standard DMARDs fail. The use of composite tools to measure disease activity has become standard assessment tools in the clinic with an aim of achieving remission or low disease activity. We set out to study the changing patterns of disease activity and disability in RA over the last 20 years.

Methods: Retrospective cross-sectional surveys were undertaken at four time points from two secondary care rheumatology departments in London. Patients included had a diagnosis of RA by the 1987 criteria of the American College of Rheumatology. The surveys collected data between (i) 1996-97; (ii) 2001-3; (iii) 2009-10; (iv) 2012-14. Data collected comprised demographic details (age, sex and disease duration), 28 joint disease activity score (DAS28) and its component parts. Disability measures using the Health Assessment Questionnaire (HAQ) scores were also available for the first, second and fourth cohorts.

Results: Overall 1324 patients were studied. The groups had similar demographic features (76-80% were female; their mean ages were 58-60 years; and their mean disease durations were 9.1-10 years. Disease activity fell over time, with the proportion of patients in remission significantly increasing from 8% in the earliest cohort to 28% in the most recent. The proportion with severe disease fell from 50% in the earliest cohort to 18% in the most recent, whilst the proportion with moderate disease remained constant (38-42%). Although the number of swollen joints has decreased in each DAS28 group over time, the more objective tender joint counts and patient global scores have increased or remained stable. In contrast, there was no fall in disability levels over time. Mean HAQ scores were 1.30 in 1996-97 and 1.32 in 2012-14, with a slightly higher mean HAQ of 1.52 in 2001-03. Comparing disability change over time across the disease activity groups, mean HAQ scores in patients in remission and low disease activity states increased. The correlation between disease activity and disability became weaker over time; in 1996-97 Spearman's rho was 0.56, in 2001-03 it was 0.55 and in 2012-14 it was 0.44.

Conclusion: Our data add to the existing evidence base, confirming that the trends towards milder disease are continuing. There is a widening gap between the subjective and objective components of DAS, with climbing tender joint counts in the face of reduced numbers of swollen joints. Other factors such as comorbidity including psychological disease, may be very relevant. Depression and anxiety are highly prevalent in RA. Our data show that the relationship between disease activity and disability has changed over time. Further research is needed to understand how to best manage non-severe RA, that now makes up the largest burden of clinic attenders. Strategies to address comorbidity and mental health needs should to be evaluated.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) diagnosis includes determination of autoantibodies and, their presence can represents 33% (2/6) to 50% (3/6) of the 2010 ACR/EULAR classification criteria [1]. Rheumatoid factor has three isotypes, of which IgM is the most used because of its sensitivity and specificity [2]. The aim of this study is to evaluate the performance of RF isotypes alone and in combination with anti-cyclic citrullinated peptide (anti-CCP) antibodies in the RA diagnosis.

Methods: An observational, retrospective and analytical study was made. We selected all results of RF and anti-CCP sent to our laboratory between March 2014 and March 2015 with an inflammatory arthritis suspicion. We collected final diagnosis according to medical records and classified patients with RA (2010 ACR-EULAR), Osteoarthritis (OA, ACR), Systemic lupus erythematosus (SLE,1987 ACR criteria) and Primary Sjögren syndrome (pSS, 2012 American-European-Consensus-Group (CETA) criteria). RF isotypes evaluated was IgA, IgM and IgG measured by ELISA (ORGENTEC®) with a cut-off > 20 IU and anti-CCP2 antibodies by ELISA (ORGENTEC®) with a cut-off> 25 IU. We made a descriptive analysis of the seropositivity according to different diseases. Then, we performed an analysis of sensitivity and specificity using autoantibodies alone and in different combinations for the final RA diagnosis.

Results: We included 62 (44.3%) RA patients, 10 (7.1%) patients with SS, 5 (3.5%) patients with SLE, and 52 (37.1%) patients with OA. In table 1 we described autoantibodies frequencies according to different diseases. Sensitivity and specificity to RA diagnosis was represented in Table 2 with autoantibodies combinations.

Conclusion: The combination of the four autoantibodies increased sensitivity for RA detection, although we observed a decreased of global specificity of the test.

Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Numerous studies have reported increased cardiovascular morbidity and mortality in rheumatoid arthritis (RA) patients that cannot be explained by traditional risk factors. In a non-RA cohort, our collaborators identified specific biomarkers of nitrative stress which act to impair endothelium dependent nitric oxide function and were found to be predictive of future CV events in an at risk population. These biomarkers [asymmetric dimethylarginine (ADMA), symmetric dimethylarginine (SDMA), and N-mono-methylarginine (MMA)] are produced by methylation of arginine, the sole nitrogen source for NO synthesis. We believe these biomarkers of subclinical endothelial dysfunction may serve as an early non-invasive predictor of accelerated atherosclerosis in RA patients. The aim of this study is to investigate if these biomarkers of endothelial dysfunction are increased in patients with RA compared to healthy controls and to examine the effects of disease modifying treatments, statin therapy, and seropositive status on levels of these biomarkers.

Methods:

The plasma from 119 RA patients (83.6% female, 60.2± 13.6 yrs of age) seen in a tertiary care center from October 2014 to April 2015 was analyzed for ADMA, SDMA and MMA levels by stable isotope dilution HPLC with online electrospray ionization tandem mass spectrometry compared to controls. The Arginine Methylation Index (ArgMI) was estimated by the ratio of [(ADMA+SDMA)/MMA]. The effects of statin and DMARD therapy, as well as seropositivity (anti-CCP antibody or RF>20) on these biomarkers were evaluated. The Student t test or Wilcoxon Rank sum test for continuous variables and chi squared test for categorical variables were used in statistical analysis.

Results:

ADMA and SDMA biomarker levels and ArgMI were statistically larger in the RA cohort ($p<.0001$) when compared with their age and gender matched healthy controls (see Table 1). Surprisingly, seronegative patients exhibited statistically significant higher ArgMI compared with seropositive patients. Statin and DMARD therapy showed no significant effect on any nitrative stress biomarkers.

Conclusion:

These elevated nitrative stress biomarkers in RA patients suggest an important avenue for detecting subclinical endothelial dysfunction in RA. Surprisingly, DMARD treatment, known to decrease systemic inflammation, did not suppress biomarkers of nitrative stress, which points towards a disconnect between systemic inflammation and endothelial dysfunction. Furthermore the elevated ArgMI seen in seronegative patients, a group that is perceived as having a more benign course and CV risk phenotype, warrants additional study. Future studies which prospectively follow patients for CV outcomes have the potential to identify RA patients at increased CV risk and provide them with appropriate preventative intervention.

Table 1.

Nitrative Stress Biomarkers	Healthy Controls (n=244)	Rheumatoid Arthritis (n=119)	P Value
ADMA, (µmol/L)	0.62 (0.55-0.69)	0.76 (0.68-0.82)	**<0.0001**
SDMA, (µmol/L)	0.46 (0.39-0.53)	0.52 (0.45-0.58)	**<0.0001**
MMA, (µmol/L)	0.20 (0.17-0.25)	0.20 (0.17-0.25)	0.9816
ArgMI,	5.30 (4.40-6.40)	6.21 (5.33-7.00)	**<0.0001**

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Environmental factors may play a crucial role in auto-immune diseases. Besides tobacco, other factors like vitamin D are suspected to impact the onset and the subsequent activity of inflammatory arthritis including rheumatoid arthritis (RA), but its association with severity of the disease has not been evaluated yet. The purpose of the study was to examine the association of baseline vitamin D serum level with RA severity, disability, disease activity, response to treatment over the first year in early arthritis patients.

Methods: Patients presenting with synovitis of at least 2 joints for 6 weeks to 6 months were included in the multicenter French ESPOIR cohort. 25OH vitamin D2 and D3 was measured at baseline and then separated into 3 groups: deficiency (<10 ng/ml), insufficiency (10-30 ngl/mL), normal level (≥30ng/mL). Correlation between vitamin D levels and DAS28, HAQ and van der Heijde modified total Sharp score (mTSS) were assessed at baseline by a Spearman correlation analysis. Bivariate analyses of the association between baseline vitamin D level and other outcomes were conducted: radiographic progression (defined by an increase of at least 1 point of the mTSS at 12 months); disability (defined by an HAQ≥1); disease activity (DAS28) and RA diagnosis (2010 ACR/EULAR criteria) at baseline, 6 and 12 months; response to treatment (EULAR response) at 6 and 12 months. Forward stepwise multiple logistic regression was used to evaluate independent association between baseline variables and formerly described outcomes.

Results: Among 813 patients included in the cohort, 810 were analyzed and 138 (16.97%), 522 (64.21%), 150 (18.45%) had vit D<10, 10-30 and ≥30ng/mL respectively. Vitamin D levels were found to be correlated with DAS28, mTSS and HAQ at baseline (Rho=-0.11, p=0.0016; Rho=-0.07, p=0.0335 and Rho=-0.11, p=0.0016 respectively). In bivariate analyses, patients with vitamin D deficiency had more radiographic progression at 12 months compared to vitamin D normal group (OR=1.82 95% CI 1.05-3.15, p=0.0323). Patients with a HAQ ≥ 1 were more frequent in deficiency group compared to normal group at baseline and 6 months (OR=1.89 95% CI 1.18-3.03, p=0.008 and OR=2 95% CI 1.15-3.49 p=0.0146 respectively). Patients with DAS28>5.1 were more frequent in deficiency group compared to normal group at baseline (OR=1.84 95%CI 1.15-2.87 p=0.011). There was no link between vitamin D level and RA diagnosis at baseline, 6 and 12 months nor with response to treatment at 6 and 12 months. In multivariate analysis, radiographic progression at 12 months was associated with vitamin D deficiency (OR=1.82 95% CI 1.01-3.06, p<0.001), age, ACPA, CRP, sex, alcohol consumption and smoking status. Likewise, disability at baseline was associated with vitamin D deficiency (OR=1.73 95% CI 1.05-2.85, p=0.03), age, CRP, corticosteroid use and disease duration; furthermore disability at 6 months was associated with vitamin D deficiency (OR=2.01 95% CI 1.15-3.52, p=0.025), age and sex.

Conclusion: Vitamin D deficiency may be predictive of radiographic progression at 1 year and is associated with increased disability at baseline and 6 months in early arthritis patients.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Rheumatoid Arthritis (RA) is associated with loss of muscle mass, exacerbating impairments in physical function. The 20-question Health Assessment Questionnaire (HAQ) is an accepted measure of physical function. However it only demonstrates modest correlations with muscle mass. The aim of this study was to develop and validate a tool that consists of a subset of questions from HAQ that demonstrate superior correlation with muscle deficits.

Methods:

Three cohorts of patients with RA with data on body muscle mass, fat mass and HAQ scores were included from three large independent academic centers in the United States. Whole-body DXA measures of skeletal muscle [appendicular lean mass index (ALMI)] and fat mass index (FMI) were converted to age, sex, and race specific Z-Scores using NHANES reference ranges. Associations between individual HAQ questions and ALMI Z-Score were assessed in a development cohort (consisting of the two larger cohorts) adjusting for age, sex, and FMI Z-Score. HAQ questions independently associated with ALMI in multivariable models ($p<0.1$) after stepwise deletion, were included and a simple estimating equation was developed based on regression coefficients. The performance of the muscle-HAQ was tested in the validation cohort (consisting of the third, smaller cohort). A low lean mass for age was defined as a standard or fat-adjusted ALMI Z-Score of ≤ -1.

Results:

In the development cohort (n=320), eight questions were independently associated with ALMI Z-Score. Specifically, having difficulty 1) lifting a cup, 2) running errands, 3) bathing, 4) self-hygiene and 5) opening a car's door were associated with lower ALMI whereas difficulty 6) climbing stairs, 7) dressing and 8) washing were associated with higher ALMI. [Muscle-HAQ= (1*climb+1*dress+1*wash-1*cup-1*errands-1*bath-1*hygiene-1*caropen -4)*-1]. In the validation cohort (n=85), the standard HAQ was not associated with ALMI or fat-adjusted ALMI Z-Score while the muscle-HAQ was strongly associated (Table 1). Patients with a muscle-HAQ ≥ 6 (n=16/85) had ALMI Z and fat adjusted ALMI Z Scores approximately 1 SD lower (Figure1) and greater odds of a low ALMI and fat adjusted ALMI Z-Score [OR 4.54 (1.38, 14.9) p=0.01 / OR 4.36 (1.25, 15.19) p=0.02]

Conclusion:

The muscle-HAQ demonstrates superior correlation with muscle mass deficits in RA, potentially capturing a domain of disability. These observations add new utility to the HAQ in clinical practice and research as a screening tool for muscle deficits or outcome in interventional studies.

Table 1	Age and sex-adjusted associations between unadjusted/fat-adjusted measures of ALMI with HAQ/Muscle HAQ score in the validation cohort.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Morning stiffness (MS) is a complex symptom involving pain and functional limitation. It is not included in the ACR/EULAR 2010 classification criteria for rheumatoid arthritis (RA) nor is a component of Disease Activity Scores, which generally serve as the primary outcome measures to assess efficacy of therapies for RA. However, this symptom at first presentation is a risk factor for more severe disease reflected by structural damage or disease persistence. Despite this, the best way to evaluate morning stiffness has been controversial.

Background/Purpose: To compare the severity and duration of MS, assessed by physician and by a self-report questionnaire, with disease activity and functional disability in a cohort of patients with RA.

Methods: We conducted a cross-sectional observational study that included consecutively patients with established RA (ACR 1987 criteria) from two rheumatology centers. Patients were assessed for MS: approximately half of them were asked about the duration (in minutes) and the rest of them were evaluated using a self reported questionnaire which included the intensity (VAS) and duration (in minutes and Likert Scale) of MS. Physician global assessment, pain and global status by VAS, functional disability (HAQ-DI), tender and swollen joint count (total of 28), erythrocyte sedimentation rate and disease activity (DAS28 and CDAI) were evaluated. Regression models were used to estimate possible associations between these variables and morning stiffness.

Results: One hundred and eleven patients were included, 88% were women (n=96). Mean age was 52 years (SD 13) and median disease duration was 8 years (IQR 4-12)**.** Fifty seven patients (51%) reported MS, 27 out of 52 were asked by the physician and 30 out of 59 were assessed by the questionnaire. MS measured in minutes by the physician showed a significant correlation with functional disability scores HAQ-DI (r= 0.72, p<0.001), whereas there was an acceptable correlation (r=0.61, p<0.001) between DAS28 and severity of MS measured by VAS (TABLE). When intensity of MS was evaluated by VAS (assessment in both numerical and non-numerical scales), we observed that a value ³ 5.5 centimeters (0-10) was associated to severe disease activity (DAS28 > 5.1) with a sensitivity of 44% and specificity of 100% (AUC 0.76).

Conclusion: Duration of morning stiffness evaluated through patient interview appears to reflect functional disability while the severity of morning stiffness was associated more strongly with inflammatory activity in this cohort of RA patients.

Table: MS correlation (assessed by different methods) with DAS28, CDAI and HAQ-DI

MORNING STIFFNESS		DAS 28	CDAI	HAQ-DI

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is characterized by inflammation of the joints and fatigue. Although many studies have identified risk factors for RA-associated fatigue, few studies have comprehensively examined the role of C - reactive protein (CRP) on fatigue. We investigated the association of CRP on fatigue using the Patient Reported Outcomes Measurement Information System

(PROMIS) in a cohort of patients with RA.

Methods: RA subjects enrolled in the University of Pittsburgh Rheumatoid Arthritis Comparative Effectiveness Registry (RACER) and who completed the PROMIS29 questionnaire were included (N=180). RA specific risk factors (disease activity measured by the Clinical Disease Activity Index [CDAI], physical function, RA treatment [conventional Disease Modifying Anti-Rheumatic Drugs (DMARD), anti - tumor necrosis factor [TNF], other biologics, disease duration, pain level), non-RA risk factors (sleep, anxiety, depression, Charlson comorbidity index) as well as CRP were assessed using descriptive statistics to summarize the distribution of the variables. Fatigue identified by PROMIS29 was the primary outcome. Spearman correlations and univariate analyses were first conducted to evaluate associations with fatigue. Multiple linear regression analyses were performed to investigate whether CRP is an independent predictor of fatigue. Mediation analysis was performed to explore if there is any indirect relationship between CRP level and factors associated with fatigue.

Results: Mean (±SD) subject age was 63.9 (±12.2) years with disease duration of 7.7 (± 0.8) years. Univariate analyses identified 7 covariates (age, CDAI score, global pain intensity, physical function, sleep, anxiety, depression) initially as potential predictors of fatigue. In multivariate analyses, physical function, sleep, and depression were independently associated with fatigue, but CRP or RA treatments did not have significant association with fatigue. (Table.1) CRP was inversely correlated with physical function ($\rho = -0.23$, $p=0.016$). However, there was no mediation effect between CRP and physical function in association with fatigue.

Conclusion: Out study suggests that poor sleep, decreased physical function, and depression have significant effect on fatigue. CRP level was not associated with fatigue directly or indirectly.

Table.1 Rheumatoid arthritis (RA)-specific and non -RA specific risk factors for fatigue (CDAI: Clinical Disease Activity Index, CRP: C-Reactive Protein, TNF: Tumor Necrosis Factor)

		Mean (SD) or N
RA specific risk factors	CDAI	10.28 (8.14)
	Disease duration	18.03 (13.52)
	CRP (mg/dL)	0.77 (0.92)
	Pain level (global pain intensity 0-10)	4.30 (2.54)
	Treatment	
	DMARD (N)	96
	Anti-TNF (N)	11
	Non-TNF biologics (N)	9
Non-RA risk factors	Sleep (t score)	50.82 (8.09)
	Anxiety (t score)	51.04 (9.56)
	Depression (t score)	49.53 (8.80)
	Comorbidity index	2.32 (2.00)

Table.2 Associations of fatigue with RA specific and non-RA specific factors by multiple linear regression analyses. Among RA associated and non-RA associated risk factors, 4 variables identified by univariate analyses were included in Model 1. Model 2 was adjusted as model 1 plus CRP and RA treatment. (β unstandardized coefficient, SE : Standard Error).

A Brief Patient-Reported Measure of Physical Function Is Sensitive to Changes in a Composite Disease Activity Measure in a Diverse Rheumatoid Arthritis Clinic Setting

Elizabeth R. Wahl[1,2], Andrew Gross[2], Vladimir Chernitskiy[2], Laura Trupin[2], Jinoos Yazdany[3] and Patricia P. Katz[2], [1]Medicine/Rheumatology, San Francisco Veterans Affairs Medical Center, San Francisco, CA, [2]Medicine/Rheumatology, University of California San Francisco, San Francisco, CA, [3]University of California, San Francisco, San Francisco, CA

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) patients' physical function is a strong predictor of clinical outcomes. A brief patient-reported measure of physical function, the PROMIS PF-10a (PF-10a), is increasingly being used to measure physical function in RA patients, but its sensitivity to changes in disease activity has not been described in a real world clinical setting. In this study, we assess the relationship between changes in a commonly used measure of disease activity, the clinical disease activity index (CDAI), and changes in PF-10a.

Methods: Clinical and demographic data were abstracted from the electronic health record for all patients seen at a university-based rheumatology clinic between February 2013 and February 2015, who had at least two ICD-9 codes for RA. All patients had PF-10a and CDAI scores documented on at least two occasions. We categorized changes in CDAI score as improved, stable, or worse using Minimally Important Difference (MID) criteria of a 12-point change in score, and compared changes in PF10a scores across these three groups. We then evaluated sensitivity to change by modeling the relationship between changes in disease activity (CDAI) and changes in PF-10a over time with multilevel mixed effects linear regression.

Results: Of 326 individuals included in the analysis, mean age (SD) was 59 (14), 83% were women, 53% were Caucasian, and 48% had moderate or severe disease activity by CDAI. Using MID criteria, CDAI scores were improved in 11% of encounters, were stable in 83%, and worse in 6%. Among those whose disease activity improved, PF-10a score improved by 4.4 ± 6.0 points (mean ± SD). Among those with stable disease activity, mean PF-10a score did not change (-0.1 ± 6.3 points), and among those with worsening disease activity, PF-10a scores worsened by 3.6 ± 8.1 points (Figure). These differences were significant (ANOVA p=0.0001). In a multivariate model adjusting for starting CDAI, age, and gender, changes in CDAI score were associated with changes in PF-10a scores ($p<0.001$).

Conclusion : The PROMIS-PF10a, a patient-reported measure of physical function, appears sensitive to changes in RA disease activity as measured by CDAI, suggesting it could play an important role in the clinical setting. Future studies should evaluate discordance between measures of function and disease activity by evaluating the role of disease duration, disability, and comorbidities such as chronic pain or depression.

Contribution of Subjective Patient Reported Components of Disease Activity Scores Differs in Disease Activity Measures and Their Changes over Time Are Closely Associated with Objective Measures

Yong Gil Hwang[1], Juan (June) Feng[2], Heather Eng[2], Jason Lyons[2], Anthony Fabio[3] and Larry W. Moreland[4], [1]Department of Medicine, University of Pittsburgh, Pittsburgh, PA, [2]Epidemiology Data Center, University of Pittsburgh, Graduate School of Public Health, Pittsburgh, PA, [3]Department Of Epidemiology, Graduate School of Public Health, University of Pittsburgh, Pittsburgh, PA, [4]Rheumatology & Clinical Immunology, University of Pittsburgh, Pittsburgh, PA

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Patient reported measures are influenced by many non-rheumatoid arthritis (RA) factors and they are reflected variably among various composite disease activity scores (DAS). We investigated relative contribution of patient reported measures and changes over time in two most widely used DAS.

Methods: For RA subjects enrolled in the University of Pittsburgh RA Comparative Effectiveness Research (RACER), cross-sectional and longitudinal analyses were performed to compare relative contribution of subjective patient reported components to DAS28-C-Reactive Protein (CRP) and Clinical Disease Activity Index (CDAI). Relative of the contribution of the patient reported measures (Tender Joint Count (TJC) and Patient Global Assessment (PtGA) in DAS28-CRP (DAS-P) and CDAI (CDAI-P) were calculated at baseline and follow-up visit within 3 months. DAS28-CRP changes was categorized by European League Against Rheumatism (EULAR) response criteria and CDAI changes were grouped into major (improvement ≥ 14), moderate (≥ 6), mild (<6). Wilcoxon signed ranks tests were performed for comparison. Univariate and multivariate regression analyses were performed to investigate factors associated with changes of subjective domains.

Results: For the 740 subjects analyzed, age was 60.2 ±13.7 (Mean±SD) years with disease duration of 14.4 ±12.4 years. 312 subjects had follow up visit within 3 months (1.7 ± 2.2 month). DAS-P was increased linearly with higher disease activity score. In contrast, CDAI-P remains similar with wider variation in remission or low disease activity (CDAI ≤ 10) (Figure.1). Significant reduction in the DAS28-P score was observed at follow up visit in all response groups, with greater reduction of DAS28-P in good responders. However, CDAI-P did not differ between the index and follow up visit (Figure.2). Multivariate analyses showed Swollen Joint Count (SJC) and Physician Global Assessment (PhGA) at the index visit had significant association with DAS-P changes at the follow up visit. CDAI-P changes were also significantly associated with HAQ (Table.1).

Conclusion: Contribution of patient reported components and their changes over time are substantially different between DAS28-CRP and CDAI. Objective findings such as SJC and PhGA predict changes of subjective patient reported measures at the follow up visit.

Figure.1 Scatterplot at index visit: (a) DAS-P(%) vs DAS28-CRP (a), (b) CDAI-P (%) vs CDAI, contribution of subjective patient reported components by disease activity categories (remission, mild, moderate, severe): (c) DAS-P(%) vs DAS28-CRP, (d) CDAI-P (%) vs CDAI (DAS-P: Subjective components of DAS28 relative to the total DAS28, CDAI-P: Subjective components of CDAI relative to the total CDAI)

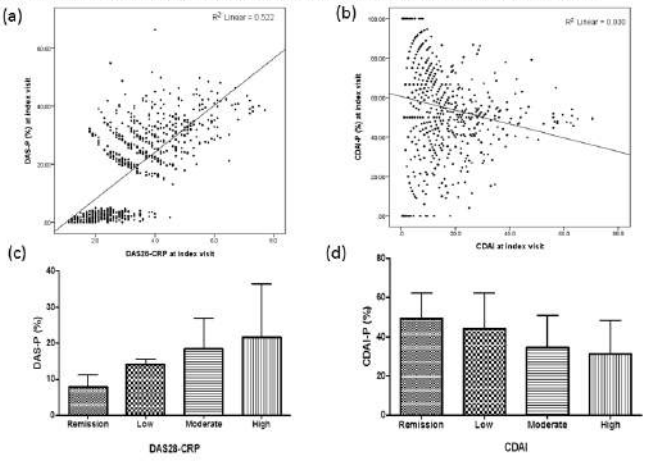

Figure.2 Changes of contribution of subjective patient reported components over time by treatment response criteria: (a) DAS-P (%) changes by EULAR response criteria, (b) CDAI-P (%) changes by CDAI response criteria (DAS-P: Subjective components of DAS28 relative to the total DAS28, CDAI-P: Subjective components of CDAI relative to the total CDAI)

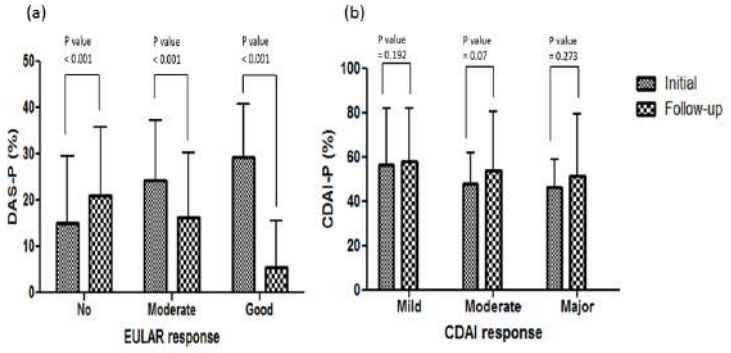

Table.1 Associations of subjective patient reported component changes with clinical variables at baseline by multiple linear regression analyses (β unstandardized coefficient, SE: Standard Error, DAS-P: Subjective components of DAS28 relative to the total DAS28, CDAI-P: Subjective components of CDAI relative to the total CDAI, SJC: Swollen Joint Count, PhGA: Physician Global Assessment, HAQ: Health Assessment Questionnaire)

	DAS-P change			CDAI- P change

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Anxiety and depression (A&D) are important comorbid conditions that affect patients with rheumatoid arthritis (RA). It is not known whether they impact on disease outcome in early RA (eRA). The aim of this study was to understand if A&D are: 1) associated with disease activity (DAS28) or disability at time of eRA diagnosis, 2) predictors of DAS28 and disability after 12 months of treatment.

Methods: An inception cohort of eRA patients was studied. At baseline, patients completed a detailed questionnaire recording self-rated quality of life (EQ5D) and disability (modified health assessment questionnaire (HAQ)). A categorical variable for level of anxiety and depression (A&D) was created from the EQ5D (0=none, 1=moderate, and 2=extreme levels of self-reported A&D). Disease activity (DAS28), DAS28 remission (<2.6), and HAQ were recorded at baseline and at 12 month review. Associations with A&D were explored: 1) at baseline using simple descriptive statistics, and 2) with 12-month outcomes using age and gender adjusted logistic regression.

Results: At baseline, 126 eRA patients had complete data. 36 (28.6%) patients reported moderate levels, and 14 (11.1%) extreme levels of A&D. Increasing A&D was significantly associated with elevated HAQ, and DAS28 at baseline (Table 1).

Age and gender adjusted logistic regression revealed that baseline A&D predicted a reduced likelihood of: 1) DAS28 remission (OR_{adj} 0.38 [95%CI 0.18, 0.81]), and 2) good EULAR response (OR_{adj} 0.41 [95%CI 0.13, 1.03]), at 12 months. No difference was observed in initial DMARD therapy. Baseline A&D was not significantly associated with mean change in DAS28 (OR_{adj} 1.06 [95%CI 0.85, 1.32]), or minimal clinically significant improvement in HAQ (OR_{adj}1.95 [95%CI 0.91, 4.20]). However, those reporting extreme level A&D at baseline were 5 times more likely to report HAQ above 1.0 at 12-months compared to without A&D (OR_{adj} 5.78 [95%CI 1.72, 19.52]).

Conclusion: Anxiety and depression at diagnosis of eRA is a strong predictor of poor outcome (disease activity and disability) at 12 months. Whilst A&D predict reduced likelihood of good EULAR response, no significant associations were observed with absolute change in HAQ or DAS28 after 12 months of DMARD therapy. This suggests that patients with A&D may benefit from additional treatment, targeted to reduce A&D, combined with usual DMARD treatment in order to optimise outcomes. Understanding the impact of confounding effect of anxiety and depression is important when assessing DMARD response in eRA.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Vitamin D deficiency is highly common in patients with rheumatoid arthritis (RA) (1). In vitro, vitamin D has anti-inflammatory effects and vitamin D has been linked to disease activity in RA due to its immuno-modulatory properties (1,2). The aim of this study is to investigate the association between vitamin D status and disease activity in newly diagnosed RA patients before start of therapy.

Methods: Consecutive patients with active, newly diagnosed RA (symptom duration <2 years), were randomized for treatment with COBRA or COBRA-light therapy (3). Before start of therapy, baseline values were determined, including Disease Activity Score (44 joints; DAS) and serum 25-hydroxy vitamin D (25(OH)D) levels. Based on the widely used cutoff values, patients were stratified into three groups based on baseline serum 25(OH)D levels: <50 nmol/l, 50-74 nmol/l, and ≥75 nmol/l.

Results: Baseline serum 25(OH)D levels were determined in 147 of 164 included RA patients in the COBRA-light trial (90% of trial population). Serum 25(OH)D levels of the different groups are presented in Table 1. Patients with a baseline serum 25(OH)D level ≥75 nmol/l had a significant lower mean DAS compared to patients with a baseline serum 25(OH)D <75 nmol/l (p=0.001). Vitamin D deficient patients (<50 nmol/l) had a significant shorter symptom duration (p=0.003), and were more often rheumatoid factor positive (p=0.015) compared to patients with sufficient serum 25(OH)D levels.

Table 1. Vitamin D status and disease related factors of patients with newly diagnosed rheumatoid arthritis before start of therapy

	Serum 25(OH)D <50 nmol/l (n=62; 42%)	Serum 25(OH)D 50-74 nmol/l (n=50; 34%)	Serum 25(OH)D ≥75 nmol/l (n=35; 24%)
Disease Activity Score (DAS, 44 joints)	4.2 (0.7)	4.0 (0.9)	3.6 (0.7)*
Symptom duration (weeks)	12 [8,21]*	18 [8,49]	25 [13,36]
Health Assessment Questionnaire Score (HAQ, 0 to 3)	1.5 (0.8)	1.3 (0.6)	1.2 (0.6)
Serum 25(OH)D (nmol/l)	36 [25,46]	61 [54,67]	87 [81,100]
Rheumatoid factor positive (n(%))	44 (72)†	22 (45)	20 (57)
aCCP positive (n(%))	44 (71)	26 (53)	25 (71)

*Values are reported as mean (SD) or median [IQR], unless otherwise specified; * Differs significantly from both other groups (p-value<0.05); † Differs significantly from serum 50-74 nmol/l (p-value<0.05); 25(OH)D: 25-hydroxy vitamin D; aCCP: antibodies against cyclic citrullinated peptides.*

Conclusion: Newly diagnosed RA patients with serum 25(OH)D levels ≥75 nmol/l demonstrate a significant lower disease activity than patients with a serum 25(OH)D level <75 nmol/l before start of therapy. This study cannot distinguish whether a lower DAS at baseline is caused by immuno-modulatory properties due to higher serum 25(OH)D levels, or that higher serum 25(OH)D levels are caused by more frequent outdoor activities related to a lower DAS. Since 75% of the newly diagnosed RA patients have insufficient serum 25(OH)D levels (<75 nmol/l), vitamin D supplementation should be considered in every newly diagnosed RA patient.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Several studies assessed disease activity with ultrasound in rheumatoid arthritis (RA) patients who were in clinical remission. These studies found ultrasound synovitis in 48-73% of the patients. Ultrasound synovitis is associated predicts short-term relapse in RA patients. So far, little is known about the association between ultrasound synovitis and patient reported outcomes (PROs). Our first objective was to evaluate the frequency of ultrasound synovitis in RA patients in clinical remission while they are continuing synthetic and biological DMARDs. Our second objective was to compare PROs between patients in clinical remission with and without ultrasound synovitis.

Methods: RA patients who are treated with the combination of a synthetic DMARD and biological DMARD (adalimumab or etanercept) and have low disease activity (DAS44<2.4 and SJC ≤1) were examined by ultrasound at baseline and after three months

follow-up. Ultrasound examination included 26 joints (MCP2-5, PIP2-5, wrists, MTP2-5) graded on greyscale (GS;0-3) and power Doppler (PD;0-3). A joint with ultrasound synovitis was defined as GS>1 and/or PD>0. Data on clinical and psychological characteristics, demographics, pain scores, functional ability (HAQ) and health-related quality of life (SF-36) were collected at baseline and at three months. Coping (Pain Coping and Cognition List [PCCL]), depression/anxiety symptoms (Hospital Anxiety and Depression Scale[HADS]) and fatigue (Bristol RA Fatigue Multi-Dimensional Questionnaire [BRAF-MDQ] and Fatigue Assessment Scale [FAS]) were collected at three months follow-up. Ultrasound synovitis positive and negative patients were compared on their PROs using the Wilcoxon-Mann-Whitney test and Chi-square test.

Results: At baseline, 89 RA patients were included of which 71 patients had had their three months evaluation. Ultrasound revealed synovitis in 64% of the patients at baseline and in 68% at three months. In 44% of the patients ultrasound synovitis was detected at both measurements. Table 1 shows baseline characteristics and patient reported outcomes at baseline and after three months. No clear pattern emerged on the PROs scores between ultrasound synovitis positive and negative patients. At baseline functional ability differed between the two groups while health-related quality of life was similar. At three months similar levels were observed for functional ability, health-related quality of life, coping, depression symptoms and fatigue. HADS anxiety differed at 3 months.

Conclusion: Ultrasound synovitis is common in RA patients in clinical remission while they continue synthetic and biological DMARDs. In our study population we could not find a clear association between ultrasound synovitis and PROs.

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Patient-reported outcome has been considered as an important aspect in the evaluation of patients with rheumatoid arthritis (RA). Recently, ultrasonography (US) has been used as a valid and objective tool for joint assessment for both joint synovitis and tenosynovitis. Therefore, the objective of this study was to elucidate the clinical significance of self-reported joint pain and stiffness of each joint by examining the association of those subjective findings with US joint synovitis and tenosynovitis.

Methods:

A total of 40 patients with RA were enrolled in this study between October 2014 and June 2015. All the patients reported the presence of pain and/or stiffness in each joint of hands including bilateral interphalangeal (IP) joints of the thumb, proximal interphalangeal (PIP) joints, metacarpophalangeal (MCP) joints and wrist joints. They also received joint examination by rheumatologists for the presence of tenderness and swelling, and US joint examination for the presence of joint synovitis and tenosynovitis. The medical records were reviewed for the patient characteristics and laboratory data.

Results: The median age was 66.5 years and the median disease duration was 3.7 years. The median DAS28-ESR was 2.7. Thirty-two patients (80%) were seropositive for either rheumatoid factor or anti-cyclic citrullinated peptide antibody. Although joint pain and stiffness were similarly observed among IP/PIP, MCP and wrist joints (pain in 9-11% of joints and stiffness in 5-6% of joints), US joint synovitis was detected in 6% of IP/PIP joints, 16% of MCP joints and 38% of wrist joints, and US tenosynovitis in 2% of IP/PIP joints, 8% of MCP joints and 18% of wrist joints, respectively (Table 1). The concordance defined by κ value indicated poor correlation of subjective joint pain with US synovitis (κ=0.19) and tenosynovitis (κ=0.03), as well as joint stiffness with US synovitis (κ=0.13) and tenosynovitis (κ=-0.04), respectively, although joint swelling showed a moderate correlation with US synovitis (κ=0.43).

Conclusion:

Patient-reported joint symptoms, especially joint stiffness, were not sensitive enough, and they did not correlate well with US joint findings.

Table 1. The presence rate of clinical findings at each joint level.

	Pain	Stiffness	Swelling	US joint synovitis	US tenosynovitis
IP/PIP	9%	5%	5%	6%	2%
MCP	10%	6%	7%	16%	8%
Wrist	11%	5%	20%	38%	18%
Total	9%	5%	7%	13%	6%

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Ethnic disparities in outcomes of RA patients have been attributed to delayed presentation to specialty care and access to DMARDs, greater disease burden, and less years of education. Recent literature supports a role for socioeconomic status (SES) as a determinant of RA disease status, including clinical disease activity measures, mortality, seropositivity, and treatment delays. The purpose of this analysis was to delineate the association of SES versus race/ethnicity with RA autoantibody status in a diverse cohort of RA patients.

Methods:

Ethnic Minority RA Consortium (EMRAC) participants with recorded anti-CCP positive markers at time of enrollment visit were abstracted for analysis; demographics (age, gender, race, years of education), clinical features (tobacco use, erosions, disease duration), and clinical outcomes (RAPID3) were also abstracted. An estimate of SES was derived from the median housing income of the city of each enrollment site. Median incomes less than two-fold the 2014 poverty line ($47,700) defined lower SES status. Logistic regression was used to model risk factors and their association with positive anti-CCP.

Results:

346 EMRAC participants with self-reported race/ethnicity were abstracted for analysis; 284 (82%) were female. The average values for the following parameters were: age 56.1 (±15.6) years, disease duration 9.4 (±10.1) years, and education 13.8 (±3.7) years. Ninety-nine (28.6%) of EMRAC participants were enrolled at sites servicing lower than the twice poverty line. With this SES indicator, significant differences in participants' disease duration, education years, clinical features, and outcomes were observed (**Table**). In logistic regression modelling, being below the twice poverty line was significantly associated with the presence of anti-CCP [13-fold increase; odds ratio=14.2] (**Figure**). Both African-American and other race participants also had increased odds of the presence of anti-CCP compared to Caucasian subjects, but less than that for low SES. Tobacco use and erosions could not be modeled due to missing clinical data. However, in a full model with both smoking and erosion indicators, lower SES remained the strongest risk factor associated with positive anti-CCP.

Conclusion:

In a diverse ethnic cohort, disparity in income as an estimate of SES was a stronger risk factor of RA autoantibody status than race/ethnicity. As autoantibody status is a poor prognosticator, policies that improve access to specialty care and RA medications must be paralleled by improvements in overall SES of individuals in order to minimize the impact of disease.

Figure. Odds Ratio Ladder Plot with 95% Confidence Intervals Depicting Logistic Regression Model Associating Risk Factors with Positive Anti-CCP

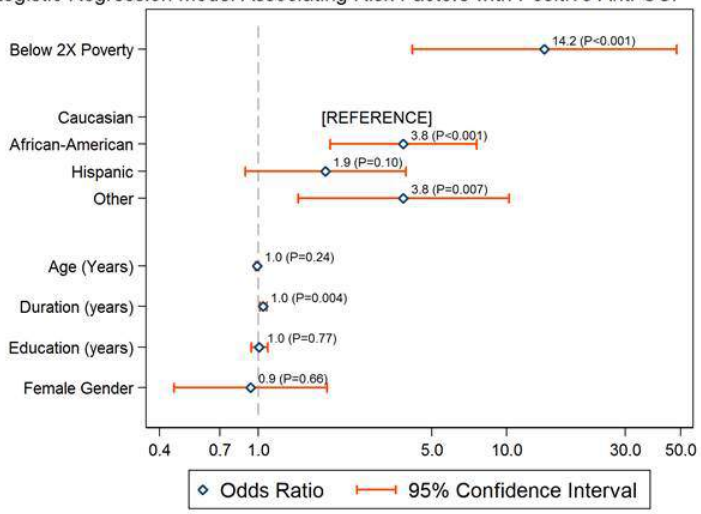

Table. Demographics, Clinical Features and Outcomes by SES Indicator

	Twice 2014 Poverty Line		
	Higher	Lower	P

Discrepancies Between Patients and Physicians in Their Perceptions of Rheumatoid Arthritis Disease Activity Are Multifactorial in Early Rheumatoid Arthritis

Cécile Gaujoux-Viala[1], Nathalie Rincheval[2], Laure Gossec[3], Francis Guillemin[4], Maxime Dougados[5], Jean-Pierre Daures[6] and BG Combe[7], [1]Nîmes University Hospital, Rheumatology Department; EA 2415, Montpellier University, Nîmes, France, [2]Biostatistic, EA 2415, Epidemiology unit, Montpellier, France, [3]Rheumatology, Pitié Salpetriere Hospital, Paris, France, [4]University of Lorraine,

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Patients and physicians often differ in their perceptions of rheumatoid arthritis (RA) disease activity, as quantified by the patient's global assessment (PGA) and by the evaluator's global assessment (EGA).

The aim of this study was to explore the extent and reasons for this discordance.

Methods:

-Patients: from the French cohort of early arthritis ESPOIR (at least 2 swollen joints for less than 6 months, DMARD naïve), fulfilling the ACR-EULAR criteria for RA at baseline

-Analyses: At baseline, agreement between PGA and EGA (Bland-Altman plot) was assessed. Multivariate linear regression was used to analyze data to determine the patient and early arthritis features independently associated with discordance (calculated as PGA - EGA). Logistic regression was used to analyze discordance as $\left|\text{PGA} - \text{EGA}\right| \geq 20$.

Results:

In 645 patients with early RA (mean age=48.8±12.2 years, 77% female, 48.7% ACPA +) agreement was better at both ends of the spectrum of the disease activity perception, especially for patients with high disease activity. The direction of the discrepancy usually points toward a higher rating by the patients than by physicians themselves.

In multivariate linear regression center-adjusted, higher PGA has been found to be associated with absence of fulfilling ACR 1987 revised criteria for RA (p=0.0005), higher level of fatigue (p<0.0001) and lower number of swollen joint counts (SJC) (p=0.0022). With logistic regression center-adjusted, low number of SJC (OR 95%CI=0.522 [0.343-0.794]), low mental component of the SF-36 (OR 95%CI=0.550 [0.371-0.815]) and living alone (OR95%CI=0.595 [0.388-0.914]) were associated with discordance between PGA and EGA.

Conclusion:

In early RA, the discordance between PGA and EGA is multifactorial with objective measures like low SJC and absence of fulfilling ACR 1987 revised criteria for RA, but also patient reported outcomes like high level of fatigue and low mental status, and environmental factor: living alone. Understanding the reasons for a discordant view of disease activity will help to facilitate the sharing of decision-making in the management of RA. In addition, our findings represent a call to treat fatigue and anxiety-depression, as this may create better consensus about the course of treatment.

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Few studies of which joints most affect physical function in rheumatoid arthritis (RA) patients have been conducted. The present study investigated the effect of bilateral and unilateral disease in the shoulder, elbow, wrist, hip, knee, ankle, finger, and toe joints on Modified Health Assessment Questionnaire (MHAQ) scores using the National Database of Rheumatic Diseases by iR-net in Japan (NinJa), a multicenter, rheumatic disease database.

Methods: The subjects were the 9,212 patients (1,766 men, 7,466 women) with complete medical records among the 10,367 patients registered in NinJa in 2011. The presence or absence of disease in each joint (swelling and pain were considered as disease) and whether the disease was bilateral or unilateral were investigated. At least one metacarpophalangeal joint or proximal interphalangeal joint were considered as finger and toe joint's disease. The correlations between bilateral and unilateral disease of each joint and MHAQ scores were investigated using logistic regression analysis.

Results:

Patients were aged 63.2±12.9 years and their duration of symptoms was 12.2±10.7 years. The majority of subjects had moderate disease activity (mean baseline 28-joint Disease Activity Score, 3.3±1.3). The MHAQ scores median were 0.25. The 2 most frequently affected joints were the finger joints (42.2%) and wrist (36.6%) joint, followed by the knee (21.2%), ankle (20.9%), toe joints (18.7%), elbow (17.8%), shoulder (11.5%). In contrast, the frequencies of hip joint involvements were small (2.0%). Significant correlations were observed between the MHAQ scores and bilateral and unilateral disease of all joints apart from bilateral disease of the hip and bilateral and unilateral disease of the toes. The odds ratio for each joint (95% confidence interval) bilaterally and unilaterally, respectively, were as follows: shoulder, 4.0 (2.9 to 5.6) and 1.8 (1.5 to 2.1) ; elbow, 2.6 (2.1 to 3.4) and 1.8 (1.5 to 2.1); wrist, 1.9 (1.7 to 2.2) and 1.5 (1.3 to 1.7); hip, 1.7 (0.7 to 4.7) and 3.0 (2.0 to 4.7) ; knee, 2.6 (2.2 to 3.2) and 1.9 (1.7 to 2.2) ; ankle, 2.3 (1.9 to 3.0) and 2.0 (1.8 to 2.4) ; finger, 1.4 (1.2 to 1.5) and 1.2 (1.0 to 1.3) ; and toe, 1.0 (0.8 to 1.3) and 1.1 (0.9 to1.3). Regarding the odds ratio, an integer score was assigned to each identified risk factor as follows: each joint (bilaterally/unilaterally) points, shoulder (4/2); elbow(3/2); wrist(2/2); finger(1/1); hip(0/3); knee(3/2); ankle(2/2). The total risk scores for each patient ranged from 0 to 18. The results of the ROC analysis were as follows: cut-off value, 3 points; area under the ROC curve, 0.709; sensitivity 58.6%; and specificity, 72.8%.

Conclusion: While MHAQ scores were significantly affected by disease in almost all joints, a greater effect was exerted by the major joints, in increasing order of ankle, knee, elbow and shoulder. Bilateral disease tended to have a greater effect than unilateral disease in these major joints and the wrist

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) musculoskeletal ultrasound (MSUS) literature reports good reliability of scoring still images with training, but inconsistent reliability of scoring during acquisition, likely a key factor for reproducibility and sensitivity to change. The aim of this study was to systematically optimize MSUS acquisition and real-time scoring reliability prior to conducting a multicenter MSUS-based RA study.

Methods: This two-site MSUS study evaluated the following joints: bilateral radio-carpal, intercarpal, radioulnar, MCP 1-5, PIP 1-5, knees and MTP 2-5. Reliability among three ultrasonographers with >5 years MSUS experience was assessed in 2 stages: 1) face-to-face 1 [F2F1] Aug 2014, and 2) face-to-face 2 [F2F2] Feb 2015. A reference MSUS RA atlas was modified during serial teleconferences and multiple reliability still-image exercises. After each reliability exercise, the most discrepant images were discussed and the draft atlas was updated. Factors affecting discordance were identified and comprehensively addressed prior to F2F2: *Environment and Machine* (consensus of room temperature, lighting, machine settings); *B-Mode Optimization* (permitting adjustment of frequency, depth, focus, and positioning of deformed joints); *Power Doppler Optimization* (standardization of gel layer, strict adherence to Doppler settings, color map adjustment to accommodate color blindness); *Scoring Optimization*(consensus rules on scoring cutoffs, scoring rules on compound joints such as the wrist). Intra- and inter-reader reliability was examined using weighted-kappa, intraclass correlation coefficient (ICC), and Spearman correlation. Reliability statistics were compared between stages using permutation tests to compute empirical distributions for differences in those statistics.

Results: Acquisition intra-reader reliability improved from F2F1 (0.52-0.71) to F2F2 (0.7-0.86) for weighted kappa, ICC and Spearman correlation (Table). Ultrasonographer-1 (US-1) achieved significant improvement in reliability from F2F1 to F2F2 ($p<0.05$). Inter-reader reliability also improved from 0.5-0.66 to 0.64-0.74 as a result of between-meeting consensus activities. Improvement was

statistically significant for inter-reader reliability between F2F1 to F2F2 for weighted kappa (p=0.03) and a trend for Spearman correlation (p=0.07).

Conclusion: By determining and addressing factors that influence acquisition and scoring, improved real-time scoring reliability can be achieved.

The Patients Evaluation of Pain and Disease Activity As Well As Improvement during One-Year Follow-up on Etanercept Treatment Is Highly Associated to Subjective Factors and Not to Objective Assessments Including Ultrasound

Hilde Berner Hammer[1] and Jon Lampa[2], [1]Rheumatology, Diakonhjemmet Hospital, Oslo, Norway, [2]Dep of Medicine, Rheumatology unit, Karolinska Institute, Karolinska Institute, Stockholm, Sweden

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Patient reported outcomes (PROs) are important for evaluation of treatment response in patients with rheumatoid arthritis (RA). Ultrasound (US) is a sensitive method for assessing inflammation, including grey scale synovitis (GS) and vascularization (power Doppler (PD)). The present objective was to explore the associations during biologic treatment between subjective evaluations of disease activity and more objective assessments of inflammation including US.

Methods:

93 patients with RA (mean (SD) age 50 (13) years, disease duration 8 (7) years, 77% women, 76% anti-CCP positive) were included when starting etanercept 50 mg/week (79% biologic naïve, 54% using prednisolone). The patients were assessed at baseline and after 1, 2, 3, 6 and 12 months with PROs (joint pain VAS, patient's global disease activity VAS, Rheumatoid Arthritis (RA) Impact of Disease (RAID) score, MHAQ), clinical examination (assessor's disease activity VAS, tender and swollen joints (of 32) performed by a study nurse) and laboratory variables (ESR and CRP). DAS28 and CDAI were calculated. Pain catastrophizing was assessed by the

sum of two questions from the Coping Strategies Questionnaire (CSQ, score 0-6) and Swollen/Tender Ratio of 28 joints (STR) was calculated to assess the pain component of arthritis. All US examinations (semi-quantitative scoring (0-3) of GS and PD (PIP 2-3, MCP 1-5, wrist (RC, IC, RU), elbow, knee, talo-crural, MTP 1-5 and ECU/TP tendons bilaterally) were performed by one rheumatologist (HBH) (Siemens Acuson Antares, excellence version, 5-13 MHz probe, optimized settings). Last observation carried forward was used for missing data. Correlations were explored by use of Spearman's, Wilcoxon explored changes from baseline and Mann-Whitney examined differences between two independent groups.

Results:

The 62 patients fulfilling 12 months treatment showed decrease in all variables during the study ($p \leq 0.001$, table). The correlations between patient's global VAS and number of swollen joints, ESR, CRP and US sum scores were low during the study (median (range) r= 0.13 (0.00-0.33). Patients with pain catastrophizing (score 3-12) and low STR (<1.0) had significantly higher subjective variables, but there were no different objective assessments of disease activity (table).

Conclusion:

Subjective evaluations of disease activity were weakly associated with objective assessments of inflammation. Patients with catastrophizing and low STR may not reach DAS28 remission in spite of objectively decreased disease activity. The different expression of pain and PRO scoring in these patients should be acknowledged during biologic treatment.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To compare patient and disease characteristics over the first 8 years of disease in a large inception cohort of early RA patients included 1992 to 1999 and 2000 to 2006, respectively.

Methods: In all 1911 RA patients from the early BARFOT prospective multi-centre observational study, who had completed the 8 year follow-up, were recruited. All patients fulfilled the ACR 1987 criteria. The patients were divided into two groups, group 1 (N=928, 68% women) included 1992 to 1999 and group 2 (N=1010, 70% women) included 2000 to 2006. DAS28, VAS pain, HAQ and radiographs of the hands and feet scored by the van der Heijde modified Sharp method (SHS) were assessed during the 8 years. Statistical comparisons between groups were done by t-test and Chi2.

Results: At inclusion, the women in group 2 were, compared with those in group 1, older, mean (SD) 55 (15) vs 52 (14) years, $p<0.001$, were more frequently RF positive, 64% vs. 58%, $p=0.031$ and had worse radiographic score, mean total SHS (SD) 5 (9) vs 3 (6), $p<0.001$, whereas the men did not differ in these aspects.

Over time DAS28 decreased in both groups, and as from 6 months in men and 12 months in women the mean DAS28 was significantly lower in group 2 compared with group 1 and remained so during the 8 year follow-up. HAQ and VAS pain decreased similarly in the two groups with no differences between women at any time point. Men in group 1 had higher mean VAS pain at 6 months and at 2 years follow-up, with no differences between the groups at 8 years.

In both groups women and men progressed radiographically over 8 years, $p<0.001$ respectively. Women in group 1 had more progression than women in group 2, mean (SD) change SHS 20 (27) vs. 16 (20), $p=0.009$. In men there were no difference in mean change SHS over 8 years 16 (19) vs 14 (18), $p=0.186$.

The patients in group 1 started with methotrexate (MTX) in 26%, with sulphasalazine (SAL) in 30%, and with other DMARDs in 10%, the corresponding figures for group 2 were 61%, 19% and 3%. After 8 years patients in group 1 got MTX in 32%, combination therapy in 8% and biologics in 13%, in group 2 the corresponding figures were 40%, 7% and 26%.

Conclusion: Women diagnosed in the 2000s had higher disease activity, more pain and worse radiographic joint damage at inclusion than those diagnosed in the 1990s. They achieved lower disease activity and less radiographic progression over 8 years compared with the women included in the 1990s. This difference may reflect the more active medical treatment in the 2000s. Despite that, HAQ and pain did not differ between women in the two groups during follow-up.

Men diagnosed in the 2000s had higher disease activity and more tender joints at inclusion than those diagnosed in the 1990s. As for women disease activity decreased more in those diagnosed in the 2000s, though there was no difference in radiographic progression between the groups, neither in HAQ or pain reduction at the 8-yearfollow-up. HAQ and pain seems thus not solely depend on inflammatory activity or radiological damage in either gender.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Anti-TNF-alpha therapies are able to control rheumatoid arthritis (RA) disease activity and to limit structural damage. Nevertheless, no predictive factor of response to anti-TNF-alpha, has yet been identified. The metabolic profile can vary in response to different inflammatory rheumatisms and hence determining this profile can considerably improve diagnosis and, consequently, prognosis.

The aim of this study was to determine, by mass spectrometry, whether there is a variation in the metabolome in patients treated with anti-TNF alpha in order to predict the therapeutic response.

Methods:

Blood samples were taken before (M0) the initiation of anti-TNF-alpha treatment in 140 patients with active RA. Plasma was deproteinised, extracted and analysed by coupled reverse phase chromotography / QToF mass spectrometry. Extracted and normalized ions were considered in univariate and ANOVA analysis and were confronted to PLS-DA (partial least-squares regression-discriminant analysis). An OSC (Orthogonal Signal Correction) were also used in order to filter data from unwanted non-related effects. Disease activity scores, obtained at M0 and M6, and metabolome variation findings were correlated to identify a metabolite that is predictive of therapeutic response to anti-TNF-alpha.

Results: After 6 months of anti-TNF therapy, 100 patients were considered as good responders and 40 patients as non-responders according to EULAR criteria. Metabolomic investigations suggested two different metabolic fingerprinting splitting good responders group and non-responders group. A global effect of discriminative ions is concrete even if we could not report one single discriminating biomarker that could simplify the daily management of RA. The univariate analysis in positive mode revealed 24 significant ions ($p < 0,05$) and 31 significant ions in negative mode ($p < 0,05$). Once intersected with PLS results, only 35 ions remained. Especially, carbohydrate derivates seemed to be determining of therapeutic response.

Conclusion: This is the first study describing metabolic profiling in response to anti-TNF-alpha treatments using plasma samples. Our study highlighted two different metabolic fingerprinting splitting good responder group and non-responder group.

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The purpose of this study is to explore new biomarkers for early diagnosis of rheumatoid arthritis (RA). For better discrimination power, we especially investigated the samples of early RA (eRA) patients whose onset of RA were less than 1

year.

Methods: We examined the serum cytokines and the gene expression profiles of peripheral mononuclear cells from early rheumatoid arthritis (eRA). eRA samples were compared with advanced RA (aRA, disease duration more than 1 year) and osteoarthritis. Serum obtained from 44 patients with eRA were evaluated for cytokine panels, including IFN-r, IL-12, IL-2, IL-4, IL-10, IL-17 and IL-6. Gene expression profiles of eRA (n=11), using microarray analysis, were compared with OA (n=8) and aRA (n=7). Biomarker candidates were positively selected by pathway analysis using NCBI database about Th17 cell differentiation genes.

Results: Mean age of eRA and aRA were 51.9 and 58.1 respectively. CRP level was higher in aRA than eRA (3.27 vs 1.19 mg/dL, *P<0.02*). Th17 cell-related cytokines like IL-6 and IL-17 were prominent than other cytokines in eRA patients. IL-17 concentration was statistically higher in eRA than aRA. Positive percentage of IL-6 was more than 50% in eRA patients. IL-6 were well correlated with ESR (r=0.3, *P=0.006*) and CRP (r=0.6, *P<0.001*). Interestingly, IL-17 levels were correlated with disease activity DAS28 (r=0.45, *P=0.003*). 255 genes were upregulated in eRA (|F.C|>1.3, *P<0.05*). 10 genes were selected from 255 genes by association analysis with Th17 differentiation as followings, TMEM140 (transmembrane protein 140), NUAK2 (NUAK family, SNF1-like kinase 2), SULT1A3 (sulfotransferase family, cytosolic, 1A, phenol-preferring, member 3), HIST1H4H (histone cluster 1, H4h), NAPSB (napsin B aspartic peptidase pseudogene), FEN1 (flap structure-specific endonuclease 1), PROS1 (protein S alpha), RPS6KA2 (ribosomal protein S6 kinase, 90kDa, polypeptide 2), CDKN3 (cyclin-dependent kinase inhibitor 3), JAM3 (junctional adhesion molecule 3).

Conclusion: Th17-related cytokines were dominant at early stage of RA and associated with disease activity. Th17-related candidate genes could give a new insight as biomarkers for early diagnosis and therapeutic target for eRA.

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: 28 joints-disease activity score (DAS28) is routinely used in clinical practice to assess disease activity in rheumatoid arthritis (RA). DAS28, particularly its subjective components [patient visual analogue scale (VAS), tender joint count (TJC)] might not always reflect inflammation. No study to date has assessed the relationship between PRO and the DAS28 components in a large cohort of patients, among different countries. The main objective of this study is to assess the associations between patient and physician reported outcomes and the objective components of DAS28 across different geographical populations, using the COMORA dataset[1]('Prevalence of Comorbidities in Rheumatoid Arthritis and evaluation of their monitoring: results of an international, cross-sectional study'). The study will also assess the relationship between patient and physician perception of disease activity, and PRO and number of comorbidities.

Methods: Demographics, clinical characteristics, including DAS28 and PRO, treatment and comorbidities were recorded. Using Spearman's rho, we assessed pairwise correlations among patient global, patient fatigue, physician global, quality of life (EQ5D) and the DAS28 components for each country. We then looked at the inter-relationship of patient/physician reported outcomes. Finally, the correlation between PRO and comorbidities was calculated.

Results: 3674 patients from 17 countries were included in the analysis (mean age 56 years; 82% female). Mean (SD) DAS28 was moderate at 3.72 (1.55). DAS28, SJC, TJC and ESR varied significantly between countries. ESR showed very weak correlation with all PRO for the majority of the countries. SJC correlated moderately with PRO and the association varied between countries, but

showed good correlation with physician global for almost all assessed countries(r>0.5 for 16/17). TJC had good correlation with patient global, physician global and EQ5D and showed little variation between countries. TJC and patient fatigue correlation varied between countries. Patient and physician global correlated with each other. No significant correlation was found between number of comorbidities and PRO.

Conclusion: PROs generally associated well with the more subjective components of DAS28 whilst physician global seemed more consistent with the objective elements and this was observed across most countries. Geographical variation however was particularly observed with tender joint and patient-reported fatigue. This might have implications in the interpretation and applicability of International clinical trials.

Phenome-Wide Association Study of Rheumatoid Arthritis Subgroups Identifies Association Between Seronegative Disease and Fibromyalgia

Jayanth Doss[1], Huan Mo[2], Leslie J. Crofford[1] and Joshua C. Denny[2], [1]Rheumatology, Vanderbilt University School of Medicine, Nashville, TN, [2]Biomedical Informatics, Vanderbilt University School of Medicine, Nashville, TN
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: The differences between seronegative and seropositive rheumatoid arthritis (RA) have not been widely reported. We performed an electronic health record (EHR)-based phenome-wide association study (PheWAS) to identify disease associations that differ between seropositive and seronegative RA.

Methods: A validated algorithm identified RA subjects from the de-identified EHR (1). Serotypes were determined by values of rheumatoid factor (RF) and anti-cyclic citrullinated peptide antibody (ACPA). A PheWAS uses logistic regression to identify ICD9 codes that are more likely to be present in one group of patients versus another. A PheWAS comparing seropositive and seronegative patients was performed and identified disease associations (i.e. ICD9 codes) for each serotype. Following PheWAS, select disease associations were manually reviewed and fibromyalgia was specifically evaluated using a validated algorithm.

Results: A total of 2199 individuals were identified with RA and with serologic testing. Of these, 1382 (63%) were seropositive. Seronegative RA was associated with “Myalgia and Myositis” (odds ratio [OR] 2.1, $P=3.7x10^{-10}$) and back pain. A manual record review showed 80% of Myalgia and Myositis codes were used for fibromyalgia, and follow-up with a specific EHR algorithm for fibromyalgia confirmed that seronegative RA was associated with fibromyalgia (OR=1.8, $P=4.0x10^{-6}$). Seropositive RA was associated with Chronic Airway Obstruction (OR=2.2, $P=1.4x10^{-4}$), tobacco use (OR=2.1, $P=3.8x10^{-4}$), and other pulmonary

phenotypes.

Conclusion: This PheWAS study in RA patients identifies a strong association between seronegativity and fibromyalgia. It also replicates a well-known association between seropositivity and chronic airway obstruction related to tobacco use. These findings demonstrate the utility of the PheWAS approach to discover novel phenotype associations within different subgroups of a disease.

Table 1

	All Patients (n = 2199)	Seropositive (n = 1382)	Seronegative (n = 817)
Demographic Characteristics			
Age, mean ± SD years	52.1 ± 14.5	53.17 ± 13.4	51.7 ± 14
Sex, no. (%) female	1669 (76)	1012 (73)	657 (80)
Race, no. (%)

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: RA is an autoimmune, inflammatory and chronic disease which aetiology is unknown. It presents different autoantibodies such as RF and ACPA. A population of CD4 T cells expressing CXCR5, Bcl6, PD-1, ICOS, CD40L and IL-21, named Follicular helper T cells (Tfh), collaborates with B cells to produce antibodies. Increased levels of peripheral blood Tfh cells have been implicated in the development of systemic autoimmunity. Differential expression of CXCR3 and CCR6 whitin $CD4^+CXCR5^+$ T cells defines three mayor subset: $CXCR3^+CCR6^-$ (Tfh1), $CXCR3^-CCR6^-$ (Tfh2) and $CXCR3^-CCR6^+$ (Tfh17). The aim is to ascertain if differents subsets of $CD4^+CXCR5^+$ T cells are alterated in RA patients and if their percentages correlate with disease activity.

Methods: In this study participated RA patients (n=24), healthy controls (HC) (n=22) and undifferentiated arthritis (UA) patients (n=16) (Table 1). Percentage of $CD4^+CXCR5^+$ T cells and their subsets $CXCR3^+CCR6^-$, $CXCR3^-CCR6^-$ and $CXCR3^-$ $CCR6^+$ from PBMCs were analysed by flow cytometry. Pearson or Spearman correlation coefficients were used for statistics.

Results: Figure 1 shows flow cytometry analysis. No differences were found in the % of $CD4^+CXCR5^+$ T cells between RA vs HC or RA vs UA (mean±SD, RA 12,89±7,73; HC 10,48±3,9; UA 11,71±5,04). Either in the % of Tfh1 (12,75 ± 9,72; 11,22 ± 7,48; 12,81 ± 6,13), or Tfh2 (32,66 ± 11,46; 39,53 ± 12,12; 27,56 ± 11,25), or Tfh17 subsets (37,94 ± 11,34; 40,79 ± 8,17; 37,34 ± 7,16) between previous groups (Figure 2). There was not correlation between $CD4^+CXCR5^+$ T cells (r=-0,19 p=0,37), or Tfh1 (r=0,09 p=0,68), or Tfh2 (r=0,36 p=0,09), or Tfh17 (r=-0,20 p=0,35) vs DAS-28, like either between each subset and ESR (r=-0,18 p=0,39, r=-0,08 p=0,71, r=-0,01 p=0,97, r=-0,25 p=0,23, respectively). Unexpectedly, there was positive correlation between Tfh17 cells and CRP

r=0,47 *p*=0,021. Finally, there was not correlation between $CD4^+CXCR5^+$ T cells vs mutated citrullinated vimentin (MCV) r= 0,38 *p*=0,07, either between Tfh1, Tfh2 and Tfh17 subsets vs MCV(r=-0,04 *p*=0,84, r=-0,14 *p*=0,51, r=-0,19 *p*=0,37, respectively) or all of them vs RF (r=0,30 *p*=0,15, r=-0,18 *p*=0,39, r= -0,15 *p*=0,46, r=0,01 *p*=0,98, respectively).

Conclusion: In concordance with our results, $CD4^+CXCR5^+$ T cells and their subsets would not be involved in the RA development.

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is associated with increased cardiovascular disease, insulin resistance, and disability. Our objectives were to analyze levels of skeletal muscle inflammatory cytokines and gene expression pathways in RA patients compared to controls without RA in order to determine whether increased muscle inflammation was related to disease activity, insulin resistance, and/or disability. We hypothesized that greater disease activity would be associated with greater muscle inflammation and worse insulin resistance

Methods: 39 individuals with RA were matched with 39 individuals based on age, gender, race, and BMI. Exclusion criteria included diabetes, cardiovascular disease, recent medication changes, and prednisone use greater than 5 mg/d. All underwent measurements of disease activity (DAS-28), disability (HAQ-DI), glucose tolerance, plasma inflammatory cytokines, thigh CT imaging, physical activity (accelerometry), and vastus lateralis muscle biopsies. ELISAs were used to measure muscle (m) inflammatory markers: interleukin (mIL)-1β, mIL-6, mIL-8, tumor necrosis factor-alpha (mTNFα), and Toll-like receptor 4. Gene expression was measured in muscle from 5 matched case-control sets using Illumina Expression BeadChips. Differentially expressed genes were identified with Partek and used in pathway analyses performed with Ingenuity Pathway Analysis.

Results: Despite elevated systemic inflammation (C-reactive protein, IL-6, TNFα; $P<0.05$) in RA compared to controls, the only muscle cytokine with higher concentrations was mIL-6 ($P=0.006$). Nonetheless, in RA, higher mIL-1β and mIL-8 were correlated with higher DAS-28 ($r=0.35$, $r=0.30$, $P<0.05$). Higher mIL-1β and mIL-6 levels were associated with higher HAQ-DI ($r=0.33$, $r=0.33$, $P<0.05$). Higher concentrations of mIL-1β, mIL-6, and mIL-8 were associated with less exercise ($r=-0.38$, $r=-0.40$, $r=-0.38$, $P<0.05$), while higher mIL-1β and mIL-6 were related to less physical activity ($r=-0.35$, $r=-0.33$, $P<0.05$). Muscle cytokines had minimal correlation with insulin resistance and serum cytokines ($P>0.05$). Pathways with the most differences in muscle gene expression ($P<0.05$) had central molecules associated with the NF-kB and Ras/MapK pathways.

DAS_{ESR}-28 = Disease activity score with 28 joint count and ESR=erythrocyte sedimentation rate; HAQ-DI= Health Assessment Questionnaire Disability Index; DMARD=Disease Modifying Anti-Rheumatic Drug; hsCRP = High sensitivity C-reactive protein; IL = Interleukin; Hu= Hounsfield units; TNF=Tumor Necrosis Factor; TLR-4=Toll-like receptor 4; Hu= Hounsfield units; METs= Metabolic Equivalents					

Conclusion: While muscle inflammation is not a recognized feature of RA and does not relate to insulin resistance, higher levels of muscle inflammatory cytokines were related to worse disease activity, disability, and pain, as well as less physical activity. MapK and NF-kB are both important transcription factors that may activate signaling cascades resulting in higher levels of mIL-6 in RA patients. Further analyses are ongoing to better understand the role of skeletal muscle inflammation in RA.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Rheumatoid arthritis (RA) is characterized by synovitis leading to bone erosions and joint destruction, but little is known about bone structure in the joints of patients before they are diagnosed with RA.

High Resolution peripheral Quantitative Computed Tomography (HR-pQCT) is a new imaging technique allowing detailed automatic evaluation of bone structure.

The aim was to quantify the cortical and trabecular bone structure in the metacarpophalangeal (MCP) joints of anticitrullinated peptide antibody (ACPA) positive patients with arthralgia and compare with healthy controls.

Methods:

Using a cross-sectional study design patients were recruited from local rheumatologists and controls from a website for test subjects. All individuals underwent medical history interview, clinical examination, and biochemical screening including ACPA. Patient inclusion criteria were positive ACPA and arthralgia. Exclusion criteria were fulfillment of the 2010 ACR/EULAR criteria for RA and other rheumatologic or metabolic bone diseases. Exclusion criteria for controls were known rheumatologic or metabolic bone disease, current or prior arthralgia, arthritis, and positive ACPA.

The right hand MCP joints were imaged with HR-pQCT using an isotropic voxel size of 82 µm.

A region of 1.2 cm located proximal to the articular surface of the MCP head was evaluated in the 2nd and 3rd finger using a semiautomatic program. Volumetric bone mineral density (vBMD), bone volume fraction (BV/TV), trabecular number (Tb.N), trabecular thickness (Tb.Th), trabecular separation (Tb.Sp), average cortical thickness (Ct.Th), and cortical area (Ct.Ar) were evaluated. Nine patients were rescanned after repositioning and the coefficient of variation (CV) was calculated. Values are mean(SD).

Results:

Twenty-six ACPA positive patients without clinical arthritis (age 50.4(13.8)) and 26 healthy controls (age 49.9(14.5)) were included. CV of the HR-pQCT parameters was 0.64–3.53%.

The overall bone density was similar in the groups since vBMD and BV/TV did not differ. In addition, the cortical bone was not affected in patients, as we found no difference in Ct.Th and Ct.Ar between the groups. In contrast, the trabeculae were significantly ($p <$ 0.05) thinner in both 2nd (87.7(9.7) µm vs 93.3(9.8) µm) and 3rd (83.7(9.7) µm vs 89.9(10.2) µm) MCP head compared with controls, whereas Tb.N and Tb.Sp did not differ.

Conclusion:

It has earlier been demonstrated that inflammation of the synovium and bone marrow is crucial for development of erosions in RA. In the present study we demonstrate that the trabecular thickness is affected very early, i.e. before the onset of clinical arthritis. Therefore, up-regulation of bone resorption in the bone marrow may be an early feature of RA. Bone loss before clinical RA warrants earlier diagnosis and treatment.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: The adaptive immune response in Rheumatoid arthritis (RA) is influenced by an interaction between host genetics and environment, particularly the host microbiome. To define the role of host microbiome, we characterized intestinal microbiome signatures in patients with RA.

Methods: To identify an RA biomarker profile, fecal samples from 40 RA patients and 32 healthy non-RA comparator subjects were sequenced for the 16S ribosomal DNA. Bray-Curtis distances were constructed and PERMANOVA was used to test for an association between variables of interest and the overall microbiota composition. PICRUSt was used to infer the abundance of functional categories (KEGG pathways) based on the 16S rRNA data, depending upon which differential abundance analysis was performed. Differential abundance analysis was also performed using LEfSe software. The machine learning algorithm 'Random Forest' was used to build a predictive model, and identify the most discriminatory taxa between patients and controls.

Results: Patients with RA exhibited decreased gut microbial diversity compared to controls. Increased rheumatoid factor levels and disease duration were associated with decreased species richness and diversity ($P<0.05$ and $P<0.1$ respectively) (Fig 1A). PERMANOVA based on Bray-Curtis distance showed that the structure of the microbiota of patients with RA differed significantly from control subjects (Fig 1B). A taxon-level analysis suggested an expansion of the rare taxa, Actinobacteria, with a decrease in abundant taxa in patients with RA compared to controls. The abundance of Actinobacteria correlated strongly with high levels of IL-17A. Prediction models based on the Random Forests algorithm suggested that 3 genera segregated with RA. Increased abundance of Actinobacteria was associated with decrease in the expression of tight junction protein in epithelial cells and abundance of metabolite alpha aminoadipic, a marker for age-associated changes in collagen.

Conclusion: These observations suggest dysbiosis in patients with RA resulting from the abundance of certain rare bacterial lineages. A correlation between the intestinal microbiota and metabolic signatures could determine a predictive profile for disease causation, progression, and drug efficacy.

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The HLA-DRB1 is the strongest genetic risk factor for rheumatoid arthritis (RA). Although this fact suggests a pivotal role for adaptive immunity in RA, the linkage between HLA-DRB1 genotype and lymphocytes activation remains unclear.

Methods: We analyzed 91 HLA-DRB1 genotyped RA patients and 110 healthy donors by 24-subset immunophenotyping of peripheral blood mononuclear cells (PBMC) combined with CXCR4 expression analysis, HLA-DR quantification, and multiplex serum cytokine analysis. The correlation between these biomarkers and clinical parameters, such as the titer of anti-citrullinated peptide antibody (ACPA) and DAS28esr, was examined. 20 RA patients were analyzed at the initiation of CTLA4-Ig treatment and after 6-months of treatment. PBMC of healthy donors were cultured for 5 days with IL-21 and anti-HLA-DR antibody to assess CXCR4 expression on $CD4^+$ T cells.

Results: The frequency of CXCR4-expressing memory $CD4^+$ T cells, not that of classical Th1 or Th17 cells, was significantly associated with DAS28esr and the titer of ACPA. RA patients with susceptible haplotype of HLA-DR (shared epitope: SE) displayed significantly higher frequency of memory $CD4^+$ T cells and higher positivity for CXCR4 on memory $CD4^+$ T cells than healthy donors and RA patients without SE. Moreover, the frequency of CXCR4-expressing memory $CD4^+$ T cells displayed a significant correlation to the expression level of HLA-DR on B cells, which was elevated in RA patients with SE. In vitro experiments indicated that the increased CXCR4 expression on RA memory CD4+ T cells was dependent both on IL-21 and HLA-DR expression on antigen presenting cells. In clinic, higher frequency of CXCR4-expressing memory $CD4^+$ T cells predicted better therapeutic effects of CTLA4-Ig.

Conclusion: These findings demonstrate a potential contribution of HLA-DR on B cells to the development of memory $CD4^+$ T cells which is associated with disease activity. Identification of CXCR4 on memory T cells as a biomarker may promote the understanding of the linkage between genetic risk factor and adaptive immunity in RA.

Reduction in Matrix Metalloproteinase-1 and -2 Secretion from Fibroblast-like Synoviocytes after Induction of Adipogenesis By a Natural Peroxisome Proliferator-Activated Receptor Gamma Ligand, Arterpilin-C

Eiji Sugiyama[1], Satoshi Yamasaki[1] and Je-Tae Woo[2,3], [1]Department of Clinical Immunology and Rheumatology, Hiroshima University Hospital, Hiroshima, Japan, [2]Department of Biological Chemistry, Chubu University, Aichi, Japan, [3]JT WOO, Okinawa Research

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Fibroblast-like synoviocytes (FLS) play important roles in rheumatoid arthritis (RA) by producing matrix metalloproteinase (MMP) and cytokines, and hence, these cells are a therapeutic target. Another unique characteristic of FLS is their ability to differentiate into mesenchymal multilineage cells, such as osteoblasts, chondrocytes, and adipocytes. Based on this characteristic, we proposed that the induction of adipogenesis in FLS would ameliorate RA activity by reducing cytokine and protease secretion from the cell. Thus, in this study, we treated FLS with plant-derived natural PPARγ ligands—arterpilin-C —to induce adipogenesis in FLS and evaluated the MMP secretion from FLS following adipogenesis induction.

Methods: The FLS derived from RA patients (Articular Engineering, USA) were maintained in Dulbecco's Modification of Eagles Medium with 10% fetal bovine serum. To induce adipogenesis via FLS, we added arterpilin-C to the culture medium in the presence or absence of dexamethasone. Lipid deposition in FLS was examined by using Oil red O or LipidTOX™ (Molecular Probes, USA) staining. To confirm adipogenic differentiation, we used anti-fatty acid binding protein 4 antibodies for immunostaining. A quantitative polymerase chain reaction using SYBR Green was performed to determine the expression levels of the transcripts.

Results: Droplets were observed in the cytoplasm of FLS after a 3-week culture with arterpilin-C (30 μM) in the presence of dexamethasone. Oil red O or LipidTOX staining confirmed adipogenesis by FLS. The expression of FABP4, an adipocyte-specific protein, was also noted in the cells with droplets by immunostaining. However, adipogenesis by arterpilin-C was achieved only in the presence of dexamethasone in a dose-dependent manner. The minimum dexamethasone concentration required for adipogenesis induction by arterpilin-C in FLS was 10^{-7} M. PPARγ protein expression was clearly enhanced in FLS treated with a dexamethasone concentration of 10^{-7}M. Moreover, the MMP1 and MMP2 mRNA expressions were lower in the FLS following adipogenesis induced by arterpilin-C, compared to the FLS treated only with dexamethasone.

Conclusion: These data suggest that the natural PPARγ ligands, arterpilin-C , can be used to induce adipogenesis in FLS. Importantly, the expressions of MMP1 and MMP2 were significantly reduced in FLS following adipogenesis induced by these natural PPARγ ligands. Since these proteinases are important in RA disease progression, induction of adipogenesis in FLS may contribute to inhibiting joint destruction in RA.

Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Damage-associated molecular patterns (DAMPs) are proposed to drive aberrant stimulation of Toll-like receptors (TLRs) in the rheumatoid arthritis (RA) joints resulting in increased expression of proinflammatory cytokines and chemokines. In the current study we investigated the role of the neutrophil-derived lactoferrin (LTF), as an endogenous ligand for TLR4

in the inflammatory response of RA synovial fibroblasts (RASF).

Methods: Recombinant human neutrophil-derived LTF was purchased from Sigma. LTF solution was screened for lipopolysaccharide contamination before using. RASF were treated with LTF and/or TNFα, and the expression of proinflammatory cytokines in RASF was measured by real-time quantitative PCR and multi-cytokine assay system. The levels of phosphorylated p38 mitogen associated phosphokinase (MAPK) in RASF stimulated with LTF were determined by immune blotting. To repress the TLR4 signaling pathway, TAK243, a small molecular inhibitor of TLR4, was used. The role of the nuclear factor of activated T cells 5 (NFAT5) in the TLR4 signaling pathway in RASF was investigated using a small interfering RNA targeting NFAT5.

Results: Stimulation of RASF with LTF significantly increased the mRNA and protein expression of proinflammatory cytokines, such as IL-6, IL-8 and CCL20 ($p=0.01$). Furthermore, LTF enhanced the expression of IL-6, IL-8, and CCL20 mRNA in RASF stimulated by TNFα ($p=0.01$). The phosphorylation of p38MAPK increased in LTF-stimulated RASF. TAK243, the TLR4 inhibitor, repressed the expression of proinflammatory cytokines and chemokines in RASF stimulated by LTF. Silencing of NFAT5 significantly decreased the expression of proinflammatory cytokines and chemokines in RASF treated by LTF ($p= 0.01$).

Conclusion: This is the first study to demonstrate that LTF can induce the proinflammatory response in RASF mediated by TLR4 and the activation of NFAT5. Neutrophil derived LTF is is an endogenous ligand for TLR4 in RASF. The activity of NFAT5 is important in the inflammatory response of RASF induced by LTF via TLR4.

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The AAA-ATPase valosin containing protein (p97) and histone deacetylase 6 (HDAC6) interact with each other and are implicated in the degradation of ubiquitin-labelled proteins. We recently described a resistance to apoptotic cell death induced by proteasome inhibition and a hypersensitivity to autophagy-associated cell death under conditions of severe endoplasmic reticulum (ER) stress in rheumatoid arthritis synovial fibroblasts (RASF) compared to osteoarthritis synovial fibroblasts (OASF). The objective of this study was to investigate the role of p97-HDAC6 controlled poly-ubiquitin turnover in apoptotic and autophagy-associated cell death in RASF and in an *in vivo* arthritis model.

Methods: p97, HDAC6 and poly-ubiquitinated proteins were evaluated by immunohistochemistry, Real-time PCR, immunoblotting and proximal ligation assay. RASF were transfected with siRNA targeting p97 or HDAC6 or treated with the selective p97 inhibitor DBeQ (5 μM). To induce cell death, RASF were treated with TRAIL (100 ng/ml) for 24 hours or the ER stress inducer thapsigargin (TG, 5 nM-5 μM) for 72 hours. 3-methyladenine (5 mM) was used as an autophagy inhibitor. Cell death was evaluated by flow cytometry using annexin V/ propidium iodide staining and a caspase-3 activity assay. Collagen-induced arthritis (CIA) was induced in Lewis rats. Scrambled or p97 siRNA-atelocollagen complexes were injected into ankle joints of rats. CIA was scored according to paw thickness and ankle diameter. Bone erosion was assessed by micro-CT. Proliferation of fibroblasts in rat synovial tissue was quantified by immunolabeling for Hsp47.

Results: The expression of p97 and the expression of HDAC6 were restricted to the lining layer of synovial tissues and were similarly detected in RA and OA patients. The expression of p97 in RASF and OASF was positively related with the expression of HDAC6 at both mRNA ($R^2 = 0.77$, $n = 31$) and protein ($R^2 = 0.77$, $n = 14$) level. Interactions of p97-ubiquitin, HDAC6-ubiquitin and p97-HDAC6

were detected in RASF. The siRNA-mediated knockdown of p97 in RASF decreased the expression of HDAC6 but not vice versa. Knockdown of p97 in RASF increased cell death induced by TRAIL ($p = 0.009$, $n = 6$), accompanied by caspase-3 activation. Both knockdown and inhibition of p97 in RASF boosted cell death induced by 5 μM TG, accompanied by a massive cytoplasmic vacuolization and the formation of poly-ubiquitinated protein aggregates, and cell death was inhibited by 3-methyladenine. Smaller amounts of TG (50 or 500 nM) induced a cytoplasmic vacuolization and the formation of poly-ubiquitinated protein aggregates in p97-inhibited RASF but not in control RASF. Intra-articular injection of p97 siRNA significantly suppressed CIA ($p = 0.002$, $n = 6$), bone erosion ($p = 0.02$), cartilage destruction ($p = 0.03$) and proliferation of synovial fibroblasts ($p = 0.004$) in rats.

Conclusion: Our data indicate that the inhibition of the ATPase p97 promotes both apoptotic and autophagy-associated cell death in RASF and suppresses CIA and proliferation of synovial fibroblasts *in vivo*. The p97-HDAC6 controlled poly-ubiquitin turnover may be a new potential target in the treatment of arthritis.

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Concepts of erosion pathogenesis in rheumatoid arthritis (RA) have been based on radiographs, although MR images are much better able to visualise erosions. Statistical shape models (SSM) allows bones and erosions to be aligned, correcting for size and patient shape, allowing the 3D study of systematic effects. This study employed SSMs to visualise the spatial distribution of erosions, and their probability of arising at a particular location, in a population of early RA patients.

Methods: 90 baseline MR images were selected at random from an exploratory Phase 2 multicentre study (NCT01164579). Inclusion criteria were as follows: MTX-naïve adult patients with early RA (duration ≤ 2 years); diagnosis using ACR criteria, unequivocal evidence of radiographic erosion, and clinical evidence of synovitis. 7 images were not analysed due to image quality.

Bones and erosions were manually segmented and independently reviewed. 3D bone and erosion surfaces were generated, and rigidly warped to the mean bone shape. A population image was created; containing the number of times that each voxel was found within an erosion. Voxels which were present in >2 erosions were displayed along with the mean bones. (Figure 1)

Results: Erosions were present in low numbers of patients. In 18 patients there were no erosions visible in MR despite reported radiographic erosions. Over half had only 0 to 2 bones with an erosion. Erosions exhibited a clear spatial pattern. In the metacarpals, the erosions were most prevalent in MCP2 and 3 (Table 2). In the wrist, there were typically 20 erosions per bone for half of the bones; the trapezium, trapezoid and proximal metacarpals had ~10. Erosions occurred at consistent sites, with only one or 2 sites within each bone where the erosion was found in >2 patients.

Conclusion: This is the first study to provide an accurate 3D visualisation of erosion sites in early RA. Erosions occurred at only a small number of entheseal sites. Erosions in the metacarpals occurred in the area containing the collateral ligament and capsular attachments. In the wrist, the erosions were located primarily on the palmar side of the bone, and had a more complex arrangement. Although multiple ligament, capsular and tendon attachments exist in close proximity on each bone, we observed that erosion sites were usually those in which there was a deep attachment site in non-eroded patients. This suggests that the attachments which will generate an erosion are those which experience the highest mechanical load. Further careful study will be required to pursue the detail of these anatomical locations, and will significantly help our understanding of the pathogenesis of RA erosions.

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-citrullinated protein antibodies (ACPAs) are specific to rheumatoid arthritis (RA) and are associated with disease severity. Although ACPAs are associated with disease progression, mechanisms driving this relationship are not well understood. The objective of this study was develop an *in vitro* model incorporating bovine bone chips and micro-CT (μ-CT) to investigate the effects of ACPA on bone remodeling.

Methods: PBMCs were isolated from the blood of normal controls. Osteoclasts (OCs) were generated by culture in α-MEM media containing 1% penicillin/streptomycin and 10% heat inactivated FBS along with RANKL (1 ng/ml) and MCSF (10 ng/ml) for 14 days. Sera from ACPA positive RA patients was obtained and IgG was isolated using Staph Protein G columns. Antibody to citrullinated type II human collagen (Cit-C-II) was purified using CNBR Sepharose beads coupled with Cit-C-II. F(ab')2 and Fc fragments were generated using pepsin columns and were added to differentiated OCs in the presence and absence of C-II and Cit-C-II and incubated with bone chips for 3 days (n=3 chips/group). Bone chips were then scanned with μ-CT for bone mineral density (BMD) and pit volume (PV). Bone specific alkaline phosphatase (BAP) and cathepsin-K (CTPK) were measured on media using ELISA. BAP/CTPK ratios served as the primary measure of bone turnover.

Results: Activated OCs in the absence of ACPA increased PV and decreased BMD (Figure), although these differences did not reach

significance. Compared to OCs stimulated with F(ab')2 + C-II + Cit-C-II, the substitution of Fc fragments for F(ab')2 led to significant increases in BAP (4.24 vs. 1.89 ng/ml, p=0.006) and CTPK (7.07 vs. 2.83 ng/ml, p = 0.011); BAP/CTPK ratio was higher, but not significantly, in OCs incubated simultaneously with Fc and F(ab')2 antibodies along with C-II and Cit-C-II as compared to OCs alone (Figure; p= 0.181 and p= 0.071, respectively). Across groups, BAP values were positively correlated with PV (r= 0.52, p=0.015). Addition of the F(ab')2 or Fc fragments led to a numeric increase in PV and decreased BMD, although differences compared to OCs alone did not reach significance.

Conclusion: The differential effects of Fc and F(ab')2 fragments of anti-Cit-C-II antibody along C-II and Cit-C-II antigens suggests that the action on bone could be mediated by both the type of antibody fragments and the amount and type of antigen present. Additional studies with a larger number of samples will be needed to perform more robust statistical comparisons including the evaluation of alternative doses and different ACPA. This novel model, incorporating bovine bone chips with µ-CT, appears to be a practical and reproducible approach for studying the osteoimmunology of ACPA and citrullinated antigens.

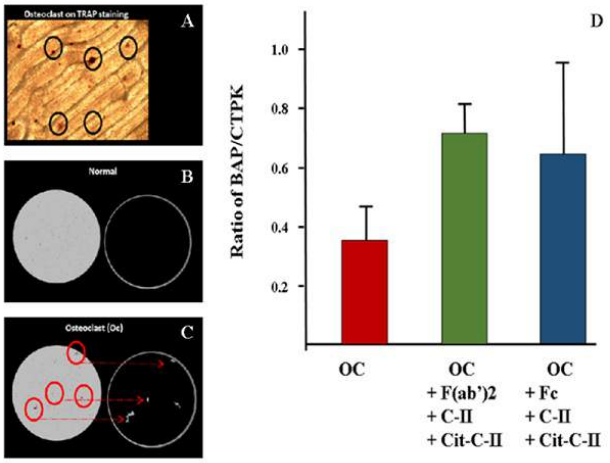

Figure: A) OCs detected on bovine bone chip; TRAP staining; B) normal bone chip by µ-CT; C) bone chip with OCs resulting in decreased BMD (p= 0.163) and increased PV (p= 0.096); and D) Increased BAP/CTPK ratios in OCs vs. OCs + F(ab')2 + C-II + Cit-C-II (p=0.071) vs. OCs + Fc + C-II + Cit-C-II (p=0.181).

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: An increased expansion of Th17 cells in the synovial membrane have shown to play a key role in causing persistent synovitis leading to cartilage and bone destruction in RA. MRI is superior to conventional X-rays in detecting erosions in early disease. In this study we sought to see the association of level of peripheral circulatory Th-17 and Th-1 cells with MRI changes in RA

Methods:

RA patients satisfying ACR Criteria 2010 with active disease (DAS28 >3.2) and within 3 years of onset who had not received prior DMARDs or steroids were recruited. MRI of dominant hand and wrist was done using 0.2 Tesla extremity MRI and was scored using OMERACT RA MRI Scoring system 2002 by two radiologists. Peripheral blood Th1 (CD3+ CD4+ IFNγ +) and Th17 (CD3+ CD4+ IL17+) were enumerated by flow cytometry. Th-1and Th-17 levels were measured in 25 healthy controls. Statistical analysis was done by non-parametric tests using SPSS statistics 21version software.

Results:

Thirty-two consecutive patients (26 females and 6 males) with RA after obtaining consent were included. The median age at presentation was 38.5 years (Range 19 – 65 years) with median disease duration of 11.5 months (Range 1-36 months). The median DAS 28 score was 4.35 (Range 3.22 – 6.24). All the patients were seropositive. MRI evaluation revealed synovitis in 93.8%(30/32), Osteitis in 31.3%(10/32) and erosions in 75% (24/32) of patients. On subgroup analysis erosions were present in 67% (12 /18) of cases of early (≤ 1year) RA and in 86% (12/14) of established (> 1 year) RA. OMERACT RA MRI scoring revealed a significantly ($p<0.05$) higher erosion score (17.8 ± 19.9) in established RA compared to early RA (5.4 ± 11.4) whereas synovitis and osteitis were similar in both groups. Synovitis score showed modest correlation with ESR (r= 0.43, p =0.02), CRP(r= 0.38, p =0.03), and DAS28 (r= 0.43, p =0.02), while osteitis and erosion score did not correlate with the same.Percentage of Th17 cells in serum were significantly ($p<0.05$) elevated in patients (1.57 ± 0.69) compared to healthy controls (0.84 ± 0.45) while Th1 cells did not differ between the groups. However, the increased frequency of Th17 cells did not show any correlation with acute phase reactants, DAS28 score and MRI proven synovitis or osteitis.

Conclusion: Peripheral blood Th17 subset was significantly elevated in patients with RA, though they did not correlate with the synovitis, osteitis or erosions in MRI.

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Smoking represents an independent risk factor for rheumatoid arthritis (RA) (1). In response to infectious agents, neutrophil granulocytes can extrude their nuclear contents as nucleoprotein threads, known as neutrophil extracellular traps (NETs) (4). Recently, it has been shown that RA neutrophils show a vastly greater propensity to form NETs than those from normal controls (2,3). Since NETs are pro-inflammatory and immuno-stimulatory, and neutrophils show increased activity in inflammatory lung conditions, we investigated the responsiveness of peripheral blood neutrophils in RA and controls to cigarette smoke exposure.

Methods:

Regular smokers without (n=8) and with (n=6) RA were examined at baseline and after a 16 hour abstinence from smoking. Then they smoked two cigarettes within 10 min and measurements were repeated at 30, 60 and 120 min. Parameters measured were exhaled carbon monoxide (CO), myeloperoxidase (MPO), neutrophil elastase (NE) and cell free nucleosomes by ELISA. Routine laboratory tests included blood counts, CRP, BSR and clotting parameters. In addition, neutrophils from healthy donors were incubated with cigarette smoke extract (CSE) for assessing NET formation by SytoxGreen extracellular DNA staining and combined immunohistochemistry (ICH) with anti-MPO, anti-cit-H3 and DAPI.

Results:

RA smokers started from higher baseline CO levels, but showed similar courses as the controls after re-exposure to cigarette smoke. They exhibited higher baseline MPO, NE and nucleosomes compared to controls. Re-exposure caused a pronounced increase of peripheral blood leucocytes and neutrophils in RA smokers compared to controls. No changes were observed concerning parameters of inflammation and clotting.

Re-exposure of RA patients to cigarette smoke led to a 3- fold rise of MPO und NE at 30 minutes after exposure and a subsequent gradual reduction of serum levels up to 120 min. Unexpectedly, this was paralleled by a sharp reduction in circulatory cell free nucleosomes with a decrease to the baseline at 120 min.

Freshly isolated control neutrophils showed diminished PMA-driven NET release in vitro after 3 hours of treatment with CSE. This was confirmed by MPO and citrullinated H3 ICH and morphometric analysis. Activated neutrophils with a delobulated citH3 positive nuclear phenotype were also remarkably higher in CSE-treated neutrophils.

Conclusion:

RA smokers show increased peripheral blood markers of neutrophil pre-activation compared to non-RA smokers. Cigarette smoking causes a rapid increase of MPO and NE, indicating the systemic release of neutrophil granular contents, and a rapid concomitant decrease of cell free nucleosomes. This is paralleled by the in vitro reduction of CSE-induced NET formation. Our findings provide evidence that cigarette smoking in RA patients provokes the immediate release of toxic neutrophil granular enzymes into the circulation and that NET formation is transiently reduced in the immediate aftermath of smoke inhalation.

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is characterized by hyperplastic synovial pannus tissue, which mediates destruction of cartilage and bone. Fibroblast-like synoviocytes (FLS) are a key component of the invasive pannus and have a major role in the initiation and perpetuation of destructive joint inflammation. NecroX-7 is a small chemical compound that exhibits cytoprotective effects and anti-oxidant activity. We investigated the inhibitory effects of NecroX-7 on the aggressiveness of TNF-α stimulated RA-FLS.

Methods: RA-FLS were cultured from synovial specimens obtained from RA patients undergoing joint replacement therapy. The cell viability was determined using CCK-8 colorimetric assay. The wound healing and transwell migration assay were performed to evaluate the effects of NecroX-7 on the migration of RA-FLS. Intracellular reactive oxygen species (ROS) generation was assessed by fluorometric assay. Matrix metalloproteinase-2 (MMP-2) and MMP-9 activity was measured using gelatin zymography. The expression of p-ERK1/2, p-p38, p-JNK and p-IκB was detected by Western blot analysis. The location of NF-κB p65 in RA-FLS was detected by immunofluorescence microscope.

Results: NecroX-7 had no significant cytotoxicity and inhibited migration of RA-FLS activated by TNF-α *in vitro*. NecroX-7 suppressed TNF-α-induced NF-κB activation by inhibiting ERK1/2 phosphorylation and IκB degradation and it prevented the nuclear translocation of NF-κB p65 with subsequent decrease in synthesis of MMP-2 and MMP-9. NecroX-7 reduced the generation of intracellular ROS (hydrogen peroxide, mitochondrial superoxide, cytosolic superoxide and peroxynitrite) in TNF-α-treated RA-FLS.

Conclusion: NecroX-7 reduces activities of MMP-2 and MMP-9 via inhibition of NF-κB signaling pathway and intracellular ROS formation in activated RA-FLS, suggesting that NecroX-7 might suppress the aggressiveness of RA-FLS *in vivo*. NecroX-7 may provide a new therapeutic option in treatment of RA.

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a complex autoimmune disorder in which several genetic and environmental factors play a role. Recent data suggest that the gut and oral microbiome might potentially contribute to the priming of an aberrant systemic immune response characteristic of RA. Among studied microbiota, both *Porphyromonas gingivalis* in the oral cavity and *Prevotella copri* in the gut have been implicated. Intriguingly, airway abnormalities and increased lung tissue citrullination is found in both RA patients and individuals at at-risk for the development of disease. This suggests the possibility that the lung could be yet another site of autoimmunity generation in RA. Our objective was to study whether the RA lung microbiome contains distinct taxonomic features associated with local and/or systemic autoimmunity.

Methods: Bronchoalveolar lavage (BAL) samples from 20 subjects with RA, 10 with sarcoidosis and 24 healthy controls were obtained by research bronchoscopy. 16S rDNA sequencing was performed to define microbiota composition. Levels of arginine/citrulline were measured in BAL fluid using GC-MS for all samples. Autoantibodies, including anti-CCP, RF and ACPAs were also measured in BAL and sera of RA subjects. Statistical analysis was performed using wilcoxon test and Spearman correlation.

Results: There were no differences in demographic or clinical characteristics (including smoking status) between groups. 16S sequencing data showed similar alpha/beta diversity between RA and DC groups, but significantly different from controls. Taxonomic comparison between groups was performed using LEfSe, which revealed several significant differences (LDA score>2). Multiple taxa, including *Rhanella* and *Rhodanobacter* were present only in the RA and DC groups, but completely absent from healthy subjects ($p<0.001$). While RA BAL samples were enriched with *Sphingobacteria*, sarcoidosis BAL was enriched with *Bacteroidia*, *Rhizobiales*, *Nitrospirales*, and *Campylobacter*. GC-MS showed similar levels of arginine and citrulline in BAL for the sarcoidosis and RA groups. Raoultella and Barnesiella correlated with CCP2 levels in BAL (rho= 0.49 and 0.47; p-value= 0.026 and 0.032 respectively). Serum levels of CCP-IgA had a negative correlation with Massilia and Tannerella (rho= -0.63 and 0.53; p-value 0.003

and 0.016, respectively), and a positive correlation with Vagococcus and Lactobacillus (rho= 0.59 and 0.54; p-value 0.006 and 0.014, respectively). Unclas_Lactobacillales also had a positive correlation with serum levels of RF-IgA (rho= 0.71; p-value <0.001). Serum levels of anti-CCP2 antibodies had a positive correlation with *Porphyromonas*, *Rahnella* and *Chryseobacterium*(rho=0.46, 0.46 and 0.45; p-value= 0.03, 0.03 and 0.04 respectively).

Conclusion: Despite the relatively small number of samples analyzed, several taxonomic differences were noted between groups. Correlations between relative abundance of specific taxa in RA BAL with serum autoantibodies (i.e., anti-CCP) support an association between the lung microbiome and the host immune phenotype in RA. Further evaluation of functional aspects of this microbiome may provide further insights into its possible contribution to RA.

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Although it has been traditionally assumed that most glycosylation occurs on membrane or secreted proteins and lipids, it is well known that cytoplasmic or even nuclear proteins can be glycosylated, through an O-GlcNAc (O-linked β-N-acetylglucosamine) modification coupled to Ser or Thr residues. Its evaluation in diseases such as cancer or metabolic syndrome has led to the suggestion that they play an active role both in cell metabolism, intracellular signaling and transcription regulation. However, there are still no studies comparing the level of O-GlcNAc between Rheumatoid Arthritis (RA) patients and healthy donors. To compare the levels of O-GlcNAc in the cytoplasm of peripheral blood mononuclear cells (PBMC) of healthy donors and patients with RA, as well as its possible relationship with clinical parameters.

Methods: Patients were evaluated at the Hospital General de Cuernavaca, SSM. RA disease activity was evaluated through DAS28. The donor blood samples were obtained from the sate blood bank. After isolating the PBMC (Ficoll Hypaque), cytosolic proteins were recovered, in the presence of protease inhibitors. Levels of O-GlcNAc were evaluated using Western blot, employing a specific LR2 antibody. The levels of O-GlcNAc transferase (OGT) and O-GlcNAcase (OGA) expression, responsible for the addition and elimination of the GlcNAc group, were evaluated in parallel. Differences between groups were evaluated using Student's t and Mann Whitney's test and their correlation with DAS28 was evaluated using Spearman's test.

Results: 21 patients with RA and 20 healthy donors were included. A global comparison showed that patients had significantly less immunoreactivity than donors. The glycosylation pattern was clearly different in patients compared to donors, where the 73 and 112 kDa glycoproteins seem to be exclusive of RA patients. These results were consistent with a greater OGT/OGA balance in donors with respect to patients. On the other hand, levels of O-GlcNAc showed a significant negative correlation with DAS28 (rho=-0.579, p<0.008).

Conclusion: The results seem to suggest that patients with RA present a reduced ratio of OGT:OGA expression, as well as less O-GlcNAc glycosylation, compared to donors. The relationship between the levels of O-GlcNAc and DAS28 suggests that this glycosylation patterns could reflect a functional state of PBMC in patients with RA. Study financed by CB-2010-2#155392 (CONACyT).

A Novel Paradigm in the Clinical Context of Rheumatoid Arthritis: Role of Tfh and Th17 Cells in Autoimmunity

Magdalena Budziakowska[1], Arif Shahzad[1], Jerry Pounds[1], Shikha Singla[1], Jerald M. Zakem[1,2], Kismet Collins[1], Tamika Webb-Detiege[1], William E. Davis[1,2], Zongbing You[3], Robert Quinet[1,2] and Xin Zhang[4], [1]Rheumatology, Ochsner Medical Center, New Orleans, LA, [2]University of Queensland School of Medicine, Brisbane, Australia, [3]Tulane University Health Science Center, New Orleans, LA, [4]Laboratory of Cellular Immunology, Institution of Translational Research, Ochsner Medical Center, New Orleans, LA

Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Rheumatoid Arthritis (RA) is an autoimmune disease characterized by chronic inflammation of synovium, which causes progressive joint destruction and reduction in quality of life for patients. The Th1/Th2 paradigm is a model for the induction and regulation of immune responses. Th1 cells participate in cell-mediated immunity whereas Th2 cells support humoral immunity. Recently, Tfh and Th17 cells have emerged as the novel T cell subsets controlling autoimmunity. Identifying their roles may break the Th1/Th2 axis dichotomy, bridge the knowledge gap of T cell lineages on RA immunopathogenesis, and lead to novel therapeutic approaches for RA patients. We examined the frequency of Tfh and Th17 cells in RA patients, and investigated their correlation with disease activity, autoantibody levels, and inflammation.

Methods:

Peripheral blood was collected from 51 RA patients meeting 2010 ACR/EULAR RA classification criteria and 51 age-/gender-matched healthy donors. Clinical disease activity was quantified using the Disease Activity Score in 28 joints (DAS-28). RA patients were divided into remission (DAS-28<2.6) and active disease groups (DAS-28>2.6) based on their DAS-28. Serum laboratory measurements including Rheumatoid Factor (RF), Anti-cyclic Citrullinated Peptide antibody (anti-CCP), Erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) were obtained. The frequency of Tfh cells ($CD4^+CXCR5^+ICOS^+$ $PD\text{-}1^+$) and Th17 cells ($CD4^+CCR4^+CCR6^+$) were measured by flow cytometry and analyzed by sequential gating. The plasmablasts ($CD20^{lo}CD38^+CD138^-$) in the peripheral blood were measured by flow cytometry. Correlation of the frequency of circulating Tfh cells and Th17 cells with DAS-28, plasmablasts, and laboratory parameters were statistically determined.

Results:

Both circulating Tfh cells ($CD4^+CXCR5^+ICOS^+$ $PD\text{-}1^+$) and Th17 cells ($CD4^+CCR4^+CCR6^+$) were significantly increased in RA patients, expecially in moderate/severe patients ($p<0.05$), comparing to healthy donors. The frequency of circulating Tfh cells correlated with the percentage of plasmablasts and the level of pathogenic anti-CCP antibody, whereas the frequency of circulating Th17 cells correlated with the serum level of RF and CRP as well as DAS-28.

Conclusion:

Our data suggests that Tfh and Th17 cells may play different roles in RA pathogenesis. Tfh cells may contribute to B cell differentiation and autoantibody production, while Th17 cells may be involved in the inflamation and pathogenesis of RA. Thus, disrupting the signals provided by Tfh and Th17 cells may offer new therapeutic stategies for severe RA patients and shift their immune system toward homeostasis.

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

A number of studies have shown that synovial mast cells (MCs) are activated, and elicit a pro-inflammatory role in rheumatoid arthritis (RA). Synovial MCs are located around the microvasculature, but also adjacent to the synovial lining and subsynovium where synovial fibroblasts (SFs) reside. Despite that mediators produced by MCs have been demonstrated to activate SF, the effector function of SF on MC activation is not well known.

Methods:

In vitro SF cultures were obtained from knee synovium of RA patients. Co-culture of SF ($2.5x10^4$ cells) and human mast cell (HMC)-1 line was done with IMEM phenol red free media including 10% fetal bovine serum in a 24 well plate. We used the b-hexosaminidase (HXSA) assay as the readout for MC degranulation (1, 6, 12, 24 hours) after direct/indirect co-culture or PMA/ionomycin treatment. HMC-1 was treated with SF conditioned medium (SFCM) to study migration, cytoskeletal rearrangement, proliferation, and degranulation. Antibody based proteins array was utilized to assay cytokines increased after SF/HMC-1 co-cultures.

Results:

Indirect, as well as direct co-culture of SF/HMC-1 showed significantly increased activity of b-HXSA compared with controls. HMC-1 primed in SFCM for 48 hours burst out 3.6 times of b-HXSA activity compared with naïve HMC-1. In addition, HMC-1 transformed into a spindle-shaped cell after cultured in SFCM for 24 hours; surface adherence increased up to 58.3 times compared with cells in control media (figure). Moreover, not proliferation, but HMC-1 migration was induced in the SFCM environment; 2.3 times more than controls. Co-culture of SF/HMC-1 significantly induced soluble interleukin 1 receptor-like 1 (or ST2) and cytokines associated with cell migration or adhesion (endoglin, urokinase receptor (uPAR)).

Conclusion:

Our data indicate that interactions between RA SFs and MCs, independent of direct contact, result in activating MCs into migratory, innate effector cells in the synovium.

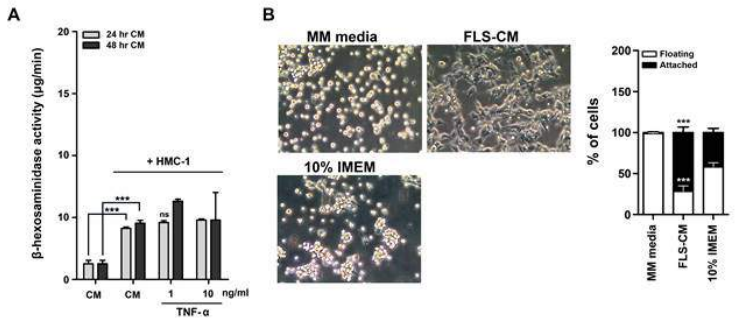

Figure. (A) Increased HMC-1 b-hexosaminidase activity (24 hours) after treated with rheumatoid arthritis synovial fibroblast conditioned media (CM). (B) Transformed HMC-1 cells after treated with CM (24 hours).

Increased Frequency of Dysfunctional Hematopoietic Stem and Progenitor Cell Subpopulations in Treatment Naïve Rheumatoid Arthritis Patients

Natalia Regine de Franca Shimabukuro[1], Kelsey Ann O'Hagan Wong[2], Marie Hudson[3], Sabrina Fallavollita[1] and **Ines Colmegna**[2], [1]Rheumatology, McGill University, Montreal, QC, Canada, [2]McGill University, Montreal, QC, Canada, [3]McGill University, Jewish General Hospital, Montreal, QC, Canada

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Hematopoietic stem and progenitor cells (HSPC) are responsible for the lifelong production of immune cells. Accumulation of DNA damage occurs in HSPC during normal ageing, impacts immune regeneration and has been implicated in the increased risk of malignant transformation. Similarly, age-independent premature accumulation of DNA damage occurs in HSPC from rheumatoid arthritis (RA) patients. Among HSPC the $CD34^+CD38^-$immunophenotype defines a rare primitive subpopulation of progenitor cells, enriched in their colony forming unit ability, and which numbers are increased in the elderly. In this study we characterized the frequency, phenotype and function of HSPC subpopulations in treatment naïve rheumatoid arthritis (RA) patients.

Methods: Peripheral blood circulating $CD34^+$ cells were isolated from treatment naïve, recent onset, ACPA positive RA patients (n=19) and from age/sex matched healthy controls (HC, n=19). The frequency of viable HSPC subpopulations ($7AAD^-/CD34^+/CD38^{+/-}$) and their proliferative responses (CFSE) were assessed by FACS. Clonogenicity was assessed in colony-forming cell (CFC) assays and DNA damage was quantified by single cell gel electrophoresis assay (comet assay). All results are shown as mean ± SEM, non-parametric tests were used for group comparisons.

Results: Treatment naïve RA patients have an increased proportion of circulating $CD34^+CD38^-$ HSPC (5.30 ± 0.84 % vs 2.83 ± 0.76 % respectively, $p<0.05$, n=9). The frequency of $CD34^+CD38^-$ does not change following 6 months of methotrexate treatment (5.21 ± 2.39 % vs 5.49 ± 2.20 %, p=0.375, n=3). Compared to HC, RA-CD34 produced fewer colonies (n=7) [CFU-GEMM (1.82 ± 0.37 vs 4.71 ± 1.10 respectively, $p<0.05$), CFU-GM (6.89 ± 1.01 vs 18.54 ± 3.97 respectively, $p<0.05$) and BFU-E (10.71 ± 1.95 vs 15.43 ± 3.57 respectively, $p>0.05$)]; accrued DNA damage (32.25 ± 5.27% vs 7.63 ± 2.57% DNA in tail respectively, $p<0.0001$), and had impaired proliferative responses to hematopoietins (Day 4 expansion index (EI): 3.21 ± 0.20 vs 4.28 ± 0.28, $p<0.01$, n=11); and increased number of $CD34^+$ that remained non-proliferating (generation 0: 27.42 ± 4.06 % vs 18.65 ± 2.74 % respectively, $p<0.05$, n=11). The EI of RA-$CD34^+CD38^-$HSPC was significantly reduced (3.61 ± 0.48 vs 5.00 ± 0.62 expansion index respectively, $p<0.05$, n=10).

Conclusion: The function of the most primitive HSPC subpopulations in treatment naïve RA patients is impaired mimicking the HSPC phenotype of healthy elderly individuals. The disruption of HSPC homeostasis is an early event in RA with potential implications in immune-regeneration and carcinogenesis.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The aims of the present study were to investigate the role played by natural killer T (NKT) cells in osteoclastogenesis and their effects on inflammatory bone destruction.

Methods: Patients with RA (n=25) and healthy controls (n=12) were enrolled in this study. *In vitro* osteoclastogenesis experiments were performed using peripheral blood mononuclear cells (PBMCs) in the presence of M-CSF and receptor activator of nuclear factor kB ligand (RANKL). PBMCs were cultured *in vitro* with α-galactosylceramide (αGalCer), and proliferation indices of NKT cells were estimated by flow cytometry. *In vivo*effects of αGalCer-stimulated NKT cells on inflammation and bone destruction were determined in collagen-induced arthritis (CIA) mice.

Results: *In vitro*osteoclastogenesis was found to be significantly inhibited by αGalCer in healthy controls, but not in RA patients. Proliferative responses of NKT cells and STAT-1 phosphorylation in monocytes in response to αGalCer were impaired in RA patients. Notably, αGalCer-stimulated NKT cells inhibited osteoclastogenesis mainly via interferon-g production, in a cytokine-dependent manner (not by cell-cell contact), and down-regulated osteoclast-associated genes. αGalCer-treated mice showed less severe arthritis and reduced bone destruction. Moreover, proinflammatory cytokine expression in arthritic joints was found to be reduced by αGalCer treatment.

Conclusion: This study primarily demonstrates that αGalCer-stimulated NKT cells have a regulatory effect on osteoclastogenesis and a protective effect on inflammatory bone destruction. However, it also shows that these effects of αGalCer are diminished in RA patients, and that this is related to NKT cell dysfunction. These findings provide important information for those searching for novel therapeutic strategies to prevent bone destruction in RA.

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Endoplasmic reticulum (ER) stress is a cellular signal, which is triggered by the failure to fold newly synthesized ER proteins. ER stress plays an important role in the pathogenesis of some human diseases. Recently it was revealed that the rheumatoid arthritis (RA) causes synovial cell tolerance against ER stress during secretion of inflammatory cytokines. ER stress transducer IRE1 is one of the canonical transducers. The activation of IRE1 was identified in RA. Here, we report that IRE1 is a master

regulator of the unfolded protein response in RA synovium. And, we demonstrated that the tolerance for ER stress was reduced by inhibiting IRE1 in RA synovial cells. Furthermore, this is the first report to apply STF-083010, a novel small-molecule inhibitor of IRE1, for treatment of RA synovitis.

Methods: Synovial fibroblasts from the knee joint of RA patient who underwent total knee replacement were prepared by digestion with collagenase. We assessed the ER-related genes in the RA patient's primary cultured synovial fibroblasts.

To investigate the effectiveness of suppressing the synovitis by IRE1 inhibitor, we prepared antigen induced arthritis (AIA) mice model. To prepare the AIA mouse model, arthritis was induced in knee joints of 8-week-old wild-type mice by intra-articular injection of methylated bovine serum albumin (mBSA; Sigma) in mice preimmunized with mBSA. On day 1, mice were preimmunized by a 100 μL intradermal injection at the base of the tail with an emulsion containing 100 μg of mBSA and an equal volume of Freund's complete adjuvant (Sigma). On day 10, animals were treated with intra-articular mBSA injected into the left and right knee joints. On day 17, the knee joints were harvested and processed using standard procedures.

Results: Although all ER stress transducers were up-regulated with the time, IRE1 exhibited dynamic up-regulation in response to inflammatory stimulation in RA synovial fibroblast group. To assess the effectiveness of IRE1 inhibitor, STF-083010, we also performed TUNEL staining using RA patient's synovial fibroblasts. We found that the TUNEL-positive cells were significantly increased especially in the STF-083010-treated group. The synovitis of AIA was significantly suppressed in STF-083010-treated AIA group.

Conclusion: STF-083010 inhibited IRE1 activity through ER stress shown in both *in vitro* and *in vivo* assays. Treatment with STF-083010 resulted in a significant reduction in cell viability in primary cultured human RA synovial fibroblasts. Similarly, STF-083010 successfully suppressed synovial activity in AIA mouse models as the result of less tolerated to ER stress. This procedure could be considered 'the molecular targeted synovectomy'. The application of this novel IRE1 inhibitor supports the hypothesis that IRE1 is a promising target for alternative therapy in RA synovitis.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: The synovium is primarily formed by fibroblast-like synoviocytes (FLS). Its multicellularity requires precise coordination to generate a tissue that confers specialized functions critical to joint homeostasis. Cell-to-cell communication facilitates the concerted behavior of FLS within the synovium. Using a 3D model of the synovium, we analyzed FLS capacity for exchange of cytoplasmic content.

Methods: Human FLS were prepared from synovial tissues obtained as discarded specimens following joint arthroplasty. Cells were cultured in spherical matrigel micromasses with an average size of 2 mm Ø. Data was acquired by confocal live cell imaging and transmission electron microscopy. Analysis of the resulting 4D movies was done with Imaris® software.

Results: To examine intercellular cytoplasmatic transfer, we labeled 50% of FLS with red cell tracker dye and loaded the other 50 % with green non-degradable microspheres. In a time series (8 days), we found that microspheres do indeed appear in red labeled cells. First evidence was found on Day 1 and over the course of the following days microspheres accumulated in red labeled cells with a transfer rate of 10 % of newly affected cells/day. Additionally, red vesicles also appeared in green labeled cells. They first occurred on day 1, however, their transfer rate reached a steady state at about 20%, presumably due to degradation following transfer in the receiving cell. A similar experiment in 2D demonstrated microsphere movement within interconnecting nanotubes. Transfer rates for microspheres into red cells were identical. By contrast, rates for red vesicles into green cells were much higher than in 3D cultures. Thus, cells in 2D culture may have easier access to released vesicles as compared to 3D tissues. Transmission Electron Microscopy revealed transfer via exocytosed vesicles as well as open intercellular connections.

Conclusion: These studies suggest transfer of cytoplasmic cargo between FLS. We identified two ways for cytoplasmic transfer between cells; 1) through vesicles and 2) through interconnecting open nanotubes. Further studies will demonstrate the significance of directed cargo exchange for cellular cooperation and the function of the normal as well as the diseased synovium.

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: The synovial lining tissue consists of fibroblast-like synoviocytes (FLS) and monocyte-derived macrophage-like synoviocytes (MLS) within a self-built meshwork of dense extracellular matrix (ECM) components. FLS are thought to direct ECM synthesis, assembly and degradation. Whether FLS themselves or the ECM network serve as guiding structures for MLS migration is incompletely understood. We studied the dynamics of tissue modeling as well as MLS migratory behavior using a 3D synovial tissue in vitro model.

Methods: Human FLS were prepared from synovial tissues obtained as discarded specimens following joint arthroplasty. CD14+ monocytes (MO) were isolated from peripheral blood. Fluorescently labeled FLS and MO were cultured in spherical extracellular matrix micromasses with an average size of 1.5 mm for up to two weeks. Second harmonic generation was used for the visualization of collagen fibers (ECM). Cell migration was monitored by real-time confocal/multi-photon microscopy.

Results: FLS spontaneously formed a synovial lining-like layer at the surface of the 3D cell culture within 3 days. The first signs of collagen fibers co-localized with FLS clusters and appeared as early as day 1. ECM density increased during the establishment of the lining layer.

The majority (98%) of MO was found to be in close contact with the FLS network with low tendency for migration. On the surface of 3D cultures at the tissue/medium interface a minor fraction of MO displayed directed cell movement with an impressive maximum speed of up to 15 mcm/min. MO migration occurred in intimate contact with FLS but did not necessarily follow individual FLS of the network. Inside the synovial tissue, MO migration followed the FLS network rather than the ECM fibers. For both MO contact with FLS seemed to be more important than contact with the ECM.

Conclusion: The 3D synovial tissue culture system allows for monitoring and analyzing the dynamics of synovial lining modeling. Both, FLS and MO appear to cooperate in the organization of the synovial lining tissue with subtle migration patterns of MO in relation to the organized synovial lining architecture. Ongoing experiments address molecular mechanism(s) of MO – FLS interaction in order to identify potential targets for future therapeutic intervention in arthritis.

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Fibroblast-like synoviocytes (FLS) play an important role in the progression of rheumatoid arthritis (RA). Particularly, FLS of RA patients (RA-FLS) exhibit pro-migratory and invasive characteristic reminiscent of cancer cells, destroying cartilage and bone. However, key regulators or signaling molecules responsible for this characteristic are not fully documented. Recently, we have demonstrated that nuclear factor of activated T cell 5 (NFAT5), an osmo-protective transcription factor, is crucial to the development of experimentally-induced arthritis in mice (Kim WU, et al. Arthritis Rheum 2011). Here, we investigated if NFAT5 controls migration and invasion of RA-FLS.

Methods:

The FLS were obtained from synovial tissues of RA patients. Messenger RNA (mRNA) in RA-FLS and embryonic fibroblasts, which were deficient of NFAT5 gene, were profiled using microarray technology. NFAT5 expression in the presence of interleukin 1β (IL-1β) or transforming growth factor β (TGFβ) was analyzed by western blot analysis and real-time PCR. The expression levels of tissue factor and CCL2 were measured by flow cytometry analysis and ELISA, respectively. Wound migration assay and invasion assay using matrigel chamber were conducted *in vitro*.

Results:

The mRNA profiling of RA-FLS transfected with NFAT5 short interfering RNA (siRNA) and embryonic fibroblasts of NFAT5 knockout mouse revealed that NFAT5 is involved in the migration and invasion in RA-FLS. Transcriptome analysis also suggested that tissue factor and CCL2 were the key target genes of NFAT5 responsible for these processes. Consistent with these results, NFAT5 was up-regulated in RA-FLS stimulated with pro-migratory and pro-invasive cytokines, including IL-1β and TGFβ. Interestingly, tissue factor and CCL2 were independently increased by TGFβ and IL-1β, respectively, although both of which were commonly regulated by NFAT5. Moreover, knockdown of NFAT5 or tissue factor using siRNAs resulted in a marked suppression of migration and invasion of RA-FLS; particularly, TGFβ-induced RA-FLS invasion and lamellipodia formation were blocked by knockdown of NFAT5 or tissue factor transcripts. SB203580, a p38 inhibitor, down-regulated TGFβ-induced NFAT5 expression, suggesting that p38 is an up-stream regulator of NFAT5 under high TGFβ conditions.

Conclusion:

The present study demonstrates first that NFAT5 is a critical regulator responsible for the migration and invasion of RA-FLS. These data also provide the evidence for a novel role of the TGFβ-NFAT5-tissue factor axis in RA-FLS invasiveness, which could be a

potential target for anti-FLS therapy retarding cartilage and bone destruction.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Periodontitis, a polymicrobial infectious and inflammatory disease of tooth-supporting structures, shares pathogenic mechanisms with rheumatoid arthritis (RA) and may trigger its onset. Most studies have focused on *Porphyromonas gingivalis* (*Pg*), and serologic responses to periodontal pathogens, rather than direct detection of organisms. One prior study by Scher et al. found enrichment of *Prevotella* and *Leptotrichia* species in the oral microbiota of new-onset RA patients, irrespective of periodontal disease status. Here we studied the subgingival plaque biofilm of patients with new-onset and chronic RA.

Methods:

43 subjects, 23 RA patients, all meeting 2010 ACR/EULAR criteria, and 20 age- and gender-matched healthy subjects without periodontitis or RA completed standardized dental examination performed by a single periodontist. Dental parameters were measured at 6 sites per tooth. A total of 86 subgingival plaque samples (2 per subject) were evaluated for the presence of 41 bacterial taxa associated with periodontitis biofilms by checkerboard DNA-DNA hybridization.

Results:

Typical of RA cohorts, the 23 patients were mainly female (87%) with median age of 48; 15 had DMARD-naive early disease. The majority (61%) was seropositive for ACPA, 43% were positive for rheumatoid factor, and they had a range of disease activity from mild to severe. None were current smokers. All but one patient received routine dental care with cleanings every 6 months.

Of the 23 patients, 10 (43%) had gingivitis, a precursor of periodontitis, 9 (39%) had periodontitis, and only 4 patients (17%) had healthy periodontal tissue. Compared with the 20 healthy subjects, the 23 RA patients had significantly increased pocket depth ($P<0.000001$), clinical attachment loss ($P=0.001$), and bleeding on probing ($P=0.0001$). There were no differences in dental parameters between former vs. never smokers.

The RA patients had a distinct subgingival biofilm. Accounting for multiple comparisons, 10 of 41 pathogens had higher DNA probe counts (levels) in RA patients versus controls ($P \leq 0.002$). Although RA patients had higher levels of classic “red-complex” pathogens (*P. gingivalis, Tannerella forsythia,* and *Treponema denticola*) than healthy controls, differences were not significant. Compared with chronic RA, new-onset patients had significantly higher levels of several pathogens, including *Gemella morbillorum, Propionybacterium acnes, Streptococcus gordonii,* and *Leptotrichia buccalis* ($P \leq 0.05$), regardless of whether they had periodontitis on examination. *L. buccalis* was present in 67% of new-onset RA patients versus only 13% of those with chronic RA ($P=0.02$). Finally, levels of *L. buccalis* and *P. acnes*tended to correlate with multiple disease activity measures ($P \leq 0.07$).

Conclusion:

Despite routine dental care, most of our patients had gingivitis or periodontitis on examination and abundance of periodontal pathogens in subgingival plaque. Although *P. gingivalis*, a classic periodontal pathogen is of interest in RA pathogenesis, several other organisms including the previously implicated *Leptotrichia* species, may be more specifically associated with new-onset RA and may warrant further study as candidate triggers of RA.

Cyclic Phosphatidic Acid (CPA) Suppresses Expression of Cartilage Degrading Enzymes Such As MMP-3, MMP-13 and Adamts-4 in Inflammatory Synovial Fibroblasts and Articular Chondrocytes Induced By IL-1 Beta and/or TNF ALFA

Ikuko Masuda[1,2], Kodo Okada[3], Hisashi Yamanaka[1] and Shigeki Momohara[1], [1]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan, [2]Rheumatology, Jyujyo Takeda Rehabilitation Hospital, Kyoto, Japan, [3]SANSHO, Co. Ltd., Tokyo, Japan

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Cyclic phosphatidic acid (cPA) is one of bioactive lipid, has been implicated as an mediator of various biological effects including inhibitory effects of proliferation, invasion and metastasis of cancer cells. We have previously confirmed that cPA stimulated HAS-2 production on human osteoarthritic chondrocytes and synovial fibroblasts (SFs) in vitro. Furthermore, intra-articular administration of cPA has shown its suppressing effect of pain, swelling, and articular cartilage destruction in rabbit experimental osteoarthritis. We have shown that cPA might had direct inhibitory effect of cartilage degrading enzymes on rheumatoid synovial fibroblasts (SFs) in vitro. Inflammatory arthritis such as rheumatoid arthritis and early stage of OA involves synovial inflammation and subsequent production of cartilage degrading enzymes. cPA is naturally occurring mediator even exists in human serum. cPA may be possible another therapeutic option for degenerative arthritis. The aim of this study was to evaluate the direct effects of cPA on cartilage matrix degrading enzymes using SFs and articular chondrocytes under influence of inflammatory cytokines.

Methods: In vitro studies were performed using SFs and chondrocytes obtained from arthritis patients at joint replacement surgery. cPA 0-25 μM was added to cell cultures and effects of cPA on ADAMTS-4, -5, MMP-3, -13, TIMP-3 expression were assessed by real time PCR using specific primers to corresponding genes. SFs or chondrocytes were also cultured with IL-1β (2.5ng/ml) and/or TNF-α (10 ng/ml), to study attenuated effect of cPA. Beta-actin was used as endogenous expression control for PCR. Newly synthesized MMP-3, -13, TIMP-3 from SFs or chondrocytes in cultured media were measured by sandwich ELISA.

Results: cPA itself repressed cartilage degrading enzymes, ADAMTS-4, ADAMTS-5, MMP-3, and MMP-13 expression in both SFs and chondrocytes was all repressed by low dose of cPA, even after these expressions was stimulated by cytokines. Expression of these enzymes were repressed more in chondrocytes by cPA. ELISA results also confirmed the inhibitory effect of cPA on MMP-3, MMP-13, and PGE2 production.

Conclusion: The in vitro results confirmed that cPA had suppressing effect of cartilage degrading enzymes on SFs and chondrocytes, supports the hypothesis that cPA might have played direct role to suppress inflammation and also protect articular cartilage in arthritic condition. Molecular mechanism of cPA to prevent cartilage degradation remains to be elucidated, however, further study should be warranted for cPA as a novel candidate for therapeutic agent of arthritis.

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The importance of type I interferons (IFN-α and others) as a driver of pathogenesis in autoimmunity, including rheumatoid arthritis (RA) is well recognized. However, in this context, the contribution of type II interferons (IFN-γ) has been ambiguous. The interferon gamma receptor (IFNGR) is a heterodimer of proteins encoded by *IFNGR1* and *IFNGR2*. The expression of *IFNGR2*, not plasma levels of INF-γ, has been shown to be the limiting factor for receptor binding. We recently reported a strong association between the presence of RA and the level of expression of the INF-γ receptor gene *IFNGR1* in peripheral blood mononuclear cells (PBMC). We also analyzed 576 RA patients and found that *IFNGR2* in PBMC strongly associated with radiographic severity (P=0.03 for erosions, P=0.04 for joint space narrowing, and P=0.03 for total radiographic score). These data implicate and important pathogenetic function of the IFN-γ signaling pathway in RA.

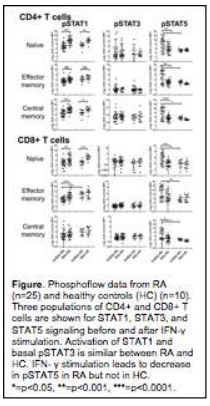

Figure. Phosphoflow data from RA (n=25) and healthy controls (HC) (n=10). Three populations of CD4+ and CD8+ T cells are shown for STAT1, STAT3, and STAT5 signaling before and after IFN-γ stimulation. Activation of STAT1 and basal pSTAT3 is similar between RA and HC. IFN- γ stimulation leads to decrease in pSTAT5 in RA but not in HC. *=p<0.05, **=p<0.001, ***=p<0.0001.

Methods: We sought to determine the mechanistic significance of the elevated expression of INF-γ receptors within subpopulations of CD4 and CD8 T cells, B cells, and monocytes. To address this question, we used a phosphoflow approach (high-definition multi parameter flow cytometry with simultaneous evaluation of activation of multiple STAT signaling molecules). We analyzed STAT1, STAT3, and STAT5 cell signaling in na•ve and memory CD4+ and CD8+ T cells (differentiated by CD45RA and CCR7), Tfh cells (CD4+/CXCR5-), na•ve and memory B cells, and monocytes (CD11b+) in PBMC of RA (n=25) and healthy controls (HC) (n=10).

