SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Previous analyses in patients (pts) with rheumatoid arthritis (RA) have evaluated the relationship between controlling disease activity and achieving long-term improvements in health-related quality of life (HRQoL) using the DAS28 or ACR20 to assess clinical response. However, the clinical disease activity index (CDAI) is more commonly used among community practicing rheumatologists. This analysis examined the predictive value of achieving low disease activity (CDAI≤10) and normalization of long-term HRQoL.

Methods: In the phase 3 GO-FURTHER trial, 592 pts with active RA despite MTX therapy were randomized (2:1) to IV golimumab (GLM) 2mg/kg+MTX or placebo (PBO)+MTX at wks 0 and 4, then q8w; PBO pts crossed over to GLM at wk16 (early escape) or wk24 (crossover). In this post-hoc analysis, disease activity was measured using the CDAI, and HRQoL was assessed using patient-reported outcomes: FACIT-Fatigue, HAQ-DI, and SF-36 physical/mental component summary (PCS/MCS) scores and individual domain scores. Normalization of HRQoL (based on the means for the general population) was defined as follows: FACIT-Fatigue ≥43.6, HAQ-DI ≤0.5, and SF-36 PCS/MCS and domain scores ≥50. Logistic regression analyses (adjusted for gender, age, current smoking status, and baseline CDAI score and PRO assessments) were performed to evaluate the relationship between achieving low disease activity (CDAI ≤10) and normalization of HRQoL at each time point through 2 years. Additionally, the predictive value of achieving CDAI≤10 at wk12 and wk24 and normalization of HRQoL at 1 year and 2 years was also assessed.

Results: Greater proportions of pts in the IV GLM 2mg/kg+MTX group achieved CDAI ≤10 compared with the PBO+MTX group at wk12 (19.6% vs 9.8%; p=0.0026) and wk24 (38.2% vs 18.5%; p<0.0001) (PBO-controlled period). Achieving a CDAI ≤ 10 was strongly associated with normalized HAQ-DI, FACIT-Fatigue, SF-36 PCS/MCS scores and SF-36 domain scores at each time point through 2 years (p<0.0001 for most variables). Pts who achieved CDAI ≤10 at wk12 or wk24 were more likely to achieve normalized HAQ-DI, FACIT-Fatigue, SF-36 PCS/MCS scores, and SF-36 domain scores at 1 year than were pts with CDAI >10 (Odds ratio [OR] range: 1.8-5.9 and 1.7-6.6, respectively). Similar results were observed for pts with CDAI ≤10 at wk12 or wk24 and normalized HRQoL at 2 years (OR range: 2.2-4.6 and 2.0-3.7, respectively).

Conclusion: Greater proportions of GLM+MTX pts achieved CDAI ≤10 at wks 12 and 24 compared with PBO+MTX. Achieving low disease activity (CDAI ≤10) at either wk12 or wk24 was predictive of achieving normalized HAQ-DI, FACIT-Fatigue, SF-36 PCS/MCS scores, and SF-36 component scores at 1 year and 2 years in pts with active RA.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Despite a proliferation of early arthritis (EA) clinics intended to expedite the diagnosis of rheumatoid arthritis (RA), patients continue to experience substantial and multifactorial delays between symptom onset and treatment initiation. In this study we determined whether time to treatment following symptom onset differs between rheumatoid arthritis (RA) patients according to autoantibody status.

Methods:

A single-centre retrospective analysis of a UK early RA inception cohort was undertaken to identify those components of the “patient journey” that differed by serological sub-type. Where available, the components studied included (i) symptom onset to assessment in primary care, (ii) primary care assessment to secondary care rheumatology referral, (iii) rheumatology referral to rheumatology assessment, and (iv) rheumatology assessment to disease modifying anti-rheumatic drug (DMARD) initiation. Non-parametric ANOVA were used to compare groups, and time-to-event data were analysed using Kaplan-Meier survival plots.

Results:

173 RA patients were diagnosed over a 31 month period, of whom 80 (46%) were anti-citrullinated peptide antibody / rheumatoid factor “double-seropositive” (ACPA+/RF+), 53 (31%) ACPA-/RF-, 17 (10%) ACPA+/RF- and 23 (13%) RF+/ACPA-. Overall, ACPA+/RF+ patients experienced significantly longer symptom duration before disease modifying anti-rheumatic drug (DMARD) initiation (p=0.006). This was accounted for by delays in their presentation to primary care following symptom onset (Figure 1A). By contrast, ACPA-/RF- patients were significantly more likely to experience delays in DMARD initiation after presenting to secondary care (Figure 1B).

Conclusion:

Causes of treatment delays in early RA differ according to patients' autoantibody status. More insidious symptom onset and/or distinct health-seeking behaviours amongst ACPA+/RF+ patients may contribute to late presentations in primary care, whereas ACPA-/RF- patients experience delayed diagnosis and treatment in secondary care. These observations

could inform future design of service delivery for early arthritis patients.

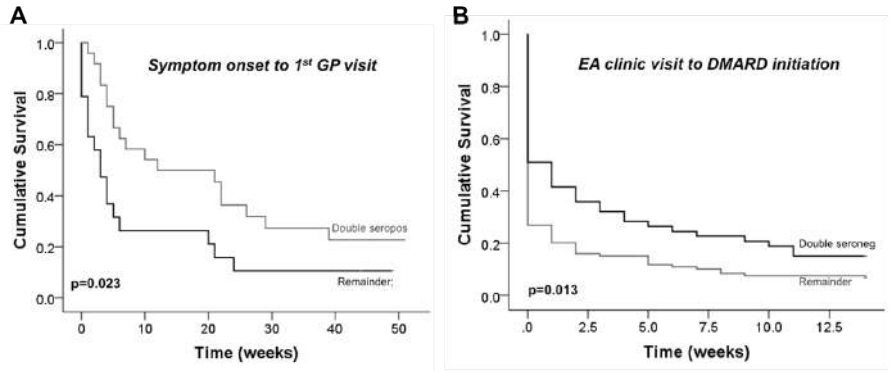

Figure 1. "Survival" from (A) symptom onset to 1st primary care visit and (B) 1st EA clinic consultation to DMARD initiation, stratified by autoantibody status as indicated.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Finnish national combination treatment trials have demonstrated excellent outcomes in patients with ERA including 90% of patients reaching DAS28 remission at 6 months. Whether similar results are reached in

clinical praxis are not known. We herein report characteristics, disease activity and DAS28 remission rates at 6 months in ERA patients treated in 5 Finnish outpatient clinics.