Results: Although STAT1 is the primary STAT activated following stimulation with INF-γ, we found no difference in the activation of STAT1 between RA and HC in all cell populations. However, we found that basal active STAT5 (as assessed by phosphorylated tyrosine at position 694 [pY694-STAT5]) was elevated in RA compared to HC (p=<0.05). Strikingly, this active basal pSTAT5 was down-modulated following stimulation with INF-γ in CD4 and CD8 T cell populations but not in B cell populations or monocytes from RA (see figure).

Conclusion: Our novel preliminary findings suggest that decreased levels of pSTAT5 following stimulation of T cell populations and Tfh cells with INF-γ contribute to the pathogenesis of RA and its severity. Ongoing studies reveal that this down-modulation of STAT5 may render cells hyporesponsive to regulatory cytokines such as IL-2.

Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Mechanisms regulating the chronic autoimmune response in rheumatoid arthritis (RA) are not well understood. However, activated T CD4+ play a pivotal role initiating and perpetuating the chronic inflammation characteristic for the disease. The objetive is evaluate the number and distribution of circulating CD4+ T lymphocytes and their CD4+ naïve T cells (TN), central memory (TCM), non-terminated effector memory (TNTEM) and terminated effector memory (TTEM) T cells subsets in a population of recently diagnosed DMARD naive RA patients before and along the first 6 months of methotrexate (MTX) treatment.

Methods: The number of circulating CD4+ T lymphocytes, and of their TN, TM, TCM and TEM subsets in fifty untreated patients with RA before MTX treatment and at 3 and 6 months of treatment were assayed using a multiparametric flow cytometry. We also studied twenty-four age- and sex-matched healthy subjects as controls.

Results:

RA naïve patients show a significant ($p<0.05$) expansion of the circulating CD4+ TNTEM subset. MTX non responder naïve RA patients show from basal conditions a significative expansion of CD4+ TNTEM lymphocytes and develop significant expansion of CD4+ TCM, and CD4+ TEM lymphocyte subsets along MTX treatment.

Conclusion: Recently diagnosed DMARD naive RA patients show involvement of the circulating CD4+ T lymphocytes activation/differentiation stage subsets. MTX treatment show immunomodulatory effects on CD4+ T lymphocyte compartment with different behavior in responder and non-responder patients.

Secular Trends in Use of Disease Modifying Anti-Rheumatic Drugs for the Treatment of Rheumatoid Arthritis in the United States

Rishi J. Desai[1], Daniel H. Solomon[2], Jun Liu[3] and Seoyoung C. Kim[4], [1]PharmacoEpidemiology & PharmacoEconomics, Brigham and Women's Hospital, Boston, MA, [2]Rheumatology, Brigham and Women's Hospital, Boston, MA, [3]Division of Pharmacoepidemiology, Brigham and Women's Hospital, Boston, MA, [4]Div. of Pharmacoepidemiology and Pharmacoeconomics, Div. of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Boston, MA
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III
Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Treatment of rheumatoid arthritis (RA) with disease modifying anti-rheumatic drugs (DMARDs) has undergone major advances in last two decades. More than 10 non-biologic DMARDs and 9 biologic DMARDs are currently approved in the United States for the indication of RA. Yet, little is known about the population level time-trends in use of these agents. Therefore, we described secular trends in use of DMARDs for initial and subsequent treatment of RA in publicly and privately insured patients.

Methods: Claims data derived from private (United HealthCare, 2004-2013) or public (Medicaid Analytic eXtract (MAX), 2000-2010) insurance programs were used to conduct a retrospective cohort study. RA patients were identified from either data source based on at least two medical claims with ICD-9 code of 714.xx and classified into three groups by their DMARD use in a 12-month baseline period: 1) DMARD-naïve patients, 2) biologic-naïve patients, or 3) biologic-exposed patients. In a 12-month follow-up period, we identified initiation of the first ever DMARD among DMARD-naïve patients, initiation of the first ever biologic agent among biologic-naïve patients, and initiation of a second or later biologic agent among biologic-exposed patients. Among the patients initiating the new DMARD of interest during follow-up in each group, we calculated the proportion of patients initiating individual DMARDs for all available calendar years and reported time-trends.

Results: A total of 75,545 RA patients with private and 95,624 with public insurance were identified as eligible for this study. Mean age (SD) the cohort was 48 (12) years and 78% of the patients in the cohort were female. Among DMARD-naïve RA patients, methotrexate (42%), hydroxychloroquine (32%), and sulfasalazine (9%) were the three most commonly used agents as the first-ever DMARD during our study period. Among biologic-naïve patients, etanercept (45%) was the most commonly initiated agent as the first-ever biologic, followed by adalimumab (25%) and infliximab (20%). A decreasing trend for infliximab was observed between 2001 and 2012 as the first ever biologic agent; while newer agents, abatacept and certolizumab, showed increasing trend in use since their introduction ($p<0.05$) (**Figure 1**). Among biologic-exposed patients, a decreasing trend in the use of adalimumab and infliximab, while an increasing trend for abatacept, golimumab, and certolizumab as the second-line biologic of choice was noted since their introduction ($p<0.05$ for all trends).

Conclusion: Use of etanercept as the most common first-line agent has remained relatively stable over the past decade; however, use of adalimumab and infliximab is decreasing and the use of newer biologics, especially abatacept, golimumab, and certolizumab, is increasing as both first-line and second-line agents in recent years.

The Effect of Prior Disease Duration and Prior DMARD Use on Treatment Outcomes in Patients with Early or Established Rheumatoid Arthritis

Josef S. Smolen[1], Daniel Aletaha[2], Su Chen[3] and Stefan Florentinus[3], [1]Department of Rheumatology, Medical University of Vienna, Vienna, Austria, [2]Division of Rheumatology, Department of Internal Medicine III, Medical University of Vienna, Vienna, Austria, [3]AbbVie Inc., North Chicago, IL

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: A delay in effective treatment is known to negatively affect long term treatment outcomes in patients (pts) with rheumatoid arthritis (RA). The purpose of this study was to compare the effects of disease duration and the number of prior failed disease modifying anti-rheumatic drugs (DMARDs) before effective treatment, on the achievement of long term outcomes in pts with early or established RA.

Methods: Data from two randomized controlled trials, PREMIER and DE019, were used. In PREMIER, pts with mean RA duration < 1 year (yr), who were TNF inhibitor-(TNFi) and MTX-naïve received adalimumab (ADA), methotrexate (MTX), or ADA+MTX. In DE019, TNFi-naïve pts with mean RA duration 11 yrs, and an insufficient response to MTX received 20 mg/40mg ADA every other week +MTX, or PBO+MTX. The association of either variable (prior disease duration or prior DMARDs) with the endpoints was modeled while controlling for the other variable using linear or logistic regression. RA duration and number of prior DMARDs were grouped and the groups were treated as ordinal variables. For PREMIER, RA duration groups were ≤1yr, >1 to ≤2yr and >2yr and for prior DMARDs, groups were: 0 or ≥1 DMARD. For DE019, RA duration groups were: ≤1yr, >1 to ≤5yr and >5 to ≤10 yr, and >10yr, and for prior DMARDs groups were: MTX+0 or 1 DMARD, MTX + 2 DMARDs and MTX +>2 DMARDs. The effect of RA duration/ exposure to prior DMARDs was determined for the following endpoints: week (wk) 52 ACR 20/50/70 response rates, mean DAS28 / SDAI / CDAI and HAQ; and mean changes from baseline (BL) to wk 52 in DAS28 / SDAI / CDAI/ HAQ (for changes from BL, a positive regression coefficient indicates a smaller change) .

Results: In PREMIER, in the ADA+MTX arm (268 pts), longer RA duration led to a smaller change from BL to wk 52 in CDAI and SDAI (2.95 and 3.59 respectively; $p<0.05$); higher absolute DAS28, CDAI and SDAI scores, and lower ACR response rates at wk 52. In DE019, for pts receiving ADA 40 mg +MTX (207 pts), an exposure to a larger number of prior DMARDs was significantly associated ($p<0.05$) with increased (by 0.21) DAS28 scores at wk 52, and a smaller (by 0.15) change in HAQ scores from BL to wk 52 ($p<0.01$). Longer RA duration was significantly associated ($p<0.05$) with an increase of 0.13 in wk 52 HAQ scores. Larger number of prior DMARDs or longer RA duration were associated, although not significantly, with lower ACR response rates at week 52.

Conclusion: In early RA, disease duration but not number of prior DMARDs, was significantly associated with a smaller change from BL to wk 52 in SDAI and CDAI, higher CDAI and SDAI scores and lower ACR response rates at wk 52.

Table: Association of wk 52 outcomes with number of prior DMARDs or disease duration. Regression coefficient estimate (95% CI)

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: BI 695501 is a proposed adalimumab biosimilar currently in development and was evaluated for pharmacokinetic (PK) similarity to both US-licensed and EU-approved reference products.

Methods: Healthy male subjects aged 18 to 55 years (N = 327) were randomized to receive one dose of either BI 695501 40 mg/0.8 mL, or US-licensed adalimumab or EU-approved adalimumab 40 mg/0.8 mL (NCT02045979). In each treatment group, 108 subjects received the trial medication, which was administered by subcutaneous injection. Primary and secondary PK endpoints included were total drug exposure as measured by the area under the concentration–time curve (AUC) from time zero to infinity ($AUC_{0\text{-}inf}$), AUC from time zero to the last measurable concentration ($AUC_{0\text{-}tz}$), and maximum observed plasma concentration (C_{max}), as well as several time truncated AUCs. Statistical PK similarity of BI 695501 vs. US licensed and vs. EU approved adalimumab was assessed by an ANCOVA model on the log-transformed primary PK parameters (with fixed effects for treatment and trial site as well as age and body weight as continuous covariates) for the ratios of the geometric means for each treatment and compared with the pre-specified boundaries of 80% to 125%. Safety and immunogenicity were also evaluated.

Results: Demographics and baseline characteristics were similar between the three treatment groups. Mean plasma concentration–time profiles for BI 695501, US-licensed and EU approved adalimumab were similar over the entire profiling interval (See figures). Body weight at baseline was a statistically significant predictor of C_{max} and AUC ($P < 0.0001$ for all pairwise analyses). Subject age was a statistically significant predictor of C_{max} ($P < 0.026$ for all pairwise analyses) but not for AUC ($P > 0.149$ for all pairwise analyses). Based on the predefined hypothesis test, the primary and secondary endpoints were met. PK parameters were similar for all comparisons of BI 695501 vs. US-licensed and vs. EU-approved adalimumab. Single subcutaneous doses of BI 695501, US-licensed or EU-approved adalimumab were generally well tolerated, and there were no notable differences in safety between the three treatment groups. Immunogenicity was also comparable and will be reported elsewhere.

Conclusion: BI 695501, US-licensed, and EU approved adalimumab are bioequivalent and have similar safety and tolerability profiles.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Biologic (b)DMARDs have advanced the standard of care in RA, reducing unmet needs and increasing remission rates. Abatacept (ABA) is approved for the management of moderate-to-severe RA. In clinical trials, ABA showed efficacy similar to TNFi.[1] In clinical practice, TNFi are the predominantly used bDMARDs in the management of RA, but data comparing ABA to bDMARDs are limited. The primary objective was to assess baseline (BL) characteristics of RA patients (pts) receiving ABA or other bDMARDs in clinical practice. The secondary objective was to evaluate changes from BL to Month 12 in disease activity measures (DAS28 [CRP], CDAI and SDAI) and pt-reported outcomes (PROs; physical functioning [modified Health Assessment Questionnaire (mHAQ)], quality of life [EQ-5D] and arthritis active/pain today). **Methods:** Data from pts enrolled in the Brigham and Women's Hospital RA Sequential Study (BRASS) registry, established in 2003, were analyzed. The registry comprises mostly pts with established RA who were evaluated annually on clinical measures and semi-annually on multiple clinical PROs and resource utilization parameters. The current analysis is based on pts who had exposure to bDMARDs and available data on at least one disease activity measure during 12-month follow-up in the registry. Descriptive statistics were used to summarize BL differences in demographics, disease activity measures and laboratory measurements between RA pts prescribed ABA vs other bDMARDs. Mean change from BL to 12 months in disease activity measures and PROs were assessed using univariate and multivariate regression analyses that controlled for BL covariates, including BL ABA vs bDMARD treatments. **Results:** 748 pts were included in the analysis: 102 (13.6%) received ABA and 646 (86.4%) received other bDMARDs; 83% of ABA pts had prior exposure to bDMARDs. At BL, ABA pts (vs other bDMARD patients) were older (mean [SD] age: 59.5 [10.7] vs 54.8 [14.2] yrs; p=0.0015), with higher CRP levels (17.09 [41.5] vs 8.1 [19.2] mg/L; p=0.0004), higher DAS28 (CRP) (4.42 [1.58] vs 3.68 [1.65]; p≤0.001), higher mHAQ (0.59 [0.52] vs 0.37 [0.47]; p≤0.001) and lower EQ-5D (0.71 [0.15] vs 0.80 [0.17]; p≤0.001). After controlling for BL covariates, the mean changes from BL to 12 months in disease activity measures and PROs were comparable in ABA and other bDMARD pts (Table).

Table: Change from baseline to 12 months between ABA vs bDMARD on disease activity and patient-reported outcomes*

	bDMARD patients	ABA patients	p-value
	Mean (95% CI)	Mean (95% CI)	
DAS28 (CRP)	–0.915 (–1.276, –0.554)	–0.606 (–1.123, –0.090)	0.147
CDAI	–8.406 (–11.819, –4.992)	–5.098 (–10.238, 0.042)	0.119
SDAI	–8.673 (–12.353, –4.994)	–7.004 (–12.348, –1.659)	0.299
mHAQ	–0.023 (–0.085, 0.039)	–0.038 (–0.137, 0.062)	0.239
EQ-5D	0.003 (–0.022, 0.028)	0.022 (–0.018, 0.063)	0.231
Arthritis active today	–0.285 (–0.708, 0.138)	–0.709 (–1.357, –0.061)	0.904
Arthritis pain today	–0.199 (–0.585, 0.187)	–0.595 (–1.187, –0.003)	0.944

*Negative values indicate a reduction in disease activity and improvement in patient-reported outcomes except for EQ-5D, where positive values indicate an improvement

Conclusion: RA pts prescribed abatacept (vs other bDMARDs) in clinical practice tend to be older, with longer disease duration, higher disease activity scores, higher acute-phase reactant and most had prior bDMARD exposure. Despite this, mean changes from BL to 12 months in disease activity measures and PROs in pts on abatacept and other biologic therapies were comparable.[2]

Clinical and Radiographic Outcome of Iguratimod for Rheumatoid Arthritis

Tsuneo Kondo, Akiko Shibata, Ryota Sakai, Jun Kikuchi, Kentaro Chino, Ayumi Okuyama, Hirofumi Takei and Koichi Amano, Department of Rheumatology and Clinical Immunology, Saitama Medical Center, Saitama Medical University, Saitama, Japan
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Iguratimod is a new small-molecular drug for rheumatoid arthritis (RA), which was approved on June, 2012 in Japan. The agent inhibits the production of immunoglobulins and various inflammatory cytokines (interleukin-1, -6 and -8 and TNF), and exerts anabolic effects on bone metabolism by stimulating osteoblastic differentiation and inhibiting osteoclastogenesis in mice through inhibiting the nuclear transcription factor NF-κB, but not its inhibitor, IκBα. In addition this agent is very cheap (1.5$/25 mg tablet) , so 50 mg/day iguratimod therapy costs only 3$/day. A few clinical efficacies have been reported, while radiographic efficacy have never reported. In this study, We evaluate the clinical and radiographic efficacy of iguratimod for RA patients.

Methods:

62 patients who were administered iguratimod at a dosage of 25mg qd during the first month, then 50mg qd thereafter, and followed up for 24 weeks were enrolled. Efficacy was evaluated by composite measures such as DAS28, SDAI, HAQ-DI and modified Total Sharp Score (mTSS), and safety was evaluated by adverse events.

Results: The mean age was 61.3 years and 75.8% of patients were female. MTX was used in 46.8%, the average dose was 8.6±2.9 mg/week. LOCF analysis revealed that DAS28-ESR and SDAI decreased significantly from 4.49±1.33 to 3.12±1.08 and from 18.5±10.9 to 8.3±6.34 in 52 weeks respectively (P<0.01). Remission and LDA rate in DAS28-ESR were 29.0% and 24.2%. HAQ-DI score also decreased from 1.2±0.8 to 0.85±0.79. The percentage of patients with no radiographic progression(ΔmTSS <0.5) was 56.8%, while that of rapid radiographic progression(ΔTSS >5) was 13.5%. The mean estimated yearly progression was 9.9 ± 15.6 at baseline. After 52 weeks of IGU treatment, the mean change was significantly reduced to 1.2 ± 2.5(P<0.01).The difference between the efficacy of igurarimod with and without MTX was not significant. 35.5%(n=22) of the patients discontinued iguratimod within 52 weeks. The reason of cessation consisted of adverse events (21.0%) and lack of efficacy (6.5%). Adverse events were digestive symptom (n=6), liver dysfunction (n=4), nasal hemorrhage (n=2) and so on. There's no severe adverse event.

Conclusion:

IGU reduced disease activity and radiographic progression with RA patients. IGU is generally safe and tolerable and may have a good cost effectiveness. So iguratimod be a new useful option as small molecule DMARDs.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Baricitinib (bari) is an oral Janus kinase (JAK) 1 /JAK2 selective inhibitor, representing a potentially effective treatment for patients with moderately to severely active rheumatoid arthritis (RA). This study evaluated the effect of bari 2 and 4 mg on patient-reported outcomes (PROs) in patients with RA with an inadequate response or intolerance to conventional synthetic disease-modifying antirheumatic drugs (csDMARDs), including methotrexate, and who have not previously been treated with a biologic DMARD (bDMARD). This study has previously shown that bari improved signs and symptoms of RA (Dougados M et al, Ann Rheum Dis 2015;74(S2):79).

Methods:

In this multicenter, double-blind, double-dummy, outpatient study, patients aged ≥18 yrs with active RA were randomized in a 1:1:1 ratio to placebo (PBO) or bari (2 or 4 mg, once a day) for 24 weeks. PRO measures assessed with daily patient diaries through 12 weeks included duration and severity of morning joint stiffness (MJS), worst tiredness and worst joint pain. PROs assessed at study visits included the Health Assessment Questionnaire-Disability Index (HAQ-DI), Functional Assessment of Chronic Illness Therapy Fatigue (FACIT-F) scale, Short Form 36 (SF–36), European Quality of Life-5 Dimensions-5 Level (EQ-5D), Patient's Global Assessment of Disease Activity, and patient's assessment of pain. PRO data from treatment groups were compared at Week 12 for diary data and at Weeks 12 and 24 for study visits. Analyses were conducted on an intention-to-treat basis.

Results:

684 patients were randomized. **After 12 and 24 weeks of therapy, bari-treated patients achieved statistically significant improvements in most PROs compared with PBO (Tables). For PROs collected via daily patient diaries, bari-treated patients achieved statistically significant improvements at Week 12 in MJS duration, severity, tiredness, and joint pain.**

Conclusion:

In this phase 3 study of patients with RA with an inadequate response to csDMARDs, and not previously treated with a bDMARD, treatment with bari produced significant clinical improvements in disease activity. This analysis showed that treatment with bari also resulted in significant improvement in patient-reported outcomes across different domains including pain, functional disability and fatigue.

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: For patients with rheumatoid arthritis (RA), there are limited real-world data on factors that predict persistency on biologic therapy or whether use of biologics as monotherapy vs in combination with conventional synthetic disease-modifying antirheumatic drugs (csDMARDs) affects persistency. This analysis compared persistency of the interleukin-6 receptor α inhibitor tocilizumab (TCZ) initiated as combination therapy vs monotherapy and evaluated predictors of persistency in patients with RA.

Methods: Corrona is a US-based, prospective, observational cohort of nearly 40,000 patients with RA. Patients who newly initiated TCZ on or after October 1, 2008, within the Corrona registry and who had ≥ 1 follow-up visit were included in this analysis. Persistency was defined as time to the switch to a new biologic, regardless of possible gaps between TCZ discontinuation and switch to a new biologic. Kaplan-Meier analyses estimated the persistency for all eligible TCZ initiations and by combination therapy vs monotherapy. Multivariable Cox proportional hazards models evaluated associations of type of therapy (combination therapy vs monotherapy) and other baseline factors with persistency of treatment.

Results: Of the 1001 initiations of TCZ included in this analysis, 80.7% of patients were female, median (IQR) age was 58 (49-66) years and median (IQR) duration of RA was 9 (5-17) years. At the time of TCZ initiation, 33.0% initiated TCZ as monotherapy, 52.6% had high disease activity (Clinical Disease Activity Index > 22) and 90.8% had received prior tumor necrosis factor inhibitors (TNFis). The overall median (95% CI) time to switch from TCZ to a new biologic was 33.5 (28.0-41.0) months (**Table**). In patients who initiated TCZ as monotherapy, the median (95% CI) time to switch was comparable with those who initiated TCZ in combination with csDMARDs (36.4 [29.6-not estimable] months vs 28.0 [22.4-40.0] months, respectively; $P = 0.162$). Compared with initiation of TCZ as monotherapy, initiation of TCZ as combination therapy was not associated with an increased likelihood of switching from TCZ to a new biologic (adjusted hazard ratio [HR; 95% CI], 0.81 [0.64-1.04]; $P = 0.100$). Previous and current smokers were significantly more likely to switch to a new biologic (HR [95% CI], 1.32 [1.02-1.73] and 1.50 [1.10-2.06]; $P = 0.040$ and 0.010, respectively), while prior use of 1 TNFi was significantly associated with a 47% decreased likelihood of switching compared with TNFi-naive patients (HR [95% CI], 0.53 [0.34-0.81]; $P = 0.003$).

Conclusion: In this real-world setting of patients with RA, persistency on TCZ was similar when initiated as monotherapy or as combination therapy. Among TCZ initiators, prior use of 1 TNFi was associated with a decreased likelihood of switching to another biologic compared with those with no prior TNFi exposure, whereas smoking was associated with an increased likelihood of switching to another biologic.

Table. Median Time to End of Persistency by Type of Therapy in Patients Initiating TCZ

	N	Persistency of TCZ, Median (95% CI), Months[a]	*P*-value[b]
Overall persistency	1001	33.5 (28.0-41.0)	
Persistency by type of therapy at initiation			
Monotherapy	220	36.4 (29.6-NE[c])	0.162
Combination with csDMARDs	671	28.0 (22.4-40.0)	
Persistency within TCZ combination therapy groups			
TCZ + MTX alone	413	36.4 (29.0-NE[c])	0.757
TCZ + other csDMARDs	72	NE[c] (22.7-NE[c])	
TCZ + other csDMARDs (excluding MTX)	186	33.4 (26.0-NE[c])	
Persistency by number of csDMARDs[d]			
TCZ + 1 csDMARD	568	35.0 (29.0-NE[c])	0.595

csDMARD, conventional synthetic disease-modifying antirheumatic drug; MTX, methotrexate; NE, not estimable; TCZ, tocilizumab.
[a] End of persistency was the *switch* to a new biologic regardless of possible gaps between TCZ discontinuation and switch to a new biologic.
[b] *P*-value from log-rank statistic comparing Kaplan-Meier estimates of median time to discontinuation for combination therapy vs monotherapy and for combination therapy subgroups.
[c] Median or upper CI values NE due to censoring.
[d] The median (95% CI) persistency of TCZ + ≥ 2 csDMARDs (n = 103) was NE.

The Effect of Adrenocorticotropin Gel (HP Acthar Gel) in Combination with MTX in Newly Diagnosed RA Patients from a Clinical and Structural Perspective

Norman B. Gaylis[1], Steven Needell[2] and Joanne Sagliani[1], [1]Arthritis & Rheumatic Disease Specialties, Aventura, FL, [2]Boca Radiology Group, Boca Raton, FL

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Although adrenocorticotropin (ACTH) gel was approved by the FDA for the treatment of RA in 1952, data on its clinical and structural benefits for the treatment of RA are limited. Emerging evidence related to the melanocortin system suggests that mechanisms of ACTH gel, in addition to steroidogenesis, may produce anti-inflammatory and immunomodulatory effects,[1] which can have a significant impact in the management of inflammatory disorders such as RA. The objective of this study was to evaluate the effects of ACTH gel on the widely accepted clinical and structural endpoints in patients with early RA.

Methods: Fourteen patients with early RA, were enrolled in a 24-week, open-label study using 15 mg methotrexate (MTX) weekly and 80 U ACTH gel weekly or biweekly. Each subject had a minimum of 6 tender and swollen joints, a Clinical Disease Activity Index (CDAI) score of >6.0 (with a mean score of 39.3) and presence of at least 1 of the following: osteitis, synovitis, or erosions on MRI (Esaote 0.3T) upon enrollment.

Results: We report interim results on 7 patients dosed weekly and 7 patients dosed biweekly with 80 U ACTH gel. In the biweekly-dosed group, all patients showed a clinical response, with an average of 84% improvement in CDAI score after 6 months (Table 1). Two patients in this group achieved remission, 3 low disease activity, and 2 medium disease activity. In the weekly-dosed group, 5 of 7 patients showed a clinical response, with a group average of 61.1% improvement in CDAI score after 6 months (Table 1). One patient remained at high disease activity and 1 patient terminated early due to lack of efficacy. Taking into consideration both groups, 12 of 14 patients showed a clinical response beginning at 3 months (71.2% CDAI improvement), which persisted through 6 months of treatment (71.0% CDAI improvement).

Structural MRI findings varied between treatment groups. In the biweekly-dosed group, 5 patients showed regression in synovitis, while 2 patients showed regression in osteitis. In the weekly-dosed group, 3 patients showed regression in synovitis and 3 patients showed regression in osteitis. Overall, erosions were unchanged or regressed in 9 patients and progressed in 3 patients. No significant adverse events were reported.

Conclusion: The results of this interim analysis suggest a clinical and structural benefit with the use of ACTH gel in combination with MTX in early RA. It appears that the biweekly-dosed group obtained a more robust clinical and structural response; at 6 months this group showed an improved, sustained outcome. These data suggest that use of ACTH gel may result in a very effective treatment combination with MTX for early RA, possibly reducing the need for step-up biologic therapy over time. Further research is needed to determine if these results can be maintained on MTX therapy alone after discontinuation of ACTH gel.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Telomere is a component of chromosome, and protects end of chromosome from various stress. Telomere shortens during cell division, and telomerase maintains telomere length. It was reported that telomerase activity of lymphocytes is upregulated when the lymphocytes are activated.

Abatacept suppress the activation of T lymphocytes which are involved in pathogenesis of rheumatoid arthritis. Therefore we investigated effect of abatacept on telomerase activity of lymphocytes of patients with rheumatoid arthritis.

Methods:

This study included 16 patients who were diagnosed with rheumatoid arthritis based on ACR 2010 criteria and received treatment of abatacept from August 2012 to August 2013. We collected their clinical data and peripheral blood samples before starting abatacept, 4, 12, 24, and 52 weeks after the treatment. Then we extracted peripheral blood mononuclear cells using ficoll. And CD3 positive lymphocytes and CD19 positive lymphocytes were sorted by magnetic beads. Using these cells, we measured telomerase activity by Telomeric Repeat Amplification Protocol.

Results:

Mean age of patients was 59.2. Before using abatacept, patients were received various treatment including prednisolone, conventional disease-modifying anti-rheumatic drugs and biologic therapy. DAS28-CRP before treatment of abatacept was 3.43, and that after the treatment was 1.54.

Telomerase activity of CD3 positive lymphocytes declined from 0.413 to 0.156 ($p<0.05$) at 52 weeks after the treatment, and that of CD19 positive lymphocytes also declined from 0.755 to 0.187 ($p<0.05$). Telomerase activity of CD19 positive lymphocytes was significantly downregulated at 4 weeks after the treatment, although that of CD3 positive lymphocytes was not significantly downregulated. (figure)

Conclusion:

Treatment of rheumatoid arthritis including abatacept suppressed the activition of T lymphocytes and B lymphocytes. Telomerase activity of B lymphocytes was downregulated before that of T lymphocytes. It is suggested that abatacept directly suppress the activation of B lymphocytes.

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The options for treatment of rheumatoid arthritis (RA) with tumour necrosis factor (TNF) inhibitors is constantly growing. As a consequence monitoring of drug levels (DL) and Anti-Drug Antibodies (ADA) in clinical practice is advisable in order to complement clinical assessment and optimize patient treatment. However, a common objection that limits implementation of measurements in medical practice is the claim that assay standardization is lacking. The purpose of this study was to validate new assays to monitor golimumab (GLM) and antibodies to GLM (ATG), and evaluate the correlation and agreement between different commercially available technologies to monitor GLM therapy in patients with rheumatic diseases.

Methods: Trough levels of GLM and ATG were analysed in a retrospective cohort of 48 rheumatic patients (102 serum samples) initiating or under maintenance therapy with GLM for up to three years. Samples were assayed using Promonitor-GLM and Promonitor-Anti-GLM ELISA kits (Progenika, Spain), and in parallel with ELISA and radioimmunoassay (RIA) offered by Sanquin Blood Supply (Amsterdam, The Netherlands) to measure GLM levels and ATG, respectively. Promonitor tests were validated according to Clinical & Laboratory Standards Institute (CLSI) guidelines. Spearman and Mann-Whitney tests were used to study correlation and difference between the two DL tests; the difference (bias) in values obtained with both GLM assays was also assessed with Bland-Altman analysis. Percentage of positive and negative agreement was used to study the association between the ADA methods.

Results: Promonitor tests met performance criteria as recommended in the CLSI guidelines. Both types of ELISA for GLM determination showed a statistically significant relationship (Spearman´s r=0.98, $p<0.0001$). There was no significant difference between the two assays (median 575 vs 600 ng/mL, IQR 0 - 1614 vs 0 - 1600 ng/mL; t-test $p=0.907$ for Promonitor-GLM and Sanquin, respectively). Bland-Altman analysis showed a perfect agreement between both assays (bias -33.4 ng/mL 95% CI -92.3 to 25.3; $p>0.05$). Both tests gave identical results for ATG analysis (positive and negative percentage agreement of 100%). Antibodies were detected in 3 samples (3 patients, 6%) regardless of the test used. ELISA sensitivity proved to be equal to RIA for the detection of ATG

in this cohort.

Conclusion: Validation according to CLSI guidelines proved adequate Promonitor ELISA performance for an in vitro diagnostic setting. Despite different reagents and technologies, no significant differences in GLM and ATG levels were observed between assays, suggesting that future development of optimal ranges values is viable and not influenced by the type of assay, and therefore both methods should result in similar correlations with clinical outcomes and comparable therapeutic actions.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: It has been postulated that patients with longstanding RA have more treatment-resistant disease. We propose to examine whether disease duration is an independent predictor of treatment response among patients with RA initiating abatacept in a US national observational cohort. **Methods:** Using the Corrona RA registry, we identified new initiators of abatacept between February 2006 and January 2014, with a follow-up visit at 1 year (±3 months), and assessment of disease activity using CDAI at both the time of initiation and the 1-year follow-up, stratified by disease duration (0–2, 3–5, 6–10, >10 years). The primary outcome was mean Δ in CDAI, with a secondary outcome as achievement of low disease activity (LDA; CDAI ≤10) among those who initiated abatacept in moderate or high disease activity, or achievement of remission (CDAI ≤2.8) in those who initiated abatacept in low, moderate or high disease activity. For patients who switched agents before 1 year, the last observation before the switch was used to calculate mean Δ in CDAI. Switchers were imputed as non-responders for calculation of LDA and remission. **Results:** We identified 1746 abatacept initiators who met inclusion criteria (disease duration 0–2 years: 243; 3–5 years: 313; 6–10 years: 431; >10 years: 759). Patients with longer disease duration were more likely to be older, not working (including disabled and retired), more impaired (based on modified Health Assessment Questionnaire), and with a greater number of prior biologics used (Table 1). Unadjusted mean Δ in CDAI at 1 year ranged from –9.8 in those with 0–2 years' disease duration to –5.9 in those with >10 years ($p<0.001$; Table 2). Unadjusted rates of LDA occurred in 44.7% of those with 0–2 years' disease duration but diminished to 30.1% of those with >10 years ($p=0.002$). Similarly, unadjusted rates of remission were observed in 20.8% of those with 0–2 years' disease duration but diminished to 11.7% of those with >10 yrs ($p=0.005$). These differences were attenuated in multivariable models and lost significance. The proportion of patients remaining on abatacept at 1 year among those with 0–2 years' disease duration was 70% compared with 63.9% of those with >10 years' disease duration ($p=0.07$). **Conclusion:** Treatment with abatacept was associated with significantly greater improvement in those with shorter disease duration in unadjusted analyses. This significance was lost in adjusted models, but the trend remained. Further exploration is needed to assess whether earlier treatment with abatacept is independently associated with better outcomes.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is associated with work disability and lower employment rates (evidence shows 20–30% of pts are work disabled in the first 3 yrs and up to 40–50% in the first 10 yrs of RA). Improvements in workplace/household productivity with certolizumab pegol (CZP)+MTX have been reported in established RA.[1] Here we estimate the RA burden on work disability in DMARD-naïve early RA vs established RA and assess the CZP+MTX effect on workplace/household productivity in DMARD-naïve early RA pts over 52 wks.

Methods: C-EARLY (NCT01519791) is a phase 3 study assessing efficacy and safety of CZP in DMARD-naïve pts with severe, active and progressive RA (≤1 yr since diagnosis) and poor prognostic factors.[2] RAPID1 (NCT00152386) and RAPID2 (NCT00160602) reported efficacy and safety of CZP in pts with active RA of ≥6 months' duration on MTX for ≥6 months prior to baseline (BL).[1] The burden of early/established RA on workplace and household productivity was assessed at study BL in C-EARLY (full analysis set [FAS]) and pooled RAPID1/2 studies (intent-to-treat [ITT] population), using the validated arthritis specific Work Productivity Survey (WPS).[3] WPS responses (LOCF imputation) in C-EARLY were compared between groups using a non-parametric bootstrap-t method.

Results: At BL, mean age, disease activity and functioning were similar between early and established RA pts (early/established RA: age 50.6/52 yrs; DAS28(ESR) 6.7/6.9; HAQ-DI 1.6/1.6) with differences in mean disease duration since diagnosis (early/established RA: 2.9 months/6.1 yrs) and mean prior synthetic DMARD use (early/established RA: 0/1.3). More early RA pts were employed vs established RA; (52.2% vs 40.9%); more established RA pts were RA work disabled vs early RA (22.3% vs 10.5%) (Table A). High RA burden was reported at BL in both early and established RA pts with >2 wks of paid work (mean 13.3 vs 11.4 days), >2 wks of household duties (mean 18.9 vs 18.1 days), and mean 5.2 vs 5.6 days of social activities affected over previous month, respectively (Table A). At Wk52 in DMARD-naïve pts, greater improvements were reported in CZP+MTX arm vs PBO+MTX in household productivity, and in absenteeism and presenteeism (employed pts only) (Table B).

Conclusion: DMARD-naïve pts with early severe RA and poor prognostic factors have a similar high burden on workplace and household productivity to that reported in established RA, which could lead to large financial burden for pts and society. CZP+MTX showed greater improvements at 1 yr in workplace and household productivity in DMARD-naïve pts with severe, active, progressive RA (≤1 yr since diagnosis), which could reduce the economic burden of this disease.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor for the treatment of RA. Patients (pts) with RA often have comorbidities that may affect treatment response. This post-hoc analysis evaluated whether predefined clinical phenotypes influenced treatment response, as assessed by different efficacy and safety outcomes.

Methods: Data from Phase 3 randomized studies of tofacitinib 5 mg BID in RA as monotherapy (ORAL Solo [NCT00814307], ORAL Start [NCT01039688]) or with background conventional synthetic DMARDs (csDMARDS; mainly methotrexate [MTX]) (ORAL Scan [NCT00847613], ORAL Sync [NCT00856544], ORAL Standard [NCT00853385]) were included. Pts in ORAL Start were MTX-naïve while pts in other studies had an inadequate response to biologic or csDMARDs, mostly MTX. Efficacy and safety of tofacitinib was evaluated in subgroups of monotherapy and combination therapy populations with different high-risk comorbidities: diabetes (history of diabetes and/or treatment with anti-diabetic medication at baseline [BL]); obesity (BMI $\geq$30 kg/m^2) and hypertension (history of hypertension and/or treatment with antihypertensive medication at BL); or obesity and dyslipidemia (total cholesterol >2g/L and/or treatment with lipid-lowering medication at BL). Efficacy outcomes at Month 3 included the proportion of pts achieving low disease activity (DAS28-4(CRP) $\leq$3.2); ACR50 response; and mean change from BL in Health Assessment Questionnaire-Disability Index (HAQ-DI) score. Safety outcomes included incidences of serious adverse events (SAEs) up to Month 3, discontinuations due to AEs, and serious infections (SIEs).

Results: In total, 616 pts received tofacitinib 5 mg BID monotherapy (243 from ORAL Solo and 373 from ORAL Start) and 840 pts received tofacitinib 5 mg BID with background csDMARDs. Efficacy and safety outcomes by pt subgroups are presented in the Table. Tofacitinib 5 mg BID was similarly efficacious across different high-risk clinical phenotypes.

Incidence rates for discontinuations due to AEs were numerically higher for the csDMARD group than the monotherapy group.

Efficacy and safety outcomes in these subpopulations were within the ranges of the overall populations for the respective Phase 3 studies.

Conclusion: These findings suggest that tofacitinib 5 mg BID, when administered as monotherapy or combination therapy, has a consistent efficacy and safety profile up to Month 3 in RA pts with different high-risk clinical phenotypes, such as diabetes. Although these pts are at high risk of further AEs, they appear to experience a short-term safety profile with tofacitinib similar to the overall clinical program population. Limitations include the relatively few pts in each clinical phenotype subgroup, and that the monotherapy group included MTX-naïve pts, whereas the csDMARD group included DMARD inadequate responders only.

A Comparison of EQ5D Index from the UK, US, and Japan Preference Weights Model, and Mapping Algorithm from Clinical Outcomes in Patients with Rheumatoid Arthritis: Results from Golimumab Intravenous Study

Chenglong Han[1], Clifton O. Bingham III[2], Rene Westhovens[3], Michael Weinblatt[4], Lilianne Kim[5], Daniel Baker[5], Steven Peterson[6] and Elizabeth C. Hsia[5,7], [1]Outcomes Research, Janssen Global Services, LLC, Malvern, PA, [2]Johns Hopkins University, Baltimore, MD, [3]Rheumatology, UZ Gasthuisburg, Leuven, Belgium, [4]Brigham & Women's Hospital, Boston, MA, [5]Janssen Research & Development, LLC, Spring House, PA, [6]Janssen Global Services, LLC, Malvern, PA, [7]University of Pennsylvania, Philadelphia, PA

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: To compare the EQ5D index from the UK, US, and Japan preference weights models in patients with rheumatoid arthritis (RA), and to examine the relationship of each index with clinical outcomes for developing mapping algorithm.

Methods: GO-FURTHER was a multicenter, randomized, placebo-controlled study. Adult patients with active RA were randomized to PBO + MTX (PBO group) or GLM (2mg/kg) plus MTX at wk 0, 2, and every 8 wk thereafter (GLM group). Patients in PBO group with <10% improvement in tender and swollen joint count from baseline at wk 16 entered early escape (EE) and received a 2 mg/kg GLM infusion at wks 16 and 20. Clinical and patient-reported outcomes measures including EQ5D domains, EQ VAS scale, Health Assessment Questionnaire (HAQ) were collected. The EQ-5D index was calculated using preference weights from the US (D1) [1], UK (N3)[2], and Japanese [3]population weights. Pearson's correlation and linear regression model were used to test correlation and established mapping algorithms. Comparisons between groups in EQ5D index were performed using t-test.

Results: The study population had moderate to severe RA with a HAQ score of 1.6 and DAS28 score of 5.9 at the baseline. The UK model predicted a lower EQ5D index (0.36 ±0.33), compared to the US model (0.54 ±0.21) and Japan model (0.52 ±0.13).The differences in EQ5D index between UK and US or Japan model were moderate in patients with mild to moderate disability (HAQ-DI<1) (0.64 vs. 0.72 and 0.64), but were more than twofold in patients with severe disability (HAQ-DI>1.5) (0.19 vs.0.42 and 0.45). The Pearson's correlations coefficient of EQ5D index from the US model with HAQ, DAS28 score, pain, SF-36 PCS and MCS was -0.70, -0.40, -0.51, -0.57, -0.55, respectively (all p value <0.001), and were highly consistent across 3 models and sensitive to change. Comparing mapping algorithms based on linear regression models, HAQ model was equally predictive to each EQ5D index. However, the UK N3 model was more responsive to active treatment compared to US D1 or Japan model. Compared to PBO+MTX group, the change in EQ5D index in GLM+MTX group at wk24 were 0.26±0.32 vs. 0.11±0.37 in UK model (p<0.001), 0.17±0.21 vs. 0.11±0.23 in US model (p<0.01), and 0.13±0.16 vs. 0.05±0.17 in Japan model (p<0.001).

Conclusion: Although HAQ was highly predictive to EQ5D index derived from US, UK or Japan model, the EQ5D scores from each model were not equivalent, and were significantly influenced by disease severity, warranting caution in the cost-utility analysis across trials.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: The long term sustainability of ETN as monotherapy (mono) or in combination (combo) with methotrexate (MTX) is uncertain in patients with longstanding RA responding to ETN after MTX failure.

Objectives: The purpose of this study was to evaluate the long term sustainability of ETN for efficacy in ETN responsive patients after MTX failure when initiated as mono or combo therapy.

Methods: A retrospective cohort based on a chart review of 140 pts from a single rheumatology center who initiated ETN as their first biologic was carried out. Only data from 104 (74.3%) pts who had achieved DAS 28 low disease or remission by 18 months (mo.) were considered for analysis in order to more stringently define secondary ETN efficacy failures in the survival analysis. Pts discontinuing ETN before 18 mo or for adverse effects at any time were excluded from the long term survival analysis. Three groups of pts were included in the long term survival analysis: (i) pts initiating combo ETN plus MTX, (ii) patients initiating ETN mono because of prior intolerance to MTX, (iii) patients initiating ETN mono after withdraw of MTX from the ETN/ MTX combo.

Results: Of the 140 total ETN treated pts, 36(25.7%) discontinued ETN for efficacy before 18 mo: 11 (7.9%) before 6 mo, 17 (12.1%) between 6-12 mo and 8 (5.7%) between 12-18 mo. In the 104 pts achieving low disease or remission for 18 mo, 93(82%) were women, mean (SD) age 52.4(12.6) with a disease duration of 22.4(9.7) years of which 71(77.2%) were seropositive. Baseline disease activity (at ETN initiation) of the 46 pts initiating ETN mono revealed a tender joint count (tjc) of 4.9(7.0) a swollen joint count (sjc) of 7.5(5.9), an ESR of 29.5(21.3) and DAS28 score of 4.3(1.4). Of 35 patients adding ETN to the MTX combo, the baseline (at MTX initiation) tjc was 4.9(5.1), sjc 9.1(5.9), ESR 40.4(31.1) and DAS28 score of 4.8(0.9). A separate population of 23 pts receiving combo therapy withdrew MTX (mean (SD) time from withdrawl was 21.8 (19.3) mo with a median of 16 mo). The baseline (at MTX initiation) tjc was 2.52(3.8), sjc 9.1(4.5), ESR 25.6(14.3) and DAS28 score of 3.8 (1.1) The results of the survival analysis of the 104 pts (figure 1) revealed comparable survival of the all 3 groups at 10 years (log rank 0.8582). Survival of ETN after MTX withdrawl appeared greater than the other groups but its survival analysis was initiated 18 months after MTX withdrawl.

Conclusion: In this preliminary analysis of extremely long standing RA pts, ETN responders who achieve low disease or remission by18 months have a high likelihood of ETN sustainability whether initiating ETN as mono or combo therapy or withdrawing MTX from the combo. Larger pt populations need to be studied for confirmation of the results.

Image:

Survival curves in RA pts achieving low disease or remission after 18 months for biologic naïve patients initiating ETN mono therapy or adding ETN in combination with MTX, or initiating ETN mono after discontinuing MTX from combo therapy.

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Sustained clinical remission is crucial in the RA. However, baseline predicting factors for sustained clinical remission in RA patients treated with abatacept (ABT) are little known.The ABROAD (ABbatacept Research Outcomes as a first-line biological Agent in the real worlD) study is the prospective multicenter observational cohort study, in which 43 institutions in the west side of Japan participate to investigate both efficacy and safety of ABT in biologic-naïve RA patients. The purpose of the present study was to

determine the useful markers associated with sustained clinical remission by the intravenous ABT infusion treatment in different age groups (age ≥ 65 vs < 65 years old).

Methods:

Two-hundred and seventy-seven RA patients with high or moderate disease activity (female = 84.8%, mean age at the ABT initiation = 63.2 years old, disease duration = 7.9 years) were enrolled. DAS28-CRP remission rate at 24, 36, and 48 weeks after the initiation of ABT treatment were examined. Then, patient profiles, disease activity, concomitant drug use, and laboratory findings at baseline associated with sustained clinical remission (>12 weeks) during the last 24 weeks in the whole treatment period (48 weeks) were determined by logistic regression analysis.

Results:

The proportion of patients, who achieved DAS28-CRP-defined clinical remission at 24 and 48 weeks, were 35.1% and 36.5% in elderly patients (≥ 65 years old) and 34.9% and 43.4% in younger patients (< 65 years old), respectively. In elderly patients, ACPA positivity (Odds ratio [OR] = 5.378, 95% confidence interval [CI] = 1.225-38.512, p = 0.0241) was significantly associated with sustained clinical remission. In elderly patients without ACPA, a significant change in DAS28-CRP was observed only 4 weeks from baseline. However, the DAS28-CRP improved persistently until 24 weeks in the elderly patients having ACPA. On the other hand, in younger patients, concomitant MTX use (OR = 4.981, 95% CI = 1.426-23.621, p = 0.0103) was the predictive factors for sustained clinical remission. Significant improvement in the DAS28-CRP score was observed from the baseline to 12 weeks in younger patients without MTX use, while in younger patients who did use MTX, improvement was noted from the baseline to 24 weeks. Mean DAS28-CRP values were similar throughout the entire study period regardless of the presence or absence of ACPA in the younger patients group, and any concomitant MTX use in elderly patients.

Conclusion:

The efficacy of ABT in biologic-naïve RA patients was equivalent between elderly and younger patient groups, while the baseline clinical characteristics in association with clinical remission were totally different. ACPA positivity in elderly and concomitant MTX use in younger patients may be the useful predicting factors for achieving sustained clinical remission with ABT. We recommend treatment with ABT particularly for biologic-naïve RA patients who are elderly and have ACPA, and also for those who are younger and have received MTX.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor for the treatment of RA. In a Phase 3 study (ORAL Start; NCT01039688), tofacitinib monotherapy in MTX-naïve patients demonstrated significant, durable, and clinically meaningful improvements in RA signs and symptoms and physical functioning, and inhibition of progression of structural damage, vs MTX over 24 months.[1] Here, we present a post-hoc analysis of ORAL Start to assess the efficacy and safety of tofacitinib monotherapy in patients

with early RA or established RA as defined by disease duration. Interim data have previously been presented.[2] **Methods:** Patients were randomized 2:2:1 to tofacitinib 5 mg twice daily (BID), tofacitinib 10 mg BID, or MTX (mean MTX dose at end of titration [Month 3], 18.5 mg/week). Clinical efficacy was assessed in cohorts of patients with disease duration at baseline <1 (early RA) and ≥1 year (established RA), using ACR20/50/70, Disease Activity Score (DAS)28-4(ESR)<2.6 (DAS28-4[ESR]-remission) and ≤3.2 (low disease activity), and HAQ-Disability Index (HAQ-DI). Safety assessments included recording the incidence and severity of all adverse events (AEs). **Results:** Although not pre-defined in the original study, a total of 515 patients had early RA (N=201, N=207, and N=107 for tofacitinib 5 mg BID, tofacitinib 10 mg BID, and MTX, respectively) and 441 patients had established RA (N=172, N=190, and N=79 for tofacitinib 5 mg BID, tofacitinib 10 mg BID, and MTX, respectively). For all efficacy parameters at Month 12 and Month 24 within each cohort, response rates and improvements from baseline were significantly greater ($p<0.05$) for both tofacitinib doses vs MTX, except for patients with established RA treated with tofacitinib 5 mg BID (ACR20, ACR50, and ACR70 at Month 12; change from baseline in HAQ-DI, DAS28-4(ESR)≤3.2, and DAS28-4(ESR)<2.6 at both Month 12 and Month 24) and tofacitinib 10 mg BID (DAS28-4(ESR)<2.6 at Month 12). Numerically more tofacitinib-treated patients with early RA achieved ACR20/ACR50/ACR70 responses, DAS-defined remission and low disease activity and numerically greater changes from baseline in HAQ-DI at both Month 12 and Month 24 compared with patients with established RA (Table 1). Odds ratios for early RA vs established RA were greater than 1 for all efficacy parameters from Month 1 through Month 24. In general, there was no difference in AEs or discontinuations due to AEs when patients were sub-grouped by baseline disease duration. **Conclusion:** Tofacitinib monotherapy significantly improved signs and symptoms and physical function vs MTX in MTX-naïve patients with early (<1 year) and established (≥1 year) disease. There were generally greater numerical improvements observed in patients with shorter disease duration. AEs and discontinuations due to AEs were similar between groups. **References:** 1. SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor for the treatment of RA. This post-hoc pooled analysis was designed to assess the efficacy and safety of tofacitinib, as monotherapy or combination therapy with nonbiologic DMARDs, in Latin American (LA) patients with an inadequate response to prior DMARDs.

Methods: Phase 3 data were pooled from LA patients receiving tofacitinib 5 or 10 mg BID or placebo as monotherapy (ORAL Solo [NCT00814307]) or combination therapy (ORAL Scan [NCT00847613], ORAL Sync [NCT00856544] and ORAL Standard [NCT00853385]). Patients included in the analysis were from Brazil, Dominican Republic, Colombia, Mexico, Chile, Peru, Argentina, Venezuela and Costa Rica. Efficacy outcomes assessed at 3 months were ACR20, 50 and 70 responses, and the health assessment questionnaire – disability index (HAQ-DI). Adverse events (AE) and clinical laboratory parameters were also assessed.

Results: 451 patients were included in the pooled analysis with a mean age (range) of 49.2 (18-75) years in the combination therapy arm and 50.4 (22-77) years for monotherapy. Tofacitinib 5 and 10 mg BID as monotherapy or combination therapy had higher ACR20, 50 and 70 response rates than placebo, with similar response rates between monotherapy and combination therapy for both doses of tofacitinib (Table). Mean change from baseline in HAQ-DI score was similar for monotherapy and combination therapy with either dose. Adverse events occurred more frequently with tofacitinib 5 and 10 mg BID compared with placebo, and numerically more events with combination therapy were noted compared with monotherapy in some parameters (Table). Seventeen tofacitinib treated patients withdrew due to adverse events (monotherapy, 4; combination, 13), and four patients withdrew due to infection (monotherapy, 1; combination, 3). Patients receiving combination therapy were more likely to develop elevations in liver enzymes. No patients developed severe neutropenia or lymphopenia, with either monotherapy or combination therapy.

Conclusion: In this short-term post-hoc analysis of pooled, Phase 3 data from LA patients with RA, tofacitinib demonstrated similar efficacy as monotherapy or combination therapy and patients on tofacitinib monotherapy appeared to have fewer discontinuations due to adverse events and fewer elevations in liver enzymes compared with combination therapy over Months 0-3. These data are consistent with data from the global population of tofacitinib-treated patients.[1]

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose*:* Management guidelines recommend patients (pts) with RA should be treated with the intent of reaching a clinical target of low disease activity or remission at 6 months. To compare long-term efficacy outcomes for MTX-naïve RA pts in the GO-BEFORE trial grouped by their treatment target status at week 24 using DAS28-CRP score (<2.6, 2.6 to ≤ 3.2, >3.2) and SDAI

(≤3.3, >3.3 to ≤11, >11).

Methods: In GO-BEFORE, 637 MTX-naïve pts with active RA were randomized to placebo (PBO)+MTX, golimumab (GLM)100mg +PBO, GLM 50mg+MTX, or GLM 100mg+MTX. Most PBO+MTX pts crossed over to GLM 50mg+MTX at wk52. In this analysis, pts were grouped by their treatment target status at wk24 using DAS28-CRP score (<2.6, 2.6 to ≤ 3.2, >3.2) and SDAI (≤3.3, >3.3 to ≤11, >11). Efficacy outcomes at 5 years (wk256) were evaluated for these mutually exclusive groups using observed data.

Results: At wk24, 150 pts had DAS28-CRP <2.6, 85 had DAS28-CRP 2.6 to ≤3.2, and 368 had DAS28-CRP >3.2. Of these, 23%, 31%, and 31%, respectively, discontinued treatment before wk256; 3%, 2%, and 3%, respectively, were due to lack of efficacy. Greater proportions of patients treated with GLM+MTX than patients treated with PBO+MTX improved from having DAS28-CRP >3.2 at wk24 to DAS28-CRP <2.6 at wk 52. Among pts achieving treatment targets at wk24, the majority either maintained a DAS28-CRP <2.6 (80%) or improved to DAS28-CRP< 2.6 (72%) at week 256. Over 50% of pts with DAS28-CRP >3.2 at wk24 achieved treatment targets at wk256. Pts with DAS28-CRP≤3.2 at wk 24 had less progression in vdH-S scores and lower HAQ, SJC, TJC, pain, and pt/physician global assessment of disease (GAD) scores at wk 256 vs. patients with DAS28-CRP >3.2 at wk 24 (Table). Also, pts with DAS28-CRP 2.6 to ≤3.2 at wk24 had higher TJC (but not SJC), pain, and pt/physician GAD scores at wk256 than pts with DAS28-CRP <2.6 at wk 24. HAQ and change in vdH-S at wk256 were not significantly different between pts who achieved either DAS28-CRP <2.6 or DAS28-CRP 2.6 to ≤3.2 at wk 24. Of note, CRP levels at wk256 were similar among the three groups. Similar results were observed using SDAI scores (Table).

Conclusion: In GO-BEFORE, the majority of patients who achieved DAS28-CRP or SDAI score treatment targets at wk24 maintained or had improvement in clinical response at 5 years. At wk 256, efficacy outcomes, including clinical, functional, and radiographic scores, but not CRP level, at wk256 were significantly better among pts who had achieved DAS28-CRP <2.6 at wk24 vs pts with DAS28-CRP >3.2 at wk24. More subjective outcomes (TJC, pain, and pt/physician GAD) were also better at wk 256 for pts with DAS28-CRP <2.6 at wk 24 vs pts with DAS28-CRP 2.6 to ≤3.2 at wk24.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Clinical trials of anti-TNF therapies have shown that concurrent methotrexate (MTX) therapy enhances the efficacy of TNF inhibitors. A scarcity of data exists on the benefits of combination therapy with IFX and MTX vs. leflunomide (LEF) in a real-world setting; therefore the BioTRAC Registry database was used to explore this question.

Methods: BioTRAC is an ongoing, prospective registry of patients initiating treatment for RA, AS, or PsA with IFX or golimumab as first biologics or after having been treated with a biologic for <6 months. RA patients treated with IFX who were enrolled between 2002-2014 were included in this analysis. Treatment durability was assessed with the Kaplan Meier (KM) estimator of the survival function and Cox regression.

Results: 723 RA patients were included; at baseline 516 (71.4%) were on IFX+MTX, 115 (15.9%) on IFX+LEF, and 92 (12.7%) on IFX+MTX+LEF. The mean (SD) age was 55.5 (13.6) years, 76.2% were female and mean (SD) disease duration was 8.7 (9.2) years. The majority of patients were from Ontario (50.6%), followed by Western Canada (25.8%), and Quebec (20.9%). There were 217 (30.0%) patients who discontinued due to lack/loss of response, disease progression, adverse event (AE) or change in therapy with a KM-based mean (SE) time to discontinuation of 83.9 (3.0) months. Upon adjusting for potential confounders, higher durability was observed for the IFX+MTX group vs. IFX+LEF [hazard ratio -HR- (95% CI): 0.50 (0.25-1.01), P=0.055]. Moreover, factors independently associated with premature treatment termination were earlier enrolment period [HR2006-09 vs. 2002-05 (95% CI): 0.15 (0.02-1.15, P=0.068; HR2010-2014 vs. 2002-05 (95% CI): 0.09 (0.01-0.70), P=0.021], shorter baseline disease duration [HR (95% CI): 0.97 (0.93-1.00), P=0.054], and increased baseline pain levels [HR (95% CI): 1.14 (1.03-1.26), P=0.013]. 2,016 AEs were reported by 343 patients (106.8 events/100 patient-years) and 156 SAEs by 96 patients (8.3 events/100 patient-years). The incidence density ratio (IDR) (95% CI) was higher in the groups IFX+MTX vs. IFX+LEF for both AEs and SAEs with 1.44 (1.25-1.67) and 1.60 (0.94-2.73), respectively, however the latter was not statistically significant. When examining the triple combination therapy (IFX+MTX+LEF), higher durability was observed compared to both IFX+MTX [HR (95% CI): 3.68 (1.14-11.92); P=0.030] and IFX+LEF [HR (95% CI): 6.34 (1.72-23.34); P=0.006].

Conclusion: The results of this real-world observational study have shown that combination therapy with IFX+MTX is associated with significantly higher treatment durability compared to IFX+LEF in RA patients with increased risk for AEs but not for SAEs.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: In November 2012, the first oral Janus kinase (JAK) inhibitor tofacitinib was approved in the US for the treatment of RA with or without methotrexate. Given its recent introduction to the market, limited real world data are available in patient (pts) with RA receiving tofacitinib vs. TNFi. Here, we compare characteristics of pts with RA initiating tofacitinib vs. adalimumab (ADA) and etanercept (ETN) in a US administrative claims database and describe the feasibility of matching treatment cohorts to yield comparable pts for an outcomes evaluation.

Methods: This was a retrospective cohort study of pts aged ≥18 years at index with an RA diagnosis (ICD9: 714.0x-714.4x and 714.81) newly initiating tofacitinib in the Optum Research Database (11/12-7/14). Pts starting TNFi were also selected. Pts were continuously enrolled for ≥12 months (mos) pre-index and ≥6 mos post-index (tofacitinib or TNFi start). Pts with index medication use in prior 12 mos were excluded. Initial propensity score matching (1:1) was conducted among biologic-naïve and biologic-experienced subgroups (using a variable-length [VL] baseline starting 12/06) based on demographics, 12-mo pre-index total RA-related costs and opioid use, and number of prior biologics in the VL baseline (for biologic-experienced subgroup).

Results: Prior to matching, 647 tofacitinib pts, 703 ADA pts, and 1864 ETN pts met the cohort selection criteria. Tofacitinib pts had significantly ($p<0.001$ all comparisons) higher 12-mo pre-index mean RA-related costs ($20,067 vs. $4,405 and $4,305) and opioid use (72% vs. 58% and 60%), VL baseline biologic experience (81% vs. 22% and 14%) and index monotherapy regimen use (55% vs. 41% and 41%). After matching (Table) among biologic-naïve pts, those initiating tofacitinib had significantly higher VL baseline RA-related out-of-pocket costs, more rheumatologist visits (vs. ADA), more Medicare Advantage pts (vs. ETN), and greater use of monotherapy (vs. ADA) and leflunomide. In matched biologic-experienced cohorts, 49% (ADA) – 53% (ETN) of pts had prior experience with the respective index treatment. Significantly more ADA and ETN pts had prior ETN and ADA use, respectively, while more tofacitinib pts had abatacept, certolizumab pegol (vs. ETN) and tocilizumab (vs. ETN) use.

Conclusion: Tofacitinib was more likely to be used as monotherapy and in biologic-experienced pts vs. ETN and ADA. Initial attempts to match treatment cohorts were not feasible given prior treatment history with respective TNFi comparators and channeling bias with tofacitinib.

Table. Summary of propensity score matched cohorts						
	Tofacitinib	ADA	*P-value*	tofacitinib	ETN	*P-value*

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The options for treatment of rheumatic diseases is constantly growing. Tocilizumab (TCZ) is an anti-interleukin 6 receptor monoclonal antibody indicated for the treatment of severe active and progressive rheumatoid arthritis (RA) and active systemic juvenile idiopathic arthritis (sJIA). Monitoring of drug levels (DL) and anti-drug antibodies (ADA) in clinical practice is highly advisable in order to establish normal therapeutic ranges, complement clinical assessment and optimize patient treatment. As a consequence several tests and technologies have been developed. However, a common objection that limits implementation of biological drug monitoring in medical practice is the claim that the magnitude of measurements varies among assays and that assay standardization is lacking. The purpose of this study was to evaluate the correlation and agreement between different commercially

available tests to measure TCZ and antibodies to TCZ (ATT) in patients with rheumatic diseases.

Methods: Trough levels of TCZ and ATT were analyzed in a retrospective cohort of 26 rheumatic patients (42 serum samples, 88% RA and 12% sJIA) under maintenance therapy with TCZ for up to two years. Samples were assayed using Promonitor-TCZ and Promonitor-ANTI-TCZ ELISA kits (PR, Progenika, Spain), LISA-TRACKER Duo Tocilizumab ELISA kit (LT, Theradiag, France), and by Sanquin Blood Supply testing service (SQ, Amsterdam, The Netherlands) that uses ELISA and RIA technologies to measure TCZ and ATT levels, respectively. One-way analysis of variance (ANOVA) and Spearman´s test was used to study correlation between the DL tests; the difference (bias) in values obtained with DL assays was also assessed with Bland-Altman analysis. Percentage of positive and negative agreement was used to study the association between the ADA assays.

Results: TCZ trough level in patients are much higher than other biological treatments like anti-TNF infliximab and adalimumab. ANOVA analysis showed that the differences in the median values among the three DL assays are not statistically different (median 4.4 vs 4.7 vs 5.4 µg/mL, IQR 0 – 8.7 µg/mL vs 0 – 7.8 µg/mL vs 0 – 9.4 µg/mL for Promonitor-TCZ, LISA-TRACKER and Sanquin ELISA tests, respectively, p=0.693). Spearman´s coefficient showed a very high correlation between the each pair of assays (r=0.951, 0.935 and 0.944 for PR vs LT, PR vs SQ and LT vs SQ, respectively, p<0.0001). Bland-Altman analysis shows an excellent association between each pair of DL assays with no significant difference in bias (-0.3, -0.5 and -0.2 µg/mL for PR vs LT, PR vs SQ and LT vs SQ, p>0.05). Antibodies to TCZ were not detected with any of the assays in the patient cohort confirming the low immunogenicity of TCZ.

Conclusion: Despite different reagents, assay formats and technologies, all tests studied here provide exactly the same results and measure the same magnitude of TCZ in rheumatic patients. Assays can be safely exchanged in a clinical setting even in the absence of a gold standard test, and should lead to similar drug therapeutic ranges and actions.

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

The CAnadian Methotrexate and Etanercept Outcome (CAMEO) study, an open-label trial in patients with active rheumatoid arthritis (RA), revealed that patients achieving low disease activity (LDA) after 6 months of etanercept (ETN) plus methotrexate (MTX) therapy had similar clinical outcomes at 12 months if they continued ETN+MTX, or switched to ETN alone, at month 6 (M6). Conversely, those who did not achieve LDA at M6 had a reduced response after switching to ETN monotherapy. This analysis assessed the different discontinuation rates between treatment arms in the CAMEO trial by examining study completion and ETN retention over 25 months, and the association between ETN discontinuation and disease activity.

Methods:

Anti-TNF naïve patients with active RA (≥ 3 swollen joints, disease activity score [DAS28] ≥ 3.2), despite MTX treatment (≥ 15 mg/week or 10 mg/week if intolerant) for > 12 weeks, were enrolled. After 6 months of ETN (50 mg/week subcutaneously) + MTX treatment, patients were randomized (1:1) to ETN+MTX or ETN alone for another 18 months. ETN retention was assessed by physician prescribing information at the end of study. Cox regression analysis determined associations of study completion and ETN retention

with DAS28 score at M6 (continuous variable; not dichotomized to LDA and moderate/high disease activity), reimbursement type, and demographics.

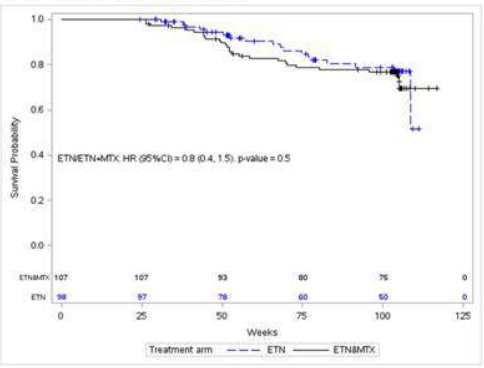
Results:

A total of 258 patients enrolled (76% female, mean age 54.7 ± 12.5 years, disease duration 8.9 ± 8.4 years, baseline DAS28 5.4 ± 1.1) and 205 (79%) were randomized at M6 (98 ETN, 107 ETN+MTX). Of the 205 patients randomized, 50 (51.0%) and 75 (70.1%) in the ETN and ETN+MTX groups completed the study, respectively, with the remainder discontinuing due to adverse events, lack of efficacy, or other reasons**.** Patients on ETN alone were twice as likely to discontinue the study as those on ETN+MTX (HR [95% CI] 2.0 [1.2, 3.1], p=0.004), and with increasing DAS28 score at M6, the chance of study discontinuation increased by 20% in both treatment arms (HR [95% CI] 1.2 [1.1, 1.5], p=0.005). Of the 205 patients randomized, 80 (81.6%) and 80 (74.8%) in the ETN and ETN+MTX groups, respectively, continued ETN at the end of the study but some randomized to ETN alone restarted MTX. ETN retention did not differ between treatment arms (HR [95% CI] 0.8 [0.4, 1.5], p=0.5), but higher DAS28 at M6, increased the chance of discontinuing ETN in both groups (HR [95% CI] 1.4 [1.1, 1.8], p=0.0017). Reimbursement and demographics were not associated with study and/or ETN discontinuation.

Conclusion:

Lower disease activity at M6 increased the chance of study completion and ongoing ETN treatment. Patients on ETN+MTX vs. ETN alone, and those achieving LDA at M6, regardless of treatment group, were more likely to complete the study. Both treatment arms had high ETN retention rates at the end of the study, with those reaching LDA at M6 being more likely to remain on ETN.

Time to ETN discontinuation:



Time to study discontinuation:

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with RA and longer disease duration generally do not respond as well to treatment with DMARDs as patients with shorter duration of disease. It has been reported that long-term disease control can be improved with earlier use of biologic DMARDs.[1,2] Patient-reported outcomes (PROs) that are of particular importance to those with RA were compared in patients with varying lengths of disease duration enrolled in the AGREE (Abatacept study to Gauge Remission and joint damage progression in MTX naïve patients with Early Erosive RA),[1] and the AVERT (Assessing Very Early Rheumatoid arthritis Treatment)[3] trials. Both studies evaluated the efficacy of abatacept + MTX versus MTX alone. **Methods:** In each study, PROs analyzed were fatigue (visual analog scale), HAQ-DI, activity limitation (Activity Participation Questionnaire [APaQ]), and physical and mental function (short form-36 health survey [SF-36]). This *post hoc* analysis included all randomized and treated patients (last observation carried forward). PROs were evaluated in patients with early RA and ≤3 months' disease duration compared with those with >3 months' disease duration after treatment with SC abatacept + MTX or MTX alone. The mean changes in PRO from baseline to Month 6 (Day 169) were calculated for each trial with adjustment based on analysis of covariance, with treatment as a factor and baseline value as a covariate. Combined weighted means were then calculated.

Results:

Irrespective of baseline disease duration, changes from baseline in PROs for fatigue, HAQ-DI response, activity limitation (APaQ), and SF-36 physical component summary (PCS) and mental component summary (MCS) scores for the AGREE and AVERT trial data were generally greater for patients treated with abatacept + MTX than MTX alone at 6 months (Table). Patients treated with abatacept + MTX with shorter disease duration (≤3 months) demonstrated reduced fatigue, improved physical function (HAQ-DI) and mental function (MCS) compared with those with longer disease duration (>3 months; Table).

Conclusion:

Although patients with RA of both short and longer disease duration benefited, those with shorter disease duration (≤3 months) generally reported improved PROs compared with those with longer duration (>3 months) following treatment with abatacept + MTX for 6 months. These results support the use of abatacept earlier in the course of RA.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: FPA008 is a humanized IgG4 anti-CSF1R antibody that blocks the binding of CSF1 and IL34 ligands to CSF1R, resulting in inhibition of the activation and survival of inflammatory macrophages and osteoclasts, thus providing a potential therapeutic benefit in RA. Data from healthy volunteers in this 3-part Phase 1 study were reported previously (***J Hambleton et al., ACR Annual Meeting 2014***). Here, we report preliminary results from Part 3 in RA pts.

Methods: Part 3 consists of open-label dose escalation and randomized portions. In the open-label portion, FPA008 is being evaluated at 1, 3, and 6 mg/kg IV every 14 days for 2 or 3 doses. Three to 9 RA pts without adequate response to biologic or nonbiologic disease modifying anti-rheumatic drugs (DMARDs) are treated in each dose cohort. All pts are required to be on stable dose methotrexate (MTX) during the study. ACR 20/50/70, EULAR responses as well as change in DAS 28 from baseline and MRI are assessed at wks 4 and 12. The randomized portion will be based upon the open-label results.

Results: As of May 13, 2015, 3 pts each were treated with FPA008 at 1 or 3 mg/kg for 2 doses. The median age was 59, ranging from 53 to 66 yrs old. Five were female and one was male. No pts had prior biologic DMARDs. Median MTX dose was 17.5 mg, ranging from 10 mg to 25 mg wkly with 3 pts requiring methylprednisolone 2 to 4 mg daily. All 3 pts receiving 1 mg/kg completed the study (through Study Day 141) and all 3 pts receiving 3 mg/kg completed the Study Day 85 visit. Reduction in CD14+CD16++ nonclassical monocytes were observed as expected. Reported treatment-related AEs were periorbital edema/eyelid edema in the 3 mg/kg cohort and all were self-limiting. Expected, reversible dose-dependent asymptomatic elevations of AST, ALT, LDH and CK were noted, but not associated with abnormalities in total bilirubin, troponin, aldolase or EKGs.

Preliminary efficacy data are reported below:

FPA008 Dose Cohort		**Day-1**	**Week 4**					**Week 12**				
Dose regimen	Subjects	DAS28CRP	ACR 20/50/70	ACR hybrid	EULAR	DAS28CRP	DAS28 change	ACR 20/50/70	ACR Hybrid	EULAR	DAS28CRP	DAS28 change
1 mg/kg x 2 doses	3101	3.44	0	-5.14%	no	3.74	-0.31	0	-6.00%	no	3.83	-0.39
	3102	4.35	0	11%	moderate	3.26	1.09	0	6.29%	moderate	3.22	1.13
	3103	7.06	ACR50	52.86%	moderate	3.87	3.19	ACR50	53.86%	moderate	5.22	1.83
3 mg/kg x 2 doses	3104	4.17	ACR 20	49.99%	good	2.94	1.23	0	19.99%	moderate	3.55	0.62
	3105	5.40	0	19.99%	good	2.28	3.12	0	8.57%	moderate	4.44	0.96
	3106	4.50	0	-1.43%	no	4.13	0.37	0	8.71%	moderate	3.73	0.77

Conclusion: FPA008 was well tolerated up to 3 mg/kg in RA pts with no new safety signals. Dose escalation is ongoing. Updated safety, PK/PD and preliminary efficacy from open-label dose escalation will be presented.

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: In Germany, treatment with Tocilizumab (TCZ) is primarily used in rheumatoid arthritis patients with previous failures of biologic DMARDs. Effectiveness and adherence of TCZ in patients with multiple bDMARD failures has rarely been investigated.

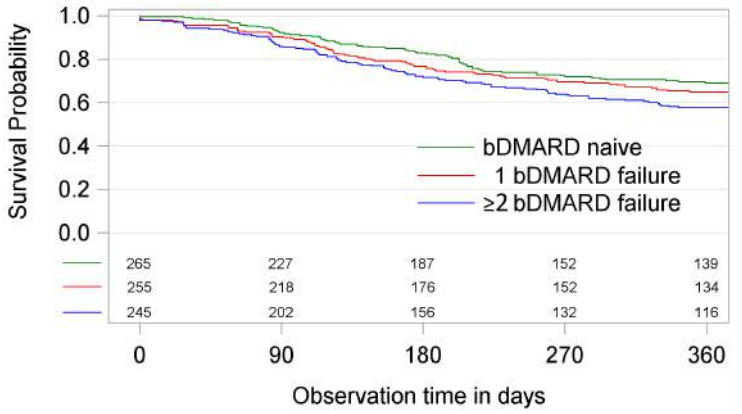
Methods: We included 765 RA patients enrolled between 2009 and 2015 in the German biologics register RABBIT (**R**heumatoid **a**rthritis: O**b**servation of **bi**ologic **t**herapy) starting with TCZ. Patients were stratified according to the number of bDMARD failures prior to the initiation of TCZ: biologic naive (n=265), 1 bDMARD failure (n=255) and ≥2 bDMARD failures (n=245). Therapy discontinuation within 12 month after the start of TCZ was investigated using Kaplan-Meier and Cox-proportional hazard regression. Discontinuation was defined as the stop of TCZ therapy. Effectiveness regarding control of disease activity (DAS28-ESR) after 3, 6 and 12 month were examined with linear mixed effects models.

Results: Compared to biologic naive patients those with prior bDMARD failures at start of TCZ were younger (1 failure: -1.6y (p=0.09); ≥2 failures: -2.8y (p=0.01)), had significantly longer disease duration (8.1 vs. 11.4 vs. 14.1 years; p<0.01) and more csDMARDs failures (p<0.01). Loss of physical function, pain and fatigue were significantly higher in patients with bDMARD failures (p<0.01). No differences were found regarding the initial composite score DAS28 (5.2 vs 5.3 vs 5.3), its components: TJC and SJC and the concomitant use of csDMARDs (p=0.3). During follow-up disease activity (DAS28) was significantly reduced in all treatment strata. At month 3, 6 and 12 differences between treatment strata were statistically not significant (Table).

Crude survival on TCZ therapy was significantly lower if patients had bDMARD failures, unadjusted hazard ratios (HR) compared to bDMARD-naive patients were 1.17 (p=0.34) and HR=1.50 (p<0.01) (Figure). Adverse events were the most frequent reason for discontinuation, particularly in patients with prior bDMARD failures.

Table: Means of DAS28 [95% confidence interval] at month 3, 6 and 12 after enrollment with TCZ. Estimates were adjusted for age, disease duration, physical function, comorbidities and concomitant use of csDMARDs (yes vs. no).

	DAS28 at month 3	DAS28 at month 6	DAS28 at month 12
bDMARD naive	3.02 [2.82; 3.22]	2.84 [2.63; 3.04]	2.88 [2.66; 3.10]
1 bDMARD failure	3.19 [3.01; 3.38]	3.04 [2.84; 3.24]	3.07 [2.87; 3.28]
≥2 bDMARD failure	3.37 [3.17; 3.56]	3.21 [3.00; 3.42]	3.06 [2.82; 3.29]



Conclusion: Treatment with TCZ is effective in patients with and without prior bDMARD failures, the majority of patients achieves low disease activity (DAS28<3.2) within 6 month and maintains controlled disease activity throughout month 12. However, the higher susceptibility of adverse events in patients with prior bDMARD failures needs further investigation.

Assessment of the Effect of CYP3A Inhibition, CYP Induction, OATP1B Inhibition and Administration of High-Fat Meal on the Pharmacokinetics of the Potent and Selective JAK1 Inhibitor ABT-494

Mohamed-Eslam Mohamed[1], Steven Jungerwirth[2], Armen Asatryan[1], Ping Jiang[2] and Ahmed Othman[1], [1]AbbVie, North Chicago, IL, [2]AbbVie Inc., North Chicago, IL

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

ABT 494 is an oral selective JAK1 inhibitor that is being developed for treatment of rheumatoid arthritis and Crohn's disease. ABT-494 is metabolized by cytochrome P450 (CYP) enzymes including CYP3A and approximately 20% of the dose is eliminated unchanged in urine. The objectives of this work were to assess the effect of high-fat meal, ketoconazole (a strong CYP3A inhibitor), and rifampin (a broad CYP inducer and an OATP1B inhibitor) on the pharmacokinetics of ABT-494 in humans.

Methods:

Two studies were conducted. In the first study, using a randomized, two sequence, cross-over design, healthy adult subjects (N = 12) received a single dose of 3 mg ABT-494 in three different occasions: after 10 hours of fasting, 30 minutes after starting a high-fat breakfast, and on Day 4 of a 6-day regimen of once daily ketoconazole (400 mg) under fasting condition. In the second study, healthy adult subjects (N = 12) received single doses of 12 mg ABT-494 on three sequential occasions: alone, with the 1st, and with the 8thdose of a 9-day regimen of once daily rifampin (600 mg). Serial blood samples were collected to determine ABT-494 plasma concentrations and safety and tolerability were monitored. Pharmacokinetic parameters for ABT-494 were calculated using non-compartmental analyses.

Results:

Relative to administration under fasting conditions, high-fat meal delayed ABT-494 T_{max} by approximately 1 hour, decreased ABT-494 C_{max} by 23% and had no impact on ABT-494 AUC. Administration of ABT-494 with repeated doses of ketoconazole increased ABT-494 C_{max} and AUC by 70% and 75%, respectively. Repeat-dose administration of rifampin decreased ABT-494 $C_{max}$and AUC by 51% and 61%, respectively, whereas single dose co-administration of rifampin had no effect on ABT-494 AUC. ABT-494 was well tolerated by subjects.

Conclusion:

Food has no clinically meaningful effect on ABT-494 plasma exposure. Strong inhibition of CYP3A results in a limited increase in ABT-494 exposure (i.e. weak pharmacokinetic interaction). The broad CYP inducer rifampin reduces ABT-494 exposure by approximately half, while lack of effect of the first dose of rifampin on ABT-494 AUC suggests no interaction of ABT-494 with OATP1B inhibitors.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: :

Unlike rheumatoid arthritis (RA), the pattern of joint involvement in psoriatic arthritis (PsA) is usually asymmetric. Furthermore, PsA may demonstrate oligoarthritis or polyarthritis, while RA usually manifests in multiple joints. The aim of this study was to describe the most commonly affected joints in patients with RA and PsA at baseline and after 6 months (mos) of treatment with infliximab (IFX) in a clinical practice setting.

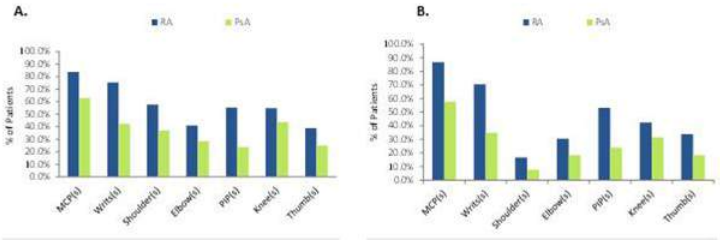
Methods :

BioTRAC is an ongoing, prospective registry of patients initiating treatment for RA, ankylosing spondylitis, or PsA with IFX as first biologics or after having been treated with a biologic for <6 mos. RA patients treated between 2002-2012 and PsA patients treated with IFX between 2005-2012 were included. Based on the 28-joint involvement 7 groups were created: shoulder(s), elbow(s), metacarpophalangeal (MCP(s)), wrist(s), proximal interphalangeal (PIP(s)), knee(s), and thumb(s). The impact of treatment on joint swelling/tenderness was assessed with the McNemar test while the Chi-square test was used to compare the affected joints between disease groups.

Results:

832 RA patients (mean age: 55.8 yrs disease duration: 10.2 yrs) and 92 PsA patients (age: 48.7 yrs; disease duration: 6.8 yrs) were included. At baseline, mean DAS28, SJC28 and TJC28 in RA vs. PsA patients were 5.8 vs. 4.1 ($P<0.001$), 10.7 vs. 4.0 ($P<0.001$), and 12.6 vs. 5.9 (<0.001), respectively. Among RA patients, the joints most commonly swollen at baseline were MCPs (86.8% of patients), wrists (70.5%), and PIPs (53.2%). Knees, thumbs, elbows and shoulders were swollen in 42.3%, 33.7%, 30.5%, and 16.7% of patients, respectively (Figure 1A). With respect to tenderness, MCPs were tender in 83.8% of patients, wrists in 75.3%, shoulders in 57.8%, knees in 54.8%, PIPs in 55.3%, thumbs in 38.8%, and elbows in 41.0% (Figure 1B). Statistically significant differences were observed between RA and PsA patients both in the frequency of joint swelling/tenderness, which were lower in PsA, and the profile of affected joints. Among PsA patients, MCPs, wrists, and knees were the joints most commonly swollen, affected in 57.6%, 34.8%, and 31.5% of patients, respectively; MCPs, knees, and wrists were the joints most commonly tender (63.0%, 43.5%, and 42.4% of patients, respectively). Upon 6 mos of treatment, significant improvement in swelling/tenderness in all the most commonly affected joints in both RA and PsA patients was observed. The joints most resistant to treatment, still remaining affected at 6 mos, were MCPs in both patient groups.

Figure 1. Types of Swollen (A) and Tender (B) Joints at Anti-TNF Treatment Initiation in RA and PsA



Conclusion:

Significant differences exist in both the frequency and the profile of swollen and tender joints in RA and PsA patients although both diseases shared the MCPs as the joint most commonly affected and most resistant to treatment. Treatment with IFX for 6 mos resulted in a significant reduction in the 28-swollen and tender joint counts in both RA and PsA patients

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The all-patient postmarketing surveillance (PMS) of tocilizumab (TCZ; PMS7901), which followed 7901 rheumatoid arthritis (RA) patients for 28 weeks (wks), showed that patients with high probability of remission and low probability of developing serious infections (SIs) were most likely to be those in early and less advanced stages of RA and who had not received biologics previously. The FIRST Bio study aimed to evaluate the overall effectiveness and safety of TCZ in biologics-naïve RA patients in the real clinical setting.

Methods: The FIRST Bio study was a 52-wk PMS. Patients who met the ACR/EULAR 2010 classification criteria and experienced inadequate response or were intolerant to ≥1 DMARDs received 8 mg/kg intravenous (IV) TCZ every 4 wks with or without DMARDs. Paired *t*-test was used for comparisons of continuous variables and X-squared test was used for categorical variables.

Results: Overall, 839 patients were observed. Patients from the FIRST Bio study had shorter mean disease duration (FIRST Bio, 7.5 years [y]; PMS7901, 10.4 y), and a higher percentage had less advanced Steinbrocker's stage and class than those in PMS7901. At Wk 52, 72.3% of patients continued to receive IV TCZ (total, 718.4 patient-years [pty]). The mean Clinical disease activity index (CDAI) improved from baseline (23.3) to Wk 52 (6.6; p<0.0001). At Wk 52, CDAI remission rate was 36.8% and Boolean remission rate was 33.1%. Boolean remission rate was better in the FIRST Bio study at Wk 24 (27.7%) than in PMS7901 at Wk 28 (15.1%). The mean HAQ score improved from baseline (1.0) to Wk 52 (0.5; p<0.0001); in 65.1% patients, HAQ-DI score was ≤0.5 at Wk 52. While the CDAI remission rate was significantly higher in the <2-y vs ≥10-y disease duration categories at Wk 24 (p<0.0001), it increased in the ≥10-y group after Wk 24, making the difference not statistically significant at Wk 52 (Table). However, the remission rate in patients with HAQ score ≤0.5 was higher in the <2-y vs ≥10-y disease duration categories at Wk 24 and Wk 52. The incidence (events/100 pty) of total adverse events (AEs) and serious AEs (SAEs) was 75.7 and 18.1, respectively. Infections were the most frequent AEs (17.8) and SAEs (5.8). The incidence rates of SAEs and SIs were lower in FIRST Bio than in PMS7901 (PMS7901: SAEs, 27.4; SIs, 8.6). The mean dose of concomitant MTX decreased from baseline (9.1 mg/wk) to Wk 52 (6.4 mg/wk), and 19.3% patients discontinued MTX. The mean dose of concomitant glucocorticoid (GC) also decreased from baseline (5.4 mg/day) to Wk 52 (2.6 mg/day), and was suspended in 34.0% of patients. CDAI remission rate did not decrease in patients who discontinued MTX or GC.

Conclusion: The FIRST Bio study confirmed the high effectiveness and safety of TCZ in the real clinical setting in patients with less advanced RA who had not received biologics previously.

Table. Changes in CDAI and HAQ-DI remission rates over time in the FIRST Bio study

		Week 0	Week 12	Week 24	Week 36	Week 52
CDAI remission rate (%)	Total (*n*=722)	0.4	17.9	31.1	33.2	36.8
	<2 y (*n*=240)	0.8	21.6	40.2	40.4	42.9
	≥10 y (*n*=176)	0	12.6	20.5	27.3	33.5
HAQ-DIremission (≤0.5) rate (%)	Total (*n*=559)	34.3	59.8	62.0	64.9	65.1
	<2 y (n=183)	33.9	69.69	69.36	75.41	77.6
	≥10 y (*n*=140)	30.0	48.8	48.5	50.0	46.4

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The CD40-CD40L pathway may play a major role in autoimmune disorders like rheumatoid arthritis or SLE. Blocking this pathway may be a promising new treatment for patients suffering from autoimmune diseases. BI 655064 is a novel humanized antagonistic anti-CD40 monoclonal antibody free of agonistic activity and without antibody-dependent cellular- or complement- dependent cytotoxicity. Safety, tolerability, PK and CD40 receptor occupancy (RO) were investigated in a single ascending dose study in Asian male healthy volunteers.

Methods: This was a randomized, double-blind within dose groups, placebo-controlled, two-sites, single rising dose trial evaluating single subcutaneous (SC) doses (80, 120, 180 and 240 mg) of BI 655064. Blood samples were taken for analysis of PK, immunogenicity and CD40 RO throughout the entire trial duration (10 weeks).

Results: Thirty-two Chinese and 32 Japanese subjects, mean age 26.8 years, were treated: 48 received BI 655064 and 16 received placebo. All doses of BI 655064 were well tolerated in both ethnicities. There was no-drug related serious adverse event (AE) or significant AE reported. All AEs were mild, except 1 moderate (Chinese 120 mg; contusion), and all recovered. The percentage of subjects reporting any AE was the same (31.3%) for subjects treated with BI 655064 or placebo. AEs did not show a dose relationship. Nineteen of the 20 subjects that reported at least 1 AE during the treatment phase were Chinese. The most frequently reported AEs were upper respiratory tract infections (reported in 8.3% subjects on BI 655064 vs. 12.5 % on placebo). AEs rated as drug –related by the investigator were only reported in Chinese subjects and did not show a dose relationship. The only drug-related AE that was reported for more than 1 subject was diarrhoea (1 Chinese in each 80 mg and 240 mg treatment). There was no evidence of thromboembolism or bleeding, hypersensitivity reaction, cytokine release and relevant change in safety laboratory tests including coagulation parameters.

Plasma concentrations of BI 655064 increased gradually after a single SC administration of BI 655064, reached a peak at 96 to 144 hours post dose and then declined with the terminal half-life ranging from 105 to 242 hours. The exposure increased more than proportionally with the dose indicating target mediated drug disposition. Single dose of 120 mg SC resulted in >90% CD40-RO and the duration of >90% CD40-RO increased with increasing dose. Anti-drug antibodies were detected in most of the subjects (45 out of 48 subjects) who received BI 655064 with relatively low to moderate titer (mostly ≤ 400, median titer ≤ 80) and median onset time of 41 days.

Conclusion: These data demonstrate that BI 655064 has a favorable clinical safety profile and high potential to block the CD40-CD40L pathway in Chinese and Japanese population. This is in line with results in Caucasians and supports the inclusion of Asian subjects in global clinical trials with BI 655064.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor for the treatment of RA. A modified-release (MR) formulation to provide a once-daily (QD) dosing alternative to the available 5 mg twice-daily (BID) immediate-release (IR) formulation has been developed.[1] The objective was to determine the most relevant pharmacokinetic (PK) parameter driving the clinical response of tofacitinib to inform clinical development of the MR formulation.

Methods: Clinical efficacy data (DAS and ACR 20/50/70 responses) from 5 Phase 2 RA dose-ranging studies of IR 1-30 mg BID and IR 20 mg QD across ~1,500 patients were analyzed. Dose and exposure-response (E-R) models were developed to characterize the time course of changes in DAS, including quantifying the delay between concentration and response, and to compare the predictive abilities of various PK parameters (total drug exposure as measured by area under the concentration-time profile [AUC], and peak [C_{max}] and minimum [C_{min}] plasma concentrations). Non-clinical efficacy data from a dose-fractionation study of multiple IR QD and BID doses using the murine collagen-induced arthritis (mCIA) model were also analyzed to delineate the predictive ability of PK parameters. The relationship between tofacitinib exposure metrics and incidence of safety outcomes were explored using linear logistic models.

Results: The E-R model yielded an equilibration half-life of 3.2 weeks for changes in DAS, substantially longer than the PK half-life of tofacitinib (~3 hours). Application of this model to plasma PK profiles of MR and IR yielded predicted effective superimposable concentrations for both regimens (Fig 1). In a dose-ranging Phase 2 study, analyses of the IR 20 mg QD dose (similar AUC to the IR 10 mg BID dose, but 86% lower C_{min} and ~2-fold higher C_{max}) demonstrated similar efficacy to the IR 10 mg BID dose. DAS mean [standard error] change from baseline was -1.72 [0.14] for IR 20 mg QD vs -1.82 [0.15] for IR 10 mg BID; ACR 20/50/70 rates were 56/36/24% for IR 20 mg QD vs 58/28/12% for IR 10 mg BID, respectively, at Week 12. Statistical comparison of PK parameters favored AUC as a better predictor ($p<0.05$) of DAS changes than C_{max} or C_{min}, with little added value of C_{max} or C_{min}. In the mCIA model, BID and QD E-R curves were well aligned for AUC as the predictor, as demonstrated by concordance of concentrations producing 50% of maximum response. Comparing the predictive ability of AUC, C_{max}, and C_{min} for safety events of interest (eg serious infections) also supported AUC as the most relevant PK parameter (data not shown).

Conclusion: Collectively, these analyses support AUC as the relevant predictor of tofacitinib clinical response and inform clinical development of an MR formulation of tofacitinib for QD dosing.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: The objective of this real-world analysis was to examine the impact of the interleukin-6 receptor α inhibitor tocilizumab (TCZ) on patient-reported outcomes (PROs) in a US observational cohort of > 40,000 patients with rheumatoid arthritis (RA; Corrona).

Methods: Between October 1, 2010, and March 31, 2015, patients with RA who newly initiated TCZ monotherapy while not in remission (based on Clinical Disease Activity Index) and had a follow-up visit at 1 year (± 3 months) were identified. Changes in PROs, assessed 1 year from baseline and stratified by prior tumor necrosis factor inhibitor (TNFi) use, included patient global assessment of disease, pain and fatigue (0-100); morning stiffness (hours); modified Health Assessment Questionnaire (mHAQ; 0-3); and Euro Quality of Life 5 dimensions questionnaire (EQ-5D). Improvement in EQ-5D domains was defined as patients improving from moderate to no disability or severe to moderate or no disability. Outcomes between the 1 and ≥ 2 prior TNFi groups were compared using chi-square or *t*-tests, as appropriate.

Results: Of the 255 TCZ monotherapy initiators included, 24 (9%) were TNFi naive, 93 (37%) received 1 prior TNFi and 138 (54%) received ≥ 2 prior TNFis. Baseline PROs showed that patients were substantially impacted by their disease, with similar scores

reported across TNFi exposure groups (**Table**). Patients reported median (IQR) global disease activity, pain, fatigue and mHAQ scores of 55 (40-75), 60 (40-76), 60 (33-80) and 0.63 (0.25-1.00), respectively, and a median (IQR) of 1 (0.5-2.5) hour of morning stiffness at baseline. Baseline proportions of patients reporting difficulties in EQ-5D domains are shown (**Table**). At 12 months, improvements were reported in all PROs with no significant differences across TNFi exposure groups. Median (IQR) improvements in patient global, pain and fatigue were 10 (-5-30), 10 (-5-30) and 5 (-10-23), respectively. 46% of patients reported no reduction in morning stiffness, 35% reported 1-60 minutes reduction and 19% reported > 60 minutes reduction. Improvement in EQ-5D is shown (**Figure**). A significantly lower proportion of patients with ≥ 2 prior TNFis had improvement in walking and usual activities compared with patients with 1 prior TNFi.

Conclusion: Real-world data showed that quality of life in patients with RA newly initiating TCZ monotherapy was substantially impacted by their disease. Improvements at 1 year were reported in all measures, regardless of prior TNFi history; however, patients who received TCZ therapy earlier in the line of treatment had better response with respect to walking and usual activities than those treated with ≥ 2 prior TNFis.

Table. Baseline EQ-5D Measures Among TCZ Monotherapy Initiators

	Total N = 255	TNFi Naive N = 24	1 Prior TNFi N = 93	≥ 2 Prior TNFis N = 138	*P*-value[a]
Patients experiencing at least some difficulty in EQ-5D categories, % (n/N)					
Walking	72.9 (151/207)	78.9 (15/19)	72.6 (53/73)	72.2 (83/115)	0.45
Self-care	51.7 (106/205)	58.8 (10/17)	50.0 (37/74)	51.8 (59/114)	0.19
Usual activity	81.6 (168/206)	88.9 (16/18)	80.8 (59/73)	80.9 (93/115)	0.58
Pain/discomfort	94.1 (190/202)	88.9 (16/18)	94.5 (69/73)	94.6 (105/111)	0.94
Anxiety/depression	43.8 (91/208)	47.4 (9/19)	41.1 (30/73)	44.8 (52/116)	0.87

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

ABP 501 is being developed as a biosimilar candidate to adalimumab (Humira®), a fully human recombinant monoclonal antibody. Evidence from analytical and pharmacokinetic comparisons indicates that ABP 501 is highly similar to adalimumab. Primary efficacy endpoints and safety results from a phase 3 study comparing ABP 501 with adalimumab in subjects with rheumatoid arthritis (RA) are reported separately. Here we report the secondary efficacy endpoints of the study. The objective was to evaluate and compare American College of Rheumatology 20% response criteria (ACR20), ACR50, and ACR70, as well as the change from baseline in Disease Activity Score in 28 joints using C-reactive protein (DAS28-CRP) over weeks 2–24 for ABP 501 and adalimumab based on results from a phase 3 study.

Methods:

This was a randomized, double-blind, active-controlled study in adult subjects with moderate to severe RA who had an inadequate response to methotrexate. Subjects were randomized in a 1:1 ratio (ABP 501: n=264; adalimumab: n=262) to receive either ABP 501 or adalimumab 40 mg subcutaneously every 2 weeks. The primary endpoint was risk ratio (RR) of ACR20 assessed at week 24 with a safety follow-up to week 26 (end of study). Here we report descriptive results of the secondary efficacy endpoints that included risk difference (RD) of ACR20, RR of ACR50 and ACR70, and difference in change from baseline of DAS28-CRP over the entire study.

Results:

Baseline characteristics were well balanced between groups. The table shows the response rate for ACR20, ACR50, and ACR70 throughout the study. At week 24, the RD of ACR20, ACR50 and ACR70 for ABP 501 vs adalimumab was 2.60% (2-sided 90% CI, –3.728% to 8.936%), –2.84% (90% CI, –10.220 to 4.547) and 3.15% (90% CI, –3.177 to 9.470), respectively. The RR of ACR50 and ACR70 was 0.95 (90% CI, 0.819–1.097) and 1.13 (90% CI, 0.872–1.464), respectively, at week 24. The differences in mean change from baseline in DAS28-CRP between ABP 501 and adalimumab were –0.08 (90% CI, –0.24 to 0.08) at week 8, –0.09 (90% CI, –0.26 to 0.07) at week 12, –0.09 (90% CI, –0.25 to 0.08) at week 18, and –0.01 (90% CI, –0.18 to 0.17) at week 24. The overall safety and immunogenicity profile of ABP 501 was comparable to that of adalimumab and is reported separately.

Table. Response Rate (%) of ACR20, ACR50, and ACR70 by Visit and Treatment

	ACR 20		ACR 50		ACR 70	
Week	ABP 501	adalimumab	ABP 501	adalimumab	ABP 501	adalimumab
2	35.4	24.5	11.0	6.2	0.8	1.9
4	51.5	45.0	19.5	17.8	5.1	3.9
8	63.5	62.5	31.1	28.5	10.4	10.2
12	74.6	65.5	41.3	43.5	15.3	13.3
18	77.3	75.9	50.0	47.2	19.6	22.8
24	74.6	72.4	49.2	52.0	26.0	22.9

Conclusion:

Along with the primary endpoint, these data support the results that efficacy of ABP 501 was similar to adalimumab.

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Up to 40% of RA patients on anti-TNF agents fail to respond either due to primary or secondary inefficacy. One explanation is immunogenicity leading to the development of anti-drug antibodies (ADAb) and low drug levels, observed with monoclonal antibodies (adalimumab and infliximab). Data from prospective studies on the value of pharmacological testing in certolizumab-treated RA patients is lacking. An additional challenge is the practicality of obtaining trough drug levels and impact on service delivery. Our aims were to evaluate (i) the association between random certolizumab drug levels, ADAbs and treatment response in patients with RA; (ii) factors associated with ADAbs and certolizumab drug levels.

Methods:

115 patients on certolizumab were selected from the Biologics in RA Genetics and Genomics Study Syndicate prospective cohort. Serum samples were collected at 3, 6 and 12 months following initiation of therapy. ADAbs were measured using RIA and drug levels using ELISA assays at 3, 6 and 12 months. Disease activity (DAS28) scores were measured at each visit and 12 month EULAR response was calculated. Patient self-reported adherence was collected longitudinally. Ordinal logistic regression and generalised estimating equation (GEE) were used to test the association between random drug levels on treatment response, between ADAbs and drug levels, and factors associated with drug levels.

Results:

253 serial samples were tested for certolizumab drug levels (n=230 suitable for ADAb measurement). Mean age: 56 ± 13 years; 75% female; baseline DAS28 score: 5.9 ± 0.8; median BMI 27.5 (IQR 23.6-32.3). 87% were on a DMARD (58% MTX). ADAbs were detected in 37% (cut off ≥20 AU/ml; 42/112 patients at ≥1 time points by 12 months). The presence of ADAbs were significantly associated with lower drug levels over 12 months using GEE (β=-0.037, 95% confidence interval [CI]-0.055 to -0.018, $p<0.0001$) but not independently with 12 month EULAR response (β=0.0013 [95% CI:-0.0032, 0.00061], p=0.18). Drug level was associated with 12 month EULAR response (β=0.035 [95% CI: 0.0018-0.069], p=0.039). Patients who developed ADAbs had longer disease duration (8.3 years [5.7-15.3]) vs. patients who did not (6.0 years [3.3-12.4], p=0.01). Factors associated with certolizumab drug level in the univariate GEE analysis were gender, adherence, BMI, CRP and ADAb level (Table). In the multivariate model after adjustment of confounders, ADAb level and adherence remained significant (Table).

Table: Predictors of drug levels in certolizumab treated RA patients using generalised estimating equation		
Variable	**β Coefficient (95% confidence intervals)**	**P value**
Univariate analysis

*p <0.05; †Adjusted for variables significant in the univariate analysis		

Conclusion:

Drug levels in certolizumab-initiated patients may be clinically useful even in the absence of trough levels to determine treatment response. Adherence and ADAb levels are associated with low certolizumab drug levels, whilst high disease duration prior to biologic initiation associated with ADAbs. ADAb measurement may help determine the aetiology of a low drug level, but were not associated with 12 month EULAR response.

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: With the increasingly widespread use of biological agents (BA), a thorough knowledge of their long-term behavior in clinical practice is fundamental. The purpose of our study was to assess and compare the long-term survival of Biological Agents (BA) in elderly patients with Rheumatoid Arthritis (RA) in clinical practice. Factors associated to discontinuation were also investigated.

Methods: Observational longitudinal study from 1999 to 2013 was conducted. RA patients followed in outpatient clinic at Hospital Clínico San Carlos, which started BA treatment after 65 years of age, were included. Primary outcome: BA (Etanercept; Infliximab; Adalimumab; Rituximab; and other BA [including Golimumab, Certolizumab, Abatacept and Tozilizumab]) discontinuation due to: adverse drug reaction (ADR), inefficacy, and other causes. Covariables: sociodemographic, clinical and therapy. Incidence rates of discontinuation (IR) per 100 patient-years were estimated using survival techniques with their respective 95% confidence interval [95% CI]. Comparison between BA discontinuation rates and other associated factors were run by Cox regression models.

Results: We included 286 courses of BA therapy in 146 patients (604 patient-years). Of these, 78% were women with a mean age at diagnosis of 66.5 ± 7 years and a median time to the start of the first BA of 6 ± 4 years. Adalimumab (27.3%), followed by Infliximab (22.4%), Etanercept (21.3%), and Rituximab (19.2%) were the most frequently used. Treatment was suspended in 199 cases (IR: 33 [28.6 -37.8]), 21.7% due to inefficacy (IR: 10.2 [8-13.5]), 39% to ADRs (IR: 18.4 [15.2- 22.1]), 2.8% to patient choice and 2.8% to improvement. In the first year of therapy 60% continued on BA, and after ten years, the retention rate didn´t exceed 5%. The crude IR of discontinuation was higher for Rituximab (IR: 39.2 [28-54]) compared to TNF- antagonists. In the multivariate analysis, after adjusting with calendar time, age and sex, we did not find differences between Adalimumab, Etanercept, Infliximab and Rituximab. Concomitant therapy with Disease Modifying Antirheumatic Drugs or corticoids, functional loss, positive anti–citrullinated protein antibodies and specific comorbidities were independent factors associated to discontinuation.

Conclusion: After several years of BA treatment in clinical practice, the survival in our cohort was low, mainly as a result of ADRs and inefficacy. We did not find any statistical differences between Adalimumab, Etanercept, Infliximab and Rituximab discontinuation rate. But we have found other clinical and therapy factors that modify their survival. This study contributes to increasing knowledge of long-term survival of these drugs in RA patients over 65 years and in real life conditions.

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The investigational drug sarilumab is a human mAb directed against the IL-6 receptor.[1] The phase 3 part of MOBILITY (NCT01061736) examined sarilumab + MTX vs placebo + MTX in patients with active, moderate-to-severe RA with inadequate response to MTX.[1] Both sarilumab doses (150 and 200 mg subcutaneously every 2 weeks [q2w]) were generally well tolerated and demonstrated statistically significant improvements in signs and symptoms of RA, improvements in physical function, and inhibition of radiographic progression. The incidence of treatment-emergent adverse events (TEAEs) was greater with sarilumab than placebo. The most common TEAEs were infections, neutropenia, injection-site reactions, and increased transaminases. In the present study, efficacy of sarilumab across prespecified subpopulations from MOBILITY was assessed.

Methods: The MOBILITY study design and methods have previously been reported.[1] Incidence of ACR20 at week 24 and least-squares mean difference in change from baseline in HAQ-DI at week 16, coprimary endpoints in MOBILITY, were evaluated for placebo (n=398), sarilumab 150 mg q2w (n=400), and sarilumab 200 mg q2w (n=399) in prespecified subpopulations. Treatment-by-subgroup interactions were assessed by a logistic regression model for ACR20 at week 24 and by a mixed-effect model for repeated measures for HAQ-DI at week 16.

Results: No treatment-by-subgroup interactions were observed in the proportion of patients achieving ACR20 response at week 24 (Table), indicating that, across all subgroups, the efficacy of sarilumab was consistent with the overall study findings. There appeared to be a trend toward lower efficacy in patients with increasing weight and BMI, particularly in the sarilumab 150 mg q2w group (Figure). No treatment-by-subgroup interactions were observed for HAQ-DI improvements at week 16, and the trends observed with ACR20 response in regards to lower efficacy with increased weight and BMI were not observed.

Conclusion: ACR20 and HAQ-DI responses with sarilumab were generally consistent across all subgroups in MOBILITY, although ACR20 responses may be decreased in patients with increasing weight and BMI.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Chronic inflammation in RA is characterized by biochemical changes, including decreased hemoglobin, elevated CRP, changes in lipid metabolism, and hypoalbuminemia.[1] Some parameters, including CRP, are associated with RA disease activity, rapid structural disease progression, and comorbidities (eg, cardiovascular disease).[2,3] Chronic inflammation in RA is also associated with non-focal complaints[4]; some, like weight loss, are not measured by response-to-treatment measures routinely used in clinical studies. In the phase 3 MOBILITY study (NCT01061736), investigational agent sarilumab (150 or 200 mg every 2 wks [q2w]) + MTX demonstrated efficacy vs placebo (Pbo) in adults with active, moderate-to-severe RA with inadequate response to MTX.[5] The most common treatment-emergent adverse events with sarilumab included infections, neutropenia, injection site reactions, and increased transaminases. Laboratory abnormalities were consistent with IL-6 blockade. In the present analysis of MOBILITY, effect of sarilumab on laboratory parameters associated with chronic inflammation was assessed.

Methods: Changes in laboratory parameters from baseline through 52 wks with Pbo (n=427), sarilumab 150 mg q2w (n=431), and sarilumab 200 mg q2w (n=424) were assessed.

Results: Laboratory parameters remained relatively unchanged in the Pbo group through wk 52 (Table). Decreases in serum amyloid A, fibrinogen, and CRP were observed in the sarilumab group beginning at wk 2 and remained below baseline through wk 52. Increases in hemoglobin and albumin were also observed. An increase in total cholesterol levels was observed starting at ~4 wks in all 3 groups (mean increase of ~20 mg/dL for both sarilumab groups) and remained at these levels through wk 52. Low-density lipoprotein (LDL) cholesterol increased from <160 to ≥160 mg/dL in more patients treated with sarilumab (27.8% in 200 mg, 21.1% in 150 mg vs 11.5% in Pbo). Slight weight gain was observed with either dose of sarilumab (1.32 and 1.85 vs Pbo, 0.07 kg), with more patients treated with sarilumab 150 or 200 mg (32.7% and 34.2%, respectively) experiencing a ≥5% increase from baseline (vs 15.0% with Pbo).

Conclusion: Inhibition of IL-6 signaling via sarilumab was associated with changes in parameters associated with chronic inflammation including a decrease in CRP, an increase in hemoglobin, normalization of albumin and fibrinogen, and an increase in total and LDL cholesterol. Increase in weight was also observed in both sarilumab groups across the 52-wk study.

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The investigational agent sarilumab is a human mAb directed against the IL-6 receptor. In the phase 3 MOBILITY study (NCT01061736), sarilumab (150 or 200 mg every 2 wks [q2w] + MTX) demonstrated efficacy in adults with active, moderate-to-severe RA with inadequate response to MTX.[1] The most common treatment-emergent adverse events (TEAEs) with sarilumab included infections, neutropenia, injection site reactions, and increased transaminases. Lab changes observed were consistent with IL-6 signaling blockade. This analysis examined dose reduction of sarilumab that occurred during an open-label, long-term, follow-up study (EXTEND, NCT01146652) that evaluates long-term safety and efficacy of sarilumab with or without concomitant non-biologic DMARDs. Eligible patients were adults with RA who participated in prior sarilumab studies.

Methods: Patients initially entering EXTEND received sarilumab 150 mg every week (qw). Following dose selection for phase 3 studies, patients were switched to or initiated on sarilumab 200 mg q2w. Per protocol, investigators could have reduced the dose to sarilumab 150 mg q2w for absolute neutrophil count (ANC) ≥0.5 to 1.0 Giga/L in the absence of infection, platelet count ≥50 to 100 Giga/L in the absence of bleeding, or alanine aminotransferase (ALT) ≥3 to 5 × ULN. The majority of patients included in these analyses were enrolled from MOBILITY; efficacy data from EXTEND were analyzed after dose reduction in these patients (n=138).

Results: The study is ongoing. As of April 2015 interim analysis, dose reduction from 200 to 150 mg sarilumab q2w occurred in 15% of patients. The most common reasons for sarilumab dose reduction were decrease in neutrophil counts (9.5%) and elevations in ALT (3.3%) (Table 1). Infection was the most common non-laboratory reason for dose reduction (0.4%). Approximately 76% of patients who dose reduced are continuing treatment, with a mean duration of treatment after dose reduction of 1.5 years. Improvements in ANC and ALT were observed over the 6 months following dose reduction (Table 2). Efficacy of sarilumab in MOBILITY patients was maintained following dose reduction in EXTEND as assessed by ACR20 response at wk 24: 83%.

Conclusion: In this study, reducing the dose from 200 mg q2w to 150 mg q2w to manage laboratory abnormalities allowed the majority of patients to continue in the study for a mean duration of >1.5 years. For patients continuing in the study, these laboratory abnormalities improved during the 6 months following dose reduction, and efficacy was maintained.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Filgotinib is an oral, selective Janus kinase 1 (JAK1) inhibitor combining clinical efficacy and a rapid onset of action with a good safety profile in patients with rheumatoid arthritis (RA). Its once-daily oral administration is supported by the long half-life of an active metabolite with the same JAK1 selectivity profile as the parent compound. Given genetics may cause differences in drug metabolism and pharmacokinetics (PK), and pharmacodynamics (PD) resulting in variability in clinical response, filgotinib was studied in Japanese healthy volunteers to evaluate the potential for different dosing requirements compared to Caucasians/ Compare the PK, PD and safety of filgotinib between Japanese and Caucasian healthy volunteers after repeated dosing of 200 mg filgotinib.

Methods: In a single-center Phase 1 study, 10 Japanese (1st and 2nd generation residing outside Japan for less than 5 years) and 10 Caucasian healthy volunteers received once daily 200 mg filgotinib or placebo for 10 days. The PK of filgotinib and its main active metabolite were evaluated, and the overall PD effect was assessed in whole blood using *ex vivo* IL-6 induced phosphorylation of STAT1 (pSTAT1) as biomarker for JAK1 activity and GM-CSF induced phosphorylation of STAT5 (pSTAT5) for JAK2 activity. Standard safety assessments were performed throughout the study duration.

Results: Steady state in plasma concentrations for filgotinib and its active metabolite was attained after 2 to 3 days of administration in both Japanese and Caucasian volunteers. Overall exposures for filgotinib and its metabolite were similar in the two groups, with the main active metabolite showing plasma concentrations well exceeding those of filgotinib. Both in Japanese and Caucasians, IL-6 induced pSTAT1 was inhibited over the entire 24 hour post-dosing period, with maximum inhibition observed between 1 and 5 hours post dose. No relevant inhibition of JAK2 activity was observed in any group, confirming filgotinib's selective inhibition of JAK1 over JAK2. In Japanese and Caucasian healthy volunteers, filgotinib was generally safe and well tolerated with no relevant differences in safety profile among the ethnic groups.

Conclusion: Filgotinib showed comparable PK, PD and safety profiles in Japanese and Caucasian healthy volunteers. The similarity in the PK and PD response suggests that there are no relevant differences among the groups in drug metabolism or selective inhibition of JAK1. These data support that filgotinib may be administered at similar doses in Japanese and Caucasian RA patients.

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: The objective of this report was to clarify and compare the retention rate of first biologics used to treat elderly Japanese patients with rheumatoid arthritis (RA).

Methods: A prospective analysis was performed on 289 patients of age over 65 years with RA followed up in our multicenter registry after September 2010 (approval date of abatacept as the 5th biologic agent for RA, two years after tocilizumab in Japan). We assessed the age, sex, disease duration, Steinblocker's Stage and Class, Disease Activity Score 28-Erythrocyte Sedimentation Rate, past

operation history, complications, methotrexate use and dose, and corticosteroid use and dose as baseline characteristics, and compared cumulative survival and reasons of discontinuation among patients treated with the TNF-inhibitors (TNF-i), abatacept, and tocilizumab.

Results: Of the 289 patients, 146 (50.5%) were treated with TNF-i, 117 (40.5%) with abatacept, and 26 (9.0%) with tocilizumab. The patients in the abatacept group had older age and longer disease duration, worse stage and class, fewer complications, and lower methotrexate use than those in the TNF-i group (see table). However, the cumulative survival was longer in the abatacept group than in the TNF-i group (P = 0.013, log-rank test).

Conclusion: In our cohort of elderly patients with RA, the abatacept group, despite a relatively worse RA presentation at baseline, had better retention rate compared with the TNF-i group. This result provides valuable information in managing active RA in elderly patients.

Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: The objective of this report was to clarify and compare the retention rate of first biologics used to treat elderly Japanese patients with rheumatoid arthritis (RA) in clinical practice.

Methods: A prospective analysis was performed on 197 patients of age over 75 years with RA who were followed up in our multicenter registry since its establishment. We assessed the age, sex, disease duration, Steinblocker's Stage and Class, Disease Activity Score 28-Erythrocyte Sedimentation Rate (DAS28ESR), past surgical history, complications, methotrexate use and dose, and corticosteroid use and dose as baseline characteristics, and compared cumulative survival and reasons for discontinuation among patients treated with TNF-inhibitors (TNF-i), abatacept, and tocilizumab.

Results: Of the 197 patients, 140 (71%) were treated with TNF-i, 48 (24%) with abatacept, and 9 (5%) with tocilizumab. Patients in the abatacept group were older and had worse Steinblocker's Class, fewer complications, and lower methotrexate use than those in the TNF-i group; however, they had similar DAS28ESR at baseline (see table). As a result, the abatacept group was superior to the TNF-i group in terms of cumulative survival (p = 0.002, log-rank test).

Conclusion: In our cohort of patients of age over 75 years with RA, the abatacept group, despite a relatively worse RA presentation at baseline, had a better retention rate than the TNF-i group. This result should be valuable in managing active RA in elderly patients.

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Despite disease modifying anti-rheumatic drugs (bDMARDs), glucocorticoids (GCs) are still widely prescribed in rheumatoid arthritis (RA). GCs are associated with numerous potential side effects, in particular for prolonged use and high doses. Thus, tapering GC to the minimal required dose remains a major therapeutic objective in RA management. GC sparing effects in real life practice have been demonstrated with anti-TNF agents, but only few studies have analyzed this effect with non-anti-TNF agents. The objective of this study was to investigate the impact of abatacept (ABA) on the evolution of concomitant GC dose in patients with RA

Methods:

This is a pooled observational database analysis of 9 European RA registries (ARTIS-SE, ATTRA-CZ, BIOBADASER-ES, DANBIO-DK, GISEA-IT, NOR-DMARD-NO, ORA-FR, SCQM-CH, Reuma.PT). Inclusion criteria for this analysis were a diagnosis of RA, initiation of ABA and available information on time-varying GC use. The primary endpoint was mean GC dose over time. Because GC dose was not normally distributed and there were a significant number of zeros (non GC users), we used a 'Hurdle Model' to analyze the longitudinal evolution of mean GC dose over time.

Results:

We identified 2409 patients initiating ABA with 5054 pt-years (PY) of follow-up with complete time-varying information on concomitant GC use. At baseline, the mean age was 58.6 years, 78% were female, and mean BMI was 26.4 kg/m^2. Disease characteristics suggest long-standing RA with severe disease (mean disease duration of 13.4 yrs, DAS28 5.0, HAQ score 1.32, ESR 31 mm/h, RF positive 72%, anti-CCP positive 68%). Most patients have failed several biotherapies before starting ABA (prior N° of biotherapies: 2 [IQR: 1 – 3]) and several conventional synthetic DMARDs (prior N° of csDMARDs; 2 [IQR: 1 – 4]).

At initiation of ABA, 87.4% of patients received concomitant GCs at a mean dose of 7.8 (95% CI: 0 – 18) mg (median dose [IQR] of 6.4 [5.0 -10.0] mg) of prednisone per day. The average GC dose slowly but continuously decreased after ABA initiation at a mean rate of -0.6 mg/year per patient. After one year, 11.5% of patients had stopped concomitant GC altogether. Significant predictors of lower concomitant GC use were female sex, older age, lower baseline disease activity, and less prior biotherapy failures.

Conclusion:

Data from this Pan-European registry analysis reveals that concomitant GC use is very common in patients starting ABA, with established and severe RA and a history of multiple failures on biotherapies. The average GC dose and the proportion of patients requiring GC decreases continuously after ABA initiation, demonstrating indirectly the effectiveness of ABA in this population. GC dose reduction in patients responding to ABA may contribute to a decrease in the burden of co-morbidities.

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: In certain chronic diseases, such as rheumatoid arthritis (RA), atherosclerosis is more prevalent. RA patients have a higher incidence of cardiovascular disease and at least two-fold enhanced cardiovascular risk, as compared to the general population. This is in part due to persistently present inflammation shown to be a risk factor for atherosclerosis. Serum amyloid A (SAA) is an acute phase protein, highly upregulated in sera of RA patients and reported to activate endothelial cells. Our aim was to determine the effects of medications used in RA patients on selected adhesion molecules, cytokines and chemokines involved in atherosclerosis and coagulation in human coronary artery endothelial cells (HCAEC) following stimulation with SAA. **Methods:** Primary HCAEC at passage 5, grown to confluency in 6-well plates were preincubated for 30 min with medications from sterile ampules at indicated final concentrations (Dexamethasone 1µM, Methotrexate 1µM, Certolizumab pegol 100µg/ml, Etanercept 100µg/ml, Meloxicam 100µM, Diclofenac 10µM) or dissolved in medium (Captopril 10µM) or DMSO (Fluvastatin 10µM, Etoricoxib 100µM, Rosiglitazone 30µM). Human recombinant SAA1/2 (Peprotech, London, UK) was used to stimulate HCAEC at a final 1000 nM concentration. After 24 hours, supernatants were collected, centrifuged and frozen at -20 C. IL-6, IL-8, sVCAM-1, PAI-I were measured by ELISA. The number of viable cells was determined by colorimetry (CellTiter MTS assay, Promega). **Results:** SAA-stimulated levels of released IL-6, IL-8 and VCAM-1 in HCAEC supernatants were significantly attenuated by Methotrexate, Fluvastatin and Etoricoxib. Both Certolizumab pegol and Etanercept significantly decreased PAI-1 by an average of 43%. Captopril did not significantly alter either the cytokine or chemokine profile released by SAA stimulation of HCAEC. Rosiglitazone caused only slight lowering of IL-6, but significantly inhibited VCAM-1 by 58%. Among the NSAID group of medications, Diclofenac and Etoricoxib showed a trend towards lowering IL-6 and IL-8, while Meloxicam showed just the opposite. Diclofenac and Etoricoxib significantly attenuated VCAM-1 released supernatant levels, while Meloxicam was less effective. Diclofenac and Etoricoxib increased PAI-1, which was significantly reduced by Meloxicam. **Conclusion:** The most successful agent in lowering cytokine production was Fluvastatin. None of the medications significantly influenced cell viability. Methotrexate also showed strong beneficial effects on lowering released cytokine/chemokine/adhesion molecule levels from SAA-treated HCAEC. An interesting duality was observed in the NSAID group of medications, with Meloxicam exhibiting opposite effects from Diclofenac and Etoricoxib.

Table 1: Influence of medications used in RA patients on released IL-6, IL-8, sVCAM-1, PAI-1 protein levels and viability of SAA-activated HCAEC compared with the influence of SAA alone

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Among rheumatoid arthritis (RA) patients who progress beyond their first biologic disease-modifying antirheumatic drug (bDMARD), in-class cycling between different tumor necrosis factor inhibitors (TNFi) has been common practice. The introduction of newer bDMARDs targeting other mechanisms of action (MOA) offer additional treatment options and could introduce changes in clinical practice guidelines that directly impact real-world clinical practice. This analysis aims to examine the trend of US RA patients who switch bDMARD treatment following an initial TNFi, and to identify patient and physician factors associated with switching to a bDMARD with a different MOA rather than in-class cycling to a second TNFi.

Methods: Data were drawn from the Adelphi RA-DSP, a cross-sectional geographically diverse survey of US rheumatologists about their RA patients using samples from the 1st quarter (Q1) of 2011 and Q1 2014. Rheumatologists provided patient demographics, clinical details, and treatment history. All patients had previously received a TNFi bDMARD as their first bDMARD therapy. Patients who subsequently cycled in-class to a second TNFi were compared to those switching to a bDMARD with a different MOA. Multivariate analysis was performed to identify independent patient and physician characteristics associated with switching to a bDMARD with a different MOA as the second treatment strategy rather than in-class cycling to a second TNFi.

Results: Included in the analysis were 246 RA patient cases that had previously received a TNFi as their first bDMARD therapy and had progressed onto a second bDMARD: mean age 56.0 years, 74.0% female, 83.1% RA-seropositive, 63.3% commercially insured, 25.3% Medicare, and 8.2% Medicaid. The main reasons for discontinuing the first TNFi therapy included: loss of efficacy (55.2%), lack of response (43.6%), adverse events (17.8%), and cost reasons (4.3%).

Comparing patient cases collected in 2011 and 2014, a significant increase was observed in switching to bDMARDs with a different MOA (compared to in-class cycling to a second TNFi), from 30% in 2011 to 43.1% in 2014 ($P = 0.035$). Multivariate analysis indicated that patients were more likely to switch to a bDMARD with a different MOA if the switch occurred after Q1 2011 and if they had received their first line of TNFi intravenously, but less likely to switch to bDMARDs with a different MOA when they had a high number of concomitant conditions (Figure).

Conclusion: This study suggests that when switching between bDMARDs occurred, US physicians increasingly switched their RA patients to a bDMARD with a different MOA rather than in-class cycling to a second TNFi.

Figure: Forest Plot Describing Patient Factors Associated with bDMARD Switching After First TNFi Therapy.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Switching of disease-modifying antirheumatic drugs (DMARDs) in rheumatoid arthritis (RA) patient treatment is common in real-world clinical practice. The context for why patients switch has not been well described and various factors may impact switching behavior. The purpose of this analysis is to characterize factors associated with DMARD switching using an US clinical RA registry, JointMan®. This database provides a practical outcome tool to manage patients with RA in a traditional office-based setting.

Methods: A retrospective analysis using the JointMan®registry was conducted in RA patients (N = 5,817) diagnosed by rheumatologists. Adult RA patient inclusion parameters were: a physician prescription record of a tumor necrosis factor inhibitor (TNFi) (infliximab, etanercept, adalimumab, golimumab, certolizumab) from April 1, 2010 through March 31, 2015; and a subsequent follow-on prescription of TNFi or a novel mode of action (MOA) DMARD (abatacept, anakinra, rituximab, tocilizumab, tofacitinib). Patients were divided into 2 cohorts: those who switched from previous TNFi to another TNFi (TNF cyclers), and those who switched to a novel MOA DMARD. Differences in baseline characteristics and reasons for discontinuing prior TNFi were analyzed using bivariate analysis. Multiple logistic regression was used to identify independent factors associated with switching.

Results: 519 adult RA patients were included in the study: mean age 56.5 years, 79.4% women, 86.3% Caucasian, 95.8% US West Coast resident, clinical disease activity index (CDAI) 22.8, mean prior TNFi treatment duration 29.4 months. Reasons for discontinuing prior TNFi therapy were primary lack of efficacy (38.9%), secondary loss of efficacy (20.0%), adverse events (12.1%), cost/insurance-related reasons (5.6%), and 23.3% other. After discontinuing index TNFi, more than half of patients switched to another TNFi (n = 278, 53.6%) rather than novel MOA DMARDs (n = 241, 46.4%). Patients switching to a novel MOA DMARD were older (57.8 vs. 55.4 years, $P = 0.0332$), less likely to be commercially insured (61.51% vs. 50.21%, $P = 0.001$), and more likely to be Medicare insured (46.06% vs. 35.61%, $P = 0.0156$) than patients cycling to another TNFi.

Multivariate analysis showed that patients were more likely to switch to a novel MOA DMARD than cycling to another TNFi if the first TNFi was administered intravenously (adjusted odds ratio [aOR] [95% CI] = 4.18 [2.50-6.99], $P < 0.0001$). Additionally, those with positive rheumatoid factor (aOR = 2.13 [1.28-3.56], $P = 0.0038$) and those with higher CDAI (aOR = 1.02 [1.01-1.04], $P = 0.008$) were more likely to switch to a novel MOA DMARD. Patients were less likely to switch to novel MOA DMARDs than to another TNFi if the reason for discontinuing the prior TNFi was insurance/cost-related (aOR = 0.30 [0.32-0.95], $P = 0.0094$) or loss of efficacy (aOR = 0.50 [0.32-0.95], $P = 0.0321$).

Conclusion: TNF cycling in RA treatment is common in clinical practice. The main reasons for discontinuation of prior TNFi therapy were lack or loss of efficacy. Increased understanding of switching patterns in RA patients may help improve patient care and foster further definition of drug development.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Remission is an important clinical outcome in RA[1] and is associated with improved physical function and health-related quality of life.[2] Several definitions of remission have been proposed on the basis of score thresholds of disease activity measures.[3] Recent ACR/EULAR updates to the criteria for remission found a Boolean-based definition (categorical in structure) and SDAI (composite index of RA activity) to be more clinically relevant.[3] In the phase 3 MOBILITY study (NCT01061736), both doses of sarilumab (150 or 200 mg every 2 weeks [q2w]) + MTX) demonstrated statistically significant improvement in signs and symptoms of RA, improvement in physical function, and inhibition of radiographic progression.[4] The most common treatment-emergent adverse events (TEAEs) with sarilumab included infections, neutropenia, injection site reactions, and increased transaminases. Laboratory changes were consistent with IL-6 signaling blockade. The objective of this prespecified analysis was to assess the ability of sarilumab to induce remission in patients with active, moderate-to-severe RA using 4 different disease activity measures.

Methods: Remission was defined as DAS28-CRP <2.6, CDAI ≤2.8, SDAI ≤3.3, and Boolean-based ACR/EULAR remission, which includes tender joint count and swollen joint count (28 joint count) ≤1, CRP ≤10 mg/L, and patient global VAS ≤10. Patients who started rescue medication or discontinued study were considered not in remission. Differences in incidence of DAS28-CRP, CDAI, SDAI, and Boolean remissions between the active treatment arms and placebo in the ITT population were assessed using 2-sided Cochran-Mantel-Haenszel tests stratified by prior biologic use and region.

Results: Baseline demographics and disease characteristics were generally similar between patients who achieved remission and the general ITT population with 2 exceptions: patients with remission had slightly shorter RA duration and fewer patients had used prior biologic therapies. Proportion of patients achieving DAS28-CRP, CDAI, SDAI, and Boolean-based remission at week 24 was higher in the sarilumab-treated groups vs the placebo group (all $P<0.006$, except for Boolean remission in the sarilumab 150 mg q2w group), and these observations were maintained at week 52 (Table). In all groups, DAS28-CRP remission had the highest and Boolean-based remission had the lowest frequency.

Table. Incidence of Clinical Remission in ITT population

	Placebo + MTX (n=398)	Sarilumab 150 mg q2w + MTX (n=400)	Sarilumab 200 mg q2w + MTX (n=399)
DAS28-CRP remission			
Week 24, n (%)	40 (10.1)	111 (27.8)	136 (34.1)
P value vs placebo		<0.0001	<0.0001
Week 52, n (%)	34 (8.5)	124 (31.0)	136 (34.1)
P value vs placebo		<0.0001	<0.0001
CDAI remission			
Week 24, n (%)	20 (5.0)	41 (10.3)	55 (13.8)
P value vs placebo		0.0053	<0.0001
Week 52, n (%)	19 (4.8)	59 (14.8)	72 (18.0)
P value vs placebo		<0.0001	<0.0001
SDAI remission			
Week 24, n (%)	19 (4.8)	41 (10.3)	52 (13.0)
P value vs placebo		0.0032	<0.0001
Week 52, n (%)	16 (4.0)	60 (15.0)	74 (18.5)
P value vs placebo		<0.0001	<0.0001
Boolean-based ACR/EULAR remission			
Week 24, n (%)	15 (3.8)	26 (6.5)	42 (10.5)
P value vs placebo		0.0810	0.0002
Week 52, n (%)	12 (3.0)	42 (10.5)	56 (14.0)
P value vs placebo		<0.0001	<0.0001

ITT, intent-to-treat; MTX, methotrexate; q2w, every 2 weeks.

Conclusion: Sarilumab plus MTX induced clinical remission at weeks 24 and 52 as defined by DAS28-CRP, CDAI, SDAI, and Boolean-based remission, although Boolean-based remission was not achieved for sarilumab 150 mg q2w at week 24. Remission at week 24 was maintained at week 52.

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

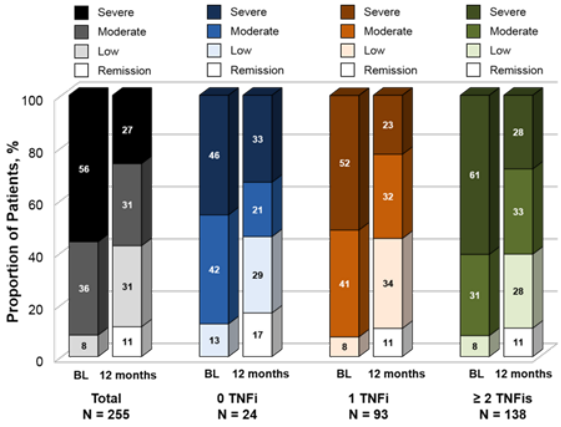
Background/Purpose: Little is known regarding the real-world use and effectiveness of the interleukin-6 receptor α inhibitor tocilizumab (TCZ) as monotherapy. The effectiveness of TCZ monotherapy in patients with rheumatoid arthritis (RA) was evaluated using a US national observational registry with > 40,000 patients with RA (Corrona).

Methods: Between October 1, 2010, and March 31, 2015, patients with RA who newly initiated TCZ monotherapy while not in remission (based on the Clinical Disease Activity Index [CDAI]), and who had a follow-up visit at 1 year (± 3 months) with CDAI measurements at both visits were identified. Outcomes assessed at 1 year included change in disease activity (median change in CDAI), meaningful improvement in the modified Health Assessment Questionnaire (mHAQ; change > 0.25) and achievement of a modified American College of Rheumatology (mACR)20/50/70 response from baseline in all TCZ initiators and were stratified by prior tumor necrosis factor inhibitor (TNFi) use. Outcomes between the 1 and ≥ 2 prior TNFi groups were compared using chi-square tests or *t*-tests, as appropriate.

Results: Of the 255 patients who newly initiated TCZ monotherapy, 24 (9.4%) were TNFi naive, 93 (36.5%) received 1 prior TNFi and 138 (54.1%) received ≥ 2 prior TNFis. At baseline, median (IQR) CDAI was 19.5 (13.0-34.5), 22.2 (14.0-30.0) and 25.2 (19.0-34.1) in patients who were previously treated with 0, 1 and ≥ 2 TNFis, respectively. At 12 months, there was improvement in the proportion of patients who achieved remission or low disease activity in the overall cohort and across all TNFi groups (**Figure**). CDAI remission occurred in 16.4%, 10.8% and 10.9% of patients in the 0, 1 and ≥ 2 TNFi groups, respectively. The overall median decrease in CDAI from baseline to 1 year and decreases stratified by TNFi group each exceeded the minimal clinically important difference, with similar improvement in both those with 1 and ≥ 2 prior TNFis (**Table**). Meaningful improvement in mHAQ and mACR20/50/70 responses were also observed overall, with no statistically significant differences across TNFi groups. Overall, the rate of serious infections was 2.1 per 100 patient-years (PY) and the rate of cardiovascular events was 1.0 per 100 PY; no differences were observed by prior exposure to TNFis.

Conclusion: In this real-world cohort of TCZ monotherapy initiators with primarily moderate to high disease activity and prior TNFi exposure, substantial improvements in all clinical outcomes were observed, with > 40% of patients overall achieving remission or low disease activity (46%, 45% and 39% for patients with 0, 1 or ≥ 2 prior TNFis, respectively).

Figure. Changes in CDAI From Baseline to 12 Months in Patients Newly Initiating TCZ Monotherapy Stratified by Prior TNFi



BL, baseline; CDAI, Clinical Disease Activity Index; TCZ, tocilizumab; TNFi, tumor necrosis factor inhibitor.
Remission was defined as CDAI ≤ 2.8; low disease activity as CDAI > 2.8 to ≤ 10; moderate disease activity as CDAI > 10 to ≤ 22; and severe disease activity as CDAI > 22.

Table. Improvement in Disease Activity at 12 Months in Patients Newly Initiating TCZ Monotherapy Stratified by Prior TNFi

	Total N = 255	TNFi Naive N = 24	1 Prior TNFi N = 93	≥ 2 Prior TNFis N = 138	*P*-value[a]
CDAI, median change (IQR)[b]	9.8 (8.2-11.4)	7.4 (1.7-13.0)	10.6 (7.7-13.6)	9.6 (7.6-11.6)	0.55
mACR20, % (95% CI)	37.8 (32-44)	45.8 (26-67)	25.3 (25-46)	38.1 (30-47)	0.66
mACR50, % (95% CI)	24.5 (19-30)	29.2 (13-51)	25.3 (17-35)	23.1 (16-31)	0.71
mACR70, % (95% CI)	11.6 (8-16)	25.0 (10-47)	11.0 (5-19)	9.7 (5-16)	0.75
Meaningful improvement in mHAQ (> 0.25), % (95% CI)	26.1 (21-32)	29.2 (13-51)	28.6 (20-39)	23.9 (17-32)	0.43

CDAI, Clinical Disease Activity Index; IQR, interquartile range; mACR, modified American College of Rheumatology; mHAQ, modified Health Assessment Questionnaire; TCZ, tocilizumab; TNFi, tumor necrosis factor inhibitor.
[a] The *P*-value represents comparison between those patients with 1 prior TNFi versus those with ≥ 2 prior TNFis.
[b] The overall minimal clinically important difference was defined as a decrease in CDAI of ≥ 6 (Curtis JR, et al. Abstract presented at the 2013 ACR Annual Meeting; October 25-30, 2013; San Diego, CA [Abstract 2866]).

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: TNF blockade is a mainstay of treatment for rheumatoid arthritis (RA), but a significant proportion of patients fail to respond to treatment or lose clinical response over time. B cells play a critical role in the disease process and can become activated in germinal center (GC) reactions in secondary lymphoid tissue and ectopic GCs in synovium. TNF and lymphotoxin (LT) blockade have been shown to alter GC reactions in mouse models, but the potential impact of anti-TNF therapy on the B cell compartment remains controversial. The purpose of this study is to characterize the peripheral B cell compartment longitudinally during anti-TNF therapy in RA and determine the relationship between B cells and treatment response.

Methods: We randomized subjects in a 2:1 ratio to receive standard dosing regimens of etanercept or adalimumab for 24 weeks. Eligible subjects met the 1987 ACR criteria for RA, had clinically active RA (DAS28>4.4), and were on methotrexate. Disease activity and response was assessed based on DAS28-CRP. B cells from 54 patients were analyzed by multi-color flow cytometry at baseline and longitudinally at 12 and 24 weeks. The primary endpoint was the change in memory B cell fraction in the peripheral blood from baseline to week 12. All B cell results are expressed as a mean percent (+/- SE) of the CD19+ or parent population.

Results: Of the 63 eligible subjects, 43 and 20 were randomized to etanercept and adalimumab, respectively. The mean DAS at baseline was 5.3. After 12 weeks of treatment, 43% (n=24) of patients were identified as good responders, 45% (n=25) moderate responders, and 13% (n=7) non-responders (NR). The primary endpoint was not met as B cell subsets remained remarkably stable over the course of the study regardless of treatment group, and the remainder of the results report secondary endpoints. Repeated measures

analysis of variance (with unstructured covariance) was used to compare trends over time between NR and moderate or good responders (R). In NRs, the mean % CD27-IgD- (DN) memory B cells was significantly higher than R over all visits (R: baseline 6.2±0.4, WK12: 5.3±0.4, WK24: 5.1±0.4; NR: baseline: 8.7±1.1, WK12: 8.6±1.1, WK24: 7.6±1.1; p=0.01 over all visits, p<0.05 by visit). There was a significantly higher frequency of CD21- activated B cells over all visits in both SM (NR: baseline 11.8±2.1, WK12 13.9±1.9, WK24 15.2±2.3; R: baseline 8.5±0.8, WK12 8.7±0.7, WK24 8.6±0.8, p=0.02 over all visits, p<0.05 at WK12, WK24) and DN B cells (NR: baseline 36±5.2, WK12 34.1±4.6, WK24 37.5±4.8; R: baseline 19.0±2.0, WK12 19.1±1.7, WK24 19.0±1.8, p=0.001 over all visits, p<0.05 at each visit) in NRs vs. Rs.

Conclusion: Our results suggest a relationship between activated memory B cells and the response to anti-TNF treatment, with higher activated memory associated with a less robust response. Examination of peripheral lymphoid and target tissue may be necessary to define changes in B cell subsets with anti-TNF.

Novel Mechanisms of Action for Methotrexate and Doxycycline: Prevention of Protein Adduct Formation and Free Radical Scavenging

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Oxidative stress and free radical formation play an important pathogenic role in rheumatoid arthritis (RA) and a number of other inflammatory diseases. Oxidative stress promotes the formation of malondialdehyde-acetaldehyde (MAA) protein adducts, leading to robust inflammatory responses and tolerance loss. We have previously demonstrated that MAA adducts are markedly over-expressed in inflammatory synovitis and that anti-MAA immune responses are strongly associated with both anti-citrullinated protein antibody (ACPA) and RA disease activity. Whether disease-modifying therapies used to treat RA impact MAA adduct formation or exhibit free radical scavenging properties is unknown. In this study, we sought to examine whether the prevention of MAA adduct formation or free radical scavenging could represent novel mechanisms of action for RA treatments, utilizing both methotrexate (MTX) and doxycycline (DOX).

Methods: Molar equivalents of MTX or DOX were incubated in the presence of acetaldehyde, malondialdehyde (substrates in MAA formation) and albumin at pH 3.0, 5.0, and 7.0 for 1-3 days at 37^0C. Fluorescent activity of MAA was measured at 398 nm to quantify adduct formation. To measure free radical levels in the above reactions, electron paramagnetic resonance (EPR) spectroscopy and the EPR spin probe 1-hydroxy-3-methoxycarbonyl-2, 2, 5, 5-tetramethylpyrrolidine (CMH) were utilized.

Results: Incubation of human albumin with MDA and AA resulted in MAA-adduction of 8×10^4 fluorescent units (FU). MAA adduct formation was significantly reduced in the presence of both MTX (5.6×10^4 FU; P<0.05) and DOX (1.5×10^3 FU; P<0.001). When these reactions were evaluated for free radical levels by EPR, DOX and MTX reduced the levels of free radicals generated by MDA and AA at the different pH levels tested. For example, at pH 5 .0 MDA + AA resulted in 1.74×10^6 EPR arbitrary units (AU). In contrast, addition of MTX (1.23×10^6 EPR AU) or DOX (7.19×10^5 EPR AU) to the reaction significantly decreased the free radical levels by 30% and 41%, respectively (see figure).

Conclusion: MTX and DOX significantly decreasing MAA-adduction of proteins (human albumin in this case) *in vitro* is highly important given the known effect of MAA adduction on tolerance loss and the promotion of both humoral and cell-mediated immunity. Moreover, our data suggest that these agents have the capacity to directly scavenge free radicals *in vitro*, an effect that has not

previously been reported. For the first time, these results lend insight into novel mechanisms of action for two agents routinely used in the treatment of RA and other inflammatory diseases. The degree to which these agents' disease-modifying properties are dependent on direct free radical scavenging requires further investigation.

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Abatacept is a selective T cell costimulation modulator indicated for active Rheumatoid Arthritis (RA). Since August 2013, in Italy, the drug has also been available in a subcutaneous(sc) formulation, consisting in a fixed weekly dose of 125 mg. Aim of our study was to analyze the clinical response and the longterm outcome of a series of patients (pts) with RA previously treated with monthly iv infusion and then converted to the sc formulation based on their subjective preference about the way of administration.

Methods: We have retrospectively included 49 pts with RA, converted to sc Abatacept from October 2013 to April 2014. We divided them into two groups, depending on their need to return to the iv administration for the appearance of a disease flare. The main clinical and serological features of the two groups were compared using the Chi-square, T-test or the Mann-Whitney test.

Results: Fifteen pts (30.6%) returned to the iv administration due to a disease flare (mean DAS28: 4.8 vs 2.1, p:<0.001), after a mean of 15 injections (range 4-48): in these pts it has been observed a significant increase of the CRP values (mean:0.29 vs 0.86 mg/dl, p:0.004) and of the number of painful (mean:0.6 vs 4.9, p:<0.001) and swollen joints (mean 0.5 vs 4.2, p:<0.001).The remaining 34 pts (69.4%) continued with the sc formulation. The compared parameters between the two groups are summarized in Table 1. In pts with arthritis flare, disease activity decreased again (mean DAS28: 4.16 vs 2.43, p:<0.001) after returning to the iv infusion, with a significant decrease in the CRP values (mean 0.9 vs 0.4 mg/dl, p:0.04) and in the number of painful (mean:4.9 vs 1.7, p:0.003) and swollen joints (mean:4.2 vs 1.2, p:0.003).One patient discontinued the sc formulation for the onset of headache and nausea, not reported with the iv administration.Twelve months after the switch we have evaluated the persistence in treatment with Abatacept of the original cohort: 32 of the 34 patients (94%) were still treated with sc Abatacept (one withdrawn for sustained remission and one for repeated infections) while only 10 over the 15 (67%) pts who returned to iv Abatacept were still treated with the drug because 5 of them were swapped to other biologics for reactivation of arthritis (p:0.0368).

Conclusion: Although the safety profile of the sc Abatacept seems to confirm the data previously obtained with the iv use of the drug, a high rate of our patients complained a reduced efficacy, also confirmed by the subanalysis of the objective components of the DAS28 index (CRP values and joints involvement). We failed to identify clear risk factors that may help toward the selection of pts to which propose the formulation switch, however, if an arthritic flare occurs, the return to the iv administration seems to ensure a good control of the disease again. Nevertheless the switch failure seems to predict a reduced persistence efficacy of abatacept during time.

What Factors Are Associated with Starting an Intravenous Vs. Sub-Cutaneous Biologic in Patients with RA?

Kaleb Michaud[1,2], **Sofia Pedro**[2] and Steven Peterson[3], [1]Internal Medicine, University of Nebraska Medical Center, Omaha, NE, [2]National Data Bank for Rheumatic Diseases, Wichita, KS, [3]Janssen Global Services, LLC, Malvern, PA

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

To characterize which factors are associated with RA patients' preferences for biologic administration: sub-cutaneous or intravenous.

Methods:

Using a large US observational cohort, the National Data Bank for Rheumatic Diseases (NDB), we characterized RA patients who were on a biologic from Jan 2006 onwards, one year after Medicare changed reimbursement policies to cover more biologics than infliximab. Only the patient's first biologic or second (if already on their first biologic) were considered. Patients were assigned into 3 groups based on biologic administration: intravenous (IV), sub-cutaneous (SC), or "both" if they had taken IV and SC biologics in the same 6-month period. All patients enrolled via FDA-mandated drug safety registries were excluded, as well as those who had not had any change on biologic use after enrollment.

One–way Anova and chi-squared tests were used when applicable, with 5% significance level. Polytomous logistic regression models were used, with SC as reference, controlling for confounders, and results were presented as relative risk ratios (RRR). All explanatory variables were 6-month lagged, including: socio-economic status, marital status, markers of clinical status such as HAQ, Patient Activity Score, SF-36 physical component summary score, and dependency on others for help.

Results:

From 4,318 eligible RA patients, 1,609 (37.3%) were taking an IV biologic, 2,562 (59.3%) were on a SC biologic and 147 patients (3.4%) were on both (Figure 1). Patients in the IV group tended to be older, have longer RA duration, more likely on Medicare, and depended less frequently on others for help (Table 1). They also tended to have greater disability and worse disease activity (IV vs. SC RRR for HAQ, 1.21 [1.09-1.34]; both vs. SC, 1.61 [1.23; 2.12]).

Patients who switched between IV and SC were more likely to have uncontrolled disease activity. Most patients on biologics (70.8%) did not switch between classes, and the most common order of switching was from SC to IV (62.3%). which is consistent with the premise that patients/physicians may have preferences for one format over the other.

Conclusion:

Our results consistently characterized patients on IV biologics as more likely to choose and/or require the professional help that comes with IV administration. As most patients did not switch, this may indicate overall preferences by the patient and/or physician.

Profiling Compounds in Human Primary Cell-Based Disease Models Guide Indication Selection

Jason Ptacek, Ellen L. Berg and Alison O'Mahony, BioSeek, a division of DiscoveRx Corp., South San Francisco, CA

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: In vitro co-cultures of human primary cells, including immune cells, fibroblasts, smooth muscle, keratinocytes, epithelial or endothelial cells were developed to capture the complexity of various disease states. Compound effects on protein biomarkers in these assay systems were used to generate phenotypic signatures to inform how drugs may behave in these settings. These activity profiles could also be used to help guide indication selection for either novel compounds or repurposing of approved drugs. With a library of clinically validated and experimental compounds in the BioMAP reference database, novel compounds can be mapped to the current therapeutic landscape as well as help guide indication expansion.

Methods: Three benchmark RA drugs, a DMARD (Methotrexate, MTX), an anti-TNFα antibody (Adalimumab, Humira, ADA), and a small molecule JAK kinase inhibitor (Tofacitinib, Xeljanz, TOF) were profiled across a panel of 12 human primary cell based systems to generate phenotypic profiles. Drug effects on a broad scope of disease relevant readouts related to immune cell activation, proliferation, vascular inflammation, epithelial cell activation, matrix remodeling, fibrosis, and tissue remodeling were used to generate sentinel effects consistent with the RA indication. Three development candidates, BIRB-796 (p38MAPK inhibitor), apremilast (PDE IV inhibitor), and idelalisib (PI3Kδ inhibitor) were similarly profiled to assess indication selection.

Results: ADA and TOF were broadly anti-inflammatory with decreased cytokines (TNFα, IL-17F) and inflammation markers (VCAM-1, Eotaxin-3). In contrast, MTX was more selectively active in a system modeling T cell dependent B cell activation (BT). Correlation of activities with impact on disease relevant processes such as vascular inflammation, immune cell activation and proliferation, modulation of matrix, and epithelial activation was used to confirm RA as a primary indication best suited to these drugs. Analysis of the developmental compounds BIRB-796, apremilast, and idelalisib, was performed to assess which compound best mapped to which indication. BIRB-796 and apremilast, but not idelalisib, suppressed TNFα production from LPS-stimulated monocytes, similar to ADA. Although analysis of BIRB-796 revealed impacts on RA relevant processes, there were additional pro-inflammatory activities in a wound-healing model using dermal fibroblasts. Skin adverse events (AEs) have been reported in clinical trials of BIRB-796 and other p38 MAPKi. The data support the repositioning of p38 inhibitors for indications such as lung disease including COPD. Conversely to

the broad activities of BIRB-796, idelalisib's anti-inflammatory activities were selective to the BT system, similar to MTX and TOF. These data suggest that idelalisib may be better suited for indications such as lupus or oncology (CLL) where B cell dysfunction is of greater importance with respect to the disease.

Conclusion: These in vitro human primary cell-based model systems provide a phenotypic screening platform that can used to evaluate indication-related efficacy, dosing, and safety.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: In general, drug retention rate reflects the effectiveness and tolerability of the drug. TNF inhibitors include fusion protein agent such as etanercept (ETN) and antibody agent such as adalimumab(ADA),golimumab(GLM). There is few data comparing the retention rates between these biological therapies without concomitant methotrexate(MTX) for RA patients in daily clinical practice. The purpose of this study is to compare the drug retention rates of biological therapies with different TNF inhibitors that include fusion protein agent and antibody agent without MTX.

Methods: We collected the data from the patients who started ETN, ADA, GLM as first-biologics without MTX since 2008 and registered in the multicenter, large cohort of RA patients (Tsurumai Biologics Communication Registry; TBCR). We devided patients into two groups including ETN group and antibody group(ADA,GLM).We surveyed the following information: demographic data, disease activity (DAS28-CRP) at the baseline of each biological treatment. Drug retention rates were calculated by the Kaplan-Meier analysis and compared using the log-rank test among two groups. We investigated drug retention rates for discontinuation due to insufficient effectiveness and adverse events.

Results: We analyzed 356 patients of 2324 patients registered in TBCR until March 2013 (244 patients in the ETN group, 112 patients in the antibody group including, 78 patients with ADA,34 patients with GLM). The mean follow up time was 34.7 months. Table shows baseline characteristics of the groups (Table). Cumulative incidence rate for discontinuation due to insufficient effectiveness was significantly lower in the ETN group (p=0.0017, Fig.1A). There was no significant difference in cumulative incidence rate for discontinuation due to adverse events (p=0.342, Fig.1B).

Conclusion: We demonstrated that ETN therapy without concomitant MTX had a lower discontinuation rate due to insufficient efficacy compared with antibody agent without concomitant MTX.

Table

Variables	ETN (n=244)	Antibody drug (n=112)	P value

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Long-term prospective observational studies are complementary to controlled clinical trials in exploring the effectiveness and safety of biological therapies in rheumatoid arthritis (RA). We sought to study abatacept survival, reasons of discontinuation and clinical responses in everyday clinical practice.

Methods:

Prospective, observational, single-center study at the Rheumatology Clinic, University Hospital of Heraklion, Greece. Patient demographics, co-morbidities and disease characteristics were recorded at baseline, while drug discontinuations, disease activity and adverse events were monitored during follow-up, All patients who received abatacept intravenously between 29/6/2017 till 31/8/2014 were analyzed.

Results:

243 RA patients (84% women, 44% with destructive arthritis) with median (IQR) age 61 (15) years (37% aged >65 years), disease duration 7.9 (11) years and DAS28 5.9 (1.6) at baseline were included. Total follow-up time was 407 patient-years [median (IQR): 1.4

(1.3) years per patient]. Abatacept was used as first, 2nd or 3rdbiologic agent in 28%, 34%, and 38% of the patients, respectively.

Forty percent of the patients discontinued therapy after median (IQR) 1.0 (1.1) years. Reasons for discontinuation were treatment failure in 88 patients, adverse events in 8, other reasons in 3. In multivariable regression analysis controlling for potential possible confounding factors (demographic, disease characteristics, treatments), independent predictors of abatacept survival were male sex, older age, abatacept used as 1st or 2nd (as compared to ≥3rd) biologic agent, lower CRP and higher DAS28 and HAQ at baseline.

Regarding responses at 6 (12) months of therapy, 5.7% (13.2%) of patients had good and another 46.3% (47.6%) had moderate EULAR response, while 10.8% (16.5%) and 5.9% (7.8%) of the patients had DAS28 ≤3.2 or remission, respectively. The response rate at 12 months was higher in patients who received abatacept as 1st or 2nd as compared to ≥3rdbiologic agent (p= 0.021).

257 adverse events were registered, 43 being serious adverse events (SAE). The rate of total or serious infections was 37 and 2.7 per 100 patients/year respectively, while the median (IQR) time to first serious infection was 1.3 (1.8) years. SAE (including 5 cancers and 11 infections, mainly of the respiratory tract) occurred more frequently in geriatric RA patients (p=0.05).

Conclusion:

In this large, single-center observational study with abatacept-treated RA patients, nearly 60% of the patients remained on therapy and only 9% of drug discontinuations were due to adverse events. The majority of patients discontinued therapy due to inadequate response, mainly when abatacept was the third or more biologic agent administered. Abatacept when used as 1st or 2nd line biologic agent has better survival and efficacy profile.

Abstract Number: 2779

Better Drug Survival of Non-TNFi Compared to TNFi Biologics after Non-TNFi Failure in RA Patients: A Single Center Experience

Konstantinos Thomas, Christos Koutsianas, Argyro Lazarini, Christina Tsalapaki, Chrisoula Hatzara, Anna Kandili, Katerina Antonatou and Dimitrios Vassilopoulos, University of Athens Medical School, Clinical Immunology and Rheumatology Unit, 2nd Department of Medicine and Laboratory, Athens, Greece

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

There are sparse data in the literature regarding the drug survival of TNFi vs. non-TNFi biologics in rheumatoid arthritis (RA) patients who have already failed non-TNFi treatment in a real-life setting. We studied the drug survival of non-TNFi versus TNFi biologics in RA patients after failure of the first non-TNFi biologic in daily clinical practice.

Methods:

Data were collected retrospectively in RA patients treated with different biologics in our center from January 1, 2003 to June 1, 2015. Analyses were stratified by the first type of biologic agent after the 1st non-TNFi failure and then by RF status, csDMARD and corticosteroid co-administration and previous TNFi use. Kaplan-Meier survival analysis and log-rank test of equality pairwise over strata were performed.

Results:

Among 237 biologic treated RA patients, 40 patients with non-TNFi failure (rituximab-RTX n=16, abatacept-ABA n=16, tocilizumab-TCZ n=8) were included; 28/40 (70%) had previously failed TNFi, 39/40 (97.5%) were women, 20/40 (50%) were RF and/or anti-CCP+, their mean age was 61.8 ± 11.3 years with a mean follow-up of 27.2 ± 23.4 months (median 17.5). 70% of patients (28/40) were

switched to a 2nd non-TNFi (TCZ n=17, RTX n=6, ABA n=5) and 30% (12/40) to an TNFi. The baseline characteristics did not differ significantly between the 2 groups with the exception of previous TNFi exposure [non-TNFi: 25/28 (89%) vs. TNFi: 3/12 (25%), p<0.0001]. The mean estimated drug survival after switching to a 2nd non-TNFi was significantly longer (33.8 ± 5.8 months) compared to switching to a TNFi (5.4 ± 1.1 months) (p<0.0001). The corresponding survival rates at 12 months were 74% vs 8.3% and at 24 months 53.8% vs 0%, respectively (p<0.0001). This difference in survival maintained its statistical significance when the groups were stratified according to RF positivity and csDMARD co-administration. All 3 non-TNFi drug classes (RTX, TCZ, ABA) had significantly better survival when compared to TNFi.

Conclusion:

In this observational real life study, in RA patients who had failed the 1st non-TNFi, switching to a 2nd non-anti-TNFi was associated with better drug survival compared to switching to a TNFi, regardless of serological status or csDMARD co-administration.

Relationship between immunogenicity, hypersensitivity reactions and skin tests against Infliximab, Etanercept and Adalimumab in patients with rheumatoid arthritis and ankylosing spondylitis

Background/Purpose:

Anti-TNF drugs can cause systemic or local hypersensitivity reactions.In this study, we aimed to investigate relationships between serum antidrug antibody (ADA), systemic hypersensitivity or local injection site reactionsduring anti-TNF drugs treatmentand to detect the role of skin tests in the diagnosis of hypersensitivity reactions to anti-TNFs.

Methods:

According to 1984 Modified New York Criteria and 1987 ACR classification criteria, 69 AS patients who were using Infliximab, Adalimumab, and Etanercept (n=25, 21, and 23 respectively) and 46 RA patients who were using Infliximab, Adalimumab, and Etanercept (n=9, 20, and 17 respectively) were enrolledin the study.Demographical data, ESR and CRP levels in the serum of the patients were determined, and BASDAI for AS patients and DAS28 for RA patients were assessed.Serum levels of anti-TNFs and ADA to these agents were measured with ELISA methods (Progenika Biopharma SA, Derio Spain). The patients withanti-TNF associated hypersensitivity reactions were evaluated withskin prick (full strenght)/ intradermal tests (1/1000 to 1/10 dilutions) with implicated anti-TNF agents..Readings were conducted after 15 min and 24, 48, and 72 hoursand considered positive if the size of the initial wheal had increased by at least 3 mm in diameter and was surrounded by erythema.

Results:

In total, 28.6% of patients had a history of hypersensitivity reaction to the anti-TNF drugs. Statistically significant relation was identified between hypersensitivity reactions and skin test positivity in all patients (p=0,001) (Table 1). Statistically significant relation was identified between injection site reactions and skin test positivity in patients using Etanercept and Adalimumab (p=0,001, p=0,02 respectively). No relation was found between skin test positivity and the presence of ADAto Anti-TNFs, and disease activity scores.Skin testswith anti-TNFs results in significantly more positive in patients with normal drug levelscompared with patients with low drug levels (table 2).

Conclusion:

This study demonstrates that patients whoexhibit a hypersensitive reaction to anti-TNF drugs produce notably positive results to skin testing without maintaining a direct relationship to serum levels of ADA. There is a need for more comprehensive studies in this field.

Table 1. Relationship allergic reactions and skin test positivity

	Skin test negative		Skin test positive		P
	Number	%	Number	%	
No history of allergy in Infliximab users	24	70,6

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

The distinct role of JAK family members (JAK1, JAK2, JAK3 and TYK2) in signaling for cytokines and growth factors has established these kinases as therapeutic targets for inflammatory diseases and cancer. JAK1 plays a dominant role in signalling for inflammatory cytokines, JAK2 signals for erythropoietin and thus is central to haematopoiesis, and JAK3 is key to the adaptive immune system. We hypothesized that inhibiting JAK1 would provide an efficacious treatment for rheumatoid arthritis (RA), while avoiding effects associated with the inhibition of other JAKs. Filgotinib (GLPG0634) demonstrated selectivity for inhibition of JAK1 over JAK2, JAK3 and TYK2 in biochemical and cell assays. In phase 2 clinical trials, filgotinib rapidly improved signs and symptoms of RA within 1 week with good tolerability and safety. The data presented here bring additional evidence for its clinical JAK1 selectivity in RA patients.

Methods:

RA patients (n=91) with insufficient response to MTX were randomized to receive placebo or 30, 75, 150, or 300 mg filgotinib once-daily orally for 4 weeks as add-on to MTX in a double-blind phase 2a study. Blood was sampled pre-dose and on the last day of treatment. CRP, Chitinase-3 L1 (CHI3L1) and VEGF plasma concentrations were measured using an ELISA assay from R&D Systems and the Myriad RBM InflammationMAP© assay. Hemoglobin concentration was measured using the Siemens Advia technology. Red blood cell (RBC) and reticulocyte counts as well as $CD8^+$ and natural killer (NK: $CD3^-$ $CD16^+$ $CD56^+$) cell percentages were measured by flow cytometry.

Results:

4 weeks of treatment with filgotinib decreased plasma concentrations of the inflammatory disease markers CRP, CHI3L1/YKL-40 and VEGF, whose expressions are controlled by STAT factors. The mean blood concentration of haemoglobin increased by up to 0.4 g/dL at 300 mg (from 12.5 g/dL to 12.9 g/dL), while reticulocyte and RBC counts, which are all directly controlled by erythropoietin, were not impacted by treatment, indicating that JAK2 activity was not inhibited at these doses and regimen. Similarly, no effects were observed on blood $CD8^+$and NK cell percentages, suggesting that the gamma chain signalling, mostly dependent on JAK3 signalling, was not inhibited by filgotinib.

Conclusion:

In patients with active RA, 4 weeks of treatment with filgotinib, a selective inhibitor of JAK1, reduced plasma concentrations of inflammatory markers. This correlates well with the previously reported improvement in signs and symptoms of RA. Treatment did not adversely influence erythrocytes and reticulocytescounts and showed a mean improvement in haemoglobin, supporting the hypothesis that JAK2 signalling was not inhibited. There were no effects on CD8+ or NK cell counts, which are regulated by JAK3 signalling. Thus, these data provide further evidence for the JAK1 selectivity of filgotinib in RA patients. Future studies will need to establish potential clinical correlates of the observed increase in haemoglobin, such as an improvement in fatigue or lower rates of infections with less decrease in immune cells.

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

For active rheumatoid arthritis patients with inadequate response to synthetic disease modifying antirheumatic drugs (DMARDs), biologic agents are indicated. However, the cost of biologics, including tocilizumab (TCZ), is very high, which makes it difficult for all patients to receive biologics because of the associated expenses. A period of 4 weeks has been recommended as the interval between TCZ infusions in active rheumatoid arthritis patients (1). In our clinical experience, however, we observed that longer intervals could also be effective. The aim of the present study was to clarify that not only 5 but also 6 weeks intervals of TCZ infusion induce clinical remission in patients with active rheumatoid arthritis.

Methods:

The rheumatoid arthritis patients who showed inadequate response to synthetic DMARDs and the patients who showed inadequate response to TNF inhibitors and who agreed with TCZ therapy of six weeks interval were enrolled in the present study. Initially, active rheumatoid arthritis patients were infused with 8 mg/kg of TCZ every 6 weeks with oral medicines. The patients who did not achieve clinical remission after 6 months of TCZ infusions at 6 weeks intervals were administered TCZ infusions every 5 weeks or 4 weeks, along with the same doses of the oral medicines. After one year of treatment with same intervals, we evaluated the clinical conditions. The disease activities were evaluated with clinical symptoms, VAS, CRP, and DAS28 score, and clinical remission was estimated as DAS28 score less than 2.6.

Results: In total, 103 patients were enrolled in the present study, and 82% of patients achieved clinical remission with TCZ infusion. Twelve patients did not achieve clinical remission even at 4 weeks intervals. Seven patients dropped out from the study because of personal reasons. Among the patients who achieved clinical remission with TCZ infusion, 71% of patients were with 6 weeks intervals, and 24% were with 5 weeks intervals. To our surprise, the patients who needed 4 weeks intervals of TCZ infusions to achieve remission were less than 5%. In patients who achieved remission with 6 weeks intervals of TCZ infusion, 27% could discontinue both prednisolone (PSL) and methotrexate (MTX), 43% received PSL (5 to 1mg), and 3% received MTX, and 27% received PSL and MTX. Severe adverse events that led to the discontinuation of treatment, including tuberculosis and death, did not occur, and the frequency of other adverse events with infusions at 6 weeks intervals was lower than that at 4 weeks intervals.

Conclusion:

The present study has provided evidence that not only 5 but also 6 weeks intervals of TCZ infusion induce clinical remission in patients with active rheumatoid arthritis, and the finding should be of great interest for patients for both financial and labor reasons.

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Although the majority of RA patients respond to treatment with anti-TNF agents, some patients present with refractory disease (1ry failure) while others show some initial clinical response and eventually lose responsiveness (2ry failure). Assessing primary and secondary failure, and thus the extent of non-response to anti-TNF agents, is complex due to the use of different definitions and variations in the timing of patient assessment in routine clinical care. The purpose of this analysis was to assess the rate of non-response based on different definitions among RA patients treated with anti-TNF in a large observational cohort.

Methods: Patients enrolled in the Ontario Best Practices Research Initiative (OBRI) that were treated with an anti-TNF agent and had available information on treatment discontinuation were included in the analysis. Those who discontinued anti-TNF due to 1ry failure, 2ry failure, or an adverse event (AE) as per the judgment of the treating physician were classified in three different types of failure, based on (i) time of failure (<6 months, 6-12 months, >12 months); (ii) response to treatment, i.e. whether they achieved DAS28 low disease activity (LDA) prior to discontinuation, and; (iii) time and response criteria. Time to treatment discontinuation and time to LDA were assessed with the Kaplan-Meier (K-M) estimator of the survival function.

Results:

953 patients (81.6% female) were included with a mean (SD) age at OBRI enrolment of 56.0 (12.5) and disease duration of 9.8 (9.5). Mean (SD) disease parameters were: DAS28: 4.6 (1.2); SJC: 6.1 (5.2); TJC: 6.8 (6.5); physician global: 4.8 (2.5) cm; patient global: 5.2 (2.7) cm.

After a mean (SD) follow-up of 32.8 (30.6) months, 259 (27.2%) patients were discontinued due to some type of failure; 187 (19.6%) due to non-response and 72 (7.6%) due to safety reasons with mean (SD) K-M-based time to failure of 9.3 (0.4) years. Table 1 summarizes the incidence of each type of failure by type of definition. Among patients failing anti-TNF treatment after 12 months half achieved DAS28 LDA before failure after a median of 37 months.

Table 1: Rates of 1ry and 2ry Anti-TNF Failure Based on Different Definitions

	Failure Definition					
% of patients	**Time Criteria**		**Response Criteria**		**Time & Response Criteria**	
1ry Failure	<6 mos	5.6%	No LDA	14.9%	No LDA	14.9%
Partial Response	6-12 mos	4.5%	-	-	<12 mos + LDA or >12 mos + LDA after 12 mos	2.0%
2ry Failure	>12 mos	9.5%	LDA	4.7%	>12 mos + LDA before 12 mos	2.7%
Safety	-	-	AE	7.6%		-
Early Safety	<6 mos	3.3%	-	-	<6 mos + AE	3.3%
Intermediate Safety	6-12 mos	1.7%	-	-	6-12 mos + AE	1.7%
Late Safety	>12 mos	2.6%	-	-	>12 mos + AE	2.6%

Conclusion: The results of this analysis have shown that the rate of primary failure to anti-TNF treatment may range from 6% to 15% depending on the failure definition used highlighting the need for standardization. Furthermore, approximately half of the patients showing some initial clinical response can achieve LDA over a 3-year period.

Faecal Levels of Calprotectin Are Increased in Patients with Primary Sjögren's Syndrome and Correlates with Disease Activity

Thomas Mandl[1], Bodil Ohlsson[2] and Kristofer Andreasson[3], [1]Dept of Rheumatology, Skåne University Hospital Malmö, Lund University, Malmo, Sweden, [2]Dept of Internal Medicine, Skane University Hospital Malmo, Lund University, Sweden, Malmo, Sweden, [3]Dept of Rheumatology, Skane University Hospital Lund, Lund University, Sweden, Lund, Sweden
First publication: September 29, 2015

SESSION INFORMATION
Session Title: Sjögren's Syndrome: Translational Insights into Sjögren's Syndrome
Session Type: ACR Poster Session C

Background/Purpose: FC is a validated biomarker differentiating inflammatory bowel disease from irritable bowel syndrome. We have evaluated faecal levels of calprotectin (FC) in patients with primary Sjögren's syndrome (pSS) in reference to patient reported indices of gastrointestinal discomfort as well as clinical features of pSS.

Methods: Fourty-four consecutive pSS patients (median 62 (IQR 55, 69) years, 43 females), diagnosed according to the American-European Classification Criteria (AECC), were recruited from the open clinic at the Dept of Rheumatology, Malmö, Sweden and included in the study. Patients were evaluated by patient reported indices of GI disease (the Rome III diagnostic questionnaire for the adult functional GI disorders and Scoring Algorithm) and Sjögren's syndrome (the EULAR Sjögren's syndrome patient reported index, ESSPRI). Disease activity was evaluated by the EULAR Sjögren's syndrome disease activity index (ESSDAI). FC was measured in stool samples with a commercially available ELISA using a monoclonal antibody (Bühlmann Laboratories, Schönenbuch, Switzerland). For comparison, FC levels were evaluated in 21 healthy hospital workers (median age 56 (IQR 47, 58) years, 17 females), not currently treated with non-steroidal anti-inflammatory drugs or proton pump inhibitors.

Results: pSS patients displayed significantly increased levels of FC in comparison to healthy controls (41 mg/g (20, 118) vs. 20 mg/g (20, 53); p=0.036). Of the pSS patients, 39% fulfilled the Rome III criteria for IBS. FC levels correlated significantly with the ESSDAI total score (rs=0.40; p=0.008) whilst not with the ESSPRI total score. Furthermore, patients fulfilling Rome III criteria for IBS had significantly increased ESSDAI (10 (7,10) vs. 5 (0, 9); p=0.028) and ESSPRI total scores (7 (6, 9) vs. 6 (4, 7); p=0.029), but did not show any increased levels of FC (47 mg/g (20, 70) vs. 41 mg/g (20, 128); p=0.415).

Conclusion: FC levels are moderately increased in pSS patients and show a moderate association with disease activity. pSS patients fulfilling the criteria for IBS did not show increased levels of FC but had higher disease activity as well as increased scores in the Sjögren's syndrome patient reported index. We suggest that FC has potential as an objective biomarker in pSS.

SESSION INFORMATION

Session Title: Sjögren's Syndrome: Translational Insights into Sjögren's Syndrome

Session Type: ACR Poster Session C

Background/Purpose: Sjögren syndrome (SjS) is one of the autoimmune disease characterized by the production of autoantibodies. Patients with SjS frequently observe psychiatric manifestation such as depression, anxiety and cognitive dysfunction as is often seen in patients with systemic lupus erythematosus (SLE). Anti-glutamate receptor subunit NR2 antibodies (anti-NR2) is one of the pathogenic autoantibodies related to psychiatric disorder (PD) in patients with SLE. However, anti-NR2 in patients with SjS has not been clarified. The aim of this study is to investigate the association of anti-NR2 and PD in patients with primary SjS (pSjS).

Methods: We examined 35 patients with pSjS, 17 patients with rheumatic diseases other than SLE or SjS as disease control (DC) and 36 healthy individuals (HC). Anti-NR2 in serum were measured by ELISA.

Results: The level of anti-NR2 in serum was significantly elevated in patients with pSjS (47.3±69.4U/ml), compared to those with DC (14.0±16.6, p=0.0043) or HC (16.8±9.6, p=0.0226). In pSjS patients with PD, the serum anti-NR2 level was significantly higher than that in patients without PD (p=0.0003). Also, the positivity of anti-NR2 in serum from patients with pSjS was found to be a significant risk factor for PD in pSjS patients (OR 38.0, 95%CI 5.5-789.3, p=0.0018) by logistic regression analysis.

Conclusion: Anti-NR2 are significantly associated with PD in patients with pSjS.

miR200b-5p: A Possible Predictor of Lymphoma Development in Sjögren's Syndrome (SS)?

Efstathia K. Kapsogeorgou[1,2], Vasiliki C. Gourzi[1] and Athanasios G. Tzioufas[1], [1]Pathophysiology, School of Medicine, National University of Athens, Athens, Greece, [2]Pathophysiology, School of Medicine, National University of Athens, Greece, Athens, Greece

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Sjögren's Syndrome: Translational Insights into Sjögren's Syndrome

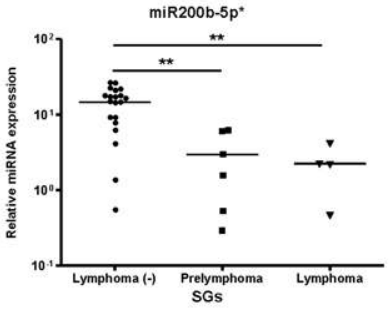
Session Type: ACR Poster Session C

Background/Purpose: miR200b miRNAs (miR200b-3p and miR200b-5p) are critical regulators of the expression of oncogenes and tumour suppressor genes. Herein, we sought to investigate whether their expression in salivary gland tissues (SG) is related to SS-related lymphoma development.

Methods: miR200b-3p and miR200b-5p expression in SG tissues was analyzed by real-time PCR in total RNA from 30 SS patients (all women), including 20 patients that did not develop SS-lymphoma during follow up (lymphoma(-); median follow up time since biopsy performance, range: 3.8yrs, 3.4-10yrs), 6 patients that develop MALT-lymphoma in the future (prelymphoma; median follow up time till lymphoma diagnosis, range: 4.0yrs, 1.0-5yrs) and 4 patients that had MALT-lymphoma at the time of biopsy (lymphoma). Significant differences in miR expression between SS subgroups were analysed by Tukey's multiple comparison test, whereas associations with other histologic futures by Mann-Whitney test.

Results: miR200b-5p, but not miR200b-3p, was significantly down-regulated in SG tissues of prelymphoma ($p \leq 0.01$) and lymphoma ($p \leq 0.01$) SS patients compared to lymphoma(-) SS patients (mean relative expression±SE: 2.97±1.09, 2.24±0.75 and 14.67±1.76, respectively) (Figure). On the contrary, miR200b-3p levels in SGs were significantly reduced in SS patients with SG infiltrates that organize into ectopic germinal centres (GC) compared to those without (1883±682 vs 51090±28330, p=0.05, respectively).

Conclusion: The significantly lower expression of miR200b-5p in SS patients that had or developed SS-related MALT lymphoma in the future implicates it in lymphomagenesis, whereas its significant downregulation in prelymphoma SGs possibly suggests that miR200b-5p represents a potential prognostic marker for future lymphoma development. Evaluation of its expression in a larger cohort is needed. Finally, considering that GC formation has been linked to lymphomagenesis, the deregulated expression of its paired miRNA, miR200b-3p, in SS patients with GCs could represent a continuum of lymphomagenesis.



Disclosure: E. K. Kapsogeorgou, None; **V. C. Gourzi**, None; **A. G. Tzioufas**, None.

Expression of Interferons Lambda in Salivary Glands of Patients with Sjögren's Syndrome

Eirini Apostolou[1], Efstathia K. Kapsogeorgou[1], Orsia D. Konsta[1], Maria Ioanna Saridaki[2], Evangelos Andreakos[2] and Athanasios G. Tzioufas[1], [1]Pathophysiology, Faculty of Medicine, School of Health Sciences, National and Kapodistrian University of Athens, Athens, Greece, [2]Clinical, Experimental Surgery and Translational Research, Biomedical Research Foundation Academy of Athens, Athens, Greece

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Sjögren's Syndrome: Translational Insights into Sjögren's Syndrome

Session Type: ACR Poster Session C

Background/Purpose: Type I and II interferons (IFNs) have been implicated in the pathophysiology of Sjögren's Syndrome (SS). Recently a new family of IFNs, namely type III IFNs or Interferons lambda (IFNλs), has been identified, containing three distinct members; IFNλ1/IL29, IFNλ2/IL28A and IFNλ3/IL28B. IFNλs share IFNλR1/IL10R as a common signaling receptor. Despite the fact that their function and regulation has not been completely understood, they exhibit significant antiviral activity. Initial studies implicate IFNλs in several human disorders, including cancer and autoimmune diseases. In this study we sought to investigate the pattern of their expression in SS patients.

Methods: The expression of all IFNλs and their common IFNλR1 receptor was investigated in salivary gland (SG) biopsies from 45 patients with primary SS (according to the American–European Consensus Group criteria) that had variable degree of infiltration (mild, intermediate or severe) and 17 non-SS sicca complaining controls. mRNA and secreted IFNλ levels were measured from salivary gland epithelial cells (SGECs), both resting or following polyinosinic-polycytidylic acid (polyI:C) treatment, in representative samples from the aforementioned groups.

Results: Expression of all IFNλs and their common IFNλR1 receptor was detected in SGs of both SS patients and controls. IFNλ1 (IL29) was detected in ductal epithelia, displaying higher intensity in SGs from SS patients and particularly those with intermediate lesions. IFNλ2 (IL28A) and IFNλ3 (IL28B) were expressed in both ductal and acinar epithelia, as well as in infiltrating Mononuclear Cells (MNCs). Interestingly, regarding IFNλ2, higher expression was observed in the epithelia of SS patients compared to controls. The common receptor IFNλR1 is expressed in all types of cells except fibroblasts, and in higher levels in SGs from SS patients. Importantly, high expression of IFNλR1 was additionally identified to infiltrating plasmatocytoid Dendritic Cells (pDCs). Moreover, TLR3

stimulation by polyI:C treatment, produced high levels of IFNλ1/IL29, IFNλ2/IL28A and IFNλ3/IL28B in all SGECs.

Conclusion: Our findings implicate IFNλs in SS pathophysiology. Identification of all IFNλs and their common signaling receptor locally in SG suggests a potential role for IFNλs in autoimmune responses that govern SS. Further studies are needed to elucidate the role of IFNλs in SG physiology and SS.

SESSION INFORMATION

Session Title: Sjögren's Syndrome: Translational Insights into Sjögren's Syndrome

Session Type: ACR Poster Session C

Background/Purpose: The previous reports showed that DNA microarray in Sjögren's syndrome (SS) identified the genes associated with mononuclear infiltrates such as immunoglobulin, human leukocyte antigen, T cell receptor and interferon-inducible genes. However, it is possible that the results might reflect nonspecific gene expression due to inflammatory cell infiltration, since the controls were healthy individuals. Therefore, we conducted DNA microarray analysis in labial salivary glands (LSGs) of SS patients and those of IgG4-related disease (IgG4-RD) patients, which also show inflammation, to compare gene expression in LSGs of SS patients with IgG4-RD patients and to identify genes specifically involved in the pathogenesis of SS.

Methods:

1) Gene expression was analyzed by DNA microarray in LSGs of SS patients (n=5), IgG4-RD patients (n=5) and healthy controls (HC) (n=3). All patients with SS and IgG4-RD fulfilled the Japanese Ministry of Health criteria for the diagnosis of SS (1999) and the comprehensive diagnostic criteria for IgG4-RD (2011), respectively. Moreover, all of the patients had not received steroids or any immunosuppressive agents. After the obtained microarray data were normalized by FARMS algorithm, Differentially expressed genes (DEGs) upregulated in SS than in IgG4-RD were identified in pairwise comparisons (false discovery rate<0.05) by rank products method. Approval for this study was obtained from the local ethics committee and a signed informed consent was obtained from each subject.

2) Validation of the results was performed by quantitative PCR using LSGs obtained from other patients with SS (n=11), IgG4-RD (n=11), and HC (n=3) than those examined by DNA microarray.

3) The protein production of validated genes and expressing cells in LSGs from SS patients and IgG4-RD patients were examined by immunofluorescence assay.

4) Functional analysis of the DEG was performed using $CD4^+$ T cells isolated from peripheral blood mononuclear cells (PBMCs) by comparing the gene expression of the DEG in peripheral $CD4^+$ T cells and the population of Th17 cells differentiated from peripheral $CD4^+$ T cells in Th17 polarizing conditions between patients with SS and HC.

Results:

1) In patients with SS, 1785 up-regulated probe sets (corresponding to 1320 up-regulated genes) were identified as DEGs in comparison with those with IgG4-RD.

2) CXCL9, NR4A2, DPP4, SGK1, and PDK1 were selected as candidate genes for validation, according to rank<150, high expression levels, small variance and relation to T cell functions. PCR validated significantly higher expression of NR4A2 and DPP4 in SS patients than in IgG4-RD patients.

3) Immunofluorescence staining in LSGs revealed higher production of NR4A2 and DPP4 in SS patients than in IgG4-RD patients and localization of NR4A2 in IL-17$^+$ CD4$^+$ T cells of SS patients.

4) Peripheral CD4$^+$ T cells of patients with SS showed significantly higher expression of NR4A2, and more preferably differentiated into Th17 cells than those of HC.

Conclusion:

The gene expression pattern of LSG in patients with SS was different from that in those with IgG4-RD.

NR4A2 might be a novel molecule involved in the pathogenesis of SS via Th17 differentiation.

SESSION INFORMATION
Session Title: Sjögren's Syndrome: Translational Insights into Sjögren's Syndrome
Session Type: ACR Poster Session C

Background/Purpose: To determine whether B-cell markers (blood and minor salivary gland (SG) B-cell depletion (BCD), autoantibodies, BAFF) are associated with clinical response to rituximab in patients with primary Sjögren's syndrome (pSS).

Methods: 45 pSS patients were included: 14 who received low-dose rituximab (two 375 mg/m² infusions) in an open-labelled study (group I); and 17 who received full-dose rituximab (two 1000 mg infusions) from a randomized-controlled study (group II), as well as their 14 placebo. SG B-cell proportion was assessed using a pixel-based software analysis of digitized double-immunostained (CD3/CD20) whole SG slides. Response was defined at W24 according to the Sjögren's Syndrome Responder Index (SSRI)-30.

Results: Response rate was 50% in both groups of rituximab-treated patients. Duration of blood BCD was similar in the 2 groups despite the difference in rituximab dosage, and was highly correlated with residual serum rituximab levels as lately as W16. SG B-cell dynamics mirrored blood B-cell levels, with a drastic SG B-cell proportion decrease at W12 (group I), but an increase at W24 in half of the patients from group II who had already experienced blood B-cell return. Duration of BCD was not associated with the clinical response, but responders had lower baseline SG B-cell proportion. Baseline serum BAFF level correlated with SG B-cell proportion, as well as with other B-cell activation markers (serum free-light chains, serum IgG, beta-2 microglobulin, or auto-antibody levels). This global B-cell hyperactivation was associated with the clinical response, with higher serum BAFF levels in non-responders.

Conclusion: In pSS patients, intense BAFF-driven B-cell activation is associated with nonresponse to a single rituximab course.

Leflunomide/Hydroxychoroquine Combination Treatment Additively Inhibits T Cell Receptor/Toll-like Receptor 9-Triggered Th1 and Th17 Cytokine Secretion

SESSION INFORMATION

Session Title: Sjögren's Syndrome: Translational Insights into Sjögren's Syndrome

Session Type: ACR Poster Session C

Background/Purpose: Primary Sjögren's Syndrome (pSS) is a systemic auto-immune disease, leading to an exocrinopathy of mainly salivary and lachrymal glands. T- and B-cell-driven immunity is critically involved in its immunopathology. Recently we demonstrated synergistic T- and B-cell activation upon T-cell triggering and TLR7/9-driven B-cell activation in pSS patients, accompanied by synergistic induction of immunoglobulins and IFNγ- and IL-17- producing T-cells. In addition, TLR7/9-expressing activated pDCs associated with increased type I IFNs and IFN-inducible genes are increased pSS patients. Several studies have shown that the DMARDs leflunomide (LEF) and hydroxychloroquine (HCQ) inhibit immune activation in pSS, but given separately only show moderate efficacy[(1-4)]. However, LEF and HCQ target different pathways with overlapping, but also potentially additive mechanisms, where LEF primarily targets T- and B-cells and HCQ TLR7/9-driven B-cell and pDC activation.

Objective: To assess the additive effects of LEF and HCQ on CD4 T- and B-cell activation and Th cytokine and IFN-α secretion *in vitro,* employing T cell receptor/TLR9-triggered PBMC.

Methods: PBMCs from healthy persons and pSS patients were cultured with antigen (SEB), TLR9-agonist (CPG-C) and their combination (n=11), in presence or absence of different dosages of LEF, HCQ and their combination (at least n=4). Proliferation of T- and B-cells (using Cell Trace Violet) and release of IFN-α, IFN-γ and IL-17 was measured (Luminex).

Results: In line with robust T and B cell activation, IFN-γ and IL-17 production and synergistic IFN-α production, indicative of pDC activity, was achieved by a combination of SEB and TLR9 ((all $p<0.001$). Both HCQ and LEF potently and dose-dependently inhibited B- and T-cell proliferation and IFN-α production. Mean inhibition of IFN-a was 99% and 85% at 10 µM HCQ and 100 µM LEF, resp and 100% using LEF/HCQ combination (both $p<0.05$). At the latter concentrations HCQ and LEF additively inhibited IFN-γ production (mean: HCQ 41%, LEF 35%, and combination 75%, all $p<0.05$; both HCQ and LEF vs combination $p<0.05$) and IL-17 production (mean: HCQ 68%, LEF 77%, and combination 85%, all $p<0.05$, HCQ vs combi $p=0.05$ and LEF vs combi $p=0.19$). Both T- and B-cell proliferation were additively and significantly inhibited by a combination of HCQ and LEF (all $p<0.05$).

Conclusion: HCQ and LEF robustly inhibited lymphocyte proliferation and cytokine production with additive inhibition of Th1 and Th17 cytokine secretion (IFN-γ and IL-17) and T- and B-cell proliferation. These findings could indicate the potential surplus value of combination therapy with HCQ and LEF for patients with pSS.

SESSION INFORMATION
Session Title: Sjögren's Syndrome: Translational Insights into Sjögren's Syndrome
Session Type: ACR Poster Session C

Background/Purpose:

Three prime Repair Exonuclease 1 (TREX-1) is an exonuclease involved in DNA repair preventing genomic instability. TREX-1 variants have been previously associated with activation of type I interferon (IFN) pathway in patients with Aicardi-Goutieres syndrome, as well as in Familial chilblain lupus. Primary Sjogren's syndrome (SS) -a chronic autoimmune disorder affecting the exocrine glands with a high predilection for B-cell lymphoma development- is also characterized by the presence of type I IFN signature in approximately half of affected individuals. The goal of the present study was to explore whether TREX-1 variants rs11797 (A>G, p.Y177Y), 5'UTR rs3135941 (C>T, NG_009820.1:g.5439T>C) and rs3135945 (intronic, G>A) polymorphisms could influence the risk of SS and SS related lymphoma.

Methods:

Three single nucleotide polymorphisms (SNPs) of the TREX-1 gene (rs11797, rs3135941 and the rs3135945) were evaluated in 229 SS-non lymphoma, 89 SS-lymphoma (19 non-MALT, 70 SS-MALT) and 240 healthy controls (HC) by PCR-based assays. All patients were followed in the Department of Pathophysiology, School of Medicine and the Department of Rheumatology, General Hospital of Athens between 2008-2014 and fulfilled the 2002 American/European criteria for the classification of primary SS. Allele and genotype frequencies in primary SS patients and HC were determined by SHEsis and SNPStats software.

Results:

No statistically significant differences were detected in the frequency of the above SNPs tested between SS-non lymphoma, SS-lymphoma patients and HC ($p>0.05$). However, SS non-MALT lymphoma patients had significantly increased prevalence of the SNP rs11797 G allele compared to HC (OR: 2.28, $p=0.02$). Of interest, the presence of the GC haplotype (rs11797 and rs3135941) conferred increased susceptibility for SS-non MALT lymphoma patients compared to both HC and SS-non lymphoma patients [OR 95% (CI): 2.33 (1.01-5.36), $p=0.04$ and 1.53 (1.02-2.28), $p=0.04$, respectively). The TREX-1 SNP rs3135945 was observed in 1/257 SS patients but not in the HC group.

Conclusion:

Increased frequency of the TREX-1 GC haplotype (rs11797 and rs3135941) in SS individuals complicated by non-MALT lymphoma may imply impaired DNA repair as an additional mechanism for SS-related lymphomagenesis.

Not Only Sjögren's Syndrome. EBV Infection Reactivation As a Risk Factor of the Dryness Symptome Development

Maria Maslinska[1] and Anna Zuk-Wasek[2], [1]Clinic of Early Arthritis, Institute of Rheumatology, Warsaw, Poland, [2]2. National Institute of Public Health – National Institute of Hygiene (NIPH – NIH, Warsaw, Poland
First publication: September 29, 2015

SESSION INFORMATION
Session Title: Sjögren's Syndrome: Translational Insights into Sjögren's Syndrome
Session Type: ACR Poster Session C

Background/Purpose:

The glandular cell apoptosis in Epstein-Barr virus (EBV) infection may play role in primary Sjögren's Syndorme (pSS) development, possibly causing progressive gland damage and dysfunction, reflected by the reduced secretion and classic clinical symptoms. The aim of the study was to investigate: (i) EBV infection status in healthy individuals and patients with confirmed pSS or isolated dryness symptoms; (ii) searching for differences in salivary gland imaging among these individuals.

Methods:

We evaluated 3 groups of individuals: (i) 58 patients with established diagnosis of pSS (mean age 52±15), that included 49 (84%) female (F) and 9 (16%) males (M); (ii) 36 subjects with symptoms of eye or/and mouth dryness [mean age 55±12; 34 (94%) F, 2 (6%) M] and (iii) 20 healthy volunteers [mean age 45±11; 15 (75%) F and 5(25%)M]. Profile of IgM/IgG antibodies specific to EBV proteins was determined by ELISA test, allowing indication of recent/past EBV infection or reactivation. Sjögren's specific antibodies A (SS-A) and B (SS-B), anti-nuclear antibodies (ANA), rheumatoid factor (RF) were also identified. The ocular tests included Schirmer test and corneal staining (fluorescein and lissamine green). In 93(88%) patients the salivary gland ultrasonography (SGUS) examination was performed. Differences between groups were analyzed using the χ2-square test (categorical variables) or U Mann-Whitney test (continuous variables). Statistical significance was set at $p<0.05$. The study was approved by Ethics Committee; subjects gave informed consent.

Results:

The majority of patients with pSS (n=44; 76%) had reactivation of EBV infection, with 11 (19%) having markers of past infection, 2 (3%) of primary infection, and only 1(2%) was without EBV exposure. By contrast, in healthy volunteers EBV reactivation was stated in 40% (n=8), past infection was found in 50%(n=10), one person (5%) had primary infection and another one was not exposed to EBV. The differences in EBV infection status between pSS and healthy control group were statistically significant (p-value >0,031). All patients with dryness symptoms without pSS, were exposed to EBV and 83%(n=30) had EBV reactivation, 11% (n=4) past infection, 6% (n=2) primary infection. There were no statistically significant differences between patients with pSS with EBV reactivation and ones with past EBV infection as to the presence of SS-A/SS-B antibodies or RF, the ocular test values or the degree of focus score in histopathological evaluation. Parenchymal heterogeneity was more frequent in pSS group than in patients with symptoms of dryness alone: 77% vs 23% (p<0,001). There was no change in SGUS allowing differentiation of patients with EBV infection or reactivation.

Conclusion:

EBV reactivation is significantly more often observed in individuals with pSS or dryness symptoms, than in healthy volunteers. There were no differences in SGUS in patients with past exposure or reactivation of EBV. SGUS of pSS patients confirmed previous observations of parenchymal heterogeneity as most common abnormality.

The study was supported by National Science Center; grant no. 2012/05/N/NZ5/02838.

SESSION INFORMATION

Session Title: Sjögren's Syndrome: Translational Insights into Sjögren's Syndrome

Session Type: ACR Poster Session C

Background/Purpose: Primary Sjögren's Syndrome (pSS) is an autoimmune disease mediated by B-cells as evidenced by the occurrence of non-Hodgkin lymphoma and increased B-cell markers in salivary glands and serum of pSS patients. Interleukin 35 (IL35) is a new anti-inflammatory and immunosuppressive cytokine secreted by B-regulatory cells that could play a major role in controlling autoimmune diseases. We decided to study the link between IL35 and disease activity in pSS patients.

Methods: IL35 serum level was quantified using an ELISA kit (BioLegend®) on 385 patients from the French multicentric pSS ASSESS cohort and 50 healthy controls. The difference in IL35 serum level between patients and controls was assessed using a Mann Whitney test. The association between IL35 level and several subsets of patients was assessed using a chi-square test. IL35 high level has been defined as the upper quarter of cytokine level in ASSESS cohort.

Results: IL35 serum level was significantly decreased in pSS patients compared to healthy controls (p=0.0001, mean 7.31 [5.75-8.82] ng/ml and 8.66 [4.45-12.86] ng/ml, respectively). Within the cohort, we observed a higher proportion of patients with low disease activity defined by an ESSDAI score <5 in the group with high level of IL35 compared to those with low level of IL35 (72% and 60%, respectively; p=0.05). We observed that 99% of patients with high serum levels of IL35 did not developed lymphoma *versus*93% in the group with low IL35 (p=0.03).

Conclusion: This study suggests that the level of the immunosuppressive cytokine IL35, usually secreted by regulatory B cells and plasma cells, is decreased in the serum of patients with pSS and essentially in patients with the more active disease. Further studies in pSS on regulatory B cells and plasma cells as well as in animal models of autoimmune diseases assessing the effect of recombinant IL35, would help to decipher whether this regulatory cytokine could be of interest for future therapeutic approaches.

SESSION INFORMATION

Session Title: Sjögren's Syndrome: Translational Insights into Sjögren's Syndrome

Session Type: ACR Poster Session C

Background/Purpose: A new consensual scoring system for Ultrasonography (US) of the salivary gland in pSS is required and endorsed by an international group of experts (US-pSS Study group).

The objectives were to define and validate relevant ultrasonographic components of the salivary glands in Sjogren.

Methods: A consensus exercise about definitions of the different ultrasonographic components of the salivary glands was done and discussed between experts on the field of US pSS during 2 annual meetings. Using these preliminary definitions, a reliability exercice was done on static images (60 images of both parotid and submandibular glands were read twice). Then an interreliability exercise was performed by a group of 5 experts with acquisition on 20 pSS patients. On this basis, we selected the most relevant US components, to build the new US-pSS score

Results: Eight different components evaluating the abnormal parenchyma of salivary glands were defined (echogenicity, homogenicity, presence or absence of hyperechoic bands, number of hypoechoic ares, and location of hypoechoic areas, lymph nodes, presence or absence of calcifications, visualisation of posterior border) in Sjögren. Concerning reliabilities, the web exercise demonstrated good inter and intra observers agreements applying these definitions on US parotid gland and submandibular glands (table 1) particularly in taking homogeneity as the principal important item in this definition. In contrast posterior border or presence of calcification had low agreement. The inter reliability exercice on pSS patients showed good kappa values concerning parotids glands but very low for submandibular glands

Conclusion: This is the first consensus-based US definitions on salivary glands and its elementary components. These results of the reliability exercice on static images showed good results and permit to apply these preliminary definitions on pSS patients with good results in parotids glands. With these results, a new US score could be assessed and used in routine practice

SESSION INFORMATION
Session Title: Sjögren's Syndrome: Translational Insights into Sjögren's Syndrome
Session Type: ACR Poster Session C

Background/Purpose: To identify independent predictors of fatigue in primary Sjogren's Syndrome (pSS) patients taking into account clinical, laboratory and psychological features and to explore the potential role of interferon (IFN)-induced gene indoleamine 2,3-dioxygenase (IDO-1), anti-21 hydroxylase [anti-21(OH)] antibodies and soluble B-cell activating factor (sBAFF).

Methods: Detailed clinical and laboratory characteristics were recorded for 106 pSS patients. FACIT-F, Zung Depression Scale, State-Trait Anxiety Inventory, Eysenck Personality Questionnaire Scale and Athens Insomnia Scale were adopted to assess fatigue, depression, anxiety and sleep disturbances respectively. Peripheral whole blood expression levels of IDO-1, as well as type I and II IFN-induced genes were calculated using qRT-PCR. Serum anti-21(OH) antibodies and sBAFF levels were determined by a radioimmunoassay and an ELISA, respectively. Univariate and multivariate models were performed to identify determinants of fatigue.

Results: Fatigue was detected in 32 out of 106 (30.2%) of pSS patients. In univariate analysis, fatigue was associated with arthralgias/myalgias, hydroxychloroquine therapy, both state and trait anxiety scores, depression and neuroticism, as well as impaired sleep patterns. Multivariate analysis revealed neuroticism [OR=6.0 (95%CI:1.5-23.8)], depression [OR=3.4 (95%CI:1.0-12.2)] and state anxiety [OR=3.0 (95%CI:0.9-10.6), as independent predictors of fatigue. sBAFF levels, anti-21(OH) autoantibodies and IDO-1 mRNA expression did not significantly differ between fatigued and non-fatigued pSS patients.

Conclusion: Depression, anxiety and neuroticism play a major role in pSS-associated fatigue and should be addressed, in clinical practice, with active collaboration between rheumatologists and mental health professionals. Further studies are warranted in order to

explore underlying pathophysiological pathways that might explain fatigue in the setting of pSS.

Elevated Serum Immunoglobulin G Is a Prognostic Factor for Progression of Interstitial Lung Disease in Primary Sjögren's Syndrome

Eriko Ishioka[1], Katsuya Suzuki[2], Naoshi Nishina[2], Hidekata Yasuoka[3], Kunihiro Yamaoka[2] and Tsutomu Takeuchi[2], [1]Division of Rheumatology, Department of Internal medicine, Keio University School of Medicine, Tokyo, Japan, [2]Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan, [3]Division of Rheumatology, Keio University School of Medicine, Tokyo, Japan

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Sjögren's Syndrome: Translational Insights into Sjögren's Syndrome

Session Type: ACR Poster Session C

Background/Purpose: Lung involvement is a systemic manifestation of primary Sjögren's syndrome (pSS), however, the prevalence in pSS is various (9-75 %) and details are still unclear. In addition, interstitial lung disease (ILD) associated with pSS shows several radiographic patterns such as nonspecific interstitial pneumonia (NSIP) and usual interstitial pneumonia (UIP). Although UIP pattern is known as a prognostic determinant in idiopathic interstitial pneumonia, risk factors for progression of ILD in pSS has not been established.The aim of this study is to investigate clinical features of lung involvement in pSS and prognostic factors for exacerbation of pSS-ILD.

Methods: Total 300 consecutive patients with pSS diagnosed according to the 1999 revised Japanese criteria for the diagnosis of pSS, between January 2012 and September 2014 at our division were enrolled after exclusion of secondary SS. Clinico-radiographic characteristics were retrospectively investigated and statistically analyzed. ILD progression was defined by exacerbation on chest computed tomography (CT) image or pulmonary function test.

Results: To screen lung involvements, chest X-ray was underwent in 239 patients and chest CT was evaluated in 111 patients. Lung involvements were confirmed in 31.4%. Mean age was 68.5 years old. This included ILD (n=23, 9.6%), chronic airway lesion (n=11, 4.6 %), cystic lesion (n=3, 1.3 %), and malignant lymphoma (n=3, 1.3 %). Notably, the prevalence of smoking history (≥10 cigarettes per day, p=0.03), and elderly (≥65 years old, p<0.01) were higher in pSS with lung involvement than pSS without lung involvement. Radiological patterns of 23 pSS-ILD were followings: 17 for NSIP (73.9%), 5 for UIP (21.7%) and 1 OP (4.35%). 9 were progressive and 17 were stable during observation periods. Comparing ILD progressive group with stable group, serum immunoglobulin (Ig) G were significantly elevated (2263 +/- 479 vs 1726 +/- 519 mg/dl, p=0.02) and ESSDAI was higher (10.8 +/- 1.9 vs 6.1 +/- 1.3, p<0.01).There was no significant difference in the extent of reticular abnormality, ground glass attenuation, consolidation, and micronodules between two groups. On the other hand, UIP patterns having honeycombing were significantly higher in ILD-progressive group (p=0.04). Remarkably, serum IgG levels were significantly elevated in the progressive case with UIP pattern (p=0.02), but not with NSIP pattern.

Conclusion: This study demonstrated that serum IgG levels was elevated in progressive group in pSS-ILD and a prognostic factor particularly in pSS-ILD patients with UIP pattern. In the pSS patients with UIP pattern and serum IgG elevation, careful observation should be needed for appropriate management of ILD.

SESSION INFORMATION

Session Title: Sjögren's Syndrome: Translational Insights into Sjögren's Syndrome

Session Type: ACR Poster Session C

Background/Purpose: Primary Sjögren's syndrome (pSS) is a systemic autoimmune disease characterized by dry eye and mouth. Measurements of un-stimulated salivary flow and Schirmer's test are classically used as assessment of salivary and lachrymal gland dysfunction. However, these tests tend to be easily affected by environmental and psychological factors, and thus development of more stable and effective surrogate marker has been strongly desired for the objective evaluation in the clinical setting. In this study, we investigated novel serum protein biomarkers for the salivary dysfunction of pSS patients.

Methods: Serum protein concentrations were measured by comprehensive high throughput proteomics assay (SOMAscan™). Candidate biomarkers positively correlated with glandular dysfunction of pSS patients were statistically analyzed. As objective indicators represents glandular dysfunction, uptake and excretion rate (%) of parotid gland (PG), submandibular gland (SMG) examined by 99m Tc schintigraphy and Greenspan's grade score, and other clinical information were also applied to the study.

Results: A total of 1128 serum proteins in 30 pSS and 30 untreated rheumatoid arthritis (RA) patients, and 30 healthy controls were comprehensively screened using SOMAscan™. We first screened differentially up- and down-regulated proteins among the three groups, 55 proteins were statistically extracted ($p<0.05$ in the U-test, and fold change ≥ 1.2 or ≤ 0.83). To then extract biomarker for the glandular dysfunction, the correlation between protein levels and data of schintigraphy or lip biopsy in pSS patients. Next, we calculated association 55 up-regulated proteins in pSS with intake and excretion rate. Finally, we identified that LAG3, TNF-R2, LKHA4, MMP-12, granzyme A, β2-microglobulin, HCG, PF-4 were negatively correlated with intake and excretion rate of salivary gland scintigraphy. Greenspan's grade was positively correlated with β2-microglobulin, MCP-3, EPHB2, CCL28, and TRAIL-R4.

Conclusion: We successfully identified novel serum proteins associated with salivary dysfunction of pSS. These proteins may be potential therapeutic targets for salivary dysfunction.

SESSION INFORMATION

Session Title: Sjögren's Syndrome: Translational Insights into Sjögren's Syndrome
Session Type: ACR Poster Session C

Background/Purpose: Protein tyrosine phosphatase non-receptor 22 (PTPN22) gene encodes a protein tyrosine phosphatase previously shown to inhibit antigen-receptor signaling in T cells and promoting type I interferon (IFN) production by myeloid cells. PTPN22W* represents a single nucleotide polymorphism (SNP), namely C1858T (rs 2476601), which has been previously shown to increase susceptibility of various autoimmune diseases including Type 1 Diabetes, SLE and RA. In regard to Sjögren's Syndrome (SS), available data so far is rather inconclusive. SS is a chronic autoimmune disease, with a prominent peripheral type I IFN signature in approximately half of patients. In the present study, we sought to explore whether the PTPN22W* risk variant would influence the risk of primary SS in a Greek population and investigate potential associations with clinical, laboratory features as well as type I IFN scores in peripheral blood.

Methods: PTPN22W* was identified with Real-Time PCR by TaqMan SNP genotyping assay in peripheral blood DNA samples derived from 326 patients with primary SS (91 SS-lymphoma and 235 SS non-lymphoma) according to the 2002 revised version of the European criteria proposed by the American-European Consensus Group, as well as from 448 unrelated healthy controls (HC) of similar age and sex distribution. Available peripheral blood from 121 SS patients was subjected to Real-Time PCR for 3 interferon inducible genes (IFIGs) preferentially induced by type I IFN and a type I IFN score was determined. Clinical characteristics, demographics and laboratory parameters were analyzed for possible associations with PTPN22W* using SPSS 21.0.

Results: Increased prevalence of the PTPN22W* variant was detected in primary SS population compared to HC [32/326, 9.8% vs 21/448, 4.7%, OR 95% (CI): 2.2 (1.3-3.9), p-value: 0.006]. Of interest, the presence of the PTPN22W* variant was associated with lower type I IFN scores in peripheral blood (Figure 1). After we stratified primary SS patients into low and hi IFN subgroups, the corresponding frequencies were 12.7% and 3.4%, respectively. PTPN22W* carriers had a 3-fold increased risk for low-IFN SS development compared to HC [OR 95% (CI): 3.0 (1.2-7.0), p=0.01]. No association with autoantibody status or presence of lymphoma was observed.

Conclusion: PTPN22W* may be involved in SS genetic predisposition implying an additional shared etiological origin in autoimmune disorders. Association of PTPN22W* with low IFN scores in peripheral blood of SS patients provides further evidence of the role of genetic contributors as determinants of distinct IFN patterns in patients with autoimmune diseases.

SESSION INFORMATION

Session Title: Sjögren's Syndrome: Translational Insights into Sjögren's Syndrome

Session Type: ACR Poster Session C

Background/Purpose: Increasing data has suggested that individuals with systemic lupus (SLE) are at increased risk of herpes zoster (HZ) reactivation compared to healthy controls and patients with rheumatoid arthritis, although the immunological basis of increased risk remains unknown. Primary Sjogren's syndrome (PSS) shares several immunologic abberations with SLE, but disease manifestations are often less severe and are less likely to be treated with immunosuppression: risks of HZ in this population has remained unstudied.

Methods: We mailed a single-page self-completing questionnaire to participants of 3 established Oklahoma Cohorts: the Oklahoma Lupus Cohort, the Sjogren's Research Cohort, and the Oklahoma Community Engagement Cohort (individuals without autoimmune diseases recruited to serve as control subjects). Questionnaires covered questions about recall of chicken pox infection, HZ reactivation, complications, and therapy, as well as receipt of the Zostavax vaccine. Stored blood samples from respondents were analyzed for cytokines using the xMAP bead assays for 12 cytokines from eBiosciences using a Bio-Rad Bioplex 200 system and BLyS levels were assessed by ELISA to identify cytokines that may be associated with HZ susceptibility.

Results: Completed questionnaires were returned from 635 participants: 350 healthy controls (HC), 163 with PSS and 122 with SLE. The mean age of respondents was 53 years, and the majority were Caucasian women. Fewer than 20% of HC reported HZ reactivation, compared to 30.7% of PSS and 36.4% of SLE subjects. The mean age at development of first HZ episode was 10 years younger for SLE than for PSS or HC (39 vs 49 years, $p<0.001$). Although many cytokine concentrations were higher in SLE than PSS or HC, these differences were not statistically significant (Table 1). Multivariate logistic regression found the Odds Ratio for HZ was 1.03 (95% CI 1.02-1.05) for each year of age, 1.8 (95% CI1.2-2.8) for PSS, and 2.7 (1.7-4.3) for SLE. Ro positivity, but not age, was associated with HZ in SLE patients; both age and anti-Ro status were relevant in pSS. Among SLE patients, Ro positivity was predictive of earlier age of HZ; this was not seen for pSS. Tested cytokines were not associated with development of HZ.

Conclusion: Subjects with PSS have increased rates of HZ compared to healthy individuals, although less so and at older ages than SLE patients. Ro seropositivity, but not cytokines, was associated with development of HZ in both SLE and pSS.

SESSION INFORMATION
Session Title: Sjögren's Syndrome: Translational Insights into Sjögren's Syndrome
Session Type: ACR Poster Session C

Background/Purpose: To evaluate bone mineral density (BMD), microarchitecture, strength and prevalence of vertebral fractures (VF) in primary Sjögren's syndrome (pSS).

Methods:

We evaluated 71 female pSS patients and 71 healthy age-, race-matched women. In this case-control study, demographic and clinical data including the risk factors for osteoporosis (OP)/fragility fractures were collected through a standardized protocol. BMD and VF were analyzed by dual-energy X-ray absorptiometry (DXA). Bone microarchitecture was assessed by high-resolution peripheral quantitative computed tomography (HR-pQCT) at radius and tibia.

Results:

Patients and controls had comparable age, body mass index, daily calcium intake, smoking, menopausal status and family history of hip fracture ($p>0.05$). OP/low BMD for age (33.8% vs. 5.6%, $p<0.0001$) and FV (19.7% vs. 5.6%, $p=0.043$) were more frequent in patients than controls. In addition, HR-pQCT showed deterioration of cortical and trabecular microarchitecture components and strength at radius, and a deficit on cortical compartment at tibia ($p<0.05$) in pSS patients compared to controls. Further analysis revealed that prednisone use duration, and deterioration of bone microarchitecture on cortical and trabecular components and strength were significantly higher in pSS patients with OP/low BMD for age than pSS patients without OP/low BMD for age ($p<0.05$). Multivariate logistic regression analysis revealed that these alterations in bone microarchitecture and strength were independent factors associated with OP/low BMD for age ($p<0.05$). pSS patients with VF presented cortical bone deterioration (density and thickness) compared with pSS patients without VF ($p<0.05$).

Conclusion: This study shows increased frequencies of OP and VF associated with cortical and trabecular bone microarchitecture and strength deterioration in pSS. The identification that cortical deterioration is the most important abnormality detected by HR-pQCT in patients with VF suggests that this parameter may be involved in pathogenesis of VF in pSS.

SESSION INFORMATION
Session Title: Sjögren's Syndrome: Translational Insights into Sjögren's Syndrome
Session Type: ACR Poster Session C

Background/Purpose: Interferon signatures are upregulated in patients with primary Sjogren's syndrome (pSS) and interferons are considered to have a pathogenic role in pSS. As Janus kinase (JAK) mediates interferon signaling pathway, we investigated whether tofacitinib would ameliorate disease-related parameters in non-obese diabetic (NOD) mice, the animal model SS.

Methods: Tofacitinib (1.5mg/kg or 15mg/kg) or vehicle (10% DMSO) was intraperitoneally injected twice per week from 8 weeks after birth. Salivary flow rate (SFR) and serum level of immunoglobulin(Ig) were addressed on 8 weeks, 12 weeks and 16 weeks. Histologic analysis was performed on 16 weeks. Various T and B cell subpopulations were evaluated using FACS and RT PCR with *ex vivo* splenocytes and cervical lymph node cells.

Results: The SFR of NOD mice all three groups decreased over time. On 16 weeks, the salivary flow rates of tofacitinib-treated mice were higher than those of controls. Serum level of IgM was also lower in tofacitinib-treated mice on 16 weeks. Histologic evaluation of the salivary gland revealed that the lymphocytic infiltration of salivary gland was markedly reduced in the mice treated with tofacitinib. Tofacitinib suppressed Th1 differentiation *in vitro* and the expression of B cell activation markers (Bcl-6, AID) was lower in ex vivo B cells of tofacitinib-treated mice compared with controls.

Conclusion: Tofacitinib suppressed lymphocytic infiltration in the salivary gland of NOD mice, which suggests the therapeutic potential of tofacitinib in pSS.

SESSION INFORMATION
Session Title: Sjögren's Syndrome: Translational Insights into Sjögren's Syndrome
Session Type: ACR Poster Session C

Background/Purpose: Autoantibodies reactive with Ro52/TRIM21 are detected in almost 70% of primary Sjögren's syndrome (pSjS)

patients and their presence is associated with higher severity of the disease. However, anti-TRIM21 are also present in patients with systemic lupus erythematosus, dermatomyositis, primary biliary cirrhosis, and in mothers of children with congenital heart block. How immune responses to Ro52 exert pathogenic effects in such a diverse group of autoimmune disorders is not clear. TRIM21 belongs to a large and structurally conserved C-IV family of the tripartite motif containing (TRIM) proteins. Two other proteins within this family, TRIM38 and TRIM68, have been previously reported to be autoantigens in pSjS. This study investigates the hypothesis that auto-reactivity against multiple TRIM proteins is associated with the pathogenesis of pSjS. In this study, the frequency and clinical relevance of autoantibodies reactive with TRIM38 was investigated in pSjS patients.

Methods: Serum samples from pSjS patients (n=225) and controls (n=50) were analyzed for reactivity to *in vitro* transcribed and translated TRIM38 and TRIM21 proteins. The association of anti-TRIM38 with different clinical parameters of disease such as: anti-Ro/SSA, van Bijsterveld scores, Schirmer's test scores, minor labial salivary gland biopsy scores, and unstimulated whole saliva volume were evaluated. To analyze antibody cross-reactivity, affinity purified anti-TRIM38 antibodies were used to immunoprecipitate TRIM21. To analyze cross-reactivity at T cell epitope level, TRIM21 reactive T cell hybridomas generated in HLA-DR3 transgenic mice were used.

Results: TRIM38 reactive autoantibodies were detected in the sera of 24/225 pSjS patients and in 2/50 controls. The presence of anti-TRIM38 was significantly associated with the presence of anti-Ro/SSA. Almost 20% of anti-TRIM21 positive patients had anti-TRIM38 and all patients with anti-TRIM38 were positive for anti-TRIM21. Clinically, the co-occurrence of anti-TRIM38 and anti-TRIM21 was significantly associated with higher van Bijsterveld scores and reciprocally lower Schirmer's test scores. In contrast, anti-TRIM38 did not worsen the clinical measures of salivary gland disease. Despite the structural homology between TRIM38 and TRIM21, affinity purified anti-TRIM38 antibodies did not immunoprecipitate TRIM21. Interestingly, a T cell hybridoma reactive with $TRIM21_{300\text{-}312}$ peptide was stimulated by $TRIM38_{138\text{-}150}$ peptide.

Conclusion: Our data demonstrate that the co-occurrence of anti-TRIM38 and anti-TRIM21 is specifically associated with higher severity of dry eye in pSjS patients. Anti-TRIM38 is a distinct autoantibody specificity arising in a subset of pSjS patients and T cell cross-reactivity might be involved in the diversification of autoantibody responses from TRIM21 to TRIM38. Our data also suggests that the heterogeneity of clinical manifestations accompanying anti-TRIM21 in different rheumatic disorders might be associated with the co-existence of autoantibodies reactive with other TRIM proteins.

Systemic Interferon Type I and Type II Signatures Present in Distinct Subsets of Primary Sjögren's Syndrome: En Route Towards More Selective Targeting

Naomi I Maria[1], Cornelia G. van Helden-Meeuwsen[1], Eline C. Steenwijk[1], Arne S. IJpma[2], Zana Brkic[1], Paul L. van Daele[1,3], P. Martin van Hagen[1,3], Peter J. van der Spek[2], Hemmo A. First publication: September 29, 2015

SESSION INFORMATION

Session Title: Sjögren's Syndrome: Translational Insights into Sjögren's Syndrome

Session Type: ACR Poster Session C

Background/Purpose: Primary Sjögren's syndrome (pSS) is a systemic autoimmune disease with a large heterogeneity in clinical phenotype. The IFN type I signature is present in over half of PSS patients, associated with higher disease activity [Brkic Z. et al. Ann Rheum Dis 2013]. Novel evidence in pSS salivary glands indicates IFN activation to be also partly attributed to IFN type II [Hall J.C. *et al.* PNAS 2012]. Furthermore, a large modular analysis revealed distinct Type I and Type II IFN signatures related to disease severity in systemic lupus erythematosus (SLE) [Chiche L. *et al.* Arthritis Rheumatol 2014]. Increasing interest in development of therapeutic interventions to target the IFN signalling pathway is emerging. To date, clinical trials with anti-IFNα monoclonal antibodies in SLE have generated mixed results. Better understanding the molecular pathways causal to the IFN signature is essential for specific therapeutic targeting. Thus, identifying the pathways responsible for the sustained IFN overactivation in pSS could lead to a more

selective, targeted therapy. The aim of this study was to investigate the contribution of IFN type II, to the IFN signature in pSS.

Methods: Here we used previous findings from the modular transcriptional repertoire analysis described by Chiche *et al.*, the 3 IFN-annotated modules: M1.2=mild (predominantly IFNα), M3.4=moderate (predominantly IFNβ), and M5.15=strong (also IFNβ and IFNγ), in a class comparison to find overlapping genes in pSS. Differentially expressed genes were considered significant using a cut-off: $p<0.05$ and Fold change≥2. Whole blood mRNA expression of the top genes was validated in a cohort of 36 healthy controls (HC), and 55 pSS patients fulfilling the 2002 AE-criteria (stratified in 20 IFNnegative and 35 IFNpositive pSS).

Results: Class comparison analyses between pSS genome wide microarray data, and the genes annotated for the IFN modules M1.2, M3.4 and M5.12, revealed n=19 genes overlapping in M1.2, n=31 genes in M3.4 and n=10 genes in M5.12. For M1.2 most genes were already previously validated to determine the IFN type I signature, thus predominantly driven by IFNα (MxA ($p<0.0001$), IFI44L ($p<0.0001$), IFIT3 ($p<0.0001$) e.g.). Interesting genes validated for M3.4 were amongst others ZBP1 ($p<0.001$), GBP1 ($p<0.001$), PKR ($p<0.001$), IFIH1 ($p<0.0001$) and for M5.12 ISG20 ($p<0.01$), IFI16 ($p<0.001$) and TAP1 ($p<0.001$), all significantly upregulated in IFNpositive compared to HC and IFNnegative pSS. Similar to findings in SLE, only a subset of IFN type I positive pSS patients showed upregulation of M3.4 genes and an even smaller subset for M5.12 genes. We are currently assessing the relation of these findings to disease activity and other aspects of disease such as fatigue and depression. Data will be further validated using the gene expression data from the UK pSS registry (n=29 HC and n=133 pSS).

Conclusion: Here we find evidence for the presence of complex IFN signatures driven by IFN type I and IFN type II in pSS. Subtyping pSS patients according to distinct IFN signature modules might aid in more selective therapeutic targeting, as well as better disease monitoring and control.

Session Title: Spondylarthropathies and Psoriatic Arthritis Pathogenesis, Etiology Poster I

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

MicroRNA (miRNA) are small non-coding RNAs that play an important role in posttranscriptional gene regulation and their involvement in the pathophysiology of several autoimmune diseases has been proposed. The role of miRNA in Ankylosing spondylitis (AS) has not been well studied. Recent advances in quantitative polymerase chain reaction (qPCR) allow simultaneous measurement of hundreds of miRNAs. The objective of this study is to use this technology to identify differentially expressed whole blood miRNA in AS patients compared to healthy controls. We hypothesize that AS patients have a distinct whole blood miRNA profile that has potential predictive and pathophysiological significance.

Methods:

We investigated the miRNA profile in AS whole blood compared to controls using a multiplex qPCR platform. We obtained whole blood samples from 10 AS patients from the Prospective Study of Outcomes in Ankylosing Spondylitis (PSOAS) cohort and 10 age-, gender- and ethnicity matched unaffected controls. All patients met modified New York Criteria for AS. Blood was obtained at each study visit for disease activity, genetic markers.Total RNA was isolated using PAXgene blood miRNA kit and examined by Exiqon LNA-enhanced miRNA qPCR platforms. Levels of 752 miRNAs were determined. Patient and control sample miRNA levels were compared using univariate t-test at $p<0.05$. In this hypothesis generating study, a correction for multiple comparisons was not

performed.

Results:

Whole blood profiling of miRNA revealed a list of 20 miRNA with differential expression in AS patients (table 1). Interestingly the main finding was the high expression of miR-204-5p (12 fold higher than controls, *p 0.004*). This miRNA has been described particularly in the oncology literature (dysregulation was observed in colon, gastric and pancreatic cancer). Studies in this field show an important role as a regulator of autophagy pathways. Considering the recent discovery of the importance that autophagy pathways play in the pathophysiology of AS this miRNA might play an important role in the pathogenesis of AS.

Conclusion:

AS patients have a whole blood miRNA "signature" based on specific dysregulated miRNA compared to healthy controls. In our study, we found that there is a high expression of miR-204-5p in AS patients compared to controls and this could have implications in the pathophysiology of AS. MiRNA analysis of a larger study population is required to further characterize potential epigenetic factors that may have a role in AS susceptibility.

Enteric flora in newly diagnosed spondyloarthritis: a collaborative study

Background/Purpose: Spondyloarthritis (SpA) affects 1% of the population in the United States. We have previously shown altered microbiota in children with established as well as newly diagnosed juvenile SpA (enthesitis-related arthritis; ERA). A limitation of this study is that many of the subjects had been exposed to long-term immunosuppressive therapy. Thus, through the CARRA network, we designed a study in which newly diagnosed subjects with ERA from around the country submitted fecal specimens for assessment of baseline microbiota. We hypothesized that we would identify similar alterations in microbiota in these newly diagnosed ERA subjects.

Methods: This is a collaborative study with nine participating sites. At each site, subjects newly diagnosed with ERA and unexposed to systemic immunosuppressive therapy are enrolled. Each site also enrolls normal healthy controls. Stool specimens are collected at home and shipped overnight to the PI via commercial carrier. Purified DNA undergoes PCR amplification using primers designed to the conserved region flanking the variable IV region from the 16S rDNA gene. The PCR products are run on the MiSeq flowcell. Analysis is performed with the Quantitative Insight into Microbial Ecology (QIIME) suite, and taxonomic comparisons are performed with LEfSe.

Results: Nine sites agreed to participate in the study. So far, six sites have enrolled a total of 24 subjects, of whom 17 have submitted fecal specimens. Nine of them, along with 12 newly diagnosed ERA subjects from Childrens of Alabama and 21 controls matched for age and sex, underwent 16S sequencing. Preliminary analysis shows no obvious clustering from samples from different sites, supporting the validity of pooling their specimens; however, principal coordinates analysis revealed that there was substantial clustering by diagnosis (Figure 1). Diminished alpha diversity was observed among ERA patients, consistent with findings at the taxonomic level of decreases in a number of rare bacteria among this group (Figure 2.) This result is consistent with a recent study in adults with psoriatic arthritis.

Conclusion: Although we have not so far been able to replicate previous findings of decreased *F. prausnitzii* levels in ERA, our data does suggest that diminished microbial diversity may be part of disease pathogenesis.

Bacterial Skin Microbiome in Psoriatic Arthritis Ã¢â‚¬â€œ Pilot Data from Psoriatic Plaques on Dry Skin Sites from Patients with Psoriasis (PsC) and Psoriatic Arthritis (PsA)

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis Pathogenesis, Etiology Poster I
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

In complex traits like psoriasis (PsC) and psoriatic arthritis (PsA) interactions between genetics and environmental factors are thought to result in the development of disease. Among candidate environmental triggers, the microbial flora in immediate contact with the immune system at several sites, including the skin, are likely to be influential in disease. Topographical diversity exists in the microbial flora based on the skin niche: dry (extensor surfaces of the limbs), sebaceous (scalp, trunk) and moist (flexural surfaces), and bacterial microbiota differ in psoriatic plaques from normal skin. We present data for the bacterial microbiota in psoriatic plaques from the dry skin niche of individuals with psoriatic arthritis and psoriasis, to determine whether the bacterial microbiota are consistent both temporally and from different physical sites

Methods:

Twelve individuals with PsA and 9 individuals with plaque psoriasis were recruited from three centres in North West England, UK. Informed written consent was obtained; skin swabs from multiple psoriatic plaques on the extensor surfaces of the upper and/or lower limbs of each individual were collected and DNA extracted using the MoBio PowerSoil DNA Isolation Kit. The V3-V4 hypervariable region of the 16S rRNA gene was amplified. The samples were sequenced using the MiSeq. OTUs were generated using QIIME 1.6 after quality checks and chimera removal. The data was analysed using R 3.2.0.

Results:

Table 1. Baseline Demographics

Demographic variables	PsC (n=9)	PsA (n=12)
Age mean (range) yrs	48 (22-79)	56 (40-66)
Gender Female (%)	4 (44)	3 (25)
Duration of Psoriasis mean (median) yrs	20.3 (23)	21.7 (20.5)
Type 1 Psorasis (Age at onset <40yrs) (%)	7 (77)	7 (58)

39 skin samples comprising 25 samples from PsA and 14 from PsC individuals were available analysis. There was no significant difference in the alpha (Shannon) diversity index between the two groups (Wilcoxon rank sum test: W=163, p-value=0.7855).

The data was analysed using unweighted UniFrac for the principal co-ordinate analysis (PCoA) and the Bray-Curtis method for the Non-metric Multidimensional Scaling (NMDS). Samples from two time points for clinically stable individuals (n=3) clustered together, as did skin samples from the same individual taken from different dry sites (n=14).

Multivariate analysis using the Adonis method was carried out based on UniFrac and Bray-Curtis distance. Inter-individual differences accounted for most of the variance (>70%), regardless of PsA/PsC status ($p<0.001$; $F=3.4268$ and 5.7337; $R^2=0.76$ and 0.84). A statistically significant ($p<0.015$; $F=1.9237$;$R^2= 0.053$) difference was observed when samples were grouped for disease (PsA vs PsC) using the UniFrac metric but only explained ~5% of the variance.

Conclusion:

In our study, the skin microbiota from psoriatic plaques is consistent for the dry skin type regardless of the physical site and time of

sampling in clinically stable individuals. We found no significant differences in the bacterial skin microbiota from the dry skin plaques of individuals with PsA vs PsC.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis Pathogenesis, Etiology Poster I
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Up to 44% of patients undergoing total hip arthroplasty (THA) show radiographic evidence of heterotopic ossification (HO). Patients with psoriatic arthritis (PsA) and a subset of patients with osteoarthritis (OA) demonstrate an increased risk of HO after THA. The molecular and cellular mechanisms responsible for HO are poorly defined. We conducted a comprehensive genomic and molecular comparison of synovium taken from patients at the time of THA. We compared three groups of patients: osteoarthritis (OA) patients who had developed HO after a previous THA, OA patients who had not developed HO after a previous THA, and PsA patients undergoing a first THA.

Methods: Synovium samples were obtained at the time of THA from three groups: OA patients with previous HO after a primary THA (n= 7), or OA patients without HO (n=7) after a primary THA; and patients with PsA undergoing an initial THA (n=7). RNA-seq was performed to identify shared and differentially expressed genes (DEGs). DEGs were considered with a cut-off of fold change >2.0 and false discovery rate <0.05. Ingenuity Pathway Analysis (IPA) was utilized to identify canonical pathways among shared and DEGs.

Results: A comparison of PsA vs. OA and HO vs. OA transcripts revealed 631 differentially expressed genes unique to the PsA vs. OA group and 91 differentially expressed genes unique to the HO vs. OA group. 76 genes were shared between these groups. When PsA is directly compared to HO there are 386 shared genes. The top canonical pathways from IPA based on these shared genes include IL12 signaling and production in macrophages, 4-IBB signaling in T lymphocytes, Inhibition of angiogenesis by TSP1, Nitric oxide signaling in the cardiovascular system, Leptin signaling in obesity, BMP signaling pathway, and TGFβ signaling.

Conclusion: In this study we show similarities and differences in gene expression of synovium from patients with OA with HO, OA without HO, and PsA. To our knowledge, this is the first study to use RNA-seq to define the transcriptomes of synovium in these conditions. It is also the first study to compare these populations. Genes shared between HO and PsA might suggest a common bone anabolic pathway and direct future therapies for these conditions.

Session Date: Tuesday, November 10, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis Pathogenesis, Etiology Poster I
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Polymorphisms in the endoplasmic reticulum aminopeptidase genes *ERAP1* and/or *ERAP2* are strongly associated with the diseases AS, psoriasis, IBD and Behcet's disease. Robust genetic interaction exists between *ERAP1* and the HLA Class I alleles HLA-B27 and –B40 (associated with AS), -Cw6 (in psoriasis), and -B*51 (in Behcet's disease). In AS, two *ERAP1* haplotypes are disease associated, tagged either by rs30187 (thought to be directly disease-associated) or rs10050860 (which lies on a disease-associated haplotype). Protective alleles of rs30187 are associated with reduced peptidase activity. We hypothesized that other AS-associated *ERAP1* and *ERAP2* genetic variants would also either lead to reduced function or expression of the respective gene.

Methods: RNA sequencing was performed on PBMC derived total RNA from 54 AS cases and 70 healthy controls. This data was analysed to investigate the gene and isoform expression profiles of *ERAP1* and *ERAP2*. The consequences of *ERAP1* variants on the protein level were then validated by mass spectrometry.

Results: Considering markers in linkage disequilibrium with rs30187, multiple showed effects on expression of *ERAP1* ($P=5.27x10^{-7}$ for lead variant rs39840), with protective variants invariably leading to reduced ERAP1 expression. The same property was noted for multiple protective *ERAP2* variants associated with ERAP2 expression (lead SNP rs2910686, $P=1.71x10^{-6}$, after correction for rs2248374 which leads to nonsense mediated decay of ERAP2 transcripts). On the second *ERAP1* haplotype tagged by the SNP rs10050860, a subset of variants alter the expression of two isoforms of the gene. The risk allele at the lead putative splice altering polymorphism, rs7063, correlated with a significant increase in expression of the canonical 19-exon ERAP1 isoform ($P=8.7x10^{-12}$, expression level 2x greater in AS-risk genotype carriers), and a significant decrease in the expression of a second 20-exon isoform ($P=1.0x10^{-17}$, expression level 0.47x lower in risk genotype carriers). The proportion of the 19-exon isoform was also significantly greater in cases than controls (P=0.047). The correlation between *ERAP1* disease risk genotype and isoform profile was replicated at the protein level. Protein expression of the second isoform was greatly reduced, rendering individual carrying the protective genotype at rs7063, with predominant production of this transcript variant, with significantly less total *ERAP1* overall ($P =1.58x10^{-6}$).

Conclusion: *ERAP1* and *ERAP2* genetic variants operate by effects on protein function, expression and sequence to influence the risk of developing AS and related diseases.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis Pathogenesis, Etiology Poster I
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Ankylosing spondylitis (AS) is the prototypic and most common form of spondyloarthritis (SpA). It was recently suggested that IL-23 could play a pivotal role in the pathophysiology of SpA. Indeed, there is a strong genetic association of SpA with polymorphisms of the *IL-23* receptor (IL-23R) gene. In experimental models, IL-23 is produced during the misfolding phenomenon of HLA-B27 heavy chain in the endoplasmic reticulum. Furthermore, in animal models, IL-23 overexpression induced a SpA-like disease *via* resident IL-23$^+$ T cells infiltrating entheseal structures and producing IL-17 and IL-22. In addition, there is an increased number of circulating cells producing IL-17 in patients with AS. Recent data also suggested that IL-17A is a potential target in the treatment of patients with AS.

Objectives: Cells that expressed IL-23R, as well as those producing IL-17 and/or IL-22 have been poorly characterized in AS and/or SpA. Thus, we aimed to better delineate the peripheral blood T cells that expressed IL-23R and the IL-17 and IL-22 producing cell subsets, notably conventional T cells as well as mucosal-associated invariant T cells (MAIT) in patients with AS.

Methods: 36 patients with AS (modified NY criteria; 27 M; age: 44.7 ± 2.6, disease duration: 12.7 ± 1.6; all under NSAIDs or traditional DMARDs) and 31 healthy controls (HC) (8 M; age: 46 ± 2.3) were evaluated. For each subject, peripheral blood T cell subsets were assessed using multi-color flow cytometry. Intracellular cytokine IL-17A, IL-22 and IFN-γ were evaluated after phorbol myristate acetate and ionomycine activation and permeabilization and analysed by flow cytometry. MAIT cells were identified by using TCRVα7.2 specific monoclonal antibodies. IL-22 serum levels were determined by ELISA using commercially available kit.

Results: the number and percentage of CD3$^+$ T cells, CD3$^+$CD4$^+$ and CD3$^+$CD8$^+$ T cells were comparable between patients and HC. Circulating IL-22 levels did not differ between patients and HC (22.6 ± 8.4 *vs* 15.1 ± 4.4 pg/ml, p = 0.7). IFN-γ producing CD4$^+$ and CD8$^+$ T cells were decreased in AS compared to HC (4.6 ± 1.7 *vs* 11.4 ± 2.5 % and 23.3 ± 1.9 *vs* 34.3 ± 2.3 %, respectively, p = 0.005 and p = 0.002). CD8$^+$ T cells expressing IL-23R were significantly increased in AS: 72.8 ± 1.5 *vs* 65.2 ± 2 % (p = 0.009). The percentage of MAIT T cells did not differ between patients and HC but we found an increased percentage of MAIT cells that produced IL-17 and IL-22: MAIT IFN-γ$^-$ IL-17$^+$: 0.43 ± 0.1 *vs* 0.12 ± 0.008 %, p = 0.006; MAIT IFN-γ$^-$ IL-22$^+$: 0.83 ± 0.1 *vs* 0.3 ± 0.1 %, p = 0.004. No correlation was found between the percentage of IL-23R$^+$ CD8$^+$ T cells and measurements of disease activity, as well as between IL-17$^+$ or IL-22$^+$ MAIT cells and disease activity.

Conclusion: These preliminary results suggest that the peripheral blood of patients with AS is enriched in IL-23R$^+$ CD8$^+$ T cells, as well as IL-17 and IL-22 producing MAIT cells. Since MAIT cells are involved in antibacterial immunity and bacterial agents are potentially involved in SpA, our preliminary data suggest that this T cell subset could potentially play a role in AS *via* IL-17 and IL-22 production. This remains to be clarified by future and complementary studies.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis Pathogenesis, Etiology Poster I

Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: The strong genetic association between the HLA-B27 gene and ankylosing spondylitis (AS) has been known for over 40 years. Among AS patients, HLA-B27 positivity is associated with worse disease outcome. The long-term outcome of AS is determined by both inflammation and structural damage. The latter is characterized by new cartilage and bone formation, often leading to ankylosis. In this study, we investigated the *in vitro* and *in vivo* impact of HLA-B27 (over)expression in model systems of cartilage and bone formation.

Methods:

We used different *in vitro* systems mimicking endochondral bone formation. We set up micromasses with ATDC5 cells and human periosteal derived cells (hPDCs) transduced with a HLA-B27 or HLA-B7 (as a control) lentiviral vector. Micromasses were kept for 21 (ATDC5) or 14 (hPDCs) days in culture. RNA extraction and colorimetric tests were performed at different time points (d1, d7, d14, d21). For the ATDC5 cells, after 14 days the chondrogenic medium was switched to mineralization medium. To specifically study osteogenesis in hPDCs, cells were kept in monolayer for 28 days and stimulated with osteogenic media. We also set up micromasses from limb bud cells derived from HLA-B27 transgenic and wild-type (WT) C57BL/6 mice embryos at day 12.5E. These cells are also known to undergo endochondral bone formation *in vitro*. Samples were taken for RNA extraction at d1, d7 and d14. Chondrogenesis (Col II, Aggrecan, Col X) and osteogenesis associated markers (OSC, ALP, Runx2) were studied by quantitative RT-PCR. Stainings with alcian blue, alizarin red, picosirius red and safranin O were performed to measure proteoglycans, mineralization and collagens. For the *in vivo*study, we induced collagen antibody induced arthritis (CAIA) in HLA-B27 transgenic and WT C57BL/6 mice (n=10 in each group). Clinical scoring was performed twice a week. µCT scans were performed at baseline and 3 and 6 weeks after disease induction to study new bone formation. Statistical analyses were performed by 2 way ANOVA taking into account repeated measurements as appropriate.

Results: There was no difference in expression of Col II, Aggrecan or Col X in the HLA-B27 ATDC5 micromasses compared to the HLA-B7 micromasses. There was no difference between the stainings at the different time points. For the hPDC micromasses, there was no difference in expression of the chondrogenesis markers between HLA-B27 and HLA-B7 micromasses. Stainings with alcian blue could not show any difference between the two conditions. Expression of osteogenesis markers en alizarin red staining was comparable in the HLA-B27 and the HLA-B7 hPDCs in monolayer. The limb bud micromasses showed no difference in expression of chondrogenesis associated genes between HLA-B27 transgenic and WT embryos. In the CAIA experiment, the HLA-B27 transgenic mice showed more severe arthritis compared to WT mice. µCT analysis showed no increased bone formation in the post-inflammatory phase when HLA-B27 transgenic mice were compared to WT.

Conclusion: The presence of HLA-B27 seems to enhance joint inflammation in the CAIA model in C57BL/6 mice. These *in vivo* and the *in vitro*data do not support a direct role for HLA-B27 in new cartilage or bone formation leading to ankylosis.

Higher Serum Level of Leptin Protects from Radiographic Spinal Progression in Patients with Ankylosing Spondylitis

Agnes Hartl[1], Kay-Geert Hermann[1], In-Ho Song[1,2], Joachim Listing[3], Martin Rudwaleit[1,4], Joachim Sieper[1] and **Denis Poddubnyy**[1], [1]Charité Universitätsmedizin Berlin, Berlin, Germany, [2]Abbvie, Chicago, IL, [3]German Rheumatism Research Centre, Berlin, Germany, [4]Klinikum Bielefeld, Bielefeld, Germany

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis Pathogenesis, Etiology Poster I
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Fat tissue synthesizes and releases a series of biologically active substances (adipokines), which are involved in bone metabolism through effects on bone formation and resorption. Leptin, one of the most important adipokines derived from fat tissue, seems to be

responsible for the major part of effects of adipose tissue on bone.

The aim of this study was to investigate the role of leptin serum levels as a predictor of radiographic spinal progression in patients with ankylosing spondylitis (AS).

Methods:

Altogether 120 patients (82 men and 38 women) from the Effects of NSAIDs on Radiographic Damage in AS (ENRADAS) trial who completed the study per protocol were included into the analysis. Spinal radiographs (lumbar and cervical spine, lateral views) were scored independently by two trained readers in a concealed and randomly selected order according to the modified Stoke Ankylosing Spondylitis Spine Score (mSASSS) scoring system. Radiographic spinal progression was defined as 1) mSASSS worsening by ≥2 units after 2 years, and 2) development of at least one new syndesmophyte or progression of existing syndesmophytes (i.e., formation of a bridging syndesmophyte) after 2 years. Leptin serum levels were measured at baseline by ELISA.

Results:

Mean baseline leptin levels were significantly lower in patients with mSASSS worsening by ≥2 units after 2 years (n=29) as compared to those without progression (n=91): 10.3±8.8 vs. 15.9±13.7 ng/ml, respectively, p=0.002, and in patients with syndesmophyte formation (n=25) as compared to those without syndesmophyte formation (n=95): 10.1±9.6 vs. 15.7±13.4 ng/ml, respectively, p=0.002. This difference was especially evident in males, but not in females. Remarkably, in females the serum level of leptin at baseline was significantly higher than in males: 30.0±21.0 vs. 10.7±8.2 ng/ml, p<0.001.

In the ROC analysis leptin had an area under the curve (AUC) of 0.69 (95% CI 0.57-0.81) for no mSASSS worsening by ≥2 units and 0.70 (95% CI 0.57-0.82) for no syndesmophyte formation. Leptin serum level of >7.5 ng/ml had a sensitivity of 78%, a specificity of 55%, and an odds ratio (OR) = 4.2 (95% CI 1.7-10.6) as a protector from mSASSS worsening by ≥2 units after 2 years (after adjustment for baseline syndemophytes, elevated CRP, smoking, body mass index, sex, and NSAIDS intake index, the OR increased to 9.2, 95% CI 2.5-34.0). The same serum level of leptin demonstrated a sensitivity of 77%, a specificity of 56%, and an OR = 4.2 (95% CI 1.7-10.6) as a predictor from syndesmophyte formation (after adjustment for the same variable as above, OR = 11.7, 95% CI 2.8-47.8).

In the logistic regression analysis with baseline leptin serum level as a scale variable, a protective role of higher leptin serum level regarding radiographic spinal progression was confirmed: OR = 1.15 (95% CI 1.02-1.3) for no mSASSS worsening by ≥2 units, and OR = 1.28 (95% CI 1.1-1.5) for no syndesmophyte formation.

Conclusion:

Higher serum levels of leptin seem to protect patients with AS from radiographic spinal progression. Interestingly, female patients with AS have significantly higher leptin levels that might explain lesser extent of structural damage in the spine in female AS patients in general.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis Pathogenesis, Etiology Poster I

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Axial spondyloarthritis (axSpA) defines a group of chronic inflammatory diseases which includes non-radiographic axSpA (nr-axSpA) who do not have definite sacroiliitis on pelvic X-rays. Disease burden seems to be similar between nr-axSpA and AS, however differences or similarities in disease progress and pathogenesis are not completely clear. Thymoquinone (TQ) is the active ingredient of *Nigella sativa* and it's anti-inflammatory, anticancer and immunoregulatory role has been demonstrated in various diseases. The aim of this study was to investigate the cytokine production of peripheral blood mononuclear cells (PBMC) in pts with axSpA (AS and nr-axSpA) and the effect of thymoquinone on the cytokine profile.

Methods: Pts with axSpA who met the ASAS axSpA classification criteria and age-matched healthy controls (HC) were enrolled in this study. Pts were DMARD naive (biologic or synthetic), and 23 pts were using only NSAIDs (19 on demand, 5 regular full dose). All of the pts had pure axial involvement and none had peripheral arthritis or psoriasis or IBD. Peripheral blood mononuclear cells (PBMCs) were cultured in RPMI medium with and without TQ (12.5 µM). PBMCs were stimulated for 48 hours with 10 µg/ml phytohemagglutinin and secretion of TNF-α, interleukin-4 (IL4), IL6, IL8, IL10, IL17 and VEGF was measured in the supernatant by ELISA (lab investigators were blind to pts/controls clinical diagnosis/variables).

Results: Twenty-nine pts with axSpA (14 male, 37.2±12.6 yrs) and age- and gender-matched 14 healthy controls (7 male, 35.6±9.6 yrs) were included. In axSpA group 15 pts were nr-axSpA (mean symptom duration; 5.3±6.7 yrs) and 14 pts were AS (10.4±8.6 yrs). Disease activity assessed by BASDAI and ASDAS-CRP were similar in pts with AS (4.4±2.3 and 2.9±1.3) and nr-axSpA (3.8±1.9 and 2.6±1.1). Cytokine levels without TQ are given in Table 1. Interleukin-4 (Il-4), Il-8, TNF-α and VEGF were significantly different in pts with axSpA compared to HCs. Cytokine profiles were similar in pts with AS and nr-axSpA. TQ supressed cytokine secretion in pts with axSpA and HCs (Table 2). However VEGF secretion increased with TQ, particularly in pts with AS (nr-axSpA 18.4±5.1 vs AS 29.1±13.2 pg/ml, p=0.011).

Conclusion: This is the first study reporting similar cytokine profile of stimulated PBMCs in patients with AS and nr-axSpA and the suppressive effect of TQ on cytokine production of PBMCs. Also our results showed increased production of VEGF by PBMCs despite TQ particularly in patients with AS.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis Pathogenesis, Etiology Poster I
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: IL-17 is elevated in both the lesional skin and arthritic joints of psoriatic arthritis (PsA) patients, however, the direct effect of IL-17 on myeloid cells in PsA is less understood. We recently identified a unique molecule, Wdfy3, associated with IL-17 and neutrophil-driven epidermal hyperplasia. Using a cre-lox system to selectively ablate Wdfy3 in myeloid cells, we report the effect of Wdfy3 in protecting against epidermal hyperplasia.

Methods: We performed gene transfer of IL-17 by hydrodynamic delivery of minicircle (MC) DNA in control (C57BL/6) mice and mice treated with topical imiquimod. The psoriatic features were analyzed and scored for disease progression histologically. Further phenotypic analysis of cell populations was performed by flow cytometry, RT-qPCR, and *in vivo* imaging using nanoprobes in *Il23r*$^{-/-}$*Rag*$^{-/-}$, *Tcrd*$^{-/-}$ and Wdfy3-LysM^{Cre} transgenic mice.

Results: Histological analysis of dorsal skins from IL-17 MC-injected Wdfy3-LysM^{Cre} at day 4 revealed reduced skin thickness and absence of epidermal hyperplasia and Munro's microabscesses in contrast to IL-17 MC-injected WT controls. Consistent with the histology findings we observed a reduction in gene expression of *K16, S100a8, Cxcl1, Cxcr2 and Ltb4r1* in IL-17 MC-injected Wdfy3-LysM^{Cre} dorsal skins compared to IL-17 MC-injected WT mice. Histological analysis of dorsal skins from IL-17 MC-injected Wdfy3-LysM^{Cre} at day 4 showed reduced apoptotic cells compared to IL-17 MC-injected WT controls. We found that deletion of *Wdfy3* in Ly6G^{+} cells resulted in reduced NET formation, which was consistent with a reduction in NET-associated neutrophil elastase compared to WT or LysM^{Cre} controls.

Conclusion: Collectively, our data underscore the importance of IL-17 in IL-23 and T cell independent skin pathology and its direct association with neutrophil activation and Wdfy3 in epidermal hyperplasia; a pathological feature of various skin diseases and paves the way for the design of novel therapeutics to combat this disabling condition.

Session Title: Spondylarthropathies and Psoriatic Arthritis Pathogenesis, Etiology Poster I
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: The increased risk of major adverse cardiovascular events (MACE) in patients who suffer from systemic inflammatory conditions such as Rheumatoid Arthritis (RA), Systemic Lupus Erythematosus (SLE), and Psoriatic Arthritis (PsA) is well established. A recent population-based cohort study quantified the risk of MACE among patients with RA, PsA, and psoriasis compared to the general population after adjusting for traditional cardiovascular risk factors. The risk of MACE was elevated by 40-50% in patients with RA but only 20% in patients with PsA. Our group has explored potential mechanisms to explain the attenuated risk of MACE in PsA compared to RA. Previous clinical studies have suggested that increased serum levels of IL-10 are associated with a more favorable prognosis in patients with acute coronary syndromes. Murine models have shown IL-10 to have atheroprotective effects. IL-10 has also been shown to favorably effect reverse cholesterol transport in THP-1 macrophages via increases in the expression of ABCA1, ABCG1, and Liver X receptor α. We sought to determine if IL-10 present in PsA plasma modulated the expression of the major cellular cholesterol transport proteins ABCA1 and CD36, and prevented foam cell formation.

Methods: The study was performed under a Winthrop University Hospital IRB-approved protocol. Level of IL-10 was evaluated by ELISA (Milliplex). THP-1 differentiated macrophages (10^6/ml, phorbol dibutyrate, 100nM, 48h), were incubated (37^0C, 5% $C0_2$, 18h) ± 1, 10, 50 and 100 pg/ml of recombinant human IL-10 ± 100 ng/ml of anti-IL10 (R&D) for neutralization. Macrophages were exposed to 10% plasma from 8 PsA±100 ng/ml of anti-IL10 (R&D). Expression of major cholesterol transport proteins: ATP binding cassette transporter (ABC) A1 and CD36 were quantified by real-time PCR, foam cells were identified by oil-red-O staining.

Results: Purified IL-10 had a bimodal effect on expression of the cholesterol efflux gene ABCA1. ABCA1 was increased by IL-10 1.3±0.04 fold at 10 pg/ml and reaching 2.4±0.2 fold at 50 pg/ml (n=3, $P<0.05$) but had no effect at 100 pg/ml. Neutralization of IL-10 by anti-IL10 antibody decreased the expression of ABCA1 to the baseline level of untreated cells. CD36 expression was not affected.

In THP-1 macrophages exposed to 10 % PsA plasma (~24 pg/ml) inhibition of IL-10 binding significantly decreased expression of ABCA1 71±9.0% (n=8, $P<0.001$) with expression in macrophages exposed to PsA plasma set at 100%. In addition, neutralization of IL-10 increased expression of CD36 to 133.4±6.9% (n=8, $P<0.001$). Results were confirmed by Western blot. Consequently, neutralization of IL-10 increased foam cell formation by 20%.

Conclusion: Compared to pro-atherogenic changes induced by RA plasma, PsA plasma displays a modest pro-atherogenic pattern consistent with the clinically observed attenuated risk of MACE in PsA compared to RA. IL-10 in PsA plasma demonstrates an artheroprotective effect on cellular cholesterol transport. This study suggests a role for IL-10 in the attenuation of MACE observed in PsA.

A Comparison of Th17 Gene Expression in Psoriatic Arthritis Synovial Fluid and Peripheral Blood

Fatima Abji[1], Remy Pollock[2], Kun Liang[3], Vinod Chandran[4] and Dafna Gladman[4], [1]Rheumatology, Toronto Western Hospital and University of Toronto, Toronto, ON, Canada, [2]University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, [3]Department of Statistics and Actuarial Science, University of Waterloo, Waterloo, ON, Canada, [4]Rheumatology, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada
First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis Pathogenesis, Etiology Poster I
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is a destructive inflammatory arthritis that develops in approximately 30% of patients with cutaneous psoriasis. Th17 cells infiltrate psoriatic skin and joints and are central to the pathogenesis of PsA. The aim of this study was to identify Th17 cell signaling genes that are dysregulated in the affected joint of PsA patients and if these differences are detected in peripheral blood.

Methods: Synovial fluid cells from 8 PsA and 4 gout patients undergoing routine joint aspirations were obtained and stored in TRIzol reagent. RNA was isolated by phenol-chloroform extraction and purified with RNeasy miniprep kits. Peripheral blood from 24 PsA and 19 controls was stored in Tempus tubes and total RNA was extracted according to the manufacturer's instructions. Quantitative RT-PCR arrays were used to profile expression of 84 genes related to the Th17 regulatory network in synovial and peripheral blood cells. Expression was quantified by the ΔΔCt method and fold change differences were compared in synovial cells by logistic regression and in peripheral blood by Student's t test ($p<0.05$).

Results: Out of 16 genes significantly dysregulated in PsA compared to gout synovial cells, 15 genes were up-regulated and one gene (STAT4) was down-regulated (Table 1). In peripheral blood, 5 genes (IL-15, CXCL6, CLEC7A, CD3D and TLR4) were elevated and 21 genes, including IL-8, IL-17C, CD4, STAT3, NFKB1 and TGFB1, were reduced in PsA compared to controls. Five genes (CD4, CLEC7A, CXCL6, NFKB1 and IL8) were significantly altered in both synovial and peripheral blood cells of PsA patients compared to controls (gout or normal). Additionally, gene expression was compared in paired synovial and peripheral blood cells in 4 PsA patients. Eight genes were increased and 13 genes were reduced in PsA synovial cells compared to peripheral blood cells (Table 2).

Conclusion: We identified gene expression differences that may distinguish PsA from other inflammatory arthritides such as gout. Five genes (CD4, CLEC7A, CXCL6, NFKB1 and IL8) were altered in both synovial fluid and peripheral blood, potentiating their use as biomarkers of PsA. Differences between synovial and peripheral blood cells contribute to our understanding of the biology of PsA and warrant further investigation.

Table 1: Differences in expression of Th17 signaling genes ($p<0.05$) in synovial cells obtained from patients with PsA compared to that obtained from gout

Is the Gender Difference in As Linked to IL-23?

Johannes Nossent[1] and **Gunnstein Bakland**[2,3], [1]Medicine, University of Western Australia, WA, Australia, [2]Dept. of Rheumatology, University Hospital Northern Norway, Tromsø, Norway, [3]University of Tromsø, The Arctic University of Norway, Tromsø, Norway

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis Pathogenesis, Etiology Poster I
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Ankylosing Spondylitis (AS) has traditionally been portrayed as a disease where male patients outnumber female patients by a factor 3 to 4. It has also been suggested that female patients have a less severe disease course and a longer diagnostic delay due to a more protracted radiological progression. We wanted evaluate several SNPs with an acknowledged association to AS to identify a possible influence of gender on the distribution among patients.

Methods:

We identified 306 patients with AS according to the modified New York criteria in a population of northern European descent

(Northern Norway). The distribution of 10 different SNPs where evaluated in the population using Taqman RT-PCR. These SNPs were describing variation in ERAP-1, IL-1, TNF and IL-23R The statistical analyses where performed using SNPstats (http://bioinfo.iconcologia.net/SNPstats).

Results:

We could only find a correlation to gender within the IL-23R-gene, and only two SNPs (rs11209032 and rs10489629) in the IL23R-gene showed a distribution significantly associated with gender, p=0.016 and 0.026 respectively. There was no association with the examined SNPs from ERAP1, IL1 or TNF. We could not find a correlation between IL-23 levels and SNP distribution.

Conclusion:

Our data suggest that a variation of rs11209032 and rs10489629 is associated with gender distribution in AS. Considering IL23 has been identified as a cytokine central to active inflammation in enthesitis, this could be the link to the observed gender difference in AS. To our knowledge, this correlation has not previously been reported. However, studies reporting on radiographic progression in AS find that male patients have a more rapid progression and pronounced tendency to syndesmophyte formation. We suggest that this observation might be linked to IL23, but future studies are needed. Given the difference in gender distribution reported in radiographic and non-radiographic axial Spondyloarthritis, this could be a population where a study of IL-23/IL-23R could bring further understanding to the pathogenesis of the spondyloarthritidis.

Session Title: Spondylarthropathies and Psoriatic Arthritis Pathogenesis, Etiology Poster I

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Reactive arthritis (ReA) is an inflammatory arthritis that typically follows infection. Several agents microbial agents have been implicated, particularly *Shigella, Salmonella, Campylobacter* in the gastrointestinal tract and *Chlamydia trachomatis* in the genitourinary tract. However, the intestinal microbiome in these patients has never been characterized. The objective of this study was to determine the community composition of pathogenic and commensal gut microorganisms of ReA subjects from a highly prevalent region.

Methods: We performed a prospective case-control study among patients with an infection (urogenital or gastrointestinal) in the 3-6 months prior to enrollment (January through October 2014). ReA was defined using the ASAS peripheral SpA criteria. Cases were identified in the AGAR rheumatology clinic. Controls were recruited from primary care clinics in the same hospital system in Guatemala. Fecal samples from 33 subjects with ReA and 31 controls were obtained and bacterial DNA was extracted. 16S rDNA amplicons targeting V4 region were sequenced using MiSeq (Illumina) to define the microbiota composition. The obtained 16S rRNA sequences were analyzed using the Quantitative Insights into Microbial Ecology (QIIME) pipeline for analysis of community sequence data.

Results: There were no significant differences in age, gender, HLA-B27 positivity or type of infections between the groups. 16S sequencing data showed that ReA patients had significantly less intestinal microbial diversity compared to controls, as calculated by chao ($p<0.05$) and phylogenetic tree ($p<0.05$; Figure 1). Taxonomic comparison between groups was performed using LEfSe, which revealed a few significant differences (LDA score>2). While ReA microbiome samples were enriched with *Bifidobacteriaceae* ($p<0.05$), there was a notable and significant decrease in intestinal *Peptococcaceae* ($p<0.001$; Figure 2). At the operational taxonomic unit (OTU) level, there was a virtual absence of *Paraprevotellaceae* in the ReA group ($p<0.01$).

Conclusion: Despite the relatively small number of samples analyzed, the intestinal microbiome of ReA patients appears to be less

diverse than that of controls. Taxonomic differences were also noted between groups, including the lower abundance of gut pathobionts *(i.e., Peptococcaceae)*. Further evaluation of functional aspects of this microbiome and its relationship to intestinal commensals and pathogens in various patients' phenotypes may provide further insights into its possible contribution to ReA.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Pathogenesis, Etiology Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Ankylosing spondylitis (AS) is an inflammatory disease affecting spine which may lead to new bone formation and disability. However, the radiographic severity of AS shows great variance. The genetic determinants for the new bone formation and for this great variance have not been fully understood yet. By using a well-categorized group of patients representing two extreme ends of AS radiographic severity, we aimed to determine the effects of interleukin-23 receptor (*IL23R),* bone morpogenetic protein-6 *(BMP6)* and prostaglandin endoperoxide synthase-1 (*PTGS1)* gene variants on radiographic severity of AS.

Methods: rs11209026 (*IL23R*), rs1235192 and rs270378 (*BMP6*), and rs1236913 (*PTGS1*) single nucleotide polymorphisms (SNPs) were genotyped in 241 AS patients (F/M=97/144, mean age 42.0±11.0 years, 60.6% HLA-B27[+]) fulfilling the modified New York criteria. Patients were classifed as mild and severe radiographic AS according to modified Stoke AS spinal score (mSASSS). Mild AS is defined as having mSASSS of "0" despite ≥10 years of disease duration. Whereas severe AS is defined as having mSASSS of >20 (without counting scores with "1") regardless of the disease duration.

Results: Seventy (29%) and 171 (71%) patients were classified as severe and mild radiographic AS, respectively (mean mSASSS 48.2±17.3 vs 0, *P*<0.0001). Severe AS patients were mainly male and significantly older, had longer disease duration, more extra-articular and coxofemoral joint involvement, smoking rates, HLA-B27 positivity and ever TNFi usage. The genotype distributions and allele frequencies of the 4 SNPs were not different in severe group compared to mild group. After adjustment for clinical differences between two groups by logistic regression analysis none of the alleles in those SNPs were found to be associated with radiographic severity of the AS (Table 1). The genotype frequencies also did not change when groups were categorized according to gender and HLA-B27 status. However, HLA-B27 was associated with radiographic severity only in male patients (OR=3.23, 95% CI [1.11 to 9.41], *P*=0.032). No association with these SNPs and other clinical manifestations of AS, coxofemoral joint involvement, uveitis and enthesitis, could be demonstrated. Severe group patients had higher CRP levels, likewise patients with elevated CRP had higher mSASSS scores (22.1±26.9 vs 10.4±22.4, *P*=0.001). However no difference was identified.in genotype distributions and allele frequencies of patients with and without elevated CRP.

Conclusion: In a radiographically well-categorized AS cohort *IL23R* rs11209026, *BMP6* rs1235192 and rs270378 and *PTGS1*rs1236913 SNPs are not found to be associated with radiographic severity of AS. HLA-B27 is associated with radiographic severity only in male AS patients.

Table 1. The distribution of allele frequencies of *IL23R, BMP6* and *PTGS1* SNPs of mild and severe radiographic AS patients*

	Mild radiographic AS (n=171)	Severe radiographic AS (n=70)	*P* value	OR (95% CI)

Session Title: Spondylarthropathies and Psoriatic Arthritis - Pathogenesis, Etiology Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: RORγt is a nuclear hormone receptor expressed in Th_{17} cells and distinct subsets of lymphoid cells, including innate lymphoid cells (ILC), and γδ T-cells. RORγt is required for Th_{17} cell and innate lymphocyte differentiation and regulates the transcription of the effector cytokines genes including IL17A and IL22. Ankylosing spondylitis (AS) is characterized by a peripheral oligoarthritis and enthesitis. A key feature of AS is the imbalance between bone resorption and formation leading to aberrant bone formation and ankylosis. The contribution of IL23/IL17 axis to the pathogenesis of AS is supported by several lines of evidence. The protective IL23R variant (R381Q) is associated with decreased expression of Th_{17} genes. Elevated levels of serum IL23 and IL17 and increased numbers of circulating Th_{17} cells have been reported in AS patients. Finally, anti IL17A antibody (Secukinumab) therapy has been demonstrated to be efficacious in AS. Overexpression of IL23 using minicircle DNA technology is characterized by a rapid and pronounced skin and rheumatic phenotype characterized by synovitis, enthesitis, and aberrant bone formation in the B10RIII mouse (Sherlock et al.). Furthermore, significant expression of IL23 pathway associated genes including IL17A and IL22 was observed in the entheses tissue. The potent and selective RORγt antagonist (Compound A), was utilized to test the hypothesis that antagonism of RORγt can inhibit the IL23 pathway in the context of synovial and entheseal inflammation and subsequent bone remodeling.

Methods: Adult B10RIII female mice were administered 1.5 mg/mL (3 mg dose) of IL23 minicircle DNA via hydrodynamic injection on day 1. Starting on day 2, mice received a 10 mg/kg dose of Compound A, p.o. *bid*for 28 days. Mice were monitored daily for signs of arthritis. Arthritis severity was graded using a 0-4 score per paw for a maximum score of 16. Upon sacrifice (Day 28) serum was collected for cytokine analysis. Enthesis tissue was collected for biomarker analysis and paws were collected for histologic assessment (Bolder Biopath, Boulder, CO). Medullary trabecular and cortical bone were assessed for erosion. Presence of osteoclasts was also incorporated in the bone erosion score. The distribution and widths of periosteal bone proliferation were used to assess aberrant bone formation.

Results: Administration of 10 mg/kg Compound A, p.o. *bid* for 28 days resulted in significant inhibition (49 ± 7%) of arthritic score (AUC). Entheses tissue biomarkers including IL-17A, IL-22, S100a8 and S100a9 were significantly inhibited (>80%) at the 10 mg/kg dose. In addition, biomarkers of bone erosion including RANKL and MMP9 were inhibited 99 ± 1% and 94 ± 3% respectively at day 28. Histological analysis demonstrated a significant inhibition of both synovitis and enthesitis. Finally, bone erosion and aberrant bone formation were inhibited 95 ± 4% and 98 ± 2% respectively at day 28.