Methods: FIN-ERA is the first national multicenter observational cohort of adult patients with early inflammatory arthritis, clinically diagnosed as RA between Oct 2011 and Sep 2014. Data comprising demographic, clinical and treatment characteristics were collected as a part of routine care. Treatment decisions were made by treating rheumatologists with cooperation with the patient. Finnish treatment recommendations emphasize early and active therapy with combination of csDMARDs and prednisolone starting at the diagnosis, and unlimited glucocorticoid injections to all swollen joints.

Results: Out of 605 recruited patients, 566 completed baseline, 3 and 6 months visit and had full data for disease activity score (DAS28-3) with ESR. In the entire cohort, the mean age was 56±16 yrs, the median (IQR) duration of symptoms was 6(3,11) mo, rheumatoid factor (RF) and anti cyclic-citrullinated peptide antibodies (anti-CCP) were evident in 68% and 69%, respectively. At baseline, a total of 23% of patients had radiographic erosions. A total of 484 (86%) fulfilled the ACR/EULAR 2010 classification criteria for RA at baseline. Figure 1 represents the mean DAS28-3 for RA patients at baseline, 3 mo and at 6 mo at FIN-ERA clinics A-E. The respective mean HAQ and DAS28 (with ESR, 4 variables,DAS28-4) at baseline were 1.0±0.7 (data for 83%) and 4.3±1.4 (data for 88%). The corresponding values for HAQ and DAS28-4 at 6 mo were 0.4±0.5 (data for 86%) and 2.1±1.1 (data for 93%). A total of 73% met DAS28-4 remission at 6 mo. Remission rates were similar in patients classified as undifferentiated arthritis (14% of the cohort), and did not differ significantly according to serology. A total of 57% of ERA patients were in sustained DAS28-4 remission at 3 and 6 mo. Figure 2 represents DAS28-4 remission rates at 3 and 6 mo at 5 FIN-ERA clinics. In a multivariate model, lower disease activity at baseline and male gender predicted remission (DAS28-3<2.6) at 6 mo, while age, RF/anti-CCP, erosiveness, or clinic remained statistically unsignificant. A total of 75% received MTX based combination csDMARD therapy at baseline, and 1.4% bDMARDs within 6 mo.

Conclusion: A majority of ERA patients reach early and sustained DAS28 remission in Finland.

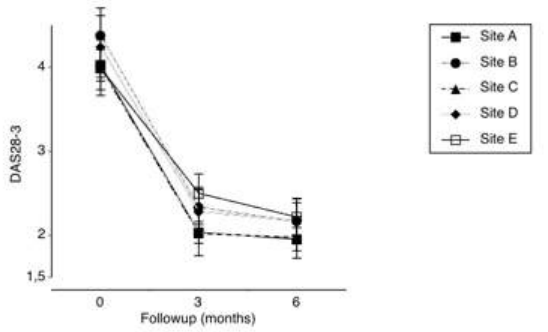

Figure 1. DAS28-3 (mean, 95% CI) in patients with early RA in 5 FIN-ERA clinics

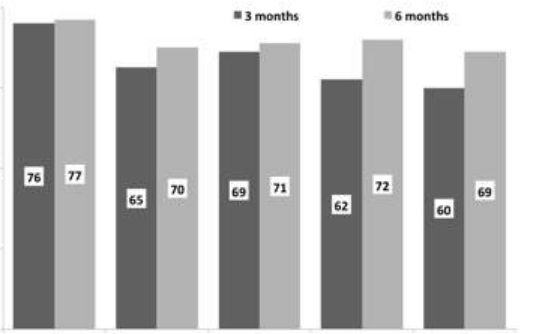

Figure 2. DAS28-4 remission rates at 5 FIN-ERA sites (P = n.s. between sites, χ2-test)

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Holiday seasons can present a major problem to RA patients treated with weekly subcutaneous biologics, including subcutaneous (SC) abatacept. Therefore an evaluation of the use of IV-abatacept treatment to cover a 4-week break may present an acceptable alternative.

Objective:

To study the efficacy and safety of a single intravenous (IV) course with abatacept in Patients with rheumatoid arthritis currently receiving weekly injections of SC abatacept to simulate a patient “vacation” followed by a switch back to SC abatacept.

Methods:

This open label, prospective, single arm 24-weeks trial recruited patients with established RA and in low disease activity (LDA) under treatment with SC abatacept for at least 3 months to receive a single dose of IV abatacept (day 0) and to be continued on SC abatacept from day 28 on (NCT01147341). DMARD- and/or biologic-inadequate responders were included and previous exposure to IV abatacept was allowed in a maximum of 50% of the patients.

Results:

Baseline characteristics of the 49 patients (per protocol) were typical for a cohort of RA patients with established disease (mean disease duration 8.31 years) in LDA under treatment. Two patients dropped out of the study (1 flare, 1 patient decision). The proportion of patients with DAS 28 $\leq$3.2 at day 28 was 93.9% (95%CI 83.5-97.9) at day 28, 91.7% (95%CI 80.4-96.7) at day 84 and 93.6 (95%CI 82.8-97.8) at the end of the study, day 168. This proportion

remained stable throughout the entire follow up. The average DAS 28 at baseline was 1.74 (SD ±0.72) at baseline, 2.03 (SD ±1.03) at day 28, 1.86 (SD ±0.91) at day 84 and 1.96 (SD ±0.92) at the end of the study, day 168. Pre-exposure to IV abatacept and having failed MTX or anti TNF did not influence the average DAS 28 or the proportion of patients maintaining LDA. The average HAQ-DI was stable throughout the study. Adverse events occurred in 75% of subjects. Four serious adverse events (SAE) were described during the study. None of them was related to the investigational product and all SAE could be resolved during hospitalization. Discontinuation of abatacept was not necessary in these patients. There were no deaths, neoplasms, and opportunistic or other serious infections (intention to treat).

Conclusion:

This prospective, open label study of abatacept shows for the first time that switching from weekly SC to IV abatacept and back after 4 weeks is an effective and safe way to bridge holidays in RA patients in LDA.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

It is well accepted that patients studied in pharmaceutically sponsored clinical trials do not always represent the types of patients seen in clinical practice. Therefore, a description of clinical and laboratory data of patients in community practice may provide important and perhaps unique information.

The purpose of this analysis is to characterize the type of patients in a real world (RW) setting receiving tofacitinib (TFA) using the rheumatoid arthritis (RA) registry, JointMan® (JM). This database was launched in 2009 with a mission to provide a practical outcome tool to manage patients with RA in a traditional office based clinical setting.

Methods:

This is a descriptive, observational study comparing the patient characteristics of a clinical office based population of

patients enrolled in JM to the ORAL Step study (OS), a pharmaceutically sponsored study of TNF-IR patients receiving TFA.