Conclusion: These data support the hypothesis that antagonism of RORγt can attenuate IL23-dependent inflammation in entheseal tissue and attenuates both bone erosion and aberrant bone formation in the joint in vivo. Correlations between entheseal tissue biomarker responses and bone endpoints are being established.

Session Title: Spondylarthropathies and Psoriatic Arthritis - Pathogenesis, Etiology Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Children with enthesitis-related arthritis (ERA) and adults with spondyloarthritis are at risk for intestinal inflammation. We have previously shown altered microbiota in children with ERA similar to inflammatory bowel disease. However, the mechanisms by which an altered microbiota might predispose to arthritis and intestinal inflammation remain unclear. Therefore, we explored expression profiles from fecal samples of children with ERA.

Methods: Fecal samples were obtained from patients with ERA and healthy controls. For metabolomics, samples were subjected to acid extraction and analyzed by nanoscale liquid chromatography coupled to tandem mass spectrometry (MS). Data analysis was performed with the mummichog for metabolomics program on the output of the positive and negative modes MS analyses, comparing metabolites identified by mass : charge ratio with at least a 1.5 fold difference between patients and controls, and a p-value of <0.05. This was repeated on a second cohort of largely newly diagnosed ERA patients and healthy controls. For metagenomics, fecal samples from a subset of the second cohort (10 with ERA & 8 controls) were subject to DNA purification and shotgun sequencing using MiSeq.

Results: The initial metabolomics run involved 12 ERA patients and 11 controls. Among the negative mode ions, pathway analysis revealed 5 pathways relatively under-represented in patients: metabolism of biopterin, tryptophan, glycerophospholipid, urea cycle, and tyrosine. The repeat run was performed on 15 non-overlapping patients with largely newly diagnosed ERA and 11 controls. Tryptophan metabolism again emerged as under-represented in patients among the negative mode ions, as did the butanoate pathway. Additionally, both runs revealed far more ions over-represented in controls as compared to patients. Metagenomics analysis was generally consistent with the metabolomics: more genes and pathways were represented in the controls compared to patients. In addition, the patients had less taxonomic diversity.

Conclusion: Multi-omics analysis of children with ERA compared to healthy controls indicates lower functional metabolic potential and activity in ERA patients, decreased taxonomic diversity, and possible differences in the fecal microbial metabolism of tryptophan. Thus, we have identified functional correlates to the diminished microbial diversity seen in many disease states. Also, tryptophan metabolism has been linked to the balance between Th17 and regulatory T cells; thus, it appears that the fecal microbiota may affect T cell development towards a pro- or anti-inflammatory phenotype. This may help to explain findings of intestinal inflammation and arthritis in children with ERA.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Pathogenesis, Etiology Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Immunological, genetic and therapeutic studies have implicated the IL-17A/IL-23 inflammatory axis in SpA. GM-CSF is emerging as a cytokine that marks out a pathogenic subset within this inflammatory axis, and inhibition of this cytokine pathway is currently in clinical trials for rheumatoid arthritis. We sought to investigate the role of GM-CSF in SpA pathogenesis.

Methods:

Blood, synovial fluid and synovial tissue from patients with SpA was studied ex-vivo and in-vitro using SpA joint tissue explant assays. GM-CSF production from different cell types were characterised using multi-colour flow cytometry (FACS) and time-of-flight cytometry (CyTOF).

Results:

CyTOF analysis revealed ex-vivo GM-CSF production from multiple lymphoid but not myeloid cell lineages with CD4 cells clearly the main producers upon whole PBMC stimulation (Fig. 1). CyTOF findings were validated with flow cytometry (fig 2). The percentage of CD4 cells producing GM-CSF was significantly increased in AS PBMCs ex-vivo compared to healthy controls (mean 6.89% vs 3.30% n=31, p=0.006). Further characterisation of GM-CSF-producing T cells showed overlap with both classical Th1 and Th17 phenotypes. The mean percentage of GM-CSF-positive CD4 cells from ex-vivo synovial fluid mononuclear cells (SFMCs) was 34.27% and significantly higher compared to matched PBMCs (n=3, p=0.0391). CD4 cells from SpA synovial tissue mononuclear cell explant cultures also showed high levels of GM-CSF production by CD4 cells (n=6).

Conclusion:

Increased numbers of CD4 T cell produce GM-CSF in the blood and joint in SpA. GM-CSF may be a key pathogenic cytokine in SpA and can potentially be targeted therapeutically. Anti-GM-CSF monoclonal antibodies are already in phase three clinical trials for other inflammatory diseases and have shown an acceptable safety profile.

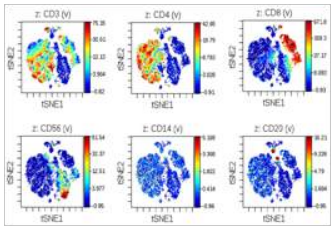

Figure 1: CyTOF shows CD4 cells to be the main producers of GM-CSF upon ex-vivo PBMC stimulation in AS.

Representative multi-dimensional viSNE analysis of all GM-CSF producers upon ex-vivo AS PBMC stimulation shows CD4 cells to be the predominant GM-CSF producing population. GM-CSF is also produced by populations of CD8, $CD56^{+}$ NK cells.

Figure 2: Flow cytometry confirms CD4 cells to be the predominant GM-CSF producers upon ex-vivo PBMC stimulation in AS.

Pooled sunburst analysis (Cytobank) from ex-vivo stimulated PBMCs of AS patients (n=5). CD4 cells account for greater than 50% of all GM-CSF production with smaller contributions from the CD8, γd-T Cell and $CD56^{+}$ NK cells.

Session Date: Tuesday, November 10, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Pathogenesis, Etiology Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The IL-23 axis and Th17 type immunity has been implicated in the pathogenesis of Ankylosing Spondylitis (AS) and an enrichment of gamma delta (gd) T cells expressing IL-23R in AS patients has previously been reported (Kenna et al Arthritis Rheum. 2012). However, the relationship of these cells with clinical phenotype remains to be determined. We aimed to deepen the understanding of the relationship between the IL-23 axis, gd T cells and clinical phenotype in the immunopathogenesis of axial spondyloarthritis (axSpA) by examining cellular expression of IL-23 axis molecules on gd T cells in peripheral blood of highly active biologic naïve AS subjects.

Methods: Thirty nine patients diagnosed with active AS meeting ASAS criteria with sacroiliitis by imaging were recruited to a longitudinal observational study and phenotypically characterized using disease activity (ASDAS-CRP), radiographic vs. MRI only imaging changes, HLAB27, extraspinal features and medication use in first 6 months. Peripheral blood was obtained at baseline and multicolor flow cytometry performed to determine the expression of IL-23R and the IL-23 axis molecule CCR6 on gd T cells relative to healthy volunteer (HV) controls (n=20) .

Results: Of the 39 patients studied, 18 (46%) were male, mean (SD) age was 41.7 (15.3), symptom duration 9.6 (8.3) yrs, 15 (38%) were HLA-B27+, CRP (1.5 (1.4) mg/dl and ASDAS-CRP 2.7 (0.7). 11 (52%) of those with follow-up started TNFi therapy within 6 months. All had confirmed sacroiliitis, 15 (38%) by radiographs (rad), 18 (46%) by MRI (non-rad) sacroiliitis, and 6 (15%) by both. There were no significant clinical differences between sexes or those with radiographic/MRI findings. Similar to previously published studies, an increase in the % gd TCR+ cells was observed in SPA subjects vs control. Moreover, analysis of CCR6 expression on the gd subset demonstrated that 61.5% of SpA patients showed increased levels (mean % ± 2 s.d vs. HV) of CCR6+, gd + T cells in peripheral blood (CCR6 Hi) while 38.5% of the subjects were similar to HV controls (CCR6 Lo). The percentage of IL-23R+, gd T cells was also significantly increased in CCR6hi patients vs. CCR6lo patients (Table 1). Also, a correlation between the density of IL-23R and % CCR6+ gd cells in the SpA subjects was observed (r = 0.422, p=0.0074). Analysis of ASDAS-CRP scores showed that within the CCR6 Hi, gd subjects, 21% of the patients demonstrated severe disease (score >3.5) versus 6.6% in the CCR6 Lo group. Also, a trend towards increased CCR6 receptor expression on gd cells and severity of ASDAS-CRP was seen in CCR6 Hi subjects (r = 0.43)

Expression in Peripheral Blood

Cell Type	Marker	HV Control N=20	Mean ± SEM axSpA CCR6^{LO} N=15	axSpA CCR6^{HI} N=24
gd TCR+ CD3+ T cells	%CCR6+	21.60 ± 2.04	20.86 ± 3.11	65.32 ± 3.31
gd TCR+ CD3+ T cells	%IL-23R+	2.50 ± 0.83	1.22 ± 0.46	10.31 ± 3.36
gd TCR+ CD3+ T cells	IL-23R (MESF)*	66.25 ± 36.46	81.79 ± 22.57	299.30 ± 63.85

*** Molecules of Equivalent Soluble Fluorochrome**

Conclusion: These data sugg est that CCR6+, IL-23R+ gd T cells play a role in more active AS. Further understanding of how these cells contribute to the disease phenotype may lead to improved strategies for patient selection and treatment approaches for AS.

Session Date: Tuesday, November 10, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Pathogenesis, Etiology Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Human HLA-B27 and β_2-microglobulin transgenic rats (B27 rats), an animal model for spondyloarthropathies, spontaneously develop inflammatory colitis and bone loss. We have previously demonstrated that B27 rats lack specific myeloid cell populations but it is not known whether gut inflammation drives systemic symptoms. Here we have examined central and peripheral myeloid cells, focusing on osteoclast precursors. To investigate the link between colitis and the peripheral disease we have assessed the effects of oral antibiotic treatment on intestinal pathology, and the subsequent systemic impacts.

Methods: Bone marrow (BM) and blood, from 14-16 week old B27 and control (B7) rats, were evaluated by flow cytometry for expression of CD90, CD3, CD45RA, Igκ, CD172a, CD43, and CD11b, and uptake of fluorescent M-CSF and CCL2. Plasma CCL2 levels were measured by ELISA. Monocytes from BM and blood were FACS sorted and cultured in pro-osteoclastogenic medium to evaluate osteoclastogenic potential. Mature osteoclasts, tartrate-resistant acid phosphatase positive multinucleated cells, were counted. Some B27 rats were given oral antibiotics for 4 weeks. Guts were collected for H&E staining and monocytes were analysed by flow cytometry. BM cells were cultured in pro-osteoclastogenic medium ± TNF-α and the generated osteoclasts were counted.

Results: Rat central and peripheral monocytes comprise two main subsets: $Lin^-(CD90^-CD3^-CD45RA^-Ig\kappa^-)CD172a^+CD11b^+CD43^{hi}$

and $Lin^-CD172a^+$ $CD11b^+CD43^{low}$. A $Lin^-CD172a^+CD43^{low}CD11b^{low}$ BM monocyte subset has also been described. In B27 rats, there was a substantial increase in the number of circulating $Lin^-CD172a^+CD43^{low}$ monocytes, which significantly correlated with higher levels of plasma CCL2. Interestingly, this population of monocytes (in BM and blood) has the greatest *in vitro* osteoclastogenic potential. Antibiotic treatment of rats substantially reduced colitis, plasma CCL2 levels, and the number of central and circulating $Lin^-CD172a^+CD11b^+CD43^{low}$ monocytes. Finally, antibiotic treatment also prevented the previously described TNF-α enhanced osteoclastogenesis observed in transgenic B27 rats.

Conclusion: B27 rats have increased numbers of myeloid osteoclast progenitors in the circulation and bone marrow, and higher levels of the monocyte chemokine CCL2, potentially contributing to enhanced inflammation and bone loss. Importantly, antibiotic treatment not only reduced gut inflammation but also decreased circulating levels of CCL2 and $Lin^-CD172a^+CD11b^+CD43^{low}$ cells. This study therefore provides a link between colitis and systemic inflammation, and a mechanism connecting these with altered bone homeostasis.

Autoantibodies Against CD74 – a New Diagnostic Marker for Spondyloarthritis (SpA)

Bruno Larida, AESKU.DIAGNOSTICS INC, Oakland, CA
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Pathogenesis, Etiology Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Spondyloarthritis (SpA) is a common debilitating inflammatory disorder. The pathogenesis of axial spondyloarthritis (axSpA) including ankylosing spondylitis (AS), although known to be strongly associated with genes such as the human leukocyte antigen HLA-B27, is still largely unclear. Establishing the diagnosis is difficult, since abnormalities in conventional X-rays develop with a latency of several years and only HLA-B27 is used as a laboratory marker. Additionally, the presence of radiographic sacroiliitis is now essential for the diagnosis of SpA. Furthermore, to prevent destructive effects of the disease, early diagnosis and intervention in patients with SpA may be important. Therefore, the goal of our study was to evaluate antibodies to the human leukocyte antigen class II-associated invariant chain peptide (anti-CD74) as a diagnostic marker of SpA.

Methods:

Sera of SpA and non-SpA patients were analyzed for IgA and IgG antibodies against CD74 by ELISA. Sera for the ELISA were obtained from 117 patients with axial SpA. Sera of 38 blood donors served as controls. All donors provided informed consent for the study, which was approved by the local ethics committee (project number 4928).

Results:

We analyzed 155 sera from 117 SpA and 38 non-SpA patients. SpA patients were more often male and younger. HLA-B27 status was available in 112 patients. Anti-CD74 antibodies were detected in 85.1% of the SpA patients but only in 5% of the non-SpA patients ($p \leq 0.0001$). The detection of both IgG and IgA anti-CD74 antibodies for diagnosing SpA revealed a sensitivity of 77% and a specificity of 90%. Remarkably, IgA autoantibodies against CD74 alone had a sensitivity of 67% and a specificity of 95%, the likelihood ratio (LR) LR+ was 12.7 and LR- was 0.35. Moreover, IgA anti-CD74 antibodies were even more frequent in SpA patients with short disease duration and significantly correlate with more advanced radiological sacroiliitis and reduced spinal mobility.

Conclusion:

Anti-CD74 IgA antibodies were strongly associated with SpA. Antibodies against CD74 could provide an important additional tool for diagnosis of SpA.

Session Title: Spondylarthropathies and Psoriatic Arthritis - Pathogenesis, Etiology Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Ankylosing spondylitis (AS) is an immune-mediated inflammatory disease associated with trabecular bone loss and concomitant aberrant bone formation in the spine. Over 40 genes or genetic regions have been associated with the risk of developing AS. The impact of these genes on disease pathogenesis and the cell types that mediate these effects remain largely unknown. To begin to address these questions we generated induced pluripotent stem cells (iPSCs) from fibroblasts of axial spondyloarthritis (AxSpA) patients and healthy controls (HC), differentiated them into disease-relevant cell lineages like mesenchymal stem cells (MSCs) and osteoblasts (OBs), and analyzed comprehensive gene expression patterns and expression levels of AS risk genes in iPSCs and MSCs using whole blood as a comparison.

Methods: Dermal fibroblasts from two AxSpA patients and one HC were reprogrammed using a Sendai virus vector encoding OCT4, SOX2, KLF4 and MYC. Virus-free iPSCs were differentiated into MSCs using a TGF-β inhibitor. MSCs were differentiated into osteoblasts, by culturing them in cell type specific differentiation media. Immunofluorescence microscopy and flow cytometry were conducted to evaluate the expression of lineage specific markers. Genome-wide gene expression patterns in iPSCs and MSCs were compared with whole blood using RNA-Seq followed by Principle Components Analysis (PCA) and Ingenuity Pathway Analysis (IPA).

Results: Reprogrammed lines expressed iPSC-specific genes and proteins, and iPSCs were successfully differentiated into functional MSCs. Gene expression analysis revealed distinct cell type-specific clusters and differentially expressed pathways identified by IPA. The expression of known AS risk genes in iPSCs and MSCs was compared to peripheral blood, revealing several genes that were highly enriched in MSCs (e.g. EDIL3, ANO6, HAPLN1) or expressed at high levels, but comparable to blood (TNFRSF1, TYK2, SH2B3, and STAT3). MSCs were further differentiated into osteoblasts. Differences in osteoblast mineralization potential between subject-derived lines were consistent in duplicate iPSC derivations, with the AxSpA patient exhibiting 3-fold higher mineralization than the HC along with increased expression of alkaline phosphatase (ALP) mRNA in patient lines, whereas other genes associated with osteoblast differentiation (etc. RUNX2, Osterix) were expressed equally in all lines.

Conclusion: AxSpA patient-derived iPSCs demonstrated pluripotency, lineage-specific gene expression patterns, and could be differentiated into disease-relevant cell types. A subset of risk genes was expressed predominantly in MSCs, underscoring the potential utility of these cells in studying pathogenic mechanisms. Moreover, enhanced OB mineralization potential was reproducible in separate iPSC derivations from the same individuals. We are currently generating more lines to determine whether this is a disease characteristic. In summary, skin fibroblast-derived iPSCs provide a powerful system to explore the functional genomics of AS risk genes that may impact bone formation.

Stimulation of Autophagy Reduces Misfolded HLA-B27 in a Rat Model of Spondyloarthritis

Fatemeh Navid[1], Gerlinde Layh-Schmitt[1] and Robert A. Colbert[2], [1]NIAMS/NIH, Bethesda, MD, [2]National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, MD

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Pathogenesis, Etiology Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: HLA-B27/human $\beta_2$microglobulin transgenic rats develop spondyloarthritis (SpA) characterized by inflammation in the gut and peripheral joints by mechanisms that remain poorly defined, but do not require CD8+ T cells. HLA-B27 has a tendency to misfold and dimerize, and when upregulated, aberrant forms can accumulate in the endoplasmic reticulum (ER) and on the cell surface. ER accumulation can activate an unfolded protein response (UPR), which promotes pro-inflammatory cytokine production, and cell surface accumulation may trigger effector immune cells expressing certain killer immunoglobulin receptors (KIRs), both of which may contribute to disease. Here, we examined whether autophagy is involved in the degradation of HLA-B27 in transgenic rats and whether alteration of this pathway may affect accumulation of aberrant forms and the generation of ER stress.

Methods: Bone marrow-derived macrophages (MΦ) were obtained from HLA-B27-transgenic (TG), HLA-B7-TG and Lewis wild type (WT) rats and autophagy was induced with rapamycin treatment for 2 hours. Chloroquine or bafilomycin were used to block autophagic flux. The level of autophagy was measured by the amount of cytosolic microtubule-associated protein 1 light chain 3B-II (LC3B-II) expression detected by western blot (WB), flow cytometry (FACS) or immunofluorescence (IF). Expression of HLA-B27 was determined by WB analysis of cell lysates or after immunoprecipitation (IP) with the HC10 antibody. XBP1 mRNA splicing was used as an early marker to determine whether the UPR is activated after stimulation with IFNγ and TNFα in the presence or absence of bafilomycin or rapamycin.

Results: There was no difference in autophagy in HLA-B27-expressing MΦ compared to WT and HLA-B7-expressing cells based on WB and FACS analysis of LC3B-II expression upon stimulation of autophagy (rapamycin) or inhibition of autophagic flux (chloroquine). LC3B-II expression determined by IF showed a cytosolic vesicular pattern in all cells confirming LC3B-II localization in autophagic vesicles. However, inhibition of autophagic flux (bafilomycin) during upregulation of HLA expression with IFNγ resulted in an accumulation of HLA heavy chains, and in particular misfolded forms of HLA-B27. There was also significant exacerbation of ER stress (which itself is induced by blocking autophagic flux) as measured by XBP1 mRNA splicing. In contrast, activation of autophagy with rapamycin reduced the accumulation of aberrant forms of HLA-B27 induced by IFNγ, and resulted in diminished XBP1 splicing.

Conclusion: These results demonstrate that blocking autophagic flux causes ER stress, and that HLA-B27 expression exacerbates this response. More importantly, induction of autophagy can reduce the accumulation of misfolded forms of HLA-B27, and may alleviate ER stress. Current studies are assessing effects of autophagy on the cellular distribution of aberrant forms of HLA-B27. Alteration of the autophagic pathway may be a promising therapeutic tool worthy of further investigation in the treatment of SpA.

Session Date: Tuesday, November 10, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Pathogenesis, Etiology Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: HLA-B27 and human beta 2-microglobulin expression in rats (transgenic; TG) induces a spontaneous inflammatory disease resembling human spondyloarthritis (SpA) with associated gastrointestinal inflammation. While aspects of rat SpA have been studied in detail, our understanding of gut inflammation remains limited. We recently showed that HLA-B27 affects the

gut microbiota in TG rats. Therefore, the aim for our current project was to determine the association between intestinal microbiota and host gut transcriptome among TG rats developing SpA-like disease. Lewis (LEW), Fischer (F344), and Dark Agouti (DA) rats with same transgene locus (33-3) at 2, 3 and 6 months of age along with strain-specific controls were studied. TG LEW and F344 rats develop SpA beginning with colitis at about 8 weeks of age, while TG DA rats are disease resistant. Arthritis develops later in LEW and F344 TG animals, and is more variable.

Methods: To determine gut inflammation, tissue samples from cecum and colon were stained with H&E and scored for histology. Gut transcriptome differences were analyzed using Illumina HiSeq 2000 and differential gene expression was assessed. To characterize microbial profiles, 16SrRNA gene from gut microbiota was amplified and sequenced using Illumina MiSeq. Data were quality-filtered using Quantitative Insights Into Microbial Ecology (QIIME) and relative frequency was calculated.

Results: Inflammation in the cecum and colon occurred earlier and was more severe in F344 TG rats compared to LEW based on histology scores. Differential gene expression in LEW and F344 TG animals revealed marked up-regulation of IL-17 (A, F) as well as upregulation of *Il23a.* Interferon (IFNg) and IFN response genes were upregulated in TG rats, as were apoptotic signaling and oxidative stress pathways (upregulation of *Gpx2, Nox1*, *Duox2* and downregulation of *Apoa1*). Although there was no significant gut inflammation in DA TG rats, we observed upregulation of many of these genes at 2-3 months, followed by return to normal at 6 months of age. Microbial profiling revealed increased relative frequency of *Akkermansia* in F344 TG and LEW TG rats. Increased abundance of *Candidatus Arthromitus*, a segmented filamentous bacteria (SFB) implicated in inducing Th17 responses, was detected in the F344 and LEW animals. Interestingly we were unable to detect SFB in DA, which could account for the lack of Th17 cytokines and absence of SpA including gut inflammation.

Conclusion: Transcriptome analysis of the HLA-B27 TG reveals upregulation of interferon and Il23/Il17 mediated pathways suggesting a proinflammatory shift in the immune microenvironment of the gut. In TG rats, microbial dysbiosis is associated with a decrease in *Firmicutes*, and an expansion of *Proteobacteria, Prevotella spp.* and *Akkermansia muciniphila.* Protective effects of DA background may be linked to the absence of SFB in the gut. Ongoing analyses underway correlating microbial communities with activation of the IL-23/IL-17 axis, IFN signaling, and oxidative stress pathways will establish links with disease severity. This should increase our understanding of SpA associated IBD and generate mechanistic hypotheses as well as potential biomarkers for diagnosis and treatment.

Session Time: 9:00AM-11:00AM

Background/Purpose:

IgA production is the main barrier mechanism of mucosal surfaces. High affinity IgA is generated through T cell-dependent mechanisms and preferentially binds to invasive or pathogenic bacteria, whereas low affinity IgA is T cell-independent and binds commensal bacteria. Next-generation sequencing of IgA-coated bacteria (IgA-SEQ) identified consortia of bacteria from mouse or human gut microbiota that exacerbate murine colitis, including unclassified *Prevotella* and *Bacteroides* species. The colitogenic species, *Prevotella copri,* was associated with new-onset rheumatoid arthritis, and *Prevotella spp*. were increased in the cecum of HLA-B27 transgenic rats. BALB/c ZAP-70^{W163C} (SKG) mutant mice treated with beta-glucan (curdlan) develop an IL-23-dependent disease recapitulating human spondyloarthritis, in which ileitis is microbiota-dependent. SKG mice housed in specific pathogen-free (SPF) conditions have a dysbiosis in which Gram negative bacteria are over-represented. Furthermore, ileitis severity is decreased in TLR4-deficient SKG mice. Our aim was to study SKG mice colonized with a limited bacterial consortium or an unrestricted microbiota to define bacteria driving dysbiosis and the development of ileitis in a genetically susceptible host.

Methods:

Fecal and tissue samples were collected from germ-free (GF) SKG and GF-BALB/c mice recolonized with a limited bacterial consortium known as altered Shaedler microbiota (ASM) (*Eubacterium plexicaudatum*, *Lactobacillus murinus*, *Mucispirillum schaedleri*, 2 *Clostridium* sp., *Lactobacillus* sp., *Parabacteroides* sp., *Firmicutes* bacterium). Fecal samples were collected from naive SKG mice housed under SPF conditions and IgA-coated bacteria were enriched by magnetic-activated cell sorting, then the IgA^{bright} and IgA^{dim} bacteria were enriched by fluorescence-activated cell sorting. Real-time PCR identified the fecal microbiota composition in ASM mice. IgA-, IgA^{dim} and IgA^{bright} bacteria were identified by deep sequencing.

Results:

After colonization of GF mice with ASM, four bacterial strains were detected in ASM-SKG and ASM-BALB/c mice: *Clostridium* sp., *Lactobacillus murinus*, *Mucispirillum schaedleri*, *Parabacteroides* sp. ASM-SKG microbiota exhibited dysbiosis relative to ASM-BALB/c in that the Gram positive *Clostridium* sp. and Gram negative *Parabacteroides* sp. were decreased in SKG faces. However, the dominant bacterial species in both strains of mice was the *Parabacteroides* sp. In naive SKG mice housed under SPF conditions, Gram negative *Prevotellaceae* were enriched among IgA^{bright} bacteria, while Gram negative *Lactobacillaceae* were diminished. Conversely *Lactobacillaceae* were enriched among IgA^{dim} bacteria and *Prevotellaceae* were diminished.

Conclusion:

Interaction of the microbiota with the immune system of SKG mice alters the composition of both a limited consortium and an unrestricted bacterial community. The most immunogenic IgA^{bright} bacteria within the microbiota of naïve SKG mice are enriched in *Prevotellaceae*, which have been associated with rheumatoid arthritis and inflammatory bowel disease. IgA-SEQ is a powerful tool to identify potentially immunogenic bacteria from a highly diverse microbiota.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Pathogenesis, Etiology Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: *TBX21* encodes T-bet, a T-box transcription factor, and lies within a locus with genome-wide significant association with AS (rs11657479, odds ratio=1.13, $P=6.16x10^{-10}$). T-bet is implicated in both innate and adaptive arms of immunity. However, the role of T-bet in AS pathogenesis is unclear

Methods:

We examined the role of T-bet in disease development and progression in peripheral blood mononuclear cells (PBMCs) from 172 AS cases and 83 healthy control (HC) carrying either risk or protective alleles of rs11657479, the peak AS-associated *Tbx21* SNP, by qPCR and flow cytometry. We also examined kinetics and localization of T-bet expression in the SKG mouse model of spondyloarthropathy, and the impact of *Tbx21* knockout on arthritis development in SKG mice.

Results:

T-bet expression by qPCR was increased in AS cases compared with HC ($P=3.6x10^{-5}$), and was associated with rs11657479

genotypes in AS cases (P=0.0017), with risk genotype carriers having higher expression (ΔΔCt=0.064±0.074) than protective (ΔΔCt=0.022±0.020, P=0.0003) genotypes. The proportion of cells expressing T-bet was increased in both CD3-positive and -negative PBMCs in AS vs HC (CD3- 1.3x increase, P=0.0012; CD3+ 3.9x increase, $P<10^{-4}$). A marked expansion of T-bet CD3+ CD4- CD8+ T cells was seen in AS cases (31.47±8.45%) compared with healthy controls (3.00±2.54%)(P<0.0001), with all AS cases studied having higher proportions of these T-bet expressing cells than all controls studied. This increase in AS case T-bet expression was particularly prominent in interleukin-17- (IL-17) producing NK cells (3.4x increase % cells expressing T-bet, P=0.0005) and cytotoxic T ($T_C17.1$) cells (5.6x increase % cells expressing T-bet, $P<10^{-4}$). In curdlan-treated SKG mice, T-bet expression increased early after disease initiation and persisted, from 7 days onward, throughout the course of AS-like disease. In Tbx21-/- compared with wild-type SKG mice, there was marked reduction in both gut and peripheral joint inflammation, and reduced numbers of $T_C17.1$ cells.

Conclusion: *Tbx21* genetic variants operate to increase the risk of AS through effects on T-bet expression. T-bet, through influences on the function of innate and adaptive immune cells, plays a major role in the pathogenesis of spondyloarthropathy in humans and mice.

Session Date: Tuesday, November 10, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Pathogenesis, Etiology Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: We have previously shown that synovial fluid mononuclear cells (SFMCs) of patients with Reactive arthritis (ReA) and undifferentiated Spondyloarthropathy (uSpA) proliferated to low molecular weight fractions of outer membrane proteins (OMP) of *S typhimurium*. Proteomic analysis of the the stimulatory fractions predicted to consist of 10 proteins including OMPA and OMPD . In this study, we examined the *in vitro*immunogenecity of recombinant (r) OMP A and D by measuring frequency of antigen specific CD4+ and CD8+ T cells against rOMP A and D in the synovial fluid (SF) of patients with ReA/uSpA. Further, induction of proinflammatory cytokines (IFN- γ, IL-17 and IL-23) were measured by SFMC stimulated by rOMPA and rOMP D in these patients.

Methods: Patients presenting with typical clincial picture of asymmetric lower limb oligoarthritis with a history of preceding diarrhoea within 4 weeks were labelled as Rea and uSpA patients fulfilled ESSG criteria. Synovial fluid were aspirated from inflammed knee joint prior to steroid injections and monnonuclear cells (SFMC) were isolated and cultured with crude extract of s typhimurium OMP and rOMPA/D for flow cytometry, ELISPOT and cytokines in the culture supernatant. Intracellular IFN-γ and IL17 producing SF T (CD4+CD69+ and CD8+ CD69+) cells was enumerated by Flow cytometry (Beckman Coulter, USA) Antigen specific IFN-γ producing T cells were also measured by ELISPOT. A positive response was taken if the ratio of % cells or mean spots/well with antigen/Control ≥ 3. IFN-γ (BD,USA) , IL17 and IL23 (ebioscinces, USA) levels were measured by commericial ELISA in the culture supernatant of antigen treated SFMCs.

Results: Out of 20 patients recruited, 17 were males with a median age 27.6 years (range 15-65 year). Eleven patients were ReA. The median duration of current episode was 15 days (range 3-180) days. HLA B27 were positive in 13/19 patients. Thirteen out of 20 patients with ReA/uSpA, showed a CD8+CD69+IFN+ response to crude OMP suggesting triggered by *S. typhimurium*. Of these 13, 9 patient's SF CD8+CD69+T cells positive for intracellular γ-IFN in response to rOMPA as compared to 4 patients who responded to rOMPD. The mean frequency (%) of antigen specific CD8+CD69+ T cells were 0.56±0.5 to rOMPA and 0.24±0.15 to rOMPD in

comparison to blank 0.18±0.17. Regarding CD4+T cell response, 6 out of 15 were postive against crude OMP and of these 4 responded to rOMPA and only 2 responded to rOMPD. By ELISPOT assay 13, 7 and 3 patients showed increased IFN-γ producing T cells to crude OMP, rOMPA and rOMPD respectively. Only 1 RA patients SF CD8+T cells showed response to crude OMP. SFMC upon stimulation with rOMP A and not rOMP D produce significant IFN-γ, IL-17 and Il-23 in comparison to non treated cells (Table)

Table . Induction of pro inflammatory cytokines by SFMC stimulated by rOMP A /D

Cytokine (pg/ml)	Blank, (a)	rOMP A (b)	Significance b vs a	rOMP D c	Significance c vs a
IFN γ	691.98±999.27	3129.4±5365.48	P<0.05	1793.2±2842.79	No signifiance
IL17	36.42±62.64	74.33±129.27	P<0.05	41.58±72.54	No significance
IL23	44.86±41.98	208.59±269.56	P<0.05	49.87±59.43	No significance

Conclusion: OMPA is a major antigenic target in patients with *Salmonella* triggered ReA/uSpA.

A Subset of Natural Killer Cells Are Expanded in Synovial Fluid of Patients with Reactive Arthritis and Undifferentiated Spondyloarthritis

Abhra Chandra Chowdhury, Smriti Chaurasia, Amita Aggarwal and Ramnath Misra, Clinical Immunology, Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Pathogenesis, Etiology Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

We have previously shown that there is an increase in IL-17 in the synovial fluid of patients with Reactive arthritis(ReA) and undifferentiated spondyloarthropathy(uSpA). Besides Th17 cells, IL-17 is produced by several innate cells such as NK, NKT , γδT and double negative T cells(DNT) To account for increased IL-17 we have enumerated these innate cells in the peripheral blood and synovial fluid of patients with ReA/uSpA.

Methods:

Patients were labelled as Reactive arthritis if they had a typical clinical history of acute or subacute onset of asymmetrical oligoarthritis with a preceding history of diarrhoeal illness within 4 weeks and as uSpA if patients fulfilled ESSG criteria but didnot fit into any defined spondyloarthropathy. 10 to 30 ml of Synovial fluid was aspirated from the inflammed knee joint prior to corticosteroid injection along with peripheral blood in EDTA for cell analysis. Peripheral blood (PB) of 28 patients with ReA/uSpA and paired synovial fluid (SF)in 20 patients were collected between September 2014 and June 2015 for analysis. The percentage of NK cells(CD56+CD3-)/NK cells($CD56^{bright}$) / NK cells($CD56^{dim}$) / NKT cells(CD3+/CD56+) , DNT cells($CD4^-/CD8^-$ αβTCR+CD3+)and γδT cells(γδTCR+CD3+) were determined by flow cytometry (Beckman Coulter, USA) using a panel of monoclonal antibodies (BD biosciences, USA) In paired samples the percentage of cells were compared between the synovial fluid and peripheral blood by non parametric tests(Wilcoxon signed ranks test)

Results:

28 patients(male-25 female–3) with a median age 24(IQR 20-31) years were recruited .Of these 12 were ReA and 16 were uSpA.4 patients had chronic symptoms whereas 24 had acute episode.Knee was the most common joint involved followed by ankle.11 patients had evidence of enthesitis (most common-achilles tendinitis)whereas 3 patients had extra-articular involvement. The median frequency and interquartile range of various cell population in the peripheral blood and synovial fluid are presented in Table 1.

Table 1. Percentage (median and interquartile range) of various innate cells in peripheral blood and synovial fluid

Innate cells	Peripheral blood % median(interquartile range)	Synovial Fluid % median(interquartile range)
NK cells(CD56+CD3-)	8 (6.3-10.5)	10.6(5.7-13)
CD56 ^{bright}NK cells	0.5 (0-0.9)	4.4(0.35-8.45)**
CD56 ^{dim} NK cells	6.8 (0-10.3)	1.35(0.15-2.80)**
NKT cells	3.3(1.2-5.6)	2.2(1.40-3.75)
DNT cells	1.7(0.9-2.0)	1.8(1.2-2.2)
γδT cells	3.3(1.4-5.4)	1.5(0.85-3.15)*

** $p < 0.005$ * $p < 0.05$

CD56 ^{bright} NK cells was significantly increased in synovial fluid(p=.000) and CD56 ^{dim}NK cells was significantly decreased in synovial fluid(p=0.001) in comparison to peripheral blood. As it is known that CD56 bright NK cells can produce IL17 , these cells can be a innate source of IL17 in the inflamed joints.Also γδT cells was significantly increased in peripheral blood (P=.022).

Conclusion:

CD56 ^{bright} NK cells which are cytokine producers are expanded in the synovial compartment as compared to peripheral blood and may be contributing to the production of IL-17 in ReA and uSpA. The increase of peripheral blood γδT cells is most likely related to its origin from the gut.

Session Date: Tuesday, November 10, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Pathogenesis, Etiology Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

AS is a chronic inflammatory disease, of unknown aetiology, characterized by pathological ossification. We aimed: 1) To analyze the profile of inflammation, oxidative status and bone turnover in plasma and leukocyte subsets, as well as the endothelial function (EF) in AS patients. 2) To evaluate the relationship among those biomarkers and their correlation with disease activity.

Methods:

Thirty AS patients and 30 healthy donors were included in the study. Disease function and activity status were analyzed by BASFI and BASDAI indexes. EF was determined by the post occlusive hyperaemia test. Biomarkers of oxidative stress, inflammation, thrombosis and bone turnover were analyzed in lymphocytes, neutrophils and monocyte subsets (MON1: $CD14^{+}/CD16^{-}$; MON2: $CD14^{+}/CD16^{+}$; MON3: $CD14^{dim}/CD16^{+}$) by RT-PCR and flow cytometry. Antioxidant enzyme activities, nitric oxide (NO) and total antioxidant capacity (TAC) of plasma were measured by specific kits.

Results:

Compared to healthy donors, a significant EF alteration was observed in AS patients. The analysis of inflammatory markers showed increased expression of TNFα and signal transducter and activator of transcription 3 (STAT3) in neutrophils, and of IL6, IL23, IL2 and STAT3 in lymphocytes. The monocyte analysis demonstrated a reduction in %MON1, along with an increase in %MON2. MON1 showed a specific alteration of STAT3, I kappa B kinase (IKK), TNFα and IL6, whereas MON2+MON3 displayed elevated levels of IL23, macrophage inflammatory protein-1α, tissue factor and IKK. Osteogenic markers significantly elevated in neutrophils were ALP and dickkopf (DKK)-1. Lymphocytes displayed reduced levels of DKK1 and osteoprotegerin (OPG) whereas MON1 showed an alteration of BMP2, DKK1, OPG and TGFß1. Oxidative stress study showed that leukocyte subsets from patients display an increase in oxidative stress markers and mitochondrial dysfunction, along with an alteration of TAC and NO at plasma level. *In vitro* treatment of healthy leukocyte subsets with pooled serum from patients displaying structural damage and low inflammation status caused a significant increase in oxidative stress markers, as well as prominent changes in inflammatory and osteogenic gene expression.

Correlation studies showed that AS development was associated with endothelial dysfunction, inflammation and osteogenesis. Oxidative stress and mitochondrial dysfunction were associated with inflammatory and osteogenic markers. Endothelial dysfunction was correlated with inflammation and mitochondrial dysfunction. Osteogenesis was associated with inflammatory markers.

Conclusion:

1) AS patients show an endothelial dysfunction directly associated with the inflammatory profile and disease progression. 2) Circulating leukocyte subsets in AS patients seem to contribute to the inflammatory and bone turnover processes, so that neutrophils and MON1 seem to mediate both processes whereas lymphocytes and MON2+MON3 seem to be more associated with the inflammatory process. 3) The oxidative stress and, particularly, the mitochondrial dysfunction, might also mediate the inflammation and ossification processes present in AS

Session Date: Tuesday, November 10, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Pathogenesis, Etiology Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriatic Arthritis (PsA) is a chronic immune-mediated inflammatory disease, characterised by proliferation of synovial tissue and progressive destruction of articular cartilage/bone associated with psoriasis. These processes may be governed by microRNA (miRNA), a class of small non-coding RNAs which exert their function through suppression of specific target genes. Altered miR-23a expression has been previously associated with angiogenic and pro-inflammatory mechanisms in other diseases. To date, altered miRNA expression and regulation has not been examined in PsA.

Methods: Synovial tissue biopsies were obtained under direct visualisation from site of inflammation by needle arthroscopy, along with peripheral blood mononuclear cells (PBMC) from PsA (n=8), osteoarthritis (OA) (n=7), and healthy controls (n=8). To examine possible factors involved in regulating miRNA expression, primary PsA synovial fibroblasts (SFC) were isolated and cultured with candidate pro-inflammatory stimuli including TLR ligands: Pam3CSK4 (1 µg/ml), LPS (1 µg/ml), polyIC (10 µg/ml) and pro-inflammatory cytokines: IL-1β (1 ng/ml), TNFα (10 ng/ml) and IL-17 (20ng/ml). Total RNA was extracted using the Qiagen miRNeasy kit, and expression of miR-23a was measured by Sybr Green real-time PCR. In parallel, IL-6, IL-8 and MCP-1 were quantified in culture supernatants by ELISA. Clinical demographics such as CRP, TJC, SJC and patient global were also assessed.

Results: A significant increase in miR-23a expression was demonstrated in PsA PBMC versus OA (p=0.0476) and HC (p=0.0186). In contrast, a significant decrease in miR-23a expression was observed in PsA synovial tissue compared to OA (p=0.0172). In PsA, synovial miR-23a expression negatively correlated with matched PBMC miR-23a (r=-1.00, p=0.0167), demonstrating a dissociation in miR-23a expression between systemic and local inflammation. Furthermore, miR-23a expression in PsA synovial biopsies inversely correlated with DAS28-CRP (r= -0.5294, p=0.035). TLR activation *via* PolyIC (TLR3) and LPS (TLR4) significantly decreased miR-23a expression in primary PsA SFC (all $p<0.05$), with no effect observed for pro-inflammatory cytokines. This was paralleled by a significant induction of IL-6, IL-8 and MCP-1 in response to LPS and PolyIC (all $p<0.05$). Finally, *in silico* analysis identified putative targets for miR-23a including PDE4B and PTK2B, which are known to be involved in multiple immune pathways, osteoclast function and angiogenic mechanisms.

Conclusion: This is the first report of altered expression and regulation of miRNA in PsA, levels of which were inversely associated with increased joint inflammation. MiR-23a may be an important regulator of pathogenesis in PsA and may represent a potential target for therapeutic strategies. Further work will examine the functional role of miR-23a and it's implications on disease pathogenesis in PsA.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Pathogenesis, Etiology Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriatic arthritis (PsA), an inflammatory musculoskeletal disease, develops in approximately 30% of patients with psoriasis. We previously identified C-X-C motif chemokine 10 (CXCL10) as a predictive biomarker of PsA in patients with psoriasis. This study explores the expression of CXCL10 in the joint of PsA patients.

Methods: Synovial fluid (SF) was obtained from patients with PsA, osteoarthritis (OA) and gout undergoing routine joint aspirations. PsA patients with paired SF and serum samples were identified from the cohort of patients followed prospectively. The expression of CXCL10, TNFα, IL-17A and IFNγ were measured using the Milliplex MAP human chemokine/cytokine magnetic bead panel (EMD Millipore), according to the manufacturer's instructions. Data was acquired using the Luminex 200 system and analyzed with the Bio-Plex Manager software (Bio-Rad Laboratories). Statistical differences in protein levels between groups were identified by Wilcoxon signed rank test for paired samples and by Wilcoxon rank sum test for comparison between PsA patients and controls ($p<0.05$ was accepted as significant).

Results: Cytokine and chemokine expression was measured in SF from 40 patients with PsA and 17 controls (OA and gout). CXCL10 (5.87 ± 4.53 vs. 1.73 ± 2.08 ng/ml, $p=4.6x10^{-5}$) and IL-17A (14.3 ± 11.6 vs. 3.13 ± 3.1 pg/ml, p=0.0001) were significantly elevated in PsA patients compared to controls (Figure 1). In paired samples from 11 PsA patients (mean age 43 years, 91% males, psoriasis duration 17 years, PsA duration 11 years, PASI 7.7, tender joint count 2, swollen joint count 2), CXCL10 was significantly (p=0.001) increased in SF (6.3 ± 4.3 ng/ml) compared to serum (0.4 ± 0.3 ng/ml) while both TNFα (53.7 ± 68.0 vs. 9.0 ± 6.5 pg/ml, p=0.001) and IFNγ (154.3 ± 318.6 vs. 16.3 ± 24.3 pg/ml, p=0.01) were significantly reduced. Additionally, we measured the change in CXCL10, TNFα, IL-17A and IFNγ in SF from 15 PsA patients after follow-up, however no significant differences were found.

Conclusion: This study confirms previous reports of elevated synovial CXCL10 and IL-17A in PsA patients. The differences in SF and serum levels of CXCL10, TNFα and IFNγ that were observed may be important in the pathogenesis of PsA.

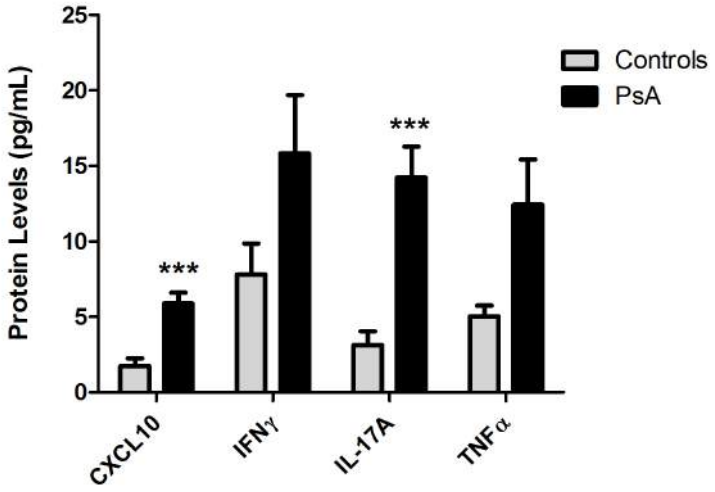

Figure 1: Histogram of CXCL10, IFNγ, IL-17A and TNFα expression in SF from 40 PsA patients and 17 controls (OA and gout). ***indicates a significant difference compared to controls. CXCL10 concentration was converted to ng/ml.

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Previous reports of RAPID-PsA (NCT01087788) have demonstrated the efficacy of certolizumab pegol (CZP) in patients (pts) with psoriatic arthritis (PsA) over 96 weeks (wks),[1] and have shown that improvements in ACR responses and skin manifestations were similar regardless of prior anti-TNF exposure.[2] Here we report the efficacy of CZP for the treatment of joint and extra-articular manifestations (EAMs) of PsA in pts with and without prior anti-TNF exposure over 96 wks of the RAPID-PsA trial.

Methods:

RAPID-PsA was double-blind and placebo-controlled to Wk24, dose-blind to Wk48 and open-label to Wk216. Pts had active PsA, had failed ≥1 DMARD, and ≤40% pts could have received 1 prior anti-TNF. 409 pts were randomized at baseline (BL) to either placebo or CZP (200 mg Q2W/400 mg Q4W, following 400 mg loading dose at Wks 0, 2, 4). The primary clinical endpoint was Wk12 ACR20

response.[3] Joint disease activity was assessed in all pts using the tender joint count (TJC), swollen joint count (SJC) and DAS28(CRP). EAMs were assessed in pts with BL involvement and included nail psoriasis (modified nail psoriasis severity index [mNAPSI], BL involvement = BL mNAPSI >0; for some pts the nail analyzed was different at one or more visit to Wk96), enthesitis (Leeds enthesitis index [LEI], BL involvement = BL LEI >0) and dactylitis (Leeds dactylitis index [LDI], BL involvement = at least 1 digit affected and with a difference in circumference ≥10% compared to the contralateral digit). Observed data are presented for all pts originally randomized to CZP with and without prior anti-TNF exposure.

Results:

There were 409 pts randomized, 273 received CZP from Wk0, of whom 54 (19.8%) had prior anti-TNF exposure. Of the 273 CZP-randomized pts, 197 (72.2%) had BL nail psoriasis, 172 (63.0%) BL enthesitis and 73 (26.7%) BL dactylitis. BL scores for joints and EAMs were similar in pts with and without prior anti-TNF exposure (Table).

By Wk4, CZP treatment was associated with rapid improvements in all measures of joint disease activity, including TJC, SJC and DAS28(CRP). Improvements in all outcomes continued through to Wk96 and were very similar in pts with and without prior anti-TNF exposure (Table). Similarly, improvements in nail psoriasis, enthesitis and dactylitis were seen to Wk96 of CZP treatment in PsA pts regardless of their prior anti-TNF exposure (Table). However, these analyses were limited by the low number of pts with prior anti-TNF exposure.

Conclusion:

Improvements in joint outcome measures and EAMs of PsA were observed over 96 wks of CZP treatment. These improvements were seen across multiple joint outcome measures and in all EAMs assessed, including nail psoriasis, enthesitis and dactylitis. Similar improvements were observed in pts with and without prior anti-TNF exposure.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: ABILITY-2 has demonstrated the efficacy of adalimumab (ADA) vs. placebo (PBO) over 12 weeks (wk) in patients (pt) with peripheral spondyloarthritis (pSpA)[1] and sustained response following up to 2 years (yr) of ADA. The purpose of this study is to determine predictors of long-term remission in pts with pSpA.

Methods: In ABILITY-2 pts were randomized to receive ADA 40 mg every other wk or PBO during a 12-wk double-blind period, followed by an open-label period of up to 3 yrs of treatment. PSpARC1 remission was defined as SJC ≤1 plus 4/5 of the following: Physician's Global Assessment (PGA) of Disease Activity ≤20 mm (visual analog scale, VAS); PGA-pain ≤20 mm VAS, TJC ≤1, enthesitis count ≤1, dactylitis count ≤1. ASDAS inactive disease (ASDAS ID) was ASDAS score <1.3. Possible predictors for remission at 1 and 3 yrs of ADA treatment were selected a priori. Categorical variables included symptom duration, abnormal baseline (BL) hs-CRP, HLA-B27+, and response at wk 12 for BASDAI50, PSpARC, and ASDAS categories. Continuous variables included BL values for TJC, SJC, enthesitis count, BASDAI, ASDAS, Patient Global Assessment of disease activity (PtGA), PGA, and hs-CRP. Univariate logistic regression was used to evaluate predictors for remission variables at yrs 1 and 3. Multivariate analysis was done to determine predictors of achieving sustained (≥ 3 consecutive visits) remission at any time during the study.

Results: 165 pts (ADA 84/PBO 81) were randomized. Among pts completing both yr 1 and 3, 48.2% (54/112) of pts achieved PSpARC remission and 58.9% (63/107) were in ASDAS ID at yr 3. Univariate analysis showed that wk 12 responses were more consistent predictors of remission at yr 1 or 3 (Figure) than most BL disease characteristics. Abnormal BL hs-CRP was a predictor of PSpARC remission at yr 3, but not at yr 1. Furthermore, abnormal BL hs-CRP was not a predictor of ASDAS ID at yr 1 or 3. 44.9% (74/165) and 57.6% (95/165) achieved sustained PSpARC remission and ASDAS ID, respectively, during the 3-yr study. Multivariate analysis demonstrated that PSpARC remission at wk 12 predicted sustained PSpARC remission (Odds ratio (OR) 95.96, *P*=0.0023) and ASDAS ID at wk 12 predicted sustained ASDAS ID (OR 46.29, *P*=0.0084).

Conclusion: Early response to ADA in pSpA patients is a better predictor of long-term remission for up to 3 years, whether at a single point in time or sustained over time, than baseline disease characteristics.

Session Date: Tuesday, November 10, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-TNF agents are efficacious in the treatment of ankylosing spondylitis (AS). The switch to another TNF blockage can be an alternative in cases of lack or loss of efficacy and side effects. There are, however, no clear evidence for a beneficial effect of co-therapy with conventional synthetic DMARDs in AS. The aim of this study was to determine the efficacy and predictors of anti-TNF switch in the long-term follow-up of AS patients, in a routine clinical care center.

Methods: Data from an ongoing longitudinal electronic database of AS patients under anti-TNF therapy between June 2004 and August

2013 were assessed. Demographic and clinical parameters, concomitant therapy and treatment responses by ASDAS were recorded. ASDAS remission(<1.3) and ASDAS inactive/moderate(<2.1) were analyzed to characterize the switch of TNF blockage. Final assessment of switch response excluded patients who underwent anti-TNF therapy less than 24 weeks and patients that stopped a given anti-TNF treatment course due to non-adherence, adverse events or infection (without further drug introduction).

Results: Of 117 AS patients treated with anti-TNF (mean treatment duration: 39.4 ± 30.1 months) 69(59%) received solely the first anti-TNF, 48(41%) switched to a second anti-TNF (58% failure and 42% side effects) and 13(11%) to a third anti-TNF (62% failure and 38% side effects).The choice of the second anti-TNF did not influence the maintenance of the therapy; it was comparable among patients who started and switched to monoclonal antibody (infliximab or adalimumab) and those who started with monoclonal antibody and switched to etanercept (66% vs. 77%, p=0.72). At the final assessment, 42 patients still under the first anti-TNF (non-switcher group) achieved more frequently ASDAS remission-ESR (62% vs. 36%, p=0.04) and ASDAS inactive/moderate-ESR (88% vs. 58%, p=0.03) than patients treated with more than one anti-TNF. The switch to a third anti-TNF resulted in a lower response rate with 25% reaching inactive/moderate disease activity (p<0.001) and 12.5% achieving ASDAS remission (p=0.03). Duration of the last anti-TNF treatment was comparable in all groups (p=0.24). Non-switchers achieved lower BASDAI (p=0.04) and BASFI (p=0.03) than switcher groups. Switchers due to failure or adverse effects were comparable regarding demographic and clinical parameters at baseline and at final assessment. The analysis of predictors at baseline revealed that non-switchers were more often treated with sulfasalazine (SSZ) (63.8% vs. 41.7%, p=0.02) than switcher patients. Further evaluation of the use of this drug revealed that non-switchers with pure axial involvement also used more frequently SSZ than switchers (70.8% vs.15% vs. p=0.03). In contrast, the frequency of SSZ use was comparable in non-switchers and switchers AS patients with peripheral involvement (58.1% vs. 48.7%, p=0.51).

Conclusion: This study provides novel evidence that SSZ comedication reduces anti-TNF switch in AS patients, particularly in those with pure axial disease. The underlying mechanism remains unknown and may involve the prevention of anti-drug antibodies formation and/or an additional anti-inflammatory effect.

Session Date: Tuesday, November 10, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Spondyloarthritis (Spa) is a group of inflammatory diseases in which ankylosing spondylitis (AS) is the prototype. Despite recent advances in pathophysiology and treatment, this group is still a challenge, particularly regarding the understanding of the inflammatory pathways involved, predictors of anti-TNF response and risk factors for radiographic progression. The aim of our study was to investigate the long-term influence of TNF-blockage in IL-23/IL-17 axis of ankylosing spondylitis (AS) patients.

Methods: Eighty-six AS anti-TNF naïve patients, 47 referred for anti-TNF therapy (active-AS; BASDAI ≥4) and 39 with BASDAI<4 (control-AS) were included. The active group was evaluated at baseline, 12-months and 24-months after TNF blockage and compared at baseline to control-AS group and to 47 age- and gender-matched healthy controls. Plasma levels of IL-17A, IL-22, IL-23 and PGE2 were measured. Radiographic severity and progression was assessed by mSASSS.

Results: At baseline, active-AS group presented higher IL-23 and PGE2 levels compared to control-AS group (p<0.001 and p=0.008) and to healthy controls (p<0.001 and p=0.02). After 24-months of TNF blockage, IL-23 and PGE2 remained elevated in which group (I suppose active-AS but you don't mention control-AS here) with higher levels compared with the healthy group (p<0.001 and p=0.03) in spite of significant improvements in all clinical/inflammatory parameters(p<0.001). Further analysis of 27 anti-TNF-treated patients who achieved a good response(ASDAS-CRP<2.1,with a drop≥1.1) at 24-months revealed that IL-23 plasma levels remained higher than healthy controls(p<0.001) and higher than control-AS group with similar disease activity (ASDAS-CRP<2.1, p=0.01). In active-

AS group(n=47), there was a strong positive correlation between IL-23 and IL-17A at baseline, 12-months and 24-months after anti-TNF therapy($p \leq 0.001$).

Conclusion: This study provides novel data demonstrating that IL-23/IL-17 axis is not influenced by TNF blockage in AS patients despite clinical and inflammatory markers. In this context, the IL-23/IL-17 blockage emerges as a potential additional target in AS.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Apremilast (APR), an oral phosphodiesterase 4 inhibitor, acts to regulate immune responses in psoriatic arthritis (PsA). PALACE 3 compared the efficacy and safety of APR with placebo (PBO) in patients with active PsA, including active skin disease, despite prior conventional DMARDs and/or biologics. We report the efficacy and safety of APR treatment over 104 weeks in PALACE 3.

Methods: Patients were randomized (1:1:1) to PBO, APR 30 mg BID (APR30), or APR 20 mg BID (APR20) stratified by baseline DMARD use (yes/no) and psoriasis involvement of the body surface area (<3%/≥3%). The PBO-controlled phase continued to Week 24, with an early escape option at Week 16. At Week 24, all remaining PBO patients were re-randomized to APR30 or APR20. Double-blind APR treatment continued to Week 52; subsequently, patients could continue APR for up to 4 additional years in an open-label extension study.

Results: 505 patients were randomized and received ≥1 dose of study medication (PBO: n=169; APR30: n=167; APR20: n=169); 82% of patients entering the second year of APR therapy completed 104 weeks of treatment. Patients receiving APR at Week 104 demonstrated sustained decreases in disease activity. At baseline, 65.7% and 27.7% of APR30 patients and 61.8% and 28.6% of APR20 patients had moderate (DAS-28 [CRP]): ≥3.2 to ≤5.1) and severe (DAS-28 [CRP]: >5.1) disease, respectively; 43.4% (APR30) and 44.0% (APR20) achieved DAS-28 (CRP) remission at Week 104 (Table). Sustained relief of signs/symptoms and improvements in physical function were demonstrated by the swollen/tender joint count mean percent change, HAQ-DI mean change, proportion of patients with HAQ-DI score exceeding the minimal clinically important difference (MCID) ≥0.30 threshold, modified ACR20/ACR50/ACR70 response rates, and PASI-75/PASI-50 response rates (Table). No new safety concerns were observed with treatment through Week 104; long-term findings indicate that APR tolerability improved with long-term exposure. During Weeks >52 to ≤104, adverse events (AEs) occurring in ≥5% of APR-exposed patients were nasopharyngitis and upper respiratory tract infection; most AEs were mild/moderate in severity. Serious AEs occurred in 5.8% (APR30) and 6.2% (APR20) during Weeks 0 to ≤52 and 8.7% (APR30) and 7.5% (APR20) over Weeks >52 to ≤104. Fewer discontinuations due to AEs occurred during Weeks >52 to ≤104 (3.5%) than during Weeks 0 to ≤52 (7.5%).

Conclusion: Over 104 weeks, APR demonstrated sustained, clinically meaningful improvements in PsA disease activity, physical function, and associated psoriasis. APR continued to demonstrate a favorable safety profile and was generally well tolerated.

Outcomes at Week 52 and Week 104 (Data as Observed)				
	Week 52		Week 104	
	APR30 n=194*	APR20 n=178*	APR30 n=161*	APR20 n=135*

PALACE 1-3 compared APR efficacy/safety with placebo in patients with active PsA despite prior conventional disease-modifying antirheumatic drugs (DMARDs) and/or biologics. We report the safety of APR treatment during Weeks 0 to ≤104.

Methods: Patients were randomized (1:1:1) to placebo, APR 30 mg BID (APR30), or APR 20 mg BID (APR20) stratified by baseline DMARD use (yes/no). The placebo-controlled phase continued to Week 24, with an early escape option at Week 16. Double-blind APR treatment continued to Week 52; patients could continue to receive APR during an open-label, long-term treatment phase.

Results: 1,493 patients were randomized and received ≥1 dose of study medication (placebo: n=495; APR30: n=497; APR20: n=501). A total of 1,441 (1,209.3 patient-years) patients received APR in Weeks 0 to ≤52, with 1,028 (907.7 patient-years) continuing treatment during Weeks >52 to ≤104. Of the 1,441 patients randomized, 698 (48.4%) had a full 2 years of exposure. During Weeks 0 to ≤52, adverse events (AEs) occurring in ≥5% of APR-exposed patients were diarrhea, nausea, headache, upper respiratory tract infection, and nasopharyngitis (Table). Most diarrhea and nausea events were reported within the first 2 weeks of treatment and usually resolved in 4 weeks without medical intervention. Most AEs were mild or moderate in severity during the Weeks 0 to ≤104 APR-exposure

period; no increase was seen in the incidence and severity of AEs with longer term exposure. During Weeks >52 to ≤104, diarrhea (2.9%), nausea (1.8%), and headache (3.0%) occurred at lower rates vs. Weeks 0 to ≤52 (Table). Reported serious AEs (SAEs) with APR30 between 0 to ≤52 and >52 to ≤104 weeks were comparable at 6.5% and 6.3%, respectively. Reported SAEs were higher with APR20 at 7.5% between >52 to ≤104 weeks compared with 5.6% between 0 to ≤52 weeks with no cluster indicating any specific organ involvement. Most SAEs were reported by 1 patient each. The cardiac, malignant neoplasm, opportunistic infection, or psychiatric disorder related SAEs were comparable between 0 to ≤52 and 52 to ≤104 weeks, and no cases of tuberculosis (new or reactivation) were reported with either APR dose. Discontinuations due to AEs occurred at a lower rate (2.3%) during Weeks >52 to ≤104 than during Weeks 0 to ≤52 (7.5%). Marked laboratory abnormalities were infrequent, and most returned to baseline with continued treatment or were associated with a concurrent medical condition.

Conclusion: APR demonstrated a favorable safety profile and was well tolerated for up to 104 weeks. These data continue to support the lack of a need for specific laboratory monitoring with APR. No new safety concerns were identified with long-term exposure to apremilast.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Over the past decade, the treatment of PsA has improved significantly. The purpose of this study was to describe real-world treatment patterns among PsA patients following initiation of TNF inhibitor (TNFi) and non-biologic (MTX) therapy over time to understand if increasing clinical evidence for the benefit of TNFi therapy has led to changes in treatment patterns.

Methods: Using data on PsA patients from Corrona, a national multicenter registry of RA and PsA patients, PsA patients were identified between 1/1/2004 and 12/31/2012 and stratified into 3 cohorts; those who had initiated TNFi monotherapy (mono), MTX monotherapy or combination (combo) therapy (TNFi and MTX). Patients with at least 6 months of follow-up data after first therapy initiation were included. The 3 patient cohorts were further stratified over three different time periods (2004-2006, 2007-2009, and 2010-2012) based on year of initiation. Baseline demographic and clinical characteristics were assessed at drug initiation. The key outcome measures of interest were persistence on index medication therapy; gaps in therapy and therapy restarts; therapy changes, including treatment switches and add-on therapy; and length of time on therapy. Persistence was defined as continuous use of therapy over a 12-month period.

Results: There were 520 PsA patients who met inclusion criteria. The 3 groups differed demographically in terms of baseline characteristics. The proportion of patients initiating TNFi mono has decreased over time, while the proportion starting combination therapy has remained steady (Table). Over the three time periods, patients were noted to start TNFi earlier in their disease course; however, time to initiating TNFi mono was longer than time to initiating combo therapy. Mean CDAI at initiation was highest among the combo group and has remained above 12 for all therapy groups in all time periods. Time on initial therapy decreased as the time period cohorts became more contemporary, but persistence on TNFi mono was higher than the other two cohorts across all time periods (in 2010-2012 persistence was 53% on TNFi mono, 34% on MTX mono, and 36% on combo therapy). Patients appear less likely to remove MTX from their combo therapy in recent years (70% in 2004-2006, 34% in 2010-2012), yet no patients dropped TNFi from their combo therapy. In the most recent time period, 11% of mono TNFi users became combo users, whereas 28% of mono MTX users became combo users.

Conclusion: Treatment patterns in PsA patients have changed from 2004-2012, including earlier TNFi initiation and more cycling. This may be due to the increasing number of treatment options available and increased focus on achievement of low disease activity state. However, physicians do not appear to be more likely to initiate patients on TNFi monotherapy even though the clinical evidence supporting their effectiveness has increased over this same time period and patients remain more persistent with it.

Table. Patient characteristics at drug initiation and persistency patterns for PsA patients who enrolled into Corrona 2004-2012 and initiated mono TNFi or mono MTX or combo TNFi/MTX at enrollment or during the follow-up

	2004-2006	2007-2009	2010-2012
Treatment initiation (%)			
TNFi monotherapy	46.4	36.0	32.1
MTX monotherapy	32.7	43.2	45.0
Combination therapy	20.9	20.8	22.9
PsA duration (time to initiation, years)			
TNFi monotherapy	8.4	6.7	6.6
MTX monotherapy	2.8	4.3	2.7
Combination therapy	7.6	7.2	4.2
CDAI score at initiation (mean score)			
TNFi monotherapy	12.8	12.6	14.4
MTX monotherapy	16.8	14.4	14.9
Combination therapy	17.7	17.7	17.9
Treatment persistence (%)			
TNFi monotherapy	71	70	53
MTX monotherapy	64	59	34
Combination therapy	52	65	36
Duration of persistence (time on initial therapy, months)			
TNFi monotherapy	46	31.8	19.6
MTX monotherapy	38.3	30.2	17.5
Combination therapy	46	31.2	21.3

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Several studies have demonstrated that Tumor Necrosis Factor Inhibitors (TNFi) are efficient in non-radiographic axial spondyloarthritis (Nr-AxSpA). However, few investigations have directly compared ankylosing spondylitis (AS) patients with Nr-AxSpA patients, and fewer still have compared response rates to first line TNFi treatment. The purpose of this study, which involved a tertiary care cohort, was to (i) evaluate baseline characteristics of Nr-AxSpA and AS treated by TNFi; (ii) assess the response to first-line TNFi treatment; (iii) compare drug-survival.

Methods: Inclusion criteria were patients with axial SpA (ASAS criteria) who initiated first-line TNFi treatment between April 2001 and July 2014 and followed up for at least 3 months. Efficacy criteria at 3 months were an improvement of at least 2 points (on a 0 –10 scale) or a 50% improvement in BASDAI. Baseline characteristics, responses at 12 months, and drug survival were compared between AS and Nr-AxSpA.

Results:

A total of 361 patients were included in the study (AS: n=263; Nr-AxSpA: n=98). AS patients were more often male (65.02% vs. 45.92%; p=0.001) and had longer symptom duration (11.71 ±9.52 vs. 7.34 ± 9.30; p<0.001). Median levels of acute-phase reactants (CRP and ESR) were significantly higher in AS patients (p<0.001 for both). Median BASDAI scores at first line TNFi initiation were not higher in Nr-AxSpA patients than in AS patients (59 [49-70] vs. 60 [50- 70]; p=0.73). BASDAI 20 and BASDAI 50 response rates at 12 months were not statistically different between AS patients and Nr-AxSpA patients (74.58% vs. 64.58%; p=0.19 and 61.02% vs. 50.00%; p=0.19 respectively). No statistically significant difference in terms of survival was observed between AS and Nr-AxSpA patients (p=1.00) (Figure 1).

Conclusion: Treatment response, drug survival and patient outcome in our study were similar in patients with AS and Nr-AxSpA after first line TNFi initiation.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Apremilast (APR), an oral phosphodiesterase 4 inhibitor, has demonstrated clear efficacy and good tolerability in psoriatic arthritis (PsA) and psoriasis. Longer term data are crucial for chronic diseases such as PsA. PALACE 1 compared APR efficacy and safety with placebo (PBO) in patients with active PsA despite prior conventional disease-modifying antirheumatic drugs (DMARDs) and/or biologics. We evaluated the longer term efficacy and safety of APR treatment over 156 weeks.

Methods: Patients were randomized (1:1:1) to PBO, APR 30 mg BID (APR30), or APR 20 mg BID (APR20) stratified by baseline DMARD use (yes/no). The PBO-controlled phase continued to Week 24, with an early escape option at Week 16. At Week 24, all remaining PBO patients were re-randomized to APR30 or APR20. Double-blind APR treatment continued to Week 52; patients could continue APR for up to 4 additional years. Efficacy assessments in Years 2 and 3 were conducted at Weeks 65, 78, 91, 104, 117, 130, 143, and 156.

Results: 504 randomized patients received ≥1 dose of study medication (PBO: n=168; APR30: n=168; APR20: n=168). In an "as observed" analysis, 53.2% of APR30 patients and 59.6% of APR20 patients achieved a modified ACR20 response at Week 52 (Table), regardless of whether APR was started at Week 0, 16, or 24; 65.3% (APR30) and 60.9% (APR20) of patients showed these responses at Week 104. Of the patients entering the third year of therapy, 92% (260/284) completed the Week 156 visit; this is overall 52% (260/504) of patients randomized at baseline. Patients receiving APR at Week 156 demonstrated sustained improvements, as shown by ACR20/ACR50/ACR70 response rates modified for PsA by the addition of the distal interphalangeal joints of the toes and the carpometacarpal joints to the total joint count, swollen/tender joint count mean percent improvement, HAQ-DI mean change, proportion of patients with HAQ-DI exceeding the minimal clinically important difference (MCID) ≥0.30 threshold, mean change in DAS-28 (CRP), achievement of DAS (CRP) <2.6, and PASI-50/PASI-75 responses (Table). No new safety concerns were identified with up to 156 weeks of APR treatment. During Weeks >104 to ≤156 of APR exposure, the only adverse event (AE) occurring in ≥5% of patients was upper respiratory tract infection; most AEs were mild/moderate in severity. Diarrhea (2.1%) and nausea (2.1%) occurred at low rates in Weeks >104 to ≤156. Serious AEs occurred in 6.9% (APR30) and 6.4% (APR20) of patients, and few discontinuations (0.7%) due to AEs occurred over Weeks >104 to ≤156.

Conclusion: Over 156 weeks, among patients remaining in the study on treatment, APR demonstrated sustained and clinically meaningful improvements in PsA signs/symptoms, including physical function and associated psoriasis. APR continued to demonstrate an acceptable safety profile and was generally well tolerated.

	Outcomes at Week 52 and Week 156 (Data as Observed)

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Nail psoriasis is associated with decreased finger mobility and pain in patients (pts) with moderate to severe plaque psoriasis and psoriatic arthritis (PsA).[1,2] Secukinumab, a fully human IgG1κ monoclonal antibody to interleukin-17A, provides significant and sustained improvements in the signs and symptoms of psoriasis and PsA.[3–5] Here we report the efficacy of secukinumab on skin and nail disease in two randomized, double-blind, placebo (PBO)-controlled phase 3 studies: TRANSFIGURE (NCT01807520), a study in pts with moderate to severe psoriasis with significant nail involvement, and FUTURE 2 (NCT01752634), a study in pts with PsA, a subset of whom had nail involvement.

Methods: In TRANSFIGURE, 198 pts with nail psoriasis were randomized (1:1:1) to subcutaneous (s.c.) secukinumab 300 mg, 150 mg, or PBO at baseline (BL), Weeks (Wks) 1, 2, and 3, and then every 4 wks (q4wk) from Wk 4. In FUTURE 2, 279/397 enrolled pts had nail psoriasis (nail subset) and 192/397 had ≥3% body surface area affected by psoriasis (psoriasis subset) at BL. Pts were randomized (1:1:1:1) to s.c. secukinumab 300 mg, 150 mg, and 75 mg or PBO at BL, Wks 1, 2, and 3, and then q4wk from Wk 4. In TRANSFIGURE, the primary endpoint was the percentage change from BL in total fingernail NAil Psoriasis Severity Index (NAPSI) score at Wk 16. In FUTURE 2, the primary endpoint was the proportion of pts achieving a ≥20% improvement from BL in ACR response criteria at Wk 24, with change from BL in total fingernail modified NAPSI (mNAPSI) score a pre-specified exploratory endpoint in the nail subset. Both studies included additional pre-specified assessments of psoriasis burden, including PASI 90.

Results: The primary endpoints were met in both studies. In TRANSFIGURE, the mean percentage change from BL in NAPSI was superior with both doses of secukinumab vs. PBO at Wk 16 (P<0.0001). At Wk 16, mean NAPSI score improved (decreased) from BL by 45.3%, 37.9%, and 10.8% for secukinumab 300 mg, 150 mg, and PBO, respectively. In FUTURE 2, mNAPSI scores at Wk 24 were improved vs. PBO with all secukinumab doses (all P<0.01). At Wk 24, mean mNAPSI score improved (decreased) from BL in the nail subset by 66.5%, 55.9%, and 61.6% for secukinumab 300 mg, 150 mg, and 75 mg, respectively, vs. 28.0% with PBO. PASI 90 responses at Wk 16 in TRANSFIGURE were 72.5%, 54.0%, and 1.7% for 300 mg, 150 mg and PBO, respectively; all P<0.0001). In FUTURE 2, PASI 90 responses at week 24 in the subset of pts with psoriasis were 48.8%, 32.8%, 12.0%, and 9.3% for 300 mg, 150 mg, 75 mg, and PBO, respectively (all P<0.01).

Conclusion: Secukinumab improved nail and skin symptoms in pts with psoriasis with significant nail involvement and in pts with concomitant PsA and nail involvement.

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Etoricoxib 90 mg, a selective COX-2 inhibitor, provides symptom relief in ankylosing spondylitis (AS) patients. A prior study established etoricoxib 90 mg as safe and effective in treating AS symptoms. The current study was conducted to determine the efficacy and safety of etoricoxib 60 mg in AS patients.

Methods:

This was a 2-part, double-blind, active comparator-controlled non-inferiority study in AS. Part I (6 weeks) assessed the efficacy of etoricoxib 60 mg and 90 mg compared to naproxen 1000 mg. Part II (6 weeks) evaluated whether subjects with inadequate pain relief on etoricoxib 60 mg in Part I benefited from increasing to etoricoxib 90 mg in Part II. Patients were ≥18 years of age with AS as classified by the Modified New York criteria and a history of clinical response with NSAIDs. Patients were required to have a disease flare after NSAID washout prior to randomization. Eligible patients were randomized to naproxen; etoricoxib 60 mg in Part I & II; etoricoxib 60 mg in Part I 90 mg in Part II; or etoricoxib 90 mg in Part I & II in a 4:9:9:4 ratio respectively. The primary objective was to compare the effect on spinal pain intensity (SPI) score (0 to 100 mm VAS) after 6-weeks of treatment in Part I. The non-inferiority margin was set at 8 mm for the SPI measure based on prior literature findings. The overall safety and tolerability of etoricoxib in AS patients was assessed including independent adjudication of all thrombotic cardiovascular and serious upper GI AEs.

Results:

In total, 1015 patients were randomized; 70.9% were male; the mean age was 45.2 years, 84.6% were Caucasian, 919 patients completed Part I and all continued to Part II. In Part I, both etoricoxib doses were non-inferior to naproxen based on change in SPI score from baseline (Table 1A). There was a mean decrease of ~2 mm SPI score for etoricoxib 90 mg versus 60 mg; (Table 1B). Patients who had inadequate pain response in Part I with 60 mg, had a small but significant improvement in SPI score after switching to 90 mg (Table 1C). In both Part I and II, the incidences of AEs, drug-related AEs, and SAEs were similar between the 3 treatment groups. Independently adjudicated AEs were also similar between treatment groups).

Conclusion:

Both doses of etoricoxib were non-inferior to naproxen. Etoricoxib 60 mg and 90 mg had similar efficacy in relieving the pain associated with AS. Among inadequate responders to etoricoxib 60 mg, dose escalation to 90 mg daily resulted in a statistically significant decrease in SPI score as compared to those subjects remaining on 60 mg. Both etoricoxib 90 mg and 60 mg were well tolerated, and no new safety signals were identified.

SPI (0 to 100 mm VAS) time-weighted average change from baseline

A Part I (Non-Inferiority: Per-protocol Population)			
Treatment (6 weeks)	N	LS Mean change†	Between etoricoxib and naproxen difference in LS mean change† (95% CI)
Etoricoxib 60 mg	660	-29.0	1.59 (-2.19, 5.37)
Etoricoxib 90 mg	144	-31.23	-0.64 (-5.47, 4.19
Naproxen 1000 mg	143	-30.59	
B Part I (Non-Inferiority: Modified Intention to Treat Population)			
Treatment (6 weeks)	N	Between Etoricoxib doses	
		Difference in LS Mean Change† (80% CI)	P-Value†
Etoricoxib 60 mg	694		
Etoricoxib 90 mg	153	-1.58 (-3.96, 0.81)	0.396
C Part II Average Change from Week 6 at Weeks 10 and 12 in SPI among Pain Inadequate Responders from Part I (Superiority: Modified Intention to Treat Population)			
Treatment Sequence (weeks 10 and 12)	N	LS Mean (95% CI)	Difference in LS Mean (80% CI)	p-Value
Etoricoxib 60 mg/60 mg	175	-7.26 (-9.73, -4.80)		
Etoricoxib 60 mg/90 mg	178	-9.97 (-12.42, -7.51)	-2.70 (-4.88, -0.52)	0.112

† The LS means, CIs, and p-values were derived from the analysis of covariance model with terms for treatment, chronic peripheral arthritis (presence, absence) and baseline values as a covariate. LS = Least Squares, CI = Confidence intervals

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Limited information exists on the long term real-world treatment patterns of biologics for psoriatic arthritis (PsA) in the US population. We assessed medication persistence and drug switching with biologics in PsA and estimated the economic costs of different treatment sequences.

Methods: We conducted a retrospective analysis of medical and pharmacy claims data from the MarketScan database (United States). The study included PsA patients >= 18 years of age, biologic-naïve (no biologic therapy in the previous 6 months), who initiated a biologic during the period from October 1, 2009 to September 30, 2010 and were continuously enrolled in a medical and pharmacy benefits program for a 3-year follow-up period. Treatment persistence, switching, modification of treatment (i.e., biologic dose adjustment or any change in concomitant DMARD therapy), and medical and pharmacy costs were analyzed for each line of biologic therapy during the 3 year follow-up period. Line of therapy was defined by the number of biologics a patient used in the follow-up peroid.

Results: Among the 990 PsA patients identified 89.0% of patients used only one line of biologic, 7.3% had a second-line biologic, and 3.7% tried 3 or more lines of biologic therapy. For all the lines of therapy, the first biologics used were: etanercept (n = 435; 43.9%), adalimumab (n = 437; 44.1%), infliximab (n = 77; 7.8%), and golimumab (n = 41; 4.1%). The discontinuation rates by line of therapy were as follows: 71.6% (n = 631) for patients who only used one line of biologics; 50.0% (n = 36) for those with second-line biologic and 18.9% (n = 7) for those who tried 3 or more biologics.The time patients spent on the first biologic was shorter for those who switched to a second-line biologic (348 days) or third-line biologic (325 days) compared to those those who only used one biologic (522 days). Overall time to treatment modification became shorter with each line of therapy; the shortest was 42 days for patient on their third line of therapy, 137 days for those on their second line, and 146 days in the first line. The most common treatment modifications in the first-line of biologic therapy were DMARD dose increase (21.1%), add-on (9.0%) and removal (7.4%). Monthly medical costs (hospitalizations, office visits, emergency department visits) per member per month were higher for patients using only one line of biologic ($322) than for those who received second-line ($167) or third-line ($217) treatment, whereas monthly pharmacy costs per member per month were lower for patients using only one line of biologic ($1985) than for those on second-line ($2045) or third-line ($2539) biologics.

Conclusion: Approximately two thirds of PsA patients discontinued their first biologic therapy. Of those who were continuous users and and moved on to second- and third-line therapies, the time of discontinuation from their first-biologic was shorter, indicating non-responders were identified early in the treatment course. Monthly medical costs were higher for those who did not switch biologic therapy, but pharmacy costs increased with the number of biologic switches. This may be because of treatment add-ons or worsening disease severity.

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Ankylosing spondylitis (AS) is associated with a significant burden of illness and has limited treatment options. The identification of predictors of response to anti-tumor necrosis factor (TNF) therapy may help clinicians select therapy and address patient expectations.

Methods:

We analyzed data from a large German multicenter, prospective, observational study of patients with active AS who initiated adalimumab (ADA) therapy during routine clinical care. Multiple regression models were used to evaluate significant predictors of improvement at month 12 in the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and the Bath Ankylosing Spondylitis Functional Index (BASFI). For both indices, higher scores indicate greater disease activity/impairment.

Results:

Patients in the full analysis set (N = 3756) had a mean age of 43.0 ± 12.2 years and a mean disease duration of 14.2 ± 10.9 years. During ADA therapy, mean BASDAI scores improved from 5.5 ± 1.9 at baseline to 3.1 ± 2.1 at month 12 and BASFI scores improved from 4.9 ± 2.4 at baseline to 3.2 ± 2.4 at month 12 in evaluable patients remaining on therapy. Although both HLAB27 status and baseline erythrocyte sedimentation rate (ESR) were positive predictors of therapeutic response for BASDAI and BASFI (Table), the strongest positive predictors were not shared between these two indices (dactylitis and baseline BASDAI for BASDAI, baseline BASFI and employment for BASFI). In contrast, most of the negative predictors of response were shared between the BASDAI and BASFI, including the two strongest predictors, mental disorder/depression and a greater number of previous biologics.

Conclusion:

AS patients showed marked improvement in BASDAI and BASFI during 12 months of treatment with ADA in routine clinical practice. Positive predictors of response to ADA therapy differ between BASDAI and BASFI in AS patients, but negative predictors are generally shared.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Multiple disease-modifying therapies for treatment of psoriatic arthritis (PsA) are available. However, there are limited data directly comparing these biologic therapies and the recently approved phosphodiesterase-4 (PDE-4) inhibitor. In the absence of head-to-head

trials, it is difficult for decision makers to make treatment choices in real world scenarios. The aim of this study was to conduct a network meta-analysis (NMA) to indirectly compare the efficacy of biologic agents and apremilast for treatment of active PsA.

Methods:

A systematic literature review was conducted to identify Phase III randomized controlled trials (RCTs) for tumor necrosis factor inhibitors (TNFi's: adalimumab, infliximab, golimumab, etanercept, and certolizumab), interleukin inhibitors (ustekinumab and secukinumab), and a PDE-4 inhibitor (apremilast) for active PsA. The relative probabilities of achieving ACR20 and PASI75 responses at week 24 with each agent were estimated via a Bayesian network meta-analysis. All arms of the network meta-analysis included FDA-approved doses for PsA except secukinumab, where all three doses examined in RCTs: 75, 150, and 300 mg every 4 weeks were included. Numbers needed to treat (NNT) were calculated as the reciprocal of the incremental response rate of each treatment versus placebo. Analyses were repeated among subgroups of patients without prior biologic therapy.

Results:

Seventeen RCTs were identified, 14 included ACR20 and/or PASI75 responses at Week 24. Among all patients and biologic-naive patients, adalimumab, golimumab, infliximab, and secukinumab (300 and 150 mg) had NNTs <3 for ACR20 responses at Week 24, and adalimumab the lowest NNT of 2.32 (95% credible interval [CrI] 1.78, 3.22; Figure 1). Among all patients and biologic-naive patients, infliximab, golimumab, and adalimumab had NNTs <2 for PASI75 responses at Week 24, and infliximab the lowest NNT of 1.53 (1.25, 2.01; Figure 2). PASI75 responses among biologic-naïve patients were not available for secukinumab, certolizumab, and apremilast.

Conclusion:

At Week 24, adalimumab, golimumab, secukinumab 300 mg, and infliximab had the lowest NNTs per ACR20 and/or PASI75 responders among all patients as well as among biologic-naïve patients.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Patients (pts) with active psoriatic arthritis (PsA) have disease involvement across multiple domains. Pts can have substantial fatigue, which is increasingly being recognized as important to pts, particularly those with chronic diseases, and can affect QoL.[1] The 2014 OMERACT PsA Working Group identified fatigue measurement as an important outcome to consider including in PsA core assessments.[2] PALACE 1-3 compared apremilast (APR) efficacy/safety with placebo (PBO) in pts with active PsA despite prior conventional DMARDs and/or biologics, including assessment of fatigue levels. We report the impact of APR treatment on fatigue over 104 wks in a pooled PALACE 1-3 analysis.

Methods: Pts were randomized (1:1:1) to PBO, APR 30 mg BID (APR30), or APR 20 mg BID (APR20) stratified by baseline DMARD use (yes/no). The PBO-controlled phase continued to Wk 24, with a Wk 16 early escape option. At Wk 24, all remaining PBO pts were re-randomized to APR30 or APR20. Double-blind APR treatment continued to Wk 52; pts could then continue to receive APR for up to an additional 4 years during an open-label extension phase. Fatigue was assessed using the Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F) v4, a 13-item questionnaire initially developed to assess anemia-associated fatigue.[3] Questions are scored from 0-4. Total FACIT-F scores range from 0-52, with higher scores denoting lower levels of fatigue. As a point of reference, mean fatigue scores of 40.1-43.6 in the general population, 35.8 in PsA patients,[4] and 23.9 in anemic cancer pts have been reported[5,6]; FACIT-F MCID in pts with rheumatoid arthritis (RA) is 3-4.[7]

Results: Baseline mean FACIT-F scores in pts receiving APR at Wks 52 and 104 ranged from 29.2-31.2, which are markedly below population norms and indicative of fatigue-related impaired QOL. Long-term improvement in fatigue was seen in APR pts at 52 wks, as shown by improvement in FACIT-F score (Table). At Wk 104, APR30 pts had sustained improvements in fatigue (mean FACIT-F=35.0), marking a shift toward population FACIT-F norms. APR30 mean change was 5.6, which exceeded the MCID for this measure in RA pts; 50.9% of APR30 pts achieved MCID for FACIT-F. APR30 mean % change in FACIT-F was 44.5%. Wk 104 findings were similar with APR20. Over 104 wks, most adverse events (AEs) were mild/moderate; in general, no increase was seen in AE incidence/severity with longer term exposure.

Conclusion: Over 104 wks, APR continued to improve fatigue in PsA pts. APR demonstrated an acceptable safety profile and was generally well tolerated up to 104 wks.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy

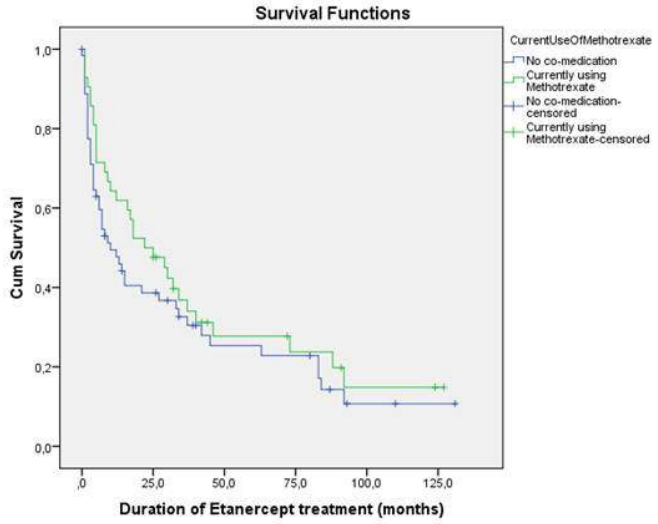
Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The role of co-medication e.g. with conventional synthetic disease-modifying antirheumatic drugs (csDMARDs), among patients with psoriatic arthritis (PsA) who are receiving tumor necrosis factor inhibitors (TNFi) remains unclear. Some studies have indicated a beneficial role in the longevity of treatment, potentially by reducing the formation of anti-drug antibodies. Etanercept has generally been found to be less immunogenic than monoclonal antibody TNFi. This study aimed to investigate the role of concomitant methotrexate on drug survival of etanercept in psoriatic arthritis (PsA).

Methods: We included consecutive PsA patients from a Norwegian out-patient clinic. Baseline characteristics and drug survival were compared between patients with and without methotrexate co-medication. The X^2 test, independent t-test and Mann-Whitney U test were applied as appropriate for group comparisons. Drug survival was explored by Kaplan-Meier analysis, and patients receiving and not receiving co-medication were compared using the log rank test. Cox regression analysis was used to identify predictors of discontinuation.

Results: We included 105 patients treated with etanercept, 42 receiving co-medication with methotrexate. Mean (SD) age was 54,3 (11,0) years, years of education 13,1 (3,7), disease duration 13,4 (8,8) years, body mass index 28,2 (4,8) kg/m^2, baseline CRP 11,1 (23,4), baseline swollen joints 2,9 (3,4), 42,9% were female and 21,9% currently smoking. Overall, 31 (29,5%) patients were previously treated with TNFi. Baseline characteristics were similar for patients with and without co-medication. Drug survival of etanercept was similar for patients receiving versus not receiving concomitant methotrexate (log rank test p=0,277, figure). In the Cox regression analysis the only identified predictor for etanercept discontinuation was previous use of TNFi. Separate analyses for first time TNFi users did not change the primary outcome.



Conclusion: In our population of etanercept treated PsA patients, we found similar drug survival for patients with and without co-medication with methotrexate. The only identified predictor for etanercept discontinuation was previous use of TNFi.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Infection is by far the most common and most important adverse effect of TNF inhibitors (TNFI) in the treatment of rheumatoid arthritis (RA) and spondyloarthritis (SpA). The aim of this study was to evaluate the risk of SIs in the TNFI-treated SpA patients in the Gruppo Italiano Studio Early Arthritis (GISEA) Registry, and assess the predictors of their occurrence.

Methods: The Registry, which is designed to collect real-world clinical data concerning RA and SpA patients receiving biological drugs as part of routine care, was approved by local Ethics Committees, and enrols patients aged ≥18 years who have given their written informed consent. The baseline information includes demographics, disease duration, HAQ, DAS-28, BASDAI, BASFI and BASMI scores, steroid use (defined as actively receiving oral steroids at the time of recruitment), smoking history and comorbidities.

Results: The analysis involved 3321 SpA patients (1731 males, 52.2%; mean age 47±13 years; median disease duration three years, interquartile range [IQR] 0, 8 years): 1065 (32%) treated with infliximab (IFN), 1052 (32%) with adalimumab (ADA), and 1204 (36%) with etanercept (ETN). Two thousand, one hundred and five (63.4%) had a median of one comorbity (IQR 0, 2], the most frequent being hypertension (701), thyroid diseases (281), diabetes mellitus (207), cardiopathy (189), and osteoporosis (145). In combination with the biological drug, 919 patients (27.7%) received steroids and 2451 (79.9%) at least one DMARD. The median follow-up was three months (IQR 12 years). During 12 years of TNFI treatment, 259 patients experienced at least one of 391 microbiologically diagnosed SIs, 32% of which were recorded in the first 12 months. Overall incidence was 43.9/1000 patient-years of follow-up (95% CI 39.6–48.4): 29.9/1000 (95% CI 23.1–38.1) among those treated with ADA; 36.1/1000 (95% CI 30.0–43.1) among those treated with ETN; and 61.4/1000 (95% CI 53.3–70.5) among those treated with IFN. The most frequent were lower respiratory tract infections (pneumonia and bronchitis), followed by cutaneous infections. Bacteria were the most frequent micro-organisms (228, 58.3%), followed by fungal infections (40, 10.2%) and viral infections including herpes zoster (22, 5.6%). Univariate analysis showed that female gender (p=0.019) and comorbidities (p<0.001) were associated with a high risk of SI, and that the use of ETN or ADA rather than IFN (p<0.001 and p0.001) was associated with a lower risk of SI. Multivariate models showed that the number of comorbidities (hazard ratio [HR] 1.29, 95%CI 1.2–1.4; p<0.001), age at the start of anti-TNF treatment (HR 0.99, 95%CI 0.97-0.99; p=0.030), steroid use (HR 1.40, 95%CI 1.1–1.8; p=0.012), male gender (HR 0.72, 95%CI 0.5-0.9; p=0.012) were statistically significant predictors of infection. The factors independently associated with a decreased risk of SIs were the use of ETN (HR 0.52, 95%CI 0.4-0.7; p<0.001) or ADA (HR 0.59, 95%CI 0.4-0.8; p=0.002) rather than INF.

Conclusion: These data add to currently available evidence suggesting that TNFI therapy is associated with a small but significant overall risk of SI in SpA patients.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is a common comorbidity in patients (pts) with psoriasis. In the ongoing Phase 3b CLEAR study (NCT02074982), secukinumab, a fully human anti-interleukin (IL)-17A monoclonal antibody, demonstrated superior efficacy (PASI 90) to ustekinumab (an IL-12/23 inhibitor) in pts with moderate to severe plaque psoriasis.[1]Here we report results of a pre-defined sub-analysis which evaluated 16-week (wk) outcomes in pts in the study who had concomitant PsA.

Methods: Pts, stratified by body weight (≤ 100 and > 100 kg), were randomized 1:1 to receive subcutaneous (s.c.) secukinumab 300 mg or ustekinumab (for pts ≤ 100 kg, 45 mg s.c.; > 100 kg, 90 mg s.c.). Secukinumab was administered at baseline (BL), Wks 1, 2, 3, and every 4 Wks from Wk 4; ustekinumab was administered at BL and Wk 4, and then every 12 wks from Wk 16. The primary end-point

was the proportion of pts achieving at least a 90% reduction from BL in Psoriasis Area and Severity Index score (PASI 90) at Wk 16. Changes from BL in the Health Assessment Questionnaire-Disability Index (HAQ-DI; score range of 0–3) were reported in the subgroup of psoriasis pts with concomitant PsA.

Results: The overall study population consisted of 676 pts. Concomitant PsA was reported in 69/337 (20.5%) pts in the secukinumab group and 54/339 (15.9%) pts in the ustekinumab group. In the overall population, a PASI 90 response at Wk 16 was achieved by 79.0% pts receiving secukinumab vs. 57.6% pts receiving ustekinumab ($P < 0.0001$) and a PASI 100 (clear skin) response at Wk 16 was achieved by 44.3% pts receiving secukinumab vs. 28.4% pts receiving ustekinumab ($P < 0.0001$). In the subgroup of pts with concomitant PsA, a higher proportion of pts in the secukinumab group achieved a PASI 90 response at Wk 16 compared with ustekinumab; 79.1% vs. 65.4%, respectively (p=0.063). A PASI 100 response at Wk 16 was achieved by 35.8% pts in the secukinumab group vs. 28.8% pts in the ustekinumab group (p=0.336). Improvements in physical function in the PsA sub-group were greater with secukinumab vs. ustekinumab; mean change from baseline in HAQ-DI at Wk 16 was –0.29 (-47.6%) with secukinumab vs. –0.13 (-37.7%) with ustekinumab. A higher proportion of pts receiving secukinumab achieved a clinically meaningful improvement in HAQ-DI (defined as at least a 0.3 decrease from baseline at Wk 16 vs. ustekinumab (34.9% vs. 26.5%, respectively).

Conclusion: Secukinumab was superior to ustekinumab at improving skin symptoms in patients with moderate to severe plaque psoriasis. In the small sub-group of patients with psoriasis and concomitant PsA, secukinumab showed a trend for improving skin symptoms and physical functioning compared with ustekinumab.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The tolerability and efficacy of golimumab (GLM) as a treatment for nonradiographic axial spondyloarthritis (nr-axSpA) were recently investigated in a randomized, double-blind (DB), placebo (PBO)-controlled, phase 3 study (GO-AHEAD).[1] We report the findings from an open-label extension (OLE) of GO-AHEAD that evaluated the long-term use of GLM in patients with nr-axSpA.

Methods: Patients completing the 16-week DB study were eligible to receive open-label GLM 50 mg every 4 weeks during the 44-week extension (36-week treatment period; 8-week safety follow-up). Safety evaluations included the incidence/severity of adverse

events (AEs). Efficacy evaluations included ASAS 20, ASAS 40, BASDAI 50, ASAS partial remission (PR; ≤20 mm score in all 4 domains), and ASDAS-C at weeks 20, 24, 32, 40, and 52. Quality of life evaluations included EQ-5D and percentage of work impairment (WPAI) at weeks 16 and 52. Data were summarized descriptively; all patients were included. Non-responder imputation was used for missing ASAS 20, ASAS 40, and ASAS PR values. BASDAI required 3 of 5 responses; LOCF imputation was used for missing values. ASDAS-C was only calculated if all components were available.

Results: Of the 197 subjects treated in the DB study, 189 entered the OLE (GLM/GLM, 93/97 [96%]; PBO/GLM, 96/100 [96%]). In total, 174/189 (92%) patients completed all visits (GLM/GLM, 85/93 [91%]; PBO/GLM, 89/96 [93%]). There were no notable differences in the number/types of AEs between the GLM/GLM and PBO/GLM groups (Table). For ASAS 20, ASAS 40, BASDAI 50, and ASAS PR, the PBO/GLM group showed notable improvement in these measures after switching to GLM in the OLE, while the proportions of responders in the GLM/GLM group remained higher than the PBO/GLM group throughout the study (Figure). For week 52 vs week 16, mean changes from baseline (BL) in ASDAS-C were similar or better in the GLM/GLM group (–2.2 vs –1.7) and were improved in the PBO/GLM group after switching to GLM (–1.7 vs –0.6). At week 52, the mean change from BL in EQ-5D Health State VAS score was 3.2 cm in the GLM/GLM group and 2.3 cm in the PBO/GLM group, and the mean change from BL in the percentage of work impairment while working was –28.1% in the GLM/GLM group and –22.8% in the PBO/GLM group.

Table. Summary of Adverse Events in the GO-AHEAD OLE

AEs,[a] n (%)	GLM/GLM N=93	PBO/GLM N=96	Total N=189
Treatment-emergent AE	39 (41.9)	52 (54.2)	91 (48.1)
Treatment-related AE[b]	12 (12.9)	16 (16.7)	28 (14.8)
Nasopharyngitis	2 (2.2)	3 (3.1)	5 (2.6)
Upper respiratory tract infection	2 (2.2)	2 (2.1)	4 (2.1)
Headache	2 (2.2)	2 (2.1)	4 (2.1)
Discontinuation due to AE[c]	1 (1.1)	2 (2.1)	3 (1.6)
Serious AE[d]	2 (2.2)	3 (3.1)	5 (2.6)
Fatal AE	0	0	0

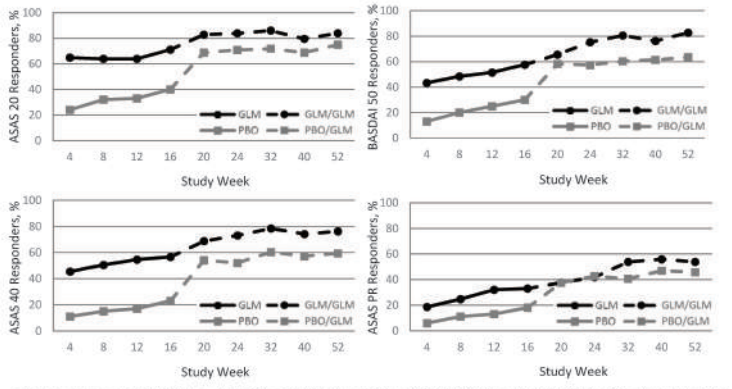
[a]Includes patients who received ≥1 dose of study drug.

[b]The most common AEs considered treatment-related (occurring in ≥3 pts in total) are shown.

[c]GLM/GLM: acute tonsillitis and treatment-related bacterial infection (n=1); PBO/GLM: hepatitis, treatment-related rhinitis (each n=1).

[d]GLM/GLM: bacterial infection, duodenitis (each n=1); PBO/GLM: treatment-related migraine, uterine polyp, staphylococcal infection (each n=1).

Figure. Proportion of Responders Over Time by Efficacy Endpoint and Treatment Group in the GO-AHEAD OLE*



*DB study (up to week 16): GLM, n=97; PBO, n=100. OLE (weeks 20 to 52): GLM/GLM, n=93; PBO/GLM, n=96. At weeks 16, 20, 24, and 32, the number of responders in the GLM/GLM group was 69, 77, 78, and 80, respectively.

Conclusion: Consistent with results of the GO-AHEAD randomized trial,[1] treatment with GLM in the OLE was generally well tolerated in patients with nr-axSpA. Improvements in disease activity were retained in patients who received GLM in the OLE and in patients

who switched from PBO to GLM.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is a chronic inflammatory disorder. AntiTNF-therapy is initiated after failure of NSAID and DMARD-treatment. Up to 30-40% of the patients are primary not responding adequately to the induced therapy. In daily practice, response is assessed by improvement of disease activity measured by clinical examination and using composite indices (ACR20 response or DAS28). Earliest after 3 months, a decision for response is made. Feasible and robust biomarkers for early prediction of therapeutic response are still missing.

Methods: Fluorescence optical imaging technique (FOI) is used as method for detection of changes in vascularisation of the hands as inflammatory marker. ICG is injected as fluorescence colour agent, stimulated by light in a specific wave length and recorded by a specific camera in the device. Overall fluorescence-signals and their intensities are measured by an automated computer-based reading of the disease activity (DACT). In a prospective multicentre study, value of FOI in measurement of disease activity and sensitivity to change in newly treated PsA patients (n=80) with Etanercept is investigated (XPLORE-study). In this first interims analysis (n=13), early changes of DACT (baseline to week 4) are measured and correlated to the clinical response (achievement of at least low disease activity: DAS28 ² 3.2) after 12 weeks of treatment.

Results: All of the patients (mean age 55 years, female:male 1:1, mean DAS28 4.6, mean PASI 5.6, mean SJC 6.4, mean TJC 12.9 (66/68 joint count) at baseline) who did not reach at least 45% improvement in fluorescence intensities after 4 weeks of treatment did

not achieve the threshold of low disease activity (DAS28 ² 3.2) at week 12. The treatment regime of most of those patients was changed after week 12. Only one patient without the described improvement was qualified as responder by DAS28 change of -3.0.

	%DACT change BL to W4	DAS28 BL	DAS28 W12	SJC BL	SJC W12	TJC BL	TJC W12	Treatment Change after 12 weeks [y/n]
01	-59	5.0	2.7	9	2	9	0	n
02	-50	2.4	2.3	6	4	4	4	n
03	>+100	5.1	4.2	5	3	22	4	y
04	-49	3.5	1.0	2	1	3	1	n
05	-14	4.3	3.5	5	8	7	11	y

Conclusion: Preliminary data of the first interims analysis of the XPLORE study illustrate high sensitivity in patients newly treated with Etanercept-therapy. Achievement of improvement of at least 45% in fluorescence intensity shows already after 4 weeks a high discriminative value for prediction of later clinical response at week 12. Only one patient was qualified as responder although he did not meet the criteria for response in fluorescence signalling. In this case, disease activity seems to be driven by other factors than inflammatory arthritis (only 1 SJC/TJC at baseline). Early change in fluorescence signalling seems to be a promising marker for prediction of clinical response in newly initiated biological treatment.

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To evaluate ustekinumab(UST) in a subgroup of psoriatic arthritis (PsA) pts with physician diagnosed spondylarthritis, as well as peripheral arthritis, from the PSUMMIT 1 & 2 trials.

Methods: Adult PsA pts with active disease were randomized to UST45mg, 90mg, or PBO at wks 0,4, and q12wks, thereafter. PBO-

pts crossed over to UST45mg at wks24 and 28 followed by q12wk dosing. At wk16, pts with <5% improvement in TJC & SJC entered blinded early escape [EE]. This post hoc analysis evaluated efficacy and safety in the subgroup of PsA patients with physician diagnosed spondylarthritis at baseline from the PSUMMIT trials (PSUMMIT 1 [bio-naïve] and PSUMMIT 2 [bio-naïve and bio-experienced]). BASDAI scores were collected at baseline and wks12 and 24; BASDAI question (#2) related to overall level of axial disease neck, back or hip pain was also assessed separately.

Results: 256 (28% of PSUMMIT 1 &2 population, including 32 bio-experienced) randomized pts (92 PBO, 164 UST combined) had spondylarthritis at baseline. In this sub-group 80.5% had enthesitis and 51.6% had dactylitis at baseline; in the overall population, 71.4% and 45.6% had enthesitis and dactylitis, respectively. Consistent with the overall population, at baseline, about 50% of patients used MTX, 77% NSAIDs, and 20.7% low dose oral corticosteroids. More UST-treated pts achieved BASDAI20/50/70 responses vs PBO at wk24(Table). The observed changes in the median score of the BASDAI question related to the overall level of axial disease neck, back or hip pain were also similar to the total BASDAI score changes for both groups, -0.45 vs -1.65, between PBO and combined UST groups, respectively. Other clinical efficacy and radiographic progression data in this subgroup are summarized (Table). During the PBO-controlled period, AE rates for PBO vs combined UST-treated groups were 41.3% vs 34.8%; SAEs were 2.2% vs 1.2% discontinuations due to AEs were 3.3% vs 0.6%; and infections were 16.3% vs 13.4%). Through 1yr, safety was consistent with the overall PsA population.

Conclusion: In this post-hoc analysis, UST significantly improved axial symptoms in a subgroup of PsA patients who also had physician diagnosed spondylarthritis. Reponses in other PsA domains and safety were similar to that observed in the overall PsA study population.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Long-term data on drug survival of TNF inhibitors (TNFi) in the treatment of spondyloarthropathies are still lacking. The aim of the study is to analyze in a setting of real-life the 8-year retention rate of the first TNFi for the treatment of psoriatic arthritis (PsA) and axial spondyloarthritis (ax-SpA) and to compare the between-group discontinuation rates for each TNFi (infliximab [IFX], etanercept [ETN], and adalimumab [ADA]).

Methods: Data were retrospectively extracted from three local registries including all patients affected by PsA and ax-SpA treated with a biologic drug between January 2002 and May 2014. The analysis was limited to patients treated with IFX, ETN, or ADA as first-line biologic agent, with at least 1-year follow-up period. The 8-year drug survival was evaluated by Kaplan-Meier method and the risk for discontinuation among the 3 treatment groups was compared by a stratified log-rank test. The comparison of reasons for drug withdrawal among treatment subgroups was performed by the Fischer's exact test.

Results: The study population (594 patients) included 322 ax-SpA (69.2% male, median age [±SD] 42 [±12.2] years, median disease duration 5.2 [±8] years), treated with ADA (n=99), ETN (n=40), or IFX (n=183); and 272 PsA (53.7% male, median age 47.9 [±12.2] years, median disease duration 9.1 [±7.3] years), treated with ADA (n=98), ETN (n=75), or IFX (n=99). The overall median survival on treatment of the whole study population was 103.6 months (105.2 and 102.6 months for ax-SpA and PsA, respectively; p=0.3768). The overall retention rate was 62.8% (68.4% versus 59.7% in axSpA and PsA, respectively) at 5 years and 53.3% (56.1% versus 52.4% in axSpA and PsA, respectively) at 8 years. No significant differences emerged in the comparison among ADA, ETN, and IFX in both ax-SpA group (p=0.1113) and PsA group (p=0.4783). The main reported reasons for treatment discontinuation were drug inefficacy (18.2% in ax-SpA versus 25.6% in PsA; p=0.0357) and adverse events (16.4% in ax-SpA and 19.2% in PsA; p=0.45).

Conclusion: In a real-life setting, the 8-year retention rate of the first TNFi in the treatment of spondyloarthropathies was about 50%, with no significant difference between ax-SpA and PsA. The risk of stopping IFX, ETN, and ADA treatment was similar in both ax-SpA and PsA group.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Inhibition of phosphodiesterase (PDE) family enzymes is now recognized as target to develop new psoriatic arthritis (PsA) drugs. We conducted a systematic review to evaluate the benefits and harms of the first PDE4 inhibitors approved by the FDA (i.e., apremilast) for the treatment of PsA.

Methods: We searched electronic databases (i.e., The Cochrane Central Register of Controlled Trials (CENTRAL), MEDLINE, EMBASE, and Web of Science) from inception to October 2014 with no restrictions. We also searched of ClinicalTrials.gov and the list of references of relevant citations to identify any additional citations not otherwise found. We included any controlled trials comparing treatment with apremilast alone or in combination with any DMARD versus placebo or other synthetic or biologic DMARD. Our primary outcome was the ACR modified response criteria for 50% improvement. Secondary outcomes included function measured by the health assessment questionnaire (HAQ), quality of life measured by the SF-36, disease activity, withdrawals, and serious adverse events. We calculated relative risks (RR) and their 95% confidence intervals (95%IC).

Results: Out of 246 citations, 5 double-blind, randomized controlled trials (RCTs) were included. All studies were funded by the manufacturer of the drug. The studies included a total of 2,005 patients (1,336 assigned to apremilast plus standard of care, and 669 to placebo plus standard of care). Mean age of participants ranged from 48.8 to 51.4 years; mean disease duration ranged from 6. 8 to 16.5 years; and between 45.5% to 52.6% were male. All studies were judged to have high risk of performance and detection bias since apremilast was compared to placebo until week 16, and then placebo non-responders received apremilast. At 16 weeks, ACR50 response rates were statistically significantly improved with apremilast 20 and 30 mg compared with control (RR 2.3, 95%CI 1.6-3.2 and 2.2, 1.6-3.2, respectively. HAQ scores were statistically significantly better with apremilast 20 and 30 mg than with control (MD -0.11, 95% CI -0.16, -0.06 and -0.16, 95% CI -0.21, -0.11, respectively). Quality of life scores were similar between apremilast 20 mg and control, but were significantly better in the apremilast 30 mg versus placebo (MD 2.6, 95%CI 1.7-3.4). There was a statistically significant reduction from baseline in the DAS28 in favour of apremilast 20 and 30 mg (MD -0.42, 95%CI -0.53, -0.31 and -0.48, 95%CI -0.59, -0.37, respectively). No differences were observed in the withdrawals rates or serious adverse events between groups. These differences were sustained even after 24 weeks (Table).

Conclusion: Our findings suggest that apremilast (either 20 or 30 mg) in combination with standard of care is significantly more efficacious than standard of care alone for improving the symptoms of PsA. Further studies are needed to evaluate its effects in preventing disease progression (structural damage).

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Recent studies suggest that patients' (pts') body weight impacts response to anti-TNF treatment in pts with spondyloarthropathies[1] including axial spondyloarthritis (axSpA).[2] Here we investigate whether efficacy of certolizumab pegol (CZP), a PEGylated Fc-free anti-TNF, is affected by weight in axSpA pts.

Methods:

RAPID-axSpA (NCT01087762) was double-blind and placebo (PBO)-controlled to Week (Wk) 24. Pts fulfilled ASAS criteria and had active axSpA. At baseline (BL), pts were randomized 1:1:1 to PBO, or CZP 200 mg Q2W/CZP 400 mg Q4W. The primary endpoint was the Wk12 ASAS20 response.[3] In this post-hoc analysis, data from the overall population were summarized by subgroups according to median BL weight (80 kg); further analyses considered BL weight ≥100 kg. Efficacy by BL BMI (<25 kg/m^2, normal weight; ≥25–<30 kg/m^2, overweight; ≥30 kg/m^2, obese) was also explored. Missing ASAS data were imputed as non-responders; LOCF was used for continuous measures.

Results:

Of 325 pts randomized, 218 received CZP from Wk0, and 107 PBO. BL characteristics, including disease activity measures, were similar between populations, though more males weighed ≥80 kg (76.5% male vs 46.2% male in <80 kg group) and CRP was higher in heavier pts (median CRP [mg/L]: pts <80 kg, 11.5; pts ≥80 kg, 14.5; pts ≥100 kg, 15.0). At BL, pt numbers between BMI categories were similar (normal weight: 114; overweight: 111; obese: 94).

At Wk12, ASAS20 and ASAS40 response rates and treatment differences were similar regardless of BL weight (Table, Figure). Similarly, there was no decreasing trend in Wk12 response rates or treatment differences for ASAS20 and ASAS40 across increasing BMI categories (Figure; CZP dose combined: ASAS20, normal weight: 56.3% CZP [n=80] vs 38.2% PBO [n=34]; overweight: 72.6% CZP [n=73] vs 42.1% PBO [n=38]; obese: 55.0% CZP [n=60] vs 35.3% PBO [n=34]; ASAS40, normal weight: 46.3% CZP vs 20.6% PBO; overweight: 53.4% CZP vs 26.3% PBO; obese: 40.0% CZP vs 5.9% PBO).

Comparable improvements with CZP treatment were observed across weight categories in clinical and pt-reported outcomes, as well as laboratory measures of inflammation (Table); though pts weighing ≥100 kg had lower BASFI improvements, possibly as a result of the independent effect of weight on function.

Similar efficacy was maintained to Wk24 regardless of pt weight, with similar outcomes observed with both CZP dose regimens (data not shown).

Conclusion:

In RAPID-axSpA, improvements to Wk12 of CZP treatment in composite clinical outcomes, pt-reported and laboratory outcome measures were similar regardless of pt weight. These results were maintained over 24 wks of CZP treatment with both CZP dose regimens.

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Compared to the general population, patients (pts) with psoriatic arthritis (PsA) suffer greater amounts of disability and substantially lower employment rates.[1] Few studies have evaluated the association between improvements in workplace and household productivity and symptom relief with available therapies in PsA pts. Here we evaluate the association between improvements in clinical and pt-reported outcomes (PROs) and improvements in productivity in the workplace and at home in PsA pts treated with certolizumab pegol (CZP).

Methods:

Associations between clinical outcomes or PROs and work and household productivity outcomes were compared using Week (Wk) 24 data from the double-blind and placebo-controlled period of RAPID-PsA (NCT01087788).[2] Clinical outcomes included achievement of ACR20/50, PsARC and PASI75 responses, and DAS28 remission (DAS28<2.6). PROs included achievement of MCID for HAQ-DI (≥0.3 decrease from baseline [BL]), pain (≥10 mm decrease from BL) and fatigue (≥1 decrease from BL). Responders and non-responders at Wk24 for clinical outcomes and PROs were compared in terms of change from BL (CFB) in workplace and household productivity, as assessed using the validated arthritis-specific Work Productivity Survey (WPS).[3] Analyses were carried out for pts originally randomized to CZP. Groups were compared using a non-parametric bootstrap-t method. Missing data were imputed using last observation carried forward for WPS outcomes and non-responder imputation for clinical outcomes and PROs.

Results:

273 CZP pts entering RAPID-PsA were included in Wk24 analyses. 61.9% of pts were employed at Wk24. Overall, pts achieving a clinical or PRO response at Wk24 also reported greater improvements in workplace and household productivity than non-responders (Table). Improvements in both joint and skin symptoms, and clinically meaningful reductions in disability, pain and fatigue were associated with improved workplace absenteeism and presenteeism. Responders also reported greater improvements in their participation in family, social and leisure activities (data not shown). Results should be interpreted with caution due to differences in the number of pts between responder and non-responder groups, and because the analyses were not adjusted for differences in BL productivity between these groups.

Conclusion:

Clinical responses in joint and skin outcomes as well as clinically meaningful improvements in PROs are associated with improved workplace and household productivity in PsA pts treated with CZP.

Treatment Patterns of Subcutaneous Biologic Agent Use Among Patients with Ankylosing Spondylitis

Sergio Schwartzman[1], Yunfeng Li[2], Huanxue Zhou[3], Vivian Herrera[2] and Jacqueline B. Palmer[2], [1]Hospital for Special Surgery, New York, NY, [2]Novartis Pharmaceuticals Corporation, East Hanover, NJ, [3]KMK Consulting Inc, East Hanover, NJ

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Ankylosing spondylitis (AS) is characterized by chronic debilitating inflammation of the spine and/or sacroiliac joints. Several biologic agents have been approved for the treatment of AS. In some instances, physicians and patients may discontinue or switch biologics during the course of therapy. These treatment patterns are not well characterized and have potential clinical implications. The objective of this study was to characterize and understand the treatment patterns of AS patients on subcutaneous biologics therapy.

Methods: We conducted a retrospective analysis of medical and pharmacy claims data from the MarketScan commercial claims database (United States). Biologic-naïve AS patients (no biologic therapy in the previous 12 months) were identified who initiated a biologic agent (etanercept, adalimumab, or golimumab) during the period from January 1, 2011, to December 31, 2012, and were continuously enrolled in a prescription drug benefit program for 12 months prior to, and 18 months following, their first biologic use. Demographic, clinical, and treatment information were analyzed.

Results: 382 AS patients met the criteria for analysis (index biologic: adalimumab, n=202 [52.9%]; etanercept, n=157 [41.1%]; golimumab, n=23 [6.0%]). They had a mean age 42.5 yrs and 66.5% male. The most common comorbidities were hypertension (18.8%), hyperlipidemia (12.6%), depression (8.9%), and uveitis (7.9%). During the follow-up period, 214 patients (56.0%) were continuous users of the index treatment (no gaps in therapy >180 days or no therapy switches for 12 months), while 168 (44.0%) discontinued (had a gap in therapy >180 days with the index therapy or switched to another therapy). Among patients who discontinued their index therapy, 53 (13.9% of the total group) switched to another agent with a treatment gap of ≤180 days; 14 (3.7%) had a gap in therapy >180 days, but restarted on their index therapy while 6 (1.6%) restarted with a different biologic therapy after discontinuation of index biologic. Among continuous users (no gap >180 days) dose escalation was infrequent: adalimumab, 9 patients (7.6%) with above label dosing (>40 mg every 2 weeks); etanercept, 1 patient (1.1%) (>50 mg/wk); golimumab 0 patients (0%) received a (>50 mg/month).

Conclusion: Almost half of AS patients will discontinue their index biologics in the year following initiation of use. Of those who continued therapy adherence was high and the approved label dosing was frequently used. Future studies are needed to further define treatment patterns, the reasons for discontinuation of the index biologic, switching and importantly the pharmacoeconomic impact of these patterns.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-TNF therapy is successful for achieving low disease activity (LDA) or clinical remission in patients with axial spondyloarhritis (axSpA). Nevertheless, this therapy has not clearly shown to slow or inhibit radiographic progression in these patients. Based on this, it is unclear what therapeutic attitude should be adopted once remission has been achieved in patients with

axSpA. The aim of this study was to evaluate if anti-TNF tapering is efficacious for maintaining remission or LDA in patients with axSpA.

Methods: A systematic literature review until August 2014 was performed using Medline, EMBASE and Cochrane databases. The research question was formulated according to the PICOS method: Population (axSpA patients); Intervention (anti-TNF dose tapering); Comparator (continue with standard dose of anti-TNF); Outcome (flare or change on disease activity); and Study design (longitudinal studies with at least 6 months of follow up after dose adjustment). Data was extracted independently by two reviewers using a form developed for this purpose.

Results: In total, 8 studies from 763 citations were included. All studies included patients with ankylosing spondylitis from single centers and no study included patients with non-radiographic axSpA. The study design was observational (n=6) and interventional (n=2). In these studies, patients receiving standard doses of anti-TNF therapy who were in remission (BASDAI<2 and normal CRP) or with LDA (BASDAI<4 and normal CRP) reduced anti-TNF therapy dose according to an established protocol (n=5) or to the physician«s criterion (n=3). Total number of patients on low-dose regimen ranged between 8 and109 patients and the follow-up period after anti-TNF tapering between 6-21 months. Administered anti-TNF therapy was etanercept (n=5), infliximab (n=1) and adalimumab/etancercept/infliximab (n=2). Data extracted for each study are shown on the table.

The percentage of patients maintaining LDA or remission after reducing anti-TNF dose was reported in 5 out of the 7 studies. These were 67%, 75%, 53-81%, 86% and 100%. The remaining three studies reported mean change in disease activity measures after reducing anti-TNF therapy. Mean BASDAI in these studies before reducing anti-TNF dose was 2.3, 1.6 and 2.1 and at the end of the study was 0.6, 1.4 and 3.2, respectively. Mean CRP (mg/L) before reducing anti-TNF dose was 0.1, 1.0 and 8 and at the end of the study was 0.1, 1.3 and 8, respectively. Anti-TNF tapering was most frequently done increasing the interval between drug administrations than decreasing the dose of the injection/infusion.

Conclusion: Published data indicates that anti-TNF therapy tapering is successful in maintaining remission or LDA during at least one year in a high number (>50%) of patients with AS. Further data are required to identify which patients with axSpA are included within this group.

Table: Results for quantitative variables are mean values.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: In patients with axial spondyloarthritis (axSpA), anti-TNF therapy is successful for clinically improving signs and symptoms of the disease. However, there is no clear evidence of the capability of this therapy to slow or inhibit radiographic progression. Based on this, it is unclear whether or not this treatment should be indefinitely sustained once the clinical goal is achieved in these patients. The aim of this study was to evaluate if discontinuation of anti-TNF therapy is successful to maintain clinical response in patients with axSpA.

Methods: A systematic literature review until August 2014 was performed using Medline, EMBASE and Cochrane databases. The research question was formulated according to the PICOS method: Population (axSpA patients); Intervention (discontinuation of anti-TNF); Comparator (continue with standard dose of anti-TNF); Outcome (flare); and Study design (longitudinal studies with at least 6 months of follow-up after anti-TNF discontinuation). Flare was assessed according to the definition employed by each study, usually BASDAI ³4 & Physician«s assessment ³4 or ÆBASDAI ³2. Exclusion criteria were: less than 12 weeks on anti-TNF treatment before discontinuation or no clinical improvement achieved during the treatment. Data were independently extracted by two reviewers using a form developed for this purpose.

Results: Five studies out of 763 citations were included, with a total of 220 patients (84% AS and 16% nr-axSpA). The study design was: observational study following participation on a RCT (n=4) and RCT (n=1). In these studies, patients receiving standard doses of an anti-TNF drug discontinued this therapy and were followed in order to assess the appearance of flare. Discontinued therapy was etanercept (n=3), infliximab (n=1), and adalimumab (n=1). Sample size ranged between 17 and 111 patients and follow-up period after discontinuation between 36 and 52 weeks. Data extracted for each study are shown on the table. The percentage range of patients developing flare during the follow-up period was 69-100%. Specifically, the percentage and corresponding period for each study were as follows: 100% (within 36 weeks), 98% (within 48 weeks), and 69%, 79% and 79% (all three within 52 weeks). Median (range) time to flare was 16 (6-24) weeks. Additionally, in 4 studies patients with flare were re-treated later using the same anti-TNF. Overall, similar response to the one achieved after the initial treatment was observed for most clinical outcomes.

Conclusion: Published data indicates that discontinuation of anti-TNF therapy in patients with axSpA leads to the appearance of flare within a few months in most cases. However, most of the published evidence is based on studies including patients with established disease. Therefore, it still remains to be evaluated whether or not this high frequency of flares is observed in patients with shorter disease duration.

Long-Term Work Productivity Improvement Associated with Apremilast, an Oral Phosphodiesterase 4 Inhibitor, in Patients with Psoriatic Arthritis: Pooled Analysis of 3 Phase 3 Studies

Frank Zhang[1], Zoe Clancy[2] and Stan Li[3], [1]Pricing and Market Access, I&I, Celgene Corporation, Warren, NJ, [2]33 Technology Drive, Celgene Corporation, Warren, NJ, [3]Celgene Corporation, Warren, NJ

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Studies have shown that patients with psoriatic arthritis (PsA) have significantly compromised physical health and quality of life, and negative effect on work productivity has been seen (Tillett W, et al. *Rheumatology [Oxford]*. 2012;51:275-283). The Work Limitations Questionnaire (WLQ) is a reliable tool for assessing limitations on work productivity in patients with chronic health conditions and was used in the PALACE 1, 2, and 3 trials, which compared the efficacy and safety of apremilast (APR), an oral phosphodiesterase 4 inhibitor, with placebo in patients with active PsA despite prior conventional disease-modifying antirheumatic drugs (DMARDs) and/or biologics. Our objective was to assess the effect of APR on work productivity and work limitations over 52 weeks in a pooled analysis of 802 patients in PALACE 1-3.

Methods: Patients were randomized (1:1:1) to receive placebo, APR 30 mg BID (APR30), or APR 20 mg BID (APR20). Early escape to active treatment was possible at Week 16 for placebo patients, and at Week 24, all patients remaining on placebo were re-randomized to APR30 or APR20. The WLQ, a 25-item questionnaire that assesses the impact of chronic health conditions on work performance and productivity, was administered at baseline, Week 16, and Week 52. Work limitations were categorized into 4 domains: physical demands (PDS), mental demands (MDS), time management demands (TMS), and output demands (ODS). An overall WLQ Productivity Score is calculated and expressed as the percentage loss in productivity associated with illness

Results: Patient demographics (age, sex, geographic region) were similar across treatment groups for patients who completed at least 1 domain of the WLQ at baseline. At Week 16, both APR30 and APR20 were associated with a greater mean change from baseline in PDS, MDS, TMS, and ODS vs. placebo, resulting in an improvement from baseline in work productivity loss. Productivity improvements in PDS, MDS, TMS, and ODS were also maintained among patients receiving APR30 and APR20 to Week 52 (Table).

Conclusion: APR30 and APR20 treatment increased work productivity and improved work limitations among patients in the PALACE 1-3 studies. Improvements in productivity loss were maintained through 52 Weeks of treatment.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Disease Modifying Anti-Rheumatic Drugs (DMARDs) are frequently used in Psoriatic Arthritis (PsA), however there is limited data regarding their survival rates. This study attempts to estimate the survival rate of the most frequently used DMARDs in a cohort of PsA patients and to determine the main causes of drug discontinuation as well as factors associated with a higher survival rate.

Methods:

Patients with PsA according to CASPAR criteria, ≥ 18 years of age, belonging to the RAPSODIA cohort were studied. Socio-demographic and clinical data were collected. Peripheral, cutaneous and axial involvement were assessed along with functional status, quality of life and disease activity. Data regarding treatment was gathered by a direct interview with the patient and from medical records in order to reduce forgetfulness bias. *Statistical analysis:* Continuous variables were compared using Mann Whitney or T test with Levene's test for homogeneity of variance, and categorical data by Chi^2 or Fisher's exact test. Kaplan Meier survival curves and log rank were used to analyse and compare drugs' survival rate. Cox proportional analysis was performed to determine associated factors with drug survival.

Results:

A total of 87 patients with PsA were included in the analysis, with a median age of 52 years (IQR 40.2-61.7) and a slight female predominance (52.9%). Median disease duration was 10 years (IQR 6-17). Seventy patients (80.5%) received methotrexate (MTX), 23 (32.9%) had to discontinue it due to adverse events (65%) or treatment failure (35%). The median survival time of MTX was 13 years (range 8.5-17.4). The cumulative survival rate after 10 years of treatment was 55%, being significantly higher among patients receiving concomitant steroid therapy (X̄16.4±2.3 years vs X̄10±2 years, p=0.01).

Of the 16 patients receiving leflunomide (LFN), 56.25% had to discontinue, estimating a median survival time of 6 years (Range 1.6-10.3). The main reasons for discontinuation were adverse events (44.5%) and treatment failure (33.3%). The cumulative survival rate after 10 years was 35%. Patient's age had a mayor impact in LFN survival; using a cut-off value of 50 years, elderly patients had higher drug survival (X̄5.5±1.5 years vs X̄3.3±1 years, p=0.03).

Conclusion:

In this cohort of PsA patients, MTX was the most frequently DMARD used, followed by LFN. MTX cumulative survival was greater than that of LFN and was favoured by concomitant steroid therapy. LFN survival was higher amongst patients with more than 50 years of age. The main reasons for drug discontinuation in both scenarios were adverse events and loss of efficacy.

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: The efficacy and tolerability of golimumab (GLM) in patients with psoriatic arthritis (PsA) has been demonstrated in several controlled clinical trials. Longitudinal observational studies assessing the real-life effectiveness of anti-TNF agents are essential to demonstrate true population-based benefits. The objective of this analysis was to assess the 12-month outcomes in PsA patients treated with GLM in Canadian routine clinical practice.

Methods: BioTRAC is an ongoing, prospective registry of patients initiating treatment for rheumatoid arthritis, ankylosing spondylitis, or PsA with infliximab or GLM. Eligible participants for this analysis included PsA patients treated with GLM enrolled since 2010. Descriptive statistics were produced for clinical outcome measures and patient reported outcomes over 12 months. Within-group changes were assessed for statistical significance with the paired-samples Student's t-test and the McNemar test. Safety was assessed with the incidence of adverse events (AEs)/100 patient-years.

Results:

There were 151 patients included in this analysis with a mean (SD) age of 51.3 (13.4) years and a disease duration since diagnosis of 4.3 (5.0) years. The proportion of males and females was even (50%). Six-month and 12-month follow-up was available for 109 (72.2%) and 69 (45.7%) patients, respectively. Upon six months of treatment, statistically significant and clinically meaningful improvements were observed for all disease parameters and were sustained over 12 months of treatment. Mean (SD) disease parameters at baseline and 12 months of treatment are shown in Table 1.

The proportion of patients with minimal disease activity (MDA) was 9.8% at baseline, 52.1% at 6 months, and 50.0% at 12 months. The prevalence of enthesitis decreased from baseline to 12 months from 27.8% to 18.8% (P=0.791), while a considerable decrease was observed for dactylitis from 27.8% to 2.9% (P<0.001), respectively. The incidence of new enthesitis cases and new dactylitis cases at 12 months was 11.1% and 1.9%, respectively.

A total of 216 AEs (172.6 events/100 patient-years) were reported by 78 (51.7%) patients and 22 serious AEs (SAEs) (17.6 events/100 patient-years) by 12 (7.9%) patients. The incidence of serious infections and malignancies were 4 (3.2 events/100 patient-years) and 5 (4.0 events/100 patient-years), respectively. There was one death reported during the course of the study judged as not related to GLM by the treating physician.

Conclusion: The results of this Canadian longitudinal observational study have shown that a significant burden of illness is observed at GLM initiation in PsA patients. Treatment with GLM was well tolerated and effective in reducing symptom severity and improving disease outcomes in PsA patients over 12 months.

Table 1: Disease Parameters Over 12 Months of Treatment with GLM

Disease Parameter, mean (SD)	Baseline	12 Months	P-Value
Enthesitis count	1.5 (3.1)	0.8 (2.2)	0.738
Enthesitis count among patients with enthesitis	5.4 (3.8)	4.6 (3.2)	0.093
Dactylitis count	1.3 (3.1)	0.03 (0.17)	0.003
Dactylitis count among patients with dactylitis	4.7 (4.5)	1.0 (1.0)	NC

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Progression of psoriatic arthritis (PsA) can lead to irreversible joint damage and functional impairment. TNF inhibitors (TNFi's) have been shown to improve signs and symptoms of PsA and, in contrast to apremilast, a phosphodiesterase-4 inhibitor, inhibit radiographic progression. The clinical impact of using apremilast prior to a TNFi is not fully understood. This study evaluated clinical responses associated with timely vs delayed use of TNFi's among patients with PsA.