JM captures RA diagnostic criteria and selected disease features, formal joint counts, outcome measures, serology, medication efficacy and safety and reason for discontinuation of medications. OS was chosen as a comparator as this patient cohort was the most comparable to the JM TFA treated group. Data was collected from Nov 2012 to March 31, 2015. Continuous covariates were compared using a T- test; categorical covariates were compared using a chi-square test. Due to the retrospective methodology, complete data was not always available.

Results:

A total of 5700 unique RA patients and 133,000 encounters have been recorded.

Over the study period, there were 156 RA patients newly prescribed TFA. All patients in JM had received at least one anti-TNF agent prior to TFA initiation and the mean number of TNF inhibitor agents used was 1.8. Only 21% of patients in JM were treated with concomitant MTX. The population treated with TFA in the JM was 81% female and in OS 85% (p=0.383). The mean age at start of TFA was 60 in JM whereas in OS it was 54.2 (p=0.004). Patients had a mean duration of disease of 3.8 years in the JM whereas in the OS cohort disease duration was 13.0 years ($P < 0.001$). If a patient lacked a definitive diagnosis date, their first JM assessment date was used. Joint count scoring differed in the two cohorts: 66/68 in OS, 28 in JM. Irrespectively, both groups had a high disease activity as measured by mean CDAI score in JM of 26.7 and DAS 28-4 (ESR) of 6.5 in the OS.

Conclusion:

In this RW setting some patient characteristics were comparable to those seen in published trials. Similar to OS, in JM there was a predominance of females with a similar mean age and patients had high disease activity at initiation of therapy. However, differences were also noted. TFA was used much earlier in the disease course than in OS. Interestingly, TFA was used more commonly as monotherapy in JM than in combination with methotrexate.

Although randomized clinical trials differ markedly from observational studies and there are limitations of both types of studies, important information can be gleaned from such a comparison. The differences in trial designs, selection bias, information bias, confounding by indication, must be considered when interpreting these results.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Tofacitinib (TFA) was approved for the treatment of rheumatoid arthritis (RA) in November of 2012. It is well accepted that patients studied in pharmaceutically sponsored clinical trials do not always represent the types of patients seen in clinical practice. There is limited efficacy data published on real world (RW) patients receiving TFA.

The purpose of this analysis was to assess the efficacy of TFA on patients in a RW setting receiving TFA using the RA registry, JointMan (JM). This database was launched in 2009 with a mission to provide a practical outcome tool to manage patients with RA in a traditional office based clinical setting.

Methods:

This is a descriptive observational efficacy study comparing the outcomes of RA patients on TFA. JM captures RA diagnostic criteria and selected disease features, formal joint counts, DAS 28, CDAI, SDAI, RAPID3, VECTRA, CRP and ESR, Rheumatoid Factor, CCP, medication use, toxicities and reason for discontinuation. Both patient and physician data is collected electronically.

CDAI score was used as the outcome measure to define treatment response. Efficacy was compared from the time of initiation of TFA used to the date to their last active encounter date. The mean average of all patients' CDAI scores at initiation and their last active encounter date were compared using a paired T-Test.

Results:

A total of 5700 unique RA patients and 133,000 encounters have been recorded since 2009. There were 156 RA patients prescribed tofacitinib, of those 91 had multiple JM encounters.

All patients in JM had received at least one anti-TNF agent and the mean number of TNF inhibitor agents used was 1.8. The mean CDAI score at initiation was 25.8 (high disease activity) and at last observation the mean was 19.8 (moderate disease activity). Comparing the means with a paired T-Test resulted in t=3.89 (p=0.002, CI 2.79 to 8.62). The percentage of patients in high disease activity decreased by 21.4 points. The distribution of patients by disease activity are displayed in Table 1. 61% of patients were still on TFA at time of analysis. Mean duration was 212 days. There were 12 missing stop reasons (13%), 32 (35%) had a non-serious adverse event some of whom discontinued therapy and the remainder of patients continued on therapy.

Initial TFA Encounter				
	N	**%**	**SD**	**CI**
High	50	56.2%	9.51	2.64
Moderate	28	31.5%	2.80	1.04
Low	11	12.4%	1.44	0.85
Remission	0	0	N/A	N/A

Last TFA Encounter				
	N	**%**	**SD**	**CI**
High	31	34.8%	9.84	3.46
Moderate	36	40.4%	2.95	0.97
Low	17	19.1%	1.97	0.93
Remission	5	5.6%	0.08	0.07

Conclusion:

The results from this study indicate that patients in a real world setting are prescribed TFA after receiving at least one anti-TNF agent and that TFA reduces disease activity from a CDAI mean of high disease activity to moderate disease

activity over a period of approximately 7 months. Most patients prescribed this agent continue therapy. Additional work is needed to identify which characteristics are critical to define variables predictive of low disease activity and remission.

Associations Between Arthritis Patient, Disease-Specific and Provider Characteristics and Medication Information Source Use

Lorie Geryk[1], Susan J. Blalock[2], Robert DeVellis[3], Joanne M. Jordan[3] and Delesha Carpenter[4], [1]Division of Pharmaceutical Outcomes and Policy, University of North Carolina Eshelman School of Pharmacy, Chapel Hill, NC, [2]Eshelman School of Pharmacy, University of North Carolina at Chapel Hill, Chapel Hill, NC, [3]Thurston Arthritis Research Center, University of North Carolina, Chapel Hill, NC, [4]Division of Pharmaceutical Outcomes and Policy, University of North Carolina Eshelman School of Pharmacy, Asheville, NC

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Few studies have described how patient, disease-specific, and provider factors are associated with medication information source use among arthritis patients. We address this research gap by describing characteristics associated with arthritis patients' use of 15 medication information sources.

Methods: Adult osteoarthritis or rheumatoid arthritis patients completed an online cross-sectional survey. Patients (n=328) self-reported sociodemographic (i.e., age, gender, race/ethnicity, education level, marital status), clinical (i.e., year of diagnosis, age at diagnosis, arthritis type, current number of arthritis medicines taken, medication adherence, arthritis severity, comorbidities), and sociobehavioral (satisfaction with doctor-provided medication support, medication self-efficacy, and arthritis medication-taking concerns) characteristics. Patients were asked how much medicine information they sought and/or were given from fifteen different information sources (e.g., doctor, Internet, spouse/partner, medicine package inserts) when they are prescribed a new arthritis medicine. Patients' responses (range: 1= "none" to 4= "a lot") were averaged and higher mean scores corresponded to greater medication information source use. Correlations were inspected and covariates significant at the $p \leq 0.05$ level were subsequently examined using multivariable linear regression analyses to investigate whether sociodemographic, clinical, and sociobehavioral factors were associated with medication source use.