Methods: A Markov model was developed to evaluate improvements in joint and skin symptoms in patients with moderate-to-severely active PsA (≥3 swollen joints and ≥3 tender joints) treated with TNFi's (adalimumab, etanercept, infliximab, or golimumab) and/or apremilast over a 1-year time horizon. In the model, PsA patients received either TNFi (timely use) or apremilast (delayed use) as initial treatment. Those who did not achieve ACR20 responses in the first 12 weeks of treatment or lost responses in the subsequent weeks either switched to a different TNFi (after timely use of first TNFi) or initiated a first TNFi (representing delayed use). Subsequent non-responses or loss of responses were followed by palliative care (both arms). Joint responses (achievement of ACR20 responses) were evaluated for all patients; skin responses (defined by 75% improvement in Psoriasis Area and Severity Index score [PASI75]) were evaluated in a subgroup of patients with moderate-to-severe psoriasis (affected body surface area [BSA] ≥3%). Efficacy inputs and distributions of patients treated with anti-TNFs were based on randomized controlled trials and market share data, respectively. Certolizumab, which was only recently approved, was excluded. Outcomes included ACR20/PASI75 response rates at year 1, mean time with ACR20/PASI75 responses, and number needed to treat (NNT) with timely vs. delayed TNFi use for achievement of ACR20/PASI75 responses in 1 patient.

Results: After one year, patients who initiated a TNFi had higher ACR20 response rates, more prolonged times as ACR20 responders and lower NNTs (**Table**) vs those initiating apremilast. Results were similar in the subgroup of patients with comorbid moderate-to-severe psoriasis: those who initiated a TNFi vs apremilast had higher combined ACR20/PASI75 response rates, more time as combined ACR20/PASI75 responders, and lower NNTs for combined responses.

Conclusion: Based on this modeling approach**,** timely use of TNFi's was a more effective strategy for management of PsA compared with delayed use of TNFi's due to sustained improvements in both joint and skin symptoms.

Outcomes at 12 Months Among PsA Patients with Timely vs Delayed Anti-TNF Use

	Arm A (timely TNFi use)	Arm B (delayed TNFi use)
Overall Population		
Joint response rates (ACR20), %[a]	70.4%	59.6%
Number needed to treat (NNT)[b]	1.42	1.68
Mean time as ACR responders, years	0.60	0.48
Subpopulation with Baseline Psoriasis		
Combined joint and skin response rates, %[a]	41.0%	30.0%
Number needed to treat (NNT)[b]	2.44	3.33
Mean time in ACR20/PASI75 responses, years	0.35	0.24

[a]Joint responses were defined as ACR20 responders; skin responses as PASI75 responders.

[b]NNT was defined as the average number of patients to be treated to gain one additional responder.

Relative Efficacy of Adalimumab Versus Secukinumab in Active Psoriatic Arthritis: A Matching-Adjusted Indirect Comparison

Keith A. Betts[1], Manish Mittal[2], Avani Joshi[2], Jinlin Song[1] and Yanjun Bao[2], [1]Analysis Group, Inc., Boston, MA, [2]AbbVie Inc., North Chicago, IL

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The phase 3 FUTURE 1 and FUTURE 2 trials demonstrated efficacy of secukinumab (SEC) for active psoriatic arthritis (PsA). However, there is limited data comparing the effectiveness of SEC with established PsA treatments. This study compared the relative efficacy of adalimumab (ADA) 40mg versus SEC 150mg and 300mg for the treatment of PsA.

Methods: An indirect comparison was conducted using individual patient data from the ADA pivotal trial (ADEPT) and published data from FUTURE 1 and 2. To adjust for the cross-trial differences, individual patients in ADEPT were re-weighted to match the mean baseline characteristics in the FUTURE trials.[1,2] Specifically, age, weight, gender, race, baseline methotrexate use, psoriasis ≥ 3% body surface area, baseline PASI score, presence of dactylitis and enthesitis, and HAQ-DI were included in the baseline matching. The ACR 20/50/70 and PASI 75/90 response rates relative to placebo at week 24 were compared. Numbers needed to treat (NNTs) to achieve one additional ACR 20 and PASI 75 responder were also calculated.

Results: After matching, mean baseline characteristics were balanced across the ADEPT and FUTURE 1 and 2 trial populations. For all outcomes, ADA demonstrated a higher relative efficacy to placebo when compared to SEC 150mg (n=302) (Figure 1). Specifically, the mean differences (95% confidence interval) between ADA and SEC 150mg in relative ACR 20/50/70 response rates were 9.5% (-4.3%, 23.3%), 3.0% (-10.1%, 16.0%), and 6.0% (-4.4%, 16.5%), respectively. The mean differences in relative PASI 75/90 response rates were 13.1% (-0.5%, 26.7%) and 6.7% (-6.4%, 19.9%). Similarly, ACR 20/50/70 and PASI 75 were higher with ADA vs SEC 300mg (n=100) (Figure 2). The NNTs to achieve one additional ACR 20 responder were 2.3 for ADA vs 3.0 for SEC 150mg and 2.7 for SEC 300mg. The NNTs to achieve one additional PASI75 responder were also lower for ADA (1.7) vs SEC 150mg (2.2) and SEC 300mg (1.9).

Conclusion: In the absence of head to head trials comparing ADA and SEC, the current indirect comparison which adjusts for differences across trial populations provides valuable and reliable evidence for physicians and payers. After adjusting for cross-trial differences in baseline characteristics, ADA was associated with higher relative ACR and PASI rates and lower NNTs compared with SEC 150mg or 300mg at week 24 among patients with PsA.

Session Date: Tuesday, November 10, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: : Previous controlled clinical trials have shown that concurrent methotrexate (MTX) therapy may enhance the efficacy of anti-TNF agents. However, real-world data on the benefits of combination therapy with MTX and golimumab (GLM) are scarce. This aim of this analysis was to compare the baseline profile of patients initiating MTX+GLM compared to patients treated with GLM monotherapy and to assess the impact of concomitant MTX treatment on GLM effectiveness.

Methods: Biologic Treatment Registry Across Canada (BioTRAC) is an ongoing, prospective registry of patients initiating treatment for rheumatoid arthritis, ankylosing spondylitis, or PsA with infliximab or GLM. PsA patients treated with GLM enrolled since 2010 were included in this analysis. Descriptive statistics were produced for clinical outcome measures and patient reported outcomes at baseline, 6 and 12 months of treatment. Within-group changes were assessed for statistical significance with the Wilcoxon t-test.

Results:

There were 152 PsA patients included in this analysis. Mean (SD) age was 51.3 (13.4) years and disease duration was 4.3 (5.0) years. The majority of patients (94.7%) in the GLM+MTX group received a high MTX dose (≥15 mg/week). 51.8% of patients had a MTX history for the GLM group vs 64.2% for the GLM+MTX group. Baseline patient characteristics and disease parameters were comparable for GLM vs. GLM+MTX although a higher proportion in the GLM group had dactylitis (39.3% vs. 21.1%. P=0.023). Statistically significant and clinically meaningful improvements were observed upon 6 months of treatment in both groups for all disease parameters which were sustained over 12 months of treatment, with the exception of PASI and HAQ-DI in the GLM group which did not reach statistical significance (Table 1). Upon adjusting for baseline levels, patients in the GLM+MTX group experienced greater improvements in most disease parameters although statistical significance was achieved only for TJC.

Table 1: Disease parameters for GLM vs. GLM+MTX at baseline and 12 months

	Group: GLM N=57			Group: GLM+MTX N=95			Between Group

HAQ-DI	0.96 (0.67)	0.76 (0.62)	0.087	1.03 (0.67)	0.67 (0.68)	***0.019***	0.726

[1] Represents within group P-value assessed with Wilcoxon test

[2] Represents between group P-value at 12 months of treatment assessed with linear regression adjusting for baseline disease parameters

The proportion of patients achieving minimal disease activity (MDA) was comparable between groups with GLM=56.0% vs. GLM+MTX=50.0% at 6 months, and GLM=47.1% vs. GLM+MTX=51.4% at 12 months.

Conclusion: The results of this analysis have shown that treatment with GLM, with or without MTX, is effective in reducing symptom severity and improving disease outcomes over a 12 month period in PsA patients. However, concomitant treatment with MTX may confer additional benefits. Additional analyses with larger sample sizes are required.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Early achievement of minimal disease activity (MDA) is recommended as a valid treat-to-target approach in psoriatic arthritis (PsA). The purpose of the current analysis was to evaluate predictors of MDA achievement in PsA patients treated with anti-TNF agents in Canadian routine clinical care.

Methods:

Biologic Treatment Registry Across Canada (BioTRAC) is an ongoing, prospective registry of patients initiating treatment for rheumatoid arthritis, ankylosing spondylitis, or PsA with Infliximab (IFX) or Golimumab (GLM). Eligible people for this analysis included PsA patients treated with IFX who were enrolled since 2005 or with GLM enrolled since 2010 and with available MDA information at baseline, 6 months, and/or 12 months. MDA was defined as the fulfillment of ≥5 of the following criteria: TJC28≤1, SJC28≤1, PASI≤1 or BSA≤3, Pain (VAS)≤15mm, PtGA (VAS)≤20mm, HAQ ≤0.5, tender entheseal points ≤1. Independent predictors of MDA achievement were assessed with logistic regression.

Results:

A total of 196 patients (51.4% male and 87.2% bionaive) were included with a mean (SD) age and disease duration of 49.8 (11.1) and 5.4 (6.3) years, respectively. The proportion of patients with MDA was 11.7% at baseline, 43.5% at 6 months, 44.8% at 12 months, and 49.1% at either 6 or 12 months. Among patients with MDA at 6 months, 75.7% had sustained MDA at 12 months. Patients achieving MDA during follow-up had significantly lower disease activity at baseline; mean (SD) disease parameters were: SJC28: 3.24 (3.58) vs. 5.47 (4.31), P<0.001; TJC28: 3.75 (4.00) vs. 8.66 (6.53), P<0.001; pain: 35.39 (25.11) vs. 55.70 (22.93), P<0.001; PtGA: 38.51 (25.00) vs. 56.15 (25.13), P<0.001; HAQ-DI: 0.71 (0.61) vs. 1.33 (0.57), P<0.001; MDGA: 4.25 (2.38) vs. 5.84 (2.07), P<0.001); enthesitis count: 2.62 (1.60) vs. 4.97 (3.48), P=0.008.

Multivariate logistic regression analysis showed that lower baseline HAQ (OR=0.243; P<0.001), lower TJC28 (OR=0.889; P=0.008), and lower enthesitis count (OR=0.817; P=0.817) were significant predictors of MDA achievement over 12 months of treatment.

Conclusion: The results of the current analysis have shown that 50% of patients treated with IFX or GLM in routine clinical care achieve MDA within the first year of treatment. Lower baseline HAQ, lower TJC28, and lower enthesitis count were identified as significant predictors of MDA achievement.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Although the efficacy and tolerability of golimumab (GLM) in patients with ankylosing spondylitis (AS) has been demonstrated in several controlled clinical trials, it is essential to assess the real-life effectiveness of therapeutic interventions in order to demonstrate true population-based benefits. The aim of this analysis was to describe the real-life effectiveness of GLM in AS patients in a Canadian routine clinical practice setting.

Methods: Biologic Treatment Registry Across Canada (BioTRAC) is an ongoing, prospective registry of patients initiating treatment for rheumatoid arthritis, ankylosing spondylitis, or PsA with infliximab or GLM. Eligible people for this analysis included AS patients treated with GLM enrolled since 2010. Descriptive statistics were produced for clinical outcome measures and patient reported outcomes over 12 months of treatment. Within-group changes were assessed for statistical significance with the paired-samples Student's t-test. Safety was assessed with the incidence of adverse events (AEs)/100 patient-years.

Results: A total of 206 AS patients were included in this analysis with a mean (SD) age of 45.6 (13.9) years and disease duration since diagnosis of 5.7 (10.2) years, the majority were male (61.2%) and 93.2% were biologic naïve. After six months of treatment, statistically significant (P<0.001) and clinically meaningful improvements were observed for all disease parameters and were sustained over 12 months of treatment (P<0.001). Mean (SD) disease parameters at baseline and 12 months of treatment are shown in Table 1. Clinically important improvement in ASDAS (change ≥1.1) by 6 and 12 months was 46.6% and 40.0%, respectively; major improvement (change ≥2.0) was achieved by 13.8% and 25.0% respectively. The proportion of patients who achieved ASDAS inactive disease (ASDAS <1.3) increased from 2.6% at baseline to 21.2% at 12 months; while very high disease activity (ASDAS >3.5) decreased from 44.4% to 21.2%, respectively. A total of 282 AEs (215.8 events/100 patient-years) were reported by 105 (51.0%) patients and 23 serious AEs (SAEs) (17.6 events/100 patient-years) by 20 (9.7%) patients. The incidence of serious infections and malignancies were 2 (1.5 events/100 patient-years) and 1 (0.8 events/100 patient-years), respectively. There were no deaths reported during the course of the study.

Table 1: Disease Parameters Over 12 Months of GLM Treatment

Parameter **Mean (SD) / %**	**Baseline** **(n=206)**	**Month 12** **(n=77)**	**P-Value**
AM stiffness: minutes	55.17 (45.29)	24.19 (30.76)	<0.001
HAQ-DI	1.02 (0.60)	0.68 (0.62)	<0.001
Patient Global (PtGA): VAS mm	55.08 (25.96)	32.41 (28.36)	<0.001
Physician Global (MDGA): NRS 0-10	5.32 (2.20)	2.42 (2.40)	<0.001
BASFI	5.10 (2.49)	3.33 (2.80)	<0.001
BASDAI	5.86 (2.13)	3.64 (2.58)	<0.001
ASDAS	3.33 (0.96)	2.46 (1.20)	<0.001
ASDAS Disease Activity (DA) *Inactive Disease* *Moderate DA* *High DA* *Very High DA*	 2.6% 9.3% 43.7% 44.4%	 21.2% 23.1% 34.6% 21.2%	<0.001
ASDAS Clinically Important Improvement (Δ≥1.1)	N/A	46.6%	N/A
ASDAS Major Improvement (Δ≥2.0)	N/A	40.0%	N/A

Conclusion: The results of this Canadian longitudinal observational study have shown that GLM is well tolerated and effective in reducing symptom severity and improving disease outcomes in AS patients over a 12 month period.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The interleukin-17 (IL-17) cytokine family plays a key role in the pathogenesis of psoriatic diseases of skin and joint. Brodalumab is a fully human anti–IL-17 receptor monoclonal antibody that blocks the activity of IL-17A, IL-17F, and IL-17A/F. Here, we evaluate the long-term safety and efficacy of brodalumab in patients with psoriatic arthritis (PsA) in an open-label extension (OLE) of a phase 2 study.

Methods: In a phase 2 study (NCT01516957), adults (18–75 years) with active PsA were randomized to brodalumab (140 or 280 mg) or placebo at weeks 0, 1, 2, 4, 6, 8, and 10. At week 12, patients could enter an OLE and receive brodalumab 280 mg every 2 weeks (Q2W); a protocol amendment in November 2013 resulted in dosage reduction to 210 mg Q2W for all patients. Outcome measures based on observed data through week 108 included percentages of patients with 20% and 50% improvement in American College of Rheumatology criteria (ACR20 and ACR50) and changes in ACR components and Psoriasis Symptom Inventory (PSI) score. Safety was assessed by adverse events (AEs).

Results: At baseline, patients were 64% female, 94% white, with mean age and weight of 52 years and 91 kg, respectively. Mean PsA duration was 9 years, 92% were rheumatoid factor negative, and mean PSI score was 12.7. Of 168 patients randomized at baseline, 156 (52 placebo, 53 brodalumab 140 mg, and 51 brodalumab 280 mg) entered the OLE and 109 (70%) remained at week 108.

Through week 108, 149 (96%) patients reported an AE and 23 (15%) reported a serious AE (SAE). The most frequent SAEs (n=2 each) were coronary artery disease, cholelithiasis, and cellulitis; the most frequent AEs (≥10% of all patients) were nasopharyngitis, upper respiratory tract infection, psoriatic arthropathy, urinary tract infection, arthralgia, diarrhea, sinusitis, and bronchitis. Exposure-adjusted AE rate (per 100 patient-years) for all patients was 526; exposure-adjusted SAE rate was 14. There were no deaths, 1 laboratory report of neutropenia, 1 case of suicidal ideation, and 11 cases of oral candidiasis.

At week 12 of the study (double-blind phase), percentages of patients with ACR20 and ACR50 (non-responder imputation [NRI] analysis) were significantly greater in each brodalumab group than placebo: ACR20 37% (140 mg) and 39% (280 mg) vs 18% (placebo); ACR50 14% and 14% vs 4%. Through week 108 of the OLE, we continued to observe meaningful clinical benefit in ACR20 and ACR50 (Figure 1, as observed). Continued clinical benefit was also demonstrated by NRI analysis. Responses for other outcome measures were also sustained from week 12 to 108 in patients remaining in the OLE.

Conclusion: Treatment with brodalumab resulted in a safety profile comparable to the overall safety profile of biologics approved for PsA and meaningful clinical benefit that was maintained through week 108 in patients with PsA in this ongoing OLE.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: As part of the update of the EULAR recommendations for the management of PsA, we performed a systematic literature review to assess the efficacy and safety of pharmacological agents for the management of PsA.

Methods: Randomised controlled trials (RCTs), including long-term extensions, comparing any two pharmacological interventions for the management of patients with PsA, were identified by searches in Medline, Embase and Cochrane datasets (2010-2014), supplemented by searches in 2013-2014 EULAR and ACR abstracts. Pharmacological interventions were defined as any biological (bDMARD), synthetic DMARD (sDMARD) either conventional or targeted, NSAID, glucocorticoid or any combination and they could be compared to any of them or placebo (PBO). Strategy trials were also included. The main efficacy outcomes were ACR20, ACR50, PASI75 and radiographic progression, and the main safety outcome was withdrawals due to adverse events. Risk of bias (RoB) was assessed according to the Cochrane tool. Multiple studies of the same intervention were meta-analysed with random effects analysis in RevMan.

Results: Of 2,278 articles and 387 conference abstracts screened, 42 (24 papers and 18 abstracts) met the inclusion criteria. A total of 19 articles/abstracts focused on 3 new drugs for the management of PsA: ustekinumab (UST), apremilast (APR) and secukinumab (SEC). All were PBO-compared trials and met their primary endpoint, ACR20; RoB was low (UST, SEC) or unclear (APR). For achieving ACR20, absolute responses are in the Table. Risk ratios (RR) versus PBO were respectively for UST90mg and UST45mg of 2.17 (95%CI 1.71-2.76) and 1.95 (1.52-2.50); for APR30mg and APR20mg of 2.06 (1.67, 2.54) and 1.84 (1.51-2.25); and for SEC300mg, SEC150mg and SEC75mg, of 3.31 (2.04-5.36), 5.82 (1.56-21.71) and 4.47 (0.66-30.26). The 3 drugs showed efficacy on dactylitis and enthesitis, with APR apparently showing less pronounced effects. These new drugs showed slightly more SAEs and withdrawals due to AEs than PBO. Eleven articles/abstracts on golimumab and certolizumab pegol demonstrated the efficacy and safety of these drugs with respect to all outcomes. A strategy trial, TICOPA, has shown better ACR responses with tight control compared to standard care. No studies were found on NSAIDs or glucocorticoids.

Table - Main efficacy outcomes of the new drugs for the treatment of PsA, at time point of the trial's primary endpoint

Trial, time point	Treatment arm	ACR 20 (%)	ACR 50 (%)	PASI 75 (%)	delta mTSS
PSUMMIT 1 24 Weeks	UST 90mg	49.5	27.9	62.4	0.4 (2.4)*
	UST 45mg	42.4	24.9	57.2	0.4 (2.1)*
	PBO	22.8	8.7	11.0	1.0 (3.9)*
PSUMMIT 2 24 Weeks	UST 90mg	43.8	22.9	55.6	**
	UST 45mg	43.7	17.5	51.3	**
	PBO	20.2	6.7	5.0	**
PALACE 1 16 Weeks	APR 30mg	38.1	NA	NA	NA
	APR 20mg	30.4	NA	NA	NA
	PBO	19.0	NA	NA	NA
PALACE 2 16 Weeks	APR 30mg	34.4	NA	NA	NA
	APR 20mg	38.4	NA	NA	NA
	PBO	19.5	NA	NA	NA
PALACE 3 16 Weeks	APR 30mg	42.8	NA	NA	NA
	APR 20mg	29.4	NA	NA	NA
	PBO	18.9	NA	NA	NA
PALACE 4 16 Weeks	APR 30mg	29.2	NA	NA	NA
	APR 20mg	32.3	NA	NA	NA
	PBO	16.9	NA	NA	NA
FUTURE 1 24 Weeks	SEC 150mg	50.0	34.7	61.1	0.13
	SEC 75mg	50.5	30.7	64.8	0.02
	PBO	17.3	7.4	8.3	0.57
FUTURE 2 24 Weeks	SEC 300mg	54.0	35.0	63.4	NA
	SEC 150mg	51.0	35.0	48.3	NA
	SEC 75mg	29.3	18.2	28.9	NA
	PBO	15.3	7.1	16.3	NA

*Results reflect a pooled analysis of PSUMMIT 1 and 2, as *a priori* pre-defined

Conclusion:

UST, APR and SEC are new drugs with efficacy demonstrated for the treatment of PsA. No major safety signals arise, but long-term studies are needed. Studies with new TNFi confirm the efficacy of these drugs. Treatment set to a therapeutic target achieves better outcome than non-targeted therapy. This review informs the update of the EULAR recommendations for the management of PsA.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

It has previously been shown that the survival of anti-TNF drugs was lower in Rheumatoid arthritis (RA) than in other chronic arthritis[1]. The objective of this study was to investigate the drug retention of Golimumab (GOL) and its effectiveness in patients affected with axial Spondyloarthritis (AxSpA), Psoriatic arthritis (PsA) and RA. Furthermore, the impact of possible baseline predictors was also evaluated.

Methods:

This is a multicenter prospective observational study of unselected patients with AxSpA, PsA and RA starting GOL because of their active disease despite prior treatment with conventional disease modifying drugs (DMARDs) or biological DMARDs (bDMARDs) in the settings of standard care from 11 rheumatologic centres of Apulia (Southern Italy). The primary endpoint was GOL drug retention at 2 years. A secondary endpoint was clinical outcomes based on DAS28 and BASDAI reduction. Time to discontinuation was defined as the time between drug initiation and last administration plus one dispensation interval. Kaplan-Meier curve analysis was used to assess drug retention, and a Cox proportional regression model, adjusting for potential confounders, including prior bDMARD exposure, patient demographics and disease characteristics, for the analysis of predictors.

Results: To date, 357 patients (PsA 154, AR 80, AxSpA 123) have been enrolled, 151 (42.3%) were “biologic-naïve”. Disease duration was 6.7 ±6 yrs for PsA, 8.1 ±7 for RA, and 7.0 ±6 for AxSpA, respectively. At 2 years (Fig.1), the crude survival rate was 74.8% (21.1 ± 0.5 months) for AxSpa, 67.5% (20.2 ± 0.8 months) for RA and 63.6% (18.8 ± 0.6 months) for PsA, being the difference not statistically significant. Analysis of predictors showed that female gender strongly correlated with GOL discontinuation (hazard ratio (HR) (95% CI): 3.82, (1.54-9.51)), while the lack of extra-articular manifestations was a negative predictor (HR (95% CI): 0.21, (0.49-0.91) for AxSpA patients. No predictors of drug survival for RA and PsA were found. Additionally, GOL was effective in all patients with a significant reduction of DAS28 and BASDAI at 12 and 24 months compared to baseline (Table 1).

Conclusion:

Unlike previous studies on TNF inhibitors, GOL seems to have similar drug survival in different chronic arthritides regardless of prior bDMARD treatment. Female AxSpA patients with extra-articular manifestations have higher hazard to discontinue the therapy .

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The use of TNF inhibitors (TNFIs) has led to efficient control of the signs and symptoms of SpA and rheumatoid arthritis (RA), and significantly improved the patients' quality of life. However, as most patients need often indeterminately long-term treatment (especially those with SpA), rheumatologists must be aware of treatment side effects such as malignances, even though nine clinical trials of etanercept in SpA patients did not find an increased risk. The aim of this study was to evaluate the risk of malignances in the TNFI-treated SpA patients in the Gruppo Italiano Studio Early Arthritis(GISEA) Registry, and assess predictors of malignancies

Methods: The Registry, which is designed to collect real-world clinical data concerning RA and SpA patients receiving biological drugs as part of routine care, was approved by local Ethics Committees, and enrols patients aged ≥18 years who have given their written informed consent. The baseline information includes demographics, disease duration, HAQ, DAS-28, BASDAI, BASFI and BASMI scores, steroid use (defined as actively receiving oral steroids at the time of recruitment), smoking history and comorbidities.

Results:

The analysis involved 3321 SpA patients (1731 males, 52.2%; mean age 47±13 years; median disease duration three years, interquartile range [IQR] 0, 8 years): 1065 (32%) treated with infliximab (IFN), 1052 (32%) with adalimumab (ADA), and 1204 (36%) with etanercept (ETN). Two thousand, one hundred and five (63.4%) had a median of one comorbity (IQR 0, 2], the most frequent being hypertension (701), thyroid diseases (281), diabetes mellitus (207), cardiopathy (189), and osteoporosis (145). In combination with the biological drug, 919 patients (27.7%) received steroids and 2451 (79.9%) at least one DMARD. The median follow-up time was three months (IQR 12 years). During 12 years of TNFI treatment, 50 patients experienced at least one of 56 neoplasias, 28% of which occurred during the first 12 months. Overall incidence was 6.3/1000 patient-years of follow-up (95% CI 4.7–8.2): 7.3/1000 (95% CI 4.1–11.8) among those treated with ADA; 6.1/1000 (95% CI 3.8–9.4) among those treated with ETN; and 5.8/1000 (95% CI 3.5–9.1) among those treated with IFN. Univariate analysis showed that age at the start of anti-TNF treatment (p=0.001), the number of comorbidities (p<0.001), and HAQ score (p=0.002) were associated with a high risk of malignancy. Multivariate models showed that male gender (hazard ratio [HR] 4.5, 95%CI1.3-16.0; p=0.020), age at the start of anti-TNF treatment (HR 1.1, 95%CI 1.01-1.11; p=0.020), and HAQ score (HR 2.8, 95%CI1.5-5.3; p=0.002) were statistically significant predictors of malignances. Ten of the 50 patients experiencing a neoplasia had had a previous solid cancer (HR 11.2, 95%CI 4.4-28.4; p<0.001).

Conclusion: TNFI therapy is not associated with a significant overall risk of malignances in SpA patients, but having had a previous solid cancer is predictive of a new neoplasia.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Subgroup analyses can be used to investigate the size and direction of treatment effects across a range of demographic and disease characteristics. The purpose of this study was to explore response consistency in subgroups of patients with nonradiographic axial spondyloarthritis (nr-axSpA) who received golimumab (GLM) or placebo for 16 wks.

Methods: GO-AHEAD was a double-blind, randomized, placebo (PBO)-controlled trial of GLM in patients with active nr-axSpA (ASAS criteria and centrally read sacroiliac (SI) joint X-rays and MRIs; disease duration ≤5 years; chronic back pain; high disease activity [total back pain ≥40 mm on a 0–100 mm Visual Analogue Scale and BASDAI ≥4 cm]; and inadequate response/intolerance to NSAIDs). Patients were randomized 1:1 to subcutaneous GLM 50 mg or PBO every 4 wks. Estimated between-group treatment differences and 95% CIs for ASAS 20 and ASAS 40 response at wk 16 were calculated for prespecified patient subgroups. Treatment and subgroup differences were compared by stratified Miettinen–Nurminen methods with baseline inflammation by SI joint MRI and screening C-reactive protein (CRP) level as stratification factors. No multiplicity control was applied.

Results: A total of 197 patients were treated (GLM=97; PBO=100). Overall, ASAS 20 at wk 16 was achieved by 71.1% of GLM patients and 40.0% of PBO patients (P <.0001). Although size of response differed somewhat across the subgroups, responses were greater to GLM than PBO in most patient subgroups (P<.05; Table). Because of the small numbers of patients within subgroups and because subgroups may not represent randomized samples, results should be considered exploratory and interpreted with caution. Treatment group differences appeared to be larger in patients with objective signs of inflammation (MRI SI or CRP>ULN). The results for ASAS 40 were very similar to those for ASAS 20.

Table. ASAS 20 Attainment at Week 16 by Treatment Group and Baseline Characteristics			
Subgroup	**GLM n/N (%)**	**PBO n/N (%)**	**Difference vs PBO[a] % (95% CI)**
Gender			
Female	21/36 (58.3)	20/48 (41.7)	14.8 (–6.9, 35.4)
Male	48/61 (78.7)	20/52 (38.5)	40.0 (21.8, 55.6)
Age			
≤30 years	41/56 (73.2)	16/45 (35.6)	39.6 (20.4, 56.0)
>30 years	28/41 (68.3)	24/55 (43.6)	26.1 (5.6, 43.7)
Disease duration			
>median	38/48 (79.2)	18/51 (35.3)	43.3 (24.1, 59.3)
≤median	31/49 (63.3)	22/49 (44.9)	18.2 (–1.4, 36.3)
HLA-B27			
Negative	8/16 (50.0)	7/18 (38.9)	11.1 (–23.3, 43.5)
Positive	61/81 (75.3)	33/82 (40.2)	35.0 (20.2, 48.2)
MRI sacroiliitis			
Yes	48/65 (73.8)	25/66 (37.9)	36.0 (19.3, 50.7)
No	21/32 (65.6)	15/34 (44.1)	21.6 (–2.6, 43.0)
CRP			
≤ULN	35/58 (60.3)	25/59 (42.4)	17.9 (–0.3, 35.0)
>ULN	34/39 (87.2)	15/41 (36.6)	50.6 (30.5, 66.6)
MRI sacroiliitis (+) or CRP >ULN	60/78 (76.9)	30/80 (37.5)	39.6 (24.6, 52.6)
MRI sacroiliitis (–) and CRP ≤ULN	9/19 (47.4)	10/20 (50.0)	–2.6 (–32.7, 27.9)
[a]Differences derived from the statistical model.			

Conclusion: Overall, patients with active nr-axSpA who received GLM were more likely to achieve ASAS 20 at wk 16 than those treated with PBO across a variety of baseline characteristics, including those with baseline objective signs of inflammation (eg, MRI SI or CRP >ULN).

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Enthesitis is characterized by inflammation at the insertion of ligaments, tendons, joint capsule, or fascia to bone, and represents a well-known characteristic feature of ankylosing spondylitis (AS) and related spondyloarthropathies.

Methods:

BioTRAC is an ongoing, prospective registry of patients initiating treatment for rheumatoid arthritis, AS, or psoriatic arthritis (PsA) with infliximab (IFX) or golimumab (GLM). Eligible people for this analysis included AS and PsA patients treated with IFX who were enrolled since 2005 or with GLM enrolled since 2010 who had available information on enthesitis. The paired sampled t-test was used to compare the enthesitis count at baseline and 12 months.

Results:

A total of 260 AS patients and 261 PsA patients were enrolled with a mean (SD) age at baseline of 46.1 (13.0) vs. 50.0 (12.0) years, respectively, and disease duration of 6.4 (9.8) vs. 5.2 (6.8) years. Among patients with AS, 28.1%, 21.7%, 22.4% had enthesitis at baseline, 6 months and 12 months, respectively. For PsA these numbers were 32.2%, 19.7%, and 22.6%, respectively. The presence of enthesitis by anatomical site and visit are described in Table 1 with higher proportions observed for the greater trochanter (GT) in AS patients and the lateral epicondyle humerus (LEH) in PsA patients.

Table 1: Presence of Enthesitis by Anatomical Site

	AS			PsA		
	Baseline (N=260)	6 Months (N=203)	12 Months (N=134)	Baseline (N=261)	6 Months (N=189)	12 Months (N=133)
LEH, %	10.8	6.9	7.5	16.1	8.5	6.8
MEH, %	8.1	5.9	4.5	12.6	7.4	6.8
PA, %	10.8	5.4	3.0	13.0	6.4	6.8
GT, %	14.2	8.4	10.4	10.7	9.0	6.0
IPF, %	7.7	3.4	4.5	11.9	5.3	3.8
SI, %	11.5	8.9	7.5	10.7	8.0	8.3
QIP, %	6.9	3.9	1.5	9.6	5.9	6.0
PATT, %	6.9	4.4	1.5	13.8	5.9	8.3

LEH: Lateral epicondyle humerus; MEH: Medial epicondyle humerus; PA: Proximal achilles; GT: Greater trochanter; IPF: Insertion plantar fascia; SI: Suprapsinatus insertion; QIP: Quadriceps insertion patella; PATT: Inferior pole patella or tibial tubercle

Presence of enthesitis in all anatomical sites was significantly associated with higher HAQ among AS and PsA patients. The mean (SD) enthesitis count at baseline and 12 months was 4.4 (3.4) vs. 2.6 (2.3) (P=0.061) among AS patients and 5.0 (3.8) vs. 3.8 (3.0) (P=0.006) in PsA patients, respectively.

Conclusion: A considerable proportion of PsA and AS patients had enthesitis at anti-TNF initiation in this Canadian real-world cohort. Overall, presence of enthesitis was associated with significantly higher functional disability. Treatment with IFX or GLM for 12 months was associated with significant reduction in the mean enthesitis count.

Treating Axial Spondyloarthritis to Target: Influence of the Population Characteristics and Comorbidities in Reaching Ankylosing Spondylitis Disease Activity Score (ASDAS) Inactive Disease in a Cohort of Patients Treated with Tnfalpha Inhibitors Agents

Sara Monti, Veronica Codullo, Vittorio Grosso, Silvia Breda, Carlomaurizio Montecucco and Roberto Caporali, Division of Rheumatology, University of Pavia, IRCCS Foundation Policlinico S. Matteo, Pavia, Italy

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The treat to target strategy (T2T), aiming at inactive disease (ID), has become the recommended approach also in the field of axial-SpA (axSpA) (1). Using the composite disease activity index "*Ankylosing Spondylitis Disease Activity Score*" (ASDAS) we assessed the real life feasibility of the T2T strategy in our cohort of axSpA patients treated with TNFα inhibitors (TNFi). We analyzed potential differences among the Ankylosing Spondylitis (AS) and the non-radiographic Ax-SpA (nr-ax-SpA) group and the influence of the population characteristics and comorbidities in reaching ID.

Methods: The study population was selected from outpatients with axSpA on a stable TNFi treatment for at least 6 months. Disease activity was cross-sectionally evaluated in terms of BASDAI and ASDAS-CRP during the latest follow up visit. ID was defined as ASDAS-CRP< 1.3. Extra-articular manifestations and comorbidities were assessed. Statistical analysis performed with STATA.

Results: General characteristics of the 125 enrolled patients are presented in Table 1. Female sex, prevalence of fibromyalgia and frequency of concomitant DMARDs were significantly more represented in the nr-ax-SpA group. On the other hand, the time from TNFi initiation was significantly shorter in nr-ax-SpA. ASDAS-CRP ID was reached by n=51 (40.8%) of our population, while a good disease control would have been reached by n=89 (71.2%) of patients in terms of BASDAI. There were no differences in the two groups, with a slightly higher prevalence of ID in the nr-ax-SpA group not reaching statistical significance (Figure 1). Multivariate logistic regression demonstrated a negative correlation of fibromyalgia (OR 0.14; CI95% 0.02-0.77), higher *Bath Ankylosing Spondylitis Metrology Index* (BASMI) (OR 0.6; CI95% 0.41-0.89) and number of previous TNFi (OR 0.36; CI95% 0.15-0.89) with the chances of reaching ID. ID achievement resulted independent from sex, age, disease duration, DMARDs, NSAIDs and other comorbidities.

Conclusion: The recommended T2T strategy represents a new challenge in the management of ax-SpA, with recently introduced methods of measuring disease activity being significantly more stringent. The prevalence of ID was not influenced by the type of disease (nr-Ax-SpA Vs AS) but was significantly influenced by the presence of concomitant fibromyalgia, decreased spine mobility and the previous number of TNFi lines of treatment.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Dactylitis is one of the most commonly reported features in spondyloarthritis. It has been hypothesized that dactylitis is a functional enthesitis at the proximal interphalangeal joints, resulting in synovitis, tenosynovitis, bone and soft tissue

oedema to the digit, and may simultaneously involve more than one digit.

Methods: BioTRAC is an ongoing, prospective registry of patients initiating treatment for rheumatoid arthritis (RA), ankylosing spondylitis (AS), or psoriatic arthritis (PsA) with infliximab (IFX) or golimumab (GLM). Eligible people for this analysis included AS and PsA patients treated with IFX who were enrolled since 2005 or with GLM enrolled since 2010 who had available information on dactylitis. The McNemar (paired Chi-square) test was used to compare the presence of dactylitis over time.

Results: A total of 260 AS patients and 261 PsA patients were enrolled with a mean (SD) age at baseline of 46.1 (13.0) vs. 50.0 (12.0) years, disease duration of 6.4 (9.8) vs. 5.2 (6.8) years, and proportion of females 40.6% vs. 48.5%, respectively. Among patients with AS, dactylitis was reported in 6.2% and 2.2% of patients at baseline and 6 months, respectively; at 6 months of treatment 73.3% of AS patients with dactylitis at baseline had no dactylitis and 1.6% developed dactylitis (P=0.057). For PsA higher proportions of dactylitis were observed with 30.7%, and 12.7%, respectively; at 6 months of treatment 69.0% of PsA patients with dactylitis at baseline had no dactylitis and 4.6% developed dactylitis (P<0.001). The distribution of dactylitis amongst digits is described in Table 1 with the highest prevalence observed for feet in AS and PsA patients.

Table 1: Distribution of Dactylitis amongst Digits in AS and PsA

	AS		PsA	
	Baseline (N=260)	6 Months (N=207)	Baseline (N=261)	6 Months (N=189)
HD1, %	1.9	0.5	4.2	2.6
HD2, %	3.1	1.0	9.2	5.3
HD3, %	3.1	2.4	8.0	5.3
HD4, %	1.5	1.0	8.0	2.6
HD5, %	1.5	1.4	5.4	3.2
FD1, %	2.7	0.5	8.0	1.1
FD2, %	3.8	0.5	12.6	3.7
FD3, %	2.3	0.5	11.1	3.2
FD4, %	2.3	1.0	14.9	5.3
FD5, %	1.5	0.0	10.0	1.6

HD=hand digit; FD=foot digit

Presence of dactylitis in hands or feet (any digit) was associated with significantly higher HAQ in AS and PsA (AS: ΔHAQ=1.36 (P≤0.001); PsA: ΔHAQ=0.64 (P≤0.001)).

Conclusion: A considerable proportion of PsA patients had dactylitis at anti-TNF initiation in this Canadian real-world cohort. Although a lower proportion of patients had dactylitis among AS patients, the presence of dactylitis was associated with higher functional disability in both AS and PsA patients. Treatment with IFX or GLM for 6 months was associated with significant reduction in the prevalence of dactylitis.

Session Date: Tuesday, November 10, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Clinical trial results have demonstrated benefits of anti-TNF therapy in improving clinical outcomes, including overall health-related quality of life (HRQoL) in patients with ankylosing spondylitis (AS)[1]. We aimed to understand how consistency of anti-TNF use in the real-world impacts patient-reported outcomes, including measures of disease activity, functional impairment, depression, HRQoL, and work productivity.

Methods: A prospective Patient Reported Outcomes Survey of Employment in Patients with AS (PROSE-AS) was conducted at rheumatologists' practices in Canada, the Netherlands, the United Kingdom, and the United States. Patients ≥18 years of age completed surveys assessing sociodemographic and clinical characteristics, drug use, and several patient reported outcomes at 3 month intervals (12 months follow-up; 5 visits total). Anti-TNF history prior to the baseline visit was not assessed. Disease activity and functional impairment were assessed using the Bath AS Disease Activity Index (BASDAI) and Bath AS Functional Index (BASFI) scales, respectively; depression with the Center for Epidemiological Studies Depression (CES-D) scale; overall HRQoL with the Short Form 36 Health Survey (SF-36) and AS Quality of Life (ASQoL) questionnaires; and work outcomes with the Work Productivity and Activity Impairment (WPAI) questionnaire. Associations between anti-TNF use (occasional vs intermittent or continuous; defined as use in 1–2, 3–4, and 5 of 5 visits, respectively) and outcomes at 12 months were assessed with multivariable regression analyses, after controlling for baseline characteristics.

Results: Of 555 patients enrolled, 227 who had ≥1 visit with anti-TNF use during study period (20 occasional, 63 intermittent, and 144 continuous) were included in the analysis. Mean age was 46 years, 93.4% were white, and 30.8% were female. At baseline, mean AS duration was 14 years; mean BASDAI and BASFI scores were both 4.4; and mean SF-36 Physical Component Summary (PCS) and ASQoL scores were 37.3 and 8.2, respectively. Of the 227 anti-TNF users, 182 (8 occasional, 30 intermittent, and 144 continuous) were on anti-TNFs at baseline. Among 149 (65.6%) patients who were employed at baseline, 30 (20.1%) reported baseline absenteeism. At month 12, patients with intermittent or continuous anti-TNF use reported significantly better BASDAI, BASFI, SF-36 PCS, and ASQOL scores than patients with occasional use; they were also significantly less likely to be depressed and to report absenteeism (**Table**). Improvements were generally greater with increasing anti-TNF use.

Conclusion: In this real-world, multi-country, prospective study of patients with AS, continuous and intermittent vs occasional use of anti-TNF medication was associated with better clinical, psychological, and HRQoL outcomes, and lower absenteeism.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Spondyloarthritides, a heterogeneous group of chronic, inflammatory disorders with overlapping organ and joint targeting, share the same therapeutic approach in regard to biological therapy. Anti-tumor necrosis factor (anti-TNF) agents have highly proved their efficacy in lowering overall disease activity. However, a number of patients who initially responded to therapy fail to maintain a satisfactory disease evolution curve. Loss of response to TNF-inhibitors in spondyloarthritis (SpA) might be due to undetectable drug serum level. Determining infliximab (IFX) serum levels in SpA patients and adjusting dose or interval administration in a personalized manner might lead to a better disease outcome.

Methods: During a period of six months (January – June 2015), thirty-three consecutive patients with established SpA were enrolled in this study, while on regular hospital visit for IFX infusion. Patient data was gathered together with serum drug levels measured by enzyme linked immunosorbent assay (ELISA), using Progenika kits (Promonitor-IFX). The statistical analysis was performed using the SPSS statistical software, version 20.0, with a standardized p value of 0.05. Differences between groups were recorded with the aid of Student t-test, whereas Spearman test was used for correlations.

Results: Out of the 33 enrolled patients (90% males; mean age 37.8 years), all presented HLA B27 antigen positivity. Mean disease duration was 89 months (SD +/- 56). Detectable IFX serum levels were measured in 60% of patients (20 patients) while 40% (13 patients) had unmeasurable drug titers. The latter had significantly higher disease activity scores such as BASDAI (mean 3.01, p .023), ASDAS-ESR (mean 2.77, p .000) and ASDAS-CRP (mean 2.48, p .001) when compared to patients with detectable serum drug (1.52, 1.39 and 1.34 respectively). Inflammatory markers determined at the same visit showed higher ESR and CRP levels in IFX-negative patients (mean ESR 37 versus 9.5 with laboratory reference values ranging 2-20 mm/h, p .000; mean CRP 25 versus 4 with normal values between 0 to 5 mg/L, p.032). Serum IFX detection correlated to ASDAS scores (r -.583 p .000 for ASDAS-ESR; r -.512 p .002 for ASDAS-CRP) and to inflammatory biomarkers (r -.607 p .000 for ESR; r -.573 p .000 for CRP). In the IFX-positive group, mean drug persistence was of 64 (SD +/-32.5) months while lower for the IFX-negative group (45 months, SD +/- 21.7, p .066), the time frame being positively correlated to drug detection (r .352, p .045). Treatment persistence also correlated to disease duration (r .719, p .000). Dosage regimen was not significantly different between the two groups (5.11mg/kg in undetectable IFX group compared to 5mg/kg for the second group) and the maintenance drug administration interval, whether at 6 or 8 weeks, positively correlated to quantitative serum IFX levels.

Conclusion: In our study, IFX serum level correlated with patient's disease activity measured through ASDAS score. Moreover, correlations to inflammatory tests highlight their importance on follow-up visits. Monitoring IFX levels might represent a useful tool in assessing patients' evolution.

Baseline Extent of Damage at the Spine Predicts Radiographic Progression in Korean Patients Using Golimumab for Ankylosing Spondylitis

Jeong Seok Lee[1], Dae Young Yu[2], Stephen Xu[3] and Eun Young Lee[4], [1]Division of Rheumatology, Department of Internal Medicine, Seoul National University Hospital, Seoul National University Hospital, Seoul, South Korea, [2]Medical Affairs, Janssen Korea, Seoul, South Korea, [3]Janssen Research & Development, LLC, Spring House, PA, [4]Division of Rheumatology, Department of Internal Medicine, Seoul National University Hospital, Seoul, South Korea

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Ankylosing spondylitis (AS) is a chronic rheumatic disease associated with radiographic damage of the spine. Golimumab had consistent efficacy in controlling disease activity through 5 years but the benefit in preventing radiographic progression was obscure at 4-year. To predict radiographic progression, we analyzed baseline characteristics of AS patients in Korean population.

Methods: All 68 Korean patients with AS participated in the phase 3, multicenter, randomized, placebo-controlled, double-blind trial which was previously described. Radiographic evaluations were performed at baseline, week 104 and 208. Baseline modified Stoke AS spine score (mSASSS) and change in mSASSS from baseline (¥ÄmSASSS) were compared in the patients of Korea and other countries. Baseline characteristics were compared between the patients with ¥ÄmSASSS>0 and ¥ÄmSASSS°Â0. The correlation between baseline mSASSS and ¥ÄmSASSS was also analyzed.

Results: Korean patients had lower baseline mSASSS and maintained consistently higher retention rate to treatment (91.6% vs. 68.1%, p<0.0002) and assessment in AS partial remission rate (44.4% vs. 31.3%, p=0.036) till week 256 when compared to the patients in other countries. However, ¥ÄmSASSS was larger in Korean patients at week 104 and 208 without statistical significance. Korean patients who did not undergo radiographic progression of spinal lesion of AS were younger when diagnosed and had shorter symptomatic duration, lower Bath AS functional and metrology index, more chest expansion and lower baseline mSASSS. The baseline mSASSS and ¥ÄmSASSS had positive correlation in Korean AS patients (Spearman's rho= 0.487, p<0.0001) (Figure 1A). Radiographic progression was more prevalent (80%) when baseline mSASSS>10 and less common (13%) with baseline mSASSS=0 (Figure 1B).

Conclusion: Korean patients with AS receiving golimumab had distinctive patterns of spinal lesion progression detected by simple radiograph at week 208. This bipolar pattern of progression could be predicted reliably by the initial severity of spinal lesion. Given this result, this study implicated the value of early and active treatment before appearance of overt spinal damage.

Figure 1. Correlation between baseline mSASSS and ¥ÄmSASSS at week 208 (Spearman's rho) (A). Population distribution stratified by baseline mSASSS and ¥ÄmSASSS at week 208 analyzed by Freeman-Halton extension of the Fisher exact probability test (B).

Session Date: Tuesday, November 10, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Fatigue is highly important to patients (pts) with psoriatic arthritis (PsA). Secukinumab, an anti-interleukin-17A monoclonal antibody, significantly improved the signs and symptoms of active PsA in the phase 3 FUTURE 2 study (NCT01752634).[1]Here we present the results of a post-hoc analysis assessing the impact of secukinumab on fatigue according to prior anti-tumor necrosis factor (anti-TNF) therapy status. The relationship between fatigue and baseline disease characteristics, as well as to other assessments of PsA response to therapy, are also presented.

Methods: Pts with active PsA were randomized to receive subcutaneous (s.c.) secukinumab (300 mg, 150 mg, or 75 mg) or placebo (PBO) at baseline, Wks 1, 2, 3, and 4, and every 4 wks thereafter. Fatigue was assessed at baseline and Wks 4, 8, 12, 16, and 24 using the Functional Assessment of Chronic Illness Therapy–Fatigue (FACIT-F) scale. Mean change in FACIT-F score from baseline up to Wk 24 was assessed using mixed model repeated measures analysis with visit, weight, and baseline FACIT-F score as covariates. A minimum clinically important difference (MCID) >4 was used to define fatigue response. A logistic regression model was used to investigate baseline predictors of FACIT-F improvement at Wk 16. The relationship between FACIT-F and ACR 20, PASI 75, PASI 90, DAS28-CRP low disease activity (LDA; ≤ 3.2) and remission (< 2.6), and Psoriatic Arthritis Response Criteria (PsARC) was assessed at Wks 8 and 16. The secukinumab 75 mg s.c. group was excluded from this analysis as it did not meet any pre-defined secondary endpoints.

Results: Of 298 pts included in this analysis, 193 were anti–TNF-naive and 105 anti–TNF-inadequate responders (IR). Mean changes from baseline in FACIT-F were improved with secukinumab 150 and 300 mg vs. placebo in both anti-TNF-naïve and anti-TNF-IR populations at the majority of timepoints up to Wk 24 with mean changes exceeding the MCID at all timepoints (Table). In a logistic

regression model of FACIT-F response at Wk 16, age was the only baseline factor found to be a significant covariate ($P<0.05$). ACR 20 responses correlated with improvements in FACIT-F at Wk 16; no relationship was seen between FACIT-F and PASI 75, PASI 90, DAS28-CRP, LDA and remission criteria, or PsARC.

Conclusion: Secukinumab improved fatigue in patients with active PsA regardless of prior anti-TNF therapy. A relationship between improvement in fatigue and improvements in the signs and symptoms of PsA was only shown for ACR 20 response and not for other assessments of disease. These results suggest that fatigue in PsA is not strongly related to disease activity but was still improved by secukinumab.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Published data have shown that epidemiological parameters such as Body Mass Index (BMI), gender and disease duration may affect the therapeutic response in psoriatic arthritis patients receiving disease modifying antirheumatic drugs (DMARDs) conventional or biologic.

Methods: We retrospectively studied 260 patients diagnosed with psoriatic arthritis (PsA) fulfilling the Assessment of SpondyloArthritis international Society (ASAS) criteria for those with axial involvement and additionally the Classification Criteria for Psoriatic Arthritis (CASPAR) for those with peripheral joint involvement. We studied the effect of BMI, gender, disease duration, and treatment in therapeutic response. The patients were followed up at predefined time points (baseline, 6 months, 1 and 5 years). The treatment response was assessed by using Bath Ankylosing Spondylitis Activity Index (BASDAI), Bath Ankylosing Spondylitis Functionality Index (BASFI), Disease Activity Score in 28 joints-CRP (DAS28-CRP), Disease Activity Score in 28 joints -TKE (DAS28-TKE) and Health Assessment Questionnaire (HAQ). The patients were categorized in two groups according their treatment: group A patients treated with biological DMARDs (anti-TNFa agents) and group B patients treated with conventional DMARDs (methotrexate, leflunomide, cyclosporine).

Results: Disease duration was positively correlated in all time points ($p<0,005$) with all disease activity scores (BASDAI, BASFI, DAS28-CRP, DAS28-TKE and HAQ). Statistical significant differences with respect to gender were observed for DAS28-CRP (3,055 - 2,616 $p=0,015$) and DAS28-TKE (3,543 – 2,640 $p<0,0001$) at 6 months. More specifically, females showed significant higher DAS28-TKE and DAS28-CRP than males in all cases. BMI was not significantly correlated with the disease activity (BASDAI, BASFI, DAS-CRP, DAS-TKE, HAQ) at any time point. Finally the two treatment groups did not differ significantly with respect to disease activity scores at any time point.

Conclusion: In the current study longer disease duration was associated with higher disease activity. Females showed higher DAS28-CRP and DAS28-TKE scores than males early on the disease course. BMI as well as treatment options did not show any significant effect in the therapeutic response.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: In patients with active, NSAID-resistant, non-radiographic axial spondyloarthritis (nr-axSpA) who participated in the multiphase, randomized, placebo (PBO)-controlled EMBARK study (ClinicalTrials.gov identifier: NCT01258738), health-related quality-of-life (HRQoL) and other patient-reported outcomes (PROs) were evaluated after 12 wks of double-blind (DB) etanercept (ETN) treatment[1] and 92 wks of open-label (OL) ETN.

Methods: Patients who fulfilled Assessment of SpondyloArthritis international Society classification criteria for axSpA, but not modified New York radiographic criteria for ankylosing spondylitis, and were unresponsive to ≥2 NSAIDs were randomized to receive ETN 50 mg/wk or PBO for 12 wks, followed by ETN 50 mg/wk to wk 104 (ETN/ETN or PBO/ETN). Background NSAID therapy was continued in all patients. Analyses of a binary endpoint (ie, minimal clinically important difference [MCID; ≥0.05] in EQ-5D utility score at wk 12) and continuous endpoints (changes from wk 0 to wk 12 and wk 104 in pain/fatigue [nocturnal back pain, MFI general fatigue], HRQoL [SF-36, ASQoL], utility [EQ-5D], and work productivity [WPAI-AS]) were conducted in the modified intent-to-treat (mITT) population (all patients with wk-12 efficacy data who continued into OL period, received ≥1 ETN dose in OL period, and had been included in DB mITT population) with observed cases. The Cochran-Mantel-Haenszel chi-square test was used for between-group comparisons of the binary endpoint; ANCOVA was used for between-group comparisons of continuous endpoints.

Results: Of 215 randomized patients (DB mITT), 205 patients entered the OL phase (ETN/ETN, n=100; PBO/ETN, n=105 [OL mITT]) and 169 patients completed it (n=83; n=86). Improvements from wk 0 to wk 12 in most pain/fatigue, HRQoL, utility, and work productivity assessments favored ETN versus PBO (table). In the OL phase, improving trends from wk 0 to wk 104 were observed in the ETN/ETN group, whereas improvements seen in patients who switched from PBO to ETN were comparable to or greater than those in the former group. At wk 12, significantly greater proportions of patients receiving ETN vs PBO achieved MCID in the EQ-5D utility score (59% [52/88] vs 45% [42/94]; $P<0.05$, between-groups); at wk 104, 76% (57/75) and 81% (64/79) of patients in the ETN/ETN and PBO/ETN groups achieved this endpoint.

Table. Long-term effects of ETN on PROs in patients with nr-axSpA in the EMBARK study*

WPAI-AS, presenteeism¶ (0-100%)	44.9 (26.7) / –21.2‡ (4.7)	42.2 (26.3) / –12.1 (4.7)	–25.5 (3.7)	–22.5 (3.5)

*mITT population; observed cases.

†$P<0.01$; ‡$P<0.05$, between-group comparisons.

#% work time missed; ¶% impairment while working.

ASQoL, AS quality of life; EQ-5D, EuroQol 5 Dimensions; MFI, Multidimensional Fatigue Inventory; SF-36: 36-item Short Form Health Survey; WPAI-AS: Work Productivity and Activity Index in ankylosing spondylitis.

Conclusion: Patients with early, active nr-axSpA and an inadequate response to NSAIDs achieved sustained improvement in pain/fatigue, HRQoL, utility, and work productivity over 104 weeks of etanercept treatment in the EMBARK study. At study end, health outcome responses were generally comparable regardless of original treatment assignment, suggesting that etanercept has a favourable long-term impact on PROs in patients with nrAxSpa.

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Secukinumab, a fully human anti–interleukin-17A monoclonal antibody, has been shown to improve the signs and symptoms of psoriasis and psoriatic arthritis (PsA).[1–3] Here, we describe the safety profile of secukinumab from a large cohort of patients (pts) with psoriasis (PsO) and pts with psoriatic arthritis (PsA), using pooled data from phase 3 studies.

Methods: Safety data were pooled from five double-blind, randomized, placebo (PBO)-controlled phase 3 studies in pts with PsO (ERASURE [NCT01365455], FIXTURE [NCT01358578], SCULPTURE [NCT01406938], FEATURE [NCT01555125] and JUNCTURE [NCT01636687]), and two double-blind, randomized, PBO-controlled, phase 3 studies in pts with active PsA (FUTURE 1 [NCT01392326] and FUTURE 2 [NCT01752634]). In the FUTURE 1 study, pts received 10 mg/kg secukinumab i.v. loading followed by s.c. maintenance dosing (75 mg or 150 mg). In all other studies pts received s.c. loading and maintenance with secukinumab (300, 150, or 75 mg). All randomized pts were included in the pooled safety analysis. Data were pooled at the patient level, and safety analyses were performed for the entire treatment period (≥ 52 weeks for FUTURE 1; Week 52 for ERASURE, FIXTURE, SCULPTURE, FEATURE and JUNCTURE; ≥ 24 weeks for FUTURE 2)

Results: 3928 pts received ≥1 dose of secukinumab (3225 pt-years of exposure, respectively). Baseline demographics, disease/medical history and concomitant medications were similar between the pooled secukinumab and PBO populations. Exposure-adjusted incidence rates for AEs/SAEs across the entire safety period (mean exposure: 299.8 days secukinumab; 105.7 days PBO) were, 240.5/7.9 and 329.6/9.9 per 100 pt-years with secukinumab and PBO, respectively; 115 (2.9%) pts discontinued secukinumab treatment due to AEs. There were four deaths in secukinumab-treated pts: one due to intracranial hemorrhage; one due to cardio-respiratory arrest; one due to alcohol intoxication; and one of unknown cause. There were two (0.05%) cases of suicidality with secukinumab; one attempted suicide and one case of suicidal ideation. Nasopharyngitis and upper respiratory tract infections were the most frequently reported AEs with secukinumab. The incidence of inflammatory bowel disease (IBD)/Crohn's, infections, neutropenia, major adverse cardiac events (MACE) and malignancy with secukinumab was low (Table).

Conclusion: Secukinumab was well tolerated in a large cohort of 3928 patients across 7 phase 3 studies with PsA and PsO. The safety profile was consistent with previous reports.

Session Date: Tuesday, November 10, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Secukinumab, an anti–interleukin-17A monoclonal antibody, improved the signs and symptoms of ankylosing spondylitis (AS) in 2 Phase 3, randomized, double-blind, placebo (PBO)-controlled studies, MEASURE 1 (NCT01358175) and MEASURE 2 (NCT01649375).[1,2]We report the safety of secukinumab in AS through ≥52 weeks (wks) using pooled data from these 2 studies.

Methods: Both studies enrolled patients (pts) with active AS with radiological evidence fulfilling the modified New York Criteria. In MEASURE 1, 371 pts were randomized to secukinumab or PBO. Pts on secukinumab received 10 mg/kg intravenously (IV) at baseline (BL), Wk 2 and 4, followed by 75 or 150 mg subcutaneously (SC) every 4 wks (q4w) from Wk 8. PBO was given according to the same IV to SC schedule. In MEASURE 2, 219 pts were randomized to receive SC secukinumab (75 or 150 mg) or PBO at BL, Wk 1, 2, and 3, and q4w starting from Wk 4. At Wk 16, PBO pts were re-randomized to receive secukinumab 150 or 75 mg SC q4w. Anti-drug antibodies (ADAs) were assessed using a Meso Scale Discovery bridging assay. Safety data were pooled at the pt level, with a data cut-off of Wk 52 visit of the last pt enrolled in each study.

Results: 571 pts received ≥1 dose of secukinumab (691.1 pt-years of exposure). Baseline demographic and disease characteristics were well-balanced in the pooled secukinumab and PBO populations. The incidence of adverse events (AEs)/serious AEs (SAEs) during the 16-wk PBO-controlled period was 65.7/3.3% and 58.7/4.1% in the secukinumab and PBO groups, respectively. Exposure-adjusted AE/SAE rates across the entire safety period (mean exposure: secukinumab, 442.1 days; PBO, 118.5 days) were 206.8/7.9 and 359.5/12.8 per 100 pt-years with secukinumab and PBO, respectively; 27 (4.7%) pts receiving secukinumab and 11 (5.6%) receiving PBO discontinued due to AEs during the study. Three deaths were reported: 1 suicide (PBO); 1 due to respiratory failure (IV→75 mg) and 1 due to an acute myocardial infarction (75 mg), both in pts with multiple cardiovascular risk factors. Nasopharyngitis was the most frequent AE with secukinumab (11.2% with secukinumab vs 6.1% with PBO during the 16-wk PBO-controlled period; 17.9 vs 19.5 per 100 pt-years during the entire study period). The incidence of inflammatory bowel/Crohn's disease, *Candida*infections, neutropenia, major adverse cardiac events, and malignancy was low with secukinumab (Table). Uveitis AEs were reported in 7 (1.2%) pts on secukinumab and 2 (1.0%) on PBO. Treatment-emergent ADAs were detected in 2 (0.3%) pts, with no associated loss of efficacy. There were no suicidality-related AEs with secukinumab.

Conclusion: Secukinumab was well-tolerated in pts with active AS, with a low incidence of SAEs and discontinuations due to AEs.

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Apremilast (APR), a PDE4 inhibitor, helps regulate immune responses in psoriatic arthritis (PsA). PALACE 1, 2, and 3 compared apremilast (APR) efficacy/safety with placebo (PBO) in patients (pts) with active PsA despite prior conventional DMARDs and/or biologics, including efficacy assessments across multiple disease aspects. Enthesitis and dactylitis, hallmark features of PsA, lead to pain and disability. We report the impact of APR treatment over 104 wks on enthesitis and dactylitis in a pooled analysis of the PALACE 1-3 studies.

Methods: Pts were randomized (1:1:1) to PBO, APR 30 mg BID (APR30), or APR 20 mg BID (APR20) stratified by baseline DMARD use (yes/no). The PBO-controlled phase continued to Wk 24, with an early escape option at Wk 16. At Wk 24, all remaining PBO pts were re-randomized to APR30 or APR20. Double-blind APR treatment continued to Wk 52; pts could then continue to receive APR for up to an additional 4 years during an open-label extension phase. Data were pooled across PALACE 1-3 at Wk 24, as prespecified in the protocol, to allow for analysis of robust numbers of pts with pre-existing enthesopathy and/or dactylitis. Enthesitis was evaluated based on the Maastricht Ankylosing Spondylitis Enthesitis Score (MASES) (range: 0-13), which indicates the number of painful entheses out of 13 entheses sites. The dactylitis count (range: 0-20) is the number of digits (hands/feet) with dactylitis present; each digit is rated as 0 (absence) or 1 (presence). Analyses at Wk 24 used last observation carried forward for missing values; Wk 52 and Wk 104 were based on data as observed.

Results: At Wk 24, mean change in MASES was -1.3 (APR30, *P*=0.0194 vs PBO), -1.2 (APR20), and -0.9 (PBO); MASES=0 was achieved by 27.5% (APR30), 27.4% (APR20), and 22.5% (PBO) of pts. Mean change in dactylitis count was -1.8 (APR30, *P*=0.0097 vs PBO), -1.6 (APR20), and -1.3 (PBO); dactylitis count of 0 was achieved by 46.2% (APR30), 45.9% (APR20), and 39.0% (PBO) of pts. Long-term improvement in enthesitis and dactylitis severity was seen in pts with enthesitis and/or dactylitis at baseline who were receiving APR at 104 wks, as shown by reductions in MASES and dactylitis counts (Table). Mean % changes in MASES were -57.5% (APR30) and -55.1% (APR20) at Wk 104. MASES of 0, indicating no pain at any of the entheses assessed, was achieved by 48.7% (APR30) and 51.5% (APR20) of pts. Mean % changes in dactylitis count were -80.0% (APR30) and -75.8% (APR20) at Wk 104. Dactylitis counts decreased to 0 in 77.5% (APR30) and 72.9% (APR20) of pts. Over 104 wks, most AEs were mild or moderate in severity; in general, no increase was seen in AE incidence and severity with longer term exposure.

Conclusion: Over 104 wks, APR continued to demonstrate efficacy in PsA treatment, including improvements in enthesitis and dactylitis. APR demonstrated an acceptable safety profile and was generally well tolerated for up to 104 wks.

Enthesitis and Dactylitis at Wk 24 (LOCF), and Wks 52 and 104 (Data as Observed)

The n at Week 24 represents pts with a baseline value and at least one post-baseline value at or prior to Week 24. The n at Weeks 52 and 104 represents the number of pts taking APR (regardless of when treatment started [baseline, Wk 16, or Wk 24]) with a baseline value >0 and a value at Wk 52 or Wk 104.
*MASES ranges from 0 to 13, with 0 indicating no pain at any assessed entheses and 13 indicating pain at all assessed entheses. §Dactylitis count is the sum of all scores for each of the 20 digits, with each digit scored as 0=absence or 1=presence of dactylitis. ‡*P*<0.05 vs PBO.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Scalp and nail psoriasis are difficult-to-manage manifestations of psoriasis and psoriatic arthritis (PsA). Nail involvement occurs in ~80% of pts with PsA and can negatively affect daily/work activities, thereby impacting pt quality of life. ESTEEM 1 and 2 are phase 3, randomized, controlled trials evaluating apremilast (APR) efficacy/safety in pts with moderate to severe plaque psoriasis. Of 1,255 pts randomized in the ESTEEM trials, 65.7% had nail and 66.3% had moderate to severe scalp involvement at baseline (BL).

Methods: Pts were randomized 2:1 to APR 30 mg BID (APR30) or placebo (PBO). At Wk 16, PBO pts switched to APR30. All pts were treated with APR30 through Wk 32, followed by a randomized treatment withdrawal phase up to 52 wks in pts randomized to APR30 at BL and identified as responders at Wk 32. The primary endpoint was the proportion of pts achieving PASI-75 at Wk 16. Nail and scalp involvement were assessed through Wk 52 in pts with Nail Psoriasis Severity Index (NAPSI) ≥1 in the target nail and Scalp Physician Global Assessment (ScPGA) ≥3 at BL.

Results: Improvements in mean PASI score occurred as early as Wk 2 in ESTEEM 1 and 2 with APR30 (-22.3% and -24.3%, respectively) vs PBO (-6.5% and -7.5%). At Wk 16, significantly more pts achieved PASI-75 in ESTEEM 1 and 2 with APR30 (33.1% and 28.8%, respectively) vs PBO (5.3% and 5.8%; both $P<0.0001$). Improvements in mean percent change in NAPSI score and NAPSI-50 achievement rates were also significantly greater with APR30 vs PBO at Wk 16 (Table). Similarly, a higher proportion of pts achieved an ScPGA of 0 (clear) or 1 (minimal) at Wk 16 with APR30 ($P<0.0001$, both studies; Table). At Wk 32, mean percent change in NAPSI as well as NAPSI-50 and ScPGA 0 or 1 achievement were sustained in pts randomized to and continuing treatment with APR30 (Table). Among pts randomized to APR30 at BL who were randomized to continue APR30 (with no addition of other treatments) through Wk 52, mean improvement in PASI score at Wk 52 was -80.5% in ESTEEM 1 and -74.4% in ESTEEM 2. Improvements in NAPSI outcomes were maintained in these pts over 52 wks: mean percent change in NAPSI was -60.2% in ESTEEM 1 and -59.7% in ESTEEM 2; achievement of NAPSI-50 was 70.7% and 68.6%, respectively. In this pt group, ScPGA 0 or 1 was reached by 83.3% of pts in ESTEEM 1 and 62.5% of pts in ESTEEM 2. AEs occurring in ≥5% of pts treated with APR30 were diarrhea, nausea, URTI, nasopharyngitis, tension headache, and headache up to 16 wks. Most AEs were mild or moderate in severity, with no increase in incidence or severity with up to ≥52 wks of treatment.

Conclusion: In the ESTEEM plaque psoriasis studies, APR30 was effective in improving skin involvement and the difficult-to-manage manifestations of nail and scalp psoriasis, with maintenance of these improvements over time. APR30 was generally well tolerated, with the most common tolerability issues occurring early and resolving with continued treatment.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Anti–TNFs are the only biologics currently approved for ankylosing spondylitis (AS). There is a significant unmet need in those patients (pts) with an inadequate response/intolerance to these agents. The efficacy and safety of secukinumab, an anti–interleukin-17A monoclonal antibody, has been assessed in two Phase 3 studies in pts with active AS, MEASURE 1 (NCT01358175) and MEASURE 2 (NCT01649375).[1,2] Here, we present the efficacy and safety of secukinumab by anti-TNF history in pts enrolled in these 2 studies.

Methods:

In MEASURE 1, 371 pts were randomized to secukinumab or placebo (PBO). The secukinumab group received 10 mg/kg intravenously (iv) at baseline (BL) and Weeks (Wks) 2 and 4, followed by subcutaneous (sc) 150 (IV→150 mg) or 75 mg (IV→75 mg) every 4 wks (q4w) from Wk 8; PBO was given according to the same dosing schedule. In MEASURE 2, 219 pts were randomized to receive secukinumab 150 or 75 mg sc or PBO at BL, Wks 1, 2, and 3, and q4w starting from Wk 4. Randomization was stratified by anti-TNF history: anti-TNF-naive, or inadequate response/intolerance to not more than one anti-TNF agent (anti-TNF-IR). The primary endpoint for both studies was ASAS20 response at Wk 16. Secondary endpoints were ASAS40, hsCRP, ASAS 5/6, BASDAI, SF-36 PCS, ASQoL, and ASAS partial remission. Wk 16 analyses used non-responder imputation (binary variables) and mixed-model repeated measures (continuous variables). Wk 52 data are as observed. Analysis of primary and secondary endpoints stratified by anti-TNF history was pre-specified.

Results:

At BL, 73% and 61% of pts were anti–TNF-naïve in MEASURE 1 and MEASURE 2, respectively. Compared with PBO, ASAS20 response rates at Wk 16 were higher with all secukinumab doses, except for the 75 mg sc dose in MEASURE 2, in both anti–TNF-naïve and anti–TNF-IR pts (Table). Improvements with secukinumab were observed for all secondary endpoints in anti–TNF-naïve pts, except ASAS partial remission in MEASURE 2, and for most secondary endpoints in anti–TNF-IR pts. No incremental increase in efficacy was observed with the IV→150 mg or IV→75 mg doses versus 150 mg sc, despite the greater exposure conferred by iv loading. At Wk 52, 319 (86.0%) pts remained in MEASURE 1 and 181 (82.6%) in MEASURE 2. Clinical responses to secukinumab were sustained or continued to improve through 52 wks of therapy in both anti–TNF-naïve and anti–TNF-IR pts (Table). Responses were generally higher in anti-TNF-naïve vs anti–TNF-IR pts. ASAS40 response rates at Wk 52 in anti-TNF-naïve and anti-TNF-IR pts were 67.1% and 45.8% with IV→150 mg, 48.8% and 50.0% with IV→75 mg, 64.1% and 45.5% with 150 mg, and 47.6% and 26.3% with 75 mg.

Conclusion:

Secukinumab 150 mg provided sustained improvements in the signs and symptoms of AS in both anti–TNF-naïve and anti–TNF-IR pts.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: PsA, a chronic systemic inflammatory disease, reduces physical function and QOL. Treatment improves/maintains functionality. PALACE 1-3 compared apremilast (APR) efficacy/safety with placebo (PBO) in patients (pts) with active PsA despite prior conventional DMARDs and/or biologics, providing one of the largest databases (N=1,489) examining physical disability in moderate to severe PsA pts. The impact of APR 30 mg BID (APR30) treatment over 104 wks on disability was assessed using the HAQ-DI in a pooled analysis of the PALACE 1-3 database.

Methods: Pts were randomized (1:1:1) to PBO, APR30, or APR 20 mg BID (APR20) stratified by baseline (BL) DMARD use (yes/no). At Wk 24, all remaining PBO pts were re-randomized to APR30 or APR20. HAQ-DI scores were collected at BL and Wks 16, 24, 40, 52 65, 78, 91, and 104. Data are analyzed by ITT, LOCF methodology for Wk 16, and described as data as observed to Wk 104, with LOCF analysis done to confirm results. HAQ-DI MCID decreases ≥0.13 and ≥0.30 were prespecified; a post hoc analysis for the most recently published MCID ≥0.35 was done. Disability categories were calculated using HAQ-DI cutoff levels ≤1.0 (clinically significant disability[1]) and ≤0.5 (MDA criteria[2]); assessments included proportion reaching levels ≤0.25. Shift categories of scores were examined with increments of 0.25 to clarify pt disability level and category shifts.

Results: Pts exhibited significant physical disability at BL (mean HAQ-DI=1.2); 60% of APR30 pts had >1.0, and 31% had >1.5, noting marked difficulty/need for assistive devices in performing activities of daily living. Major disability was noted in up to 13% with BL HAQ-DI >1.875. As early as Wk 16, physical function improved with APR30; pts exhibited a mean HAQ-DI change of -0.21 (vs. -0.07 PBO; *P*<0.0001), 56% achieved HAQ-DI ≤1.0 at Wk 16 (vs. 48% PBO pts), and 29% achieved HAQ-DI ≤0.5 (vs. 25% PBO pts). Fewer PBO vs. APR30 pts reached MCID of -0.13 (37% vs. 47%; *P*<0.005) and -0.30 and -0.35 (26% vs. 36%; *P*<0.005). At Wk 52, decreases in disability were maintained (APR30 mean change in HAQ-DI=-0.33); 48% of APR30 pts achieved MCID -0.30 and 48% MCID -0.35. Importantly, at Wk 52, 59% of all APR30 pts achieved HAQ-DI ≤1.0, 35% ≤0.5, and 25% ≤0.25 (Table). Among pts with greater BL disability (HAQ-DI ≥1.5), 64% improved by ≥1 shift category and 48% by ≥2. At Wk 104, 50% of APR30 pts achieved MCID -0.30 and MCID -0.35, with 64% achieving HAQ-DI ≤1.0, 40% ≤0.5, and 29% ≤0.25.

Conclusion: In APR30 pts, physical function improved and was sustained with long-term treatment. Most pts achieved HAQ-DI MCID -0.30 or -0.35 and HAQ-DI scores ≤1.0, with many obtaining HAQ-DI ≤0.5, defined as minimal disease in recently developed criteria. These data indicate improvement and long-term maintenance of functionality with APR treatment.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with ankylosing spondylitis (AS) have increased risk of cardiovascular disease (CVD). In the general population, CVD risk reduction can be achieved by lipid lowering therapy (LLT). We aimed to evaluate the effect of statins in AS patients and factors associated with the changes (Δ) in low-density lipoprotein cholesterol (LDL-c) and total cholesterol (TC).

Methods: In this longitudinal, observational study, 108 patients with AS underwent CVD risk evaluation. Of these, 48 patients had an indication for LLT and received statin treatment which was adjusted until lipid targets were achieved. Variables obtaining a p-value of < 0.25 in a univariate analyses were entered in forward, stepwise, linear regression models with ΔLDL-c and ΔTC as the dependent variables and were adjusted for age and gender, as well as baseline LDL-c levels (for ΔLDL-c) and intensity of LLT (for ΔTC).

Results: At first visit, median (IQR) age was 61.5 (56.0, 66.8) years, 72.9 % were male, median disease duration was 27 (17.8, 32.8) years, 12.5 % smoked daily, 70.8 % had hypertension (HT), mean (SD) body mass index (BMI) was 26.0 (3.50) kg/m^2, mean LDL-c and TC, were 3.82±1.02 and 6.04±1.16mmol/L and 70.8 % had carotid plaque(s). Twenty patients were treated with low or moderate intensity LLT (simvastatin 20 mg or 40 mg, rosuvastatin <40 mg or atorvastatin <40 mg), while the remaining 28 received intensive LLT (rosuvastatin 40 mg or atorvastatin >40 mg). LDL-c goals (50% reduction in LDL-c and /or LDL-c <2.5 /<1.8 mmol/L, for primary (n=10) or secondary prevention (n=38), respectively) were achieved in 85.4% of patients (90.0% and 84.2% for primary and secondary prevention, respectively). Reductions in LDL-c and TC were 1.60+0.41 mmol/L and 2.42+1.15 mmol/L (p<0.001 for both). Predictive variables explaining 86.5% (R^2) of the ΔLDL-c included erythrocyte sedimentation rate (ESR), established CVD and HT. Only ESR (p=0.03) and baseline LDL-c (p<0.001) contributed significantly to the final model. ESR was inversely related to ΔLDL-c. In addition, higher baseline LDL-c levels were associated with larger LDL-c reduction. The final model for ΔTC, accounting for 33.0% (R^2) of the variation, included ESR, waist circumference, BMI, non-steroidal anti-inflammatory drugs, and use of biologic and synthetic disease modifying anti-rheumatic drugs. Intensive LLT and high waist circumference were predictive of greater TC reductions (p=0.002 and 0.04, respectively).

Conclusion: Lipid lowering with statins was highly effective in AS patients. Inflammation measured by ESR was inversely related to change in LDL-c, possibly due to the suppressive effect on lipid levels. Further studies are needed to elucidate if the anti-inflammatory effect of rheumatic medication influence the lipid lowering effect of statins in patients with AS.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Chronic inflammation, back pain, and progressive spinal stiffness associated with axial spondyloarthritis (axSpA) can decrease quality of life (QoL). The purpose of this study was to determine whether golimumab (GLM) is superior to placebo (PBO) in improving the QoL of patients with nr-axSpA.

Methods: GO-AHEAD was a double-blind, randomized, PBO-controlled trial of GLM in patients with active nr-axSpA (ASAS criteria and centrally read sacroiliac joint X-rays and MRI; disease duration ≤5 years; chronic back pain; high disease activity [total back pain ≥40 mm on a 0–100 mm VAS and BASDAI ≥4 cm]; and inadequate response/intolerance to NSAIDs). Patients were randomized 1:1 to SC GLM 50 mg or PBO every 4 wk. Secondary outcomes related to QoL included the 36-item Short Form Health Survey (SF-36), Ankylosing Spondylitis Quality of Life (ASQoL), EuroQoL 5-Dimension (EQ-5D) Index and Health State (0–10 cm

VAS), and Work Productivity and Activity Impairment (WPAI) questionnaire scores at wk 16. Treatment group differences for all patients and for the objective signs of inflammation (OSI) population (baseline inflammation by centrally evaluated SI MRI and/or elevated CRP) were compared using a constrained longitudinal data analysis for continuous endpoints and Mann–Whitney test for WPAI scores.

Results: Of 197 treated patients (GLM=97; PBO=100), mean age was 31 years; 57% were male. At wk 16, patients treated with GLM had greater improvements from baseline QoL than patients treated with PBO, as measured by all scales of the ASQoL, EQ-5D, and SF-36 (Table). GLM patients also had greater improvements than PBO patients in percentages of WPAI overall work impairment (−21.1 vs −11.7, *P*=.0391) and activity impairment (−24.9 vs −8.6, *P* < .0001); impairment while working and work time missed were not significantly different between groups. Results for QoL and WPAI measures were similar in the OSI population, except that patients in the GLM group also had greater improvements in percentage of impairment while working than the PBO group (*P*=.0194).

The Majority of Patients with Moderate to Severe Psoriatic Arthritis Had Existing Structural Damage, Predisposing Them to Further Progression, Which Was Markedly Inhibited By Adalimumab

Pranav Sheth[1], Philip J. Mease[2], Yihan Li[3], Fabiana Ganz[4] and Maja Hojnik[5], [1]Group Health Associates, Trihealth, Cincinnati, OH, [2]Seattle Rheumatology Associates, Seattle, WA, [3]AbbVie Inc., North Chicago, IL, [4]Neuhofstrasse 23, AbbVie AG, Baar, Switzerland, [5]AbbVie, Ljubljana, Slovenia
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Patients (pts) with psoriatic arthritis (PsA) may experience structural damage if not appropriately treated. The purpose was to determine 1) the frequency of radiographic structural damage in PsA pts at baseline (BL), and BL patient and disease characteristics associated with having BL structural damage 2) the risk of further radiographic progression in PsA pts with/without BL structural damage 3) the inhibition of radiographic progression by adalimumab (ADA) in PsA pts with/without BL structural damage.

Methods:

The analysis used data from the ADEPT trial[1], which was a 24-week (wk) randomized placebo (PBO)- controlled trial that evaluated efficacy and safety of ADA in pts with moderate to severe PsA (mean duration of approx. 9.5 years). Pts with available radiographs of hands and feet at BL and wk 24 were included in the present analyses. Radiographic damage at BL was defined as modified Total Sharp Score (mTSS) >0.5; radiographic progression was defined as a change in mTSS by >0.5 over 24 wks. In each treatment group (ADA or PBO), the proportion of pts with radiographic progression (progressors) from BL to wk 24 was determined among pts with/without BL structural damage. The association of the following BL characteristics with radiographic damage at BL was determined by univariate and multivariate logistic regression: age, weight, swollen joint count at 28 joints (SJC28), tender joint count at 28 joints (TJC28), duration of psoriasis or PsA, C-reactive protein (CRP), and Psoriasis Area Severity Index (PASI).

Results:

Out of 313 pts randomized in the ADEPT trial (151 to ADA, 162 to PBO), 296 pts (95%) had radiographic data available at BL and wk 24. Eighty-one percent (81%; 239/296 pts) had radiographic damage at BL; 83% of pts with PsA duration ≥2 years and 72% of pts with PsA duration <2 years. Among 239 pts with BL damage, significantly fewer pts in the ADA-treated group (13/118, 11.0%) vs the PBO-treated group (43/121, 35.5%) experienced radiographic progression by wk 24 ($p<.001$). The treatment effect of ADA in pts with BL damage was larger than the treatment effect of ADA in the overall population (24.5% vs 19.2% of non-progressors). Among pts without BL damage, 1/26 (3.8%) and 1/31 (3.2%) pts in the ADA and PBO group, respectively, had further damage by wk 24. Multivariate analysis indicated that higher CRP and age at BL were associated with an increased risk of having existing BL structural damage ($p<.01$).

Conclusion:

The majority of PsA pts had radiographic damage at BL, even with < 2 years of disease duration. Pts with BL structural damage had a greater risk for further progression overall, while the inhibitory effect of ADA on radiographic progression was more pronounced in pts with BL damage. Higher CRP and age at BL were associated with BL damage. The data suggests that effective treatment to prevent further radiographic damage would be particularly beneficial in pts with existing damage, who in the ADEPT trial constituted the majority.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Ankylosing spondylitis (AS) is a chronic inflammatory disease which involves axial skeleton. NSAIDs are drug of choice and biologic disease-modifying anti-rheumatic drugs (DMARDs) are strongly recommended in case of NSAIDs failure. But some AS patients have intermittent, migratoy pain and inflammatory pain could last several days or weeks. Intraarticular injections of sacroiliac joints are recommended in these cases.

The goal of this study was to analyze the effectiveness of a fluoroscopy-guided intraarticular corticosteroid injection for the treatment of sacroiliac joint pain in patients with AS.

Methods: Between March 2012 and February 2015, a total of 62 fluoroscopy-guided intraarticular corticosteroid injections in the sacroiliac joints were performed in 58 patients with AS (37 males, 21 females; mean age 29.1 years, range 12 to 66 years). All patients had been previously diagnosed with AS according to the modified New York criteria And there were findings of active inflammation in their sacroiliac joints confirmed by pelvic magnetic resonance imaging (MRI).

The mixture of triamcinolone acetonide 40 mg and normal saline 0.5 mL was injected under floroscopic guidance.

Results: The mean disease duration before injection was 26.7 months (range 0 to 151 months) and the mean follow-up after injection was 15.1 months (range 0 to 35 months). After injection, BASDAI score and levels of acute phase reactant were decreased. The mean BASDAI score before injection was 6.26 (range 2.3 to 10.0) and the mean BASDAI score after injection was 4.81 (range 1.0 to 9.2). BASDAI 50%/20mm response rate was 27.4% (17/62). In 24 out of 62 cases (39.0%), the BASDAI score were below 4 which means optimal control of disease. No initiation of biologic DMARDs and additional intervention was required in 39 out of 54 patients (72.2%).

But 4 out of 58 patients (6.9%) needed a second injection. 3 patients already was on biologic DMARDs before injection, 15 patients newly started biologic DMRADs after injection due to their high disease activity and lack of effectiveness of intraarticular injection. There were neither discontinuity nor change of biologic DMARDs. There was no bilateral injection at once and no complication associated with the procedure. There was no significant difference between dose of medications which is prescribed before and after injection.

Conclusion: Fluoroscopy-guided corticosteroid injection into sacroiliac joint could be considered as one of treatment options instead of starting biologic DMARDs or dose escalation of medications, when AS patients complain of abrupt and severe pain in their sacroiliac joints.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster III: Therapy

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Secukinumab, an anti–interleukin-17A monoclonal antibody, improved the signs and symptoms of ankylosing spondylitis (AS) over 52 weeks (wks) in the randomized, double-blind, placebo (PBO)-controlled, Phase 3 MEASURE 1 study (NCT01358175).[1] Here, we report the long-term (104 wks) efficacy and safety of secukinumab in this study.

Methods: 371 patients (pts) with active AS were randomized to secukinumab or PBO. Pts on secukinumab received a 10 mg/kg intravenous (i.v.) loading dose at baseline, Wks 2 and 4, and then subcutaneous (s.c.) 150 mg (IV→150 mg) or 75 mg (IV→75 mg) every 4 wks from Wk 8. PBO was given on the same schedule. PBO pts were re-randomized to secukinumab 150 or 75 mg s.c. based on ASAS20 response at Wk 16, with non-responders switched at Wk 16 and responders at Wk 24. Assessments at Wk 104 included ASAS20/40, hsCRP, ASAS5/6, BASDAI, SF-36 PCS, ASQoL, and ASAS partial remission. Wk 104 data are presented as observed. Pre-specified exploratory endpoints included assessment of spinal x-ray (modified Stoke Ankylosing Spondylitis Spinal Score [mSASSS]) and sacroiliac joint x-ray and magnetic resonance imaging.

Results: 97/125 (77.6%) pts randomized to IV→150 mg and 103/124 (83.1%) pts randomized to IV→75 mg completed 104 wks. Using observed data, ASAS 20/40 response rates at Wk 104 were 79.3/64.4 % and 72.1/53.5 % with IV→150 mg and IV→75 mg, respectively (Table). Clinical improvements with secukinumab were sustained through Wk 104 across all other endpoints (Table). Sustained improvements were observed in pts naïve to anti-tumor necrosis factor (anti-TNF) therapy and in those with an inadequate response/intolerance to not more than one agent (anti-TNF-IR). ASAS 20/40 response rates at Wk 104 (observed data) in anti-TNF-naïve pts were 85.5/69.6% and 72.3/52.3% with IV→150 mg and IV→75 mg, respectively; corresponding rates in anti-TNF-IR pts were 55.6/44.4% and 71.4/57.1%. mSASSS progression over 2 years was 0.3 units for both treatment arms. Across the entire study period (mean secukinumab exposure: 631.6 days), the exposure-adjusted incidence rate (EAIR) for serious infections with secukinumab was 1.0 per 100 pt-years. No cases of TB were reported. The EAIR for inflammatory bowel disease was 0.8, malignant or unspecified tumours 0.6, and major adverse cardiac events 0.4, per 100 pt-years, respectively.

Conclusion: Secukinumab provided sustained improvement through 2 years in the signs and symptoms of AS and improved physical function and quality of life. These sustained improvements were observed regardless of anti-TNF status. The safety profile was consistent with that previously reported.

Predictors of Organ Damage Progression and Impact on Health-Related Quality of Life in Systemic Lupus Erythematosus

Alexandra Legge[1], Steve Doucette[2] and John G. Hanly[3], [1]Department of Medicine, Dalhousie University, Halifax, NS, Canada, [2]Dalhousie University and Capital Health, Halifax, NS, Canada, [3]Rheumatology, Division of Rheumatology, Capital Health and Dalhousie University, Halifax, NS, Canada

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

To describe cumulative organ damage in a longitudinal cohort of SLE patients and to evaluate the impact of key disease-related factors, medical therapies, demographic variables, and serological biomarkers on the rate of damage accrual. The relationship between cumulative organ damage and health-related quality of life (HRQoL) was also examined.

Methods:

A longitudinal database of SLE patients followed for up to 14 years was analyzed. Patients were assessed at enrollment and annually for (i) cumulative organ damage (Systemic Lupus International Collaborating Clinics (SLICC)/ACR Damage Index (SDI)) and (ii) HRQoL (Medical Outcome Survey Short Form-36 (SF-36) subscales and summary scores). The impact of demographic, disease-related and treatment-related factors on damage progression was examined using multivariable Cox proportional-hazards models. The impact of changes in SDI scores on HRQoL was assessed using linear mixed-effects modeling.

Results:

There were 273 SLE patients with a mean (SD) follow-up of 7.3 (4.3) years. Seventy-seven patients (28.2%) had preexisting damage (baseline SDI > 0) and during follow-up, 126 patients (46.1%) had an increase in SDI scores. Multivariate analysis revealed that older age, 8 or more ACR classification criteria, immunosuppressive drugs, cigarette smoking, and higher C-reactive protein (CRP) levels up to time of first SDI change were associated with an increase in SDI scores (*Table 1*). Changes in SDI scores were associated with initial declines in SF-36 scores at the time that damage occurred, with subsequent change in HRQoL comparable to that seen in patients without damage progression *(Table 2)*.

Conclusion:

Pre-existing organ damage and other risk factors, some modifiable, predict additional damage accrual in SLE patients. The negative impact of damage progression on HRQoL emphasizes the need to target modifiable risk factors and develop effective prevention and treatment strategies to reduce organ damage over time.

Table 1.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Hematuria in lupus nephritis (LN) is secondary to the passage of red blood cells (RBCs) through glomerular abnormalities. Dysmorphic RBCs are associated with glomerulonephritis, and particularly the acanthocytes that are the typical dysmorphic-glomerular RBCs. Kidney biopsy (KB) in LN–that informs the activity (Austin et al[1].), and the LN class– is helpful guiding treatment and prognosis. **Objectives:** To evaluate the correlation between the activity (in KB) and the count of total RBCs/acanthocytes in urine of patients with LN. Secondary objective was to assess if the count of RBCs, and the percentage of acanthocytes discriminate among the LN classes.

Methods: Patients with LN undergoing KB were invited to participate in our study. The morning before the KB, a urine sample was obtained and evaluated (after centrifugation) for the number of RBCs in a Neubauer chamber; the percentage of acanthocytes was also determined. KBs were evaluated by a nephro-pathologist who evaluated the class and activity of LN (0-24 points for proliferative classes); non-proliferative forms of LN were assigned as 0 of activity. Correlation was evaluated with Spearman's rho and median difference with Mann-Whitney's U. A classification tree was performed to distinguish between proliferative (III, IV, III/V, IV/V), pure membranous (V) or other classes of LN (I,II). Statistical analysis was performed using R version 3.2.0.

Results: We included 39 patients, 28 women (71.8%); three patients (7.7%) had LN class I, 3 (7.7%) class II, 5 (12.8%) class III, 13 (33.3%) class IV, 11 (28.2%) class V, 3 (7.7%) class III/V and 1 (2.6%) class IV/V. The median activity of LN was 4 (0-18). The RBCs count had a positive correlation with the LN activity ($r=0.7058$, $p<0.0001$); the number of acanthocytes had also a positive correlation with activity of LN ($r= 0.6460$, $p<0.0001$). Patients with proliferative LN had higher count of RBCs than non-proliferative LN (434,000 vs 29,000, $p<0.001$) and higher total count of acanthocytes (27,350 vs 2,860, $p= 0.0005$). The classification tree (Figure 1) shows that RBCs, the protein/creatinine ratio (PCR), and the acanthocytes percentage can be helpful for predicting LN class; the misclassification error rate of this tree was 17.95%.

Conclusion: Evaluation of urine abnormalities is a window of LN histopathology, particularly RBCs, acanthocytes, and PCR.

Session Date: Tuesday, November 10, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Although regarded as a disease of adulthood, SLE is also seen in children, and is associated with an increased risk for aggressive clinical course and major organ damage in comparison to adults. However, mortality rates and causes of death are under reported in the pediatric population, so that most of our understanding derived from generalizations of the adult literature. In France, a previous retrospective multicenter survey conducted on a ten-year period (1996-2006) identified 12 deaths in pediatric SLE patients. A better knowledge of the causes of death and the related comorbidities is pivotal to improve strategies to prevent death in children suffering SLE. The aim of the MORTALU-Ped study was to analyze the mortality profile related to pediatric SLE in France using a multiple cause-of-death analysis.

Methods:

For the 2000-2011 period, data was collected from the database of the French Epidemiological Center of Medical Causes of Death (CepiDc, Inserm) corresponding to death certificates (DC) on which SLE was listed as an underlying or non-underlying cause of death (ICD-10 code L93 or M32) were analyzed for all patients under the age of 18 years. Gender, age, sex-ratio, as well as the causes of death were assessed.

Results:

Overall, 35 DC were identified, of which 5 were excluded from further analyses (Age at death < 1 year; diagnosis of neonatal lupus with congenital heart block n=3; polymalformative syndrome n=1; cerebral hemorrhage n=1). Among the 30 remaining DC, SLE was notified as an underlying cause in 24 (80 %) and as a non-underlying cause of death in 6 (20 %). Mean number of causes of death reported on DC was 3.7 [2; 6]. The patients had a median age at death was 15 years [2; 17] and a sex ratio of 3 (23 female and 7 male). The median number of annual death was 3 [0; 5], relatively stable over time during the study period. Deaths were distributed across 20 French departments, with 1 or 2 DC by department, except for n°78 (Yvelines, n=3) and n°97 (ovserseas separtments, n=6).

For half patients (n=15), at least one severe SLE manifestation was reported: neurologic (n=4), cardiac (n=4), nephritis (n=3), hematologic (n=3), pancreatic (n=2) and pulmonary (n=1). Severe infections was reported in 9/30, 2 in a context of aplasia. Reported pathogens were Streptococcus pneumoniae (n=2), methicillin-resistant Staphylococcus aureus (n=1), Gram negative bacteria (n=1), histoplasmosis (n=1), crytpococcosis (n=1). Other noticeable causes of death were pulmonary embolism (n=1) and associated severe autoimmune condition (autoimmune cirrhosis).

Conclusion:

To our knowledge, this is the first mortality study using a multiple cause-of-death analysis in pediatric SLE. This study shows the interest of such approach to collect a more important number of cases of death in the context of a rare condition such as pediatric SLE. In pediatric SLE patients, the causes leading to death seem to be dominated by severe disease manifestations as well as by severe and/or opportunistic infections and lower sex ratio compared to the living pediatric population suggests higher severity in young male patients.

Phospholipase A2 Receptor 1 Antibody in Membranous Lupus Nephritis

Amy Sandford[1], Malvika Gulati[2], Ademola Oliatan[3], Angela Pakozdi[2], Ravindra Rajakariar[4], Andrea Cove-Smith[4] and Dev Pyne[2], [1]Barts Health NHS trust, London, United Kingdom, [2]Rheumatology, Barts Health NHS Trust, London, United Kingdom, [3]Barts Health NHS Trust, London, United Kingdom, [4]Renal Medicine, Barts Health NHS Trust, London, United Kingdom
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Recently phospholipase A2 receptor 1 (PLA2R1) has been found to be the antigenic target for primary membranous nephropathy (pMN) (1). Circulating anti-PLA2R1 autoantibody can be used as a marker for diagnosis and monitoring of pMN, and due to their high specificity, PLA2R1 antibody detection is useful in discriminating patients with pMN from those with secondary MN. A recent review calculated an overall PLA2R1 prevalence of 4.4% in membranous lupus nephritis (mLN)(2). PLA2R1 has been described in mLN patients with Chinese origin but not in Caucasians, raising the possibility of ethnic differences (3). We therefore sought to define the frequency of anti-PLA2R1 antibody in our ethnically diverse mLN population.

Methods:

This was a retrospective analysis of blood samples taken from lupus patients meeting ACR classification criteria with biopsy proven pure WHO class V or overlap (class III/V or IV/V) LN. ELISA was used to detect the presence or absence of the PLA2R1 antibody. Urinary protein : creatinine ratio (PCR) , erythrocyte sedimentation rate (ESR), dsDNA and complements were measured.

Results:

38 patients with biopsy proven mLN were tested for PLA2R1 antibody. There were 17 (44.7%) South-Asian, 14 (36.8%) Afro-Caribbean, 5 (13.2%) Caucasian, 1 South-East Asian and 1 Mixed. 5 of the 38 patients were Male (F:M ratio 6.6:1), and age range was from 21-60. 60% of the total group had significant proteinuria (uPCR>50), of whom 9 (23.7%) were in the nephrotic range. Median PCR was 91. 11 (29%) had active renal disease at the time of measurement of PLA2-R1 antibody based on significant increase of proteinuria warranting consideration of escalation of immunosuppression. 13 (39%) patients had elevated dsDNA titres, 8 (21%) patients had low complement levels and 18 (47%) patients had raised ESR >20. All patients were negative for the PLA2R1 antibody.

Conclusion:

Our results support the high reported specificity for PLA2R1 antibodies for pMN. The previously reported finding of PLA2R1 antibodies in SLE is most likely due to a chance co-occurrence of primary MN rather than ethnic differences. Since PLA2R1 has therapeutic and prognostic implications in pMN, its measurement should be considered in proteinuric lupus patients who are older and male since this is the group most likely to present with pMN.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Anti-dsDNA antibodies support the diagnosis of systemic lupus erythematosus (SLE), and their quantification is useful for the assessment of lupus nephritis (LN) and the disease activity in LN patients. However, the standardization of anti-dsDNA antibodies in terms of diagnostic accuracy and utility to measure disease activity is still poor and different test systems yield different results. Using a large cohort of well characterized SLE patients, we analyzed the usefulness of a novel anti-dsDNA microparticle chemiluminescent immunoassay (CIA) for the association with LN, and compared the assay to two traditional ELISA methods.

Methods:

Samples from 457 SLE patients from three cohorts (Canada, Spain, USA) were tested with the QUANTA Flash dsDNA CIA (Inova Diagnostics, San Diego, USA). Of these 457 SLE patients, 132 (28.9%) had LN at the time of the blood draw, or had the history of LN. Data obtained with the QUANTA Lite dsDNA SC ELISA and with the QUANTA Lite HA dsDNA ELISA (Inova Diagnostics) were available for samples from the Canadian and USA cohort (n=305), and results obtained with the HA dsDNA ELISA were available for samples from the Canada cohort only (n=234). The data were statistically evaluated using Analyse-it software (Version 3.90.1; Leeds, UK). Wilcoxon-Mann-Whitney was used to analyze the titer difference between different groups. Fisher Exact test was used to analyze antibody prevalence in different categories and p values < 0.05 were considered significant for all statistical methods.

Results:

In the total SLE group (n=457), the dsDNA CIA was positive in 59.3% of all SLE patients and in 70.5% with LN (n=132) (Fisher Exact p=0.002 compared to non-LN SLE). Anti-dsDNA antibody levels, as measured by CIA were significantly higher in LN patients compared to the rest of the SLE patients (median 67.5 *vs.* 32.4 IU/mL; p<0.0001, See Table). SLE patients who tested positive on CIA had an odds ratio (OR) of 2.0 (95% Confidence Interval, CI 1.3-3.0) for LN. Within the Canadian cohort, there was a significant difference between active *vs.* inactive LN for both the prevalence (p=0.0170) and the level (median 50.0 *vs.* 28.7 IU/mL; p=0.0160) of anti-dsDNA antibodies. When compared to the ELISA methods, the dsDNA CIA results showed the strongest correlation with LN (See Table).

	dsDNA CIA		**SC dsDNA ELISA**		**HA dsDNA ELISA**	
	Anti-dsDNA antibody level	Anti-dsDNA positivity	Anti-dsDNA antibody level	Anti-dsDNA positivity	Anti-dsDNA antibody level	Anti-dsDNA positivity
Canada (n=234)	p=0.0006	p=0.009	p=NS*	p=NS*	p=0.02	p=NS*
Spain (n=152)	p=0.0017	p=0.0226	N/A	N/A	N/A	N/A
USA (n=71)	p=NS*	p=NS*	p=NS*	p=NS*	N/A	N/A
All Cohorts (Canada + USA + Spain)	*p<0.0001*	0.002	N/A	N/A	N/A	N/A

*NOTE: NS = not significant. A p-value greater than 0.05 was considered not significant.

Conclusion:

Our results show that the measurement of anti-dsDNA antibodies obtained with the dsDNA CIA is superior to other more conventional assays for the occurrence of LN and assessment of active disease in LN patients.

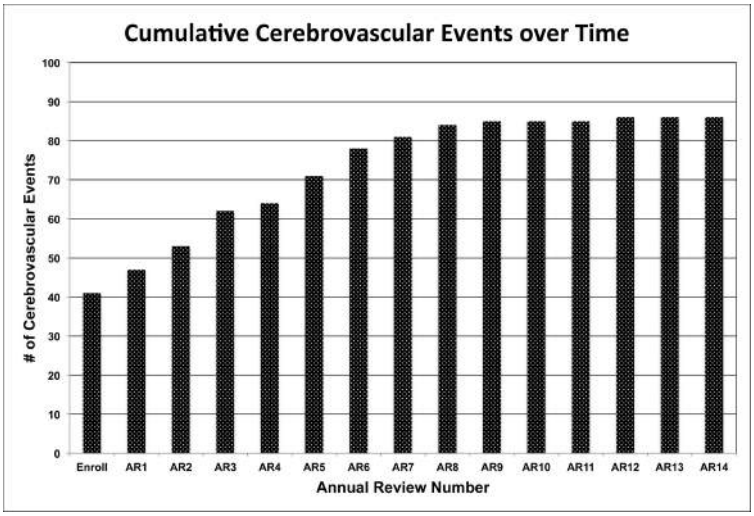
SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Neuropsychiatric (NP) disease in patients with SLE includes cerebrovascular events. We determined the frequency, characteristics and attribution in a large, multi-ethnic/racial, inception cohort of SLE patients.

Methods: A prospective study of new onset SLE patients was performed by an international network of 32 academic centers in 11 countries. Patients were evaluated at enrollment and annually for up to 14 years. Data were collected at each assessment on demographic and clinical manifestations, medications, SLE disease activity index-2000 (SLEDAI-2K) and Systemic Lupus International Collaborating Clinics (SLICC)/ACR damage index (SDI). Nervous system events were recorded using the ACR case definitions for 19 NP syndromes. These include cerebrovascular events and consisted of: (i) Stroke; (ii) Transient ischemia; (iii) Chronic multifocal ischemia; (iv) Subarachnoid and intracranial hemorrhage; (v) Sinus thrombosis. Pre-defined rules determined the attribution of NP events to SLE and non-SLE causes.

Results: Of 1,826 SLE patients, 88.8% were female, 48.8% Caucasian with mean±SD age 35.1±13.3 years. At enrollment, mean SLE duration was 5.6±4.2 months, SLEDAI-2K was 5.3±5.4, SDI was0.31±0.74. The mean follow-up was 5.8±3.8 years. Over the study 912 (49.9%) patients had 1,770 NP events of which 537 (30.3%) were attributed to SLE. Cerebrovascular events were the fourth most frequent NP event: 69/1,826 (3.8%) patients had 86 events of which 82/86 (95.3%) were attributed to SLE. Eleven (15.9%) patients had ≥ 2 cerebrovascular events (9 attributed to SLE and 2 to non-SLE factors) and other NP events occurred concurrently in 42/69 (60.8%) patients. The predominant cerebrovascular events were stroke [45/86 (52.3%)] and transient ischemia [23/86 (26.7%)] followed by subarachnoid and intracranial hemorrhage [9/86 (10.5%)], chronic multifocal ischemia [7/86 (8.1%)] and sinus thrombosis [2/86 (2.3%)]. Forty-one of 86 (47.7%) cerebrovascular events were identified at the enrollment assessment and by the fifth annual assessment 71/86 events (82.6%) had occurred (Figure).



Conclusion: Cerebrovascular events are the fourth most frequent NP event in lupus patients and are usually attributable to SLE. Over 80% of cases present in the first 5 years following the diagnosis of SLE.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The incidence and clinical consequences of rituximab-mediated late-onset neutropenia (LON) have been studied in various diseases, but data from Systemic Lupus Erythematosus (SLE) are limited. We studied the prevalence, consequences and predisposing factors for LON following treatment with rituximab in patients with SLE.

Methods: Ninety-two patients from the Karolinska SLE cohort treated with rituximab were enrolled in this retrospective observational study. Rituximab was given according to the lymphoma course (weekly for four weeks; 73 cycles), the arthritis course (at week 0 and 2; 94 cycles), or as a single infusion (16 cycles), with (60 cycles) or without (123 cycles) cyclophosphamide. LON was defined as an absolute neutrophil count <1,500 cells/µL, corresponding to a neutropenia of grade II–IV according to the National Cancer Institute Common Terminology Criteria for Adverse Events, occurring four weeks to two years after initiation of rituximab treatment, provided that other apparent causes were excluded. Cases of grade II-IV neutropenia occurring later than two years after treatment initiation, but during sustained B cell depletion, were also considered cases of LON.

Results: Thirty-two of 92 patients developed LON (17 patients developed grade II neutropenia, 7 developed grade III, and 8 patients developed grade IV neutropenia) after a median time of 222 days (range: 28–1990 days). Twenty-two patients were asymptomatic. Thirteen patients were admitted to the hospital (median hospital stay: 6 days; range: 1–47 days), either due to suspicion of infection, or for observation and/or treatment with Granulocyte-Colony Stimulating Factor. Three patients were hospitalised due to other causes during the incidence of LON. Ten patients presented with fever, and three of them developed critical conditions and had positive microbiological cultures (*Staphylococcus aureus* sepsis, *Pseudomonas aeruginosa* sepsis, *Streptococcus*fasciitis). Except for one febrile patient with grade III neutropenia, all patients with fever were treated with intravenous broad-spectrum antibiotics. The infections resolved with antibiotics; however, one patient required admission to an Intensive Care Unit. Nine patients were retreated with rituximab after the incidence of LON, and three of them developed LON following these subsequent cycles.

There was no association between neutropenia grade and severity of complications. No predictors for LON were identified among dosages of rituximab, prednisone equivalent or cyclophosphamide (concurrent or accumulated), preceding neutropenia, sex, age, and disease duration.

Conclusion: SLE patients had a higher prevalence of rituximab-mediated LON (35%) compared with patients with lymphoma (3–27%) and rheumatoid arthritis (3%). Although this phenomenon is typically self-limiting, our results demonstrate that it is a common complication in SLE patients, which can lead to life-threatening conditions, and underscore the importance of monitoring these patients for neutrophil counts, fever and infections.

Utility of Untimed Single Urine Protein/Creatinine Ratio As a Substitute for the 24 Hour Proteinuria for the Assessment of Proteinuria in Systemic Lupus Erythematosus

Jorge Medina-Rosas[1], Dafna Gladman[2], Jiandong Su[2], Arthy Sabapathy[3] and Murray Urowitz[2,4], [1]Medicine, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, [2]Rheumatology, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, [3]University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, [4]Rheumatology, U of Toronto, Toronto Western Hospital, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To determine the utility of an untimed Sample of Urine Protein/Creatinine ratio (S-UPCR) as a screening test for proteinuria and its ability to accurately measure the level of proteinuria in Systemic Lupus Erythematosus (SLE).

Methods: Analysis was performed on the data available from a single SLE cohort between May 2008-December 2014. Proteinuria was measured in a 24 hour urine sample collection (24H-P) and with the S-UPCR. Based on the 24H-P, samples were divided into: Group I: < 0.5, group II: 0.5-0.99, group III: 1-1.99, and group IV: ≥2g/day. Correlation between 24H-P and S-UPCR was measured.

Agreement was determined by Intraclass Correlation Coefficient (ICC), Concordance Correlation Coefficient (CCC) and Bland-Altman plot between 24H P/C and S-UPCR. The best cut-offs for S-UPCR predicting a 24H-P of 0.5, 1.0 and 2.0 g/day were determined with the receiver operating characteristics curve.

Results: The correlation of 24H-P and S-UPCR for all the samples overall was high, but the correlation for groups I, II, III and IV was low-moderate. The agreement for all urine samples overall was appropriate but poor for groups I, II, III and IV. On the Bland-Altman plot, the dots corresponding for groups III and IV are outside 2 Standard Deviations signifying poor agreement (Figure 1). S-UPCR cut-offs for 24H-P of 0.5, 1.0 and 2.0 g/day were 0.08, 0.16 and 0.35 g/mmol

Conclusion: S-UPCR can be used as a screening test for proteinuria, and the best cut off value to predict a 24H-P of 0.5 g/day is 0.08 g/mmol (800 mg/g). S-UPCR is not a valid test to quantify proteinuria. The accurate level of proteinuria should be measured by the gold standard test, 24H-P.

Figure 1. Bland-Altman plot for 24H-P/creatinine content and S-UPCR

Urinary Protein:Urinary Creatinine Ratio in an Untimed Urine Specimen and Estimated Glomerular Filtration Rate Are Reliable Measures of Proteinuria and Renal Function in Patients with Lupus Nephritis

Yasuhiro Katsumata, Hirokazu Nishina, Masanori Hanaoka, Yasushi Kawaguchi, Kae Takagi, Akiko Tochimoto, Yuki Ichimura and Hisashi Yamanaka, Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Renal Disease Subcommittee of the American College of Rheumatology (ACR) Ad Hoc Committee on Systemic Lupus Erythematosus (SLE) has recommended the urinary protein level in a spot (untimed) urine specimen (determined as urinary protein:urinary creatinine ratio; spot PC ratio) over a 24-hour urine protein excretion, because it is more easily and reliably obtained. In addition, the committee stated that renal function refers to the estimated glomerular filtration rate (GFR) and selected the abbreviated Modification of Diet in Renal Disease (MDRD) study equation. Accordingly, complete renal remission was defined by the ACR subcommittee as an estimated GFR of >90 ml/minute/1.73 m^2 and a urinary PC ratio of <0.2 and inactive urinary sediment. However, recent work suggests that the spot PC ratio may be inaccurate in the assessment of the degree of proteinuria in lupus nephritis (LN) as compared with other forms of chronic glomerular disease. In addition, there is no consensus as to which estimating equation is preferred for estimated GFR. In the present study, we aimed to ensure the reliability of spot PC ratio and estimated GFR as measures of

proteinuria and renal function in patients with LN.

Methods: A total of 46 patients with active lupus nephritis who were admitted to our hospital from 2010 through 2014 were included. All the patients met the revised ACR classification criteria for SLE. LN was pathologically confirmed in 44 patients and renal biopsy was not performed in the other 2 patients. Clinical and laboratory data were retrospectively collected from the medical records and statistically analyzed.

Results: The spot PC ration and the 24-hour urine protein excretion were highly correlated (n = 23, Pearson's $r = 0.80$). Agreement of the PC spot ratio >0.5 and the 24-hour urine protein excretion >0.5g was good (Cohen's kappa = 0.60). The 24-hour urinary protein:urinary creatinine ratio is also highly correlated with the 24-hour urine protein excretion (n = 32, Pearson's $r = 0.87$). The estimated GFR by the abbreviated MDRD study equation and the 24-hour urine creatinine clearance were moderately correlated (n = 38, Pearson's $r = 0.68$).

Conclusion: Our results supported the reliability of spot PC ratio and estimated GFR by the abbreviated MDRD study equation as measures of proteinuria and renal function in patients with LN. Larger and prospective studies are needed to confirm and validate these findings.

Session Date: Tuesday, November 10, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

To evaluate the association of the use of immunosuppressive agents and mortality in a longitudinal cohort of SLE patients

Methods:

Patients who fulfilled >=4 1997 ACR criteria for SLE and followed in our rheumatology clinics between 1995 and 2014 were longitudinally followed. Data on demographic characteristics, clinical manifestations and ever use of immunosuppressive agents were retrieved from our database. A propensity score for the use of individual immunosuppressive agent was calculated for each patient based on the odds ratios obtained from separate logistic regression models, with different drugs being the outcome variables. Cox regression models were established to study the effect of the use of various immunosuppressive agents and mortality of our patients over time, with adjustment by the propensity score, age at onset of SLE and sex.

Results:

803 SLE patients were studied (742 women, 92%). All were ethnic Chinese. The mean age of onset of SLE was 33.2±14 years and the mean follow-up time of the entire cohort of patients was 10.8±7.7 years. The cumulative manifestations of SLE, in decreasing order of frequency, were musculoskeletal (70.3%), renal (52%), facial rash (46%), leukopenia (36%), photosensitivity (26%), thrombocytopenia (25%), hemolytic anemia (21%) and serositis (19%). The frequencies of patients who were ever treated with various immunosuppressive drugs were as follows: prednisolone (85%), azathioprine (AZA) (63%), cyclophosphamide (CYC) (25%), mycophenolate mofetil (MMF) (27%), calcineurin inhibitors (CNI) (23%) and hydroxychloroquine (HCQ) (69%). 97 patients (12%) died (mean time to death 9.8±8.0 years) and 56 (7%) patients were lost to follow-up. The commonest causes of death were: infection (44%), cerebrovascular events (12%), cardiovascular events (10%), malignancy (8.2%), pulmonary hypertension (7.2%), interstitial lung disease (3.1%) and uncontrolled SLE activity (3.1%). Cox regression analyses adjusted for age, sex and vascular risk factors (current / past smoking, hypertension, diabetes mellitus, LDLc/HDLc >3.0) revealed that the ever use of MMF (hazard ratio [HR] 1.89[1.19-3.02]; p=0.007), CYC (HR 1.67[1.04-2.68]; p=0.04) and HCQ (HR 0.52[0.35-0.79]; p=0.002) was significantly associated with mortality. Conversely, the use of CNI (HR 1.10[0.67-1.82]; p=0.71), AZA (HR 0.98[0.64-1.50]; p=0.92), or prednisolone (HR 1.06[0.51-2.01]; p=0.85) was not significantly associated with SLE mortality. After further adjustment for the propensity scores, it was demonstrated that the ever use of HCQ (HR 0.53[0.34-0.84]; p=0.006) and AZA (HR 0.55[0.34-0.89]; p=0.02) was significantly associated with a reduction in SLE mortality (47% and 45%, respectively). The use of MMF (HR 1.42[0.87-2.32]; p=0.17) and CYC (HR 1.24[0.75-2.04]; p=0.40) was no longer significantly associated with an increase in mortality.

Conclusion:

In this longitudinal cohort of Chinese SLE patients, the ever use of HCQ and AZA was significantly associated with lower mortality. However, treatment with prednisolone, CYC, MMF or the CNIs was not associated with a benefit of survival.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Prospective cohort studies of the natural history of thrombosis in SLE, including events before diagnosis are rare. No previous study has identified risk factors prospectively for both venous and arterial thrombosis. In this study we used a large prospective SLE cohort to assess the natural history of both arterial and venous thrombosis before and after the diagnosis of SLE.

Methods: 2305 SLE patients were enrolled in a prospective cohort. Medical records were reviewed to identify the occurrence of arterial and venous thrombosis prior to cohort entry. During participation in the Lupus Cohort, arterial thrombosis was diagnosed by patient history, diagnostic enzymes tests and imaging, including arteriogram, and venous thrombosis by ultrasound, CT or venography. We calculated the rate of thrombosis per person-year in periods of follow-up defined by time since diagnosis with SLE.

Results:

The highest rates of both venous thrombosis and arterial thrombosis were observed in the 2 years before and the 2 years after diagnosis: 8.9-10.5 per 1000 patient years for arterial thrombosis and 11.4-12.5 per 1000 patient years for venous thrombosis. A second peak in incidence of arterial thrombosis (11.8 per 1000 patient years) was observed later in the course of SLE.

Table 1: Rates of Venous and Arterial Thrombosis by Time since SLE Diagnosis

	Venous Thrombosis				Arterial Thrombosis			
Time since SLE diagnosis	# Events	Number of Person-Years	Rate of events per 1000 person-years	Rate Ratios (95% CI) adjusted for age	# Events	Number of Person-Years	Rate of events per 1000 person-years	Rate Ratios (95% CI) adjusted for age
> 5 years before SLE diagnosis	49	39,704	1.2	1.0 (Ref. Grp)	16	40,128	0.4	1.0 (Ref. Grp)
2-5 years before SLE diagnosis	15	6,490	2.3	1.5 (0.8, 2.7)	12	6,610	1.8	3.5 (1.6, 7.4)
0-2 years before SLE diagnosis	50	4,370	11.4	7.0 (4.7, 10.5)	40	4,472	8.9	15.9 (8.8, 28.8)
0-2 years after SLE diagnosis	51	4,087	12.5	7.4 (5.0, 11.1)	44	4,194	10.5	17.7 (9.9, 31.9)
2-5 years after SLE diagnosis	35	5,194	6.7	3.9 (2.5, 6.1)	24	5,364	4.5	7.2 (3.7, 13.8)
5+ years after SLE diagnosis	139	15,274	9.1	5.0 (3.5, 7.2)	183	15,481	11.8	15.8 (9.2, 27.3)

Conclusion: This large cohort study indicated that prevention of both venous and arterial thrombosis is important around the time of diagnosis of SLE. Monitoring for thrombosis should occur throughout the disease course, being mindful of the arterial thrombosis risk with longer duration of SLE. Our results suggest that the mechanism of events before diagnosis is not just accelerated atherosclerosis as suggested by some investigators. Accelerated atherosclerosis would not explain the increase in both arterial and venous events that occurs before and at diagnosis. Hypercoagulability appears to be the major explanatory mechanism.

Diagnostic and Screening Accuracy of Spot Urinary Protein-Creatinine Ratio Compared to Protein Content in a 24 Hour-Urine Collection in Systemic Lupus Erythematosus: Systematic Review and Meta-Analysis

Jorge Medina-Rosas[1], Kristy Yap[2], Melanie Anderson[3], Jiandong Su[2] and Zahi Touma[2], [1]Medicine, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, [2]Rheumatology, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, [3]Library and Information Services, University Health Network, University Health Network, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To systematically review literature on the utility of spot urinary protein-creatinine ratio (PCR) as a screening test for proteinuria and its ability to accurately measure proteinuria compared with 24 hour urine collection (24H-P) in patients with Systemic Lupus Erythematosus (SLE).

Methods: Literature search (1900 – 2015) for articles comparing PCR and 24H-P in SLE patients in the databases Medline, Web of Science and Embase. Included studies and their results were critically appraised and analyzed.

Results: 13 studies (1001 patients; 84.01% women) were included. 10 studies reported on Pearson correlation (range: 0.67-0.94); 3 studies reported on Spearman correlation (range: 0.78-1). The meta-analysis of studies with Pearson correlation showed a high overall correlation of 0.80 between 24H-P and PCR (Figure 1) however with high heterogeneity (I^2=97.2%). Correlation analysis is not sufficient to evaluate the utility of a new test against the gold standard test and analysis on agreement is required. Seven studies reported on agreement: 3 studies analyzed Concordance Correlation Coefficient (0.48-0.94); 3 Intraclass Correlation Coefficient (0.66-0.95) and 1 kappa (0.58). These results confirmed that the agreement between 24H-P and PCR was inappropriate. Three studies included Bland-Altman plot and the results also demonstrated poor agreement between both tests.

Conclusion: The PCR has a utility as a screening test for proteinuria in SLE patients. The studies' results of 24H-P and PCR showed poor agreement between both tests signifying that PCR should not substitute the gold standard test (24H-P) to accurately measure proteinuria.

Figure 1. Forest plot of correlations for the 8 studies included in the meta-analysis for the overall correlation of 24H-P and PCR

A Systematic Review and Meta-Analysis of Cutaneous Manifestations in Late Versus Early-Onset Systemic Lupus Erythematosus

Jennifer Medlin[1], Karen E. Hansen[2], Sara Fitz[3] and Christie M. Bartels[4], [1]Internal Medicine, University of Wisconsin Hospitals and Clinics, Madison, WI, [2]Rheumatology/Medicine, Univ of Wisconsin, Madison, WI, [3]Department of Dermatology, Mercy Medical Center, Dubuque, IA, [4]Medicine, Rheumatology, University of Wisconsin School of Medicine and Public Health, Madison, WI
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is commonly diagnosed in females of reproductive age, with those diagnosed after the age of 50 referred to as late-onset SLE. Most prior studies comparing late and early-onset SLE manifestations were limited by small sample sizes. The last meta-analysis (Ward 1989) included just 9 studies. Given that more than one third of SLE classification criteria are cutaneous, we performed a systematic literature review and meta-analysis to assess the clinical differences in cutaneous manifestations between late and early-onset SLE.

Methods: Systematic review of the literature from inception through August 2013 was performed using PubMed, CINAHL, Web of Science, and Cochrane Library. We excluded studies that did not require the ACR SLE classification criteria, had no early-onset controls, defined late-onset SLE as <50 years of age, or were non-English language. The quality of the eligible studies was evaluated using Newcastle Ottawa Quality Scale. Forest plots were created using random effects models to compare rates of cutaneous manifestations by age of onset. Study heterogeneity was assessed using I^2.

Results: Thirty five studies, representing 1,727 late-onset and 11,189 early-onset SLE patients, met eligibility criteria. The female: male ratio was smaller in the late-onset group (5:1 versus 8:1, p<0.001, I^2 7.5%). Most cutaneous manifestations were less prevalent in the late-onset group, including malar rash (OR 0.43 (0.35, 0.52)), photosensitivity (OR 0.72 (0.59, 0.88)), alopecia (OR 0.63 (0.48; 0.82)), and Raynaud's phenomenon (OR 0.84 (0.71-0.99)). By contrast, sicca was more common in late versus early-onset SLE (OR 2.45 (1.91, 3.14)). Other cutaneous manifestations including mucosal ulcerations, discoid rash, cutaneous vasculitis, livedo, and subacute cutaneous lupus did not differ significantly. The mean Newcastle Ottawa Quality Scale score was 6.3±0.5 out of 9 possible points.

Conclusion: Many cutaneous manifestations were less common overall in late-onset SLE patients with the exception of sicca symptoms, consistent with prior studies. Increased sicca in late-onset lupus was also reported in a meta-analysis restricted to that topic (Yao 2012). Late-onset SLE with sicca symptoms might represent a distinct disease entity with characteristic features including milder disease course. Future studies should investigate etiologies for these phenomena including roles of genes, gender, immune senescence, environment, and isolated cutaneous versus systemic lupus prevalence in older adults.

Table 1: Meta-analysis summary statistics for 10 cutaneous manifestations in Late vs Early-onset SLE

Cutaneous Manifestation	Total cases n= 12,916	Late-onset n= 1,727	Early-onset n= 11,189	OR (95% CI)	Heterogeneity I^2 (%), p-value
Malar rash	**12,731**	**1,691**	**11,040**	**0.43 (0.35,0.52)**	**64, <0.001**
Mucosal ulcerations	11,697	1,616	10,081	0.88 (0.74, 1.04)	22, 0.14
Discoid rash	10,997	1,520	9,477	1.11 (0.91, 1.34)	9, 0.33
Photosensitivity	**12,318**	**1,698**	**10,620**	**0.72 (0.59, 0.88)**	**54, <0.001**
Sicca	**5,489**	**833**	**4,656**	**2.45 (1.91, 3.14)**	**13, 0.31**
Raynaud phenomenon	**8,515**	**1,194**	**7,321**	**0.84 (0.71, 0.99)**	**14, 0.26**
Alopecia	7,290	992	6,298	**0.63 (0.48, 0.82)**	36, 0.06
Cutaneous vasculitis	3,711	480	3,231	0.78 (0.49, 1.26)	37, 0.11
Livedo reticularis	1,619	197	1,422	0.63 (0.17, 2.31)	62, 0.03
Subacute cutaneous lupus	1,060	120	940	0.92 (0.43, 1.98)	0, 0.80

I^2 interpretation: low heterogeneity between studies ≤25%, moderate 50%, and high >75%

How Accurate Is Spot Urine Protein/Creatinine Ratio in Measuring the Change over Time in Proteinuria Level Compared to the 24 Hour Proteinuria Test?

Jorge Medina-Rosas[1], Murray Urowitz[2,3], Jiandong Su[2], Dafna Gladman[2] and Zahi Touma[2], [1]Medicine, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, [2]Rheumatology, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, [3]Rheumatology, U of Toronto, Toronto Western Hospital, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: The Protein/Creatinine ratio in a spot urine sample (PCR) has been accepted as a substitute for the protein content in a 24 hours urine collection (24H-P), but there is not enough evidence on its usefulness for the prospective follow up of lupus patients. The purpose of this study was to determine if PCR can accurately measure the change in proteinuria level over time when compared to the "gold standard" test 24H-P.

Methods: Analysis on data from a single lupus centre between May 2008 and December 2014 was conducted. **Results** of concurrent urine samples for PCR and 24H-P were identified. Patients with diabetes mellitus, end stage kidney disease and kidney transplantation were excluded.

The gold standard test in this study is 24H-P. At baseline visit, urine samples with abnormal 24H-P (³0.5 g/day) and normal 24H-P (<0.5 g/day) were identified. In the group with abnormal 24H-P, the first follow up visit for each patient with 50 and 100% improvement, based on 24H-P, was identified and compared to the PCR results at this visit. In the group with normal 24H-P, the first follow up visit for each patient with worsening (³0.5 g/day) based on 24H-P was identified and compared to the PCR results at this visit. Abnormal PCR is >0.05 g/mmol.

Standardized Response Mean (SRM) for 24H-P and PCR for 50 and 100% improvement and for worsening were calculated. We hypothesized that both tests (24H-P and PCR) will change in the same direction but the effect captured by 24H-P is larger than PCR.

Results:

1188 paired samples from 230 patients.

- 24H-P 100% improvement: 60 patients started with abnormal 24H-P (³0.5 g/day) and had 100% improvement on follow up. Mean duration for improvement: 17.5 months. Among this group, only 53.3% had 100% improvement based on PCR. SRM for 24H-P: -1.00 (95% CI: -1.31 to -0.69) (large effect). SMR for PCR: -0.69 (95%CI: -0.97 to -0.41) (moderate effect).
- 24H-P 50% improvement: 64 patients started with abnormal 24H-P (³0.5 g/day) and had 50% improvement on follow up. Mean duration for improvement: 13.6 months. Among this group, only 56% of patients had 50% improvement based on the PCR. SRM for 24H-P: -1.27 (95% CI: -1.61 to -0.95) (large effect). SMR for PCR is -0.63 (95% CI: -0.90 to -0.36) (moderate effect).
- 24H-P worsening: 43 patients started with normal 24H-P (<0.5 g/day) and became abnormal (³0.5 g/day) on follow up. Mean duration for worsening of proteinuria: 10.5 months. At first visit all patients had normal 24H-P but 34.9% had abnormal PCR (≥0.5 mg/g). At the first visit with abnormal 24H-P, only 79.1% of these patients had abnormal results by PCR. SRM for 24H-P: 0.81 (95% CI: 0.46 to 1.15) (large effect). SMR for PCR: 0.53 (95%CI: 0.21 to 0.85) (moderate effect).

Magnitude of change for improvement (50 and 100%) and worsening: $SRM_{24H\text{-}P} > SRM_{PCR}$

Conclusion: PCR is not as accurate as 24H-P in determining clinically important change in proteinuria levels (50, 100% improvement and 100% worsening) in lupus nephritis. Thus 24 H-P should be used to monitor improvement or deterioration in LN in clinical practice.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Tubulointerstitial disease is frequent in lupus nephritis (LN) with immune deposits being present in up to one third of patients.[1,2] Lesions including interstitial infiltration, tubular atrophy and interstitial fibrosis are all independent risk factors for LN renal outcome.[3] The aim of this retrospective study was to analyze tubulointerstitial changes on a series of repeat renal biopsies (RB) and to identify correlations with clinical variables.

Methods: Histopathological changes of 39 LN patients were analysed using the revised Austin's semi-quantitative scoring system, using a grading system of 0 to 3 (0, normal; 1, mild <25%, 2, moderate between 26 and 50%; 3, severe >50% of the interstitium affected).[4] With a similar method, chronicity indices were also calculated and included scores for glomerular sclerosis, fibrous crescents, tubular atrophy and interstitial fibrosis. Spearman's rank-order correlation was run to determine relationship between clinical variables and histological findings.

Results: Compared to the initial biopsy, we found a progression in both tubular atrophy (p=0.001) and interstitial scarring (p<0.001), but not in inflammatory cell infiltration (p=1.000) by the time of RB. The mean total tubulointerstitial score (± SD) has progressed from

2.69 ± 2.03 to 3.78 ± 2.03 (p=0.001). There was a positive correlation between serum creatinine level and the severity of tubular atrophy at time of both reference biopsy (r=0.33, p=0.048) and RB (r=0.56, p<0.001). In addition serum creatinine at time of RB showed a strong correlation with interstitial scarring (r=0.60, p<0.001). We found no association between any of the other clinical variables and the tubulointerstitial pathology. A trend was identified between the severity of interstitial inflammation on reference biopsy and the amount of tubular atrophy and interstitial scaring on RB (r=0.349, p=0.19; r=0.385, p=0.009, respectively). The mean chronicity index (CI, ± SD) increased from 3.58 ± 2.64 to 5.11 + 2.96 by the time of RBs. Patients with proliferative histopathology on initial biopsy had higher CI at both the reference biopsy (4.03 ± 2.48 vs. 2.57 ± 2.79, proliferatives vs. non-proliferatives, mean score ± SD, p=0.047) and RBs (5.77 ± 2.94 vs. 3.64 ± 2.53, proliferatives vs. non-proliferatives, mean score ± SD, p=0.019). Treatment decisions did not seem to be influenced by the progression of CI (treatment escalation in 60.9% vs. 61.1%, increased CI vs. stable/reduced CI, respectively, p=0.982).

Conclusion: Not only the glomerular pathology, but tubulointerstitial lesions are also important in LN, and they show progression in time illustrated by our study using RBs. Serum creatinine level showed good correlation with the severity of tubulointerstitial lesions. Correlation was also demonstrated between the amount of interstitial inflammation on reference biopsies and the severity of tubular atrophy and interstitial scaring on RBs, suggesting a possible predictive role of damage.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

The most common and clinically and histologically best-characterized SLE kidney disease is lupus nephritis (LN). However, other forms of kidney disease can and do occur concomitantly with LN, although their prevalence, clinical features and impact on disease course and response to therapy are not well described. We sought to determine the prevalence of other concomitant kidney pathology among patients with newly diagnosed LN, and to compare demographic and clinical features between patients with and without concomitant kidney findings.

Methods:

We identified patients age ≥18 years with ≥1 visit for LN and a kidney biopsy reviewed at our large academic hospital from 1992 to 2014. (For those with > 1 biopsy, we analyzed only the first) We ascertained demographics, clinical factors, and reviewed kidney biopsy reports for International Society of Nephrology/Kidney Pathology Society class (ISN/RPS) and concomitant findings. We calculated the prevalence of concomitant kidney diseases in this group of LN patients. Data were stratified by the type of kidney disease and analyzed to determine demographics, classification of lupus nephritis, median activity and chronicity index, HIV and antiphospholipid antibody status before or at the time of kidney biopsy. To compare those with and without concomitant kidney disease, Fisher's exact tests were used for categorical variables and Wilcoxon rank-sum tests for continuous variables.

Results:

We identified 76 patients with LN confirmed on kidney biopsy. Overall, the median age at biopsy was 37 years old (range 18-71) and racial breakdown was: Asian 6%, Hispanic 16%, Black 25%, White 29%, other/unknown 23%. The major concomitant kidney pathologic findings were thrombotic microangiopathy (TMA, 10, 13%) and collapsing glomerulonephropathy (GN, 15, 20%). Four patients (5%) had both TMA and collapsing GN. Comparisons of the demographic and clinical factors among those with and without concomitant kidney disease are given in the **Table**. Compared to those without concomitant pathology, patients with collapsing glomerulonephropathy and those with TMA were more likely to be Black (**Table**). Distributions of lupus nephritis class were different across the 3 groups defined by presence of collapsing GN or TMA or not, but there were no significant differences in median activity or chronicity indices. No patients were HIV positive. There were no differences in the proportions who had antiphospholipid antibodies. Other findings included interstitial nephritis (6, 8%), tubular injury (5, 7%) and vascular injury (10, 13%).

Conclusion:

Other concomitant pathology occurred in a substantial number of LN kidney biopsies in this population. The clinical and prognostic implications of these findings deserve further study. In future analyses, we will investigate variation in treatment and outcomes among those with and without other concomitant kidney pathologies.

Session Date: Tuesday, November 10, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: B-lymphocytes (BL) play a critical role in Systemic Lupus Erythematosus (SLE). BL depletion therapy still remains an attractive option, despite the disappointing results of randomized controlled trials (RCTs).

Methods: Twelve SLE patients [2 males, mean age 43.8 yrs (29-54)] with polyarthralgia and multiorgan involvement including class IV or III/V (ISN/RPS) glomerulonephritis (9 cases), skin lesions (9 cases, with necrotizing ulcers in 3), polyneuropathy (7 cases), CNS involvement (2), lymphoadenopathy (6) e polysierositis (5) have been treated with an IBLD protocol: Six patients were refractory or intolerant to conventional immunosuppressive therapy. Six patients were given the following induction regimen as a front line therapy. Protocol: Rituximab (RTX) 375 mg/sm on days 1, 8, 15, 22, and 2 more doses after one and two months, associated with 2 IV administrations of 10 mg/kg of cyclophosphamide, and 3 methylprednisolone pulses (15 mg/kg) followed by oral prednisone (0.8 mg/die, rapidly tapered to 5 mg/day 12 weeks). No further immunosuppressive maintenance therapy has been given.

Results: ITBLD obtained a complete depletion of CD20+ BL for 12-18 months. Patients had been followed-up for 48.9 (25-93) months. Significant decreases ($p<0.05$) were found in the levels of ESR (baseline mean value: 54.2 mm; 3 months: 33; end of follow-up: 14.9), anti-dsDNA antibodies (baseline: 192 U; 3 months: 112; end of follow-up: 17), and proteinuria (baseline: 4.9 g/24 hours; 3 months: 0.97; end of follow-up: 0.22). C4 values (baseline 11 mg/dl) significantly increased ($p<0.05$) after 3 months (22 mg/dl) and at the end of the follow-up (20 mg/dl). Three patients relapsed after 36, 41 and 72 months, respectively. They showed again a complete remission after re-treatment over 13-48 months of observation

Conclusion: A promising role of RTX in an intensified protocol of induction therapy can be envisaged in patients for whom avoiding immunosuppressive maintenance therapy and sparing steroids are particularly appealing. Moreover, our data confirm the opportunity to reconsider the regimens of BL depletion in the treatment of the most severe or refractory forms of SLE despite the disappointing results of RCTs.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic Lupus Erythematosus (SLE) a chronic disease, predominantly of young women, which may involve various organs, and is marked by periods of disease flares, activity and damage. It may interfere with training, work, social life, and performance of important roles in life. Its treatment may involve use of corticosteroids and immunosuppressive medications which may cause side effects. SLE can adversely impact various aspects of one's life and may significantly impair quality of life of patients and their loved ones. With the aim of improving patient care, we sought to determine significant modifiable and non-modifiable correlates of satisfaction with care (SC) in SLE.

Methods: Fifty consenting SLE patients fulfilling ACR classification criteria were given self-administered surveys (FACIT-Fatigue, Self-reported Fibromyalgia Tender Point, Pain, Insomnia Severity Index for Sleep, Perceived Stress Scale-4, Patient Health Questionnaire-9 for depression, LupusPRO) at routine care visits. Disease activity and damage were assessed using SELENA-SLEDAI (SS) and SLICC/ACR (SDI). Non-modifiable variables of interest were age, gender, education, marital status, disease duration, number of ACR criteria, damage, lupus nephritis (LN) diagnosis and fibromyalgia (FM) diagnosis. Modifiable variables of interest included disease activity, current use and current dose of corticosteroids, specific SLE medications, self-reported FM tender point count, pain, insomnia, fatigue, depression and stress. SC was measured using the LupusPRO SC domain items. Univariate and multivariate regression modeling was done, with SC as a dependent variable and with the above variables of interest. P value of ≤ 0.05 on two tailed test was significant. Bonferroni correction was used for the final model, and a $p \leq 0.006$ was significant on two tailed test.

Results: Mean (SD) age was 41.4+13 years, 90% participants were women. Ethnic background was as follows: 56% Blacks, 24% Whites, 10% Asians and 10% Others. Median (IQR) values of Physician Global Assessment (PGA), total SS, and SDI were 0.5 (0.8), 4.0(6.0) and 1.0(1.0), respectively. Age, education, disease duration, damage, FM diagnosis and LN diagnosis were the non-modifiable, while disease activity, current corticosteroid dose and fatigue were the modifiable correlates of SC (Table 1). Greater disease activity, disease duration and FM were associated with better SC. Together these 8 variables accounted for 51% variance in SC. After Bonferroni correction, age, education and FM were not significant in the model, but rest remained significant.

Conclusion: Fatigue and current daily dose of steroids are significant and modifiable correlates of satisfaction with care in SLE, even after adjusting for FM. We suggest proactive assessment and interventions targeted towards addressing fatigue and steroid dose reduction at each visit for SLE patients.

Table 1: Multivariate Model for Satisfaction with Care

Variable	Standardized Beta	95% CI	P value
			*significant after Bonferonni correction for multiple comparisons
Non-modifiable			
Age	-0.32	-1.28, -0.10	0.024
Education	-0.39	-23.94, -3.53	0.010
Disease duration	0.38	0.44, 2.60	0.007
Lupus nephritis	-0.63	-53.25, -17.50	0.0001*

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: To study the utility of lupus serology as a predictor for kidney graft outcome in: a) a systematic review (SR) of the literature and b) a lupus cohort.

Methods: For the SR, a literature search in Medline and Embase (inception-2014) was performed to identify the articles reporting on the serology at RT and on the outcome of RT. Included studies were critically appraised using the Newcastle Ottawa Scale (NOS).

Patients who underwent RT in the identified. RT outcomes included: a) nonfunctional graft requiring dialysis ≤ 3 weeks, b) graft failure requiring permanent dialysis after 3 weeks, c) graft survival not requiring dialysis d) death. The patients were grouped into graft failure and survival. The duration of graft failure was defined as the time between RT and subsequent dialysis. The duration of graft survival was defined as the time between RT and recipient death or the end of the study with functioning graft.

Results:

The literature search identified 539 references, excluding 119 duplicates. Of the 539, 534 were not relevant to the research question. 5 studies in addition to our lupus cohort data (n= 77 patients) were included in the SR. The majority of the grafts survived to at least 1 year regardless of whether the serology was positive or negative pre transplant which is consistent with the results of our lupus cohort (Table 1). The quality assessment of the studies using the NOS revealed limitations in the domains of outcome and selection due to small sample size and a short follow up period.

32 of 1783 patients in our lupus cohort had a RT. 2 patients had a nonfunctional graft, 5 patients had graft failure (2 patients had failure <5 years and 3 ≥5 years) and 25 patients had graft survival (11 had survival ≥5 years). 1 year prior to RT, 40% of the graft failures had positive serology compared to 52% in the graft survival (Table 2). Both failure and survival groups demonstrated no clinical disease activity at 1 year prior to RT. The time to graft failure (n=5) was 9.2 ± 6.77 years. In the failure group, 2 patients died by 12.1 ± 1.0 years, 2 patients are still alive and 1 was lost to follow-up. In the graft survival group, 5 patients died by 7.1 ± 5.6 years and 1 patient was lost of follow-up. Cause of death was ischemic heart disease in 3 patients, sepsis in 2 patients and unknown in 1 patient.

Table 1: Survival of the graft in patients with positive and negative serology at RT

	Seropositive patients n=33				**Seronegative patients n=38**					
	Failure at 6 months		**Failure at 1 year**		**Failure at 6 months**		**Failure at 1 year**		**Failure at 5 years**

Table 2. Characteristics of graft failure and survival patients in our lupus cohort

	Graft Failure n=5	Graft survival n=25	Total Grafts n=30
Sex (F)	100%	84%	86.7%
Age at lupus diagnosis (yr)	27.14 ± 9.66	22.28 ± 7.43	23.09 ± 7.87
Age at RT (yr)	33.79 ± 14.01	39.14 ± 8.83	38.25 ± 9.79
Lupus duration at 1st clinic visit (yr)	6.21 ± 4.19	7.60 ± 8.94	7.37 ± 8.30
Lupus duration at RT (yr)	6.65 ± 4.82	16.86 ± 8.22	15.16 ± 8.61
DNA +ve in 1 year prior	1/5	6/24 (NA n=1)	7/29
Low complements in 1 year prior	2/5	13/25	15/30
DNA +veand low C3/C4 in 1 yr prior	1/5	4/23 (NA n=2)	5/28
DNA +ve and/or low C3/C4 in 1 yr post RT	3/4 NA n=1	12/25	15/29
AMS-(serology) 1 yr prior to RT	4.90 ± 2.54	3.75 ± 4.59	3.90 ± 4.36
SDI at RT	4.00 ± 0.82	4.48 ± 2.43	4.41 ± 2.28
Months on dialysis prior to RT	33.43 ± 17.54	56.25 ± 45.55	51.86 ± 42.34
Source of allograft (Cadaver or Living)	2/5 Cadaver 1/5 Living 2/5 Unknown	11/25 Cadaver 13/25 Living 1/25 Unknown	13/30 Cadaver 14/30 Living 3/25 Unknown

Conclusion: The results of this SR found that the persistence of serological abnormalities at the time of RT was not associated with graft failure. These results are consistent with the results of our lupus cohort.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Many studies have reported long-term outcomes including morbidity, mortality, and end stage kidney disease (ESKD) in patients with lupus nephritis (LN). We aimed to elucidate the risk factor of the progression to chronic kidney disease (CKD) in patients with lupus nephritis, and the development of comorbidity and its impact on the renal function.

Methods: We collected 116 patients with a diagnosis of LN who were hospitalized in our division from 2005 to 2013, and were followed up for at least 1 year or died within 1 year. We retrospectively examined the demographics, the clinical course, and the progression to CKD (defined as equal to or severer than G3bA1, G3aA2, or G2A3 by the classification for CKD). We performed COX hazard regression analysis to elucidate the risk factor of the progression to CKD and examined the impact of acute kidney injury (AKI) and acute decompensated heart failure (ADHF) on the renal function and the incidence of vascular event.

Results: The ratio of female to male was 8.7 : 1 and the median age of LN onset was 32 year-old. LN as one of the first symptoms was 54%, and 52% of LN showed proteinuria ≥ 3.5 g/day at least one time during the clinical course. Clinical symptoms and laboratory data included arthritis or arthralgia (41%), facial erythema (40%), serositis (20%), neurological symptoms (12%), hematological abnormality (22%), positive anti-double stranded DNA antibody (86%), and positive anti-phospholipid antibody (30%). In 98 renal biopsy-proven patients (86%), the pathological diagnoses (WHO classification) were class II (7%), IV (III) (45%), V (32%), and IV (III)+V (16%). Kaplan-Meier analysis showed survival, ESKD (introduction of dialysis or renal transplantation)-free, and CKD-free rate at 20 years were 0.761, 0.677, and 0.433, respectively (Figure 1). Multivariate COX hazard regression analysis revealed the hazard ratio of proteinuria ≥ 3.5 g/day for the progression to CKD was 2.01 (95% confidence interval, 1.06 to 3.81; p = 0.03). ADHF, AKI, and vascular events developed in 6, 9, and 12 patients, respectively. All patients with ADHF and 8 of 9 patients with AKI progressed to CKD eventually. There was a tendency that the cumulative incidence of vascular events in patients with CKD was higher than in those with non-CKD in the late phase (0.45 vs. 0.24, Figure 2).

Conclusion: Nephrotic proteinuria was a risk factor of CKD, and ADHF and AKI may have a deteriorating impact on the subsequent renal function. In the late phase, vascular events should be cared for patients with LN who progressed to CKD.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Using light microscopy (LM) or immunofluorescence (IF), combined proliferative and membranous lupus nephritis (LN) is defined as an active proliferative class III/IV lesion and diffusely distributed membranous lesion (involving >50% tuft of >50% glomeruli) in ISN/RPS 2003. A mixed-type LN was reported to show poor prognosis[1,2]; however, an interesting case report on corticosteroid-free treatment regimen of rituximab and mycophenolate mofetil is recently published[3]. We examined the renal outcome of mixed-type LN based on renal remission, end-stage renal disease (ESRD), and death.

Methods: We retrospectively evaluated 66 cases constituting class III and IV lesions, including 22 showing mixed-type LN on renal biopsy, during 2005–2014. Mixed-type LN were divided into 2 groups; membranous findings on LM + IF (LM group; n = 18) and those on IF only (IF group; n = 4). Renal remission was defined as a spot urine protein/creatinine ratio <0.5 g/g Cr and normal or near-normal eGFR (within 10% of normal eGFR) in EULAR/ERA-EDTA recommendations and KDIGO guidelines.

Results: Clinical findings were mean age 40.6 ± 15.8 years (male:female = 6:16), disease duration 5.2 ± 5.2 years, and observation period 2.2 ± 2.0 years and concentration of urine protein 3.5 ± 2.9 g/day, serum creatinine 0.93 ± 0.49 mg/dl, dsDNA 225.2 ± 745.6 IU/ml, C3 57.6 ± 24.0 mg/dl, and C4 9.9 ± 7.0 mg/dl. Pathological findings were activity index 6.0 ± 3.1, chronicity index 2.4 ± 2.6, cellular crescents 54.6%, fibrinoid necrosis 22.7%, and chronicity of glomeruli 72.7%. Twenty of 22 cases were class IV + V and 2 cases were class III + V. Most cases received a high dose of corticosteroids (0.6–1.0 mg/kg/day) and various immunosuppressants such as cyclophosphamide, tacrolimus, azathioprine, cyclosporine, and mizoribine for remission induction and maintenance therapy. IF group cases had a tendency toward shorter disease duration than LM group cases; there were no chronic lesions. The IF group cases achieved renal remission at the last observation and no ESRD or death. The LM group cases had a statistically significant lower remission rate of 27.8%; two cases developed ESRD and death.

Conclusion: This retrospective clinico–pathological study shows that mixed-type LN, defined as per findings of LM + IF, has a poor prognosis. However, mixed-type LN determined by IF only has an unexpectedly high remission rate, probably because of early detection of membranous lesions without morphological alterations.

Do Patients with Lupus Nephritis Who Achieve Complete Proteinuria Recovery at 2 Years Have Better Long Term Outcomes Compared to Patients with Partial Proteinuria Recovery?

Zahi Touma[1], Murray Urowitz[2,3], Jorge Medina-Rosas[4], Jiandong Su[1] and Dafna Gladman[1], [1]Rheumatology, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, [2]University of Toronto, Toronto, ON, Canada, [3]Rheumatology, U of Toronto, Toronto Western Hospital, Toronto, ON, Canada, [4]Medicine, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: The tempo of Complete Proteinuria Recovery (CPR) in Lupus Nephritis (LN) is slow and while 28% achieve CPR at year 1 this increases to 52% at year 2. The long term outcomes of patients who achieve CPR or Partial Proteinuria Recovery (PPR) of≥ 50% at 2 years is not well studied.

To determine the prognostic value of PPR and CPR at 2 years on long term outcomes compared to patients who did not recover proteinuria ≥ 50% on the standard of care therapy.

Methods: All patients that are registered at a large lupus clinic from 1970–2015 were reviewed (n=1782) and patients with LN were identified. LN was defined as: Proteinuria ≥0.5g/24 hours or spot Urine Protein Creatinine Ratio≥ 0.6mg/mg on 2 consecutive occasions within one year. Patients who achieved PPR or CPR within 2 years and have at least 5 years of follow up since the onset of LN were studied.

*Endpoints:*CPR was defined as proteinuria <0.5g/24 hours or PCR<0.6 mg/mg at least on 2 occasions. PPR was a decrease of ≥50% but not to normal levels. Not recovered was defined as <50% improvement.

*Long term outcomes:*Death, eGFR<15, dialysis or kidney transplant, damage [SLICC Damage Index (SDI)] >0 and >3) and atherosclerotic events occurring after achieving PPR or CPR.

*Analyses:*Non-parametric tests, survival analyses and simple cox regression were used to study the effect of PPR/CPR on outcomes.

Results: 326 patients (85% F) with LN were studied. The age at LN onset was 34.56 ± 12.19 yrs and lupus duration at LN onset was 5.72 ± 6.71 yrs. Follow up duration from lupus nephritis was 14.97 ± 8.95 yrs.

Endpoints at 2 years: 178 had CPR, 43 PPR and 105 did meet the endpoints.

The prevalence of comorbidities(except damage) was the lowest in the CPR group, slightly higher in the PPR group and the highest in the no remission group (table 1).

Although CPR protects against the development of comorbidities (death, end stage kidney disease, dialysis and transplant, and

atherosclerosis), PPR does not. Damage accrual was not protected by CPR or PPR.

Table 1. Long term outcomes among 3 groups

Outcomes	No remission N = 105 (n and %)	PPR N = 43 (n and %)	CPR N = 178 (n and %)
Death	25 (23.8)	7 (16.3)	21 (11.8)
eGFR < 15	17 (16.2)	9 (20.9)	10 (5.6)
Dialysis or Transplant	15 (14.3)	8 (18.6)	10 (5.6)
SDI > 0	86 (81.9)	36 (83.7)	129 (72.5)
SDI > 3	30 (28.6)	20 (46.5)	44 (24.7)
Atherosclerotic Events	22 (20.9)	5 (11.6)	21 (11.8)

Table 2. Effects of CPR and PPR on long term outcomes (simple cox regression)

Outcomes	Comparisons	Hazard Ratio	95% CI	P value
Death	**PPR to no remission**	0.68	0.29-1.57	0.36
	CPR to no remission	0.54	0.30-0.96	0.035
eGFR < 15	**PPR to no remission**	1.27	0.56-2.84	0.57
	CPR to no remission	0.33	0.15-0.72	0.005
Dialysis or Transplant	**PPR to no remission**	1.31	0.55-3.08	0.54
	CPR to no remission	0.41	0.19-0.92	0.03
SDI > 0	**PPR to no remission**	0.98	0.66-1.45	0.93
	CPR to no remission	0.91	0.69-1.19	0.48
SDI > 3	**PPR to no remission**	1.43	0.80-2.53	0.23
	CPR to no remission	0.838	0.52-1.34	0.46
Atherosclerotic Events	**PPR to no remission**	0.434	0.16-1.18	0.10
	CPR to no remission	0.509	0.27-0.95	0.033

Conclusion: Achieving CPR at 2 years, from the onset of LN, protects against comorbidities. PPR at 2 years doesn't protect against comorbidities, thus physicians should aim to achieve CPR to prevent comorbidities in LN patients.

Session Date: Tuesday, November 10, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

In addition to glomerular lesion, renal vascular lesion is also an important prognostic marker of lupus nephritis (LN). Among various vascular changes thrombotic microangiopathy (TMA) presents with severe clinical manifestations and high mortality. The aim of this study was to assess the spectrum and impact of TMA on the outcomes of LN.

Methods: In this prospective observational study of one and half year duration, clinical and renal histopathological data of 102 patients with biopsy proven LN were noted and in addition evaluatation for antiphospholipid syndrome (APS) as cause of TMA in LN was also carried out. Study subjects were followed up actively for six months and various outcomes were noted. Cases were divided into two groups as LN with TMA and LN without TMA, and various features were compared between two groups. Renal TMA was defined as intertubular artery and glomerular capillary response including endothelial cell swelling, lumen narrowing or obstruction & thrombi formation by light microscopy. Swelling of glomerular endothelial cells, detachment from glomerular basement membrane and widening of sub-endothelial space were identified by electron microscopy. Outcomes noted were complete response, partial response, failure and death.

Results: In the 102 patients with lupus nephritis, 26 patients were diagnosed as co-existing with renal TMA based on strict pathological criteria. Among the 26 patients three patients were found to have concomitant APS (11.5%). As compared to cases without TMA, patients with TMA had significantly higher rates of arthralgia, malar rash, advanced renal injury i.e. serum creatinine >3mg/dl(34.6% Vs 11.84% with P= 0.008), higher percentage of fibrocellular+fibrous crescents (P= 0.018) and tubular atrophy (P= 0.006),. Even though the rates of endocapillary proliferation (73.1% Vs 56.5%), hyaline thrombhi(19.2% Vs 7.9%), and glomerular sclerosis(46.2% Vs 30.3%) were higher in TMA group compared to cases without TMA, but failed achieve statistical significance.. Patients of Lupus nephritis with TMA had poorer outcomes i.e higher rates of failure to treatment(P=0.011) and lower rates of complete response(P=0.031) compared to non TMA group. Renal TMA group is significantly associated with 7.26 times more likely poor outcomes than non TMA group(Odds ratio7.262, 95% confidence interval:1.585 to 31.303, P= 0.008).

Conclusion: Presence of TMA in lupus nephritis is associated with adverse clinicopathological presentation and poorer outcome.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Musculoskeletal, dermal and renal systems are the most commonly represented systems in lupus clinical trials. Thus, it is very important to study the time to recovery in each individual system on standard of care treatment in longitudinal studies of lupus patients. The objective of this study was to compare the time to recovery in individual lupus manifestations on standard of care treatment.

Methods: Consecutive lupus patients with active disease (SLEDAI-2K ≥6 at first visit) who attended the Lupus Clinic between 2000 and 2012 were studied. The analysis was conducted on patients who had: 1) At least 1 of the following 3 systems active by SLEDAI-2K criteria – renal (proteinuria), musculoskeletal (arthritis) or dermal (mucosal ulcers, rash and/or alopecia) and 2) started or

increased prednisone therapy. All patients had to have at least one year follow-up.

The analysis was focused on the group of patients who improved their disease activity which is defined as a decrease in SLEDAI-2K by ≥4. Time to recovery in each individual system among these patients was determined using the Kaplan-Meier curves.

Results: 158 patients fulfilled the inclusion criteria and were further studied. Of the 158 patients and at the last visit (9-12 months), 109 (69%) patients showed overall improvement and they were further studied. In 109 patients, at first visit, musculoskeletal system was present in 48 patients, renal (proteinuria) in 42 patients and dermal in 48 patients.

Time to improvement in individual lupus manifestations (Figure 1):

-Arthritis: 50% of the patients recovered by 3 months (95% CI: 3-6 months) and at 12 months, 45 out of 48 (94%) recovered. 3 patients did not recover by the last visit.

-Dermal system: 50% of the patients recovered by 6 months (95% CI: 3-12 months) and at 12 months 33 out of 48 (69%) patients recovered. 15 patients did not recover at the last visit.

-Renal (proteinuria):48% improved by 12 months (95% CI: 9-12 months). 22 patients did not recover proteinuria at the last visit.

Conclusion: The time to recovery of individual lupus manifestations on standard of care therapy varies among organ systems. Arthritis was the fastest to recover followed by the mucocutaneous manifestations and then proteinuria. These facts should be taken into consideration when determining the length of clinical trials with new agents.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III

Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

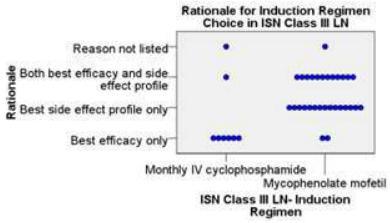
Background/Purpose: We aim to evaluate the differences and rationale behind the diagnostic and therapeutic approaches to proliferative lupus nephritis (LN) among nephrologists and rheumatologists.

Methods: A de-identified, multiple-choice survey was distributed to nephrologists and rheumatologists in the United States. The survey consisted of a demographic questionnaire and two case vignettes exploring the decision of when to biopsy for the diagnosis of LN, management of International Society of Nephrology (ISN) Class III LN, and management of refractory ISN Class IV LN.

Results: There were 38 respondents to the survey: 12 rheumatologists and 26 nephrologists. Work setting: 81% academic, 19% non-academic. Management of abnormal urinalysis findings in an asymptomatic lupus patient: 33% of rheumatologists versus 76% of nephrologists chose to biopsy. Induction regimen of ISN Class III LN: 79% of all providers chose mycophenolate mofetil (MMF) and 21% chose IV cyclophosphamide.

Choice of Induction Regimen in ISN Class III LN per Specialty

	Mycophenolate Mofetil	IV Cyclophosphamide	Total
Nephrology	18	8	26
Rheumatology	12	0	12
Total	30	8	38



Maintenance regimen of ISN Class III LN: all surveyed rheumatologists chose MMF as a sole maintenance agent compared to 32% of nephrologists who elected the addition of low-dose corticosteroids to MMF. Choice of an adjunctive agent in refractory ISN Class IV LN: 68% of all providers chose rituximab, 14% chose tacrolimus, 5% chose abatacept, and 14% elected not to add any agents listed.

Conclusion: The results of this survey suggest a significant difference among rheumatologists and nephrologists on the decision to perform initial kidney biopsy and management of ISN Class III LN. The results suggest that perception of side effect profiles play an important role in the choice of therapeutics. This study emphasizes the need for a multi-disciplinary approach toward renal disease in lupus patients. We continue to recruit subjects to complete this survey.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: End stage renal disease due to Systemic lupus erytematosus (SLE) is one of the autoimmune disorder leading to renal transplantation. In this single-center study we sought to describe the sensitization profile in renal transplant patients with end stage renal disease due to SLE.

Methods: A retrospective single center analysis in the last ten years revealed 26 renal transplant patients with SLE (20 females and 6 males). This group was matched to a 53 patient control group, without SLE, but matched for gender and age distribution. The detection and specificity of anti-HLA antibody was achieved by single-antigen bead (Luminex) assays. The HLA polymorphism for A, B, C, DRB1, DRB3/4/5, DQB1, DQA1, DPB1 was performed by reverse SSO for intermediate resolution in all patients, while high resolution SBT (Sanger) was used for 12 cases. The auto-crossmatches were performed both by complement-dependent cytotoxicity, and by flowcytometry.

Results: The HLA typing in SLE group has shown a higher (19/26, 73%) prevalence of HLADRB13/4/5 antigens when compared to control group (8/53, 15%, $p<0.05$). Furthermore, 4 SLE patients (15%) exhibited a positive cytotoxic and flow auto-crossmatch, compared to only 1 (2%) in controls ($p<0.01$). The distribution of HLA-specific antibody was 20/26 (77%) in SLE versus 18/53 in controls (33%), $p<0.01$ The class distribution in SLE group was: 19 anti-class I, and 11 anti class II, versus 11 class I and 7 class II in controls. 22 patients in SLE group exhibited anti-HLA antibody towards public epitopes resulting in a calculated PRA > 50%, while 19 SLE patients exhibited anti-HLA antibody towards public epitopes resulting in a calculated PRA > 80%. The control group had a significantly lower proportion of strong antibody towards public epitopes (4/18 and 2/18, respectively, $p<0.01$).

Conclusion: Renal transplant patients with SLE exhibited a higher prevalence of HLADRB13/4/5 self antigens, and a higher prevalence of positive auto crossmatches and strong HLA antibody towards public epitopes. This might explain their worse transplant outcomes due to higher prevalence of antiHLA antibodies in these patients.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Cognitive dysfunction (CD) significantly affects SLE patients with many contributing causal factors. The effect of disease activity on cognitive function remains unclear and currently there is no definitive measure for CD in SLE. Functional magnetic resonance imaging (fMRI) provides a sensitive measure of brain functionality during cognitive tasks. The limited studies using fMRI in SLE have shown that SLE patients employ compensatory brain mechanisms to maintain adequate cognitive function. The aim of this study is to investigate fMRI as a potential biomarker for CD in SLE and examine other factors that affect CD in SLE.

Methods:

Data from 12 healthy controls (HC), 9 SLE patients with active disease (SLE-F) and 15 stable SLE patients (SLE-S) were analysed. SLE patients met ACR 1997 criteria. Basic demographic, disease and mood variables were collected. We also performed two fMRI tasks; the n-back (working memory task) and the facial emotional recognition task (FERT). The n-back had three levels (0-, 1-, and 2-back) with the 2-back being the most difficult. The FERT displayed faces expressing different emotions: happiness, sadness, fear and neutral. Both tasks were preprocessed and modelled using SPM12. The out of scanner variables and region of interest (ROI) data

extracted from the fMRI tasks were analysed using SPSS 22.

Results:

Participants were matched on demographic and clinical variables except for the SLEDAI score and steroid dose where, as expected, the SLE-F group scored higher. The SLE-F patients had significantly higher depression scores than the SLE-S and HC. The FERT mean results for the amygdala (sad vs neutral condition) were significantly different when comparing all SLE participants to the HC group. The n-back task showed a significant difference in the blood-oxygen-level dependent (BOLD) response for the 2- vs 0-back condition in the middle frontal gyrus (MFG), with an increased response for the SLE-F group compared to the other two groups.

Conclusion:

We found an increased BOLD response using the n-back in the MFG but only in the SLE-F group. This combined with the FERT amygdala result suggests that CD in SLE is affected by both disease activity and mood disorders. Functional MRI biomarkers may help differentiate features of CD in SLE patients related to disease activity and aid better targeting of relevant pathways for interventions in this condition.

This independent research is funded by Genzyme in the context of the ISS Program.

Session Date: Tuesday, November 10, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Across the spectra of autoimmune diseases RA stands out, as biomarkers present from the onset are associated with severity and can be a guide to therapy. In contrast, in SLE, genetic susceptibility has no clinical applicability, specific autoantibodies do not predict disease course, determinants of target organ remain unknown and clinical outcome is unpredictable for individual patients. In practice, damage accrual is therefore the best measure which is used to define SLE disease severity, found to predict future mortality. The objective of this study was to test the validity of damage determinants in a single-centre cohort.

Methods: Prospectively followed SLE female patients (defined by the identification of at least 4 SLE ACR criteria - fulfillement 100%, n=76) over the past 5 years. Age of onset, ethnicity, disease duration, number of ACR criteria at the end of follow-up, cumulative: renal, neuropsychiatric and articular phenotypes, hypertension, dyslipidemia, smoking, hydroxychloroquine, immunosuppressive use and SLEDAI 2K were correlated to the presence and degree of irreversible damage, as measured by SLICC/SDI in its several domains. Accumulation of ACR criteria was measured in a sub-group of patients followed from disease onset (within a year of the first symptom ascribed to SLE) (n=39 - 51%); SLEDAI and SLICC were performed bi-annualy and annualy, respectively. Univariate statistical analysis was performed using the Wilcoxon Mann-Whitney, Chi-Square tests and bivariate analysis for non-parametric distributed data (Sig. 2-tailed $p < 0,05$).

Results: SLICC SDI index > 0 was present in 43/76 (56.6%) and significantly associated to a longer disease duration, a higher number of ACR criteria and a neuropsychiatric (NP) phenotype when compared with those with no damage. There was no effect from any other demographic or clinical features (Table I). The final number of ACR criteria accrued was positively correlated to a higher disease activity over the past 5 years of follow-up (Spearman´s rho 0.02). Mean disease activity (SLEDAI 2K ≥ 3) over the past 5 years was not correlated to damage accrual at the end of follow-up according to disease duration: ≤ 5 and < 10y (n=17); ≥ 10 and < 20y (n=32); ≥ 20 (n=27).

Table I: Univariate analysis comparing patients with and without damage according to SLICC SDI index

Characteristic	SLICC < 1 (n=43)	SLICC ≥ 1 (n=33)	P value (Sig*)	Statistical Test
Age at disease onset (years) (mean ± SD)	32 ± 11	31 ± 13	0.653	Mann Whitney (MW)
Non-Caucasian (n, %)	4 (44.4)	5 (55.6)	0.610	Pearson Chi-square (PCS)
Disease Duration (years) (mean ± SD)	14 ± 7	19 ± 8	0.007*	MW
Hypertension (n, %)	16 (36.4)	27 (61.4)	0.338	PCS
Dyslipidemia (n, %)	12 (34.3)	22 (62.9)	0.201	PCS
Smoking (n, %)	7 (43.8)	9 (56.2)	1.000	PCS
Malignancy (n, %)	0 (0)	6 (100)	0.111	PCS
Infection (n, %)	16 (39)	24 (58.5)	0.809	PCS
Neuropsychiatric (n, %)	2 (11.1)	16 (88.9)	0.004*	PCS
Renal (n, %)	13 (41.9)	17 (54.8)	0.614	PCS
Articular (n, %)	22 (39.3)	33 (58.9)	0.631	PCS
Anti-nuclear Ab (n, %)	32 (42.1)	43 (56.6)	1.000	PCS
Anti-dsDNA (n, %)	24 (41.4)	33 (56.9)	1.000	PCS
Mean SLEDAI (bi-annual, past 5 years)	2.2 ± 2.0	3.6 ± 2.9	0.054	MW
Cumulative ACR criteria - first 6 months after disease onset (n available)	4.1 ± 1.3 (n=21)	3.7 ± 1.5 (n=18)	0.280	MW
Cumulative ACR criteria - end of follow-up	5.0 ± 1.1	5.6 ± 1.4	0.046*	MW

Conclusion: Disease duration and number of ACR criteria predict SLICC SDI as previously reported[1]. In our cohort, NP disease has a major impact on damage accrual.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Preventing organ damage is a major challenge in management of Systemic Lupus Erythematosus (SLE). Few data are available on factors related to development of damage in early stages of the disease. This study aim to evaluate the early damage accrual and factors associated with development of damage in the Early Lupus Project, a prospectively followed-up inception cohort of SLE patients diagnosed within 12 months since fulfillment of four or more 1997 ACR classification criteria

Methods:

The development and progression of damage assessed by the SLICC/ACR Damage Index (SDI) were prospectively recorded during the first year of the disease. SDI represent irreversible damage occurred after onset of SLE and being present for at least 6 months; by definition, it scores 0 at disease onset.

Using univariate analysis, we assessed the contribution of covariates collected at baseline (demographic, serological, clinical by BILAG2004 domains, disease activity by ECLAM index) in the development of damage (SDI from 0 to ≥1) within 12 months since disease onset. Stepwise regression models were fitted with covariates with $p<0.1$ to identify factors independently associated with development of damage.

Results:

A total of 119 patients (93.3% Caucasians, 18 males) were eligible for this study having available data at 12 months of disease. Mean age and mean disease duration since recognition of 4 ACR criteria were 36.7±14.1 years and 2.5±3.9 months (median = 1 month; IR 0-3.1), respectively. Twenty-eight (23.5%) and 31 (26.0%) patients, had an SDI score ≥1 after 6 and 12 months since disease onset (Table 1), respectively.

Univariate analysis revealed that dyslipidemia ($p=0.01$), anti-Beta2glicoproteinI antibodies positivity ($p=0.01$), active cardiorespiratory involvement ($p=0.02$) and high disease activity calculated by ECLAM ($p=0.05$) registered at baseline were associated with development of damage. However, older age at diagnosis ($p<0.01$; OR 1.1 95% CI 1.0-1.3), higher number of active BILAG2004 clinical domain ($p<0.01$; OR 1.7 95% CI 1.2 – 2.4) and neuropsychiatric involvement at baseline ($p<0.01$; OR 6.7 95% CI 1.4-32.2) were the only independent risk factors for early development of damage in this cohort.

No influence of active renal involvement and medications prescribed at baseline was detected in our cohort, likely because they most contribute to development of late-onset damage.

Table 1. Distribution at 6 and 12 months and prevalence of organ damage stratified according to the SDI domains at 12 months of disease.

	Prevalence (patients)
SLICC 6 Months (median; IR range)	**0 (0-0)**
SLICC = 0	76.5% (91)
SLICC = 1	16.8% (20)
SLICC > 1	6.7% (8)
SLICC 12 Months (median; IR range)	**0 (0-1)**
SLICC = 0	73.9% (88)
SLICC = 1	18.5% (22)
SLICC > 1	7.6% (9)
SDI domains	
Neuropsychiatric	**10.1% (12)**
Cerebrovascular accident	5.9% (7)
Cognitive impairment	3.4% (4)
Peripheral neuropathy	1.7% (2)
Psychosis	0.8% (1)
Ocular	**5.9% (7)**
Cataract	3.4% (4)
Retinal change	2.5% (3)
Miscellanea	**5.0% (6)**
Malignancy	4.2% (5)
Diabetes	0.8% (1)
Cardiac	**3.4% (4)**
Pericarditis or pericardiectomy	1.7% (2)
Myocardial infarction	0.8% (1)
Valvular disease	0.8% (1)
Peripheral Vascular	**3.4% (4)**
Venous thrombosis with swelling, ulceration	3.4% (4)
Pulmonary	**2.5% (3)**
Pleural fibrosis	2.5% (3)
Pulmonary fibrosis	0.8% (1)
Musculoskeletal	**2.5% (3)**
Deforming or erosive arthritis	1.7% (2)
Muscle atrophy or weakness	0.8% (1)
Renal	**2.5% (3)**
Proteinuria ≥3.5 gm/24hours	1.7% (2)
Estimated or measured glomerular filtration rate<50%	0.8% (1)
Mucocutaneous	**1.7% (2)**
Scarring chronic alopecia	1.7% (2)
Gastrointestinal	**0**

Conclusion:

Development of organ damage begins early in patients with SLE. In order to prevent damage accrual in the early stage of SLE it is

necessary to identify which clinical manifestations and risk factors are associated with it.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Hydroxychloroquine (HCQ) is a safe and effective treatment for systemic lupus erythematosus (SLE), and its blood concentration is known to be closely related to the treatment response [1, 2]. However, blood HCQ concentration has been found to be widely variable in patients taking the medication at same dose and frequency [1-4], and the reason is not well understood. We sought to evaluate the association of genetic polymorphisms in Cytochrome P450 (CYP) 2D6, 3A5, 3A4 and blood concentration of HCQ and its metabolite, N-desethylhydroxychloroquine (DHCQ), in patients with SLE.

Methods: Patients meeting the 1997-updated 1982 revised SLE criteria or the SLICC classification criteria who have been taking HCQ > 3 months were recruited and were genotyped for four SNPs in CYP2D6*10, CYP3A5*3, and CYP3A4*18B. Blood HCQ and DHCQ concentrations ([HCQ] and [DHCQ]) were measured and their association with corresponding genotypes was investigated.

Results: Total 194 patients were included in the analysis. The mean patient age was 39.2 ±0.83 years, 93.8% were female, and the average daily HCQ dose per weight was 4.48mg/kg/day. The mean time between the last HCQ dose and the blood draw was 15.58 ±0.86 hours. The mean SLEDAI score was 3.44±0.2. The mean [HCQ] and [DHCQ] were 575.05±26.33 ng/ml and 449.83±21.78 ng/ml, respectively. The allele frequencies of the 2 SNPs in CYP2D6*10 were relatively frequent among our participants. However, the other SNPs in the CYP3A4 and CYP3A5 isoforms were infrequent. CYP2D6*10 polymorphisms (rs1065852 and rs1135840) were significantly associated with the ratio of [DHCQ]/[HCQ] when adjusted for age, sex, dose per weight and SLEDAI score (p=0.03 and p<0.01, respectively)(Table). The ratio of [DHCQ]/[HCQ] was the highest in patients with G/G type of CYP2D6*10 (rs1065852) polymorphism and the lowest in those with A/A type (p=0.03). Similarly, the ratio was the highest in patients with C/C type of CYP2D6*10 (rs1135840) polymorphism and the lowest in those with G/G type (p<0.01). CYP2D6*10 (rs1065852) polymorphism was significantly related to [DHCQ] (p=0.01). However, polymorphism of CYP3A5*3 and CYP3A4*18B did not show any significant association with [HCQ], [DHCQ] or the ratio which could be due to small allele frequencies.

Table. Associations between CYP genotypes and HCQ concentration

	[HCQ]*	[DHCQ]*	Ratio
rs1065852(CYP2D6*10)			
A/A	424.6(352.3,511.7)	280.6(230.6,341.4)	0.72±0.05
A/G	524.9(457.5,602.3)	405.4(350.8,468.4)	0.83±0.03
G/G	409.5(340.1,493.2)	340.7(280.2,414.2)	0.89±0.04
p value	0.06	**0.01**	**0.03**
rs1135840(CYP2D6*10)			
C/C	403(309.2,525.3)	349.4(264.5,461.7)	0.94±0.06
C/G	481.9(413.1,562.2)	391.6(333,460.4)	0.86±0.03
G/G	453.3(389.4,527.7)	305.9(260.7,358.8)	0.73±0.03
p value	0.51	0.11	**<0.01**
rs776746(CYP3A5*3)			
C/C	402.9(309,524.8)	330.5(288.3,378.9)	0.79±0.03
T/C	481.9(412.8,562.1)	380.5(320.3,452)	0.87±0.04
T/T	453.3(389.2,527.6)	255.2(140.2,464.5)	0.74±0.13
p value	0.68	0.27	0.21
rs28371759 (CYP3A4*18B)			
A/G	317.1(158.2,635.7)	304.4(145.7,636.2)	0.99±0.16
A/A	461.8(416.3,512.3)	351.9(315.2,392.8)	0.82±0.02
p value	0.29	0.70	0.32

Adjusted for age, sex, SLEDAI score, dose per weight per day

*Log transformed

Ratio: [DHCQ]/[HCQ]

Conclusion: Our study showed that the ratio of HCQ and its metabolite, DHCQ, was related to CYP2D6 polymorphisms in Korean lupus patients taking oral HCQ. CYP polymorphisms may explain why there is wide variation in blood HCQ concentration levels. Therefore, it is important to consider the role of an individual's CYP polymorphisms when one prescribes oral HCQ.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a multi-systemic inflammatory disease, characterized by an extreme variability of its expression, both between and within individuals, over time. Overall disease activity is a predictor of both mortality

and organ damage. It is therefore important to understand the burden of disease course over time among patients with SLE. We aimed to discern and describe SLE disease activity patterns over time by analyzing data from the Hopkins Lupus Cohort.

Methods: Disease activity was retrospectively studied in a cohort of 2386 SLE patients followed up quarterly for 1-28 yrs (10 367 person-yrs of F/U). SLE disease activity patterns were defined using 1) Physician Global Assessment (PGA) and 2) SLE Disease Activity Index (SLEDAI), including serology: Long Quiescent (LQ), SLEDAI/PGA=0 for 1 yr at all visits; Relapsing-Remitting (RR), periods of disease activity (SLEDAI/PGA>0) interspersed with periods of disease inactivity (SLEDAI/PGA=0) at 1 or more visits during 1 yr; Chronic Active (CA), SLEDAI/PGA scores are >0 for 1 yr at all visits. Disease activity at yearly intervals ("1-yr blocks") was readily classified into 1 of the 3 major patterns for each patient. The pattern in each patient of 3 consecutive F/U years ("3-yr blocks") was also determined: Persistent Long Quiescent (pLQ), LQ pattern in each of the 3 yrs; Persistent Remissing-Remitting (pRR), RR pattern in each of the 3 yrs; Persistent Chronic Active (pCA), CA pattern in each of the 3 yrs; Mixed, at least 2 different patterns during 3 consecutive yrs. The frequency of different pattern groups (LQ, RR, CA) in each "1-yr-block" and pattern subgroups (pLQ, pRR, pCA, Mixed) in each "3-yr-block" of F/U was examined.

Results: Three major patterns of SLE disease activity were identified: LQ, RR, and CA. The RR pattern accounted for the greatest proportion of F/U time for both the SLEDAI and PGA, representing 48% and 52**%** of total person-yrs, respectively. The CA pattern was the second most frequent pattern observed. The least prevalent pattern was the LQ, indicating that 655 patients experience 1674 LQ "1-yr-blocks", and 352 patients experience 981 LQ "1-yr-blocks", using SLEDAI and PGA, respectively. When disease activity was defined within 3-yr intervals, the Mixed pattern was the most common for both the SLEDAI and PGA, representing 55% of total "3-yr blocks". The pRR and pCA patterns were intermediate and similar in frequency. The pLQ was the least frequent subgroup. The SLEDAI was more likely to depict the LQ pattern than was the PGA.

Conclusion: In this large cohort, the three major patterns of SLE disease activity as originally identified by Barr et al. were confirmed. In the present study, the RR pattern appeared to be the most prevalent pattern type. Long quiescence was achieved in a subset of patients. Over a 3-yr perspective almost half the patient maintained their disease activity pattern.

	1-YEAR-BLOCKS			3-YEAR-BLOCKS			
	RR	CA	LQ	pRR	pCA	pLQ	Mixed
PGA	52%	38.5%	9.5%	21%	20.6%	3%	55.4%
SLEDAI	48%	35.5%	16%	18%	21%	5.7%	55%

Frequencies of different disease activity pattern groups observed at both 1-year-, and 3-year intervals.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Treatment of systemic lupus erythematosus (SLE) aims at controlling disease activity to prevent damage. In a large multi-centre cohort of prevalent SLE patients we previously described a high proportion of patients with active disease and requiring steroid treatment. We examined changes in disease activity over time in this cohort.

Methods:

Predictors of changes in disease activity over the follow-up period, including symptoms, sociodemographic characteristics, and treatment were described in our cohort. Four groups were created based on their SLEDAI score at cohort entry (T0): 1: no or low (<4); 2: moderate (4 to <6); 3: active (6 to <10) and 4: highly active (≥10). Linear and mixed regression models) were used to identify predictors of changes in SLEDAI over time.

Results:

Among 2,048 participants, 1314, 553, 271, 183 and 146 had follow-up data at 1, 2, 3, 4 and 5 years, respectively. At T0, for all patients, mean (sd) age was 42 years (17), age at diagnosis was 31 (15), disease duration 11 (10) years. There were 90% females, 84 % had completed high school, and 63% were Caucasians. At T0, almost half of the patients were in Group 1 (n=898, 44%; 95%CI: 42-46%), 1/5 were in Group 2 (n=406, 20%; 95%CI: 18-22%) or Group 3 (n=447, 22%; 95%CI: 20-24%), while 287 (14%; 95%CI: 13-16%) were in Group 4. The probability that patients in Group 1 at T0 would move to a higher disease activity level was 30% at 1 year, 36% at 2 years, 49% at 3 years, 59% at 4 years and 54% at 5 years; transitions shown in Figure 1. In linear regression of changes in the 1st year, higher SLEDAI at T0 was a very significant predictor of higher SLEDAI at year 1 (0.3 unit increase for each additional SLEDAI unit at T0; p<0.00001). Higher Income was associated with lower SLEDAI at Yr 1 (0.5 unit decrease per each higher of 5 income categories, p=0.002), but there were no demographic or clinical predictors of disease activity changes. In mixed model analyses of i. longitudinal data across follow-up, and ii. if/how variables at previous visits predict changes in SLEDAI scores at the next visit, higher T0 SLEDAI was the single significant predictor of higher SLEDAI across the follow-up (1 unit increase in Yr 0 is associated with 0.3 increase in Yr1, p=0.001; and 0.3 increase per 1 unit increase at previous visit, p<0.0001), again without significant demographic or clinical predictors of disease activity changes.

Conclusion:

In our analyses more than 1/2 the patients had active disease at T0, and 116 (64.1%) of 181 patients with moderate to high disease activity at T0, who had at least 3 years of follow-up remained in this category for at least 3 years. Higher SLEDAI was the single major independent predictor of higher SLEDAI over time. Our data support persistence of active disease over the disease course in a significant subset of patients, even in those with longstanding disease. This highlights gaps in the optimal treatment of lupus and the need for additional therapies.

Diet and Glucocorticoid Treatment in Patients with SLE

Cecilia Lourdudoss[1], Johan Frostegård[2] and Ronald F. van Vollenhoven[3], [1]Dept. of Medicine, ClinTRID, Karolinska institutet, Stockholm, Sweden, [2]Karolinska Institutet, Section of Immunology and chronic disease, Institute of Environmental Medicine, Stockholm, Sweden, [3]Department of Medicine, Unit for Clinical Therapy Research, Inflammatory Diseases (ClinTRID), The Karolinska Institute, Stockholm, Sweden

Session Date: Tuesday, November 10, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Relatively little is known about the link between diet and treatment results in SLE. Glucocorticoids (GC) are used to control active SLE but minimized whenever possible in order to avoid long-term side effects. The aim of this study was to investigate whether diet influences GC treatment in SLE patients.

Methods:

This study included 111 SLE patients from SLE Vascular Impact Cohort (SLEVIC), Karolinska institutet, Stockholm, Sweden. We linked dietary data from food frequency questionnaires with data on GC treatment from medical records for the year preceding and the year following the food survey. Associations between diet and GC treatment during the two years period were analyzed with logistic regression, adjusted for age and gender. GC treatment was considered a proxy for more active SLE; unchanged or increased GC doses were considered unfavorable outcomes.

Results:

Patient characteristics	N=111
Age (years), mean ± SD	47.9
Female, n (%)	100 (87.7)
BMI (Kg/m^2), mean ± SD	25.0 ± 4.5
Smokers, n (%)	46 (40.4)
CRP (mg/L), mean ± SD	4.9 ± 6.5
SLAM, median (IQR)	6 (4-9.25)
SLEDAI, median (IQR)	2 (0-6)
SLICC, median (IQR)	1 (0-3)
GC use at inclusion, n (%)	69 (61.6)
- Dose, (mg/day) mean ± SD	6.2 ± 3.9
GC use at -1year, n (%)	66 (63.5)
- Dose, (mg/day) mean ± SD	5.9 ± 2.5
GC use at +1year, n (%)	66 (66.0)
- Dose, (mg/day) mean ± SD	7.7 ± 7.7

Higher dietary intake of vitamin D was more common in patients treated with GC (OR=2.9). Alcohol was inversely associated with GC treatment (OR=0.3-0.4). Higher intake of vitamin B12, retinol, and calcium were related to unchanged/increased GC dose (OR=3.0-4.6), but higher intake of fatty acid C18:2 and beta-carotene were found in patients with decreased GC dose during year -1 to inclusion (OR=0.3 and 0.2 respectively). Finally, a positive association was seen between higher intake of several nutrients and GC dose levels of >2.5, >5.0, and >7.5 mg/day.

Conclusion:

Higher dietary intake of vitamin D did not protect against lupus activity. Higher intake of C18:2 (omega-6) and beta-carotene (anti-oxidant) may protect against unfavorable outcomes (need for increases in GC dose). The inverse association between alcohol intake and GC treatment/lupus activity may provide a partial explanation for the link between moderate alcohol intake and improved cardiovascular health in rheumatic diseases. The association between higher dietary intake and higher GC dose levels indicated GC's influence on increasing appetite.

Session Date: Tuesday, November 10, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III

Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: To assess the impact of thrombotic events (TE) on 1) mortality, 2) SLE-related damage accrual; and 3) health-related quality of life (HRQoL) in patients with SLE.

Methods: We included patients participating in a prospective cohort (1990-2014). Demographic, SLE-related clinical and laboratory data were extracted. The TE group included patients with any venous or arterial event occurring after enrollment in the cohort. The non-TE group included those with no TE ever. Chi-Square test, t-tests, and Kaplan-Meier survival analysis were used to identify the differences between those with and without TE in terms of: 1) mortality by all causes; 2) damage accrual since TE using the SLICC/ACR Damage Index (SDI) excluding all vascular domains (mod-SDI); and 3) HRQoL using the mental (MCS) and physical (PCS) component summary scores of the SF-36 questionnaire.

Results: A total 1015 SLE patients were included in analysis. A univariate comparison of TE (n = 151) vs non-TE (n = 864) showed: older age at SLE diagnosis (33.8 ± 14.2 vs 30.9 ± 13.1 years, P = 0.01); lower proportion of females (82.8% vs 88.7%, P = 0.04); higher frequency of antiphospholipid antibody positivity (20.5% vs 14.1%, P = 0.04); no difference in time from SLE diagnosis to first visit to the clinic (13.8 ± 17.6 vs 14.9 ± 17.4 months, P = 0.45); no difference in survival time (75% survival time: 22 vs 27 years, P = 0.70); and more non-vascular damage (mod-SDI >0: 80.8% vs 56.9%, P ≤ 0.0001; mean mod-SDI: 1.8 ± 1.8 vs 1.1 ± 1.5, P ≤ 0.0001). Among 44 patients with TE, no differences in HRQoL MCS or PCS were observed between the groups. These results did not differ by type of TE.

Conclusion: Compared to those without TE, SLE patients with TE accrued more chronic non-vascular damage. We found no difference in mortality, and in the subgroup of TE patients assessed, HRQoL did not differ between the groups.

Is Pregnancy a Risk Factor for the Onset of Systemic Lupus Erythematosus (SLE) in Women of the Reproductive Age: A Population Based Case-Control Study?

Chi Chiu Mok[1], Sau Mei Tse[1], Ling Yin Ho[2] and Kar Li Chan[1], [1]Medicine, Tuen Mun Hospital, Hong Kong, Hong Kong, [2]Dept of Medicine, Tuen Mun Hospital, Hong Kong SAR, Hong Kong
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: To evaluate whether pregnancy is a risk factor for the onset of SLE in women of the reproductive age.

Methods:

Female patients who had first onset of SLE during pregnancy between the age of 15 and 49 years were identified from our SLE cohort database (year 1999-2013). The incidence of SLE during pregnancy in women of the reproductive age was calculated by the ratio of pregnancy-onset SLE and the total number of obstetric deliveries in our hospital within the same study period (data retrieved from the obstetric registry). The observed incidence of SLE onset during pregnancy was compared with the expected incidence of SLE in women of the reproductive age (age 15-49 years) in the general population (data retrieved from a clinical registry of all public hospitals in Hong Kong using the diagnostic codes of SLE and its related complications, and the population census data in the years 2001, 2006 and 2011) by the Chi-square test (95% asymptotic confidence intervals calculated). The clinical presentations, course and prognosis of pregnancy-onset SLE were compared with other non-pregnancy-onset female SLE patients.

Results:

742 female SLE patients were in our cohort; 15 patients had first onset of SLE during their pregnancies (age of onset 29.5±5.3 years; 13% in first trimester, 47% in second trimester, 40% in third trimester). Compared to non-pregnancy-onset female SLE patients (N=727), there were more renal disease, thrombocytopenia and central nervous system involvement as initial manifestations of

pregnancy-onset SLE. Three (20%) patients also qualified the diagnosis of the obstetric antiphospholipid syndrome. Fetal outcome was poor in patients with onset of SLE during pregnancy: intrauterine death (13%), spontaneous or therapeutic abortion (33%) and preterm delivery (13%). The maternal prognosis of pregnancy-onset SLE, however, was generally good, with good response to treatment and very infrequent disease flares on follow-up. The SDI damage score was significantly lower in pregnancy-onset than non-pregnancy-onset SLE patients (0.33±0.49 vs 1.09±1.6; p<0.001). There was no mortality in pregnancy-onset SLE patients (compared to 11.4% in the remaining cohort). The total number of deliveries registered in our hospital in women of the age 15-49 years between 1999 and 2013 was 71224. The observed incidence of SLE during pregnancy was 0.014/1000 person-year. During the same time period, the incidence of new onset SLE in all public hospitals in Hong Kong relative to the mean female population (15-49 years of age) from 1999 to 2013 was 0.077/1000 person-year. The odds ratio (OR) of having new onset SLE during pregnancy was 0.22 (95%CI 0.13-0.39; p<0.001).

Conclusion:

In women of the reproductive age, pregnancy protects against the development of SLE. First onset of SLE during pregnancy often leads to poor fetal outcome. However, the maternal outcome of pregnancy-onset SLE is generally good, with good response to treatment, infrequent relapse of organ manifestations and smaller risk of organ damage in the long run.

A Retrospective Observational Study of Patients with Lupus Nephritis Treated with Rituximab in Combination with Cyclophosphamide

Nídia Oliveira[1], Mónica Ibañez[2], Natalia Ciang[3] and David A. Isenberg[4], [1]Internal Medicine Department, Hospital Pedro Hispano, Matosinhos, Portugal, London, United Kingdom, [2]Rheumatology Department, Hospital Son Llàtzer, Palma de Mallorca, Spain, London, United Kingdom, [3]Rheumatology Department, Queen Eliazbeth Hospital, Hong Kong, London, United Kingdom, [4]Rayne Institute, Centre for Rheumatology Research, UCL Division of Medicine, London, United Kingdom

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Lupus nephritis (LN) is a major cause of morbidity. Many patients with refractory disease can not tolerate conventional immunosuppressive therapy. The aims of this study were to describe the comorbidities at baseline, most relevant manifestations at diagnosis, concomitant medications used with disease-modifying anti-rheumatic drugs and prednisolone in lupus patients given Rituximab (RTX). Additionally, we identified what variables are associated with renal response at 12 months.

Methods:

A 13 year retrospective analysis was completed on 42 LN patients treated with combination therapy of RTX and cyclophosphamide (CYC). We defined Renal flare (RF), Complete (CR) and Partial (PR) Renal Response according to the EULAR/ERA-EDTA criteria. The response was defined at 12 months after the treatment with RTX.

Results:

Based on 42 patients treated with RTX 2g in combination with CYC 750 mg for active LN: 38 patients were female with a median age at diagnosis of 38 years, interquartile range [IQR: 25 – 46]. 12 (28.6%) were Caucasian, 17 (40.5%) Black, and 10 (23.8%) South-Asian. The most frequent comorbidities were high blood pressure (52.4%), dyslipidaemia (26.2%), depression (23.8%), skin (26%), pulmonary (26%) and infectious disease (28.6%). 6 (14.3%) had associated autoimmune diseases (APS 7%; Sjögren's Syndrome 4.8%). The main manifestations at diagnosis were: constitutional in 36 (85.7%), mucocutaneous in 39 (93%), musculoskeletal in 38 (90.5%), hematological in 22 (52.4%), cardiorespiratory in 19 (45.2%), gastrointestinal in 9 (21.4%), neuropsychiatric in 13 (31%) and renal in 38 (90.5%). Prior RTX administration, the most frequently medications used were: MMF in 19 patients (45%), Hydroxychloroquine in 15 (35.7%), Azathioprine in 9 (21.4%) and Prednisone <10mg/d in 25 (60%) and 11-30 mg/d in 13 (31%).

2 patients had class II, 7 class III, 20 class IV, 8 class V, and 4 with mixed (II+III; IV+V; V+III) LN.

At 12 months post-RTX therapy, 14 patients achieved renal response and 15 patients were non responders. 9 patients had a new flare before 12 months, 2 had no retrievable information and 2 patients died at 4 and 5 months post-RTX.

22 out of 42 were retreated due to a flare (Renal/Non renal). Patients with GN type 4 were more prone to flare and required re-treatment with B cell depletion.

The time between first dose of RTX and second treatment was 25 ± 22.4 months.

We found a significant association between renal response at 12 months post-RTX and age (35.64 vs 42.87; $p<0.05$); lower levels of serum creatinine (91.07 vs 120.38; $p<0.05$) and higher levels of dsDNA (1063 vs 474; $p<0.05$) at baseline; absence of dyslipidemia (15.4%; $p<0.05$) or anaemia (15.4%; $p<0.05$); absence of cardio-respiratory (23.1%; $p<0.05$) and ocular involvement (0%; $p<0.05$) at diagnosis. We determined that there was no difference with ethnicity, gender, concomitant treatments, type of GN or levels of complement.

Conclusion:

We have shown that patients who achieved a Renal Response at 12 months post-RTX were younger, had a lower levels of creatinine and higher levels of dsDNA at baseline.

More prospective studies and randomized control trials are needed to understand better this complex disease

Low Prevalence of PCP in Hospitalized Patients with SLE: Review of a Clinical Database Warehouse

Teja Kapoor[1], Jianhua Li[2], Sameer Malhotra[3], Joan Bathon[4] and Anca Askanase[5], [1]Columbia University, New York, NY, [2]Columbia University Medical Center, New York, NY, [3]Weill Cornell Medical Center, New York, NY, [4]Rheumatology, Columbia University Medical Center, NY, NY, [5]Columbia University College of Physicians & Surgeons, New York, NY

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose : The risk of Pneumocystis carinii pneumonia (PCP) in Systemic Lupus Erythematosus (SLE) is not well-established. Accordingly, this study aims to establish the prevalence of PCP in hospitalized SLE patients.

Methods : This is a retrospective cohort study evaluating the prevalence of PCP in hospitalized patients with SLE. Data was obtained from the Columbia University Medical Center (CUMC) Clinical Data Warehouse from January 2000 to September 2014. HIV-positive patients and patients with renal transplant were used as controls.

Results : Patients with SLE were identified by searching the database for an ICD-9 of 710.0; as such, 4,800 patients were identified. Chart review of a sample of 107 charts (roughly 3% of the identified 4,800) was used to verify the diagnosis of SLE. Of the 107 charts reviewed, SLE case definitions were assigned: a) met 4 out of 11 ACR or SLICC SLE criteria = 58 patients (54%), b) has 2-3 SLE criteria along with Lupus medications and/or Lupus auto-antibodies or met only 1 SLE criteria but had a previous diagnosis of SLE by a rheumatologist and were treated with SLE medication = 21 patients (20%), c) had a history of Lupus (usually "Lupus in remission") without criteria verification, of which half had +ANA = 7 (7%). 21/107 (20%) of patients in the sample did not have SLE but had a diagnosis of another autoimmune disease, such as Sjogren's syndrome, RA, scleroderma, vasculitis, or polymyositis. We decided to consider only the first two groups that met the most stringent SLE case definition to represent the true SLE cases, i.e 74% as of the 4800 patients (3,552) were extrapolated as having SLE, which is consistent with other studies of administrative databases.

A total of 9 cases of PCP in SLE patients were identified. The diagnosis of PCP was made based on clinical and radiographic evidence. PCP Gomori methenamine silver stain was negative in 8/9.

Prevalence of PCP in SLE, renal transplant, and HIV patients is presented in the following table.

PATIENTS:	PCP DIAGNOSIS based on hospital discharge
SLE, N=3,552	N=9 (0.25%)
SLE with HIV, N=40	N=3 (7.50%) P<0.05
HIV, N=9,060	N=542 (5.98%) P<0.05
Renal transplant, N=5,885	N=36 (0.61%) P=0.01

Of the 9 cases of PCP, 8 patients met SLE criteria as defined above, and 1 patient had a confirmed historical diagnosis of SLE. In addition, 3/9 patients had co-existing AIDS with a median CD4 count of 31.

All patients were treated with IV trimethoprim-sulfamethoxazole and discharged; no deaths occurred. None of the patients were on PCP prophylaxis prior to admission, which is not routinely done for SLE patients at CUMC.

Conclusion : The risk of PCP in SLE is low compared to other immunosuppressed patients, such as HIV or renal transplant. All patients responded to treatment with trimethoprim-sulfamethoxazole. This data does not substantiate the need for PCP prophylaxis, except for patients with SLE-HIV. Although rare, SLE patients admitted with bilateral infiltrates should have a low threshold for initiating PCP treatment.

Endothelial Dysfunction in SLE-the Role of Platelets and Type I Interferon

Helena Tydén[1], Christian Lood[2], Birgitta Gullstrand[3], Andreas Jönsen[4] and Anders A. Bengtsson[5], [1]Department of Clinical Sciences, Division of Rheumatology Lund University and Skane University Hospital Lund Sweden, Lund University, Lund, Sweden, [2]Department of Clinical Sciences, Division of Rheumatology, Lund University and Skane University Hospital Lund Sweden, Lund University, Lund, Sweden, [3]Department of Clinical Sciences, Division of Rheumatology Lund University and Skane University Hospital, Lund University, Lund, Sweden, [4]Department of Rheumatology, Lund University Hospital, Lund, Sweden, [5]Rheumatology, Inst of Clinical sciences, Lund, Sweden

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Type I interferon (IFN) may affect endothelial progenitor cells leading to endothelial dysfunction in SLE. SLE patients have a type I IFN signature in platelets associated with cardiovascular disease (CVD). The objectives were to investigate if there is an association between type I IFN activation, endothelial dysfunction and platelet activation in SLE and if young SLE patients have increased arterial stiffness and impaired endothelial function.

Methods:

SLE patients n=148,(n=144 fulfilling≥ 4 ACR classification criteria for SLE, 87% women, mean age 49 years old) and 79 sex- and age matched healthy controls (HC) were tested. Endothelial dysfunction (ED) and Augmentation Index (AI) were measured by EndoPAT 2000 (Itamar Medical, Israel). Elevated AI indicates increased arterial stiffness and a low Reactive Hyperemia Index (RHI) value indicates ED. Surrogate markers for ED; sVCAM-1 and vWF were measured with ELISA. Type I IFN activity was measured by a

serum IFN-reporter gene expression assay (s-IFN score), type I IFN signature was assessed in peripheral blood mononuclear cells (PBMCs) as PBMC- IFN and the type I IFN regulated protein G3BP was measured by ELISA.

Platelet activation was measured as levels of platelet C4d deposition (p-C4d dep), platelet- monocyte complex (p-mc compl) and platelet- granulocyte complex (p-gc compl), measured by flow cytometry.

Results:

A low RHI was seen in SLE patients with ongoing type I IFN activity compared to HC (OR 2.61 CI 95% 1.04-6.53 p= 0.04). No differences were seen when comparing all SLE patients with HC (OR 1.30 CI 95% 0.66-2.58 p=0.450).

ED (low RHI and/or high sVCAM-1) was seen in SLE patients with ongoing type I IFN activity measured as IFN score, G3BP and high PBMC-IFN signature.

High sVCAM-1, was seen in patients with a high value of s-IFN score (OR 6.12 CI 95% 2.21-16.93 p<0.001), a high G3BP level (OR 3.38 CI 95% 1.41-8.06 p=0.006) and high levels of PBMC- IFN (OR 7.89 CI 95% 2.87-21.7 p<0.0001). ED measured with a low RHI was seen in patients with high s-IFN score (OR 2.53 CI 95% 1.07-5.97 p=0.035) and high G3BP (OR 2.36 CI 95% 1.025-5.45 p=0.044)

Young SLE patients seemed to have increased arterial stiffness compared to HC, since AI was clearly increased (OR 2.95 CI 95% 1.24-7.02 p=0.015) in SLE patients 18-45 years of age.

High levels of p-C4d dep and p-mc compl were seen in SLE compared to HC (OR 13,5 CI 95% 4.07-45.1 p<0.000) and (OR 2.84 CI 95% 1.19-6.8 p=0.019), respectively, demonstrating more activated platelets in SLE. SLE patients with low RHI had increased levels of p-mc compl (OR 2.92 CI 95% 1.22-6.99 p=0.016). SLE patients with high sVCAM-1 had increased p-gc compl and p-C4d dep (OR 3.39 CI 95% 1.19-9.66 p=0.022) and (OR 3.33 CI 95% 1.58-7.03 p= 0.002), respectively showing more activated platelets in SLE patients with ED.

Conclusion:

Increased arterial stiffness was seen in young SLE patients, suggesting that early primary preventive treatment might be important already in younger patients.

SLE patients with activated type I IFN system have impaired endothelial function. This may act together with activated platelets due to injured endothelium, in the development of CVD in SLE.

Disease Evolution in Late Onset and Early Onset Systemic Lupus Erythematosus (SLE)

Roa'a Al Johani[1], Dafna Gladman[2], Jiandong Su[2] and Murray Urowitz[2,3], [1]Medicine, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, [2]Rheumatology, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, [3]Rheumatology, U of Toronto, Toronto Western Hospital, Toronto, ON, Canada

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To compare clinical features, disease activity and outcome in late onset versus early onset SLE over 5 years of follow up.

Methods: Patients with SLE are followed prospectively according to standard protocol and tracked on a computerized database. Patients entering the cohort within one year of diagnosis constitute the inception cohort. Patients with late onset (age at diagnosis ≥ 50 were identified and matched 1:2 based on gender and first clinic visit (+/- 5) years with patients with early disease onset (age at

diagnosis 18- 40 years). Groups were compared at baseline and 5-year follow up. Disease activity was measured by the SLE Disease Activity Index (SLEDAI-2K) and Damage was assessed by the Systemic Lupus International Collaborating Clinics/American College of Rheumatology(SLICC/ACR) damage index. All information is collected prospectively in the database.

Results: A total of 86 patients with late onset disease (84.9% female,81.4% Caucasian ,mean age ±SD 58.05 ± 7.30) and 169 patients with early onset disease (86.4% were female , 71% Caucasian, mean age± SD 27.80 ± 5.90) were identified.

Variables	At baseline			5 years		
	Late (N= 86)	Early (N=169)	P value	Late (N= 86)	Early (N=169)	P value
ACR criteria*	4.92 ± 1.05	5.32 ± 1.15	0.001	5.60 ± 1.17	6.31 ± 1.34	0.0001
SLEDAI-2K score*	4.58 ± 4.68	6.18 ± 6.24	0.006	3.41 ± 4.84	4.09 ± 4.40	0.173
Total SDI*	0.15 ± 0.43	0.17 ± 0.60	0.928	0.98 ± 1.28	0.69 ± 1.16	0.005
SLICC ≥ 1	9(10.4%)	17(10.1%)	-	43(50.1%)	88(36.1%)	-
IS use	11 (12.8%)	43 (25.4%)	0.001	19 (22.1%)	61 (36.1%)	0.001
Steroid use	60 (69.8%)	102 (60.4%)	0.083	44 (51.2%)	95 (56.2%)	0.340
Average steroids dose in mg/d	22.53 ± 13.07	30.23 ±19.35	0.021	12.58 ± 6.60	15.18±8.51	0.004
* Mean ± SD ; IS= immunosuppressive						

At enrollment, late onset SLE had a lower total number of ACR criteria, less renal and neurologic manifestations. Mean SLEDAI-2K scores were lower in late onset SLE, especially renal features and anti-DNA positivity. Over 5 years, mean SLEDAI-2K scores decreased in both groups, while mean SDI scores increased more significantly in the late onset group ; they developed more cardiovascular, renal and ocular damage , had higher prevalence of hypertension and hypercholesterolemia.

Conclusion: Although late onset SLE group had a milder presentation and less active disease, with the evolution of disease, they developed more organ damage likely a consequence of cardiovascular risk factors and aging.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The evolution on an annual basis of disease activity and damage and the annual accrual of ACR criteria and key autoantibodies in patients with SLE is not well described. We report the annual occurrence of these features in an inception cohort of patients with SLE.

Methods: An international research network comprising 33 centres from 11 countries has followed an inception cohort of SLE patients yearly according to a standardized protocol between 2000 and 2014. Of these, 748 patients followed for a minimum of 7 years constitute the study population. Clinical disease activity was assessed using SLEDAI-2K and disease damage using the SLICC/ACR

Damage Index (SLICC/DI). ANA, Anti-DNA and anticardiolipin, antibody levels, the presence of the lupus anticoagulant were assessed at each visit. Descriptive statistics were used.

Results: Of the 748 patients followed for at least 7 years, 90.2% were female, 49.1% were Caucasian, 14.8% were Black, 16.3% were Asian, 15.9% Hispanic and 3.9% other. 40.8% were married and 57.2% had at least College education. Their mean age at enrolment was 34.7±13.4years and SLEDAI-2K at enrolment was 5.6±5.7. The duration from diagnosis to enrolment was 5.5±4.2 months.

Table 1: Mean SLEDAI-2K, SDI and ACR Accumulation in the First 7 Years of Follow-up

FU	Annual SLEDAI-2K		SDI		Cumulative ACR Criteria	
	N	Mean ± std	N	Mean ± std	N	Mean ± std
0	745	5.62±5.70	632*	0.14±0.49	748	5.05±1.13
1	679	3.75±4.33	678	0.44±0.88	679	5.42±1.25
2	660	3.57±4.32	660	0.55±1.01	660	5.65±1.34
3	636	3.28±3.56	637	0.68±1.12	637	5.84±1.39
4	605	3.50±3.95	625	0.80±1.22	625	5.93±1.37
5	619	3.35±3.94	621	0.92±1.35	621	6.04±1.42
6	619	3.39±3.95	621	1.00±1.42	621	6.14±1.46
7	620	3.17±3.57	624	1.08±1.45	624	6.16±1.43

*SDI performed only in those patients with > 6 months disease duration

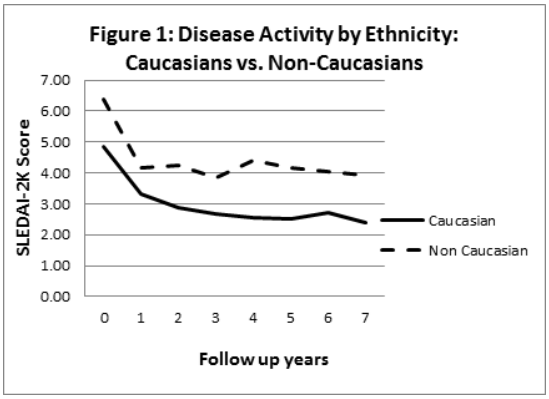

Table 2: Auto-Antibodies and Lupus Anticoagulant Over 7 Years

	Anti-Nuclear Antibody		Anti-DNA		Anticardiolipin		Lupus Anticoagulant	
FU	N	%	N	%	N	%	N	%
0	748	96.2	637	41.2	584	14.7	618	21.8
1	679	97.4	624	31.7	498	12.0	499	19.7
2	660	97.4	649	30.9	440	11.9	440	20.9
3	637	97.4	633	28.5	375	9.5	377	24.2
4	625	97.5	620	31.6	263	11.7	266	20.3
5	621	98.1	615	33.3	195	8.0	201	23.2
6	621	98.0	612	35.5	178	8.6	174	15.9
7	624	98.1	606	34.5	119	9.6	115	11.6

Mean SLEDAI-2K decreases to low levels in the first year and then remains low. SLEDAI-2K was significantly lower at each year in Caucasians compared to Non-Caucasians. Mean SLICC/DI increases progressively over the 7 years but there was no significant difference at each year between Caucasians and Non-Caucasians. Mean ACR criteria accumulation gradually increases over 7 years, with Caucasians accumulating less ACR criteria in the first 2 years of disease as compared to Non-Caucasians.

Although ANA positivity is high at enrolment, the percent positivity remains stable over 7 years. Frequency of anti-DNA positivity is high at enrolment and decreased by almost 7% over 7 years. Anticardiolipin antibody and the lupus anticoagulant decreases by 5% and 10% over 7 years respectively.

Conclusion: As expected disease activity in newly diagnosed patient's decreases over their first 7 years but disease damage increases. Similarly, key antibody levels with the exception of ANA positivity decreased over the first 7 years of disease.

Treatment Patterns Differ Based on Age of Systemic Lupus Erythematosus Onset: A Comparison of Azathioprine and Mycophenolate on the Prevention of Lupus Nephritis

J. Madison Hyer[1], Bethany Wolf[1], Jim Oates[2], Gary S. Gilkeson[3] and Diane L. Kamen[2], [1]Public Health Sciences, Medical University of South Carolina, Charleston, SC, [2]Medicine, Medical University of South Carolina, Charleston, SC, [3]Department of Rheumatology, Medical University of South Carolina, Charleston, SC

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Lupus nephritis (LN) is a major cause of morbidity and mortality among patients with systemic lupus erythematous (SLE). Studies have demonstrated efficacy and safety for mycophenolate mofetil (MMF) in LN, but use of MMF for extra-renal manifestations of SLE has not been as well-described as for azathioprine (AZA). This study was conducted to assess whether use of either MMF or AZA for extra-renal manifestations of SLE protects against development of future LN and whether treatment affects vary depending on age of SLE onset.

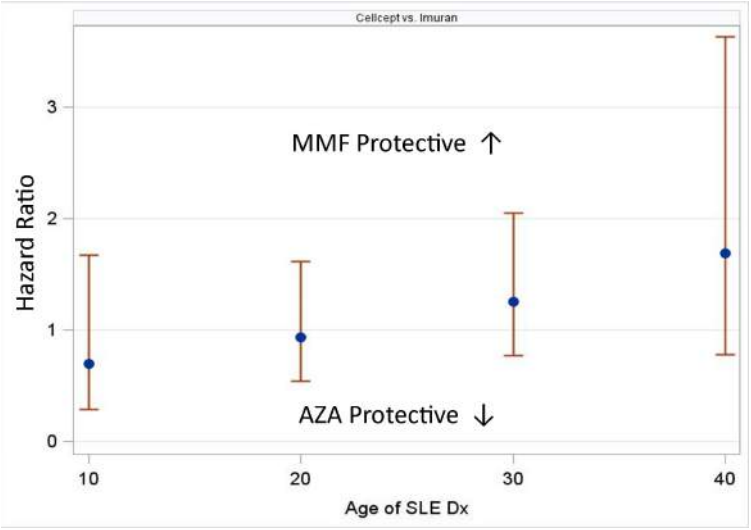
Methods:

Data was collected on patients with SLE consented and enrolled in a longitudinal registry started in 2003. Data included, but were not limited to, medication use and changes over time, medical history, and demographics. To assess the effects of treatment and the potential modification of treatment effect by age of SLE onset, Cox proportion-hazards modeling, controlling for gender, race, and hydroxychloroquine use, was utilized- allowing treatment to vary over time.

Results:

Of the 533 patients with SLE, 90.4% were female and 76.7% were African American. The average age at SLE onset was 30.4 years (sd = 13.7) with a range of 3 to 76 years of age. Among those diagnosed with LN (n = 251, 47.1%), the average time between diagnosis of SLE and LN was 6.3 years (sd = 5.4) with a range of less than a year to more than thirty years.

When comparing patients taking MMF or AZA to those not taking either: there is no increased risk of developing LN for patients taking either medications at decade-ages 10 and 20; for MMF, there was no statistically or clinically significant increased risk of developing LN at decade-ages 30 and 40; for AZA, there is a clinical risk and, at decade-age 40, a statistically significant risk of developing renal disease; for both, AZA and MMF, there is an upward trend of the risk estimates as age of SLE onset increases. When comparing AZA to MMF usage, there was no clinical or statistical difference found at any decade-age. Moreover, when comparing AZA to MMF usage, there is trend from indifference in treatment benefit to MMF benefit over AZA around decade-ages 30 and 40.



Conclusion:

Within a large registry of patients with SLE, we found increasing use of MMF for extra-renal manifestations of SLE. For patients diagnosed with SLE at a later age, our data suggests that MMF has a protective effect over AZA in preventing future LN. Although this same protective effect was not seen within patients with childhood-onset SLE, MMF was prescribed to patients across all ages who were at higher risk of LN, suggesting a possible protective effect which should be explored in prospective studies.

Baseline Predictors of Remission and Low Disease Activity Using Recently Defined International Criteria in a Multi-Center Lupus Registry Cohort

Kichul Ko[1], Alana B. Levine[2], Russell Griffin[3], Olga Dvorkina[4], Saira Sheikh[5], Jinoos Yazdany[6], Richard Furie[7] and Cynthia Aranow[8], [1]Section of Rheumatology and Gwen Knapp Center for Lupus and Immunology Research, University of Chicago, Chicago, IL, [2]Rheumatology, Hospital for Special Surgery, New York, NY, [3]University of Alabama at Birmingham, Birmingham, AL, [4]Medicine, SUNY Health Science Center at Brooklyn, Brooklyn, NY, [5]University of North Carolina, Chapel Hill, NC, [6]Rheumatology, University of California, San Francisco, San Francisco, CA, [7]Division of Rheumatology, North Shore - LIJ Health System, New York, NY, [8]Feinstein Institute for Medical Research, Mahasset, NY

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Treating to a target of remission or low disease activity state (LDAS) is an attractive potential therapeutic approach in SLE. Recently, LDAS and remission in SLE have been proposed by the Asia-Pacific Lupus Collaboration (APLC) and the Definitions of Remission in SLE (DORIS) consensus panel, respectively. We identified 1228 of the 1506 patients who completed enrollment in a real-world SLE registry composed of 17 centers in the United States and Canada who had at least ≥ 1 follow-up visit through one year following enrollment, and we evaluated the incidence and predictors of achieving these outcomes.

Methods: Using definitions created by the APLC and DORIS, subjects were classified into 4 mutually exclusive groups based on the lowest remission or LDAS category they reached and maintained for ≥ 1 year: 1) **Not optimally controlled:** SLEDAI > 4, prednisone > 7.5 mg/d OR physician global assessment (PGA) > 1.0; 2) **LDAS**: SLEDAI ≤ 4, prednisone ≤ 7.5 mg/d AND PGA ≤ 1.0 with

immunosuppressive drugs being allowed; 3) **Remission On Therapy:** Prednisone ≤ 5mg and/or maintenance immunosuppressive agents allowed, SLEDAI = 0 AND PGA ≤ 0.5; 4) **Remission Off Therapy**: No steroids or immunosuppressive agents, SLEDAI = 0 AND PGA ≤ 0.5. Characteristics of subjects at baseline were compared using chi-square and analysis of variance tests (Table 1). A multinomial logistic regression (ordered logit) ranking outcomes from remission off therapy (lowest) to not optimally controlled disease (highest) was used to examine the multivariable association between baseline predictors and ordered outcome.

Results: Among 1228 patients, 91.6 % were female, mean age was 41.1 years (±13.3 y) and median duration of disease was 9.8 years (interquartile range [IQR] 4.96 – 16.34 y). At follow-up (median duration of 2.05 years [IQR 1.54 – 2.44 y]); 930 (75.7%) patients were classified as not optimally controlled; 139 (14.9%) achieved LDAS; and 93 (7.57%) and 66 (5.37%) achieved remission on or off therapy, respectively, for ≥ 1 year. Among the groups, statistically significant differences were observed for age at diagnosis, steroid and immunosuppressive usage, PGA, patient global assessment of disease, SELENA-SLEDAI scores and ACR criteria count (Table 1). In multivariable analysis, decreased odds of a more desirable ordered outcome category were observed for increasing SELENA-SLEDAI scores (odds ratio [OR] 0.89, 95% CI 0.84-0.94), steroid usage (OR 0.74, 95% CI 0.84-0.94) and increasing patient global assessment (OR 0.993, 95% CI 0.987-0.999).

Conclusion: Optimal control of SLE disease activity through one year, defined as LDAS or remission on/off therapy, was achieved in 24.3 % of patients in the LCTC cohort. Baseline predictors of better control of SLE at follow-up included lower SELENA-SLEDAI scores, no steroids and lower patient global assessment of disease.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Tabalumab is a monoclonal antibody that neutralizes membrane and soluble B-cell activating factor. Two 52-week, randomized, double-blinded, placebo-controlled Phase 3 trials, designated BCDS and BCDT, were done to evaluate the safety and efficacy of tabalumab in non-renal disease manifestations in patients with systemic lupus erythematosus (SLE).

Methods: Patients with moderate-severe active SLE but without severe active lupus nephritis (defined as a urine protein/creatinine ratio of >200 mg/mmol or an estimated creatinine clearance of <30 mL/min) were randomized 1:1:1 to receive tabalumab (120 mg subcutaneously every 4 weeks or 120 mg subcutaneously every 2 weeks) or placebo for 52 weeks. Serum creatinine, glomerular filtration rate, urine protein/creatinine ratio, and renal adverse events were determined monthly. Data were analyzed for the intent-to-treat population and for intent-to-treat patients with a baseline urine protein/creatinine ratio >20 mg/mmol using an ANCOVA model.

Results: The trials enrolled 2262 patients. At baseline, demographics, SLE disease activity, use of SLE drugs, serum creatinine, glomerular filtration rate, and urine protein/creatinine ratio were similar among the treatment arms. In the two populations, there were no differences between treatment arms in baseline-to-endpoint change in serum creatinine, glomerular filtration rate, and urine protein/creatinine ratio (Tables 1-2). Renal adverse events were not different among treatment arms.

Conclusion: Compared to placebo, tabalumab did not significantly affect serum creatinine, glomerular filtration rate, and urine protein/creatinine ratio over 52 weeks in the intent-to-treat population or intent-to-treat patients with a baseline urine protein/creatinine ratio >20 mg/mmol. There were no significant renal safety signals.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Thrombotic events (TE) cause great morbidity and mortality in SLE patients. Studies of TE in SLE focus on early-onset TE. While the incidence of TE remains increased during later-stage disease, no study has assessed the risk factors for late-onset TE. The purpose of this study is to: a) assess the characteristics and risk factors associated with late-onset TE (> 5 years after diagnosis) in SLE; and b) compare these with early-onset TE (< 5 years after diagnosis).

Methods: One hundred and fifty-one SLE patients who developed TE after enrolment in a prospective lupus cohort from 1970 to 2014 were identified. They were matched for age, sex and disease duration with non-TE SLE patients (early-onset TE controls: n=151; and late- onset TE controls: n=77). The demographic (age, ethnicity), clinical (disease duration, ACR criteria, SLE manifestations), lab (anti-dsDNA antibody, C3, C4, nuclear antigens, lupus anticoagulant, anti-cardiolipin antibody), disease activity (SLEDAI-2K), disease damage [SLICC Damage Index with cardiovascular items removed (mod-SDI)] and treatment (prednisone, immunosuppressants, antimalarials, anti-inflammatories), as well as TE type [arterial (ATE), venous (VTE)] and traditional TE risk factor (smoking, cholesterol levels and hypertension) variables were recorded.

Results: Fifty (33%) patients developed late-onset and 101 (67%) early-onset TE. In comparison with early- onsetTE, late-onset TE

were predominantly ATE (62.0% vs 45%, *P=0.02*). In univariate analysis, significant variables associated with late-onset TE were hypertension (OR 3.97, P<*0.01*), oral/nasal ulcers (OR 2.56, *P=0.03*), CNS manifestations (OR 5.40, *P=0.01*), vasculitis (OR 3.48, *P<0.01*), elevated total cholesterol (OR 2.58, *p<0.01*), and prednisone dose within 3 years of TE (OR 1.07, *P*=0.02).

In multivariate analysis, significant predictors of late-onset TE were hypertension (OR 2.85, *P=0.03*), CNS manifestations (OR = 6.66, *P=0.04*), vasculitis (OR = 2.96, *P=0.049*), lupus anti-coagulant (OR = 4.73, *P=0.02*). Risk factors associated with late ATE included a combination of traditional TE risk factor and lupus-related factors; whereas in late VTE risk factors included predominantly lupus-related factors. Variables associated with early-onset TE were also a mixture of traditional and lupus-related risk-factors.

Conclusion: Late-onset TE in SLE is predominantly arterial, and result from both traditional and SLE-related risk factors. The risk of thrombosis remains elevated throughout the course of SLE, resulting from the combination of traditional and SLE-related risk factors. In order to reduce the burden of TE, these risk factors need to be continuously evaluated and controlled throughout the disease course.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Management of SLE and lupus nephritis is challenging as it is always a trade off between remission, prevention of relapse and long term adverse effects of drugs. No previous trial has compared oral mycophenolate mofetil (MMF) with low dose intravenous cyclophosphamide (CYC) as induction agent followed by azathioprine as maintenance agent in the treatment of less severe lupus nephritis (LN).

Methods: This study is a follow-up study of previous open label, ongoing prospective, randomized trial comparing the efficacy and safety of low dose CYC (Euro-lupus regimen) and oral MMF in subjects with class III, IV, V, III+V, or IV+V LN. Subjects with crescentic LN, serum creatinine >3mg/dl, neurological or pulmonary lupus, ongoing infection, pregnancy and prior CYC or MMF use were excluded. The dose of MMF was 2–3 gm/day for 6 months, while CYC was administered as six fortnightly infusions of 500 mg each. All subjects also received three consecutive intravenous methylprednisolone injections initially followed by oral steroids at 1mg/kg up to 2 months and then tapered to a dose of 5-7.5 mg/day. After completion of induction treatment, all subjects were prescribed azathioprine (2 mg/kg) with low dose steroid.

Results: A total of 100 subjects were randomized, of which 69 completed one year of maintenance treatment with azathioprine after receiving either MMF or CYC as induction agent. Out of these 69 subjects, thirty four (n=34) received CYC and thirty five received MMF (n=35) as an induction agent. Baseline characteristics were similar except for a higher 24 hour protein excretion in the CYC group. Sixty one of total subjects, i.e.88.4%, (n=32 in CYC and n =29 in MMF, p=ns) achieved treatment response, of which fifty seven subjects achieved remission. Mean duration to achieve remission in CYC arm was 21.81 weeks and 19.47 weeks in MMF arm. Eight patients had resistant disease (MMF =6, CYC=2), six deaths (MMF=5, CYC=1), four lost to follow up (MMF=1, CYC=3) and one patient deviated from protocol. Four subjects, 3 in MMF and 1 in CYC arm had nephrotic flare during follow up and none had nephritic flare. Gastrointestinal symptoms were more frequent in the MMF group; however there was no difference in other adverse events. Main adverse events during maintenance phase were cytopenia in one patient, herpes zoster in one and avascular necrosis of femoral head in one patient. The treatment cost of MMF was ten times more than the CYC therapy.

Conclusion: One year outcome of maintenance phase with azathioprine were similar in low dose intravenous CYC and oral MMF arm

in treatment of less severe lupus nephritis.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The CNS involvement in cSLE has been described to occur from 25-90% in childhood-onset systemic lupus erythematosus (cSLE). The aim of the study was to investigate the progression of brain and corpus callosum atrophy in cSLE patients.

Methods: We included consecutive cSLE patients followed in the pediatric rheumatology unit at the State University of Campinas. All patients had 2 magnetic resonance imaging (MRI) done during the follow-up period. MRI scans were obtained through a standardized protocol. Volumes ≤2 standard deviation (SD) from the means of controls were considered abnormal. Neurological manifestations were analyzed according to the ACR classification criteria. SLE patients were further assessed for clinical and laboratory SLE manifestations, disease activity [SLE Disease Activity Index (SLEDAI)], damage [Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index (SDI)] and current and cumulative drug exposures. Non-parametric-tests were used for statistical analysis.

Results: We included 44 cSLE patients (mean age 17.1±3.8 years). The control group consisted of 66 healthy volunteers (mean age 17.3±4.4 years) (p=0.15). At study entry, we observed smaller cerebral (mean volume 1073.1±123.8 cm^3) and corpus callosum (CC) (mean volume 11.5 ±1.7 cm^3) volumes in cSLE patients when compared to controls [mean cerebral volume 1182.9±118.9 cm^3; p<0.001 (mean difference (MD): -1139.0 cm^3; 95%CI 1114.1-1163.9)] and mean CC volume 13.6±2.1; cm^3 p<0.001 (MD -12.8 cm^3; 95%CI 12.4-13.2). Cerebral volumes were associated with anxiety (p=0.016), depression (p=0.002), antinuclear antibody (p=0.026) and anti-Sm antibody (p=0.013) in cSLE. CC volumes were associated with psychosis (p=0.039), acute confusional state (p=0.035) and low complement levels (p=0.01). After a mean follow-up mean period of 20.7±9.1 months we observed significant reduction in cerebral volume [mean 1060.6±128.9 cm^3; p<0.001 (MD -1066.8 cm^3; 95%CI: 1040.2-1093.5)] and CC volumes [mean volume 11.3±1.3 cm^3; p<0.001 (MD-11.4 cm^3; 95%CI: 11.1-11.7)] in cSLE patients. Reduction of cerebral volume was associated with corticosteroid dose per kilogram (p=0.035) and reduction of CC volume with nephritis (p=0.033) and low complement (p=0.046). Cerebral and CC volumes were stable in controls over time (p=0.3). Cerebral atrophy was observed in 9 (20.4%) cSLE patients and 1 (1.5%) controls at study entry and in 10 (22.7%) cSLE patients during the follow-up period (p=0.62). CC atrophy was observed in 9 (20.4%) cSLE patients and 1(1.5%) controls at study entry and in 10 (22.7%) cSLE patients during the follow-up period (p=0.62). Cerebral atrophy was associated with anxiety (p=0.008), depression (p=0.014) and anti-Sm antibody (p=0.04) and CC atrophy with low complement levels (p=0.002) in cSLE.

Conclusion: We observe progression of cerebral and CC volume loss in cSLE patients, although the number of patients with atrophy did not increase. Corticosteroid dose and disease activity (nephritis and low complement) were variables associated with progression of volume loss in cSLE.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Given widely varying estimates of the incidence and prevalence of Systemic Lupus Erythematous (SLE) in the US and the absence of data for certain demographic groups attention has turned to obtaining a better epidemiologic understanding of SLE across key ethnic/racial groups. Recently the Centers for Disease Control and Prevention supported four local health departments as well as the Indian Health Service to more rigorously capture cases SLE through the implementation of a population-based registry, the Manhattan Lupus Surveillance Program (MSLP), comprised of SLE patients treated in New York County. The primary goal of the MLSP is to capture information that can be used to determine the prevalence of SLE in 2007 and incidence of SLE during 2007-09 among Manhattan residents. Of specific interest are SLE rates among Hispanics and Asians where epidemiologic data are very limited.

Methods: Potential MLSP cases were identified from Manhattan-based hospitals and rheumatologists, and state population databases. More than 75,000 potential SLE patients were initially identified by screening for key ICD-9 codes. After additional screening based on Manhattan residence and deduplication, trained medical abstractors performed detailed medical chart review on the remaining ~6,400 patients for information on SLE and related conditions. Preliminary MLSP estimates of SLE were calculated based on two current criteria developed by the ACR and the Systemic Lupus International Collaborating Clinics (SLICC). Cases were defined as fulfilling 1) > 4/11 of the ACR classification criteria or 2) the SLICC criteria. Prevalence rates, based on SLE diagnosis by 2007, and incidence rates, based on new SLE diagnosis in 2007-09, and associated 95% confidence intervals (CI) were calculated using denominators obtained from the US Census data (revised 2000-2009 intercensal population files) for Manhattan.

Results: Based on the ACR criteria, the preliminary age-adjusted overall prevalence and incidence rates of SLE in New York County were 63.2 and 4.3 per 100,000 population, respectively. The overall prevalence and incidence rates were 10 times higher in females than males (Table 1). The highest prevalence of SLE was observed among black women (195.3), followed by Hispanic women (132.5), Asian women (89.5) and white women (61.9). Using the SLICC criteria generated age-adjusted overall prevalence and incidence rates of 70.4 and 5.5 per 100,000 population, respectively. Incidence and prevalence rates for all demographics were higher using the SLICC criteria for SLE than the ACR criteria (Table 1).

Conclusion: Using a more complete case finding methodology, the MLSP revealed substantial gender, ethnic and racial disparities in SLE among Manhattan residents. Black women had the highest prevalence rate of SLE followed by Hispanic, Asian and white women. The SLICC criteria provided higher SLE prevalence and incidence rates than the ACR criteria.

Preliminary Prevalence and Incidence Rates (per 100,000) of SLE in New York (Manhattan), NY

Male	18.9 (12.4 - 25.4)	19.5 (13.0 – 26.0)	1.2 (0.3 - 2.1)	1.2 (0.3 - 2.2)
Asian	55.4 (45.0 - 65.8)	67.5 (56.0 – 79.0)	3.8 (2.2 - 5.4)	6.1 (4.1 – 8.1)
Female	89.5 (71.6 - 107.4)	112.5 (92.5 – 132.5)	6.5 (3.7 - 9.3)	9.8 (6.4 – 13.2)
Male	12.3 (5.3 – 19.0)	11.4 (4.9 - 17.9)	0.5 (-0.5 - 1.5)	1.5 (-0.2 - 3.2)

Data reflects cases abstracted as of 5/31/2015. These estimates do not include all Manhattan cases for the study period. Data abstraction is expected to be completed in mid-2015.

Denominator data for NYC rates is based on NYC DOHMH intercensal population estimates.

NYC data are age adjusted to the US 2000 Standard Population.

Session Date: Tuesday, November 10, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Presepsin (sCD14 subtype) has recently been identified as a novel biomarker for predicting sepsis. Because presepsin is produced as a consequence of cellular phagocytosis, it may reflect monocyte activation. Recent evidence indicates that monocytes play an extremely important role in systemic lupus erythematosus (SLE). Little is known regarding presepsin in patients with SLE. Therefore, we tested the hypothesis that presepsin concentrations are elevated and associated with disease activity in patients with SLE without infection.

Methods: Thirty-three patients with SLE (4 men, 29 women) with a mean age of 46.6 and 22 healthy controls (5 men, 17 women) with a mean age of 48.1 were enrolled in this study. No patient had an apparent infection. Concentrations of plasma presepsin, serum C3, C4, and total hemolytic complement (CH50) levels were measured. The plasma presepsin concentration was measured using a chemiluminescent enzyme immunoassay. The levels were compared between the groups. The SLE disease activity index (SLEDAI) was calculated in the SLE group. Eight out of 33 SLE patients who underwent intensified immunosuppressive therapy were tested twice at 2 weeks after treatment.

Results: Patients with SLE had higher concentrations of presepsin [238.5 (48–741) pg/mL] than the healthy controls [118.4 (74–270) pg/mL; $P = 0.0003$]. The mean SLEDAI of all SLE patients was 10.8 (0–30). In patients with SLE, the concentration of presepsin was significantly correlated with disease activity, as assessed by SLEDAI scores ($R^2 = 0.77$; $P < 0.0001$; Fig. 1). There were significant correlations between presepsin and compliment CH50 ($R^2 = 0.12$; $P = 0.046$) and C4 ($R^2 = 0.034$; $P = 0.034$) but not between presepsin and C3 ($R^2 = 0.073$; $P = 0.12$). The concentration of presepsin was significantly decreased after treatment (before: 351.3 pg/mL; after: 134.0 pg/mL; $P = 0.016$; Fig. 2). The ROC curve analysis was conducted to compare the predictive values of presepsin. Area under the curve of presepsin was 0.7803. According to the ROC analysis, the optimal cut-off value of presepsin for the diagnosis of SLE was 156.5 pg/mL. Using this cut-off value, the sensitivity and specificity were 66.67% and 86.36%, respectively.

Conclusion: Measurements of plasma presepsin can be useful in assessing the disease activity of SLE and may be used to monitor treatment.

Session Date: Tuesday, November 10, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: While diffuse alveolar hemorrhage (DAH) is recognized as a life-threatening complication of SLE, little is known about its risk factors and response to therapy. Here, we describe 22 cases of DAH in a U.S. lupus cohort of ~1,000 patients, and compare them to 66 controls from the same outpatient cohort.

Methods: All patients met ACR classification criteria for SLE. We first captured variables pertaining to diagnoses of SLE and secondary antiphospholipid syndrome (APS) and analyzed them by Chi square (univariate) testing. Those variables with p values <0.05 were then further considered in a multivariate model. Kaplan-Meier curves were constructed for each group, and survival was analyzed by Log-rank test.

Results: Of the 22 DAH patients, 59% were diagnosed with DAH within 5 years of SLE diagnosis. By univariate analysis, several manifestations of SLE and APS were more common in DAH patients as compared to controls (**Table**). After building a multivariate model, history of thrombocytopenia and low C3 were maintained as independent risk factors. While a remarkable 19/22 DAH patients had a history of thrombocytopenia, only 5 had thrombocytopenia at the time of the DAH episode (and only 2 with platelet counts <50,000/µl), arguing that DAH was not simply a hemorrhagic complication of the low platelets. Interestingly, all patients survived their initial episode of DAH. All were treated with increased immunosuppression, including various combinations of corticosteroids, plasmapheresis, cyclophosphamide, rituximab, and mycophenolate mofetil. While the DAH patients did well in the short-term, their long-term survival was significantly worse compared to the control group (**Figure**). Interestingly, despite the history of both thrombocytopenia and DAH, several of the deaths were attributable to thrombotic complications after recovering from the DAH episode.

Conclusion: To our knowledge, this is the largest case-control study of lupus DAH reported to date. While a history of thrombocytopenia was strongly predictive of DAH (odds ratio ~40), only 2 patients had platelet counts <50,000/µl at the time of hemorrhage. A number of APS manifestations correlated with DAH in univariate testing (but not a multivariate model), and deserve further consideration in larger studies. In the short-term, this cohort of patients was treated aggressively for their DAH and fared quite well. However, over time, their survival was significantly reduced as compared to controls.

Table DAH vs. controls (univariate analysis)

History of:	Odds ratio	P-value
Thrombocytopenia *	43.2	<0.0001
Cardiac valve disease	22.1	<0.0001
Low C3 *	19.3	<0.0001
Leukopenia	13.4	0.0004
Neuropsychiatric	9.20	0.001
Hemolysis	5.85	0.0007
Arterial thrombosis	6.42	0.005
Lupus anticoagulant	5.36	0.004
Secondary APS	4.47	0.04
Low C4	3.32	0.03

* Remains significant in a multivariate model

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To investigate risk of mortality among SLE patients cohort in the NDB.

Methods: Systemic lupus erythematous (SLE) and non-inflammatory rheumatic disease (NIRD) patients were studied from 1998 through 2011 in the National Data Bank for Rheumatic Diseases (NDB), a longitudinal observational study following patients from all regions of the US through biannual questionnaires. Patients were required to have at least 2 observations or 1 observation and died before 2012. Mortality was confirmed through National Death Index-matched death records. We calculated standardized mortality ratios (SRRs) of SLE vs. NIRD based on age-, race- and sex-stratified US population data (CDC.gov). Cox regression models with time varying covariates were used to investigate the risk of mortality among diagnoses. A second Cox regression model was done at last observation using SLE specific variables.

Results: 2,374 SLE and 5,603 NIRD patients were studied. The mean (median) time in the study for SLE patients was: 2.52 (1.71) years with a total of 5,981 patient-years of follow-up, and for NIRD, 3.77 (2.12) years with a total of 21,090 patient-years of follow-up. At a random observation, SLE patients were described as: mostly male (93.3%), with an average of 50.4 (SD 13.5) years, white (73.0%), married (59%), mostly high-graduated (93.9%), with worse disease activity measures compared to NIRD (P<0.001 for the majority). At last observation, the BILD score was 3.36 (SD 2.08), PHQ8 scale 5.67 (SD 5-04) and GAD2 0.93 (SD 1.36).

The overall SRM were: 2.88 (95% CI 2.42-3.44) and 1.46 (95% CI 1.37-1.55) for SLE and NIRD patients, respectively. After multivariate adjustment (including demographic and disease severity outcomes), the hazard ratio comparing diagnoses was 0.96 (95%CI 0.74 -1.24). Among SLE patients, univariate preditors of mortality (age, age-squared and sex adjusted) were presented in Table. Almost all disease severity variables were associated with an increased risk of mortality among the SLE cohort.

Conclusion: Predictors of mortality were studied among SLE patients. Worse disease severity, more comorbidities and smoking habits were all important factors to an increased risk of mortality, among others. When comparing diagnoses, the risk of mortality did not seem to differ. The use of treatment will be further investigated in future works.

Table - Age, age-squared and sex adjusted predictors of mortality among SLE patients.

Cox regression	**HR**	**95% CI**	
Age	0.90	0.84	0.97
Age- squared	1.00	1.00	1.00
Sex	2.37	1.47	3.83

Session Date: Tuesday, November 10, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Autoantibodies (auto Abs) in cerebrospinal fluid (CSF) and inflammatory mediators (IMs) may be involved in the pathogenesis of neuropsychiatric systemic lupus erythematosus (NPSLE). Previous studies revealed that auto Abs such as anti-NMDA(N-methyl *D*-aspartate) receptor NR2 subunit (NR2) Abs are linked to a certain kind of NPSLE. We reported the association between NPSLE and CSF-anti-U1RNP Abs. What kinds of IMs in the central nervous system are stimulated by these Abs, however, remains unknown. The aim of the present study is to determine the association of both Abs with neurotoxic IMs.

Methods: Serum and CSF samples were obtained from NPSLE patients with diffuse NPSLE (n=39) or focal NPSLE (n=35), and non-NPSLE patients (control, n=13). Serum- and CSF-anti-NR2 Abs were determined by ELISA. Serum- and CSF-anti-U1RNP Ab positivity and titer were determined by RNA-immunoprecipitation assay and ELISA, respectively. CSF-IL-6, IL-8, and monokine induced by IFN-γ(MIG), which were reported to be neurotoxic, were measured by quantitative multiplex cytokine analysis. To elucidate the possibility that these IMs pass through blood-brain barrier (BBB), the permeability of BBB was evaluated by albumin quotient (Q*alb*).

Results: 1) IL-6 (67.4 vs. 17.5 pg/mL, p=0.02) and MIG (4307 vs. 109 pg/mL, p=0.03) levels, but not IL-8, were higher in CSF-anti-NR2 Ab-positive patients than controls. IL-6 level was higher in serum-anti-NR2 Ab-positive patients than in controls (50.0 vs. 17.4 pg/mL, p=0.03). There was no association of CSF-IMs with serum- and CSF-anti-NR2 Ab titer. CSF-anti-NR2 Ab positivity and titers were correlated with an increased permeability of BBB, as previously reported. 2) MIG level, but not IL-6 or IL-8, was higher in CSF-anti-U1RNP Ab-positive patients than in controls (2142 vs. 109 pg/mL, p=0.04). CSF-IMs were not correlated with serum-anti-U1RNP Ab titer. MIG level tended to positively correlated with CSF-anti-U1RNP Ab titer (r=0.49, p=0.07). 3) All the NPSLE patients were divided into 4 groups: CSF-anti-NR2 Ab +/U1RNP+ (double positive [DP], n=7), anti-NR2 Ab+/U1RNP- (NR2, n=18), anti-NR2-/U1RNP+ (U1RNP, n=9), anti-NR2 Ab-/U1RNP- (double negative [DN], n=40). In CSF-DP group, IL-6 and MIG levels, but not IL-8, were higher than in NR2 and U1RNP groups. 4) Q*alb* was positively correlated with IL-8 (r=0.45, p<0.0001) and MIG (r=0.56, p<0.0001) levels. Elevated CSF-IL-6 level, however, was not associated with an increased permeability of BBB. 5) The frequency of diffuse NPSLE in CSF-DP group (71%) tended to be higher than in the other groups. Auto Ab positivity was not associated with the brain MRI abnormalities.

Conclusion: CSF-IL-6 level was closely associated with the presence of CSF-anti-NR2 Abs, but not correlated with the BBB permeability. CSF-MIG level was associated with the presence of CSF-auto Abs and the BBB permeability. CSF-IL-8 level might be dependent of the BBB permeability alone. Thus, the involvements of auto Abs in CSF and BBB permeability in neurotoxic IM activation of NPSLE patients are different one another. The present study also suggests that NPSLE with both anti-NR2 and U1RNP Abs in CSF may have more severe manifestations.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

SLE onset may be insidious with clinically evident disease developing over years. Current SLE classification criteria may not classify patients with early SLE well. The ability of SLE classification criteria to include patients with earlier stages of SLE would allow studies of disease progression and the testing of therapies aimed at the prevention of organ involvement and damage. The aim of this multicenter study was to describe the characteristics of patients with early SLE to inform for the development of classification criteria which would capture patients with earlier stages of disease.

Methods:

Clinical and laboratory data at disease onset of patients newly diagnosed with SLE in the past 3 years (1/1/2012-12/31/2014) at 4 referral centers in Europe (2) and North America (2) were collected. All patients were diagnosed by SLE clinical experts. A data extraction form with all current ACR and SLICC items, as well as an additional list of 30 items (clinical and laboratory), was developed. Patients' medical records were reviewed and reviewers were encouraged to add to the existing list of items any other presenting manifestations. Two-step cluster analysis followed by discriminant analysis were used to identify potential subgroups of patients with distinct SLE presentations, and to identify the important variables contributing to SLE diagnosis.

Results:

Two hundred and thirty one patients (F 203; M 27) were identified, of these 73% were White, 10.5% Black and 9.5% Asian and 7% of mixed ethnicities. Mean age at first symptoms was 32.3 ±12.6 and at diagnosis 34.5 ± 12.8 years. At diagnosis, 48% of patients had < 3 ACR classification criteria, 52% had > 4. The most common clinical manifestations and serologies at diagnosis are in **Table**. Less common manifestations were oral ulcers (18%), discoid lesions (9%), CNS involvement (6%). Less than 5% of patients had alveolar hemorrhage, myocardial infarction, livedo reticularis, thrombosis, subacute cutaneous lesions and thrombocytopenia. Although the numbers were small, no statistically significant differences in manifestations at onset were observed in ANA positive (96%) vs. ANA negative (4%) patients. Twenty nine (12.6%) ANA positive patients, had no more specific serologies. Cluster analysis identified a group of 58 younger patients (29.0 vs. 33.5 years for others) with SLE onset characterized by constitutional symptoms (weight loss, fatigue, fever), thrombosis, anti-dsDNA antibodies, Coomb's test, and renal involvement.

Conclusion:

Almost half of patients had < 3 ACR criteria at diagnosis, mean duration of symptoms was 2.2 years, and 4% of patients were ANA negative. There may be a group of young patients presenting with a specific pattern of disease onset. Additional analyses are required to understand the manifestations most likely found in early SLE.

Table. The Most Common Manifestations and Serologies at Diagnosis of SLE in 4 Large Academic Referral Centers, 2012-2014	
Clinical manifestations	Prevalence (%)
Arthritis	65
Malar rash	45
Leukopenia	40
Fatigue	34
Renal abnormalities	33
Photosensitivity	29
Serositis	29
Fever	28
Raynaud's	20
Serologies and Complement	
ANA	96
Anti-dsDNA	70
Anti-SM	27
Antiphospholipid Antibodies	28
Hypocomplementemia	68

Differential Serum Cytokine Profile in Patients with Systemic Lupus Erythematosus and Posterior Reversible Encephalopathy Syndrome: A Single-Center Study

Jorge Alcocer-Varela[1], Diana Gómez-Martín[1], Javier Merayo-Chalico[2] and Ana Barrera-Vargas[1], [1]Department of Immunology and Rheumatology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico, [2]Immunology and Rheumatology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Patients with systemic lupus erythematosus (SLE) are susceptible to the development of posterior reversible encephalopathy syndrome (PRES). The main theory about the physiopathology of PRES suggests there is brain-blood barrier damage, which is associated with endothelial dysfunction, and characterized by vasogenic edema. However, to date there is no evidence about serologic markers associated with the development of PRES in SLE patients. The aim of this study was to determine whether PRES/SLE patients show a specific cytokine profile.

Methods: A transversal study was performed from November 2012 to March 2015 at the Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán in Mexico City. We included four groups of subjects: healthy controls (n=6), SLE patients in remission (n=6), SLE patients with SLEDAI scores >6 (n=6, neurological activity and infections were excluded) and patients with PRES/SLE (n=14). All SLE patients fulfilled at least 4 ACR criteria and PRES was defined as reversible neurological manifestations (seizures, visual abnormalities, acute confusional state, among others) associated with changes by magnetic resonance (iso or hypointensity in T1 and hyperintensity in T2/FLAIR). Serum samples were obtained during the first 48 hours after the PRES episode and they were analyzed by Cytometric Bead Array (Th1, Th2, Th17) and ELISA for CD40L and VEGF.

Results:

Table 1 shows clinical, laboratory and demographic patient features. IL-6 and IL-10 levels were significantly higher in PRES/SLE patients when compared to the rest of the groups (see table). There were no differences between groups regarding sCD40L levels (p=0.80), nor VEGF in SLE patients (p=0.77). There were no differences in platelets, leukocytes or hemoglobin among groups. Other analyzed cytokines (IL 2, 3, 4, 16, 17A, 18, and 12p40; IFNγ and TNFα) did not show significant differences among groups.

Conclusion:

SLE patients with PRES had higher IL-6 and IL-10 levels when compared to other SLE patients and healthy controls. Enhanced IL-6 serum levels could be associated with vascular endotelial cells activation, which might play a key role in the pathogenesis of PRES-related vasogenic edema. Moreover, increased IL-10 levels could act as a counterregulatory mechanism to contend with the inflammatory response driven by IL-6, which might explain the reversibility of the clinical manifestations that characterizes PRES. Prospective studies that include serial measurements of these serum cytokines, correlation with their levels in cerebrospinal fluid and the reversibility of image abnormalities, are needed to confirm our findings.

Using Electronic Health Record Algorithms to Accurately Identify Patients with Systemic Lupus Erythematosus

April Barnado[1], Joshua C. Denny[2] and Leslie J. Crofford[1], [1]Medicine, Vanderbilt University, Nashville, TN, [2]Biomedical Informatics, Medicine, Vanderbilt University, Nashville, TN

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To harness the data in electronic health records (EHRs) and administrative databases to study systemic lupus erythematosus (SLE), it is important to identify patients accurately. Currently, there is no validated EHR algorithm specifically for SLE. This study sought to develop and validate a novel EHR algorithm that uses International Classification of Diseases, Ninth Revision

(ICD-9) billing codes, lab values, and medications to identify SLE patients accurately.

Methods: We used Vanderbilt's research electronic database called the Synthetic Derivative (SD). The SD contains 2.5 million records with de-identified clinical data from the EHR. There were 5959 potential SLE cases with at least one SLE ICD-9 code of 710.0. Of these potential subjects, 200 were randomly selected for chart review to identify the true cases. A subject was defined as a case if the subject fit the ACR SLE criteria or was diagnosed by a rheumatologist. Positive predictive values (PPVs) and sensitivity were calculated for combinations of SLE ICD-9 code counts, a positive anti-nuclear antibody (ANA) (titer $\geq$ 1:40), ever use of antimalarials, corticosteroids, and disease-modifying antirheumatic drugs (DMARDs), and a keyword of "lupus" in the subjects' problem lists. PPVs were also calculated for excluding ICD-9 codes for systemic sclerosis (SSc) of 710.1 and dermatomyositis (DM) of 710.3. The algorithm with the highest PPV was internally validated using an additional, randomly selected 100 of the remaining potential 5959 SLE cases. **Results:** The algorithms with the highest PPVs are shown in Table 1. Excluding the SSc and DM ICD-9 codes improved the PPV as did adding ever antimalarial use, ever DMARD use, and a positive antinuclear antibody (ANA) to the SLE ICD-9 code. The algorithm with the best PPV at 95% was 3 or more ICD-9 codes and ANA positive and ever DMARD and ever steroid use while excluding SSc and DM ICD-9 codes. Using this algorithm to randomly select 100 subjects for cross-validation, 91 of the 100 subjects were classified as a case resulting in an internally validated PPV of 91%. **Conclusion:** We have designed a novel algorithm that incorporates not only ICD-9 codes but also lab values and medications to identify SLE patients with a PPV of 91% on an independent test set. Being able to identify SLE cases accurately within the EHR will expand the ability to study more SLE patients from diverse settings. Follow-up studies are ongoing to externally validate the algorithm in other institutions' EHRs.

Table 1. Positive Predictive Values of Electronic Health Record Algorithms to identify SLE cases.

Algorithm	Positive Predictive Value (PPV)	PPV (excluding dermatomyositis and systemic sclerosis)	Sensitivity
3 or more ICD-9 codes AND ANA positive AND ever DMARD AND ever steroid use	91%	95%	40%
4 or more ICD-9 codes AND ANA positive AND ever DMARD AND ever steroid use	90%	95%	38%
4 or more ICD-9 codes AND ever antimalarial use AND ANA positive	89%	92%	70%
4 or more codes AND ever antimalarial use	89%	92%	61%
3 or more codes AND ever antimalarial use	88%	91%	66%
3 or more codes AND ever steroid use AND ever DMARD use	86%	91%	34%
4 or more codes AND ever steroid use AND ever DMARD use	86%	91%	33%

Anti-NR2 Antibody and Blood-Brain Barrier Disruption in Systemic Lupus Erythematosus Patients with Cognitive Dysfunction

Gaurav Gulati[1], Philip Iffland[2], Damir Janigro[2], Bin Zhang[3] and Michael Luggen[4], [1]Division of Immunology, Allergy and Rheumatology, University of Cincinnati College of Medicine, Cincinnati, OH, [2]Cleveland Clinic Lerner College of Medicine, Cleveland, OH, [3]Cincinnati Children's Hospital and Medical Center, Cincinnati, OH, [4]Division of Immunology, University of Cincinnati Medical Center, Cincinnati, OH

Session Date: Tuesday, November 10, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Cognitive Dysfunction (CD) is one of the most common manifestations of neuropsychiatric SLE (NPSLE) and one of the most devastating. The pathogenesis of CD in SLE is not known, but in animal models, antibody to the NR2 subunit of the N-methyl D- aspartate receptor (aNR2) can cause memory impairment. However, this effect can only be demonstrated if the blood brain barrier (BBB) has been disrupted or if the antibody is introduced intrathecally. Several studies in SLE patients have failed to find an association of aNR2 with CD. None, however, has assessed the integrity of the BBB as a potential pathogenic cofactor. S100B protein is an astrocyte specific protein that has been used as biomarker of BBB disruption in traumatic brain injury and some neurodegenerative disorders. And, antibodies to this protein may indicate previous exposure to this immunologically privileged protein and might be used as an indicator of preceding BBB disruption. We hypothesized that aNR2 antibody is pathogenic in SLE patients only if there evidence of previous or ongoing BBB disruption as indicated by increased levels of S100B or anti-S100B.

Methods: Patients who fulfilled the revised American College of Rheumatology (ACR) criteria for SLE and were stable for at least 4 weeks were recruited from three different settings. Basic demographic, clinical and laboratory data was collected. The Automated Neuropsychological Assessment Metrics (ANAM), a computerized and validated tool, was utilized to measure cognitive function. The Total Throughput Score (TTS = number of correct responses/time) was used as the primary outcome measure. CD was defined as a score of less than 1.5 SD below the age, sex, and race matched RA population mean. Patients also had assessment of fatigue, depression, SLE activity and SLE damage using the FACIT fatigue score, Becks Depression Inventory (BDI), SLEDAI 2K, and SLICC respectively. Serum was analyzed by established ELISA techniques for anti-NR2 antibody, anti-S100B antibody and intact serum S100B protein.

Results: A total of 57 patients were evaluated. Twelve patients had CD. The age, ethnicity, and family income were significantly different between the two groups ($p<0.05$) **[TABLE 1]**. In a multiple regression model adjusting for the above independent variables together with simple reaction time and opioid use, no significant effects of aNR2, S100B, or aS100B on decreasing TTS were found. And, when the effects of aNR2 antibodies were evaluated at high levels of S100B and aS100B, no significant influence on TTS was found.

Conclusion: Serum antibodies to NR2 do not appear to play a role in the pathogenesis of CD in SLE even when analyzed in the context of BBB integrity. This would suggest that, if these antibodies are pathogenic, they are produced within the CNS and peripheral antibody measurements do not adequately reflect their intrathecal levels.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Attribution of neuropsychiatric manifestations to systemic lupus erythematosus *per se* ("primary NPSLE") is challenging and depends largely on physician judgment based on clinical and neuroimaging results. To facilitate physicians, attribution models have been proposed but their diagnostic performance has not been validated. We compared attribution of neuropsychiatric events as per physician judgment against different attribution models.

Methods: SLE patients with neuropsychiatric involvement were retrospectively identified. All neuropsychiatric manifestations were classified as attributed to SLE, not attributed to SLE, or uncertain, according to physician judgment. **Results** were compared against three published attribution models: the Systemic Lupus International Collaborating Clinics (SLICC) models A (most stringent) and B (less stringent), and a recently proposed algorithm by the Italian study group on NPSLE (total score 0-10). Sensitivity and specificity for each model was calculated against physician judgment. For the Italian algorithm, a receiver operating curve (ROC) analysis was also performed to calculate the area under the curve (AUC) using dichotomous outcome (attributed vs. not attributed/uncertain).

Results: A total of 242 neuropsychiatric manifestations, experienced by 191 patients, were included in the study. According to physician judgment, 136 events were attributed and 96 not attributed to SLE; for 10 events, attribution was considered uncertain. Using the SLICC models, only a small proportion of the events were attributed to SLE [34 events (14.0%) with model A, 67 events (27.7%) with model B]. Consequently, when compared with physician judgment, both models showed high specificity, but poor sensitivity (Table 1). Exclusion of so-called 'minor' neuropsychiatric manifestations (ie. cases of headache, mild depression, mild cognitive dysfunction and polyneuropathy without electrophysiologic confirmation), which are *a priori* not attributed to SLE in the SLICC models, led to moderate increases in sensitivity (27.7% and 42.0% for models A and B, respectively), but specificity was reduced especially in SLICC model B (94.8% and 65.5% for models A and B, respectively).

The AUC of the ROC curve for the Italian study group algorithm was 0.859, indicating good reliability as a diagnostic test for NPSLE attribution. When serial cut-offs of total score were tested, values ≥ 7 showed the best combination of sensitivity and specificity (82.4% and 82.9%, respectively [Table 1]).

Conclusion: Attribution models show varying levels of sensitivity and specificity, related to physician judgment. A recently proposed attribution score performs well and may be suitable for use in real-life clinical settings. SLICC model A shows the highest specificity and can be used for confirmation of doubtful cases.

Table 1. Sensitivity and specificity of different attribution models for neuropsychiatric SLE

Model	Sensitivity	Specificity	Positive predictive value	Negative predictive value
Italian model				
Score ≥ 8	42.6%	93.3%	89.2%	55.7%
Score ≥ 7	82.4%	82.9%	86.1%	78.4%
Score ≥ 6	87.5%	68.6%	78.3%	80.9%
SLICC model A (*stringent*)	22.8%	97.2%	91.2%	49.5%
SLICC model B (*less stringent*)	34.6%	80.6%	79.1%	48.2%

The Emergency Room and SLE: What Characteristics Are Associated with Increased Emergency Room Utilization in Lupus Patients?

Kimberly Trotter[1], Kichul Ko[1], Gabrielle Liu[1] and Tammy Utset[2], [1]Medicine, University of Chicago, Chicago, IL, [2]University of Chicago, Chicago, IL

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: There is sparse data examining the characteristics of SLE patients who frequent the emergency room (ER). Data suggest that lupus patients with certain sociodemographic risk factors and possibly lack of access to preventive care are more likely to go to the ER. We sought to explore which characteristics were associated with ER utilization in our lupus cohort.

Methods: 125 patients fulfilling the ACR criteria for SLE were recruited during routine ambulatory visits between November 2013 and December 2014. Demographics, disease duration, preventive care, healthcare utilization, reason for ER visit, who referred the patient to the ER, disposition, and prevention of ER visits were elicited via a patient reported questionnaire. Patients also completed the Medication Adherence Self-Report Inventory (MASRI), Visual Analog Scale (VAS) for pain, Short Form 36 Health Survey (SF-36), Beck depression Inventory, and Interpersonal Support Evaluation List (ISEL). We compared patients with no ER visits versus ≥ 1 ER visit in the past year. Categorical variables were evaluated using chi-square while continuous variables were evaluated using two-tailed Student's unpaired *t*-test, Wilcoxon rank-sum test, or logistic regression analysis.

Results: Patients with ≥ 1 ER visit were more likely to be younger, non-Caucasian, single, non-college graduates, and have Medicaid. ER utilizers also had higher pain scores, worse overall mental and physical health, and increased depression. Patients who utilized the ER were also less likely to have ever had a lipid panel (Table 1). There was no difference in frequency of PCP or rheumatology appointments, mammograms, flu shots, pap smears. In a multivariate analysis, only younger age was found to be associated with ≥ 1 ER visit.

In regards to characteristics associated with each ER visit, 57.3% of patients went to the ER due to lupus. 73% of patients self-directed themselves to the ER and felt nothing could have prevented the ER visit. Only 23.4% of these ER visits actually resulted in admission. The majority of ER visits were reportedly due to pain/arthritis (26.5%) and cardiopulmonary complaints (20.5%).

Conclusion: Frequent ER utilization was shown to be associated with certain sociodemographic features and worse self-reported outcomes. Studies from the general population have also found an association with frequent ER use and poor access to medical care. Conversely, our data showed that access to primary care, rheumatology, and preventive services was equivalent between the two groups. This suggests that access to care may not be associated with ER utilization in the SLE population. Lastly, given the majority of patients self-directed themselves to the ER and were not admitted to the hospital, we need to educate them to call their physician first to determine the utility of an ER evaluation.

Table 1

Characteristics of study population by ER Visits

Variables	No ER Visits (n=53)	Any ER Visits (n=56)	*P* Value

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Neuropsychiatric manifestations are commonly observed in both SLE and primary Sjšgren's syndrome (pSS). However, making an accurate diagnosis can be challenging. Multiple serum and CSF biomarkers have been studied, but have not yet entered into routine clinical practice. Studies of the pathogenesis of neuropsychiatric involvement in SLE and pSS have suggested new biomarker candidates, including mediators of inflammation (TWEAK), pathogenic antibodies (anti-NMDA receptor subunit 2 (NR2)), and indicators of increased BBB permeability (S100b).

Methods: In a population-based Caucasian cohort of 52 SLE and 54 pSS patients (fulfilling ACR and AECG criteria, respectively), neuropsychiatric manifestations were categorized according to the ACR classification scheme for lupus neuropsychiatric syndromes. TWEAK and anti-NR2 antibodies (ab) were measured in the serum and CSF and S100b was measured in the CSF, using ELISA. IgG index and Q-albumin were calculated by standard methods.

Results: SLE patients were significantly younger than patients with pSS, yet had longer disease duration. There was no difference in serum TWEAK between the SLE and pSS groups. While CSF TWEAK (cTWEAK) and S100b were significantly higher in pSS, patients with SLE displayed significantly higher serum (but not CSF) anti-NR2 antibody titers (Table 1).

The associations between cS100b and anti-NR2 ab and selected laboratory variables in the SLE and pSS patient cohorts were further explored by multivariable regression models (Table 2). The levels of serum and CSF TWEAK were not related to mood disorders, fatigue, psychosis, acute confusional state, headache, seizures, or cerebrovascular disorders. Analysis of possible associations with various cognitive functions is currently underway.

cS100b demonstrated significant correlation with cTWEAK in both SLE and pSS. Furthermore, cS100b was associated with higher BBB permeability in SLE but not in pSS patients. CSF and serum anti-NR2 antibodies correlated in pSS but not in SLE (Table 2).

Conclusion: Although a normal control group was not available for comparison, high cTWEAK in pSS points to a possible role of this cytokine in the pathogenesis of neuropsychiatric manifestations. In pSS, cTWEAK, serum anti-NR2 ab, and IgG index influence anti-NR2 ab in the CSF, suggesting that both leakage through the BBB and as well as intrathecal production contribute to CSF anti-NR2 ab titers. Finally, although this relationship deserves further study, an interesting and significant association was revealed between S100b and TWEAK in the CSF in both SLE and pSS.