Results: On average, patients were 56 years old (±13; range 19–85) and were taking 2.5 arthritis medications. Most patients were female (79%) and white (80%); the median arthritis duration was 11 years. In multivariate analysis, the following independent variables remained significantly positively associated with arthritis medication information source use: always adherent (b = .13, p =.024), more medications taken ((b = .09, p <.0001), more medicine-taking concerns (b = .11, p =.001), more satisfaction with doctor medication support (b = .21, <.007), and Black race (b= .25, =.002).

Conclusion: Information source use varied with patient, clinical, and sociobehavioral factors. These findings have implications for public health efforts related to medication education for arthritis patients.

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: It is valuable to predict the effectiveness of biologics in the patients with rheumatoid arthritis (RA) to avoid unnecessary side effects and to save medical resource. Few studies have addressed which patients' baseline characteristics can predict clinical response in Japanese population. The aim of this study was to determine risk factors for abatacept treatment failure in Japanese population.

Methods: Retrospective cohort study was conducted in tertiary referral hospital in Tokyo, Japan. Consecutive 32 patients who had been treated with abatacept between October 2010 and May 2015 were included. We excluded the patients with abatacept treatment for less than 24 weeks. 32 patients were divided into two groups in terms of clinical responsiveness at 24 weeks using disease activity score 28 C-reactive protein (DAS28-CRP). DAS28-CRP more than 2.1 was defined as treatment failure. Candidate variables were age, gender, disease duration, DAS28-CRP, bone erosion, concomitant use of methotrexate (MTX), previous biologics, comorbidities such as other connective tissue diseases (CTDs) and/or interstitial pneumonia (IP), smoking, alcohol consumption, family history of CTDs, laboratory values including rheumatoid factor (RF), anti-cyclic citrullinated peptide (anti-CCP) antibodies, and antinuclear antibodies (ANA). RF > 45 IU/ml was defined as highly elevated RF. We performed bivariate analyses and logistic regression analysis.

Results:

Mean age (SD) of 32 patients was 64.8 years-old (12.5). 27 (84%) were female. 18 (56%) patients had treatment failure. The median (range) of disease duration was 1783 days (127 to 14379). In bivariate analyses, non-responder were more likely to be female (71.4% vs 94.4%, P value=0.14), have more tender joints (TJ) (median (range) 4 (1 to 13) vs 6.5 (1 to 13), P=value 0.17), and high titer RF (35.7% vs 83.3% P=value 0.01). For clinical response by abatacept, crude odds ratio of age, female gender, number of TJ, highly elevated RF, DAS28-CRP and CCP positivity was 1.05 (95% CI 0.99 to 1.12, P value=0.14), 6.8 (95% CI 0.86 to 143.31, P value=0.07), 1.19 (95% CI 0.96 to 1.53,

P value=0.12), 10.5 (95% CI 1.85 to 88.66, P value=0.007), 1.5(95% CI 0.73 to 3.40, P value=0.28), 0.78(95% CI 0.13 to 3.99, P value=0.77) respectively.

In multivariate analysis, adjusted odds ratio of age, female gender, number of TJ, highly elevated RF, DAS28-CRP and CCP positivity was 1.13 (95% CI 1.00 to 1.36, P value=0.05), 18.63 (95% CI 0.45 to 4042.6, P value=0.13), 1.71 (95% CI 0.97 to 4.09, P value=0.06), 14.49 (95% CI 0.98 to 622.01, P value=0.05), 3.09 (95% CI 0.32 to 59.00 P value=0.34), respectively.

Conclusion: In contrast to previous studies, highly elevated RF is a marginally significant risk factor for abatacept treatment failure in Japanese RA patients.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Several studies have shown that females with early inflammatory arthritis have higher disease activity, worse functional impairment and worse patient-reported outcomes but do not acquire more radiographic damage. It is hypothesized that the current measurement tools for disease activity are biased against females. The Hospital Universitario La Princesa Index (HUPI) is a validated tool in early RA and has been proposed to correct sex bias by adjusting for both the tender joint count (TJC 28) and ESR for males and females. The purpose of this study was to assess for sex differences in disease activity states between males and females as measured by the DAS28 and the HUPI, and whether there are differences in escalation of therapy between the sexes.

Methods: Data from the Canadian Early Arthritis Cohort (CATCH) were used for a sex-stratified analysis of disease activity and treatment escalation at 3, 6, 12, 24 and 60- month follow-up. Patients were included if they met the ACR 1987 or 2010 classification criteria for RA and their sex was documented. For the analysis, patients were classified into remission, low disease activity and moderate/high disease activity using the DAS28 and the HUPI cutpoints.

Treatment escalation was defined as any of: 1) increased dose of methotrexate; 2) addition of a new DMARD; 3) addition of a biologic agent; or 4) switching a biologic agent.

Results: 2228 patients (1619 females, 609 males) met the inclusion criteria. Females were younger (52 vs 58 years, $p<0.001$) and more frequently seropositive (72% vs 64%, $p<0.001$). Males had more erosions at baseline (14% vs 9%, $p<0.004$) and higher swollen joint count (9 vs 7, $p<0.001$). The DAS28 was similar in both groups at baseline (5.1 vs 5.0, $p=0.6$) but HUPI score were higher in males (8.9 vs 8.3, $p<0.0001$). More females were taking NSAIDs (60% vs 52%, $p<0.001$) and steroids (81% vs 59%, $p<0.002$) at inception to the cohort but these differences resolved by twelve months. The proportion of patients on DMARDs and biologic agents did not differ by sex at any time point. There were no sex differences in the escalation of therapy when patients were stratified by DAS28 or HUPI disease activity level (Table 1). More males were in DAS28 remission at 60 months (67% vs 52%,$p=0.01$) but the same proportion were in HUPI remission (53% vs 50%). There were no sex differences in the proportion of patients with erosions at 24 and 60 months.

Conclusion: There were no sex differences in treatment or escalation of therapy by disease activity state. Increased effort to treat to target for all patients is warranted.

Table 1. Escalation of Therapy in DAS28 or HUPI Moderate or High Disease Activity States, Stratified by Sex

	DAS28 Moderate/High		HUPI Moderate/High	
	Male	Female	Male	Female
Month 3	45%	46%	45%	50%
Month 6	33%	36%	33%	39%
Month 12	20%	26%	20%	27%
Month 24	33%	26%	34%	31%
Month 60	27%	14%	27%	15%

Predictors of Real-World Treatment Sustainability in RA Patients Treated with Abatacept in Canada: Implications for Routine Care

Janet E. Pope[1], Emmanouil Rampakakis[2] and John S. Sampalis[3], [1]University of Western Ontario, London, ON, Canada, [2]JSS Medical Research, St-Laurent, QC, Canada, [3]Clinical Research, JSS Medical Research, Westmount, QC, Canada

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Treatment sustainability can measure drug effectiveness and encompasses drug effectiveness, safety, and compliance. Recent data suggest that differences in retention may exist between biologic agents even among the same class[1-3]. However, the majority of data for real-world sustainability of biologics pertains to TNF-inhibitors. This analysis assessed the durability of treatment with the T cell co-stimulatory inhibitor abatacept in RA patients in Canadian routine practice and evaluated the determinants of treatment sustainability.

Methods: Data on RA patients administered abatacept in routine practice via the Orencia Response Program network, between August 2006 and February 2011 who had at least one follow-up evaluation, were included. Treatment sustainability was assessed with the Kaplan Meier (KM) estimator of the survival function. Parameters associated with treatment sustainability were assessed with multivariate Cox regression using a backwards selection method. Potential predictors considered were: number of previous biologics, monotherapy vs. combination therapy, home vs. clinic infusions, age, sex, severity of disease, presence of comorbidity, and years since diagnosis. The impact of these parameters on HAQ was assessed with mixed models with repeated measures.

Results: A total of 1,771 patients were included with mean (SD) age of 57.6 (13.2) years and duration since diagnosis of 16.5 (11.0). The majority (77.2%) were females. Overall, 672 (37.9%) patients discontinued after a mean (SE) KM-based time to discontinuation of 26.8 (0.5) months. In multivariate survival analysis, increased number of previous biologics [$HR_{1 \text{ vs. } 0}$ (95% CI): 1.48 (1.14-1.19, P=0.004; $HR_{\geq 2 \text{ vs. } 0}$ (95% CI): 1.71 (1.34-2.18), P<0.001] and abatacept monotherapy [$HR_{\text{Mono vs. Combination}}$ (95% CI): 1.23 (1.05-1.45), P=0.011] were associated with shorter duration of treatment while home infusions [$HR_{\text{Home vs. Clinic}}$ (95% CI): 0.78 (0.67-0.93), P=0.004] and the presence of a comorbidity [$HR_{\text{Yes vs. No}}$ (95% CI): 0.68 (0.58-0.80), P<0.001] were associated with increased treatment sustainability. When assessing the impact of these parameters on HAQ, only the number of previous biologics was identified as a significant predictor of lower response (P=0.009) after adjusting for potential confounders, with lower number of biologics being associated with improved response [$B_{0 \text{ vs. } \geq 2}$ (SE): -0.12 (0.04), P=0.002; $B_{1 \text{ vs. } \geq 2}$ (SE): -0.05 (0.03), P=0.167].

Conclusion: This real-world analysis identified the number of previous biologics, concomitant DMARD use, infusion location, and presence of comorbidity as independent predictors of abatacept treatment sustainability. The number of previous biologics may be associated with differences in effectiveness as measured by the HAQ whereas the other predictors may be associated with other reasons for discontinuation.

Disease and Treatment Characteristics that Might Influence Long-term Retention with Biologics in the Real-world Clinical Setting: Experience from the Rhumadata Clinical Database and Registry

Background/Purpose: Patient adherence and sustainability of the regimen plays an important role in the long term outcomes. Biologic disease-modifying antirheumatic drugs (bDMARDs) have revolutionized the treatment of rheumatoid arthritis (RA), yet drug discontinuation is common. We aim to investigate factors that might influence long-term retention with biologics in a population-based of real-life unselected RA cohort.

Methods: RA patients (pts) treated with abatacept (ABA) or an anti-TNF inhibitor, adalimumab (ADA), etanercept (ETA), or infliximab (INF) were grouped according to their experience with biologics. Patient characteristics were compared using ANOVA with Bonferroni correction. Kaplan-Meier methods were used to compute the cumulative incidence of drug discontinuation.

Results: The first cohort included 403 pts receiving 1st line biologic (62 ABA, 111 ADA, 195 ETA, 35 INF) and the second cohort included 189 pts on their 2nd biologic (76 ABA, 47 ADA, 47 ETA, 19 INF). 11.9% of pts in the first (14.5% ABA, 8.1% ADA, 14.4% ETA, 5.7% INF) and 25.9% of pts (26.3% ABA, 27.7% ADA, 29.8% ETA, 10.5% INF) in the second cohort were on biologic monotherapy. Approximately 66% (66.7% first; 66.1% second cohort) of pts were rheumatoid factor (RF) positive. Anti-cyclic citrullinated peptide antibodies (anti-CCP) were detected in 62.0% and 55.4% of pts in the first and second cohort, respectively. Neither the RF status nor the use of biologics as monotherapy vs in combination with non-bDMARDs had a significant impact on long term retention. However, retention probability was significantly higher in the first cohort in anti-CCP positive vs negative patients, Figure 1. The anti-CCP positivity did not affect retention in the second cohort. In the second cohort treatment with ABA was associated with significantly higher retention compared to anti-TNFs, Figure 2.

Conclusion: The anti-CCP positivity was associated with significantly higher retention when biologics were used first line. This is important as anti-CCP antibodies are predictors of an aggressive disease. These results are compatible with other registries that indicate that anti-CCP might have an impact on retention rates. There were no significant differences in the retention rates in the first cohort. In the second cohort treatment with ABA was associated with significantly higher retention compared to anti-TNFs.

RA Patients with Medicare Only Insurance Have Similar Clinical Outcomes As Patients with Private Insurance Despite Having Less Access to Biologics

Marcia S. Genta[1], Amnon Sonnenberg[2] and Robert M. Genta[3], [1]Dallas Arthritis Center, Dallas, TX, [2]Medicine - Gastroenterology, Portland VAMC - Oregon Health & Science University, Portland, OR, [3]Laboratory, Dallas Arthritis Center, Dallas, TX

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: We have previously shown that patients with Medicare only coverage without financial assistance from foundations were significantly less likely to receive Biologics than patients with other types of coverage (Genta MS, *Arthr Rheumatol*, 2014;66:10:S39). In that study we did not evaluate disease activity. The purpose of the present study was to determine whether Medicare only patients were less likely to have low disease activity scores than patients covered by other insurance.