Table 1:

Demographic and selected laboratory data in 52 SLE and 54 pSS patients

	SLE	pSS	p-value
Age in years (SD)	43 (13)	57 (12)	<0.001
Female (%)	45 (87)	46 (85)	0.8
Disease duration in years (SD)	12 (9)	6 (5)	<0.001
TWEAK in serum, mean (SD)	862 (787)	947 (211)	0.5
TWEAK in CSF, mean (SD)	1027 (395)	1689 (1106)	<0.001
Anti-NR2 ab in serum, median (range)	0.9 (0.3-3.6)	0.6 (0.3-4.6)	0.05
Anti-NR2 ab in CSF, median (range)	0.4 (0.1-2.2)	0.4 (0.2-3.0)	0.4
Q-albumin, mean (SD)	4.9 (2.4)	4.7 (1.8)	0.8
IgG index, mean (SD)	0.56 (0.15)	0.61 (0.32)	0.3
S100b in CSF, mean (SD)	232 (79)	284 (92)	0.002

TWEAK, pg/mL; S100b, pg/ml; ab, antibodies; anti NR2 ab values given as a ratio against an internal calibrator with defined signal intensity; p-values based on independent samples t-test, or Chi-squared test as indicated.

Table 2:

Multivariable regression model of association between S100b and anti-NR2-antibody level in cerebrospinal fluid and selected laboratory variables in 52 SLE and 54 pSS patients

	Variables	β	*P*-value	
S100b (SLE)	cTWEAK	0.09	<0.001	
	Q-albumin	13.6	0.001	
	IgG index	-172	0.3	
	Adjusted R^2 for the model			0.43
S100b (pSS)	cTWEAK	0.03	0.004	
	Q-albumin	15.8	0.1	
	IgG index	13.8	0.7	
	Adjusted R^2 for the model			0.26
Anti-NR2 ab (pSS)	Anti-NR2 ab in serum	1.2	<0.001	
	Interaction	<0.001	<0.001	
	cTWEAK	<0.001	0.08	
	IgG index	0.8	<0.001	
	Adjusted R^2 for the model			0.6

cTWEAK, TWEAK in CSF in pg/ml; anti NR2 ab values given as a ratio against an internal calibrator with defined signal intensity; interaction, interaction between anti-NR2 ab in serum and TWEAK in CSF

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: There is an unmet need for a screening test of cognitive function that can be administered in clinic in patients with SLE. We aimed to determine the: 1) validity of Montreal Cognitive Assessment (MoCA) and Mini-Mental State Examination (MMSE) as screening tests of Cognitive Impairment (CI) in SLE and 2) associated factors with CI.

Methods: Consecutive patients followed at a single centre and seen since Feb 2014 were included. Screening tests were administered by 2 trained assessors: Hopkins Verbal Learning Test-Revised (HVLT-R), Controlled Oral Word Association Test (COWAT) via telephone interview and MoCA and MMSE via face-to-face assessment.

Patients completed Centre of Epidemiologic Studies Depression Scale (CES-D), Beck Anxiety Inventory (BAI), and Reynolds Intellectual Screening Test (RIST), and scores were compared in patients with and without CI.

Sensitivity/Specificity, Positive Predictive Value (PPV)/Negative Predictive Value (NPV) and Likelihood Ratio (LR) of MoCA and MMSE in detecting CI (HVLT-R external construct) were determined. Pearson correlation of MoCA and MMSE with HVLT-R were studied. Regression analyses were performed to test for possible associations with CI.

Results: Of 86 patients, 45% had CI using MoCA, 40% using HVLT-R, 16% using COWAT and 14% using MMSE. Sensitivity was higher for MoCA (65%) compared to MMSE (21%), though MMSE was more specific (90%) than MoCA (67%). PPV and LR were similar in MoCA and MMSE (PPV: 56% & 58%; LR: 2.0 & 2.1, respectively), but NPV was higher in MoCA (75%) than MMSE (64%). HVLT-R correlated with MoCA ($r=0.43$, $p<0.0001$). Attention, delayed recall and language domains of MoCA were lower than normal (Figure 1).

Univariate analyses: CI patients had higher CES-D scores (ie. more depressive symptoms) than those without CI (22.1±13.7 vs. 15.9±10.6, $p=0.02$). This did not hold in multivariate analysis. There were no significant differences in BAI scores, diabetes, cardiovascular events, dyslipidemia, hypertension, smoking status or antiphospholipid antibodies in patients with and without CI.

Multivariate analyses: Patients with CI had shorter SLE disease duration than patients without CI (OR=0.94; CI 95% 0.90-0.99; $p=0.01$). Each one year of SLE follow up reduces the probability of CI by 6%. More education years and high RIST score were protective against CI (OR=0.81; CI 95% 0.66-0.98; $p=0.03$ and OR=0.93; CI 95% 0.88-0.98; $p=0.006$, respectively). Each one-year increase in education decreases the chance of developing CI by 19%. Each 1 score increase in RIST decreases the chance of developing CI by 7.5%.

Conclusion: CI among SLE patients was highly prevalent (45%) using MoCA. Considerations of cost/administrative burden and appropriate psychometric properties make MoCA the preferential screening test for CI in SLE. Shorter SLE disease duration increases risk while education and high intelligence scores protect against CI.

Patients' Reported Perceived Deficits Questionnaire – 5-Item Is Not Valid to Screen for Cognitive Impairment in Lupus

Stephanie Nantes[1], Murray Urowitz[2], Dafna Gladman[2], Ashneet Dhaliwal[1] and Zahi Touma[2], [1]University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, [2]Rheumatology, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: It is unclear whether cognitive complaints in patients with SLE are indicative of true Cognitive Impairment (CI) or underlying depression or anxiety.

To determine: 1) the validity of the patient-reported outcome on CI (Perceived Deficits Questionnaire – 5-item [PDQ-5]) and 2) the association of PDQ-5 with self-reported symptoms of depression and anxiety.

Methods: Consecutive patients followed at a single centre and seen between Feb 2014 and May 2015 that agreed to participate were included in this study. Patients completed PDQ-5, which assessed perceived cognitive deficits from the patient's perspective. PDQ-5 included five questions representing four subscales: Attention/Concentration, Retrospective Memory, Prospective Memory, and Planning/Organization. Total PDQ-5 score consists of the sum of the raw scores on these 5 items and could range from 0-20 with higher scores indicating greater perceived deficit.

Patients underwent two cognitive screening tests by two trained assessors: Hopkins Verbal Learning Test-Revised (HVLT-R) via telephone interview and MoCA via face-to-face assessment. Patients also completed Center of Epidemiologic Studies Depression Scale (CES-D) and Beck Anxiety Inventory (BAI).

Prevalence of self-reported cognitive deficits (PDQ-5), depression and anxiety were determined and scores from these questionnaires were compared in patients with and without CI (based on HVLT-R). Sensitivity (Se)/specificity (Sp) and Positive Predictive Value (PPV)/Negative Predictive Value (NPV) of PDQ-5 in detecting CI (based on HVLT-R and MoCA), depression (CES-D) and anxiety (BAI) were studied.

Results: Of 71 patients, 46% self-reported cognitive difficulties occurring 'often' or 'almost always' in at least one of PDQ-5's four subscales. 45% reported depressive symptoms by CES-D, and 24% reported moderate-severe anxiety by BAI.

CES-D showed higher scores in CI patients compared to those without CI (22.1±13.7 vs. 15.9±10.6, p=0.02) [higher scores = more depressive symptoms]. There were no significant differences in BAI or PDQ-5 scores between patients with and without CI.

Se, Sp, PPV and NPV were high in both CES-D (Se 69%, Sp 75%, PPV 63%, NPV 79%) and BAI (Se 94%, Sp 69%, PPV 48%, NPV 97%) signifying that PDQ-5 is detecting anxiety and depression.

PDQ-5 was less predictive of objective CI (MoCA: Se 58%, Sp 60%, PPV 53%, NPV 65%; HVLT-R: Se 48%, Sp 52%, PPV 41%, NPV 59%) (Table 1)

TABLE 1. Sensitivity, specificity, PPV and NNP of PDQ-5 in detecting CI (HVLT-R and MoCA), depression (CES-D) and anxiety (BAI)

	Sensitivity (%)	Specificity (%)	PPV (%)	NPV (%)
MoCA	58	60	53	65
HVLT-R	48	52	41	59
BAI	94	69	48	97
CES-D	69	75	63	79

Conclusion: The PDQ-5 self-report questionnaire is not a valid test to screen for CI in SLE. Depression and anxiety among SLE patients was highly prevalent using CES-D (46%) and BAI (24%) and depression was associated with CI. Patients' cognitive complaints reported in PDQ-5 scores were not reliably associated with performance on MoCA or HVLT-R, but rather were influenced by the presence of depression and anxiety.

25-Hydroxyvitamin D3 Deficiency Independently Predicts Cognitive Impairment in Patients with Systemic Lupus Erythematosus: Results from a Controlled Study

Sen Hee Tay[1,2] and Anselm Mak[2,3], [1]National University of Singapore, Singapore, Singapore, [2]National University Health System, Singapore, Singapore, [3]Medicine, National University of Singapore, Singapore, Singapore

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Cognitive dysfunction has been reported in 20-80% of systemic lupus erythematosus (SLE) patients. Converging evidence has indicated the importance of vitamin D as a neuro-immuno-modulator for normal cognitive function. In this study, we evaluated the relationship between vitamin D, traditional neuropsychological and SLE-specific risk factors as predictors for cognitive dysfunction.

Methods:

Consecutive SLE patients who fulfilled ≥ 4 American College of Rheumatology 1997 revised classification criteria and healthy controls (HC) matched for age and gender were administered the Automated Neuropsychological Assessment Metrics (ANAM) to assess cognitive function in this cross-sectional study. The primary outcome was the mean total throughput score (TTS), defined as the total of the throughput scores for 8 ANAM subtests. Cognitive dysfunction was defined as a TTS < -1.5 SD of the HC mean. Anxiety and depression were measured using the Hospital Anxiety and Depression Scale (HADS). Levels of 25-hydroxyvitamin D [$25(OH)D_3$ and total 25(OH)D] were measured using Liquid Chromatography-Tandem Mass Spectrometry. Vitamin D status was defined as deficiency < 10 ng/mL, insufficient 10 – 29 ng/mL and sufficient ≥ 30 ng/mL. Association between cognitive function and vitamin D levels or

status was explored using linear regression models.

Results:

In total, 61 SLE patients and 61 HC were studied. SLE patients had the following characteristics: 83.6% female; median age 36.0 (Q1; Q3 26.0; 48.5); SLE duration 6.0 years (Q1; Q3 0.0; 12.0); SELENA-SLEDAI 4.0 (Q1; Q3 2.0; 5.0)]. HADS-Anxiety, -Depression and -Total scores were significantly higher in SLE patients compared to HC [HADS-Anxiety: 8.0 (Q1; Q3 4.5; 9.0) versus 5.0 (Q1; Q3 2.5; 8.0), $p = 0.001$; HADS-Depression: 3.0 (Q1; Q3 2.0; 6.0) versus 2.0 (Q1; Q3 1.0; 3.0), $p < 0.001$; HADS-Total: 11.0 (Q1; Q3 7.5; 15.0) versus 7.0 (Q1; Q3 3.0; 10.5), $p < 0.001$]. After adjusting for age, education, gender, ethnicity and HADS-Total, SLE patients scored significantly lower than HC in 4 ANAM subtests [code substitution (learning) ($p = 0.013$), code substitution (immediate memory) ($p = 0.012$), code substitution (delayed memory) ($p = 0.025$), matching to sample ($p = 0.026$)] and in the TTS ($p = 0.004$). Cognitive dysfunction was identified in 21 (34.4%) SLE patients and 1 (1.6%) HC ($p < 0.001$). There were no statistically significant differences in $25(OH)D_3$ levels, total 25(OH)D levels and total 25(OH)D deficiency between SLE patients and HC. However, more SLE patients had $25(OH)D_3$ deficiency compared to HC [12 (19.7%) versus 2 (3.3%), $p = 0.003$] contributed by vitamin D_2 supplementation [8 (13.1%) versus 0 (0.0%), $p < 0.001$]. Deficiency of $25(OH)D_3$ ($\beta = -63.667$, SE = 27.456, $p = 0.025$), but not the other vitamin D variables, independently predicted worse TTS after adjusting for age, education, gender, ethnicity, HADS-Total, duration of SLE, SELENA-SLEDAI and cumulative steroid dose in SLE patients. Age ($\beta = -4.261$, SE = 0.866, $p < 0.001$) was the only predictor of TTS after adjusting for education, gender, ethnicity, HADS-Total, vitamin D levels or status in HC.

Conclusion:

Deficiency of $25(OH)D_3$, a potentially modifiable risk factor, independently predicts cognitive impairment in SLE patients.

Session Date: Tuesday, November 10, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: About 16-95% of SLE patients have vitamin D insufficiency. Vitamin D levels, especially vitamin D deficiency, are associated with cognitive performance in adults. We aimed to analyze the association of vitamin D levels, cognitive impairment and cerebral structures in childhood-onset Systemic Lupus Erythematosus (cSLE).

Methods: We screened consecutive cSLE patients, disease-onset before the age of 18 years followed in the pediatric rheumatology unit at the State University of Campinas. Controls were matched for age, sex and demographic background. Levels of 25-hydroxyvitamin D3 were measured in serum samples, using a commercial enzyme-linked immunosorbent assay; vitamin D levels were considered deficient (<10pg/mL), insufficient (10-29pg/mL), sufficient (30-100pg/mL) and toxic (>100pg/mL). cSLE patients were assessed for disease activity by Systemic Lupus Erythematosus disease activity index (SLEDAI) and damage [Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index (SDI)]. Cognitive evaluation was performed in all participants using Wechsler Intelligence Scale, according to age and validated in Portuguese. Cognitive dysfunction was defined when scores were ≤-2 standard deviations (SD) from controls in 1 or more subtests. Magnetic resonance imaging scans were performed using a standardized protocol and volumetric 1mm T1 weighted images were used for analysis. Volumes ≤ 2 SD from the means of controls were considered abnormal. White matter (WM) lesions were analyzed in T2-weighted images using a semiautomatic computer program (Neuroline®). Non-parametric tests were used for statistical analysis.

Results:

We included 100 cSLE patients (mean age 16.8 years (SD±4.4) and 37 controls (mean age 18.7 years (SD±4.8). The mean vitamin D level was 32.4±18.7pg/ml in cSLE and 36.5±19.8pg/ml in controls (p=0.22). Cognitive impairment was observed in 27 (47%) cSLE patients and 6 (25%) controls (p=0.001). No association between vitamin D levels and cognitive impairment (p=0.219), SLEDAI (p=0.469), SDI (p=0.915) and corticosteroid use (p=0.486) was observed.

Forty-seven (47%) cSLE patients and 13 (35%) controls had vitamin D insufficiency (p=0.08). Vitamin D insufficiency was not associated with cognitive impairment (p=0.24). When analyzing individual cognitive tests, we observed that vitamin D levels were associated with forward digits span (p=0.04) and correlated indirectly with cubes (r=-0.265;p=0.05) in cSLE patients. No association with structural abnormalities [hippocampal (p=0.466), cerebral (p=0.610) and cerebellum (p=0.475) atrophy] and WM lesion (p=0.601) was observed.

Conclusion: Vitamin D insufficiency was frequent in both cSLE and controls. Although vitamin D levels were not associated with cognitive impairment and cerebral structural abnormalities, we observed an association of vitamin D insufficiency and cognitive subtests associated with retention of immediate memory, analytical skills, visual-motor-spatial coordination, perceptual speed and organization in cSLE patients. Therefore vitamin D levels may contribute to cognitive dysfunction in cSLE and should be followed closely and corrected when indicated.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Ischemic strokes in Systemic lupus erythematosus (SLE) patients contribute to increased morbidity and mortality. Little is known however, about the patterns of ischemic brain injury in SLE and how this issue impacts the clinical outcome. Our objective is to investigate the neuropsychological, neurobehavioral and physical function in SLE patients with ischemic stroke, and correlate findings with the type of arterial ischemic injury.

Methods: Consecutive SLE patients presented with first-ever ischemic stroke drawn from the Maryland Lupus Cohort from 2000 to 2014 were observed. Ischemic brain injury was categorized based on brain magnetic resonance imaging (MRI/ MRA) into infarctions of large territorial, lacuanar, localized cortical and borderzone. Angiographic findings were staged to assess severity of arterial stenotic lesion. Comparison was made to age- and gender -matched SLE patients with no stroke, and non SLE ischemic stroke subjects. Primary outcomes determined at 6 months post stroke included, cognitive dysfunction, mood disorders, emotion/ affective disorders and physical function.

Results: 56 SLE patients with stroke (mean age 35.7 years, 82 % women, 84 % African American, mean duration of SLE 5.5 years), 44 SLE patients with no stroke (mean age 32.9 years, 93 % women, 77 % African American, mean duration of SLE 6.5 years) and 20 Non SLE stroke subjects (mean age 37.5 years, 80 % women, 90 % African American) were included. There was no significant statistical difference among the three groups regarding demographic and clinical features, phospholipid syndrome, disease activity, co-morbid conditions, treatment or stroke rehabilitation care.

Poor cognitive performance in SLE patients with stroke was frequently associated with subcortical damage with and without white matter intensity (p value < 0.003), as compared to major cortical syndrome in non SLE stroke subjects (P value < 0.010), after adjusting for vascular risk factors. Cognitive domains of memory, orientation, language, and attention were more defective in SLE

patients with stroke when compared with SLE patients with no stroke or non SLE stroke subjects.

Post stroke depression and emotional incontinence were associated with cognitive impairment among SLE patients with stroke and non SLE stroke subjects, regardless of coping style, anti-depressant intake, severity of steno-occlusive disease, or phospholipid syndrome. Post stroke depression was associated with cortical (OR: 1.5, 95 % CI: 1.0- 2.7), and subcortical lesions (OR: 12.0, 95 % CI: 1.8-78.2) among SLE patients, compared to right hemispheric lesion (OR: 1.2, 95 % CI: 1.0- 2.6) in non SLE stroke subjects.

Functional impairment was greater among SLE patients with focal brain injury (OR: 2.2, 95% CI: 1.1-25.6), and those with cognitive impairment (OR: 3.0, 95% CI: 1.7- 14.8), after adjusting for co-morbid condition and severity of stroke.

Conclusion: Ischemic brain injury in SLE is associated with cognitive impairment, depression, emotional incontinence and physical disability. Better understanding of the mechanism of vascular brain injury in SLE will improve patient care and facilitate the development of therapeutic options and effective rehabilitative measures.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Calcinosis occurs in ~25% of patients with Systemic Sclerosis (SSc) and causes pain, morbidity, and decreased quality of life. The treatment of calcinosis is a major challenge in the treatment of patients with SSc. The pathogenesis of calcinosis is not fully understood but shares similarities to calciphylaxis, an ischemic vasculopathy with arteriolar calcification seen in end-stage renal disease, which has been successfully treated with intravenous sodium thiosulfate (STS). Suggested mechanisms of action of STS include calcium chelation, reduction of pro-inflammatory cytokines through anti-oxidant properties, and vasodilation. Previous case studies have reported positive outcomes for calcinosis patients treated with intravenous (IV) or intralesional STS. We report here a retrospective chart review of calcinosis patients in our practice treated with STS.

Methods:

We included all patients at our site that had been treated with STS (topical and IV) and had follow-up data available. Patient charts were reviewed for clinical and demographic data. X-rays were retrospectively assessed by a physician blinded to pre or post treatment status using the SCTC Calcinosis Working Group's scoring system accounting for density of calcinosis and relative area involved. A paired t-test was used to assess significance.

Results:

A total of 5 patients were identified, 4 of whom met 2013 ACR/EULAR criteria for SSc and 1 met criteria for juvenile dermatomyositis. All SSc patients were treated with topical STS while the dermatomyositis patient was treated with IV STS. Table 1 summarizes clinical and demographic characteristics of patients. Treatment time ranged from 3-7 months. 1 patient (STS 4) discontinued use after 2 days due to erythema and inflammation of ulcerating calcinosis. No significant change in calcinosis scores was seen between baseline and follow-up x-rays (Table 2, p=0.24).

Conclusion:

In this small retrospective study no significant changes in radiographic calcinosis score were observed, but the duration of treatment was relatively short and STS was generally well tolerated. Further evaluation of STS in calcinosis may be considered recognizing the limitations of this study, in particular the relatively short treatment period.

Table 1-Clinical and Demographic Data

Study ID	Age	Sex	Race	Disease Duration (Years)	Disease Type	SSc Antibodies	Location of Calcinosis	Concomitant Medications
STS 1	65	F	White	13	Limited SSc	RF	L & R wrists	omeprazole, minocycline, atorvastatin, diltiazem, escitalopram,
STS 2	67	F	White	14	Diffuse SSc	Pol3	R wrist	omeprazole
STS 3	52	F	White	5	Limited SSc	centromere	R Thumb and 5th digit, L wrist	esomeprazole (40mg QD), famotidine (40mg QD), colchicine (0.6 QD), eletriptan (prn)
STS 4	61	F	White	8	Limited SSc	centromere	L & R Hips	amlodipine (2.5mg QD), omeprazole (20mg BID)
STS IV	25	F	Asian	5	Juvenile Dermatomyositis	N/A	Diffuse (thighs, hips, arms)	methotrexate (5mg SQ weekly), alendronate

Table 2-Radiographic Scores*

Study ID	Baseline	3-months	6-months
SSc Patients			
STS 1	177.375	250.25	246
STS 2	42.75	51.25	N/A
STS 3	53.25	N/A	65.75
Juvenile Dermatomyositis Patient			
STS IV-Hands	3.5	5.75	N/A
STS IV-Right Thigh	20%†	20%†	N/A
STS IV-Left Thigh	5%†	5%†	N/A
STS IV-Feet	1-2%†	1-2%†	N/A

*reported as composite scores for both right and left hands according to the SCTC Calcinosis Working Group scoring system. A t-test was performed on the mean change in score giving p=0.24, NS.
†SCTC scoring system is only applicable to hand radiographs. Thus, the blinded assessor scored these images on percent involvement.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Arthropathy and tendinopathy in Systemic Sclerosis (SSc) contribute to disability and are associated with disease progression. Clinical trials in SSc sometimes include the tender joint count (TJC) and swollen joint count (SJC) as outcome measures; however, these outcomes have not yet been validated in SSc. We assessed inter and intrarater reliability of TJC and SJC and compared joint examinations with musculoskeletal ultrasound (MSK US) to determine criterion validity.

Methods: Seven patients enrolled in the Prospective Registry of Early Systemic Sclerosis (PRESS) cohort participated. Two separate 28 joint count TJC and SJC were performed on a single day by 10 rheumatologists. On the same day patients had MSK US of the bilateral hands and wrists (22 joints) which were read by a MSK radiologist for synovitis, synovial thickening, and erosions. For TJC and SJC, we computed inter and intra-rater reliability. The following values represent the following degrees of agreement: <0 – poor; 0-0.2 – slight; 0.21- 0.4 – fair; 0.41- 0.6 – moderate; 0.61-0.8 – substantial; and 0.81-1.0 – almost perfect agreement. For the validation exercise we compared the initial physician assessment of swelling or tenderness of the individual 22 joints to the MSK US. We calculated the sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) for each physician compared to MSK US as a gold standard and present the mean (SD).

Results: The mean age of the patients was 41.6 ± 19.8 years and the mean disease duration from the first non-Raynaud's symptom was 2.7 ± 0.8 years. All had diffuse cutaneous (dc)SSc; 3 were female and 4 male. The mean modified Rodnan Skin Score was 14.67 ± 4.04.

The mean TJC was 4.2 ± 2.0 (0-28 count). The interobserver reliability for the TJC was 0.97, and the intraobserver reliability for the TJC was 0.99, showing almost perfect agreement. The mean SJC was 1.3 ± 0.8 (0-28 count). The interobserver reliability for the SJC was 0.24, showing fair agreement, and the intraobserver reliability for the SJC was 0.71 denoting substantial agreement.

9.7% (15/154) of joints showed synovitis or synovial thickening on MSK US. 2% (3/150) of physician examinations of joints noted to abnormal on MSK US noted swelling, and 9.3% (14/150) noted tenderness. Additionally, in the joints that were normal on MSK-US, 4.4% (57/1302) of examinations noted swelling and 21.7% (282/1302) noted tenderness.

	Sensitivity – mean (SD)	Specificity – mean (SD)	PPV – mean (SD)	NPV – mean (SD)
Swelling of joint	0.020 (0.045)	0.956 (0.028)	0.039 (0.076)	0.894 (0.009)
Tenderness of joint	0.093 (0.034)	0.778 (0.033)	0.046 (0.014)	0.881 (0.013)

Table 1. Sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) for the initial physician assessment of swelling and tenderness for each physician compared to the MSK US as the reference standard. These were calculated for 10 physicians and are presented as mean (SD) for the group of physicians.

Conclusion: We noted excellent inter and intrarater reliability for the TJC, substantial intrarater reliability for SJC, and fair interrater reliability for SJC in patients with early dcSSc. Examination of the joint for swelling or tenderness showed low sensitivity, but high specificity when compared with MSK US. This cohort had low prevalence of MSK US abnormalities, and this may account for the low PPV observed. Further study should assess the factors associated with SJC and TJC in early dcSSc.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Treatment with cyclophosphamide (CYC) for 12 months stabilizes lung function parameters and improves respiratory symptoms of patients with systemic sclerosis and diffuse interstitial lung disease (ILD-SSc). After stopping treatment, this beneficial effect on lung function disappears at 24 months, hence the need to establish maintenance therapy after CYC. Our objective was to investigate the efficacy of mycophenolate mofetil (MMF) as a maintenance therapy following the administration of CYC in the management of ILD-SSc

Methods: An ambispective observational study was performed in 14 patients with SS (ACR/EULAR 2013 criteria) and secondary ILD confirmed by high-resolution thoracic CT (HRCT), who were treated with CYC due to severity criteria. The primary efficacy outcome was the change in pulmonary function tests (PFT) at the end of follow-up according to the following definitions from the American Thoracic Society: *a) improvement:* if an increase in FVC ≥ 10% or DLCO ≥ 15% is observed; *b) stabilization:* if changes in FVC are less than 10% or 15% in DLCO; and *c) worsening:*if FVC decreases ≥ 10% or DLCO ≥ 15%.

Results: Of the 14 included patients (12 women, mean age 58 ± 10 years), 11 had diffuse SS, one had limited SS, and two had systemic sclerosis sine scleroderma.

Regarding ILD subtypes, 13 cases corresponded to NSIP (nonspecific interstitial pneumonitis; two of them fibrosing) and one to UIP (usual interstitial pneumonitis). All had been treated with intravenous CYC having achieved, at minimum, stabilized lung function parameters: 10 patients had been administered CFM for a minimum of 12 months (six monthly boluses, followed by two to four quarterly boluses) and four patients for six months (six monthly boluses). The dose administered in the bolus was 750 mg/m^2 or 500 mg/m^{2}body surface as tolerated. MMF doses ranged from 1.5 to 2 g per day.

During follow-up, nine (64%) patients showed ILD-SSc progression with clinical and functional decline, ultimately requiring rescue treatment with rituximab (RTX). The elapsed time from the start of MMF to treatment with RTX (mean ± SD) was 21 ± 8 months (range, 8-28). The evolution of PFT values in this subgroup of patients is shown in the following table:

	Baseline (onset of MMF treatment	**End of MMF treatment**	**% of change from baseline**
FVC %	65.7 ± 20.5	51.2 ± 18.4	-22.07%
TLC %	69.2 ± 10.9	61.6 ± 9.2	-10.98%
DLCO%	51.8 ± 15.5	40.2 ± 13.6	-22.39%

In the four (36%) remaining patients, MMF stabilized PFT. The mean follow-up time in this subgroup was 18 ± 8 months (range, 8-28).

Conclusion: Maintenance therapy with MMF only manages to preserve the beneficial effect achieved with CYC in approximately one-third of cases. Despite advances in the early diagnosis of ILD-SSc, the results obtained with available treatments remain disappointing.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Histopathological hallmarks of systemic sclerosis (SSc) are perivascular infiltrates and a reduced capillary density, which precede the excessive accumulation of extracellular matrix components in the later stages of the disease. The reduced capillary density leads to a slower blood flow, to tissue ischemia. Tissue hypoxia usually initiates the formation of new blood vessels from the pre-existing microvasculature. Despite the reduced blood flow and lower oxygen pressure levels, there is no evidence for a sufficient angiogenesis in the skin of patients with SSc. Nailfold capillaroscopy (NVC) is a safe, noninvasive method for the microvascular investigation. It allows us to distinguish between primary and secondary Raynaud's phenomenon.The aim was to assess whether blood levels of angiogenic biomarkers are associated with microvasculature changes in SSc patients.

Methods: Microvasculature changes were assessed using NVC which was performed by two independent examiners. The obtained images were analysed anonymously by two investigators blinded for the clinical and serum status of SSc patients and classified as early, active and late pattern (1). Serum or plasma levels of soluble vascular adhesion molecule-1 (sVCAM-1) and soluble intercellular adhesion molecule-1 (sICAM-1) were measured by ELISA, big endothelin-1 (BET-1) concentrations using competitive enzyme-immunoassay and von Willebrand factor antigen (vWFAg) concentrations using ELISA kit were measured. As potential disease activity markers soluble receptor of interleukin-2 (sIL-2r) and interleukin-6 (IL-6) serum levels using commercial kits were assayed. For statistical evaluation Pearson's correlation coefficient and univariate analysis were used.

Results:

Total 40 patients (38 females) were investigated: 30 individuals with limited form, 5 with diffuse, 3 patients with sclerosis sine scleroderma, 1 with overlap syndrome and 1 with undifferentiated connective tissue disease. The mean age ± standard deviation (SD) of the whole cohort was 51±22 years and the mean disease duration ± SD was 10±7 years. 3 patients (7.5%) had early NVC pattern, 12 patients (30%) had active, 10 (58%) late pattern, and 15 (37.5%) had nonspecific changes or normal picture. The patients with late NVC pattern exhibited higher vWFAg levels than patients with active pattern ($p<0.01$). BET-1 and sICAM-1 serum levels were higher in the active pattern compared with late pattern ($p<0.01$ and $p<0.05$, respectively). When correlating these potential biomarkers with SSc-related clinical characteristics we found only these associations: vWFAg levels with heart arrhythmias and modified Rodnan skin score ($p<0.01$, $p<0.05$, respectively).

Conclusion: VWFAg and ET-1 increase in the late NVC pattern can be considered as an attempt to support deficient vasculogenesis. Further studies are needed to determine the role of other potential biomarkers of endothelial injury and repair in SSc.

Session Date: Tuesday, November 10, 2015

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: In patients with connective tissue disease (CTD), especially systemic sclerosis (SSc), several mechanisms have been implicated for the development of pulmonary hypertension (PH), including pulmonary arterial hypertension (PAH), PH with interstitial lung disease (PH-ILD) and PH with left heart disease (PH-LHD). The combination of such different mechanisms lead to the complexity of pathogenesis that might possibly result in less efficacy of combination therapy using PAH-specific drugs (CoTpy) for survival in PH-CTD than in idiopathic PAH. The present study therefore aimed to analyze the factors that influence the effect of CoTpy on survival of PH-CTD.

Methods: We performed a retrospective-cohort study of 118 patients with PH-CTD, including 56 SSc, 29 MCTD or 24 SLE patients, who were followed up between January 1980 and March 2015 in our hospital. PH was diagnosed based on heart catheterization (HC). Patients with PH-ILD had been confirmed to have ILD on chest CT scan. Patients with PH-LHD had been confirmed to have LHD by HC or biopsy. There were 97 PAH, 47 PH-ILD and 9 PH-LHD patients. Our CoTpy strategy for PH intended to achieve the following goals: 1) improvement in WHO-functional class and 2) reduction of serum BNP level of less than 100 pg/ml, based on our previous study as well as on the results demonstrated by Hoeper et. al, (Eur Respir J 2005; 26: 858–863). The PAH-specific drugs, including bosentan, ambrisentan, sildenafil, tadalafil, epoprostenol, and beraprost (an oral prostacyclin analog that is only available in Japan), were switched from drug to drug or adopted in combination so as to achieve these predetermined therapeutic goals once a month. We performed Cox's proportional hazard analysis for survival measured from the date of the diagnosis of PH using propensity score (PS) methods. PS for CoTpy was estimated from a variety of factors, including sex, age at diagnosis of PH and CTD, causes for PH, and complicated CTD, using logistic regression.

Results: Fifty-nine patients were treated under our CoTpy strategy. The PAH-specific medications in this group at the last observation are shown in table 1. Multivariative study demonstrated that CoTpy significantly reduced the risk for death (HR 0.324, 95%CI: 0.163-0.610) in PH-CTD. Estimated survival curves of patients with PH-CTD under CoTpy are shown in Figure 1. Thus, coexistence of PH-ILD and PAH significantly increased the risk for death (HR 1.88, 95%CI: 1.08-3.26) compared with PAH alone. Moreover, coexistence of PH-ILD and PH-LHD in addition to PAH increased the risk for death (HR 5.11, 95%CI: 0.822-24.62) compared with PAH alone.

Conclusion: The results demonstrate that combination therapeutic strategy using PAH-specific drugs markedly improved survival of patients with PH-CTD. Moreover, the data indicate that appropriate management of PH-ILD and/or PH-LHD is important for improving survival of PH-CTD patients treated with PAH-specific drugs combination therapy.

Might Troponin be a Marker for Subclinical Scleroderma Heart Involvement (SHI)?

Chiara Stagnaro[1], Anna d'Ascanio[1], Alice Parma[2], Umberto Conti[3], Michele Emdin[4], Alessandra Della Rossa[1] and Marta Mosca[1], [1]Internal Medicine, University of Pisa, Pisa, Italy, [2]University of Pisa, Pisa, Italy, [3]Cardiotoracico, Cardiologia 2, Pisa, Italy, [4]Fondazione Toscana Gabriele Monasterio, UOC Cardiologia e Medicina Cardiovascolare, Pisa, Italy

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a rare connective tissue disease with pronounced alterations of the microvascular system, frequent cellular and humoral immunity abnormalities and fibroblast dysfunction. All these events result in an overproduction of collagen with possible involvement of skin and internal organs. Cardiac involvement is common in SSc; it is often asymptomatic and insidious, but almost invariably associated with ominous outcome. For this reason it is essential to identify markers useful to early recognize any sort of SHI. The aim of this study was to investigate if high sensitivity troponin (HSTn) could be helpful to identify subclinical SHI.

Methods: for this purpose we analyzed data of 65 consecutive SSc patients (M:F = 4:61; mean age 59,4 years, range 24-95 years; mean disease duration 10,3 years; 33 with lcSSc, 32 with dcSSc) followed at our unit. Among all our SSc patients admitted in the last two years, we selected only those who underwent the following laboratory and instrumental investigations: HSTn, electrocardiogram and an echocardiogram within six months of HSTn test. Most of patients performed also N-terminal segment of proBNP (NT-proBNP) test and three patients underwent cardiac magnetic resonance imaging (cMRI). We excluded from our study patients with overt pulmonary arterial hypertension since it could alter cardiac markers. For six of the selected patients we collected data in more than one occasion. Furthermore we defined as SHI the presence of one or more of these conditions, in the absence of any other causes: diastolic dysfunction (at least grade II or grade I if patient is younger than 50 years or in presence of other manifestations of SHI), pericardial effusion, conduction abnormalities (bundle branch block or atrioventricular block) or arrhythmias, edema and/or T2 weighted non ischemic pattern showed by cMRI. Correlation between laboratory data and instrumental measurements were performed by non parametric tests for continuous variables and contingency tables for categorical variables (Stat-View, SAS). Fisher exact test was applied when indicated.

Results: among the analyzed patients 13 showed SHI and 23 and 29 had respectively high levels of HSTn and of NT-proBNP. SHI seems to be correlated only with high levels of HSTn (p 0,02) with a significant difference between the HSTn values of patients with or without SHI (59 versus 13ng/ml; p 0,0097). Moreover we observed a strictly correlation between NT-proBNP and HSTn: among patients with abnormal NT-proBNP, 18 had also out of range HSTn (spearman rank correlation 0,5; p <0.0001).

Conclusion: Our data shows a close relationship between HSTn and NT-proBNP in SSc patients with SHI. However, if we consider these 2 serological parameters independently, we observe that HSTn might be a marker of SHI while NT-proBNP seems to be a less specific index of heart dysfunction. Since SHI is often subclinical, but anyway associated with a significantly increased morbidity and mortality, a serological marker would be very useful not only to early diagnose SHI but also to select patients who need additional investigations such as cMRI. However further studies are necessary to confirm these preliminary results.

Session Time: 9:00AM-11:00AM

Background/Purpose:

Systemic Sclerosis (SSc) is a rare heterogeneous autoimmune connective tissue disease**.**Pulmonary involvement is the major cause of mortality and morbidity in Systemic sclerosis. The aim of the study is to provide a single center experience of SSc patients diagnosed at a tertiary care center over a continuous period of 10 years, in regards to the extent and characteristics of interstitial lung disease at the time of initial presentation

Methods:

Retrospectively reviewed the charts of all the SSc patients who presented to The University of Connecticut Health Center Rheumatology clinic for the first time from April,2004 to March, 2014. All patients fulfilled the 2013 ACR/EULAR classification criteria for SSc, applied retrospectively at the time of chart review. Information about patient's demographics, laboratory, imaging studies and procedures including chest x- ray (CXR), high resolution CT (HRCT) of lung , pulmonary function tests (PFT's) and esophageal transit time (ETT) done at the time of their initial presentation were collected

Results:

128 patients were identified with either limited cutaneous (111) or diffuse cutaneous (17) variant SSC, of whom 120 (94%) were female and 95 (74%) were white**.** SCL-70 was positive in 18% and anti-centromere antibody was positive in 32% of patient's. Complete report of the PFT's was available in 104 patients. FVC was less than 70% in 20 (19%) patients. Of these, 4 had normal HRCT of the lung and 16 patients had interstitial changes. DLCO was less than 70% in 16 of the 20 patients with abnormal FVC. Of the remaining 84 patients with normal FVC, 10 (12%) patients had abnormal CXR and of the 62 patients with both normal FVC and normal CXR, 15 (24%) patients had an abnormal HRCT**.**

Among the 122 patients who had HRCT lung, 52 (43%) had abnormal HRCT including the 18 patients with only minimal ground glass changes and 34 patients with honeycombing and or fibrosis mostly limited to the subpleural space . Among the 52 patients with abnormal HRCT 28 (54%) patients had either an abnormal CXR or FVC. The remaining 24 patients with an abnormal HRCT had a normal FVC and CXR which accounts for 20% of total patients.

Of the 52 patients with abnormal HRCT lung, ETT was normal in 16 (30%) patients and abnormal in 35 (67%) patients. Of the 70 patients with normal HRCT, ETT was normal in 31(44%) patients and abnormal in 36 (51%) patients. No statistically significant difference was seen in the incidence of ETT in people with and without HRCT lung abnormalities (2 tailed p value was 0.129 using Fisher's exact test)

Conclusion:

Majority of patients presenting to University of Connecticut Health Center had limited cutaneous variant of SSc .Interstitial lung disease as diagnosed with HRCT lung was seen in more than 40% of patients with Systemic Sclerosis at the time of diagnosis. More than one third of these patients had only minimal ground glass opacities. Even though HRCT lung was abnormal in one fourth of the patients with normal FVC and chest x-ray**,** none of the patients had ILD severe enough to require treatment. Esophageal dysmotility is seen more often in patients with HRCT lung abnormalities but it was not statistically significant.

Musculoskeletal Involvement in SSc Correlates with Poor Short Form 36 and SSc Health Assessment Questionnaire Scores As Well As Lower TNF-Alpha Gene Expression in PBMCs

Eliza Pelrine[1], Marie-Dominique Ah-Kioon[1], Meng Zhang[2], Franck J. Barrat[3], Robert F. Spiera[3] and Jessica K. Gordon[3], [1]Hospital for Special Surgery, New York, NY, [2]Epidemiology and Biostatistics, Hospital for Special Surgery, New York, NY, [3]Rheumatology, Hospital for Special Surgery, New York, NY

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Systemic Sclerosis (SSc) is characterized by a wide variety of symptoms and disease manifestations including joint pain, gastrointestinal dysfunction, interstitial lung disease, and cardiomyopathy. Using the Scleroderma Health Assessment Questionnaire (SHAQ) and Short Form-36 (SF-36) we explored how patient-reported physical health, mental health, and functional status related to these clinical characteristics and to cytokine levels in our scleroderma patient cohort.

Methods:

This was an observational study including 274 patients enrolled in our center's SSc registry. From those we included patients who had completed both questionnaires and had clinical data available (n=185). A subsection of 32 patients was included for cytokine analysis. Interleukin-6 (IL-6), Interleukin-1β (IL1ß), and Tumor Necrosis Factor-α (TNFα) levels were measured by Luminex and ELISA assays. Gene expression of these cytokines was measured by qPCR. Analysis was carried out using descriptive statistics, Spearman, Kruskal Wallis, and ANOVA tests as appropriate.

Results:

Musculoskeletal (MSK) involvement, as defined by the presence of myalgias, myositis, arthritis, and/or joint pain, correlated with lower (worse) SF-36 scores (χ^2=11.32,p<0.01) and higher (worse) SHAQ scores (χ^2=11.54,p<0.01). High SHAQ scores also correlated with high modified Rodnan Skin Scores (mRSS) (ρ=0.21,p<0.01). SF-36 and SHAQ scores were also compared to age, gender, race, disease duration, disease type, and other organ system involvement and no significant interactions were observed. Lower TNFα expression in peripheral blood mononuclear cells (PBMC) correlated with MSK involvement (F=103.21,p<0.01) SF-36 Mental Health component scores positively correlated with IL-6 levels in PBMC (ρ=0.81,p<0.05). Disease duration negatively correlated with TNFα expression in PBMC (ρ=-0.9,p<0.05). No other significant interactions were seen between clinical characteristics and cytokine levels.

Conclusion:

In our cohort, MSK involvement was the only clinical feature to be strongly associated with both decreased quality of life and worse functional status. Surprisingly, subjects with musculoskeletal symptoms expressed lower levels of TNFα in their PBMCs. These associations are topics for further study.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

The presence of nailfold capillary (NFC) abnormality is part of the 2013 ACR/EULAR Classification Criteria for Systemic Sclerosis (SSc). NFC findings include the presence of capillary dilation, hemorrhage, and neoangiogenesis, and it has been shown that these patterns have prognostic value. Patients in the Prospective Registry of Early Systemic Sclerosis (PRESS) cohort (diffuse SSc patients with < 2 years disease duration) have NFC evaluation using widefield microscopy (WM) at eleven centers in the United States. Our objective in this study was to assess the interrater agreement of the PRESS investigators assessment of NFC abnormalities by WM in

order to ensure the quality of our data collection.

Methods:

Investigators from the PRESS registry assessed 26 cases of patients with SSc without macrovascular changes or significant hand contractures who had been photographed using WM. The PRESS Investigators have attended training exercises to learn the capillaroscopic techniques, but no specific training was provided prior to this exercise. Each case was assessed for NFC dilation, hemorrhage, and neoangiogenesis (defined as bushy capillaries) and rated as normal, mild, moderate, or severe for each of these categories. Data were captured via surveymonkey and analyzed in two ways: 1.) using all 4 categorical variables and 2.) using a simplified approach where the variables were collapsed to normal vs abnormal. Krippendorf's alpha reliability estimate was used to assess the interrater agreement between these categorical variables. The following values represent the following degrees of agreement: <0 – poor; 0-0.2 – slight; 0.21- 0.4 – fair; 0.41- 0.6 – moderate; 0.61-0.8 – substantial; and 0.81-1.0 – almost perfect agreement.

Results:

Intrarater reliability ranged from substantial to almost perfect agreement for NFC hemorrhage to substantial agreement for dilation of NFC loops to fair agreement for neoangiogenesis. Assessment with four variables showed improved agreement when compared to 2 variables. Results are presented in Table 1.

Interrater Reliability		
	4 variables (normal, mild, moderate, severe)	2 variables (normal/abnormal)
NFC Hemorrhage - alpha (95% CI)	0.7991 (0.7528, 0.8403)	0.8205 (0.6801, 0.9262)
Dilated Capillary Loops - alpha (95% CI)	0.6538 (0.5930, 0.7093)	0.4869 (0.2846, 0.6934)
Neoangiogenesis - alpha (95% CI)	0.3738 (0.2820, 0.4644)	0.2706 (0.0879, 0.4527)

Table 1. Krippendorf's alpha reliability estimate using 4 variables (normal, mild, moderate, severe) and using 2 variables for the 3 categories of NFC abnormality assessed.

Conclusion:

Fair inter-rater reliability was observed for neoangiogenesis, moderate to substantial reliability was observed for dilated capillary loops, and substantial to near perfect agreement was noted for reading of WM photomicrographs for NFC hemorrhage among PRESS investigators. This attests to quality data collection for this procedure. Classification of specific NFC abnormalities using the terms normal, mild, moderate, and severe is feasible and can be used reliably in registries. Whether NFC abnormalities carry prognostic significance in patients with early diffuse SSc is a subject for future study in the PRESS registry.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Calcinosis is caused by deposition of calcified materials in the soft tissues (1). Hydroxyapatite (HA) is reported to be its major constituent (2). Mechanical stress and local tissue hypoxia are believed to be important in its pathogenesis (3). Our aim was to analyze spontaneously draining material from calcinosis sites in scleroderma (SSc) patients using x-ray diffraction.

Methods: In this IRB-approved study, we enrolled SSc patients meeting the American College of Rheumatology criteria for definite SSc (4). Pertinent clinical data was collected. Xray diffraction data were used to determine solid phase present (e.g., HA *versus* other Ca phosphate phase) and to approximate the % amorphous and % crystalline components using a Bruker HiStar multi-wire area detector.

Results: Ten female subjects (see Table 1) with advanced SSc were enrolled with mean disease duration 16 years; 6 had diffuse SSc. Calcinosis occurred later in the disease course and 7 had extensive calcinosis affecting multiple sites. Draining calcinosis was collected from multiple sites, most commonly the hand. X-ray diffraction confirmed HA of varying percentages in all but one specimen. Solid samples generally contained higher amounts of HA.

Conclusion: By using x-ray diffraction, our study corroborates previous published reports (2, 3) that HA crystal deposition is the main constitute of SSc-related calcinosis. Solid samples contained higher amounts of HA crystals; fluid samples observed by optical microscopy to contain solids, including HA in suspension. Further research is needed to characterize the amorphous materials associated with HA deposition in SSc patients with calcinosis.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Raynaud's phenomenon is a clinical symptom that can commonly present to a primary care provider or generalist. Proper identification of an underlying connective tissue disease in a patient with Raynaud's could allow for the prevention of possible critical digital ischemia. Capillaroscopy is a tool which can identify abnormalities associated with connective tissue disease.

Methods: Patients presenting with a complaint of Raynaud's phenomenon were assessed with capillaroscopy. In twenty consecutive Raynaud's patients 8 digits were assessed by a 200X magnification dermatoscope and an image was obtained. Each image was assessed for the following abnormalities: drop-out (<9 capillaries in 1 mm); micro-hemorrhage; dilated loops; and neoangiogenesis. These 160 images were then shown to 20 primary care physicians, who assessed these same abnormalities. The interrater reliability, a measure of agreement, of individual primary care providers with the expert provider was assessed using kappa statistics.

Results: The total agreement from the 20 primary care providers was moderate (kappa =0.50, 95% CI: 0.49, 0.55). Three raters had slight agreement (in the range 0 to 0.20), one rater had fair agreement (0.21 to 0.40), 11 raters had moderate agreement (0.41 to 0.60), 5 raters had substantial agreement (0.61 to 0.80), and no rater had almost perfect agreement (0.81 to 1.00) For the four providers with slight to fair interrater reliabilities, the most common disagreement was providing a positive diagnosis when the expert rater diagnosed the digit negative. Ten of the 20 primary care providers provided at least one additional diagnosis following an abnormal diagnosis (n= 35 digits or 35% of the 1,556 abnormal ratings by the primary care providers). The four providers with the poorest interrater reliabilities were not among the 10 providers who participated in making these additional specific diagnoses. These providers achieved the moderate agreement with the expert provider for diagnoses of micro-hemorrhage (kappa = 0.64, 95% CI: 0.57, 0.70), but fair agreement with the expert provider for diagnoses of dilated loops (kappa = 0.27, 95% CI: 0.20, 0.34) and neoangiogenesis (kappa = 0.22, 95%CI: 0.13, 0.31).

Conclusion: Capillaroscopy is a potentially contributive clinical exam skill that could assist primary care providers and generalists in identifying and qualifying changes associated with the common presentation of Raynaud's disease. However, formal training is needed to ensure accuracy and reproducibility. Furthermore, training and scoring systems should address time constraints of busy primary care practitioners.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Nailfold Video Capillaroscopy (NVC) is a reliable method to qualitatively differentiate Primary (PRP) from Secondary Raynaud Phenomenon (SRP) through diagnosis of the “early scleroderma pattern” (1, 2). Quantitative evaluation by NVC was demonstrated to be of great value for the analysis of abnormal capillary parameters (2). The purpose was to assess the presence and localization of capillary diameter abnormalities (>20µm),before the transition to SRP. Moreover, to find a threshold value for those dilations, associated to the development of giant capillaries (>50 µm), pathognomonic for the “early scleroderma pattern” (SSc).

Methods: We realized a case-control study, over a total population of 191 RP subjects with a NVC follow-up of 42.77±35.80 months. Two gruoups were identified, uniform for demographic characteristics (gender, age), RP duration (p= 0.98), treatments (p=0.13) and comorbidities (p=0.13). RP subjects were classified as SRP SSc-associated, based on the appearance of the “early” scleroderma pattern and/or ANA positivity, or confirmed with PRP. One operator performed the NVC and results were separately checked by two experts with an inter-rater/intra-rater proportion of agreement of 90% and 96%, respectively. Another observer measured on NVC images the major dilation of capillary branches (arterial, venous, apical) using a dedicated software (Videocap, DS MediGroup, Milan, Italy). More then 6112 images were analyzed. The mean diameter value for each enlarged branch (arterial, venous, apical) and the total mean diameter, were calculated. Statistics were performed by non-parametric tests. ROC curve was performed to find the SSc development associated threshold value.

Results: A statistically significant difference was found in SRP subjects, before the transition, compared to PRP subjects, for diameter values of dilations in both arterial (35.30 ± 8.79 VS 27.84 ± 5.52 µm; p<0.0001) and venous (37.19 ± 6.58 VS 28.86 ± 4.48 µm; p<0.0001) branches. No significant differences were observed for apical dilations (32.64 ± 5.77 VS 30.81 ± 6.35 µm; p=0.07). ANAs were observed in 56.2% of SRP patients (p= <0.0001). No confounding effect was observed for other demographic and clinical data. Kaplan-Meier analysis showed that 50% of SRP patients evolved to SSc in 20 months. The threshold value associated with SSc development was 30.16 µm, determined through ROC curve, with a sensitivity/specificity of 0.85/0.63 respectively, a negative predictive value (NPV) of 0.92 and a positive predictive value (PPV) of 0.44.

Conclusion: Abnormal dilations of arterial and/or venous branches, at baseline, are detectable by NVC, and are significantly more often expressed in RP subjects that will develop a SRP.Progression to “giant” capillaries (>50 µm) pathognomonic for the “early” NVC scleroderma pattern seem to be unlikely for subjects affected by RP with mean capillary diameter lower then 30.16 µm (NPV 0.92). Therefore, it is advisable to perform always the qualitative/quantitative integrated NVC during the follow up of all patients affected by RP.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Patients with systemic sclerosis (SSc) experience dyspnea for multiple reasons. Cardiopulmonary exercise testing (CPET), an important tool in the evaluation of undifferentiated dyspnea, provides integrated metabolic and hemodynamic measures during exercise. Few

studies have utilized CPET in SSc.[1] In this study we evaluated exercise limitations in SSc patients as determined by CPET combined with invasive hemodynamic measurements (level 3 CPET).

Methods:

This was a single center, retrospective review of all SSc patients who underwent level 3 CPET between February 2006 and February 2015. Level 3 CPET consists of graded exercise on a cycle ergometer with metabolic cart and simultaneous measurement of pulmonary and systemic arterial hemodynamics. Primary reasons for exercise limitation include left ventricular diastolic dysfunction (LVDD), a peripheral limit (impairment in the ability of the muscles to extract and use oxygen), a pulmonary vascular limit (PVL, i.e. PAH) or a pulmonary mechanical limit. Demographic and clinical information was extracted from medical records.

Results:

Eleven patients were included in this analysis. Nine of the eleven patients met the 2013 ACR SSc classification criteria. Two had missing information that precluded the definitive classification as SSc, but fell within the spectrum of SSc disease. Baseline characteristics are shown in **Table 1**. 91% of patients were female and the mean age was 61 years. Seven of eleven (64%) patients had a peripheral extraction limitation; the remaining four had LVDD or PVL **(Table 2)**. Three of the seven patients with a peripheral limit to exercise were anemic, defined by hemoglobin <12 g/dL, the lower limit of normal in our laboratory.

Conclusion:

Our findings provide novel insight into less explored etiologies of dyspnea and exercise limitation in SSc patients. Only one prior study reported findings similar to ours, but that study did not employ invasive CPET.[2] Of note, only three of the seven patients with a peripheral limit in our study were anemic, suggesting alternative mechanisms for impaired peripheral oxygen extraction. The systemic vasculopathy characteristic of SSc is likely present in muscle and may contribute to impaired oxygen utilization. Our findings call for larger studies to address the possible mechanisms of peripheral limitation in SSc patients, and even suggest a potential therapeutic role for agents with vascular targets that may improve peripheral extraction, resulting in improved dyspnea and exercise tolerance in SSc patients.

Exercise Intolerance Evaluated By Invasive Cardiopulmonary Exercise Testing in Connective Tissue Disease: Beyond Pulmonary Hypertension

Rudolf Oliveira[1,2], David Systrom[2], Julie Tracy[2], Abbey Karin[2], Aaron Waxman[2], Paul Dellaripa[3] and Paul Hoover[3], [1]Medicine, Division of Respiratory Disease, Federal University Of São Paulo, São Paulo, Brazil, [2]Pulmonary and Critical Care Medicine, Brigham and Women's Hospital, Boston, MA, [3]Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Boston, MA
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Exercise intolerance is common in patients with connective tissue disease (CTD) and may be related to pulmonary hypertension (PH). However, determining the exact etiology of the exercise limitation in these patients is challenging due to the multiorgan involvement of CTDs. The invasive cardiopulmonary exercise testing (iCPET) combines the non-invasive evaluation of an incremental symptom-limited cycling CPET with simultaneous pulmonary and radial artery-derived invasive hemodynamics measurements, and therefore differentiate among cardiovascular, respiratory, metabolic and peripheral limitations to exercise. In the current study, we evaluated patients with CTD and exertional intolerance (with or without interstitial lung disease, ILD) who underwent iCPET. Our aim was to determine the relative contributions of central cardiac and peripheral mechanisms underlying exertional intolerance in CTD patients. We hypothesized that CTD without ILD would have multifactorial reasons for exertional intolerance, beyond PH.

Methods:

683 clinically indicated iCPETs performed at Brigham and Women's Hospital between 2011-2015 were evaluated. Based on established diagnostic criteria 50 patients had confirmed CTD (18 SSc, 15 RA, 4 UCTD, 3 SLE, 3 antisynthetase syndrome, 2 CREST, 2 MCTD, 1 psoriatic arthritis, 1 Sjögren's, 1 Still's). ILD was defined by the presence of fibrosis on CT scans of the lungs and a forced vital capacity < 70% predicted.

Results:

From the 50 patients evaluated, 15 had CTD-ILD, of which 14 (93%) had PH. Among the 35 patients without ILD, 23 (66%) had a reduced aerobic capacity defined by maximum oxygen uptake (VO_{2MAX}) < 80% predicted. Out of these 23 patients, 10 (43%) had PH and 13 (57%) had a non-PH related exercise diagnosis, most commonly a peripheral limitation to exercise (10 of 13). Subgroup analysis of systemic sclerosis (SSc) patients revealed 10 of 18 (56%) with ILD, and PH was the most common diagnosis. SSc patients without ILD and a reduced VO_{2MAX} were more likely to have a peripheral limitation to exercise (5 of 7, Figure 1). VO_{2MAX} was 62±15% predicted for the CTD-ILD group, 60±16% for CTD without ILD with PH-related limitation to exercise, and 63±12% for CTD without ILD and a non-PH disease. There were no significant differences regarding VO_{2MAX} among these three groups ($p>0.05$).

Conclusion:

With direct measures from iCPET, we conclude that while CTD-ILD patients are more likely to present a PH-related limitation to exercise, CTD patients without ILD have a higher prevalence of peripheral limitation manifested by impaired systemic O_2 extraction. We speculate the latter may be related to skeletal muscle mitochondrial dysfunction and/or peripheral microvascular dysfunction.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Growing evidence supports the view that systemic sclerosis (SSc) is a vascular disease mediated by autoimmunity and evolving into progressive tissue fibrosis. Several vascular biomarkers have been studied, but little is known about the role of metabolic derangement in vasculopathy in SSc. Our study aimed to investigate the relationship between insulin resistance and the digital ulcer (DU) in patients with SSc.

Methods: With a cross-sectional design, 69 female patients with SSc and 109 age-matched (± 2 years) female healthy subjects were consecutively recruited at a university-affiliated rheumatology center from June 2014 to May 2015. The magnitude of insulin resistance was evaluated by the homeostatic model assessment of insulin resistance (HOMA-IR) which was calculated as [fasting serum insulin (μIU/mL) × fasting serum glucose (mg/dL) / 405] and DU ever included active and healed ulcers. Skin fibrosis in SSc patients was assessed by modified Rodnan skin thickness score (MRSS).

Results: HOMA-IR in SSc patients was significantly higher than that in healthy subjects (1.09 (0.79-2.1) vs 0.72 (0.47-0.99), p<0.001). In SSc group, the mean age was 52.8 years, the median disease duration was 84 months and 33 patients (47.8%) had diffuse SSc. Nineteen patients (27.5%) had DU ever (6 active DU, 13 healed DU). SSc patients with DU ever had a significantly higher HOMA-IR (1.95 (1.22-2.8) vs 0.99 (0.71-1.75), p=0.002) and MRSS (15 (9-22) vs 9.5 (4.8-14), p=0.004) than those without DU ever. As shown in Table 1, in multivariable logistic regression analyses, increased log-transformed HOMA-IR showed a significant association with the presence of DU ever after adjustment of confounding factors such as MRSS (OR=2.42, 95% CI=1.01-5.8, p=0.047).

Conclusion: Increased insulin resistance was independently associated with the presence of digital ulcer in patients with SSc. Our data suggest that insulin resistance may contribute to the pathogenesis of vascular damage in SSc.

Table 1. Logistic regression models for the presence of digital ulcer in patients with systemic sclerosis

Variables	Crude OR (95% CI)	p	Adjusted OR [a] (95% CI)	p
Log-transformed HOMA-IR	2.96 (1.28-6.88)	0.011	2.42 (1.01-5.8)	0.047
MRSS	1.13 (1.04-1.24)	0.005	1.12 (1.02-1.22)	0.018
ILD	1.85 (0.96-3.53)	0.064		
Disease duration, months	1.01 (0.99-1.01)	0.097		
Age, years	0.96 (0.92-1.01)	0.130		
CRP, mg/dL	0.78 (0.17-3.64)	0.746		

HOMA-IR; homeostatic model assessment of insulin resistance, MRSS; modified Rodnan skin thickness score, ILD; interstitial lung disease, CRP; C-reactive protein

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Induced sputum (IS) is a noninvasive tool, aimed at collecting cellular and soluble materials from lung airways. IS is well accepted by patients, safer than bronchoalveolar lavage (BAL) and easily repeated. IS sampling has been validated in chronic obstructive as well as in various interstitial lung disorders (ILD). Very few studies have evaluated the role of IS analysis in SSc.

Purpose

To evaluate IS cellular analysis in SSc patients compared to healthy controls and its possible relationship with disease manifestations.

Methods:

Twenty consecutive SSc patients and 16 healthy controls underwent pulmonary Function testing (PFT) (Jaeger Masterlab spirometer), single breath diffusion capacity of carbon monoxide (DLCO) and analysis of induced sputum (IS) cytology. IS was recovered after 20 min inhalation of 3% saline with an ultrasonic nebulizer by the selecting plugs method.

Results:

Group 1(SSc) : 13 (65%) with diffuse type,7 (35%) with CREST syndrome, 19 (95%) women, mean age 52.25+17.08, disease duration 8.69+7.56 years, Raynaud duration 10.3+9.22 years , eight (40%) patients had a history of ILD and none had pulmonary artery hypertension .

.Group 2 (controls): 16 healthy volunteers: 13 women (81.25%), mean age 57.93 ± 10.4years.

Lung tests:

TLC, FVC and DLCoVA were significantly lower within Group 1 vs controls . Seven patients in Group1 had a restrictive pattern.

SSc patients IS contained higher neutrophils count (p=0.091) and lower lymphocytes count (p=0.045) compared to the control group. No difference in IS cytology was found between types of SSc.

Within Group 1, a statistically significant positive correlation was

found among several clinical, PFT and IS findings (mRss score – CD3 (p=0.044); mRss –CD4 (p=0.04); mRss - % neutrophils (0.059); FVC-% neutrophils (0.002)). Neutrophils counts in IS were significantly inversely associated with TLC and FVC.

IS samples from SSc patients with PFT restrictive pattern contained a significantly lower percentage of lymphocytes (p=0.004) and CD4/CD8 ratio (0.028) compared with controls.

Among SSc, the statically significant high CD4/CD8 ratio was associated with restrictive PFT pattern (p=0.05).

A positive correlation was found between restrictive subtype of Group 1 IS cytology count and several clinical, laboratory PFT parameters (disease duration- CD4/CD8 ratio(p=0.033), TLC- CD3(p=0.053), TLC and FVC - % macrophages (p=0.033,p=0.052 respectively), DLCoVA – % macrophages (p=0.032), CRP - % lymphocytes ,% macrophages and neutrophils (p=0.019 and p= 0.008 and p= 0.006 respectively). A Negative correlation was shown between TLC and neutrophils count (p=0.043).

Conclusion:

IS analysis of SSc patients, including patients with restrictive lung disease, shows changes in cellular pattern in comparison to healthy controls and correlation with several clinical and PFT parameters.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Pulmonary arterial hypertension (PAH) is an important complication in patients with connective tissue disease and may lead to increased morbidity and early mortality. Ambrisentan, an orally active endothelin A receptor selective antagonist, has demonstrated safety and efficacy in patients with WHO Group I PAH. Due to the chronic, long-term nature of treatment, dose adjustments are often desired to enhance efficacy or attenuate adverse events. We analyzed the ARIES database to determine dose adjustments in patients with CTD-PAH treated with ambrisentan over a three year period.

Methods:

Data from the combined ARIES 1 & 2 placebo-controlled studies (ARIES-C) as well as the long-term extension study (ARIES-E) were evaluated. Available ambrisentan dosages in ARIES-C were 2.5mg, 5mg, and 10mg once daily. Patients randomized to placebo in ARIES-C who continued to ARIES-E were re-randomized to active treatment. ARIES-E was open-label; however subjects and investigators were blinded to dose for the first 24 weeks of treatment during which a single, blinded dose reduction was permitted in the case of study drug intolerance. After 24 weeks, dosage adjustments were permitted at the discretion of the investigator. The dosage of ambrisentan was recorded at each study visit for all patients continuing in the study and on therapy. At the end of 3 years, survival status was collected retrospectively for patients no longer participating in the study.

Results:

There were 124 patients with CTD-PAH who received at least one dose of ambrisentan. The numbers of patients randomized to receive each initial dose were: 2.5mg = 30, 5mg = 60, and 10mg = 34. Annual patient disposition is outlined in Table 1. Over the course of three years, approximately 40% (n=49) of patients continued to receive ambrisentan therapy in ARIES-E. Reasons for discontinuation included transitioning out of the study (n=28, 23%) or terminating participation (n=45, 36%). Retrospectively collected survival status at 3 years revealed 83 patients (67%) were still alive, 29 patients (23%) had died, and survival status was unknown in 12 patients (10%). Dose adjustments of ambrisentan over the course of three years are represented in Figure 1.

Conclusion:

Through three years of treatment with ambrisentan, those patients with CTD-PAH remaining in ARIES-E predominately remained on the dosages they were originally randomized to.

Table 1

	Year 1		Year 2		Year 3	
	Ongoing	Not Ongoing*	Ongoing	Not Ongoing*	Ongoing	Not Ongoing*
2.5mg (n = 30)	25	5	19	11	16	14
5mg (n = 60)	45	15	39	21	26	34
10mg (n = 34)	26	8	20	14	7	27

*Values of patients not ongoing for each dosage are cumulative

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To assess the benefits and harms of phosphodiesterase 5 inhibitors (PDE5) for the treatment of Raynaud's phenomenon (RP).

Methods: The Cochrane library, MEDLINE, EMBASE and Clinicaltrials.gov were searched to June 2014 for randomized controlled trials (RCTs) examining RP with PDE5. Outcomes of interest were: Frequency of RP attacks, Duration of attacks, Severity of attacks, Pain, Patient global, Withdrawals and Serious adverse events. Fixed effects models were used to calculate mean differences (MD) or standardized mean differences (SMD) for continuous outcomes and pooled risk ratios (RR) for dichotomous outcomes. Heterogeneity was determined and was considered significant if I^2>50%.

Results: Seven trials (4 with tadalafil, 2 sildenafil, 1 vardenafil) with an average duration of 5 weeks totaling 255 subjects were included; 97% had RP secondary to systemic sclerosis; SSc). Trial quality ranged from low to moderate. Many individual trials were not significantly different from placebo. PDE5 reduced the frequency of attacks by 4.2 attacks/week (95% CI 2.01-6.38) from a baseline of 26 attacks/week, or relative %change in the frequency of attacks of 22% reduction (95% CI 10-33%). Duration of attacks decreased by 6 minutes (95% CI 0.5-11); relative %reduction of 24% (95% CI 2-47%). Severity of RP attacks was assessed in one trial. Raynaud's Condition Score (RCS) improved by 0.49 cm (95% CI 0.02-0.95). Pain (VAS 0-10) improved by 1.06 (95% CI 0.09-2.03) with 25% decrease in relative %pain. The relative %reduction in disability was 39% (95% CI 18-60%). The relative risk of withdrawals was 4.42 (higher in PDE5 group). The number needed for an additional harmful outcome (NNTH) was 32 (95% CI 7 to 717). Figure shows the reduction of RP frequency and duration of attacks. Samples were too small to detect differences between PDE5 drugs.

Conclusion: PDE5 medications seem to be effective in treating RP associated with SSc.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The Prospective Registry of Early Systemic Sclerosis (PRESS) is a multicenter incident cohort study of patients with early diffuse cutaneous systemic sclerosis (dcSSc; < 2 years duration). We previously reported that gastrointestinal tract (GIT) symptoms are common at baseline in this cohort and are not associated with the choice of immunosuppressant agent. The goal of this study was to analyze the longitudinal assessment of GIT symptoms in early dcSSc as captured by the GIT 2.0.

Methods: PRESS data was collected longitudinally at various SSc centers using REDCap, a NIH funded database including demographics, disease characteristics, physical exam data, and patient-reported outcomes. PRESS patients who had a complete gastrointestinal tract questionnaire (GIT 2.0), a validated instrument for evaluation of patient-reported outcomes involving the GIT, at baseline and at one and/or two-years were included in this analysis. Statistical analysis was performed using SAS version 9.4.

Results: A total of 83 of 92 PRESS patients had a GIT 2.0 completed at the baseline visit. Thirty-seven of 15 and 12 of 15 had GIT 2.0 at one- and two- year follow-up respectively. At baseline, the mean age of this patient population was 48.9 (SD 15.1) years. Fifty-eight were women. The average BMI was 25.9 (SD 4.8). At baseline, upper GIT symptoms were more common than lower GIT symptoms. Medication use did not account for these baseline GIT 2.0 severity differences (proton pump inhibitors p=0.47; methotrexate p=1; or mycophenolate mofetil p=0.27). At one-year follow-up, 13 had worse scores for total GIT 2.0, 2 remained the same and 13 had improved scores. At two-year follow-up 6 had worse scores for total GIT 2.0 and 7 had improved total scores (Table 1). No medication changes accounted for these changes. Soilage was not present at baseline in our population, but developed in some patients at the two-year follow-up (Table 2). No PRESS patients reported a complete absence of GIT symptoms.

Conclusion: Gastrointestinal symptoms captured by the GIT 2.0 are universal in early dcSSc. Variability in change of GIT 2.0 scores may reflect variation in disease progression and GIT involvement; however the pathogenesis of developing soilage in this population wants further study.

Table 1: Severity of GIT Illness in the PRESS Population

Total GIT 2.0	Baseline (n=83)	Year 1 (n=37)	Year 2 (n=12)
Mild to Moderate	58	28	10
Moderate	17	4	0
Severe to Very Severe	8	5	2

Table 2: PRESS patient gastrointestinal symptoms captured as components of GIT 2.0 (median, Interquartile range*)

	Baseline (n=83)		Year 1 (n=37)		Year 2 (n=12)	
Variable	**Median**	**IQR***	**Median**	**IQR**	**Median**	**IQR**

Session Date: Tuesday, November 10, 2015

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Our group has previously described the sublingual frenulum abnormalities in systemic sclerosis (SSc, scleroderma). The goal of this project was to assess microvascular abnormalities in SSc by comparing perfusion of the frenulum using laser speckle contrast imaging (LSCI) in patients with SSc and healthy controls (HC). As we have observed sublingual microvascular abnormalities in SSc patients using a different technique (i.e., video-microscopy) we compared the inter-day variability of LSCI and video-microscopy of the sublingual mucosa by the Glycocheck Measurement device and software analysis in the HC.

Methods: Ten patients fulfilling 2013 ACR/EULAR classification criteria for SSc and 17 HC were recruited from the University of Utah SSc clinic and local community. Baseline perfusion (in arbitrary flux units [fu]) of the frenulum was assessed using LSCI in patients with SSc during a clinical visit and HC. Video-microscopy was assessed in 7 HC, and microvascular health was determined by penetration of red blood cells into the microvessel wall barrier region (perfused barrier region, PBR) using the Glycocheck Measurement device and software. To determine inter-day variability, HC subjects completed LSCI and video-microscopy on an additional day. All subjects were at least 2 hours without any exercise, caffeine, or food.

Results: The mean age of the SSc population was 55.1 (SD 13.7) years. Median SSc disease duration from first non-Raynaud symptom was 9.9 years (SD 9.9). When LSCI was applied to the frenulum, the perfusion index was 2308 fu (1810-3203). The perfusion index correlated negatively with disease duration, -0.64 ($p < 0.05$), but the was not significantly different from the healthy control population (2794 fu; 1368-5292). The mean age of the healthy control population was 35.9 (SD 6.25). In the healthy control population the coefficient of variation for the LSCI was 37.8±29.1% vs. coefficient of variation for Glycocheck PBR score is 5.0±2.3% ($p=0.011$).

Conclusion: This feasibility study suggests perfusion of the sublingual frenulum can be assessed by both LSCI and videomicroscopy. Although we have previously shown a decrement in microvascular health in SSc compare with HC using videomicroscopy, there were

no differences between SSc and HC using LSCI. Considering the differences in measurement variability, proper perfusion measurement of the sublingual frenulum microvasculature may be assessed more accurately by use of videomicroscopy

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: SSc is characterized by vasculopathy that precedes fibrosis and progresses to end-stage vascular manifestations such as malnutrition due to gastro-intestinal tract (GIT) involvement. Clinical management of SSc is a challenge because of limited information on the underlying pathophysiology. In this preliminary study, we aimed to determine if there were differences in sublingual microvascular health in SSc patients with/without sublingual frenulum abnormalities. We also examined the association between microvascular health and GIT scores in a pooled subset of patients.

Methods: Twenty-four patients fulfilling the 2013 ACR/EULAR classification criteria for SSc were recruited from the SSc clinic at the University of Utah. Patients had their sublingual frenulum assessed as previously described by our group and completed the GIT 2.0 validated questionnaire. Patients were grouped according to absence/presence of sublingual frenulum thickening/shortening (Fren-/Fren+, respectively). The Glycocheck videomicroscopic sublingual device was used to image the sublingual frenulum in SSc patients. This device is equipped with software that identifies > 3000 vascular segments and automatically starts when image quality is within acceptable range and automatically stops when a sufficient number have been collected. The device provides measurements of the number of well perfused vessels / mm^2 tissue surface, total number of vessels / mm^2 tissue surface, longitudinal vessel fraction that is filled with red blood cells (RBC), the fraction of vessels out of the total number that are well perfused (Dval/Dvot), RBC filled vessel density, penetration of red blood cells into the microvessel wall barrier region (perfused barrier region, PBR), and a MicroVascular Health score (MVH) which is a combined effect of these parameters (low MVH Score reflects low density and/or high PBR value = poor microvascular health). Additionally, a clinical feature of disease, SCTC GIT 2.0 was recorded examined for association across variables of microvascular health. Two tailed independent samples t-test; one-tailed Pearson correlation; mean±SE; alpha $P<0.05$.

Results: Twelve patients were recruited to each group (age, years): Fren- 57±3; Fren+ 59±4; one male per group). There were significant differences between groups in valid microvascular density (Fren- 240±23, Fren+ 149±22, $p<0.05$), total microvascular density (Fren- 328±30; Fren+ 210±29, $p<0.05$) and MVH score (Fren- 1.01±0.14; Fren+ 0.57±0.12, $p<0.05$). There were no differences in RBC filling, PBR, or Dval/Dtot (all $p>0.05$). GIT 2.0 score was negatively associated with valid microvascular density ($r=-0.39$, $p<0.05$), RBC filling ($r=-0.39$, $p<0.05$), and MVH score ($r=-0.44$, $p<0.05$). There was a trend for a negative association with total microvascular density ($r=-0.34$, $p=0.08$), PBR ($r=-0.29$, $p=0.11$), and Dval/Dtot ($r=-0.26$, $p=0.14$).

Conclusion: This feasibility study confirms that the sublingual frenulum may be indicative of perfusion abnormalities in SSc. Moreover, GIT heath scores were inversely associated with variables of microvascular health. The functional significance and pathogenesis of this abnormality warrants further study.

Measurement of Tissue Damage in Scleroderma Using Digital Mammographic Xrays: A Proof of Concept Study

John Highton[1], Terence Doyle[2] and Simon Stebbings[3], [1]Dept of Medicine, University of Otago, Dunedin, New Zealand, [2]Medicine, University of Otago, Dunedin, New Zealand, [3]Dunedin School of Medicine, University of Otago, Dunedin, New Zealand

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: We have used digital mammographic soft tissue Xrays of the fingers from patients with Scleroderma and related conditons to show damage related to the disease. Images clearly show skin thickening, fibrosis of subcutaneous tissues, calcinosis, tuft resorption and loss of tissue from the finger tips. In this study we developed a scoring sytem to give a semi-quantitative measure of these changes to investigate the hypothesis that this method could be used as a damage index and outcome measure in Scleroderma.

Methods: A Sectra Microdose C30 machine was used to take digital soft tissue images with four-finger AP views and lateral views of the index and middle fingers. Images were viewed by 2 authors and consensus reached on mild, moderate and severe changes (scored 1,2,3) for fibrosis, calcinosis and tuft resorption. Skin thickness was measured at 3 sites in each finger and averaged. Loss of tissue at the fingertip was measured according to Yune et al. Measurements were converted to scores for consistency.

Results: Xrays were scored for 6 normal subjects, 15 with lcSSc, 1 MCTD (included with lcSSc) and 7 dcSSc. Scores for calcification were higher in lcSSc for calcification: 1.2 vs 0.8 for dcSSc. Scores for tuft resorption and skin thickening were higher in dcSSc vs lcSSc: 1.8 vs 1.1 and 1.9 vs 1.1. Total damage scores were 0.17±0.1, 6.3±3.8 and 7.6±3.0 for normals, lcSSc and dcSSc respectively. These values were not statistically different. However, subjects with dcSSc had significantly more damage per year of disease duration: 1.2±0.8 vs 0.4±0.3, p=0.03.

Conclusion: We have explored the possibility that soft tissue Xrays of the fingers taken using digital mammographic methods could be used to produce a semiquantitative measure of tissue damage in Scleroderma, akin to a Sharp Index in RA. The fact that we were able to demonstrate significantly faster accumulation of damage with dcSSc compared to lcSSc even in a small number of subjects provides proof of the concept and warrants further development of this method as an outcome measure in Scleroderma.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Peripheral blood perfusion is reduced in patients affected by both primary (PRP) or secondary Raynaud's

phenomenon (SRP) (1-2). The objective of this study was to investigate blood perfusion (BP) in different skin areas of patients with PRP, SRP to systemic sclerosis (SSc), and healthy subjects (CNT), looking for differences between the groups.

Methods: Seventy SSc patients (new ACR/EULAR criteria) (3) (mean age 63±12 years, mean disease duration 6±5 years), 31 PRP patients (LeRoy criteria) (4) (mean age 48±18 years, mean Raynaud duration 3±2 years) and 68 CNT (mean age 59±19 years) were enrolled during winter time, after informed consent. BP was assessed by Laser speckle contrast analysis (LASCA) at the level of fingertips, periungual areas, dorsal and palmar aspect of 3rd finger bilaterally, dorsum and palm of both hands, and the average BP calculated as perfusion units (PU) (1). Nailfold videocapillaroscopy (NVC) was also performed to distinguish between PRP and SRP, and to detect the proper pattern of nailfold microangiopathy ("early", "active" or "late") (5). Patients were not taking vasodilator drug since al least two weeks.

Results: Both PRP and SSc patients showed a statistically significant lower BP than CNT at the level of fingertips (median 86, 88, 186 PU, respectively, $p<0.0001$), periungual (median 75, 76, 142 PU, respectively, $p<0.0001$), palmar aspect of 3rd finger (median 71, 81, 134 PU, respectively, $p<0.0001$), and palm areas (median 61, 78, 112 PU, respectively, $p<0.0001$). On the contrary, the three groups displayed similar BP values at the level of other areas of hands. Of interest, PRP patients showed lower BP values than SSc patients in all areas of hand, even if BP was found statistically different only at the level of both palmar aspects of 3rd finger ($p=0.04$) and palm of hands ($p=0.008$). The gradients of BP fingertip-phalanx-palm and periungual-phalanx-dorsum were significantly lower in PRP than in SSc patients ($p<0.0001$), as well as significantly higher in CNT when compared with both PRP and SSc patients ($p<0.0001$). A statistically significant progressive decrease of BP was observed in SSc patients with progressive pattern of nailfold microangiopathy ("early", "active", and "late") at the level of fingertips, periungual, palmar aspect of 3rd fingers and palm areas ($p<0.05$). Moreover, BP was significantly lower in PRP than in SSc patients with the "early" pattern of microangiopathy in all areas ($p<0.04$), with the exception of dorsal phalanx and hand dorsum.

Conclusion: By considering a small cohort of patients, BP of hand was found lower in PRP than in SSc patients with the "early" NVC pattern of microangiopathy. Also the gradients of perfusion between distal and proximal areas of hand were significantly lower in PRP than in SSc patients. The clinical value of this new early finding is matter of further analysis**.**

Session Date: Tuesday, November 10, 2015

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Multiple lines of evidence identify thrombin as an important mediator of lung fibrosis in systemic sclerosis (SSc). In addition to demonstrating dramatically high levels of thrombin activity in SSc bronchoalveolar lavage fluid (BALF), increased expression of the thrombin receptor PAR-1 in SSc-ILD tissue has also been shown. Previous studies established that after brief exposure to thrombin *in vitro*, normal lung fibroblasts differentiate to a SSc-like myofibroblast phenotype. In addition, it has been demonstrated that a direct thrombin inhibitor, dabigatran etexilate, prevents cleavage of the extracellular domain of the PAR-1 receptor, and in doing so inhibits thrombin-induced differentiation of lung fibroblasts to the myofibroblast phenotype, while also decreasing CTGF, α-SMA, and collagen

type I in SSc lung fibroblasts. Although there is much evidence to support a central role for thrombin in SSc-ILD, to date there has been no attempt to correlate thrombin activity to pulmonary function. Our goal is to determine if the correlation between thrombin activity and decline in pulmonary function does exist.

Methods:

Thrombin activity was measured using a fluorometric assay (Morita, et al.). Samples were analyzed in duplicate. Samples included existing specimens from MUSC patients, as well as stored BALF specimens from Scleroderma Lung Study (SLS-1) subjects (treated and untreated) for whom there were serial PFT data (baseline and every 3 months for up to 24 months). A Wilcoxon rank sum test was used to compare the thrombin levels between cases and controls, and Spearman correlations were calculated to investigate the associations between thrombin and PFT metrics at various time points. General linear mixed models (GLMMs) were also constructed to assess whether thrombin was associated with decline in PFT metrics over time among the SSc patients.

Results:

BALF samples were obtained from 75 patients with SSc. All patients fulfilled the 2013 ACR/EULAR classification for systemic sclerosis. Four samples from patients without SSc served as controls. Eighty-five percent of patients in our cohort were female, and the proportion of Caucasian and African American patients was equal (49%; 2% Hispanic). As shown in the past, the thrombin level for cases was significantly higher than controls (p=0.02). Thrombin levels were not meaningfully correlated with any of the PFT metrics at any point in time (all correlations <0.3, all p-values >0.15), and thrombin levels were not significantly (all p-values >0.22) associated with declines in PFT metrics over time.

Conclusion:

Thrombin activity may not be a useful biomarker for decline in pulmonary function, but is increased in SSc cases when compared to controls.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose : SSc related PH carries a high mortality; with SSc-PH related to restrictive lung disease (RLD) having worse prognosis and more rapid time to death.Speculation regarding potential MMF anti-fibrotic and anti-remodeling effects on parenchymal lung and vascular intimal fibrosis were supported by two prior large observational studies from the US and the UK. Here, we analyzed predictive markers of mortality of SSc patients with PH stratified for RLD and for MMF use in the prospective EUSTAR database of > 12,000 SSc patients.

Methods : SSc patients with a registry designation of elevated sPAP by either right heart catheterization (RHC) or, in absence of RHC, by echocardiography were subsequently stratified by an FVC of >70% or ≤ 70% predicted near the time of designationand by MMF

use. MMF <6 months or cyclophosphamide use were excluded. Calculations are derived from one-way ANOVA. Categorical variables were compared with Chi square. Comparison of survival was done with Kaplan-Meier analysis.

Results : Of 11,721 patients fulfilling ACR-EULAR criteria, 1,264 matched criteria and had baseline FVC results coincident with PH diagnosis, of those 965 had a baseline FVC of >70% with 43 on MMF and 927 without; and 294 had a baseline FVC≤70% with 22 on MMF and 272 without. Overall, diagnosis was made by RHC in 263/1264 patients and in the remaining patients by echo. There were no differences in disease duration. The FVC≤70 MMF+ was significantly younger with worse NYHA status and disease activity. In the FVC≤70 (RLD) groups, FVC, DLCO and FVC:DLCO ratio were significantly lower while the presence of fibrosis on HRCT and diffuse SSc subtype were significantly higher. Survival assessed numerically and by Kaplan-Meier analysis was significantly the worse in the FVC≤70 without MMF and the best in the FVC≤70 with MMF across years 2 (p=0.001) and 3, 4, 5 years (p<0.0001) despite a significantly worse disease activity score and NYHA class over the 4 groups.

Table 1. Comparison between the baseline characteristics of the four groups at time of PH diagnosis. Values reported in mean, unless otherwise stated.

	FVC >70% +MMF	FVC >70% - MMF	FVC <=70% +MMF	FVC <=70% - MMF

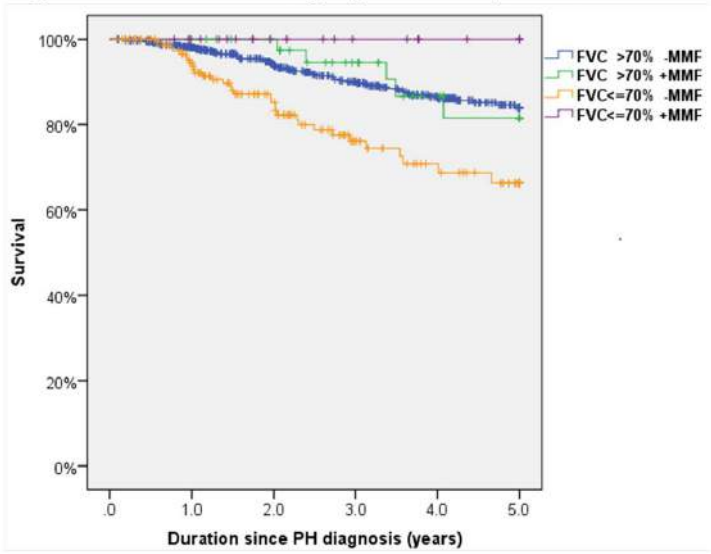
RHC performed %(n)	25.6 (11)	21.2 (196)	40.9 (9)	24.6 (67)	

Diagram 1. Survival across all groups stratified by FVC and MMF use.



Conclusion : Data trends in this registry survey suggest MMF might be associated with beneficial survival in SSc PH. Limitations of the study include mixed diagnostic methods of PH diagnosis given challenges of accuracy of echocardiogram as well as inability to assess hemodynamics in non-RHC diagnoses and therefore inability to assign WHO PH Group classification. These findings warrant further analysis of international PH-SSc cohorts to determine whether a prospective controlled trial may be developed to test the mechanisms and impact of MMF in treating this important complication of SSc.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Little has been published on systemic sclerosis (SSc) patients requiring admission to Intensive Care Unit (ICU) for organ support; published results suggest respiratory failure due to end-stage lung disease the most frequent reason for admission and need for mechanical ventilation a significant predictor of poor outcome.

Methods:

Retrospective case note review of consecutive SSc patients admitted to ICU over a fifteen year period was analysed for patient demographic and disease characteristics, acute precipitating event, end organ damage requiring organ system support on ICU and outcome.

Results:

Fifty-one SSc patients were identified, 80% female, 43% with diffuse cutaneous SSc and 41% with overlap syndromes; 24% (n=12) had clinically significant pulmonary fibrosis (PF), 12% (n=6) had pulmonary hypertension (PH), 14% (n=7) had cardiac SSc, 29% (n=15) had SSc renal crisis (SRC) and 12% (n=6) had severe SSc bowel involvement.

Sepsis (37%, n=19), pneumonia in particular (n=16), accounted for the single most frequent precipitant requiring ICU admission. Other primary reasons for admission included SRC (8%, n=4), cardiac (4%, n=2), neurological (6%, n=3) and non-infective pulmonary causes (6%, n=3). A large proportion of patients (29%, n=15) were on ICU post elective surgery.

All surgical, neurological or SRC admissions survived to ICU and hospital discharge. Sepsis on the other hand was associated with nearly 4 times higher risk of death within 1 year from ICU admission (HR 3.8, p=0.002) with 52% of these patients dying while on ICU compared to 13% of the other admissions (p=0.003).

Elective surgical patients spent up to 3 days on ICU, while the medical (n=33) and emergency surgical admissions (n=3) spent between 1 and 45 days (median 4, IQR 1, 19). On the day of admission 22% (n=8) required non-invasive mechanical ventilation, 61% (n=22) invasive mechanical ventilation, 22% (n=8) renal replacement therapy and 36% (n=13) vasopressors. Fourteen (39%) died while on ICU. While the use of mechanical ventilation and renal replacement therapy was not associated with negative short-term outcome, patients who needed vasopressor therapy were at nearly 6 times higher odds of dying while on ICU (OR 5.7, p=0.011).

Overall survival from ICU admission was 67% on day 7, 56% at 1 month and 44% at 1 year. Gender, subset, antibody specificities and overlap features did not associate with survival after ICU admission. On the other hand, compared to patients without significant organ involvement, those with PH had nearly 8 time increase of the risk of death (HR 7.7, p=0.024) and those with severe bowel disease had more than 5 times increase in the risk of death (HR 5.5, p=0.020). SRC on the other hand, was associated with good prognosis (HR 0.2, p=0.010).

Conclusion:

ICU outcomes of patients with underlying SSc seem to be better than previously reported, with best prognosis observed in post-surgical and SRC patients. Sepsis and pneumonia are most common medical precipitating events and are associated with poor prognosis. Mechanical ventilation and renal replacement therapy need is likely to reflect severity of underlying chronic disease and acute derangement and their use therefore should be guided by the overall clinical context.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The EULAR study group on Microcirculation in Rheumatic Diseases (RD) aims to build an international network of centres of excellence to facilitate collaboration and exchange knowledge within Europe. One of its aims is to study natural evolution of microvascular morphology in RD. To this end standardisation of morphological interpretation across diseases is paramount. Hence, the objective is to propose simple capillaroscopic definitions for interpretation of single capillaroscopic morphologies and assess their interrater reliability. **Methods:** The simple definitions to assess morphology were: 1) “normal”: hairpin, tortuous or crossing; 2) “abnormal”: not hairpin, tortuous or crossing; 3) “not evaluable”: whenever rater doubted in classifying between normal and abnormal (figure 1). Based upon an aimed kappa of 0.80 and default prevalences of normal (0.4), abnormal (0.4) and not evaluable (0.2) capillaries, 87 capillaries evaluated by two raters were necessary to obtain a half width of the 95% confidence interval (CI) of no larger than 0.2. Consequently, 90 single capillaries were presented to 3 groups of raters: experienced independent raters, n = 5; attendees to the 6th EULAR course on capillaroscopy, n = 34; novices after a 1 hour course, n = 11. Interrater agreement was assessed by calculation of proportion of agreement and by kappa coefficients. **Results:** Mean kappa was 0.47 (95% CI: 0.39-0.54) for expert raters, 0.40 (0.36-0.44) for attendees and 0.46 (0.41-0.52) for novices, with overall agreements of 67% (63-71), 63% (60-65) and 67% (63-70) respectively. Comparing only “normal” vs. “abnormal and not evaluable” capillaries did increase the kappa: 0.51 (0.37-0.65), 0.53 (0.49-0.58), and 0.55 (0.49-0.62). On the condition that the capillaries were classifiable, the mean kappa was 0.62 (0.50-0.74) for expert raters (n = 65), 0.76 (0.69-0.83) for attendees (n = 20) and 0.81 (0.74-0.89) for novices (n = 44). **Conclusion:** This study shows moderate reliability of “simple” capillaroscopic definitions to describe morphology of individual capillaries by rheumatologists with different expertise on the topic. Novices are capable to distinguish normal from abnormal capillaries by means of a 1-hour training session. Consequently, when encountering an abnormal capillary, they may refer the patient to an expert in nailfold videocapillaroscopy.

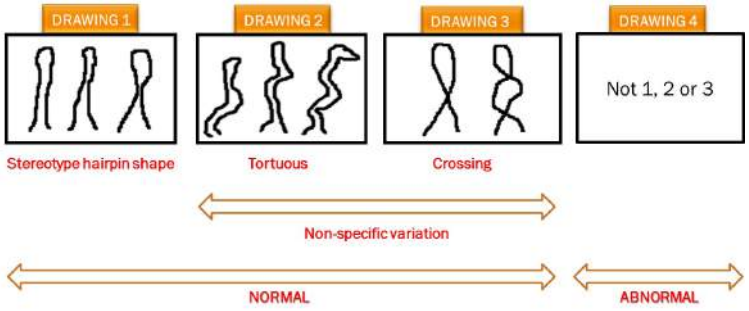

Figure 1: Information given to the raters concerning the definitions of normal and abnormal capillaries

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

1) To describe the role of MSUS, using both grey scale (GS) and Power Doppler (PD), to detect skin ulcers in SSc patients. 2) To look for initial indications that MSUS may be useful to guide therapy for SSc-ulcers.

Methods:

We examined a convenience sample of 7 SSc patients with skin ulcers by MSUS which was performed using General Electric Logic E9 scanner using a 5-16 MHz linear array transducer. PD settings: pulse repetition frequency 800 Hz, frequency 10 mHz and low wall filter. We proposed preliminary definitions of Ulcer characteristics based on normal skin reference (1). Pain and ulcer measures were obtained using 100 mm visual analogue scales (VAS).

Results:

7 SSc patients met 2013 EULAR /ACR criteria for SSc. Median (range) for mRSS: 14 (9-25). 5 patients had diffuse SSc. The 7 patients had 16 clinically apparent skin ulcers. We categorized them on GS as **a) skin ulcer (GS-SU);** characterized by loss of skin thickness both epidermal and dermal layers, or loss of epidermal layer with irregular hyper-echoic granulation tissue below the level of the surrounding epidermis (figure 1a, b), **b) Non-ulcer lesions (GS-NUL);** show no loss of epidermal layer but show irregular hyper-echoic tissue at the same or above the level of epidermis (figure 1c).

Twelve GS-SU/NUL (75%) were on the PIPs, 2 (13%) on the legs, 1 (6%) on the DIP and 1(6%) on the elbow. Two ulcers in one patient demonstrated high PD signals (presumed underlying infection). After treatment for 15 days with Ciprofloxacin, PD signal was reduced, and both pain and ulcer VASs decreased from 100 mm to 40mm (fig 2a,b). Five lesions showed underlying calcinosis (3 of 5 lesions with calcinosis had evidence of positive PD signals). Variable ulcer depths and dimensions were detected. The highest pain and ulcer VASs (100mm) were recorded in the ulcers with the highest PD signal (table 1).

Conclusion:

This is the first study to show a promising role of MSUS in evaluating skin ulcers in SSc patients. MSUS may have a role in identifying depth and underlying pathology (i.e. infection and calcinosis) of the lesion. Hence, MSUS can add clinical information and help in guiding treatment. Future studies are warranted with more SSc patients to further validate our preliminary findings.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

UCLA Scleroderma Clinical Trial Consortium Gastrointestinal Tract (UCLA SCTC GIT 2.0) Instrument is a comprehensive, self-administered survey for the assessment of gastrointestinal involvement in patients with systemic sclerosis (SSc), developed and validated in English. This study aimed to translate and validate a Romanian version of the UCLA SCTC GIT 2.0.

Methods:

Translation from English into Romanian has been performed by the forward-backward method. Sixty-four patients with SSc satisfying the 2013 ACR/EULAR classification criteria, attending a referral centre as part of an extensively studied cohort, have been approached in a consecutive manner for administration of the questionnaire. We evaluated the internal consistency, construct validity and discriminative capacity of the translated questionnaire (Romanian GIT). Reproducibility was assessed by retesting the questionnaire over a period of 8-14 days in patients who did not suffer any significant intervention during this time.

Results:

Fifty-four patients (91% females, mean age 52.4±12.1 years, median [range] of disease duration since first non-Raynaud symptom 78.5 [43-148] months, diffuse cutaneous SSc 26%) returned completed questionnaires. The median total GIT score [range] was 0.35 [0-1.51]. Internal consistency was demonstrated by Cronbach's alpha coefficient (0.931); for all subscales Cronbach's alpha was ≥0.7, with the exception of the diarrhea subscale (alpha=0.581). Construct validity was supported by moderate, but significant correlations (Spearman) of the Romanian GIT total score with the Mental Component Summary (MCS) of SF-36 (r=0.541) and among subscales, by significant correlations with the Scleroderma Health Assessment Questionnaire (SHAQ) total score (r=0.559) and a strong correlation with the gastrointestinal subscale of the SHAQ (r=0.726). Reproducibility was good with correlation indices >0.7. Divergent validity was supported by significant differences between patients with or without a clinical diagnosis of gastrointestinal disease (see table).

Romanian GIT scores and total SHAQ score for patients with/without clinical diagnosis of gastrointestinal (GI) disease

	No GI diagnosis	≥1 GI diagnosis	p
Reflux	0.250 (0.125-0.375)	0.625 (0.250-1.375)	0.016
Distension/ bloating	0.500 (0.000-1.000)	1.000 (0.500-1.625)	0.012
Fecal soilage	0.000 (0.000-0.000)	0.000 (0.000-0.000)	1.000
Diarrhea	0.000 (0.000-0.000)	0.000 (0.000-0.500)	0.021
Social Functioning	0.000 (0.000-0.330)	0.245 (0.000-0.660)	0.022
Emotional well-being	0.000 (0.000-0.550)	0.550 (0.000-1.550)	0.021
Constipation	0.250 (0.000-0.750)	0.500 (0.000-1.000)	0.208
Total GIT score	0.221 (0.042-0.378)	0.589 (0.221-0.839)	0.002
SHAQ total score (0-3)	0.884 (0.385-1.154)	1.154 (0.653-1.500)	0.160

Medians and interquartile ranges (25-75th percentiles). p values <0.05 are considered significant (Mann-Whitney U test).

Conclusion: The Romanian GIT has acceptable reliability and validity. This questionnaire can be used for the assessment of gastrointestinal involvement in patients wih SSc.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: In Systemic Sclerosis (SSc), pulmonary arterial hypertension (PAH) is often diagnosed at an advanced stage. Serum levels of N-terminal pro-brain natriuretic peptide (NT-proBNP) are typically elevated in established SSc-PAH, but it is not known if the serum levels rise prior to PAH diagnosis, and it is not known if NT-proBNP levels differ between PAH and pulmonary hypertension secondary to interstitial lung disease (PH-ILD); which is resistant to treatment. Here, we utilized serial serum samples from a large, prospective and unselected SSc cohort, and approached these two questions by testing NT-proBNP levels in sera obtained before and after PAH or PH-ILD diagnoses.

<>**Methods:** The study cohort included patients from the prospective, observational Oslo University Hospital SSc cohort (n=298) who met the 2013 ACR/EULAR classification criteria and had (A) baseline and follow-up serum samples available for NT-proBNP analyses, (B) baseline and follow-up data on systolic pulmonary artery pressure (sPAP) by echocardiography (ECHO) and diffusion capacity for carbon monoxide (DLCO), and (C) follow-up data on PAH and PH-ILD diagnoses by right heart catheterization (RHC).

<>**Results:** The study cohort included 298 consecutive SSc patients (243 female, 78 diffuse cutaneous SSc) aged 48 ± 15.4 years at disease onset. During an observation period of 11.5 ± 8.0 years 52/298 patients developed PH, of those 32/52 were diagnosed with PAH, and 20/52 had PH-ILD. Serum levels of NT-pro-BNP obtained at baseline (mean 1.4 years before PH diagnoses) did not differ between cases with and without PH (Table 1). There was, however, a difference in NT-proBNP levels between PH and non-PH cases in serum samples obtained at follow-up, mean 2.6 years after the PH diagnoses. Development of PH was positively associated with sPAP values obtained at baseline, mean 1.6 years before PH diagnosis, and at follow-up: Likewise, PH was also associated with DLCO at baseline and at follow-up (Table 1). None of these parameters could significantly segregate PAH from PH-ILD.

<>**Conclusion:** In this prospective SSc cohort we did not find any difference in baseline NT-proBNP levels between PH and non PH cases; indicating that NT-proBNP analyses are not useful for predicting PH development. In contrast, we found that the values of sPAP and DLCO differed between PH and non PH cases both at baseline and follow-up. None of the markers tested could differentiate between PAH and PH-ILD. Hence, we are still missing predictive biomarkers for the development of PAH.

Table 1: Associations between PH and baseline and follow up characteristics

	No PH N=246	PH N=52	p-value
NT-proBNP; mg/ml, SD			
A. Baseline	64.1 ± 325.9	116.1 ± 172.6	0.265
B. Follow-up	155.8 ± 546.1	399.4 ± 666.3	0.018
sPAP by ECHO in mmHg, SD			
A. Baseline	22.9 ± 10.5	50.2 ± 30.8	<0.001
B. Follow-up	26.6 ± 13.4	69.3 ± 25.2	<0.001
DLCO, % of value expected, SD			
A. Baseline	71.8 ± 20.0	51.3 ± 21.7	<0.001
B. Follow-up	64.6 ± 19.0	37.9 ± 14.8	<0.001

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Pericardial involvement is common in rheumatic disease, as rheumatoid arthritis, lupus erythematosus, mixed connective disease and systemic sclerosis. Few data are available about pathogenesis of pericardial effusion in systemic sclerosis. This study aimed at evaluating the differences in serum levels of adipokines and interleukins (IL) in systemic sclerosis (SSc) patients with and without pericardial effusion.

Methods: A total of 87 outpatients (84 female, mean age of 52,6±14,2 ys, and disease duration of 8,2±6,7 ys), who fulfilled the ACR/EULAR 2013 SSc classification criteria, were recruited in this study. The anthropometric measures, as body mass index (BMI), demographic, clinical and laboratoristic characteristics and SSc related manifestations were assessed in each patient. The presence of pericardial effusion (PE) was evaluated by means of echocardiographic techniques (the presence of fluid ≥ 5 cc was considered pathologic). Sera levels of adiponectin, leptin, resistin, visfatin, tumor necrosis factor α (TNF-α), interferon g (INF-g), IL-2, IL-10 and IL-17 were measured in SSc patients, using Multiplex Immunoassay (Bioplex 200 System), by means of two kits (Bioplex ProTM Cytokine/Chemokine and Growth Factor Assay e Bioplex Pro Diabetes Assay). The data normality was verified using Kolmogorov-Smirnov Test; the comparisons between SSc patients groups were evaluated by Mann-Whitney U test and t-student test, where appropiate. Statistic significance was set at p≤0,05. The results are expressed as median and interquartile range (IQR) or means ±1standard deviation. The data analysis were assessed using IBM SPSS statistic 20.

Results: 11 SSc patients had pericardial effusion (PE). The SSc patients groups (with and without PE) did not differ in age (46,5±13,8 ys vs 53,5±14,2 ys), sex and BMI (24,4±5,5 vs 23,62±4,12). 11 SSc patients were obese (BMI≥30) (2 with PE and 9 without PE). We observed significant differences between SSc patients with PE and without PE in sera levels of visfatin (1546,9 (8590,9) vs 388,8 (103); p=0,036), adiponectin (2845000 (4132900,0) vs 5272100,0 (8243600,0); p=0,027) and IL-17 (1,33 (3,5) vs 0,05 (0,56); p=0,45). Moreover higher leptin/adiponectin ratio was found in patients with PE (0,006 (0,01) vs 0,0017 (0,00); p= 0,032). The sera levels of adipokines and IL did not change in SSc patients with interstitial lung disease or pulmonary arterial hypertension, different videocapillaroscopy pattern, limited or diffuse skin subset.

Conclusion: The visfatin and adiponectin could play an important role in pathogetic mechanism in pericardial effusion in systemic sclerosis. Futher study are necessary to unravel a role of visfatin and adiponectin as biomarkers of SSc pathology.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: The European Scleroderma Study Group (EScSG) Activity Index developed in 2001 has some limitations due to the procedure underlying its development and the inclusion of hypocomplementemia, that was criticized for its poor face validity. The present study is devoted to overcome such limitations.

Methods: Ninety seven clinical charts of patients with SSc, all of whom satisfying 1980 ACR criteria for the disease, were retrieved from a large database. Three investigators (CD, OKB, YA) external to the enrolling centres assigned a disease activity score to each chart on a 0-10 visual analogue scale, providing a reliable scoring tool (ICC=0.786; 95%CI=0.716-0.844). The median score served as the disease activity gold standard. Another investigator (GV) evaluated disease activity as inactive, moderately active, active, and very active. Univariate and multivariate linear regression analyses were used to assess the performance of sets of criteria in predicting the "gold standard" and to identify the weight of each variable. Pending the final validation in a replication cohort, the resulting preliminary activity index was validated by the jackknife statistical procedure i.e.by leaving out one patient a time. Receiver operating curves served to assess the efficiency of the index in separating active-very active disease from inactive-moderately active disease.

Results: A preliminary weighted 10-point activity index was identified: Δ (ie. patient-assessed worsening during the previous month)-skin= 1.25, Δ- heart-lung= 0.75, modified Rodnan skin score >18=1.25; digital ulcers=1.75; tendon friction rubs=1.5; erythrocyte sedimentation rate >50 mm/h=1.0; C reactive protein >1 mg/dl= 1.5; Diffusing Lung Capacity for CO <70% of predicted=1. A cut-off ≥1.75 identified patients with active-very active disease. It resulted to be more sensitive and specific than the currently used EScSG index in identifying SSc patients with active disease in the 97 SSc patients considered for this part of the study.

Conclusion: A preliminary revised activity index has been developed. It is feasible and has face validity. It is going to be validated in a replication cohort

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster III

Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: CXCL4 is a pleiotropic antiangiogenic and immunomodulatory chemokine, that has been shown to be increased in the sera of patients with systemic sclerosis (SSc) as well as in patients previously referred to as early SSc, at present labeled as undifferentiated connective tissue disease (UCTD) at risk for SSc. We aimed to search for relationships between CXCL4 serum levels and demographic, serological, and clinical features in patients with UCTD at risk for SSc, that is patients with Raynaud's phenomenon (RP) and SSc marker autoantibodies and/or nailfold capillaroscopy (NVC) scleroderma pattern, who do not satisfy the 2013 ACR/EULAR criteria for SSc classification.

Methods: Serum levels of CXCL4 were measured in 24 autoantibody positive UCTD patients at risk for SSc and 24 osteoarthritis/fibromyalgia controls by a fluorescence-based suspension immunoassay. All patients were investigated for preclinical and clinical organ involvement, SSc marker autoantibodies, and NVC abnormalities. The new 2013 ACR/EULAR classification score for SSc was calculated for each patient at baseline and at the end of follow-up.

Results: Median serum levels of CXCL4 were increased in UCTD patients at risk for SSc (6.79 ng/ml, interquartile range - IQR- 3.4-13.8 vs 1.44 ng/ml, IQR 0.14-3 in controls, $p < 0.0001$). CXCL-4 resulted to be correlated to ICAM-1 serum levels ($r=0.44$, $p < 0.05$); had higher levels in the 6 anti-Scl70 positive patients (median 16.27 ng/ml, IQR 10.25-33.5) than in the 17 ACA positive patients (5, IQR 2.9-8.1 ng/ml, $p < 0.01$) and exceeded the 95° percentile of control values (12.24 ng/ml) in 5/15 (33.3 %) of patients who progressed to definite SSc vs 1/9 (10%) of those who did not at the end of the follow-up period (median follow-up: 2.75 years, range 0.4-8.4) ($p = 0.3$). Moreover, CXCL4 positively correlated with serum levels of soluble ICAM-1 ($r = 0.44$; $p < 0.05$).

Conclusion: Here we confirm that patients with UCTD at risk for SSc have increased serum levels of CXCL4. Moreover, we point out an association with anti-Scl70 positivity and a correlation with serum ICAM-1, a marker of endothelial activation. The predictive role, if any, of CXCL4 in patients with UCTD at risk for SSc awaits to be assessed in larger series of patients.

The Global Microrna Profile of Systemic Sclerosis Whole Skin/Dermal Fibroblasts and the Role of the Xq26.3 miRNA Cluster As a TGF-b Pathway Positive Feedback Mechanism

Gloria Salazar[1], John Hagan[2], Minghua Wu[3], Xinjian Guo[4], Xiaodong Zhou[4], Julio Charles[1], Maureen D Mayes[1] and Shervin Assassi[1], [1]Rheumatology, University of Texas Medical School at Houston, Houston, TX, [2]Neurosurgery, University of Texas at Houston, Houston, TX, [3]Feinberg School of Medicine, Northwestern University, Chicago, IL, [4]Internal Medicine, University of Texas Medical School at Houston, Houston, TX

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

MicroRNA (miRNA) are critical gene regulators that frequently play central roles in disease. Here, we report the miRNA expression signatures of systemic sclerosis (SSc) skin and dermal fibroblasts and examined the role of Xq26.3 miRNA cluster in the exaggerated fibrotic process observed in SSc.

Methods:

The global miRNA profiles of skin (10 early SSc samples and matched controls) were determined using a highly sensitive, comprehensive multiplex qPCR platform (Exiqon LNA-enhanced qPCR array) that interrogates 752 miRNAs. Similarly, global miRNA expression was investigated for early passage dermal fibroblasts from 5 SSc patients and unaffected controls. SSc patients had disease

duration < 5 years and were not treated with immunosuppressive agents. Based on these studies, we then performed targeted qPCR for 3 miRNAs located in a cluster on X-chromosome in 5 SSc and control fibroblast cell lines unstimulated and stimulated with TGF-b and 8 other key Th1/Th2/Th17 cytokines for 24 hours. Additionally, we performed global gene expression microarrays of the 5 unstimulated/stimulated control fibroblasts.

Results:

Global miRNA profile of SSc whole skin samples revealed 26 dysregulated miRNAs, 3 of which were part of a miRNA cluster located in Xq26.3. The global miRNA profiling of dermal fibroblasts revealed 24 differentially expressed miRNAs in SSc. Similar to skin studies, Xq26.3 cluster miRNA were also significantly increased in SSc dermal fibroblasts. Notably, 3 of these miRNA (miR 424-5p, miR 424-3p and miR 503-5p) are predicted to target SMAD7 per in silico algorithms, therefore we investigated them further.

The fibroblast stimulation experiments in SSc and control fibroblast cell lines revealed that these 3 miRNA were significantly upregulated after stimulation by TGF-b (compared to paired unstimulated cells). Furthermore, the highest levels of these miRNA were observed after TGF-b stimulation compared to 8 cytokines (IFNa, IFNg, IL10, IL13, IL17a, IL22, MCPI, TNFa). A similar stimulation pattern was observed in SSc and control cell lines.

As predicted in silico, Xq26.3 miRNA levels were inversely correlated with SMAD7 mRNA levels (as miRNA levels increased SMAD7 levels decreased) (mir424-5p spearman r=-1 p=<0.0001, miR424-3p r=-0.9 p=0.03, miR503-5p r=-0.9 p=-0.03). No significant correlations were observed with other gene transcripts such as SMAD4 or after stimulation with other cytokines. Furthermore, there were no significant correlations with a control miRNA (miR25).

Conclusion:

This is the first comprehensive and unbiased examination of miRNAs in SSc skin and fibroblasts. Increased miRNA from the Xq26.3 cluster were observed in both sample types. TGF-b upregulates these miRNA. Moreover, there is a strong inverse relationship between their levels and the predicted target in the TGF-b pathway (SMAD7). These miRNA are likely part of a positive feedback mechanism which is activated by TGB-b to target its natural inhibitor (SMAD7) keeping the pathway activated. Given the strong female predilection of SSc, this miRNA cluster, located on the X-chromosome, could have important ramifications for understanding SSc pathophysiology and drug development.

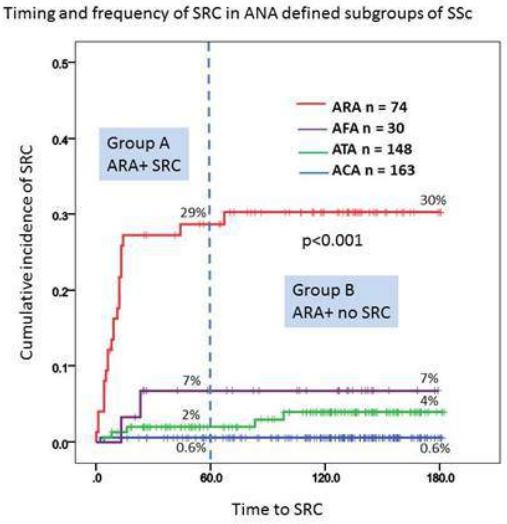
Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Scleroderma renal crisis (SRC) is a severe complication of systemic sclerosis (SSc). Most SSc cases demonstrate a disease-specific antinuclear antibody including anti-RNA polymerase III (ARA), anti-fibrillarin (AFA), anti-topisomerase-1 (ATA) or anticentromere (ACA). ARA defines a distinct sub-phenotype characterised by diffuse skin disease and risk of complications including SRC and pulmonary arterial hypertension. We used the strong association between ARA and SRC and the predominant occurrence of SRC early in disease to develop an extreme phenotype strategy for defining genetic factors in susceptibility to renal crisis.

Methods: First we analysed SRC in a well characterised group of SSc cases followed at our centre (n=415). Informed by this, 50

patients with confirmed SRC and ARA+ and another 50 SSc ARA+ that had never developed SRC were identified from our larger SSc cohort. These cases, all with Northern European ancestry, were genotyped across approximately one million SNPs using the Illumina Human Omni-express bead array chip. All data underwent quality control checks for Hardy-Weinberg equilibrium and genotyping rate in PLINK (HWE $p < 0.001$, and genotyping rate > 90%). After filtering of SNPs, a logistic regression was performed in PLINK comparing patients with or without SRC to determine the genetic signature difference between these two groups of patients.



Results: Initial analysis confirmed a strong association between ARA and SRC with 30% ARA+ SSc developing SRC compared with 7% AFA, 4% ATA and 1% ACA ($p < 0.001$). Moreover in ARA+ cases almost all SRC occurred within 18 months of disease onset, and SRC after 5 years of follow up was very rare. Thus we could define a group with SRC and another at very low risk. This dichotomy formed the basis of our genetic analysis comparing ARA+ patients with SRC history (Group A) to the control group, who had been followed for > 60 months without SRC (Group B). We performed GWAS analysis on these two groups. Quality control checks removed 2309 SNPs for missingness (GENO > 0.1) and 77122 failed MAF filters (MAF < 0.01). In total 641,489 SNPs were analysed. The logistic regression analysis identified a number of SRC associated SNPs within genes and gene regions. Top associations were found in the complement region (P= 1.66x10-5), and in other genes including EPHA5 (P= 1.87x10-5), GRIA3 (P= 2.16x10-5), HECW2 (P= 2.71x10-5) and CTNND2 (P= 2.92x10-5).

Conclusion: We present a novel study using extreme phenotypes of ARA+ SSc to identify genetic association of SRC in cases that are serologically and clinically otherwise homogeneous. We identified genes including Caterin cadherin-associated protein delta 2 (CTNND2) which is known to regulate adhesion molecules relevant to fibrosis. Genes identified from this analysis may have general relevance to SSc vasculopathy or other forms of hypertensive thromobotic microangiopathy. Additional functional and genetic replication studies are needed.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: The use of high-throughput genotyping platforms has allowed a better understanding of the genetic background underlying systemic sclerosis (SSc). Sixteen non-HLA genes have been consistently associated with SSc at the genome-wide level of significance, with *IRF5*, *STAT4*, *CD247*, *DNASE1L3*, *IL12A* and *ATG5* representing the top signals in the two most powered large-scale analyses on SSc performed to date (a genome-wide association study and an Immunochip study in Europeans). We aimed to evaluate for the first time the possible role of the above mentioned genes in SSc susceptibility in the Turkish population.

Methods: We genotyped a total of 355 SSc patients and 718 unrelated healthy controls from Turkey for the SSc-associated lead genetic variants *IRF5* rs10488631, *STAT4* rs3821236, *CD247* rs2056626, *DNASE1L3* rs35677470, *IL12A* rs77583790, and *ATG5* rs9373839. The genotyping of the whole SSc group and part of the control group (219 samples) was performed by TaqMan assays, whereas the remaining control data (499 samples) was obtained using the Immunochip platform. To test for association, we compared the minor allele frequencies of every polymorphism between cases and controls by performing 2x2 contingency tables and x2 tests.

Results: The overall analysis evidenced statistically significant associations of the global SSc with *IRF5* (P=1.48E-05, OR=1.76, CI 95%=1.36-2.27) and *CD247* (P=2.20E-03, OR=0.75, CI 95%=0.62-0.90). Trends of association were also suggested for *STAT4* (P=0.066, OR=1.21, CI 95%=0.99-1.48), *IL12A* (P=0.080, OR=4.06, Ci 95%=0.74-22.23), and *DNASE1L3* (P=0.100, OR=1.41, CI 95%=0.93-2.11). Interestingly, the subphenotype analysis showed subtype- and autoantibody-specific associations, that is, *CD247* was specifically associated with the diffuse form of the disease (diffuse SSc vs controls: P=4.91E-04, OR=0.64, CI 95%=0.49-0.82; diffuse SSc vs limited SSc: P=0.065, OR=0.75, CI 95%=0.55-1.02), and *IRF5* with the presence of anti-topoisomerase autoantibodies (ATA+ SSc vs controls: P= 8.84E-08, OR=2.28, CI 95%=1.68-3.11; ATA+ SSc vs ATA- SSc: P=8.43E-03, OR=1.70, CI 95%=1.14-2.52).

Conclusion: We were able to replicate the associations of *IRF5* rs10488631 and *CD247* rs2056626 with SSc in the Turkish population, thus confirming the relevant role that these genes may have in the pathophysiology of this disease.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics Poster II

Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Genome-wide association studies (GWASs) have resulted in the identification of several genetic *loci* involved in systemic sclerosis (SSc) susceptibility. However, GWASs are normally focused in white European ancestry populations. Indeed, in the case of SSc this hypothesis-free approach has not been followed in mixed populations such as Hispanic Americans. It should be considered that the genetic polymorphisms described in whites do not cover all the variation observed in other ethnic groups. Moreover, due to the difference linkage-disequilibrium patterns, the analysis of cohorts of multiple ancestries contributes to fine-mapping and causal variant identification. Therefore, the aim of our study was to analyze for the first time the genetic background of SSc in a Hispanic American population.

Methods: Our study comprised a total of 285 SSc patients and 261 ethnically matched healthy controls. All SSc cases and 131 controls were recruited in Houston (Texas, USA) and genotyped using the HumanOmni2.5-8 Illumina Array. Statistical power was increased by adding 130 additional controls of Hispanic descent, recruited in Oklahoma City (Oklahoma, USA) and genotyped using the HumanOmni1-Quad Illumina BeadChip. After stringent per variant and per individual quality controls, 307,939 single-nucleotide polymorphisms (SNPs) were included in our analysis. Despite the mixed ancestry of the Hispanic population in the USA, the majority of the analyzed individuals in our study, both cases and controls, were of Mexican origin. Nevertheless, stringent principal component analysis filters were applied to verify case-control overlap. Significance was calculated using 2x2 contingency tables and Fisher's exact test or χ 2 when necessary, to obtain p-values, odds ratios and 95% confidence intervals using PLINK (v1.07) software. Genomic correction was used to correct for multiple testing.

Results: We observed genome-wide level associations in the HLA region, specifically in the HLA class II region (between the *HLA-DRB1* and the *HLA-DQA1 loci*). However, we did not report any signal outside the HLA region that reached the genome-wide significance threshold. Nevertheless, we found nominally associated SNPs in a number of SSc-related *loci*, identified in white populations. The regions showing nominal associations included: *IRF5*, *STAT4*, *CD247*, *BLK*, *BANK1, IRF8*, *IRF7*, *IL12A*, *ATG5*, *PPARG*. It should be noted that, despite the replication of firm SSc-risk factors in the Hispanic population, the most associated variants for each *loci* were not normally the same than in white populations.

Conclusion: Our findings support a common genetic background for SSc susceptibility between white European and Hispanic populations. Nonetheless, our results also revealed that the associated variants were not necessarily the same in both populations. These findings may be a basis for causal variant identification in the shared *loci*.

Session Date: Tuesday, November 10, 2015
Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics Poster II

Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Microchimerism (Mc), harboring a small number of cells (or DNA) that originated in a different individual, occurs commonly due to bi-directional maternal-fetal exchange during pregnancy and long-term persistence decades later. Mc has been implicated in some autoimmune diseases, especially systemic sclerosis (SSc), but any role in pathogenesis remains unclear. We sought to identify and characterize Mc at the site of disease pathology in SSc lung.

Patients and **Methods:**

SSc lung specimens were obtained from autopsy. Of 9 patients, 7 had diffuse and 2 limited SSc; 6 were female, 3 male. SSc onset age ranged from 25 to 56 (mean 45.6) and disease duration 1 to 8 years (mean 3.1). Causes of death were primarily pulmonary (interstitial fibrosis, hemorrhage), however 3 patients had cancer (1 lung, 2 breast) and cause of death was unclear for 1 patient. 3 had undergone autologous hematopoietic cell transplants and 2 cord blood transplants. For comparison, healthy tissue from surgical lung cancer resections are being studied, to date 2 females and 2 males.

To identify and characterize Mc, two approaches were employed. When family members were available, a non-shared polymorphism of the putative Mc source was identified and DNA extracted from lung tissue interrogated for the specific polymorphism by quantitative-polymerase chain reaction (qPCR). When the Mc source was sex mismatched, fluorescence in situ hybridization (FISH) was employed with X- and Y-chromosome specific probes. Concomitant immunohistochemistry (IHC) was added for CD31, CD45, cytokeratin and SMA-α to determine cell phenotype. Cells with two distinct signals within one nucleus were counted and analyzed under bright field for IHC staining.

Results: Molecular studies indicated multiple Mc sources are detected in SSc lung, i.e. maternal, fetal and possibly sibling Mc. By polymorphism specific qPCR concentrations ranged from 1 to 144 microchimeric cell equivalents per 10^5 cell tested. By FISH 3/3 male lungs had female cells (mean: 9.3/2000, range 3-19) and 4/5 female lungs had male cells (mean: 5.8/2000, range 1-13). Among controls, 3/4 had Mc (mean: 5/2000, range 1-8). Interestingly, in male SSc patients, half or more of maternal Mc was positive for the endothelial cell marker CD31. 10% were positive for SMA-α. In females, 36% of the male Mc was positive for CD31, 9.5% for SMA-α and 3.5% for cytokeratin. No microchimeric cell was positive for CD45.

Conclusion:

These results indicate SSc lung contains Mc from multiple different sources. Microchimeric cells in the lung were not hematopoietic. The most common phenotype was endothelial, of potential additional interest in light of early endothelial cell injury in SSc. While other studies are needed, these results, along with other literature, [1] indicate that Mc can adopt different cell phenotypes so that loss of tolerance to our natural immigrants could contribute to an "auto" immune disease.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics Poster II
Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Microchimerism (Mc) is naturally acquired through bi-directional exchange of small amounts of cells or DNA between mother and fetus during pregnancy. Higher amounts of maternal Mc (MMc) have been reported in peripheral blood of patients suffering from autoimmune diseases such as systemic sclerosis (SSc), compared to healthy controls (1,2), however, it is unknown what cell type(s) is responsible for this increase. We investigated the frequencies and quantitative levels of MMc within cellular subsets isolated from peripheral blood mononuclear cells (PBMC) in patients with SSc and compared results to healthy controls.

Methods : 69 subjects were studied for MMc in T cells, B cells, NK cells and monocyte/macrophages, including 27 female patients with SSc and 42 healthy controls (32 female and 10 male). To detect and identify MMc, HLA-specific primers and fluorogenic probes were used in quantitative polymerase chain reaction (Q-PCR), targeting the non-inherited, non-shared maternal HLA allele. Therefore, HLA genotyping was performed for all the subjects and their mothers. When non-inherited maternal HLA was indistinguishable from subject's HLA, primers and probes targeting non-HLA polymorphisms developed for this purpose were used. Using fluorescence-activated cell sorting, PBMC were sorted into: T, B, and NK cells, and monocyte/macrophages to an average purity of 98.6%. The specific Q-PCR assays were then undertaken on DNA extracted from individual subsets. Prevalence of MMc was analyzed using logistic regression, and negative binomial regression model was used to asses MMc quantitative levels, with adjustment for total number of genome equivalents tested.

Results: MMc was identified in at least one cellular subset in 44.4% of SSc patients and 40.5% of healthy subjects, without a significant difference between patients and controls overall, or when comparing each subpopulation separately. However, MMc levels were significantly higher in SSc patients compared to controls, with an incidence rate ratio (IRR) of 47.4 ($P < 0.001$). Interestingly, the difference in MMc levels was greater in the adaptive immune subpopulations ($IRR_{[T\ cells]} = 109.1$ and $IRR_{[B\ cells]} = 51.2$; $P < 0.001$) compared to those of the innate immune cells ($IRR_{[NK\ cells]} = 29.8$; $P = 0.001$ and $IRR_{[Monocytes]} = 6.3$; $P = 0.117$).

Conclusion : We found higher amounts of MMc especially in adaptive immune cellular subsets in women with SSc compared to healthy controls. This incites further investigation of the immunologic functionality of MMc in health and disease, which is currently under way.

Intrinsic Gene Expression Subset Predicts Improvement in Systemic Sclerosis Patients during Dasatinib (SprycelTM) Therapy

Viktor Martyanov[1], Jonathan Goldin[2], Kim Hyun[3], Oumar Sy[4], Wendy Hayes[4], Shuyan Du[4], Michael Whitfield[1] and John Varga[5], [1]Department of Genetics, Geisel School of Medicine at Dartmouth, Hanover, NH, [2]David Geffen School of Medicine, University of California, Los Angeles, Los Angeles, CA, [3]Radiology, David Geffen School of Medicine, University of California, Los Angeles, Los Angeles, CA, [4]Bristol-Myers Squibb, Princeton, NJ, [5]Division of Rheumatology, Northwestern University, Feinberg School of Medicine, Chicago, IL

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Intrinsic gene expression subsets are molecular pathway-driven subtypes of systemic sclerosis (SSc) that have been reproduced across multiple cohorts of SSc patients. The goal of this study was to determine if intrinsic subset assignment could identify SSc patients who improved with treatment in an open-label clinical trial of dasatanib, the broad spectrum tyrosine kinase inhibitor.

Methods:

Biopsies of lesional forearm skin were performed on days 1 and 169 of the study. RNA was isolated and used for intrinsic subset assignment, differential gene expression and pathway enrichment analyses. Clinical response was determined by modified Rodnan Skin Score (mRSS) and pulmonary function was assessed at baseline and day 169. Improvement was defined by a decrease in mRSS of >5 or >20% from baseline. Quantitative image analysis of high-resolution computed tomography (HRCT) scans of the chest was performed and quantitative lung fibrosis (QLF) and ground class (QGG) scores were obtained at baseline and 6-month follow-up. Categorical variables were analyzed via Fisher's exact test and continuous variables via Mann-Whitney and Wilcoxon signed-rank test.

Results:

Among twelve subjects with baseline and post-treatment skin biopsies, three were classified as improvers and nine as non-improvers. Intrinsic gene analysis identified 3207 probes (2532 unique genes) at False Discovery Rate (FDR)<1.1% which organized study samples into fibroproliferative, inflammatory and normal-like groups. Based on the intrinsic subset assignment, improvers were normal-like or fibroproliferative while 7/9 non-improvers were inflammatory at baseline (p=0.0455). Consistent with these results, improvers were enriched in cell cycle genes (e.g. EGFR, TOP1 and TOP3A) and growth-related pathways (e.g. intracellular signal transduction and kinase cascade). Non-improvers were enriched in immune response genes (IL6, TLR2 and CCR2) and inflammatory pathways (e.g. defense response and leukocyte migration). Improvers showed stable pulmonary function (as measured by forced vital capacity (FVC) and diffusing capacity for carbon monoxide (D_LCO)) and stable QLF score post-treatment (as measured on HRCT). In contrast, non-improvers showed a trend towards decrease in FVC, a decrease in D_LCO (p=0.1289 and p=0.0156, respectively) and progression in QLF (p=0.0313). Moreover, non-improvers at baseline had a higher QGG score (p=0.0364) and tended to have a higher interstitial lung disease (ILD) score than improvers (p=0.1212).

Conclusion:

Our results indicate that the intrinsic gene expression subset of SSc may be associated with those patients most likely to respond to therapy. In this trial of dasatinib, patients classified as inflammatory at baseline displayed worse clinical outcomes in terms of skin score, pulmonary function and lung fibrosis than patients from other intrinsic subsets. To our knowledge, this is the first report showing that SSc patients from the inflammatory subset show a distinct lack of response to a drug treatment. Molecular subset information may improve clinical trial design and guide the development of personalized therapies for rare and difficult to treat diseases, such as SSc.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Scleroderma is a genetically complex autoimmune disease with substantial phenotypic heterogeneity. Previous genome-wide association studies (GWAS) have identified a large number of gene regions associated with disease risk. However, GWAS directly capture only common genetic variants that are presumably in linkage disequilibrium with causal variants, some of which may be rare

variants more frequently found in the disease population. Our goal was to identify potentially causal variants by comparing whole exome sequencing data between cases and controls. We focused on patients with severe disease, and specifically those with diffuse cutaneous systemic sclerosis (dcSSc), to limit disease heterogeneity.

Methods:

We produced whole exome sequencing data from 32 dcSSc patients on the Illumina HiSeq2500 platform with the Nimblegen SeqCap EZ v3.0 exome enrichment protocol. Paired-end 2 X 100 bp sequencing reads were generated with a mean coverage of 51X on the 64Mb of targeted exome regions. Control data came from 17 healthy control subjects whose data were produced using comparable methods, and from the 1000 Genomes and the NHLBI-ESP6500 Projects. Exome sequencing reads were processed according to the GATK Best Practices for DNAseq variant analysis. Variants were annotated and filtered with ANNOVAR and Variant Tools. We applied a gene mutation burden test to identify genes that were enriched with deleterious variants in dcSSc patients compared to controls.

Results:

We identified 96 genes that were enriched with deleterious variants in the dcSSc patients. Among the 96 genes, 10 genes (*NOTCH4, BANK1, BLK, GRB10, IRF8, KCNA5, NMNAT2 and TNFSF4*) are in previously identified scleroderma susceptibility loci or pathways implicated in scleroderma pathogenesis. In addition, we identified novel genes and 3 new pathways associated with scleroderma, including pathways related to ABC-family proteins mediated transport, extracellular matrix organization and the CD320-dependent methylmalonic aciduria.