Methods: Patients with established RA and DAS28 CRP (DAS) activity score followed in a solo practice were stratified into the following categories, based on their insurance coverage: 1) Medicare only: Medicare, no supplemental insurance, no medication-specific financial support; 2) Medicare Integrated: Medicare with a supplemental insurance (private or public insurances or Medicare part D); and 3) Private only: by a private insurance only with no public coverage. Three treatment groups were considered: DMARDs only; DMARDs and Biologics; and Biologics only. Demographics, median DAS Scores, and disease activity clinical categories were compared by unadjusted Odds Ratios (OR) and by the t test.

Results: Insurance data and DAS were available for 163 patients. The Medicare only group included 52 patients (median age 70 years, range 49-88; 77% women; 9 White, 21 African American and 22 Hispanic). There were 20 patients with Medicare Integrated (age 68, range 46-80; 85% women; 9 White, 8 African American, and 3 Hispanic). Of the 91 patients with private insurance only (age 59 years, range19-89; 79% women) 29 were White, 32 African American, and 30 Hispanic. Thus, Medicare only patients were more likely to be non-White than both other groups (OR 2.49 95% CI 1.10 – 5.64; $p<0.05$). Median DAS scores were similar in the three groups (17, 14, and 20, respectively). Treatment groups and DAS-based clinical categories are summarized in Table 1. Although patients with Medicare only were more likely to be on DMARDs only than patients in the other two groups (OR 2.29 95% CI 1.14 – 4.60; $p<0.02$) they were in a DAS Remission or Low clinical category as frequently as those with other insurance plans who were more likely to receive Biologics with or without DMARDs.

Insurance	DMARD Only (%)	Biologics Only (%)	DMARDs and Biologics (%)	No Therapy (%)	Remission or Low (%)	Moderate or High (%)
Medicare (n = 52)	36 (69)	4 (8)	11 (21)	1 (2)	45 (87)	7 (13)
Medicare+ (n = 20)	7 (35)	5 (25)	8 (40)	0	18 (90)	2 (10)
Private (n = 91)	48 (53)	7 (8)	30 (33)	6 (7)	79 (87)	12 (13)

Conclusion: This study confirms our previous finding that patients with Medicare only are less likely to receive Biologics than those who have other insurances. Nevertheless, in this small sample, it appeared that these patients were not adversely affected by this limitation, as shown by low disease activity and remission rates similar to those with other types of coverage.

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The subcutaneous (SC) formulation of abatacept (ABA) has been available in Canada since January 2014. Here we report first year experience with SC ABA in Canadian RA patients (pts). Canadian guidelines recommend the use of anti-TNFs or other mode of action biologics, including abatacept, after inadequate response to DMARD.[1] Furthermore, the availability of an SC formulation of a biologic increases the treatment options available to pts, particularly those wishing to self-administer their therapy.

Methods: Canadian RA patients who accepted treatment with abatacept (Orencia®) were enrolled in the Orencia® Response Program (ORP) registry. RA pts treated with SC ABA in routine practice between Jan – Dec 2014, were included in this analysis. Durability of treatment with SC ABA was assessed using Kaplan-Meier survival analysis.

Results: As of December 2014, a total of 1152 pts received SC ABA. Out of these, 698 (61%) received SC ABA as the first or second line biologic therapy and 454 (39%) as third or fourth line. The median age of pts prescribed SC ABA was 60 years (range 16-89); 79.3% were females; and the median time since diagnosis for the entire cohort was 11 years. 72% of pts had severe and 23% had moderate disease. The majority of pts received their treatment at home (68%), followed by rheumatology (12%) or ORP clinic (7%). Only 12 (1%) of pts received the treatment at a doctor's office. 12-month persistence rates were similar in biologic naïve and non-naïve patients: 76.7% (SD=3.7%) for pts receiving SC ABA first line (biologic naïve) and 73.6% (SD=2.2%) for biologic experienced (non-naïve pts), Figure 1.

Conclusion: This data demonstrate that SC ABA can be used early in the course of the disease (first or second line biologic therapy) as well as in patients who fail several previous lines of biologics. Treatment with abatacept resulted in high 1-year persistency rates in both biologic naïve pts as well as those who failed one or more previous lines of biologic therapy.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Abatacept (ABA) is a biological anti-rheumatic drug used in Rheumatoid Arthritis (RA). In TURKBIO, Turkish Biologic Registry, data on patient characteristics, diagnosis, previous treatment and outcomes of ABA have been collected since 2011. Drug retention is a useful measure of effectiveness since it combines both clinical response and tolerability. The objective of this study was to investigate the effect of rheumatoid factor (RF) and Anti-Cyclic Citrullinated Peptide (Anti-CCP) positivity on drug survival of ABA in clinical practice for patients with RA.

Methods: By the end of May 2015, 266 patients received intravenous and subcutaneous ABA from 5 participating centers of the TURKBIO registry were included in the analysis. Demographic and clinical data including age, sex, disease duration, drug retention rate and reasons for discontinuation of drug were collected. Kaplan-Meier survival analysis was performed to estimate the drug survival. Subgroups were compared by log-rank.

Results: Of the 266 patients receiving ABA, 83.8% were female and median age was 55.0 years (range: 19.0-81.0). The median disease duration was 9.0 years (range: 1.0 year-53.0 years). 72.6% of were treated with ABA as first line biotherapy (n=193), 21.8% as second line (n=58) and 3.4% as third line (n=9). The rate of RF positive patients was 54.1% and anti-CCP positive was 68.1% among the patients treated with ABA in the registry. Estimated drug survival rates for ABA in 6^{th} month, 1^{st} year and 2^{nd} year were 76.1 %, 65.5% and 52.2% . Median drug survival was 26 months. One-year drug survival of first line and $>1^{st}$ line ABA treatment were 68.7% and 57.9%, respectively (p=0.084). There was a trend for a higher one year drug survival rate among anti-CCP (+) patients as compared to those who were anti-CCP (-) (73.1% versus 56.4%; p=0.087), whereas one-year drug survival rates were very similar for RF (+) and RF (-) patients at 63.4% and 64.8%, respectively (p=0.462) Drug survival curves for RF (+)/(-) and Anti-CCP (+)/(-) groups are given in Figure 1 and 2, respectively.

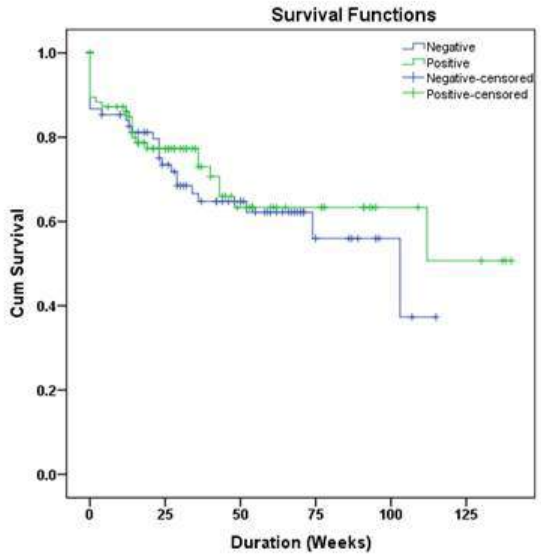

Figure 1. Drug survival curve in RF (+) and (-) patients.

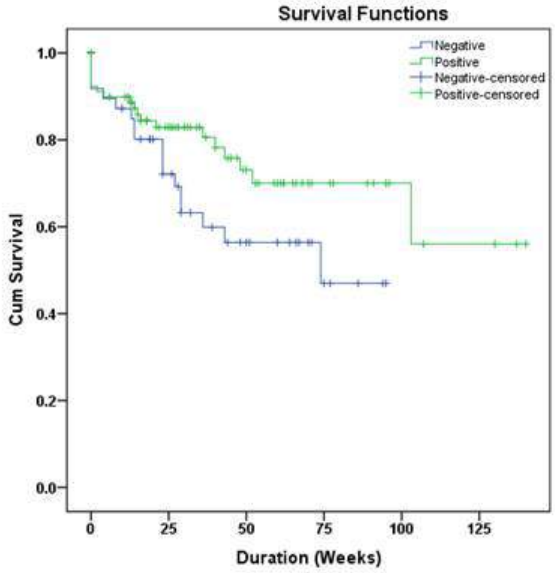

Figure 2. Drug survival curve in anti-CCP (+) and (-) patients

Conclusion: One year drug survival rate of ABA among patients enrolled in the TURKBIO registry is similar to those which has been reported in some other European countries. One year drug survival rates appear to be better among patients who are positive for anti-CCP, but not for RF as compared to those who are negative for the corresponding antibodies, which needs to be explored in future studies.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Rheumatoid arthritis (RA) is characterized by increased cardiovascular risk and metabolic changes including cachectic obesity, insulin resistance, dyslipidemia. DMARDs decrease inflammation and could thus improve cardiovascular risk but their effects on body composition and metabolic profile remain unclear. We investigated the effects of tocilizumab, an inhibitor of the IL6 pathway on body composition and metabolic profile in active RA.

Methods: We conducted an open 1-year follow-up study of 21 patients with active RA treated with tocilizumab. Waist circumference (WC), body mass index (BMI), body composition (dual-energy x-ray absorptiometry), lipid profile, fasting glucose, blood pressure, and arterial stiffness were measured at baseline when started tocilizumab, 6 months and 1 year of treatment. At baseline, RA patients were compared with 21 controls matched for age, sex, BMI and metabolic syndrome. The longitudinal data were explored using a random-effect models. To assess the issue of missing data, the estimation methods developed by Verbeke and Molenberghs were considered in this study.

Results: 21 RA patients, including 16 women with a mean age of 57.8 ± 10.5 years were included. RA duration was 8.5 years [IQR 1.7 – 21.5]. At baseline, 19 patients received a DMARD, 14 steroids, 11 cholesterol-lowering drug, 1 anti-diabetic drug, 6 antihypertensive medication. 18 patients have previously received at least one biologic. The mean DAS 28 at baseline was 4.7 ±1 and decreased significantly at 6 and 12 months (2.92±0.8 and 2.8±1.5 respectively, $p<0.001$). Compared to controls, RA patients had significantly lower total (42.1±11.1 vs 47.5±8.7, $p=0.02$) and appendicular lean mass (17.7±5.4 vs 20.1±3.9, $p=0.03$). During treatment with tocilizumab, no changes for WC, blood pressure, fasting glucose, lipid profile or arterial stiffness were observed. Significant weight gain (61.8±19.3 vs 63.7±16.1 kg $p=0.005$) and BMI (23.6±6.7 vs 24.8±6, $p<0.001$) were observed at 1 year without changes for fat composition. In contrast, lean mass (42.1±11.1 vs 43.2±11.3 Kg, $p=0.01$) and fat free mass index (16.7±3 vs 17.4±3.02, $p=0.01$) increased at 1 year. There was a significant gain in appendicular lean mass (17.7±5.4 vs 18±5.3 and 18.7±5.6 Kg, $p=0.04$ and $p<0.001$ respectively) and skeletal muscle mass index (6.7±1.4 vs 6.9±1.4 and 7.2±1.5, $p=0.03$ and $p<0.001$ respectively) at 6 and 12 months with a significant change between 6 and 12 months ($p=0.017$). Moreover, distribution of the fat was modified during the follow-up. A decrease in trunk/peripheral fat ratio (0.77±0.2 vs 0.7±0.17 $p<0.001$) and an increase in subcutaneous adipose tissue (SAT) (241.3±173.3 vs 264±154.3 $p=0.009$) were observed at 1 year whereas visceral adipose tissue (VAT) and VAT/SAT ratio did not change.

Conclusion:

Despite weight gain during treatment with IL6 inhibitor, no increase in fat but a modification in fat distribution has been observed. In contrast, muscle gain with increase in lean mass at 1 year suggested that blocking IL6 might be efficient in rheumatoid cachexia and sarcopenia.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Very few studies have compare different agents used in the treatment of rheumatoid arthritis (RA) over the very long term. The majority of them have a short duration, are open-label, have selection criteria, and compare outcome measures such as DAS score, DAS improvement, HAQ improvement and so on. Rhumadata, a real-life database and registry, enrols all patients for whom a specific diagnosis such as RA has been made thus enabling comparisons of retention rates in a large population and the analysis of potential predictors of retention. Our objectives are to compare the retention rate of adalimumab and etanercept after DMARDs failure in a population of RA patients and identify potential predictors of retention rate.

Methods: Data of RA patients prescribed either etanercept (ETA) or adalimumab (ADA) as first biologic agent on or after January 1st, 2002 was extracted. The data included age and gender, disease characteristics, clinical variables, patient and physician specific assessments, laboratory measures and composite assessment of disease activity (DAS28-ESR, SDAI and CDAI). All patients were followed until they discontinued their treatment or June 2, 2015, the date at which the data was extracted from Rhumadata®. Secondary diagnoses and comorbidities established at or before the administration of the biologic agents were coded using the ICD-9-CM codes. Infections occurring during treatment, biologic status (ongoing or stopped) and the reasons for biologic cessation were also extracted. The 10-year drug retention rates were estimated and compared using Kaplan-Meier survival estimates and potential predictors were identified using univariate proportional hazard regression models. Statistical analysis was performed using SAS version 9.4.

Results: The data from 548 RA patients (184 prescribed ADA and 364 etanercept) as first biologic agent were extracted from the RHUMADATA® clinical registry and database. The patients were mostly women (74.5%) and had an average age of 53.3(SD=12.8). The patients had an average disease duration of 7.1 years (SD=8.0) and provided 2327.3 person-years of observation. The 10-year retention rates of ADA and ETA were estimated at 27.2% (SD=3.9%) and 35.0% (SD=3.1%) respectively and an overall significant difference in retention rate was observed (log-rank p -value = 0.0031). Inefficacy of biologic was the principal reason for drug cessation (46% in both ADA and ETA) followed by adverse events (14.8% ADA and 11.7% ETA). Univariate proportional hazard models identified the biologic used (HR (ADA vs ETA) = 1.402, 95% CI: 1.120 to 1.755) and fatigue-VAS (HR (per unit increase in fatigue-VAS) = 1.402, 95% CI: 1.120 to 1.755) as significant predictors of retention (alpha=0.05). Concurrent use of nbDMARDs did not however reach statistical significance (HR (combination vs monotherapy) = 1.157, 95% CI: 0.842 to 1.591).

Conclusion: After 10 years of continuous exposure to a first biologic agent, etanercept offers a clinically small but statistically significant advantage over adalimumab in a population of RA patients.

Inefficacy of biologic was the principal reason for drug cessation (46% in both ADA and ETA) followed by adverse events (14.8% ADA and 11.7% ETA).

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Retrospective studies have promoted the idea that RA has become a milder disease over the past decades[i], [ii]. These findings are questionable because of the impact of changing treatment strategies and DMARD use in these studies.

In one rheumatologic center in Germany the strategy to treat all newly diagnosed RA patients (pts) with either MTX or parenteral gold (gold) was established already in the 1970ies and kept constant for more than 20 years. In case of inefficacy or intolerability one treatment was usually replaced by the other. MTX and gold have been shown to be almost equally effective on disease activity and radiographic progression (RP) in early RA[iii]. This provided the unique opportunity to test the hypothesis of a secular trend to milder disease course in almost uniformly treated cohorts from three different decades.

[i] Welsing PMJ et al. Arthritis Rheum 2005;52:2616–24

[ii] Sokka T et al. J Rheumatol 2004;31:1073–82

[iii] Rau R et al. Br J Rheumatol 1998;37:1220-6

Methods:

All pts first presenting in the center in the years 1978-1980, 1990 and 2000 with early (< 3 yr) physician confirmed RA were followed radiographically in regular intervals. ESR and RF status were available. Hand and feet radiographs from baseline and 1 and 3 years follow up were read with the Ratingen Score (RS) (range 0-190). Multiple regression

analysis (MRA) was performed with age, gender, belonging to one of the three cohorts, disease duration, RF status, baseline radiographic score and the first DMARD as possible influencing factors on RP.

Results:

Baseline demographics, disease characteristics, mean RS and mean annual RP in 1styear of the three cohorts are given in Table 1.

Table 1

Cohort (year)	n	Age (StD)	Gender, % female	Dis. Duration months (StD)	ESR mm/h (StD)	% RF-positive	Baseline RS (StD)	RS – Annual Progression 1st yr (StD)
1978-80	84	54.2 (± 9.2)	82.1	13.5 (±10.7)	31 (±22)	54,8	4.68 (±3.97)	1.75 (±2.15)
1990	47	58.2 (±10.7)	72.3	10.0 (± 7.0)	33 (±18)	80.9	5.00 (±3.74)	1.53 (±1.56)
2000	75	60.1 (±10.4)	72.0	8.8 (± 8.0)	37 (±19)	86.7	3.30 (±2.80)	1.52 (±1.47)

The results of the MRA are displayed in Table 2

Table 2

Variable	Parameter Estimate	Standard Error	t-Value	Pr> |t|
Intercept	-0.09621	0.12189	-0.79	0.4309
Age	0.00102	0.00170	0.60	0.5496
Cohort	-0.01948	0.02662	-0.73	0.4651
Gender	0.07271	0.04790	1.52	0.1306
Disease Duration	0.00106	0.00171	0.62	0.5366
RF Status	0.11064	0.04709	2.35	0.0198
RS at Baseline	0.02737	0.00449	6.09	<.0001
Gold as 1st Treatment	0.01697	0.05035	0.34	0.7365
MTX as 1st Treatment	0.03296	0.06115	0.54	0.5905

After MRA the increase of the RS did not differ between the cohorts (p=0.5496) with the RS at baseline (p <0.0001) and RF status (p = 0.0198) being the only parameters that showed a significant impact on radiographic progression.

Conclusion:

As almost all pts were treated with either one of two equally effective agents irrespective from the date of their first presentation, one may assume that RP was equally influenced by DMARD therapy in all three cohorts. A shift towards milder disease course over two decades would have led to less progression in the later cohorts compared to the early 1978-80 cohort. In contrast we found RP to be almost constant over time. The much better performance of many pts with early RA in recent years compared to the past is therefore most probably explained by more and better treatment options now available to most pts and that the concept of treat to target in early RA that has become widely accepted by rheumatologist.

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Methotrexate (MTX) is known as an anchor drug for the treatment of rheumatoid arthritis (RA), and MTX-associated lymphoproliferative disorders (MTX-LPD) is of current interest. However, clinical course and optimum therapies in the patients with MTX-LPD remain uncharacterized.

Methods:

We enrolled RA patients who had been diagnosed as LPD during MTX therapy from January 2009 to December 2014. Baseline data including age, sex and duration of RA and MTX treatment were collected. Histopathological diagnosis, Epstein–Barr encoding region (EBER) *in situ* and serum EB virus (EBV) DNA were assessed. We evaluated the relationship between the characteristics and clinical outcome of LPD. We also described the clinical course and the treatment for RA after the diagnosis of MTX-LPD.

Results:

Twenty-two patients (17 female and 5 male) were enrolled in this study. The age at the diagnosis of LPD was 68.4 ± 9.0 years and they were treated for 15.5 ± 14.7 years and under the treatment of MTX for 80.6 ± 80.2 months. Biopsy was performed in 18 patients, and 10 of them (55.6 %) were diagnosed as diffuse large B cell lymphoma and 2 as marginal zone B cell lymphoma. EBER *in situ* was positive in 10 of 17 patients (58.8%), and the serum EBVDNA was detected in 8 of 11 (72.7%). MTX was withdrawn immediately after the diagnosis of LPD in all cases. The withdrawal resulted in the remission of