Conclusion:

Using exome sequencing and gene mutation burden analysis, we identified 96 genes that contain functionally deleterious variants that may contribute to the development of dcSSc. This study demonstrates the potential value of whole exome sequencing for the identification of causal variants that contribute to scleroderma risk and/or severity. The candidate genes we discovered are potential targets for in-depth functional study or therapeutics development.

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Interstitial pneumonia (IP) is a chronic progressive interstitial lung disease associated with high mortality and poor prognosis. However, the exact mechanism of IP remains elusive. Recently, the pathological role of gdT cells was reported in several IP mice models. The γδT cells could produce a wide variety of cytokines, chemokines and growth factors and these cells have an important role in the regulation of the initial immune responses. In human, we previously reported that γδT cells might concern the pathogenesis of IP in systemic sclerosis patients. However, there are no reports on the properties and functional characteristics of γδT cells in pulmonary fibrosis. The purpose of this study is to clarify the role of γδT cells in bleomycin-induced IP model mice.

Methods: 1.C57BL/6 (WT) mice were injected with bleomycin (1.25mg/kg, intratracheally). After 3, 7, 14 and 21 days, the phenotypes of pulmonary γδT cells were examined by flow cytometry (FCM). 2.WT and TCRδ deficient ($TCR\delta^{-/-}$) mice were injected with bleomycin and the pathological findings were examined. 3.WT and $TCR\delta^{-/-}$ mice were injected with bleomycin. At 3, 7, 14, 21 days,

pulmonary Th17 (IL-17A$^+$ CD4$^+$ T) and Treg (Foxp3$^+$ CD4$^+$) cells were analyzed by FCM. 4.Splenic CD4$^+$T cells isolated from WT mice were co-cultured with γδT cells in condition of Th17 cell differentiation.

Results: 1.The number of pulmonary γδT cells increased at day3, 7, 14 after bleomycin exposure ($p<0.05$, $p<0.05$ and $p<0.05$, respectively). At 3 days after bleomycin exposure, pulmonary IFN-γ$^+$ γδT cells increased ($p<0.05$). On the other hands, pulmonary IL-17A$^+$ γδT cells increased at 7, 14 and 21 days after bleomycin exposure ($p<0.05$, $p<0.05$ and $p<0.05$, respectively). 2.TCRδ$^{-/-}$ mice showed pronounced hypercellularity and intimal thickening in lung parenchyma, and overproduction of collagen in lungs compared with WT mice. 3.In TCRδ$^{-/-}$ mice, pulmonary IL-17A$^+$ CD4$^+$ T cells increased at day 7 and 14 after bleomycin exposure compared with WT mice ($p<0.05$ and $p<0.05$, respectively). Pulmonary Foxp3$^+$ CD4$^+$ T cells were not significantly difference between WT and TCRδ$^{-/-}$ mice. 4.After co-cultured with γδT cells, the rate of IL-17A production in CD4$^+$ T cells and the number of IL-17A$^+$ CD4$^+$T cells were significantly decreased ($p<0.05$ and $p<0.05$, respectively).

Conclusion: Pulmonary γδT cells might play a regulatory role in the generation of bleomycin induced IP model mice via the suppression of IL-17 production.

Increased Heparanase Expression in Keratinocytes Promotes Dermal Fibrosis in Scleroderma

In-Woon Baek[1], Wan-Uk Kim[2], Chul-Soo Cho[1] and Ki-Jo Kim[3], [1]Internal Medicine, Yeouido St. Mary's Hospital, The Catholic University of Korea, Seoul, South Korea, [2]Internal Medicine, Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, South Korea, [3]Internal Medicine, St. Vincent's Hospital, The Catholic University of Korea, Suwon, South Korea

Session Time: 9:00AM-11:00AM

Background/Purpose: Interactions between keratinocyte and dermal fibroblast via paracrine loop play an important role in wound repair and keloid formation. In this study, we investigated heparanase expression in activated keratinocyte, and tested its effect on the survival of dermal fibroblasts.

Methods: Plasma heparanase levels were measured in scleroderma patients, and heparanase expression was evaluated in the skin of bleomycin-induced fibrosis mice and HaCaT keratinocyte (HaCaT). Dermal fibroblasts were cocultured with HaCaT separated by transwell insert under serum starvation, and apoptosis was determined using APOPercentage assay.

Results: Plasma heparanase levels were significantly higher in 26 scleroderma patients than in 10 healthy subjects, and positively correlated with plasma TGF-β levels. In bleomycin-induced fibrosis mice, increased heparanase expression was observed in keratinocyte layer, but not in dermal layer. Treatment of HaCaT with hypoxia resulted in significant increase in heparanase expression, and this increase was accompanied by concomitant increase of matrix metalloproteinase-9, both of which are known to degrade epidermal basement membrane components. Coculture of dermal fibroblasts and HaCaT in the presence of hypoxia significantly protected the apoptosis of dermal fibroblasts induced by serum starvation, but it was abolished by anti-heparanase antibody or transfection of HaCaT with heparanase siRNA. Dermal fibroblasts cocultured with HaCaT exposed to hypoxia exhibited increased Akt phosphorylation, and pretreatment of dermal fibroblasts with LY294002, an inhibitor of phosphatidylinositol 3-kinase, significantly abolished anti-apoptotic effect of heparanase on dermal fibroblasts.

Conclusion: These data indicate that hypoxia, caused possibly by microvascular alteration, increases heparanase production in keratinocytes, which may promote fibrosis in scleroderma by inhibiting the apoptosis of dermal fibroblasts.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a devastating fibrosing disease that primarily involves the skin, but may have life-threatening effects on the heart, lungs, gastrointestinal tract, and kidney. Although the exact pathogenesis of SSc remains unclear, one identified mechanism is the excessive extra cellular matrix (ECM) produced by fibroblast activation. Keratinocytes have recently been shown to influence fibroblast function; thus, we hypothesized that SSc keratinocytes may contribute to fibroblast activation and subsequent ECM production.

Methods: All SSc subjects fulfilled the ACR/EULAR criteria for SSc and were classified as limited cutaneous (lc) SSc and diffuse cutaneous (dc) SSc. Keratinocytes were cultured from the isolated epidermis of two 4mm forearm punch biopsies for two passages, and conditioned media was collected at passage 2. Keratinocyte population purity was assessed by morphology. Studies were performed on at least 3 lcSSc, 3 dcSSC, and 4 normal samples for each assay. Normal primary fibroblasts were stimulated for 24 or 72 hours with conditioned keratinocyte media in the presence or absence of TGF-β neutralizing antibody. Fibroblast activation was measured by expression of αsmooth muscle actin (SMA) and type 1 collagen expression via RT-PCR and with αSMA staining via immunofluorescent microscopy. Affymetric Human Gene ST2.1 microarrays were completed on cultured SSc and control keratinocytes. Pathway analysis was performed using Genomatix software.

Results: Stimulation of normal primary fibroblasts with keratinocyte conditioned media from lcSSc and dcSSc samples yielded increased collagen (lcSSc 1.6-4.5 fold, $p<0.0001$; dcSSc 1.2-4.4 fold,$p<0.0002$)and αSMA mRNA expression (lcSSc 6.6-12.5 fold,$p<0.0001$; dcSSc 6.2-13 fold;$p<0.0001$). αSMA expression was also increased on immunofluorescent staining of normal fibroblasts after exposure to scleroderma keratinocyte conditioned media. Microarray analyses and confirmation by RT-PCR demonstrated decreased TGF-β expression in both dcSSc and lcSSc keratinocytes. The addition of TGF-β neutralizing antibody to keratinocyte conditioned media did not decrease induction of αSMA or collagen expression by normal fibroblasts.

Conclusion: These results demonstrate that unstimulated scleroderma, but not control, keratinocytes are able to promote fibroblast activation, as measured by αSMA and collagen expression, independent of TGF-β production. Identification of the mediator of this activation may provide novel targets for prevention or treatment of fibrosis for SSC patients

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Pulmonary arterial hypertension (PAH) is a progressive and fatal complication in the patients with connective tissue diseases (CTD). Elevation of endothelin-1 (ET-1) levels in pulmonary arteries is suggested as one of the pathogenesis of PAH, however, mechanism for ET-1 induction in the disease circumstances is still elusive. A driving force for ET-1 synthesis is hypoxia and ET-1 has been known as a target gene of hypoxia-inducible factors (HIFs). HIFs are heterodimeric transcription factors composed of α subunit (HIF-1α or HIF-2α or HIF-3α) and β subunit (HIF-1β), operating in gene regulation in adaptive response to hypoxic condition. We have demonstrated ablation of HIF-3α gene in mice resulted in an increase in ET-1 production by pulmonary endothelial cells and human PAH-like cardio-pulmonary phenotype such as right ventricular enlargement and pulmonary arteriole musculalizations, indicating an implication of HIF-3α in the pathogenesis of PAH. In the present study, we aimed to explore the role of genetic defect or anomalies of HIF-3α in the pathogenesis of CTD-PAH.

Methods: Using genomic DNA form patients with systemic sclerosis (SSc) without PAH, SSc complicated with PAH, and normal healthy controls, we analyzed the incidence of coding single nucleotide polymorphisms (SNPs) in HIF3A gene reported in NCBI dbSNP database by PCR-direct sequencing. The m×n χ^2–test was applied to examine statistical significance of the incidence of the SNPs. Functional validations of the HIF-3α carrying the SNPs (SNP-HIF3α) were performed in the cells overexpressing SNP-HIF3α. Effect of SNP-HIF3α on ET-1 gene promoter was analyzed by reporter gene assays and chromatin immunoprecipitation assays.

Results: We found coding SNPs in HIF3A gene with significantly higher incidence in the SSc patients complicated with PAH compared to the SSc patients without PAH. Overexpression of HIF-3α carrying the SNPs (SNP-HIF3α) in the cells resulted in induction of ET-1 mRNA even under normoxic condition, indicating an implication of SNP-HIF3α in dysregulation of ET-1 production. SNP-HIF3α showed higher affinity to HIF-1β and to ET-1 gene promoter irrespectively of oxygen concentrations compared to wild type HIF-3α. Interestingly, SNP-HIF3α seemed to employ an additional cis-acting DNA sequence proximity to hypoxia response element in ET-1 gene promoter for transcriptional activation of the gene.

Conclusion: PAH-associated coding SNPs confer a novel function on HIF-3α at ET-1 gene promoter, which might contribute to the derangement of ET-1 gene regulation in patients with CTD-PAH.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is an autoimmune disease characterized by endothelial dysfunction, vascular injury,

and activation of fibroblasts leading to organ fibrosis. The precise etiology of SSc is not clear. We sought to study circulating cell-free DNA (cfDNA) and characterize it in an initial effort to determine if cfDNA is a useful biomarker in SSc.

Methods: We measured levels of cfDNA in the serum of 20 patients with SSc (13 limited cutaneous SSc, 7 diffuse cutaneous SSc) compared to 20 age-, sex-, and ethnicity-matched controls. The average age was 57.8 and 52.3 years for patients with SSc and controls, respectively (P= 0.10). The majority of subjects in this study were female (n= 17), and Caucasians (n= 19). Modified Rodanan's skin score (mRSS) was 6.5 and 20.2 for patients with limited cutaneous SSc (lcSSc) and diffuse cutaneous SSc (dcSSc), respectively. Moreover, we measured global methylation level of Cytosine in cfDNA by directly quantifying levels of 5-methylcytosine using 5-methylcytosine specific capture antibody.

Results: We demonstrate an increase in cfDNA level in patients with SSc (262.1 ng/ml) compared to healthy controls (65.9 ng/ml) (P= 0.027). The average level of cfDNA in lcSSc was (134.03 ng/ml) (P = 0.004), and (463.76 ng/ml) in dcSSc (P= 0.022). We did not find a correlation between level of cfDNA and mRSS in each subset, clinical manifestations, or type of organ involvement. We used same amount of cfDNA from each sample to measure 5-methylcytosine, and we demonstrate that cytosine methylation was significantly lower in patients with SSc (29.1%) compared to controls (54.3%) (P = 0.047). There was no significant difference in cytosine methylation between the two subsets of SSc.

Conclusion:

We demonstrate increased level of cfDNA in sera of patients with SSc, especially in patients with dcSSc in association with global hypomethylaiton of cytosine. We did not find a correlation between level of cfDNA and mRSS and/or clinical features of SSc. The origin, functional effect and suitability of cfDNA as a biomarker in SSc need further investigation.

Cold Receptor Expression and Function in Human Dermal Fibroblast: Possible Role in the Pathogenesis of Scleroderma Fibrosis

Yongqing Wang[1], John Sun[1], Shadia Nada[2], Nezam Altorok[3] and **Bashar Kahaleh**[4], [1]The University of Toledo, Toledo, OH, [2]Internal Medicine, Divison of Rheumatology, The University of Toledo, Toledo, OH, [3]Internal Medicine, Division of Rheumatology, The University of Toledo, Toledo, OH, [4]Medicine/Rheumatology, The University of Toledo, Toledo, OH

Session Date: Tuesday, November 10, 2015
Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Enhanced cold sensitivity is an early and consistent phenomenon in scleroderma (SSc). We previously demonstrated increased expression of the transient receptor potential melastatine 8 (TRPM8) in SSc microvascular endothelial cells. TRPM8 protein is a cold- and menthol-sensing calcium (Ca^{2+}) ion channel. To date, TRPM8 expression, function and intracellular signaling have not been characterized in human dermal fibroblasts (FB). In this study we evaluated TRPM8 expression in normal and SSc FB and in skin biopsies. We also investigated the effects of TRPM8 activation on selected FB fibrotic gene expression, intracellular calcium concentration ($[Ca^{2+}]_i$), intracellular reactive oxygen species (ROS) generation and SMAD3 phosphorylation.

Methods:

FB were isolated from involved SSc skin and matched control subjects. The expression of TRPM8 was determined by RT-PCR, immunocytochemistry (ICC) and western blot (WB) analysis. TRPM8 activation in FB was triggered by the TRPM8 agonist menthol (MT) or by exposure of cells to cold (18C°). The $[Ca^{2+}]_i$ was determined by Ca^{2+} calcium imaging system using Ca^{2+} indicator dye Fura 2 or Fura4. The mRNA and protein expression levels of *COL1, aSMA, FN, CTGF* and phosphoSMAD3 were determined by q PCR and WB. The production of ROS was detected by fluorescent indicator dye dihydroethidium (DHE). SMAD3 binding to CTGF promoter region was detected by chromatin immunoprecipitation assay (ChIP).

Results:

TRPM8 gene and protein expression in dermal FB was determined by RT-PCR, WB and ICC. TRPM8 mRNA and protein expression were significantly higher in SSc-FB and SSc-skin biopsies. Calcium image studies show that MT increased $[Ca^{2+}]_i$ and this response was blocked by capsazepine (CapZ), an antagonist of TRPM8. The activation of the TRPM8 by MT or cold exposure resulted in increased expression of *COL1, aSMA*, and *FN*. SSc-FB were more sensitive to MT or cold than normal FB. These effects were blocked by the addition of CapZ or TRPM8 siRNA. Furthermore, MT evoked production of intracellular ROS, which could be abolished by Ca^{2+} free solution or CapZ. The increased expression of *COL1, FN*, *aSMA* and *CTGF* by MT were inhibited by BAPTA-AM (intracellular calcium chelator) or by antioxidants (a mixture of superoxide dismutase, catalase and N-acetycysteine amide). Additionally, MT induced intracellular SMAD3 phosphorylation and facilitated nuclear accumulation of SMAD3. Finally, Chip assay confirmed that SMAD3 is recruited to the CTGF promoter after MT stimulation in FB. The addition of SB431542 and CTGF antibody partly block the *COL1* expression induced by MT.

Conclusion: Functional TRPM8 is expressed in human dermal FB and enhanced expression was observed in SSc FB and skin. The activation of TRPM8 mediated enhanced expression of the profibrotic genes *COL1*, aSMA, *FN and CTGF* via calcium influx, ROS production and SMAD3 transcription activation. SSc-FB were more sensitive to MT or cold exposure than normal FB, implicating potential involvement of TRPM8 in the pathogenesis of scleroderma fibrosis and suggesting that the blockade of TRPM8 may be a novel target for therapeutic intervention in SSc.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a multi-system autoimmune connective tissue disorder that leads to fibrosis of the skin and internal organs, resulting in significant patient morbidity and mortality. The fibroblast is considered a key target cell type for possible therapies aimed at modifying excessive deposition of extracellular matrix in affected organs. Several studies have assessed the role of protein tyrosine kinases (PTKs) in the pathophysiology of SSc fibroblasts and fibrosis. However the role of protein tyrosine phosphatases (PTPs), a family of enzymes that naturally balance the action of PTKs in signal transduction, in fibrosis remains mostly unexplored.

Methods: We analyzed the mRNA expression profile of all the PTPs (109 genes) in primary dermal fibroblasts from 9 patients with diffuse SSc compared to 9 healthy subjects. Whole transcriptome analysis by Next Generation Sequencing (NGS) was performed on normal human dermal fibroblasts (NHDF) subjected to silencing of the *PTP4A1* gene. In NHDF we investigated the effects of *PTP4A1* silencing on TGFbeta1 stimulated *COL1A2* and *ACTA2* gene expression and on SMAD3 and alphaSMA protein level by qPCR and immunoblotting, respectively. Luciferase assays were performed using a SMAD reporter in HEK 293T cell and *in vivo* experiments were carried out in mice using a bleomycin-induced fibrosis model.

Results: *PTP4A1* gene displayed increased expression in SSc dermal fibroblast lines studied (Mann-Whitney test, $p<0.05$). NGS of normal dermal fibroblasts showed that silencing of *PTP4A1* correlated with reduced expression of human pro-fibrotic genes and in particular of *SMAD3,* which pointed to a possible role of PTP4A1 in the TGFbeta-dependent pro-fibrotic pathway. NGS data for SMAD3 and other pro-fibrotic genes were confirmed at the protein level by immunoblotting. Co-transfection of HEK 293T with a

human *PTP4A1*-encoding pCDNA4 vector together with a luciferase SMAD reporter showed that PTP4A1 enhances activation of SMAD signaling after TGFbeta1 stimulation (Mann-Whitney test, $p<0.05$). *In vivo* experiments showed that knockout of PTP4A1 significantly attenuates bleomycin-induced fibrosis model in mice.

Conclusion: These results suggest that PTP4A1, a PTP overexpressed in SSc dermal fibroblasts, plays a role in the pathogenesis of SSc by promoting pro-fibrotic TGFbeta/SMAD3 signaling.

Fli1 Deficiency Contributes to the Downregulation of Endothelial Protein C Receptor in Systemic Sclerosis: A Possible Role in Pro-Thrombotic Condition

Ryosuke Saigusa[1], **Yoshihide Asano**[2], Takashi Taniguchi[2], Takashi Yamashita[2], Takehiro Takahashi[2], Yohei Ichimura[2], Tetsuo Toyama[2], Ayumi Yoshizaki[2], Tomomitsu Miyagaki[2], Makoto Sugaya[2] and Shinichi Sato[2], [1]7-3-1 Hongo, Bunkyo-ku, University of Tokyo Graduate School of Medicine, Tokyo, Japan, [2]Dermatology, University of Tokyo Graduate School of Medicine, Tokyo, Japan

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a multisystem connective tissue disease characterized by fibrosis of the skin and certain internal organs due to the constitutive activation of fibroblasts following immune attacks and vascular injury. Although the pathogenesis of SSc still remains unknown, a variable degree of luminal thrombosis following vascular injury may contribute to impaired peripheral circulation and the activation of vascular cells and fibroblasts. Endothelial protein C receptor (EPCR) predominantly expressed on endothelial cells plays a critical role in the regulation of coagulation system and also mediates various cytoprotective effects by binding and activating protein C. Since the role of EPCR has not been studied in SSc, we here investigated the potential contribution of EPCR to the development of this disease by utilizing clinical samples and its animal models.

Methods: EPCR expression was examined in skin samples and cultivated dermal microvascular endothelial cells by immunostaining and/or quantitative reverse transcription PCR. Fli1 binding to the *EPCR* promoter was assessed by chromatin immunoprecipitation. Serum EPCR levels were determined by enzyme-linked immunosorbent assay in 65 SSc and 20 healthy subjects.

Results: EPCR expression was markedly decreased in dermal small vessels of SSc lesional skin compared with those of healthy control skin. Transcription factor Fli1, whose deficiency is implicated in SSc vasculopathy, occupied the *EPCR* promoter and EPCR expression was suppressed in Fli1 siRNA-treated human dermal microvascular endothelial cells and dermal small vessels of *Fli1*$^{+/-}$ mice. In SSc patients, decreased serum EPCR levels were associated with diffuse skin involvement, interstitial lung disease and the current and past history of digital ulcers, all of which are associated with hyper-coagulation status. Furthermore, serum EPCR levels inversely correlated with plasma levels of plasmin-a2-plasmin inhibitor complex (PIC), suggesting that reduced expression of endothelial EPCR truly induces hyper-coagulation status in SSc. Moreover, circulating EPCR and PIC levels were normalized in parallel with the up-regulation of Fli1 and EPCR in endothelial cells after the treatment with bosentan, a potential disease modifying drug preventing the development of digital ulcers in SSc.

Conclusion: This is the first report demonstrating the potential contribution of reduced EPCR to the development of SSc. The present findings further reinforce the notions that endothelial Fli1 deficiency is a key feature underlying the induction of structural and functional abnormalities of SSc vasculopathy and that bosentan has a potential to reverse the vascular phenotype related to Fli1 deficiency. The reversal of impaired coagulation/fibrinolysis system is a possible mechanism underlying the preventive effect of bosentan on digital ulcers in SSc.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) primarily affects postmenopausal women. This sex bias could partly be explained by the action of estrogens on the immune system and/or fibrogenesis. Since little is known about their direct role in fibrogenesis, our aim was to evaluate the effects of estrogens i) on the pathological activation of dermal fibroblasts induced by transforming growth factor-b (TGF-β) and ii) in the development of experimental dermal fibrosis.

Methods: SSc dermal fibroblasts were stimulated with TGF-β and incubated with different concentrations of 17-β-estradiol and/or tamoxifen, a selective estrogen receptor modulator that display anti-estrogenic properties. Collagen release from fibroblasts was evaluated by mRNA levels of col1a1 and col1a2 and by measuring the concentrations of collagen in cell culture supernatants with the SirCol collagen assay. Differentiation of fibroblasts into myofibroblasts was assessed by the expression of alpha smooth muscle actin (α-SMA). Activation of the TGF-β pathway was evaluated by the expression of phospho-smad-2/3. Effects on estrogen inhibition by gene inactivation (knockout mice for the estrogen receptor-α, ERKOa) or targeted molecular strategy (tamoxifen) were evaluated in the mouse model of bleomycin-induced dermal fibrosis and in the tight skin (Tsk-1) mouse model.

Results: Treatment of SSc dermal fibroblasts with 17-β-estradiol or tamoxifen did not change significantly baseline collagen production and fibroblast differentiation. In SSc fibroblasts stimulated by TGF-β, treatment with 17-β-estradiol led to a significant reduction of COL1A1 and COL1A2 mRNA levels, as well as collagen release in cell culture supernatant. In addition, decreased α-SMA mRNA and protein levels were observed upon treatment with 17-β-estradiol in TGF-b stimulated dermal fibroblasts. 17-β-estradiol also led to a significant reduction of TGF-b dependent phosphorylation of phospho-Smad2/3. In fibroblasts stimulated with TGF-b and treated with 17-β-estradiol, the addition of tamoxifen restored TGF-b signaling and its profibrotic effects on collagen synthesis and fibroblast differentiation.

Estrogen inhibition led to more a severe dermal fibrosis induced by bleomycin. Upon bleomycin injections, ERKO-a mice and mice treated with tamoxifen had a significant increase of dermal thickness (17%, p=0.03 and 20%, p=0.04), hydroxyproline content mice (16%, p=0.02 and 36%, p=0.003, respectively) and number of myofibroblasts (22%, p = 0.01 and 20%, p = 0.04 respectively) compared to control mice. In Tsk-1 mice, treatment with tamoxifen led to significantly enhanced skin fibrosis, with a 31±8% increase of hypodermal thickening (p=0.03) and a 17% increase of hydroxyproline content (p=0.01) compared to control mice.

Conclusion: Our results demonstrate a beneficial effect of estrogen in dermal fibrosis. Estrogens reduce TGF-b dependent activation of SSc dermal fibroblasts and estrogen inhibition leads to a more severe experimental dermal fibrosis. These findings may partly explain the occurrence of SSc in postmenopausal women and the greater severity of the disease in men and open avenue to potential hormonal therapies.

Session Date: Tuesday, November 10, 2015

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a chronic fibrotic connective disease of unknown etiology that affects the skin and internal organs. Transforming growth factor-β (TGFβ) has been characterized as a key-mediator of fibroblast activation in SSc. However, the intracellular signaling cascades that control TGFβ signaling and the TGFβ-induced activation of fibroblasts are still incompletely understood. Homeobox containing transcription factor, Engrailed-1 plays a key role in embryonic development and has also been linked to disease, including cancer. EN-1 is induced by proinflammary cytokines and oxidative stress which play an important role in Systemic Sclerosis (SSc).

Methods: The expression of EN-1 in skin tissue and in human dermal fibroblasts was determined by real-time PCR, Western blot and immunohistochemistry. Knock-down and overexpression strategies were used to evaluate the effect of EN-1 on fibroblast activation. The outcome of mice with fibroblast-specific knockout of EN-1 (EN1 fibKO) was evaluated in bleomycin-induced skin fibrosis; fibrosis induced by overexpression of a constitutively active TGF-β receptor I (TBRIact) and in the Tsk model which resembled the later stages of SSc. Co-IP and CAGA Reporter assay were performed to study the physical and functional interaction between EN-1 and Smad3.

Results: A five-fold increased expression of EN-1 was detected in the upper layer of the dermis of SSc patients on fibroblasts double stained for EN-1 and anti-prolyl-4-hydroxylase. EN-1 expression was induced by TGF-β in cultured fibroblasts and treatment with the TBR inhibitor SD-208 prevented the induction of EN-1 by two-fold decrease in experimental fibrosis. Fibroblasts lacking EN-1 were less sensitive to the pro-fibrotic effects of TGF-β with impaired induction of collagen mRNA and protein. Additionally, overexpression of EN-1 enhanced the profibrotic effect of TGF-β with myofibroblast differentiation and increased collagene release. Function studies demonstrated that EN-1 interacts with Smad3 to regulate the pro-fibrotic effects of TGF-β. Co-IP demonstrated that TGF-β induces binding of EN-1 to Smad3. Reporter study and analyses of the expression of classical Smad target genes such as PAI-1 demonstrated that the binding of EN-1 to Smad3 stimulates the transcriptional activity of Smad3. In the model of bleomycin-induced fibrosis dermal thickening, hydroxyproline content and myofibroblast counts were significantly decreased in EN1 fibKO mice as compared to wildtype littermates. EN1 fibKO also protected from TBRIact-induced fibrosis and ameliorated fibrosis in the Tsk1 model.

Conclusion: We demonstrate for the first time a role of EN-1 in fibroblast activation and tissue fibrosis. Deficiency in EN-1 reduced the stimulatory effect of TGF-β on fibroblasts by interfering with canonical Smad and protected from experimental fibrosis in different mouse models. Considering the potent anti-fibrotic effects observed in this study, EN-1 might be a candidate for molecular targeted therapies of SSc.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Ubiquitination of proteins leads to their degradation by the proteasome, and is regulated by a small number of ubiquitin ligases, and a large number of susbtrate-specific ubiquitin-specific peptidases (USP). The ubiquitination process is not only key to protein recycling, and cell survival but plays also important roles in the regulation of cell metabolism and cell cycle. Here, we found that the expression of several USP is increased in systemic sclerosis tenosynovial biopsies, and we demonstrated that USP inhibition decreases TGFβ signaling in primary fibroblast cell lines.

Methods: HGU133 Plus2.0 arrays were hybridized with total RNA obtained from 5 tenosynovial samples obtained in patients with SSc and overt tenosynovial involvement, and compared to disease control synovial biopsies. Primary fibroblast cell lines were obtained from the skin of SSc patients or controls, and cultured in the presence of DMOG, a HIF1α hydroxylase inhibitor or in the presence of TGFβ +/- USP inhibitor NS-632839. HEK293 cells were stably transfected with an USP15-encoding expression plasmid.

Results: Transcriptomic profiles of tenosynovial biopsies from SSc patients were characterized by the expression of genes involved in known pathogenic pathways : fibrosis, Wnt signaling, but also by the over-expression of several USP (USP15, 16, 18, 25, 31, 36, 37, 45, 48). Immunohistochemistry experiments on the same samples confirmed the presence of USP15 in SSc biopsies.

Culture of primary fibroblast cell lines in the presence of DMOG, a HIF1α-hydroxylase inhibitor that mimics the effects of hypoxia, results in a significant induction of TGFβ, USP25 and USP36 gene expression, but not USP15.

USP15 is known to specifically deubiquinate SMAD3, and we confirmed that over-expression of USP15 in HEK293 cells results in increased SMAD3, and SMAD3 phosphorylation in response to TGFβ stimulation. Conversely, exposure of cultured fibroblasts to NS-632839, a pan-USP inhibitor decreased SMAD3 expression and phosphorylation, and expression of COLIAI, COL3A1 and fibronectin gene expression in response to TGFβ stimulation. The effect of the USP inhibitor resulted in increased SMAD3 ubiquitination (as proven by SMAD3 immunoprecipitation experiments), and was blocked by epoxomicin, a proteasome inhibitor, thereby confirming the specificity of its action.

Conclusion: Over-expression of several USP, including USP15, is observed in tenosynovial biopsies from SSc patients, and is not fully explained by the effects of hypoxia. USP15 amplifies fibrotic responses induced by TGFβ, and is a potential therapeutic target in SSc.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The adipogenesis master regulator PPAR-gamma (PPARg) is regulated by repressors such as NCoR. Systemic sclerosis (SSc) is associated with impaired PPARg expression and function and altered adipokine homeostasis. Loss of intradermal adipose tissue is prominent in the skin in SSc, as well as in mouse models of skin fibrosis.

Methods: To test the hypothesis that decreased adipose PPARg has a pathogenic role in dermal fibrosis and to ask whether rescuing its function might be beneficial, we characterized skin fibrosis in mice with adipocyte-specific NCoR ablation using the bleomycin model.

Results:

Adipocyte-NCoR null mice on a high-fat diet showed PPARg activation, enhanced insulin sensitivity and alterations in serum adipokines. Moreover, NCoR null mice were resistant to bleomycin-induced changes in adipocyte size and function and loss of intradermal adipose tissue. Importantly, NCoR null mice had attenuated skin fibrosis measured both histologically and biochemically, which was reversed by the pharmacological inhibitor of PPARg GW9662. Taken together, these findings suggest that enhanced dermal adipogenesis mediated by tissue-specific PPARg activation modulates skin fibrosis.

Conclusion: These results strongly suggest that intradermal adipose plays an active role in skin fibrosis. Targeting adipogenesis might therefore represent an innovative approach to control skin fibrosis in SSc

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Adipocytes and their progenitor cells are embedded in a network of extracellular matrix that plays a role in regulating its function. Type 6 collagen (COL6) is the most highly expressed collagen in differentiated adipocytes and its expression is upregulated in the skin in systemic sclerosis (SSc). The cleavage product of COL6α3, endotrophin, is secreted by mature adipocytes. The recently described adipokine, endotrophin, exerts a major influence locally in adipose tissue and has potential effects on triggering fibrosis and inflammation in both metabolic dysfunction and in growing solid tumors. In SSc, recent findings point to an unrecognized connection between adipose tissue, adipokines, and fibrosis. We, therefore, hypothesize that in SSc abnormal endotrophin expression contributes to dermal fibrosis.

Methods: To examine COL6 expression in SSc skin, we first queried a publicly available data set comprising genome-wide expression data from SSc and healthy control skin biopsy samples. COL6 mRNA expression was also examined in explanted fibroblasts from SSc skin biopsies and healthy controls. Tissue levels of endotrophin protein in skin biopsy samples from SSc patients with diffuse subtype and healthy controls were examined by immunohistochemistry.

Results: Levels of COL6 mRNA were found to be significantly increased ($p < 0.001$) in skin biopsy samples mapping to the diffuse-proliferative and inflammatory intrinsic subsets compared to normal-like subsets. Expression levels of COL6α3 mRNA were positively correlated with the total skin score (MRSS) ($R=0.39$, $p<0.001$). Elevated COL6 mRNA expression in SSc skin biopsy samples was confirmed by real-time qPCR ($p=0.02$). Endotrophin was markedly increased in both dermis and intradermal adipose tissue of diffuse SSc patients as compared to healthy controls ($p=0.002$).

Conclusion: Endotrophin and COL6 expression are both highly expressed in the skin in SSc. Endotrophin has potential effects on fibrosis in SSc and might be a potential target of therapy.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic Sclerosis (SSc) is characterized by progressive fibrosis of skin and multiple internal organs, severe alterations in the microvasculature, and numerous immunological abnormalities. Recently it has been suggested that endothelial to mesenchymal transition (EndoMT) may be involved in SSc vasculopathy and tissue fibrosis. Exosomes are 30-150 nm lipid bilayer bound microvesicles released from all human cells into their surrounding intercellular space and into the circulation and contain numerous macromolecules including mRNAs, miRNAs, proteins, cytokines, chemokines and growth factors. Exosomes are capable of carrying complex signals to sites removed from the cell of origin. We propose that EndoMT-activated EC induce phenotypic changes in normal/healthy fibroblasts and EC and that these effects are mediated by exosomes released into the circulation that reach normal fibroblasts and EC, fusing with them, and transferring their miRNA contents rendering them profibrotic. We examined here whether exosomes isolated from Endo-MT-activated normal human dermal and lung microvascular EC display alterations in their miRNA content that may be capable of inducing a profibrotic phenotype in normal fibroblasts and EC.

Methods: Normal human dermal or lung microvascular EC were expanded in monolayer cultures until reaching confluency, then they were cultured under control conditions or in the presence of 10 ng/ml of TGF-β1 or TGF-β2 for 48h to induce EndoMT. Following treatment the cells were washed and incubated in exosome-free culture media for additional 24h. The culture media were collected and exosomes were isolated using the ExoQuick polymer exosome purification procedure. The exosomes were pelleted by centrifugation. Exosome miRNA were isolated by lysis of the pellet and RNA purification using SeraMir RNA spin columns. cDNA was synthesized by polyadenlyation of RNA followed by reverse transcription substituting a miRNA 3' adaptor oligonucleotide in place of Oligo-dT. The resulting single-stranded miRNA-derived cDNA was utilized in qPCR profiling of profibrotic and antifibrotic miRNAs. Exosomal miRNA levels were normalized to levels of the small nucleolar RNA SNORD25.

Results: Exosomes were successfully isolated from culture media samples and sufficient RNA was extracted for RTPCR performance and relative miRNA quantification. The quantification of profibrotic and antifibrotic miRNA in the exosomes isolated from the culture media of both cell types is shown in Figure 1.

Conclusion: Exosomes were successfully isolated and purified from the culture media of human EC. TGF-β1 or TGF-β2-mediated *in vitro* induction of EndoMT in normal human dermal or lung microvascular EC resulted in a marked increase in profibrotic miRNA and a marked decrease in antifibrotic miRNA contained in exosomes released by these cells into the culture media.

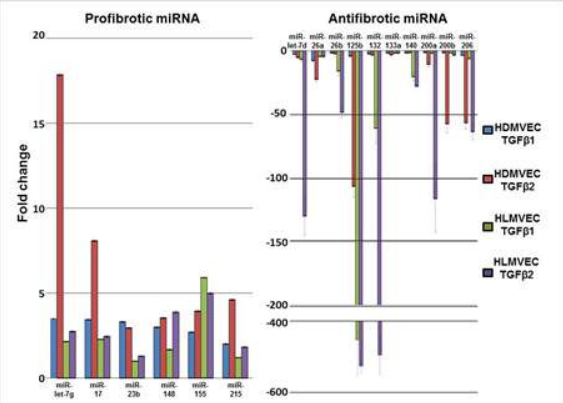

Figure 1. Levels of **miRNA contained in exosomes isolated from culture media from normal human dermal microvascular EC (HDMVEC) or normal human lung microvascular EC (HLMVEC) treated with either TGF-β1 or TGF-β2 assessed by real time PCR.** Values represent the mean (+/- SD) fold change levels of three replicates of exosomes isolated from each cell line. Content levels in samples of untreated cells were arbitrarily set at 1 fold.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Pulmonary arterial hypertension (PAH) represents a serious co-morbidity affecting up to 10% of systemic sclerosis (SSc) patients. Cardinal features of PAH include inflammation and vascular remodelling, the latter resulting from alterations in proliferation, matrix production, chemokine and cytokine expression by resident cells including pulmonary arterial smooth muscle cells (PASMCs). Previously we have shown an inhibitor of the epigenetic BET bromodomain proteins, JQ1 can antagonise the pro-inflammatory phenotype of SSc dermal fibroblasts. In this study we assessed the role of BET inhibition on PASMC cell contractile to synthetic switching, and the *in vivo* effects on vascular remodelling and development of PAH in the hypoxia/SU5416 mouse model.

Methods: The effects of siRNA knockdown and pharmacological inhibition using JQ1 on contractile and synthetic PASMCs switching and proliferation, matrix deposition and inflammatory chemokine secretion assessed by crystal violet, Western Blot and ELISA respectively. Using the hypoxia/SU5416 model of PAH, female C57BL/6 mice were maintained in a hypoxic (10% O_2) chamber and given 3 weekly doses of 20mg/kg SU5416 to induce PAH. Animals were treated with JQ1 at 15 or 60 mg/kg/day ($n \geq 6$), and haemodynamics, cardiac hypertrophy and vascular remodelling were assessed after 21 days. The effect on circulating inflammatory chemokines was determined by multiplex ELISA.

Results: Synthetic PASMCs secrete significantly ($p<0.05$) elevated IL-6, IL-8 and MCP-1 compared to contractile PASMCs (n=3).

Administration of JQ1 significantly inhibited in a concentration dependent manner, secretion of MCP1 ($P<0.01$) and IL-6 ($P<0.01$) but not IL-8 from PASMCs. Further, elevated collagen type I deposition observed in synthetic PASMCs was significantly inhibited by JQ1. Systemic administration of JQ1 *in vivo* in the pre-clinical model of hypoxia/SU5416 induced PAH, significantly attenuated right ventricular systemic pressure in a dose dependent manner ($P<0.05$) and attenuated vascular remodeling ($P<0.05$). JQ1 had no effect on mean systemic arterial pressure or heart rate at the doses tested. Furthermore, pro-inflammatory cytokines including IL-6 and IL-8 were significantly reduced in serum from JQ1-treated mice compared to hypoxia/SU5416 control (Table I). Consistent with this, JQ1 significantly attenuated the synthetic PASMC phenotype, significantly reducing IL-6 and MCP-1 secretion ($P<0.001$), as well as enhanced type-I collagen and CTGF expression.

Conclusion: This data supports a key role for BET bromodomain proteins in the pathological switching of PASMCs. Consistent with this, JQ1 inhibited vascular remodeling and the development of PAH in the hypoxia/Su5416 mouse model of PAH. Suggesting targeting of bromodomain proteins may represent a novel therapeutic approach to targeting SSc-PAH.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a complex autoimmune disease. The aetiology of the disease is largely unknown, although both environmental and a genetic factors are thought to be involved in the disease development. The genetic susceptibility of SSc has been well-addressed by powered genetic association studies. The results of these studies clearly support an important role of the immune system. In this regard, several interleukin-12 (IL-12) pathway-related genes have been identified as susceptibility factors for SSc (*IL12RB1*, *IL12RB2*, *IL12A*, *STAT4*). *TYK2* is a tyrosine kinase protein that mediates several family cytokines signaling, including IL-12, and constitutes a common risk factor for autoimmunity. On this base, we aimed to analyze the association of the *TYK2* locus with SSc susceptibility.

Methods: The complete set of individuals enrolled for this study comprised a total of 7,103 SSc patients and 12,220 healthy controls of Caucasian ancestry from Spain, USA, Germany, The Netherlands, Italy and the United Kingdom. We performed an initial screening of *TYK2* genetic region in a previously published large-scale genetic study (Immunochip). Four *TYK2*single-nucleotide polymorphisms (SNPs) were selected for follow-up (V362F [rs2304256], P1104A [rs34536443], I684S [rs12720356] and A928V [rs35018800]). Association and dependence analyses were performed by the means of logistic regression and conditional logistic regression. Meta-analyses were performed using the inverse variance method.

Results: Genome-wide significance level was reached for *TYK2* V362F common variant in our pooled analysis ($P = 3.08x10^{-13}$, OR = 0.83), while the association of P1104A, A928V and I684S rare and low-frequency missense variants remained significant with nominal signals ($P = 2.28x10^{-3}$, OR= 0.80; $P = 1.27x10^{-3}$, OR= 0.59; $P = 2.63x10^{-5}$, OR= 0.83, respectively). Interestingly, dependence and allelic combination analyses clearly supported that the highly significant association observed for V362F with SSc was a spurious signal driven by P1104A, A928V and I684S. This results are consistent with previous *in vitro* and *in silico*studies, which revealed that P1104A, A928V, and I684S were damaging mutations and impaired the catalytic activity of TYK2, leading to a reduced TYK2 response and decreasing pro-inflammatory cytokines signaling, such as IL-12.

Conclusion:

The present study reports for the first time robust evidence for the implication of *TYK2* in SSc susceptibility. These results reinforce the crucial involvement of IL-12 signaling axis in the disease pathophysiology. Thus, target therapies blocking this pathway might represent an effective treatment for the disease.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Progressive tissue fibrosis and microvascular alterations are the hallmarks of Systemic Sclerosis (SSc). The mechanisms involved in SSc pathogenesis are complex and have not been fully elucidated. One notable feature of SSc is the extension of the pathologic process to normal tissues. The mechanisms involved in this topographic extension have remained elusive. Recent studies suggested that the phenotypic transition of endothelial cells (EC) into mesenchymal cells (endothelial to mesenchymal transition; EndoMT) may be involved in the progressive tissue fibrosis and fibroproliferative vasculopathy in SSc although the mechanisms

involved have not been elucidated. We here suggest that one potential mechanism may be that EndoMT activated EC exert paracrine effects on normal/healthy fibroblasts and EC and induce them to express a profibrotic phenotype and transdifferentiate into activated profibrotic cells. The purpose of the study was to evaluate whether secreted molecules released by microvascular lung EC undergoing EndoMT exert paracrine effects on normal human pulmonary fibroblasts inducing them to become profibrotic.

Methods: Normal human lung fibroblasts and microvascular EC were isolated from normal lung tissues by enzymatic digestion with collagenase. The isolated cell suspension was incubated with CD45 microbeads to remove leukocytes. Fibroblasts and EC were isolated employing anti-human CD31 antibody magnetic beads. The CD31- fibroblasts and the CD31+ EC were expanded separately. For EndoMT induction the lung microvascular EC were treated with TGF-β1 or TGF-β2 for 48 h. Following a change of media to serum-free media for 24h the supernatants were collected and aliquotes added to triplicate wells of normal human lung fibroblasts. After 24h, culture supernatants were isolated for Western blot analysis. The cells were lysed and total fibroblast RNA isolated and cDNA generated. Expression of various fibrosis-associated +genes was assessed by quantitative real time PCR. Validation of the gene expression results was performed employing Western blot analysis of secreted and intracellular proteins.

Results: RTPCR results showed a marked increase in levels of COL1A2, COL3A1, FN1, CTGF and TGFβ1 mRNA in normal lung fibroblasts treated with supernatants from normal lung microvascular EC pretreated with TGF-β1 or TGF-β2 compared to medium from untreated EC. Increased amounts of fibronectin were found in the media of lung fibroblasts treated with supernatants from the lung microvascular EC treated with TGF-β1 or TGF-β2.

Conclusion: Treatment of normal lung fibroblasts with proteins released by cultured human lung microvascular EC induced to undergo EndoMT *in vitro* resulted in a profound change in the expression of numerous profibrotic genes. The results demonstrated potent paracrine effects of EndoMT-activated lung microvascular EC on normal target lung fibroblasts and suggest a novel mechanism for the progression of SSc-associated pulmonary fibrosis.

Session Title: T cell Biology and Targets in Autoimmune Disease Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: CD52 is a cell-surface glycoprotein that is widely expressed in lymphocytes, monocytes and eosinophils. The anti-CD52 antibody has been used to treat multiple autoimmune diseases, and its effectiveness has been reported. $CD4^{+}CD52^{high}$ T cells inhibit the activation of $CD4^{+}CD52^{low}$ T cells through the release of cell-surface CD52. Soluble CD52, which is cleaved from $CD4^{+}CD52^{high}$ T cells, works as a ligand of siglec-10 on $CD4^{+}CD52^{low}$ T cells (Nat Immunol. 2013 Jul;14(7):741-8.). $CD4^{+}CD52^{high}$ T cells were reported as distinct population from conventional regulatory T cells. The role of the immune regulation of $CD4^{+}CD52^{high}$ T cells in systemic lupus erythematosus (SLE) is unknown. We evaluated the $CD4^{+}CD52^{high}$ and $CD4^{+}CD52^{low}$ T cells in the human peripheral blood mononuclear cells (PBMCs) of SLE patients and clarified their roles in the pathogenesis of SLE.

Methods: We isolated the PBMCs of 40 SLE patients, 14 non-SLE patients (11 with rheumatoid arthritis, 3 with mixed connective-tissue disease) and 22 healthy controls (HCs). The expressions of $CD4^+CD25^+CD127^-$ T cells (Tregs), $CD4^+CD52^{high}$ T cells and $CD4^+CD52^{low}$ T cells were analyzed by flow cytometry. We also analyzed the correlations with clinical parameters including SLEDAI, anti-ds-DNA antibody titer and complement titer. The soluble CD52 was also analyzed in an ELISA among the SLE and non-SLE patients and HCs.

Results: We found that the expression of $CD4^+CD52^{low}$ T cells in the SLE patients was significantly higher than HC (p=0.003) and non-SLE (p=0.003) (Figure). The expression of $CD4^+CD52^{low}$ T cells of the SLE group were significantly correlated with SLEDAI (p-value=0.002, r=0.481803), anti-ds-DNA antibody (p-value=0.01, r=0.420842) and IgG (p-value=0.018, r=0.392004). Soluble CD52 measured by ELISA was found to be decreased in the SLE group versus the other groups (vs. HC: p=0.001; vs. non-SLE: p=0.014). No significant difference was found in the population of $CD4^+CD25^+$ $CD127^-$ cells among the groups. There was no correlation between Tregs and $CD4^+CD52^{high}$ T cells in SLE.

Conclusion: Collectively, our data suggest that increased $CD4^+CD52^{low}$ T cells along with decreased soluble CD52 are involved in the pathogenic autoantibodies production highlighting its potential as a therapeutic target for SLE.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: T cell Biology and Targets in Autoimmune Disease Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Previous studies point to qualitative and quantitative Treg insufficiencies underlying aberrant T-cell activation in SLE. GATA-3 is critical in lineage commitment and functions of murine Treg, whereas IL-21 tips the balance from Treg towards Th17 differentiation through STAT3 phosphorylation in mice. IL-21 and IL-21 receptor polymorphisms confer risk for SLE. However, roles of GATA-3 in lupus Treg biology and mechanisms by which IL-21 regulates human Treg development remain undefined.

Methods: $CD3^+$ T cells were isolated from 9 pairs of matched SLE and healthy control (HC) subjects. A part of the $CD3^+$ T cells were stained with CD4, CD25, FOXP3, and GATA-3. The remainder was cultured in RPMI culture media with 10% FCS in the presence of plate-bound anti-CD3, soluble anti-CD28 with/without 100 nM rapamycin. After 3 days in culture, IL-21 secretion in the supernatants was quantified by LUMINEX assay. Naïve $CD4^+$ T cells were isolated from 5 pairs of matched SLE and HC subjects and cultured for 3 days in the presence of anti-CD3/CD28, TGF-β, and IL-2 with/without IL-21. A portion of cells were stained with CD25, FOXP3, and GATA-3 to determine the frequency of $CD4^+CD25^+FOXP3^{hi}$ Tregs and GATA-3 expression in the $CD4^+CD25^+FOXP3^+$ Tregs by flow cytometry. Cell lysates were saved for immunoblotting with antibodies against STAT3, $pSTAT3^{Y705}$, Akt, and $pAkt^{Ser473}$. Signal intensity was normalized to actin. Statistical analysis was made using Student's t-test.

Results: GATA-3 expression in Tregs was reduced in SLE as compared with HC (relative mean fluorescence intensity: 0.81±0.09, p=0.032) in freshly isolated $CD3^+$ T cells, whereas IL-21 secretion appears to be increased in culture supernatants of SLE T cells (SLE: 415.37±207.62 pg/ml, HC: 147.38±45.28 pg/ml, p=0.10). Under Treg-polarizing conditions, IL-21 suppressed $CD4^+CD25^+FOXP3^+$ Treg differentiation in SLE (frequency of $CD4^+CD25^+FOXP3^{hi}$ cells; control: 57.06±3.35%, IL-21-treated cells: 34.80±2.13%, p=0.0002) and HC (control: 45.30±6.66%, IL-21-treated cells: 30.43±2.84%, p=0.03). IL-21 suppressed GATA-3 expression in $CD4^+CD25^+FOXP3^+$ Tregs in SLE (control 58.31±7.93%, IL-21-treated cells 26.57±5.40%, p=0.001) and HC (control: 59.53±5.32%, IL-21-treated cells: 38.47±8.51%, p=0.045). Mechanistically, IL-21 phosphorylated STAT3 (relative intensity: 1.48±0.19, p=0.033) as well as Akt (relative intensity: 1.48±0.20, p=0.037) in SLE $CD4^+$T cells cultured under Treg-skewing conditions. Rapamycin suppressed IL-21 secretion by SLE T cells stimulated with anti-CD3/CD28 (control: 415.37±207.62 pg/ml, rapamycin: 8.23±3.01 pg/ml, p=0.047).

Conclusion: The data indicate that IL-21 phosphorylates STAT3 and Akt and inhibits Treg differentiation in SLE, possibly via the suppression of GATA-3. Suppression of T-cell IL-21 secretion emerges as one of the mechanisms by which rapamycin promotes Treg expansion in SLE.

The Adaptor Protein Crkii Regulates Rap1 Activation in the Immunological Synapse

Adam Mor[1] and Inbar Alfaguter[2], [1]Rheumatology and Pathology, NYU Langone Medical Center, New York, NY, [2]NYU, New York, NY
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: T cell Biology and Targets in Autoimmune Disease Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Crk proteins are a family of adaptors that play an important role in regulating multiple T cell functions. The two main Crk isoforms are CrkII and CrkL that are encoded by separate genes. Similar to other adaptors, they bind to phosphorylated tyrosine motifs of many proteins via their SH2 domain to recruit additional effectors utilizing their SH3 domain. One of these effectors is C3G, a guanine nucleotide exchange factor regulating Rap1 activation and subsequent adhesion. T cells adhere to multiple cells including endothelial cells and antigen presenting cells (APC). The interphase between T cell and APC is known as the immunological synapse (IS). It is made of multiple T cell receptors that interact with adhesion molecules and ligands presented on the surface of the APC. The distribution of these molecules is characterized by a specific organization that can be divided into central supermolecular activation clusters (cSMACs) and peripheral SMAC (pSMAC).

Methods:

The goal of this study was to uncover the mechanism by which Crk proteins regulate Rap1 activation within the IS of primary human T cells using lipid bilayer and TIRFm microscopy.

Results:

We determined that activation of T cells trough the antigen receptor led to polarization of activated Rap1 toward the IS. Unlike other GTPases, Rap1 was excluded from the cSMAC. Notably, C3G was recruited to the same compartments as Rap1. Although both CrkII and CrkL populated both compartments of the IS, their distribution was phosphorylation dependent. While phosphorylated (and inactive) CrkII was limited to the cSMAC, CrkL phosphorylation resulted in pSMAC distribution. Subsequent biochemical and genetic studies confirmed that signaling initiated by the antigen receptor resulted in CrkII dephosphorylation that was mediated by the phosphatase SHP2.

Conclusion:

In summary, we discover a new signaling pathway where signals downstream the T cell receptor result in recruitment of SHP2 to dephosphorylate and activate the adaptor CrkII. Activated CrkII travel to pSMAC where it recruits C3G, leading to Rap1 activation and LFA-1 mediated adhesion.

Session Title: T cell Biology and Targets in Autoimmune Disease Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: A novel candidate gene, *Mosaic* (Multi-Organ System Autoimmunity in Canines), was identified as the culprit causing an early and severe multiorgan autoimmunity in a purebred canine population. This unique dog breed develops early onset Addison's disease, arthritis, autoimmune cytopenias, hepatitis and uveitis. Little is known about the function of this gene. It is conserved across all known vertebrae species including humans and mice. The affected dogs possess a single point mutation resulting in an amino acid change of a proline to leucine residue in a highly conserved region. This gene is expressed in immune cells with particularly high abundance in T regulatory (Treg) cells. Thus, we hypothesized that the deficiency in *Mosaic*disrupts normal Treg cell function in maintaining immune tolerance and leads to multiorgan autoimmunity.

Methods: The cDNA for *Mosaic*was cloned into an expression vector and transfected into 293 cells to assess cellular localization. A knockout mouse was generated carrying a reporter cassette allowing tracing of the endogenous gene expression pattern. Heterozygous knockout mice were used for flow cytometry to identify immune subsets that expressed this gene.

Results: Wild-type and mutant *Mosaic*showed nuclear localization by immunohistochemistry and western blotting in transfected cells. Heterozygous knockout mice were assessed by flow cytometry and showed expression in multiple immune cell lineages including high expression in Treg cells and activated T cells.

Conclusion: *Mosaic* was identified as the causal gene mediating a multi-organ system autoimmunity in a unique breed of dogs. This protein is localized to the nucleus suggesting a role in modifying gene expression and is expressed in multiple immune cell subsets. Further characterization of these mice will shed light on the role of this novel gene in mediating early-onset and severe multi-organ autoimmunity.

Decreased Intracellular Calcium Flux in Follicular Helper T Cells after T Cell Receptor Stimulation

Abhinav Seth[1], Edward I. Herman[2], Jason S. Weinstein[1], Jin Young Choi[3] and Joseph E. Craft[4], [1]Department of Internal Medicine (Rheumatology), Yale University School of Medicine, New Haven, CT, [2]Department of Immunobiology, Yale University School of Medicine, New Haven, CT, [3]Internal Medicine, Section of Rheumatology, Yale University School of Medicine, New Haven, CT, [4]Dept of Internal Med/Rheum, Yale University School of Medicine, New Haven, CT

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: T cell Biology and Targets in Autoimmune Disease Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Follicular helper T (Tfh) cells are a specialized subset of CD4+ helper T cells that are required for B cell maturation in germinal centers and subsequent antibody formation following infection or immunization with thymus dependent antigens. Tfh cells have also been implicated in mediating pathogenic autoantibody production in lupus and modulation of their function has been shown to ameliorate end organ disease in murine models of lupus. Understanding the molecular determinants of Tfh cell function may allow for the development of specifically targeted immunomodulating therapies for lupus and other autoantibody mediated diseases. In this study, we have systematically characterized the ability of Tfh cells from a variety of physiologic and pathologic settings to flux calcium in response to T cell receptor stimulation.

Methods:

B6 mice were immunized in bilateral foot pads with a mixture of papain and 4-Hydroxy-3-nitrophenylacetyl conjugated to ovalbumin (NP-OVA). After 5 days, inguinal and popliteal lymph nodes were harvested and lymphocytes were labeled with fluorophore-conjugated antibodies

to allow identification of different T cell subtypes by flow cytometry. Cells were loaded with the calcium sensitive dyes Fluo4 and FuraRed to allow ratiometric imaging of intracellular calcium. Cells were stimulated with anti-CD3 antibodies to initiate T cell receptor (TCR) signaling and the intracellular calcium concentration was monitored in naïve T cells, Tfh cells and other effector T cells subtypes. Similar experiments were conducted using T cells obtained from the spleens of 1) B6 mice infected with the helminth *Nippostrongylus brasiliensis*, 2) B6 mice acutely infected with lymphocytic choriomeningitis virus or 3) 6 month old lupus-prone, B6.*Sle1*.Yaa, mice.

Results:

Tfh cells, relative to naïve T cells or to their Th1 or Th2 counterparts, exhibit significantly reduced calcium flux upon TCR stimulation in the context of NP-OVA immunization (2.4-fold reduction, $p < 0.0001$), helminth infection (3.7-fold reduction, $p < 0.0001$), viral infection (2.3-fold reduction, $p < 0.0001$) or autoimmune activation in lupus-prone mice (3.3-fold reduction, $p < 0.0001$). These findings are not due to generalized defects in signaling as Tfh cells retain the ability to activate MAP kinases following TCR stimulation, suggesting a specific alteration in the ability of Tfh cells to handle calcium.

Conclusion:

Our results demonstrate that Tfh cells, in physiologic or pathogenic settings, have a selective defect in calcium mobilization upon TCR stimulation. The altered calcium handling profile of Tfh cells likely contributes to the unique molecular program of these specialized cells. These results have important implications for designing therapeutic strategies to selectively target Tfh cells in autoimmune disease.

FcÎ³riiia Mediated Signal Cause Epigenetic Changes in Human Naive CD4+ T-Cells

Ye Bi[1], Chen Chen[2], Terry Moore[3] and **Anil K. Chauhan**[4], [1]Internal Medicine, Saint Louis University, St. Louis, MO, [2]Biostatistics and Epidemiology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [3]Division of Rheumatology and Pediatric Rheumatology, Saint Louis University School of Medicine, St Louis, MO, [4]Internal Medicine-Rheumatology, Saint Louis University, St Louis, MO

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: T cell Biology and Targets in Autoimmune Disease Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Signals that trigger epigenetic changes in $CD4^+$ T-cells are unknown. To examine a role for FcγRIIIa mediated co-signal in causing epigenetic changes in human $CD4^+$ T-cells. GWAS studies have shown hypomethylation of IFN promoter region in $CD4^+$ T-cells. During IFN signaling multiple genome sites are hypomethylated. Procainamide and hydrazine, which inhibit DNA (cytosine-5)-methyltransferase 1 (DNMT1), predispose individuals to drug-induced systemic lupus erythematosus (SLE). We examined whether immune complexes (ICs) by ligating FcγRIIIa on $CD4^+$ T-cells cause epigenetic changes.

Methods:

We activated peripheral human naïve $CD4^+$ T-cells using plate bound anti-CD3+anti-CD28 and anti-CD3+ICs+C5b-9. Thereafter, we cultured these cells in T_H17 polarizing conditions. On day nine, we harvested the cells and prepared cDNA. PCR array was performed using chromatin modification array (n=6) (Applied Biosystems) and Human Epigenetic Chromatin Modification Enzyme RT^2Profiler PCR array (n=5) (SA Biosciences). We compared the relative change in DNA and histone modifying enzyme genes from ICs+C5b-9 co-stimulation over CD28 co-stimulation. Epigenetic marks were examined by ChiP assay.

Results:

In six donors analyzed by AB array, hierarchical cluster analysis showed a strong correlation among DNMT1, RBBP7, CHD4, and MBD2, which are part of deacetylases complex. All enzymes of this complex were repressed by ICs ligation to $CD4^+$ T-cells. A dramatic decrease (4.5 fold) was observed in co-activator associated arginine methyl transferase and nuclear receptor co-activator (NCOA6) (7.14 fold), which remodels chromatin with HAT1. A 7.37-fold increase was observed in activating transcription factor 2 (ATF2), which acetylates H2B and H4 histones during DNA damage response, from ICs ligation of FcγRIIIa on $CD4^+$ T-cells compared to CD28 co-stimulation. ATF2/c-Jun regulated IFN-β gene and IFN-γ production. K(lysine) acetyl transferase 6A (KAT6A) was increased 6-fold, which acetylate H3 and H4 histones. KAT6A

is a transcriptional co-activator of Runx1 and Runx2. Both T-bet and Runx generate pathogenic IFN-γ producing T_H17 cells. In addition, a 6.16-fold increase in SET domain containing lysine methyltransferases (SETD)-7, a transcription activator that generates H3K4 mark was observed. Also other SET domain proteins SET4, SET8 that generate H4K2me1 mark and SET1 that generates H3K9 mark were upregulated. Relative increase in the expression of ATF2, KAT6A, and SEDT7 was seen in both arrays.

Conclusion:

Epigenetic modifications contribute to multistep differentiation and plasticity of in vitro and in vivo-derived helper T-cells. Our results show that signal via FcγRIIIa in $CD4^+$ T-cells modulates both histones and DNA modifying enzymes. Ligation of FcγRIIIa by ICs lead to the development of IFN-γ^{high} subset. ATF2 and c-Jun bind to -53 CpG in the IFN-γ promoter in T_H1 and not in T_H2 cells. Persistent signaling from IC ligation to FcγRIIIa by up-regulating ATF2 will continue to generate IFN-γ producing cells.

FcγRIIIa-Psyk Signaling up-Regulates TLR3 and TLR5 in Human Naïve CD4+ T-Cells

Chen Chen[1], Ye Bi[2], Terry Moore[3] and **Anil K. Chauhan**[4], [1]Rheumatology/Internal Medicine, Saint Louis University, St. Louis, MO, [2]Internal Medicine, Saint Louis University, St. Louis, MO, [3]Division of Rheumatology and Pediatric Rheumatology, Saint Louis University School of Medicine, St Louis, MO, [4]Internal Medicine-Rheumatology, Saint Louis University, St Louis, MO

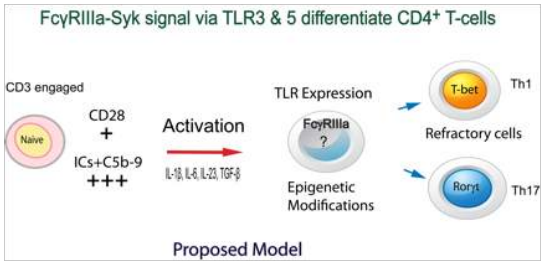
Session Date: Tuesday, November 10, 2015
Session Title: T cell Biology and Targets in Autoimmune Disease Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: To delineate mechanism of FcγRIIIa-pSyk signal in T_H17 and IFN-γ^{high} subset development. To examine whether Toll-like receptor signaling play a role in $CD4^+$ T-cell differentiation upon FcγRIIIa ligation by immune complexes (ICs).

Methods: Purified naïve $CD4^+CD45RA^+$ T-cells were co-stimulated with plate bound ICs+C5b-9 or anti-CD28 in the presence of anti-CD3 and polarized in T_H17 cytokine milieu. Flow analysis was performed for IFN-γ, IL-17A, IL-22 cytokines and pSyk. The $CD4^+$ T-cells from SLE patients (n=40) were analyzed for pSyk and CD25, CD69 and CD98. TLR signaling genes were analyzed by RT^2 Profiler QT-PCR arrays. Association of HMGB1 and MyD88 with FcγRIIIa was examined using IP and Western blotting. Cell staining was performed for co-localization of HMGB1, MyD88, TLR3, and TLR5 with labeled ICs.

Results: We show that the activated naïve $CD4^+$ T-cells express FcγRIIIa, which upon IC ligation signals via pSyk and drive $CD4^+$ T-cell differentiation in vitro. In SLE patients activated $CD4^+$ T-cells that express CD25, CD69 and CD98 show pSyk. These $pSyk^+$ cells express ICOS but not PD1. Both MyD88 dependent and independent TLRs, 2 (5.50-fold), 3 (9.89), 5 (5.17), 8 (5.09), and 10 (5.16) were upregulated. TLR7 and 9 did not show significant increase. Adaptor and TLR interacting proteins BTK, HMGB1, HRAS, and MyD88 were upregulated. Labeled ICs co-localize with HMGB1 and MyD88 in $CD4^+$ T-cells. Western blots of IPs generated with anti-FcγRIIIa antibody show association of HMGB1 and MyD88 with these receptors. These results suggest a role for FcγRIIIa-pSyk signaling by upregulation of TLR pathway in defining adaptive immune responses in autoimmune pathology.



Conclusion: Recently TLR-dependent T-cell activation in autoimmunity has been documented. While TLR2 provide a co-stimulatory signal to

$CD4^+$ T-cells, TLR4 enhance activation and persistence of T_H17 and T_H1 cells. TLR3 contribute to the development of T_H1 cells. We observed up-regulation of TLR-signaling pathway genes in $CD4^+$ T-cells from FcγRIIIa ligation by SLE-ICs. The $pSyk^+$ $CD4^+$T-cells in SLE patients produce IFN-γ and IL-17A suggesting a role of ICs in driving T-cell mediated disease pathology. A role for FcγRIIIa was further confirmed from in vitro generation of T_H1 and T_H17 like population. We propose that FcγRIIIa-pSyk signal drives the generation of refractory T_H1 and T_H17 cells that override the suppression from Tregs. Such cells are produced in response to activation from anti-CD3+anti-CD28 co-stimulation and LPS. Further MyD88 ablation impairs both T_H1 and T_H17 responses. Our data describe a new role for FcγRIIIa-pSyk mediated signaling in production of pro-inflammatory $CD4^+$ T-cells that are refractory to suppression by Tregs.

Session Title: T cell Biology and Targets in Autoimmune Disease Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Previously, we have identified leucine-rich alpha 2 glycoprotein (LRG) as a disease marker of Rheumatoid arthritis(RA). Although LRG is produced in site of inflammation such as synovial tissues, its function is still unclear. Recently, LRG has been reported to modulate TGF-β signaling. TGF-β is essential for differentiation of Th17 and Treg, and these cells play important roles in the pathogenesis of RA, for example, by regulating osteoclast differentiation. So, LRG is may be involved in the pathogenesis of RA through the regulation of T lymphocyte differentiation. In this study, we aimed to elucidate the function of LRG on T lymphocyte differentiation and to examine the involvement of LRG in the pathogenesis of RA.

Methods: Naïve T lymphocyte were isolated from WT mice to examine the effects of LRG on the differentiation into Th17 and Treg. Male C57BL/6 mice and LRG KO mice were subjected to collagen-induced arthritis (CIA).

Results: In the presence of TGF-β alone, the differentiation of Treg was promoted by LRG. However, in the presence both TGF-β and IL6, LRG enhanced the differentiation into Th17 by increasing STAT3 phosphorylation. In CIA model, the numbers of Th17 in regional lymph nodes and serum levels of IL17 were significantly lower in LRG KO mice than in WT mice.

Conclusion: We propose that LRG promote differentiation of Th17 by enhancing phosphorylation of STAT3 and Smad in naïve T cells in the presence both TGF-b and IL6, and might involve in the arthritis pathology.

Session Title: T cell Biology and Targets in Autoimmune Disease Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Mucosal-associated invariant T (MAIT) cells are innate-like lymphocytes that express a semi-invariant TCRα chain: Vα7.2-Jα33 in humans and Vα19-Jα33 in mice. MAIT cells are restricted by the MHC-related molecule-1 (MR1) and uniquely recognize microbial-derived vitamin B metabolites presented by MR1. Like other innate-like lymphocytes, MAIT cells have been suggested to play both proinflammatory and regulatory roles in autoimmune models. Although MAIT cells are rare in mice, human MAIT cells are more abundant and constitute approximately 5% of peripheral blood T cells, suggesting possible roles of MAIT cells in human autoimmune diseases. Previously we demonstrated that MAIT cells underwent activation-induced cell death and their frequency was markedly reduced in patients with systemic lupus erythematous (SLE). In this study, we aimed to investigate the mechanism by which MAIT cells are activated in SLE.

Methods: Peripheral blood was collected from SLE patients and healthy volunteers. Informed consent was obtained from all individuals according to institutional ethical guidelines. Peripheral blood mononuclear cells (PBMC) of SLE patients as well as healthy volunteers were stained with anti-human monoclonal antibodies against CD3, γδTCR, Vα7.2TCR, CD161, and CD69. MAIT cells were identified as $CD3^{+}gdTCR^{-}Va7.2TCR^{+}CD161^{high}$ cells by flow cytometetry. The activation status of MAIT cells was assessed by the expression of CD69. MAIT cells were sorted from PBMC of healthy individuals by using magnetic cell sorting (MACS) and FACS Aria. $CD19^{+}$B cells or $CD14^{+}$monocytes were isolated from PBMC of healthy controls (HC) or SLE patients by using MACS. MAIT cells were co-cultured with B cells or monocytes in the presence of MR1 ligand (MR1L), and the expression of CD69 on MAIT cells stimulated with MR1L was evaluated by FACS. The serum cytokine levels were measured by ELISA or magnetic bead-based assays. PBMC were cultured in the presence of various cytokines, and CD69 expression on MAIT cells was analyzed by FACS.

Results: MAIT cells from lupus patients with active disease expressed high levels of CD69. Although B cells from SLE patients and healthy controls equally activated MAIT cells in the presence of MR1L, the activation capacity of lupus monocytes was greatly augmented compared to healthy controls. The serum levels of cytokines including IL-12 and IL-18 were increased in active SLE and MAIT cells were activated by cytokines in the absence of exogenous antigens in vitro.

Conclusion: Monocytes and inflammatory cytokines may contribute to the hyperactivated state of MAIT cells in SLE.

CD1d Regulates iNKT Cell Autoreactivity

Meng Zhao[1,2] and Mitchell Kronenberg[2], [1]Medicine, UC-San Diego, La Jolla, CA, [2]Developmental Immunology, La Jolla Institute for Allergy and Immunology, La Jolla, CA

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: T cell Biology and Targets in Autoimmune Disease Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Invariant Natural Killer T (iNKT) cells are a unique population of lymphocytes that express an invariant TCR alpha chain, and react to lipid antigens presented by non classical MHC class I like molecule CD1d. There is highly homologous population in human. iNKT cells carry out innate-like responses and produce large amount of diverse cytokines, including IFNgamma, IL-4, IL-17 and IL-21. Therefore, iNKT cells are involved in numerous inflammatory and pathological conditions, including rheumatic diseases such as SLE and RA.

iNKT cells are autoreactive, and it is not clear how their autoreactivity is regulated. This is an important question, especially relevant for understanding the pathogenesis of many human autoimmune diseases. Our discoveries, therefore, will potentially identify novel drug targets for the treatment of patients with SLE, RA and other autoimmune diseases in which abnormal activation of iNKT cells is observed.

Methods:

We use primary iNKT cell line as a model system to study iNKT cell autoreactivity. Microarray and RNA-seq were carried out to identify new regulators of iNKT autoreactivity.

Results:

We have found that the short-term cultured iNKT cells have greatly increased sensitivity to CD1d-lipid complexes derived from multiple sources. APCs that express a tail-deleted form of CD1d are defective to stimulate the iNKT cell lines *in vitro*. iNKT cell lines distinguish previously identified self lipid Ags from their structural homologs. Transfer experiments revealed that CD1d in the periphery down regulates the autoreactivity. However, tail-deleted CD1d is unable to completely control the reactivity of iNKT cells. RNAseq identified several candidate genes that may act down stream of CD1d-TCR interaction to regulate the function of iNKT cells, one of which is PTPN6/SHP1. The development of iNKT cells is impaired in the conditional knockout mice of SHP1, thus it prevents us from directly evaluating the role of SHP1 in the pheripheral iNKT cells. However, we observed several T cell exhaustion markers, such as PD-1 and FR4, express at higher level in SHP1 deficient iNKT cells. It is consistent with our hypothesis that SHP1 acts downstream of TCR and controls the reactivity of iNKT cells.

Conclusion:

We have designed a new a reliable system that demonstrates iNKT cell autoreactivity for CD1d in bulk populations with diverse TCR beta chains, rather than requiring a single hybridoma. iNKT cell autoreactivity is modulated by CD1d in the periphery and depends on the endolysosomal localization of CD1d. Gene expression profiling reveals new regulators of iNKT cell reactivity, for example, SHP1/PTPN6.

Increased Plasticity of Non-Classic Th1 Cells Towards the Th17 Phenotype

Antonia Klose[1], Fausto Pirronello[1], Hendrik Schulze-Koops[1], Jan Leipe[2] and Alla Skapenko[1], [1]Division of Rheumatology and Clinical Immunology, University of Munich, Munich, Germany, [2]Division of Rheumatology, University of Munich, Munich, Germany

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: T cell Biology and Targets in Autoimmune Disease Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Mechanisms underlying the predominance of Th17 cells observed in RA are not fully understood. Th cell plasticity is a potential mechanism leading to enrichment of Th populations under certain conditions. Recently, two distinct subtypes of Th1 cells named classic (IFNγ+RORC-CD161-CCR6-) and non-classic (IFNγ+RORC+CD161+CCR6+) Th1 cells were described. Given that non-classic Th1 cells share several characteristics with Th17 cells, we hypothesized that non-classic Th1 cells might show an enhanced plasticity towards the Th17 phenotype. Increased frequencies of non-classic Th1 cells in RA might therefore potentially contribute to the Th17 shift in RA.

Methods: CD4 memory T cells were isolated from patients with early active and untreated RA and age- and sex-matched healthy controls (HC) by MACS. Frequencies of the *in vivo*-generated Th1 cell populations were assessed after cytokine secretion assay for IFNγ and IL-17 and surface staining for CD161 and CCR6. Viable Th1 cells (IFNγ+IL-17-) were FACS-sorted into classic Th1 (CD161-CCR6-) and non-classic Th1 (CD161+CCR6+). Sorted Th1 cell populations were trans-differentiated under Th0-, Th1-, Th2- and Th17-inducing conditions. Plastic changes were assessed *ex vivo*by analyzing the cytokine and transcription factor profile by flow cytometry on the protein and by qPCR on the mRNA level.

Results: Trans-differentiation of non-classic Th1 cells under inflammatory Th17-inducing conditions resulted in markedly high frequencies of IL-17-producing cells, Th17 cells and Th1/Th17 cells (IL-17+IFNγ+), whereas no substantial plasticity towards a Th17 phenotype was observed for classic Th1 cells (Th17 cells: 3.9% vs 0.9%, p=0.045; Th17/Th1 cells: 16.6% vs. 0.9%, p=0.00003). In marked contrast, classic Th1 cells showed higher plasticity towards IL-4-producing cells, most of them being Th1/Th2 cells (IFNγ+/IL-4+), compared to non-classic Th1 cells (Th1/Th2 cells: 8.4% vs. 3.0%, p=0.015). Consistently, for RORC higher expression was found in non-classic Th1 and for GATA-3 in classic Th1 cells *ex vivo*. The frequencies of classic and non-classic Th1 cells did not differ significantly between RA patients and healthy individuals.

Conclusion: Non-classic Th1 cells demonstrate a general substantial plasticity towards the Th17 phenotype, which might contribute to their pathogenicity, whereas classic Th1 cells show the propensity to acquire a Th2 phenotype and might therefore give rise to a less pathogenic

phenotype. Similar frequencies of *ex vivo* non-classic and classic Th1 cells between RA and HC suggest a conserved phenotype of the populations after their *in vivo* generation and might argue against the contribution of non-classic Th1 cells to Th17-biased RA phenotype.

Session Title: T cell Biology and Targets in Autoimmune Disease Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Numerous alterations in signal transduction in SLE T cells have been previously reported. Diminished expression of the ζ chain of the TCR/CD3 complex has been shown to be accompanied by the substitutive assembly of FcεRIγ chain and coupling to Syk PTK (Protein Tyrosine Kinase), rewiring downstream signaling to produce alternative functional outcomes in lupus T cells. Syk is 100-fold times enzymatically more potent than ZAP-70. In this study we examined the localization of ZAP-70 and Syk in lipid rafts of lupus T cells; lipid raft is the site in membranes where signaling molecules preferentially associate to form signalosomes.

Methods: SLE patients were diagnosed according to the American College of Rheumatology 1987 criteria. Healthy donors were recruited from the blood bank of Hospital Universitario de Caracas. All individuals signed an informed consent previously approved by the Hospital Bioethics Committee. Highly enriched T cells, obtained from peripheral blood samples and subjected to RosetteSep^{TM} isolation, were adhered to poly-L-lysine coated slides and activated for 5 and 15 minutes at 37°C, with 4.5 µm superparamagnetic polystyrene beads coated with antibodies against CD3ε and CD28. The cells were fixed, permeabilized and stained with antibodies recognizing ZAP-70, Syk and Cholera Toxin Subunit B as a lipid raft marker. The cell-bead complexes were evaluated by confocal microscopy and densitometries were obtained using ImageJ, 1.49t (National Institutes of Health, USA).

Results: We observed similar localization of Syk in lipid rafts of unstimulated lupus T cells as compared to healthy controls (0.216 ± 0.045 vs. 0.287 ± 0.056; Pearson's r ± SME, n= 6). In contrast, there was a diminished localization of ZAP-70 in unstimulated lupus T cells as compared to healthy controls (0.383 ± 0.035 vs. 0.488 ± 0.037; Pearson's r ± SME, n= 6; Student's t-test, p= 0.046,). After CD3-CD28 costimulation during 15 minutes, we observed an increased localization of Syk in lipid rafts of lupus T cells as compared to healthy controls (0.352 ± 0.033 vs. 0.235 ± 0.042; Pearson's r ± SME, n= 6; Student's t-test, p= 0.034), whereas ZAP-70 localization in lipid rafts after costimulation was similar in both groups (0.433 ± 0.040 vs. 0.402 ± 0.031; Pearson's r ± SME, n= 6).

Conclusion: Our findings suggest an abnormal pattern in the localization of key tyrosine kinases in lipid rafts after activation of SLE T cells, with a predominant translocation of Syk over the typical T-cell kinase, ZAP-70. This abnormal response may contribute to known signaling abnormalities such as displacement of transmembrane protein Linker for Activation of T cells (LAT) from lipid rafts and downstream deficient activation of Extracellular Signaling Regulated Kinases (ERK), as previously shown in our laboratory.

Session Date: Tuesday, November 10, 2015

Session Title: T cell Biology and Targets in Autoimmune Disease Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

The voltage-gated potassium channel Kv1.3 is highly expressed on activated T effector memory cells (TEM), is essential for T cell activation, and thus is a novel target for the treatment of autoimmune disorders. ShK-186 (dalazatide) is a specific, highly potent peptide inhibitor of Kv1.3 that has recently entered clinical development. Previous reports associated TEM activation with the pathogenesis of SLE, suggesting a potential for dalazatide efficacy in SLE.

Methods:

Peripheral blood from pediatric patients with SLE and healthy controls were studied. *Ex vivo* Kv1.3 expression was assayed on T lymphocyte subsets by flow cytometry. The effect of dalazatide on cytokine expression after no stimulation or following short term stimulation by PMA and thapsigargin or ionomycin was evaluated by flow cytometry.

Results:

Kv1.3 was up-regulated on $CD4^{+}$TEM from SLE patients with active disease (mean MFI 370) compared to and to patients with inactive disease (mean MFI 265, p=0.08), or to controls (mean MFI 208, p=0.005). A larger effect on Kv1.3 expression was detected in CD8+TEM (active SLE 311, inactive SLE 185, p=0.02; controls 140, p=0.005). Dalazatide at concentrations of 10 pM-1nM decreased proinflammatory cytokine production *ex vivo* in a dose-dependent fashion in TEM, but not naïve cells from SLE patients and healthy controls. In the CCR7low CD45RO+ CD4+ TEM subset, inhibition of TNF-a (mean 33-43%), interferon-g (33-55%), and IL-17 (28-53%) was detected.

Conclusion:

In vitro studies suggest that Kv1.3 on TEM may be a treatment target for SLE. In addition, Kv1.3 expression may be useful as a biomarker of disease activity in SLE.

Session Title: Vasculitis Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

The phenotype of patients afflicted by deficiency of adenosine deaminase 2 (DADA2) due to mutations in *CECR1*encoding ADA2 protein shares many features with idiopathic polyarteritis nodosa (PAN), including abundant neutrophilic infiltration in affected tissues. Immune cell responses following treatment with TNF inhibitors and the specific role of neutrophils were studied in a family consisting of 2 children with DADA2 and several family members afflicted by various autoimmune diseases including idiopathic PAN.

Methods:

Candidate-gene sequencing of the *CECR1*gene was performed in 2 children who had lacunar infarcts, livedoid rash and biopsy-proven vasculitis. Histopathology characterization was performed on affected skin and small bowel tissues. Neutrophils and low-density granulocytes (LDGs) were isolated during active disease. Neutrophil extracellular traps (NETs) were quantified and visualized by fluorescence microscopy. Neutrophils were incubated with graded concentrations of adenosine +/- ADA2 enzyme and resultant NET formation was quantified. Evaluations were conducted during active disease and 4 months later during disease remission after treatment with etanercept. Immune cell subsets before and after treatment were quantified by multi-panel flow cytometry.

Results:

Both children were compound heterozygotes for G358R and G47R mutations in the *CECR1* gene. The mother was a carrier for G358R mutation and had a history of unexplained lacunar infarct at age 45. A maternal great grandmother had a history of biopsy-proven PAN onset at age 60, and a maternal great uncle had a history of autoimmune colitis and livedo reticularis. The father was a carrier for G47R mutation and had a history of Guillian-Barré syndrome. Fibrinoid necrosis of medium-sized blood vessels, intravascular thrombi, and dense perivascular infiltrates of netting neutrophils and macrophages were visualized in affected skin and small bowel sections from children. Immunohistochemistry showed aggregates of MPO, CD163 and CD3 positive cells in the deep dermis and perivascular region. An abundance of circulating LDGs prone to spontaneous NET formation was observed during active disease and also in clinically unaffected heterozygous carriers of *CECR1* mutation. LDG numbers normalized when remission was achieved using anti-TNF agents. Various concentrations of adenosine [0.2, 0.5, 16 μM] stimulated robust NET formation, and this was inhibited by addition of recombinant ADA2. Following treatment with etanercept, there were decreases in $CD14^+/CD16^+$ monocytes (8% vs 2%), increases in memory T_{reg} cells (12% vs 23%), activated T_{reg}(2% vs 7%) and B cells (2% vs 19%).

Conclusion:

Neutrophils may play pathogenic roles in DADA2. LDGs and NETs are observed during active disease in children with DADA2 and their parents. Deficiency of ADA2 may increase risk for adenosine-induced NET formation, which is a novel mechanism of NETosis. Alterations in the adenosine-mediated signaling pathway may contribute to the pathogenesis of DADA2. The autoimmunity observed in this family suggests that carriers of *CECR1*gene mutation may have increased risk for autoimmune diseases and that DADA2 and idiopathic PAN may be genetically related.

Polyarteritis Nodosa and Cutaneous Arteritis: Are They Distinct Diseases?

Fatma Alibaz-Oner[1], Matthew J. Koster[2], Cynthia S. Crowson[3], Ashima Makol[2], Steven R. Ytterberg[2], Eric L. Matteson[2] and Kenneth J. Warrington[2], [1]Department Rheumatology, Marmara University Faculty of Medicine, Istanbul, Turkey, [2]Rheumatology, Mayo Clinic, Rochester, MN, [3]Health Sciences Research, Mayo Clinic, Rochester, MN

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Vasculitis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Polyarteritis nodosa (PAN) is a rare systemic necrotizing vasculitis predominantly targeting medium-sized visceral arteries. Cutaneous arteritis (CA) is generally limited to the medium-sized vessels in the skin. Although previously categorized as cutaneous PAN, it is now included as a form of single organ vasculitis in the revised 2012 International Chapel Hill Consensus Conference Nomenclature of Vasculitides. In this study, we aimed to evaluate and compare the demographics, clinical characteristics, treatment, and outcome of patients with systemic PAN and CA.

Methods: Retrospective cohorts of patients with PAN and CA evaluated in 1986-2014 were assembled. The demographics, clinical characteristics, treatment and outcomes of patients were abstracted from medical records. Birmingham Vasculitis Activity Score (BVAS) and the prognostic Five Factor Score (FFS) were calculated. Chi-square and rank sum tests were used to compare characteristics between the groups.

Results: The study cohort included 29 patients with PAN and 39 patients with CA. Only 1 patient presenting as CA evolved to systemic PAN during disease course. Sixteen of 29 patients with PAN and all patients with CA had histologically proven vasculitis involving medium-sized vessels. Mean follow-up duration was 6.0±5.9 years in PAN group, 5.8±4.4 years in the CA group. Angiographic abnormalities consistent with PAN were present in 16 patients. Most cases of PAN were idiopathic. Three patients in the PAN group and 2 patients in CA group had hepatitis B. One patient in the PAN group had Hepatitis C. Clinical characteristics of the groups are presented in Table 1. All patients with PAN and 90% of patients with CA were treated with glucocorticoids (GC). Additional immunosuppressive (IS) agents were used in 62% of PAN and 33% of CA. Dapsone was used in 8 (20.5%) patients in CA group. Twenty patients with PAN and 16 patients with CA were followed for at least 6 months. BVAS and FFS scores were higher among patients with PAN. However, the relapse rate was significantly higher in the CA group compared to PAN (9.8 vs 0.9 per 100 person-years; Rate ratio:7.88; 95% confidence interval:1.81-112.73). While no deaths were observed in the CA group, survival in the PAN group was 66% at 10-years.

Conclusion: Our results suggest that CA is a distinct disease rather than a limited expression of systemic PAN. Progression of CA to systemic PAN is rare. Patients with CA have a higher relapse rate compared to those with systemic PAN, possibly due to lower use of IS agents in CA.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Vasculitis Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Behcet's disease (BD) is a chronic, complex systemic vasculitis of unknown etiology characterized by orogenital ulcers, uveitis, and arthritis. Arthritis and arthralgias in BD are known to be the most common rheumatologic findings with a prevalence ranging from 40 to 70%. However, arthritis in BD is often confused with seronegative arthritis (SNA) including seronegative spondyloarthropathy (SNSpA) and seronegative rheumatoid arthritis (SNRA) because of shared clinical symptoms and the lack of definitive biomarkers for BD. The purpose of this study was to evaluate the metabolomic profiling of synovial fluid (SF) from patients with arthritis in BD and SNA to investigate possible metabolic patterns and potential biomarkers for arthritis in BD.

Methods: SF samples were collected from BD patients with arthritis (n = 6, mean age 34.8 ± 16.4 years), SNSpA (n = 13, mean age 30.9 ± 11.0 years), and SNRA (n = 5, mean age 65.8 ± 10.7 years). Metabolomic profiling was performed by gas chromatography/time-of-flight mass spectrometry in conjunction with univariate and multivariate statistical analyses.

Results: A total of 123 metabolites were identified from samples. Orthogonal partial least square-discriminant analysis showed clear discrimination between arthritis in BD and SNA. A set of 11 metabolites were identified as potential biomarkers for arthritis in BD using variable importance for projection values and the Wilcoxon-Mann-Whitney test. Compared with SNA, arthritis in BD exhibited relatively high levels of glutamate, valine, citramalate, leucine, methionine sulfoxide, glycerate, phosphate, lysine, isoleucine, urea, and citrulline. There were two markers identified, elevated methionine sulfoxide and citrulline, that were associated with increased oxidative stress, providing a potential link to BD-associated neutrophil hyperactivity. Glutamate, citramalate, and valine were selected and validated as putative biomarkers for arthritis in BD (sensitivity, 100%; specificity, 61.1%).

Conclusion: This is the first report to present potential biomarkers from SF for discriminating arthritis in BD from SNA. The metabolomics of SF may be helpful in searching for potential biomarkers and elucidating the clinicopathogenesis of arthritis in BD.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Vasculitis Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: The diagnostic utility of HLA B51 in association with Behcet's disease has been clearly identified; however the correlation of HLA B51 with other autoimmune disorders has not been well established to date. This study aims to assess the correlation

between the presence of HLA B51 with other autoimmune disorders, prevalence of Behcet's in our population and most common presenting symptoms and serologic markers.

Methods: Retrospective analysis of autoimmune conditions other than Behcet's disease in patients with HLA B51 allele, which is measured in all incoming patients to our consultation service.

Results: At our tertiary reference center, from approximately 1200 screened patients, we identified 55 patients who were HLA B 51 positive. Out of these 55 patients, 14 (25.5%) met ICBD criteria for Behcet's disease, 22 (30.7%) had history of oral ulcers, 35 (63.6%) had arthralgias, 12 (21.8%) had history of uveitis, 16(29.1%) had cutaneous features such as cutaneous vasculitis, cutaneous ulcers, digital ulceration, Erythema nodosum, positive pathergy test, papulopostules, acne or folliculitis. Mean follow-up was 3 years. Only 2 out of 55 were cocaine users. Our demographics showed 45 females (81.8%) and 32 Hispanics (58.2%), 17 Northern European (30.9%) and 4 Native American (7.3%). Regarding specific autoimmune disorders, we had 6(10.9%) patients who met SLE criteria, 4 (7.3%) that met RA criteria, 2 (3.6%) that met PMR criteria, 4 (7.3%) that met Sjogren's syndrome criteria, 5 (9.1%) spondyloarthropathies, 4 (7.3%)with scleroderma/CREST, and 1 with Dermatomyositis (1.8%). No patient had giant cell arteritis, granulomatosis with polyangiitis, Microscopic polyangiitis or eosinophilic granulomatosis with polyangiitis in this study. Thus, in this cohort 31% of HLA-B51patients had autoimmune disease other than Behcet's disease; this is remarkable, as HLA-B51 is present in only 0.2-1.5% of reference populations.

Conclusion: Our study demonstrates that 25.5% of HLA-B51 subjects in our population have Behcet's disease, but 31% of HLA-B51 positive individuals have other classic autoimmune diseases compared to 0.2-1.5% of reference populations. Thus, the results of this study confirms that HLA B51 is associated with Behcet's disease, but these data also suggest that HLA-B51 may also play a hereto unrecognized role in either inducing, modulating, or upregulating other forms of autoimmune disease to cause a 20 fold increase in HLA-51 prevalence from reference populations.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Vasculitis Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Behcet's disease (BD) is a systemic vasculitis, whereas myelodysplastic syndrome (MDS) is a heterogeneous group of clonal hematologic disorders characterized by ineffective hematopoiesis. Some patients with BD comorbid with MDS involving trisomy 8 have intestinal lesions refractory to conventional medical therapies. We analyzed BD to evaluate the concurrence of BD and trisomy 8 and to determine whether trisomy 8 plays a role in the expression of BD associated with MDS.

Methods: Ninety-five consecutive patients were assessed for the presence of trisomy 8 in the peripheral blood. The clinical manifestation and genetic components were analyzed in patients with BD and MDS.

Results: Six of 95 patients were positive for Trisomy 8. Three of these cases were diagnosed with MDS, and they underwent bone marrow

transplantation. The prevalence of MDS was as high as 50% in BD patients with trisomy 8. Gastrointestinal (GI) involvement was more common in patients with BD involving trisomy 8 than in non-trisomy8 patients (66% vs. 25%). The mean corpuscular volume (MCV) was higher in the presence of trisomy 8 than in cases lacking trisomy 8 (100.1 fl vs. 92.64 fl, P<0.01).

Conclusion: The prevalence of MDS was more higher in BD patients with trisomy 8. GI involvement seems to be an inherent feature of BD associated with MDS involving trisomy 8. When a patient with BD has increased MCV, the presence of trisomy 8 should be evaluated. Additionally, close monitoring for the possibility of MDS is necessary.

Session Date: Tuesday, November 10, 2015
Session Title: Vasculitis Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: To investigate the association between autoantibodies against non- myeloperoxidase (MPO) neutrophil granule antigens and activity of Behcet's disease (BD).

Methods: We consecutively enrolled 51 BD patients without diseases requiring the differential diagnosis of BD or infection, and assessed the clinical data. We performed blood tests including antibodies against proteinase 3 (PR3), MPO, bactericidal permeability increasing protein (BPI), cathepsin G, elastase, lactoferrin and lysozyme. We evaluated the association of autoantibodies with BD activity using patients index score of Behcet's Disease Current Activity Form.

Results: The median age of patients (25 men and 36 women) was 51.0 years. The median patients index score was 2.0 (range 0, 5.0), and 56.9% of patients had active BD. In multivariate linear regression analysis of variables with significant correlations, only anti-lysozyme showed a significant correlation with BD activity (standardized $\beta = 0.417$, $p = 0.002$). In multivariate logistic regression analysis, anti-lysozyme was only predictive value of active BD, but it achieved a borderline statistical significance (OR 5.052, $p = 0.066$). When BD patients were classified into the two groups according to the optimal cutoff value of anti-lysozyme level (2.95 IU/mL), active BD was more frequent in patient having anti-lysozyme level above the cutoff value than those below (RR 12.308, $p = 0.001$).

Conclusion: Anti-lysozyme was significantly correlated with disease activity score and it was only independent value to predict active disease in patients with BD. Furthermore, patients having anti-lysozyme level ≥ 2.95 had a significantly higher risk of having active BD than those not.

Session Date: Tuesday, November 10, 2015
Session Title: Vasculitis Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Chemokines are multifunctional mediators that control leukocyte recruitment into the inflammatory sites and enhance immune responses. It remains to be investigated which chemokines are important in Behcet's disease (BD). The objective of this study was to investigate serum levels of neutrophil and lymphocyte chemoattractants in BD patients and its association with disease activity and symptoms.

Methods:

We collected sera from patients with BD (n=64) and age-, sex matched healthy controls (n=21). Serum levels of chemokines were assayed for the neutrophil chemoattractants (CXCL1 and CXCL8) and lymphocyte chemoattractants (CXCL9, CXCL10, CXCL12, CXCL13 and CXCL16) by using a multiplex assay. Behcet's disease current activity form (BDCAF) and symptoms were evaluated at the time of blood collection.

Results:

Serum levels of CXCL8, CXCL10 and CXCL12 were significantly higher in the BD patients than in healthy controls ($p<0.001$, $p=0.050$ and $p=0.002$, respectively). Serum chemokine levels were not associated with BDCAF in BD patients. But CXCL10 levels were significantly higher in patients with erythema nodosum (EN) than in patients without EN ($p=0.008$). Additionally, CXCL10 levels were significantly correlated with number of EN ($r=0.338$, $p=0.006$). There was no difference of serum level of CXCL1, CXCL9, CXCL13 and CXCL16 between BD and healthy controls

Conclusion:

Serum levels of CXCL8, CXCL10 and CXCL12 were significantly higher in the BD patients than in healthy controls. CXCL10 levels were correlated with number of EN in BD patients.

Session Title: Vasculitis Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Behçet's disease (BD) is known to be associated with HLA-B*51:01 and HLA- A*26:01 in many different ethnic groups. Recently, HLA-A*02:07, IL-10 and IL23R-IL12RB polymorphisms have been proposed as a candidate gene for BD susceptibility. In this study, we examined the association of the HLA-A*02:07 and **single nucleotide** polymorphism (SNP) of rs1495966 located in IL23R/IL12RB region using Japanese ocular BD patients.

Methods: One hundred and thirty-six Japanese BD patients who suffered from uveitis and 213 healthy controls were enrolled for analysis of polymorphisms of HLA class Iand the SNP of rs1495966. Statistical analysis was performed mainly with odds ratio (OR) with 95% confidential interval (95%CI). Fisher's exact test was also carried out and the significance (p) was corrected by the numbers of alleles compared (pc).

Results: Twenty three and 49 alleles were observed for HLA-A and B, respectively. The phenotype frequencies (PF) of HLA-B*51:01 was significantly higher in BD patients (44.1%) than in controls (15.5%) (OR=4.31 (95%CI=2.61-7.12), pc=3.2x10E-7). The PF of HLA-A*26:01 was also significantly more frequent in BD patients (35.3%) than in controls (15.5%) (OR=2.98 (1.78-4.96), pc=6.4x10E-4). The PF of the BD patients carrying the A*26:01 or B*51:01 was extremely increased comparing to the frequency in the control (71.3% Vs 28.2%, OR=6.34 (3.94-10.22), pc=2.1x10E-12 (corrected by 23x49)). The PF of B*5201 was significantly decreased in BD (10.3% Vs 25.4%, OR=0.34 (0.18-0.63, pc=0.024). The PF of the HLA-A*02:07 tended to be increased in the BD-group without A*26:01 and B*51:01 (17.9% Vs 7.2%, OR=2.82 (1.02-7.85), pc= not significant (NS)). In addition, the PF of the HLA-B*39 was increased in the BD-group without A*26:01 and B*51:01 (17.9% Vs 3.3%, OR=6.48 (1.93-21.70), pc= NS). The allele frequency (AF) of rs1495966*A allele in IL23R/IL12RB region was significantly increased in BD patients (53.7%) than in controls (44.8%) (OR=1.43 (1.05-1.93), pc=0.024). In clinical analysis, the PF of the B*51:01 was significantly associated with complete type of BD (p=0.0416). The PF of the A*26:01 tended to be associated with posterior/panuveitis (p=0.0979). The AF of GG in IL-23R SNP tended to be associated with poor visual prognosis corresponding the best corrected-visual acuity of 0.1 or less in the worse eyes (p=0.0643).

Conclusion: Our results indicated that, (1) HLA-A*02:07 is another susceptibility gene for BD, associating independently from the B*51:01 and A*26:01, (2) HLA-B*39 is possibly associated with BD, (3) B*52:01 is a protective allele for ocular BD in Japan, (4) rs1495966*A is associated with BD and might be a disease marker for the severity of ocular disease.

Predictive Factors of Long-Term Clinical Outcome in Patients with Ocular Involvement Secondary to Behcet's Syndrome

Rosaria Talarico[1], Michele Figus[2], Anna d'Ascanio[1], Rossella Neri[1], Chiara Baldini[1], Chiara Tani[3] and Marta Mosca[1], [1]Rheumatology Unit, University of Pisa, Italy, Pisa, Italy, [2]Department of Surgical, Medical, Molecular Pathology and Emergency, University of Pisa, Pisa, Italy, [3]University of Pisa, Pisa, Italy
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Vasculitis Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Behçet's syndrome (BS) is a multisystemic, chronic relapsing inflammatory disease classified among the vasculitis. Eye involvement represent one of the most serious manifestation of BS and occurs in half of all patients. It seems more frequent and severe among young males and, unluckily, it still represents a significant cause of morbidity. The aim of the study was to identify factors able to predict long-

term outcome in patients with BS

Methods: forty-nine patients (29 males and 20 females; mean age at the onset 29±4 years) with a diagnosis of BS according the ISG criteria were studied. The probability of clinical relapse after remission of the first ocular attack was calculated using the Kaplan-Meier method. Predictors of long-term outcome were identified by univariate analysis using the log-rank test and by multivariate analysis using Cox proportional hazards regression models.

Results: The mean time between the first initial symptoms of BS and the onset of eye lesions was 3±2 years. The number of ocular attacks were the following: 32 posterior uveitis, 27 anterior uveitis, 21 retinal vasculitis, while panuveitis developed in 17 subjects. Medical treatments received at time of the study were: cyclosporine A (n=21), infliximab (n=13, azathioprine (11), adalimumab (2). The cumulative relapse rates at 1 year, 3 years, and 5 years after remission of the first ocular attack were 20%, 38.7%, and 42%, respectively. On multivariate analysis, a younger age (<30 years) at the onset of ocular involvement, male sex and medical treatments other than biological agents represent independent predictive factors for relapse in BS patients with ocular involvement.

Conclusion: As awaited, the use of anti TNF alpha agents seems to be associated with a positive effect on maintaining remission in ocular involvement due to BS. However, as literature data suggest, younger age and male sex represent predictive factors of poor long-term clinical outcome.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Vasculitis Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Conventional management of uveitis due to Behçet's disease (UBD) consists on conventional immunosuppressive drugs. However, UBD is often refractory requiring more intensive therapy.Our aim was to assess long-term response in UBD patients refractory to conventional therapy.

Methods:

Multicenter study of 165 patients with UBD followed-up in the uveitis units of 45 hospitals. All of them had inadequate response or intolerance to traditional treatment with corticosteroids and at least 1 systemic immunosuppressive drug. The degree of ocular inflammation was assessed as "the Standardization of Uveitis Nomenclature (SUN) working Group" (Am J Ophthalmol 2005; 140: 509-516), and macular thickness was assessed by optical coherence tomography (OCT). Comparisons were made between baseline and the 1st week, 2nd week, 1st month, 6th month, 1st, 2nd, 3rd,4th and 5th year.

Results:

165 patients (89 men/76 women/297 affected eyes) with a mean age of 39.3±10.5 years (range 10-67) were studied. HLA-B51 was positive in 64.8%. Prior to biologic therapy and in addition to oral corticosteroids, patients had received the following drugs: Intravenous pulses of methylprednisolone (50 patients), cyclosporine A (CyA) (134), methotrexate (MTX) (72) and azathioprine (AZA) (87). Infliximab (IFX) was the first biologic used in 96 cases (58.2%) and adalimumab (ADA) in the remaining 69 (41.8%) patients. These agents were used as a monotherapy in 46 cases or in combination with immunosuppressive drugs::CsA (58 cases), MTX (34), AZA (24), mycophenolate (1), cyclophosphamide (1) and tacrolimus (1). The most common regimens were IFX 5 mg/kg/i.v. every 4-8 weeks and ADA 40 mg sc/2 weeks. In the course of the diseases, in cases of refractory uveitis to these drugs switching to other biologic agents was performed: golimumab (n = 6), tocilizumab (5), rituximab (2), certolizumab (1) and etanercept (1). Nevertheless, in 30 cases the biologic agents were discontinued because of maintained clinical remission. Significant improvement observed since the 1sr week was observed in the visual acuity (VA), Tyndall and vitritis. OCT improvement was observed since the 2nd week (TABLE). At baseline, 57 patients (95 eyes) had macular thickening (OCT> 250μ) and 33 patients (50 eyes) had cystoid macular edema (CME) (OCT> 300μ). The OCT improved from 344.5 ± 137.3 microns to 254.2 ± 60.8 microns ($p < 0.01$). After a mean follow-up of 38.3±22.4 months the most serious side effects were miliary TB (n=1), Mycobacterium avium pneumonia (n=1), melanoma (n=1), and fatal lymphoma (n=1).

Conclusion:

Biological treatment with IFX or ADA are effective and relatively safe in UBD refractory to conventional therapy.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015

Session Title: Vasculitis Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Treatment recommended in severe and/or refractory uveitis of Behçet disease is anti-TNF-α therapy, usually infliximab (IFX) or adalimumab (ADA) (Levy-Clarke et al Ophthalmology 2014;121:785-796). However, in some cases these biologic agents are not effective, may be contraindicated or they are not well tolerated. IL-6 is a key cytokine in the pathogenesis of uveitis, including Behçet's syndrome.

Our aim was to evaluate the response to tocilizumab (TCZ) in uveitis associated with Behçet syndrome refractory to standard systemic treatment.

Methods:

Multicenter study on 7 patients with uveitis associated to Behçet disease. Patients had previously been treated with at least one conventional immunosuppressive drug and in most cases with anti-TNF-α agents. The main parameters assessed were the visual acuity (VA) and the degree of inflammation of the anterior and posterior chamber.

Results:

4 men and 3 women were studied, with a mean age 39.1 ± 15.4 years (range 22-67). Uveitis was bilateral (n=6) and unilateral (n=1) (Table). The pattern of ocular involvement was posterior uveitis (n=1), panuveitis (n=2), panuveitis + papilitis (n=1) and panuveitis + vasculitis (n=3). The clinical course was chronic (n=3) or recurrent (n=4). Besides oral corticosteroids and before TCZ onset they had received: intraocular corticosteroids (n=7), i.v. methylprednisolone pulses (n =7), methotrexate (MTX) (n=7), cyclosporin A (CsA) (n=7), azathioprine (n=2), cyclophosphamide (n=2), daclizumab and mycophenolate (n=1), Adalimumab (n=5), inflixmab (n=2) and golimumab (n=2). In all patients TCZ was prescribed at the standard dose (8 mg/kg/i.v. month). Treatment was administered as a monotherapy in 5 cases and combined with conventional immunosuppressive drugs in 2 cases (1 MTX, 1 CsA). After a mean follow up of 5.36 ± 5.1 months from the onset of TCZ, improvement was observed in the following items: a) median VA (0.2 [0.05-0.7] to 0.95 [0,4-1]; $p<0.01$); b) Median cells in the anterior chamber (1 [0-2] to 0 [0-0]; $p=0.01$); c) average vitritis (1.4±1.1 at 0±0; $p<0.01$); d) retinal vasculitis (n=8 eyes, 57.1%) that disappeared in all cases ($p<0.01$); e) OCT mean (μ) (from 335.7±82.3 to 246.4±32.6; $p<0.01$); f) 5 patients achieved remission, g) reduction in median dose of prednisone (30 [30-30] to 3.75 [0-7.5] mg/day; $p=0.18$). TCZ was withdrawn in 1 case due to an infusion reaction. No other side effects were observed.

Conclusion:

Treatment with TCZ seems to be effective in patients with refractory uveitis due to Behçet’s disease.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Vasculitis Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Interleukin-17 (IL-17) has been associated with the pathogenesis of various inflammatory diseases. The aim of our study was to investigate the expression of Th17-related immunity in two phenotypically different disorders: Behcet's disease (BD) with innate responses and Takayasu's arteritis (TAK) with adaptive immunity.

Methods: The study population consisted of three groups: patients with BD (n=37, age: 39.2 ±10.1 years), patients with TAK (n=25, age: 50.9

±15.5 years) and healthy controls (HC) (n=25, age 40.9± 6.9 years). Peripheral blood mononuclear cells (PBMC) from patients with BD, TAK and HC were cultured in Th17 inducing condition (IL-6, PHA, IL-1b and IL-23) for 6 days. Cultured cells were then stained with CD4, CD8, CD3, TCRgd, CD19 IFN-γ and IL-17 antibodies to determine the intracellular cytokine secretion by flow cytometry.

Results: In BD patients, IL-17 expression by CD4+ T cells was observed to be higher than both TAK patients and HC (8.9±10.6 vs 3.5±2.5 and 4.5±4.9, p=0.03 and p=0.02, respectively). IL-17 expression by gd+ (14.4±13.3 vs 6.3±4.4 and 6.1±4.1, p=0.001, p<0.001 respectively) and CD8+T cells (7.0±8.3 vs 3.6±3.8 and 2.3±2.1, p=0.007 and p<0.001, respectively) was also higher in BD compared to TAK and HC. No differences were observed between the groups in the IL-17 production by B cells. Under Th17 inducing conditions, production of IFN-γ by CD4+ T cells (4.8±5.2 vs 2.0±1.7 and 1.9±1.3, p<0.05) and CD8 +T cells (11.3±12.6 vs 4.3±4.4 and 4.0±3.6, p<0.05) were also higher in both BD and TAK patients compared to the HC. No differences were observed between the groups in IFN-γ production by B cells and gd+ T cells. IL-17 expression and IFN-γ production in patients with BD and TAK under immuno-suppressive (IS) treatments were not different compared to patients without IS and HC (Table 1).

Conclusion: Our preliminary results suggest that under Th17 stimulating conditions, T cells express higher IL-17 levels in BD. More prominent IL-17 and IFN-γ production by all lymphocyte subsets in BD might be associated with the increased innate responses and early tissue neutrophil infiltrations in BD, which is not observed in TAK.

Table 1. IL-17 expression and IFN-γ production in HC and BD and TAK patients with and without IS treatment

	HC	IS BD	Non-IS BD	IS TA	Non-IS TA
CD4+ IFN+	1.9±1.3	2.6±0.7	3.9±4.3	2.2±1.9	1.6±1.2
CD4+ IL-17+	4.5±4.9	7.8±8.5	8.9±11.3	3.3±2.3	3.5±3.1
CD8+ IFN+	4.0±3.6	6.1±2.6	10.2±12.1	5.2±5.0	3.3±3.1
CD8+ IL-17+	2.3±2.1	8.4±5.3	7.1±9.4	4.0±4.5	3.2±2.4
Gd+ IFN+	5.3±4.7	10.0±5.4	10.7±12.8	4.5±4.6	6.3±6.3
Gd+ IL17+	6.1±4.1	13.3±9.9	15.4±14.0	6.9±4.9	5.2±3.7

Microparticles (MPs) Derived from Cell Plasma Membranes Are Increased in Behcet's Syndrome (BS) and a Low Ratio of Tissue Factor Pathway Inhibitor Positive Mps to Tissue Factor Positive Mps (TFPI/TF) Is Associated with Thrombosis

Emon Khan[1], Nicola Ambrose[1], Miles Stanford[2], Michael A. Laffan[3] and Dorian O. Haskard[4], [1]Department of Vascular Sciences, National Heart and Lung Institute, Imperial College, London, United Kingdom, [2]Ophthalmology, Guy's and St. Thomas' Hospital, London, United Kingdom, [3]Department of Haemostasis and Thrombosis, Imperial College, London, United Kingdom, [4]Rheumatology, Imperial College, London, United Kingdom

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Vasculitis Poster III

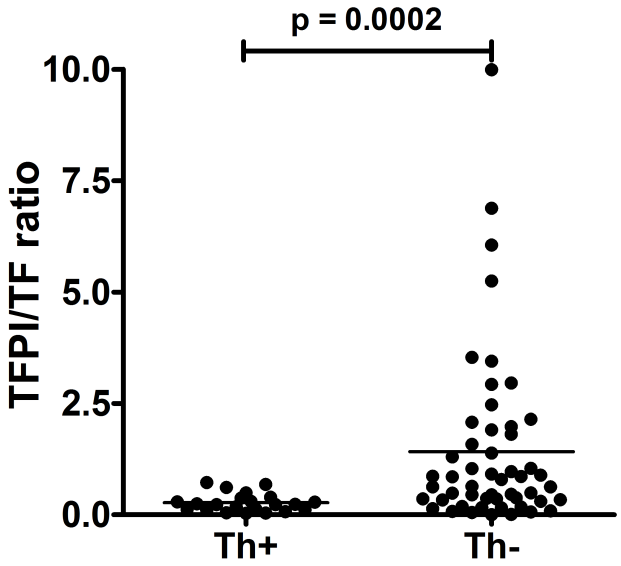
Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Thrombosis occurs in around 20% of Behçet's Syndrome (BS) patients and causes substantial morbidity. There is a clear need for better biomarkers of thrombotic risk in BS to inform treatment decisions. MPs are released from cells undergoing activation and/or apoptosis and express phosphatidylserine (PS) on their surface. MP that also express Tissue Factor (TF) provide a stimulus for blood coagulation, whereas Tissue Factor Pathway Inhibitor (TFPI) expressed by MP may be protective. We tested the hypothesis that imbalance between TF+ and TFPI+ MPs provides a biomarker for thrombotic risk in BS.

Methods: MPs were prepared from peripheral blood from 88 BS patients (who fulfilled International Study Group diagnostic criteria), and 72 age- and sex- matched healthy controls. The BS group was composed of 21 patients with a history of thrombosis (Th+) and 67 patients with no history of thrombosis (Th-). MPs were identified using flow cytometry by size (<1μm) and binding to Annexin V (to PS). MP were further characterized by binding of monoclonal antibodies to CD14 (a monocyte marker), TF and TFPI.

Results: Total numbers of plasma MPs and also CD14+, TF+ and CD14+TF+ MPs were increased in BS compared to HC (all $p < 0.0001$), and also in Th+ compared to Th- BS patients ($p \leq 0.0002$). TFPI+ MPs were higher in BS patients than HC (medians: 3.60 x 10^4/ml *vs.* 2.15 x 10^3/ml, $p < 0.0001$), but not between Th+ and Th- BS patients (medians: 3.09 x 10^4/ml *vs.* 3.74 x 10^4/ml, $p = 0.6660$). The TFPI/TF ratio was higher in BS patients than HCs (medians: 0.49 *vs.* 0.20, $p < 0.0001$) and in Th- compared to Th+ patients (medians: 0.85 *vs.* 0.23, $p = 0.0002$). Strikingly, a TFPI/TF ratio > 0.7 conferred freedom from thrombosis (Figure).



Conclusion: Monocyte-derived MP expressing TF were increased in BS patients and more so in those with a history of thrombosis. Discrimination between BS patients with and without a history of thrombosis was improved by also measuring TFPI+ MPs and generating a TFPI/TF ratio. The data suggest that the balance between TF+ and TFPI+ MPs is important for thrombotic risk in BS and raise the possibility that the TFPI /TF MP ratio may allow the identification and appropriate treatment of BS patients with a low risk of thrombosis.

Session Title: Vasculitis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Diagnosis of Behçet´s disease (BD) is challenging because is based solely on clinical features. Articular involvement in this disease may mimic other diagnosis such as enteropathic arthritis manifestations. IgM anti-alpha-enolase antibodies (AAEA) were recently described in BD, however its clinical relevance is still undefined. Therefore, this study aimed to assess IgM AAEA in systemic BD and its possible association with clinical manifestations and disease activity.

Methods: Ninety-seven BD patients were compared to 36 enteropathic arthritis patients [Crohn's disease (n=24) and ulcerative colitis (n=12)]

and healthy controls (n=87). IgM AAEA was detected by immunoblotting using human alpha-enolase transfected cells whole lysate (Santa Cruz Biotechnology Inc., USA) as antigens. Disease activity was assessed by standardized indexes, BR-BDCAF for BD, SCCI for Crohn's disease (CD) and HBI for ulcerative colitis (UC) together with c-reactive protein (CRP) levels. A longitudinal evaluation was performed in BD patients (n=56), with a minimum of two years interval, regarding IgM AAEA presence and disease activity scores.

Results: A higher IgM AAEA prevalence was found in BD compared to enteropathic arthritis and healthy controls (18.4% vs. 2.8% vs. 2.3%, p<0.001). The frequency of IgM AAEA in active BD was significantly higher than in patients with inactive disease (30.2 vs. 7.4%, p=0.006). Further longitudinal analysis after at least two years confirmed a higher IgM AAEA frequency in active BD compared to inactive BD (45.5 vs. 13.3%, p=0.02). Reinforcing these findings, the mean BR-BDCAF scores and CRP levels were higher in IgM AAEA positive group at baseline (9.11 vs. 4.95, p=0.002 and 11.9 vs. 5.0mg/L, p=0.05) and post two years (5.0 vs. 2.1, p=0.01; 9.6 vs. 3.8mg/L, p=0.008). Regarding all clinical manifestations, we observed that the subgroup with articular symptoms presented higher IgM AAEA positivity on baseline and follow-up evaluations (26.3 vs. 5%, p=0.006; 54.5 vs. 15.6%, p=0.01).

Conclusion: Taken together these data suggest that IgM AAEA may be a novel marker for BD activity, particularly related to articular involvement. Further studies are necessary to confirm their usefulness in clinical practice to distinguish BD patients with articular involvement from patients with enteropathic arthritis manifestations.

Session Date: Tuesday, November 10, 2015

Session Title: Vasculitis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Vascular involvement is seen in up to 40% of the patients with Behcet's disease (BD), with lower extremity deep vein thrombosis (DVT) as the most frequent form of vascular involvement. Chronic post-thrombotic syndrome (CPTS) develops in up to one-half of patients with DVT and is associated with varying combinations of leg pain, oedema, hyperpigmentation and varicose collateral veins. There is no data about CPTS in DVT associated with BD. In this study,we aimed to evaluate venous disease spesific quality of life (QoL) in patients with Vascular Behçet's Disease (VBD).

Methods: In this study, 62 patients (M/F: 47/15, mean age: 38.6±9.2 years) with VBD, who were regularly followed in Marmara University Behcet's Clinics and 29 patients (M/F: 20/9, mean age: 41.6±11.8 years) with DVT associated with non-BD causes, who were followed in Hematology and Vascular Surgery Departments, were assessed. Mean duration after DVT was 6.7±5 years in VBD and 1.6±1 years in non-BD group. Venous Disability Score (VDS) and Venous Clinical Severity Score (VCSS) were used to evaluate the severity of venous insufficiency. Venous disease-specific QoL (the primary outcome) was measured using the Turkish validated form of Venous Insufficiency Epidemiological and Economic Study Quality of Life/Symptom questionnaire (VEINES-QoL/Sym). After calculation, VEINES-QoL and VEINES-Sym sub-scores were identified. Higher scores shows better QoL. SF-36 and Behcet Syndrome Activity Score (BSAS) questionnaires were also fullfilled for patients.

Results: VCSS and VDS were significantly worse in non-BD group compared to VBD, similarly VEINES-QoL and VEINES-Sym were significantly better in VBD group (Table 1). There were no correlations between VEINES-QoL, VEINES-Sym score and duration after DVT, daily sitting and standing times. VEINES-QoL and VEINES-Sym negatively correlated with VCSS (r: -0.367, p<0.001 and r:-0.384, p<0.001, respectively) and VDS (r: -0.288, p=0.007 and r:-0.265, p=0.013, respectively). VEINES-Sym and VEINES-QoL also significantly correlated with BSAS (r: -0.526, p<0.001 and r:-0.496, p<0.001, respectively). Physical and mental components of SF-36 were similar between VBD and non-BD groups.

Conclusion: In VBD, we observed that venous-specific QoL and symptoms worsen together with increasing VDS and VCSS scores. These

results suggest that better control of disease activity may increase the QoL, as well as preventing the relapses in venous Behcet's disease.

Table 1: Quality of life parameters in patients with Deep Vein Thrombosis associated with Behçet's Disease and non-Behçet's Group.

	Non-Behcet's group (n=29)	Behcet's group (n=62)	p value
VCSS	6.5 ±4.5	4.2±4.6	**0.031**
VDS	1.6±0.5	0.9±0.6	**0.000**
MCS	40.8±10.2	44.9±9.5	0,071
PCS	40.3±9.3	43.1±10.5	0.222
VEINES-QoL	73.3±17.9	87.9 ±16.9	**0.000**
VEINES-Sym	32.3±9.8	39.3±9.2	**0.001**

VCSS: Venous Clinical Severity Score, VDS: Venous Disability Score, MCS:Mental component of SF-36, PCS: Physical component of SF-36, VEINES-QoL/Sym: Venous Insufficiency Epidemiological and Economic Study Quality of Life/Symptom questionnaire.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Vasculitis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Behcet's disease (BD) is a chronic systemic inflammatory disorder characterized by recurrent oral aphtae and other systemic involvement. Red blood cell distribution width (RDW) is a measurement of heterogeneity in size. RDW is commonly used in the differential diagnosis of anemia, but recently, RDW has been thought to be an inflammatory marker in many diseases. In this study, we investigated whether RDW might be a marker that reflects the disease activity of BD

Methods: 188 patients with BD were enrolled and divided into active and inactive group by Behcet's Disease Current Activity Form 2006. 100 normal healthy individuals were enrolled as control group. In addition to RDW, laboratory results including white blood cell count, hemoglobin, erythrocyte sedimentation rate (ESR), and C-reactive protein (CRP) were assessed.

Results: RDW was significantly higher in patients with active BD than both inactive BD and healthy control groups ($p < 0.05$) and also significantly higher in inactive BD group than in healthy control group ($p < 0.05$)(Figure 1). RDW was more positively correlated with disease activity index [correlation coefficient (r) = 0.299, $p < 0.05$] (Figure 2) than ESR ($r = 0.193$, $p < 0.05$) or CRP ($r = 0.221$, $p < 0.05$). Among clinical variables, RDW greater than 13.35 % was significantly associated with disease activity on univariate analysis ($p < 0.05$) and multivariate analysis revealed that the disease activity was associated with RDW only (OR 2.603 95% confidence interval 1.609, 4.214, $p < 0.05$)(Table 1).

Conclusion: RDW is independently associated with the disease activity of BD. Our findings indicated that RDW is more significant marker of the disease activity than ESR or CRP in BD.

Figure 1.

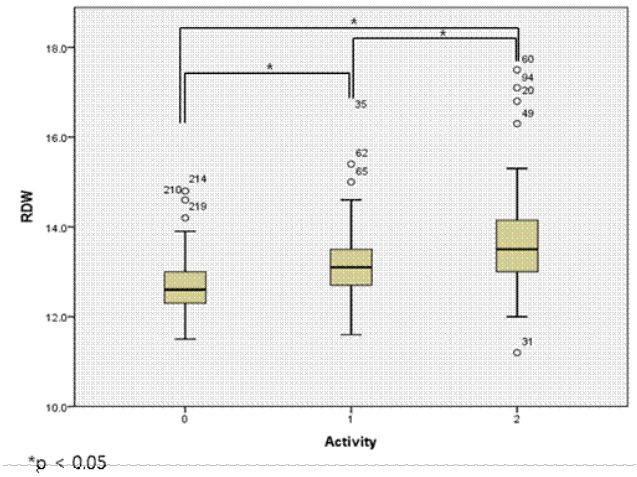

Figure 2.

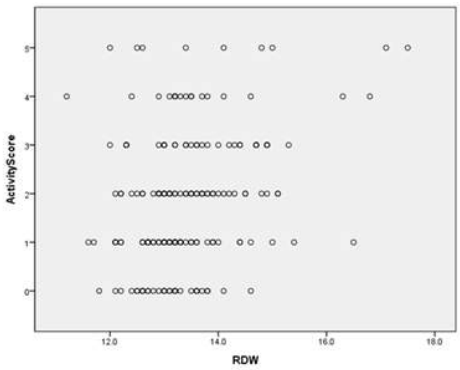

Table 1.

Variables (cut-off)	Univariate	Multivariate	
	p value	OR (95% CI)	p value
Age			0.82
Sex			0.53
WBC			0.16
Hb			0.45
RDW (13.35 %)	<0.05	2.603 (1.609,4.214)	<0.05
ESR			0.38
CRP			0.77

Session Date: Tuesday, November 10, 2015

Session Title: Vasculitis Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Behcet's syndrome (BS) is most active during young adulthood and may cause severe disability. We had previously observed a high frequency of work disability among our Behçet's patients in a cross-sectional study. This time we aimed to evaluate the sustainability of work among our patients who did have a job 5 years ago.

Methods: We had surveyed work disability among 300 consecutive Behçet's syndrome patients who attended our clinic in 2009. We had observed that after excluding students, homemakers and retired patients, among the 149 work eligible patients 29 (21%) were unemployed and 120 were employed. We now evaluated those patients who did have a job 5 years ago regarding work loss and reasons for work loss, using a standard questionnaire. We also checked their hospital charts for new types of organ involvement that developed during these 5 years, and any new medications that were started.

Results: Among the 120 patients who did have a job in 2009 (87 men, 33 women, mean age 36 ±8.6, disease duration 9.7 ±7.1 years, 48% with major organ involvement), we were able to contact 97 patients. Sixteen patients (16%) had lost their jobs during the previous 5 years. Nine of these (11%) were related with Behçet's syndrome and the rest were due to other causes (5 had retired, 1 had a baby, 1 was doing his military service). Among the 81 patients who were still working, 10 (10%) had to change their work place during the last 5 years and were unemployed for a mean of 6.7 ± 5.3 months between these jobs.

Conclusion: Work disability is an important problem among Behçet's syndrome patients. During a 5 year follow-up, 11% of patients lost their jobs due to their disease, and a further 11% had to interrupt work and change their work places. We were only able to evaluate work disability in this study, and work productivity is another important issue that needs to be studied among patients with Behçet's syndrome.

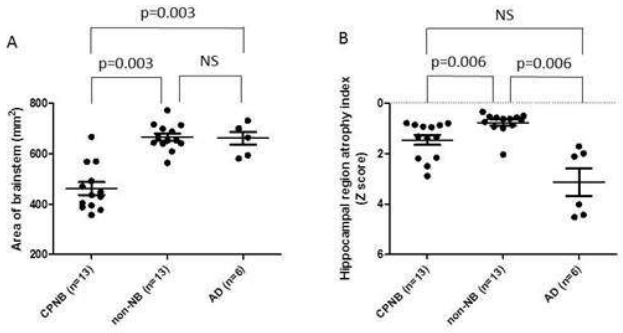
SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Vasculitis Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Central nervous system involvement is one of the most serious complications in Behçet's disease (BD). This condition is referred to as neuro-Behçet's disease (NB) and can be classified into acute NB (ANB) and chronic progressive NB (CPNB) based upon differences in the clinical course and response to corticosteroid treatment. Brainstem atrophy is significantly more frequently observed in CPNB than in ANB. It is also noteworthy that cognitive dysfunction, in addition to truncal ataxia, is frequently observed in CPNB, and this cannot be accounted for by brainstem atrophy. In the present study, we examined volumes of the hippocampus in order to identify the responsible lesions for neurobehavioral changes in CPNB.

Methods: The subjects were 32 patients, including 13 with CPNB (11 males and 2 females, age 51.2 ± 12.1 years old [mean ± SD]), 13 with Behçet's disease without NB (non-NB) (10 males and 3 females, age 54.4 ± 11.4 years old), and 6 with Alzheimer's Disease (AD) (5 males and 1 female, age 78.8 ± 7.5 years old). All patients with BD satisfied the international classification criteria for Behçet's disease. CPNB was defined as intractable, slowly progressive neurobehavioral changes and/or ataxia accompanied by persistent elevation of interleukin-6 of >20 pg/mL in cerebrospinal fluid on two different occasions at an interval of at least 2 weeks. All patients with AD satisfied the Diagnostic and Statistical Manual of Mental Disorders (DSM)-IV criteria. Sagittal sections of T1-weighted images on brain magnetic resonance imaging (MRI) were obtained from each subject. The areas of the midbrain tegmentum and pons were measured on mid-sagittal sections of T1-weighted images using image analysis software (Image J ver.1.45: NIH, USA). Severity of gray matter loss in the hippocampal region and whole brain were

investigated using Voxel-Based Specific Regional Analysis System for Alzheimer's Disease (VSRAD) software (Eisai Co., Ltd) to determine the degrees of hippocampal region atrophy (Z score) and whole-brain atrophy (WBAI).

Results: The brainstem area was significantly decreased in CPNB (461.8 ± 87.3 [mean ± SD]) compared with those in AD (661.9 ± 56.1) and non-NB (666.1 ± 50.6) (Figure 1, A). VSRAD analysis showed that Z score was significantly increased in CPNB (1.46 ± 0.70) and AD (3.13 ± 1.21) compared with non-NB (0.77 ± 0.40) (Figure 1, B). All patients with CPNB showed brainstem atrophy, but there was no significant correlation between the area of brainstem atrophy and Z score. Neither Z score nor WBAI was correlated with age in CPNB.



Conclusion: These results indicate that the hippocampus, in addition to the brainstem, is a common site for lesions in CPNB, accounting for the progressive cognitive dysfunction in this disease. The lack of correlation between brainstem atrophy and hippocampal atrophy suggests that predisposing factors might determine the lesion site in CPNB.

Evaluation of Olfactory Function in Behcet's Disease

Lutfi Akyol[1], Emre Gunbey[2], Rıfat Karlı[2], Metin Ozgen[1] and Mehmet Sayarlıoglu[3], [1]Department of Internal Medicine Division of Rheumatology, Ondokuz Mayıs University, Faculty of Medicine, Samsun, Turkey, [2]Otorhinolaryngology, Ondokuz Mayıs University, Samsun, Turkey, [3]İnternal Medicine Division of Rheumatology, Ondokuz MayÄ±s University, Samsun, Turkey
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Vasculitis Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Behçet's disease (BD) is a chronic, relapsing type of vasculitis of unknown etiology, characterized by oral and urogenital ulcers and ocular inflammation with cutaneous, musculoskeletal, vascular, and nervous system manifestations. Few cases involving the nasal mucosa have been reported in the literature, and the true prevalence of BD remains unknown. Neurological involvement associated with BD might play a more important role in causing olfactory dysfunction compared to mucosal involvement but sufficient clinical data is not available about the effect of BD on olfaction in adults. We evaluated the olfactory function of patients diagnosed with BD.

Methods: Patients were chosen from among a consecutive patient group population who visited our the internal medicine rheumatology polyclinic and otolaryngology departments of Ondokuz Mayıs University Hospital. A total of 50 participants (males and females), aged 18 to 60 years with a diagnosis of BD, and 46 healthy controls (matched to the study group for age and gender) were included. BD was diagnosed based on the criteria defined by the International Study Group for BD. A complete clinical history was taken, and a physical examination was performed, in all participants. Individuals with other rheumatic diseases; obstructive nasal pathologies leading to conductive-type olfactory dysfunction (e.g., septum deviation, nasal polyp); advanced systemic disease (e.g., hypertension, malignity); a history of antithyroid, antihistamine, antidepressant, or steroid medication within the past month; or who were current smokers, had an active upper respiratory infection or a history of otolaryngologic operations were excluded from the study**.** The results of the "Sniffin' Sticks" (SS) olfactory test were compared between the two groups.

Results: The mean age of the 50 BD patients was 35.3 ± 10 years, compared to 36.9 ± 11 years for the 46 control group patients. There was no significant group difference in age or gender distribution (p>0.05). Odor identification and overall scores were significantly lower in the BD group compared to the control group. There were no significant differences in odor discrimination scores between the BD and control groups (p>0.05).

Conclusion: This is the first study to evaluate olfactory function in patients diagnosed with BD using the SS test. Odor identification was impaired in patients with BD compared to healthy controls, but there was no group difference in odor discrimination. Patients with BD also should be assessed for involvement of olfactory function and may require treatment due to malfunction of the olfactory system that affects the quality of life.

Session Title: Vasculitis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Hemoptysis is the most frequent and feared symptom of pulmonary artery involvement (PAI) in Behçet's syndrome (BS). Some BS patients with PAI experience recurrent hemoptysis after achieving clinical response and regression or even resolution of abnormal radiologic findings with treatment. Enlargement of bronchial arteries may be the source of recurring hemoptysis in these patients.

Methods:

Retrospective chart review of 6 BS patients (all men) having repeated hemoptysis with no overt clinical or radiologic findings for active PAI.

Results:
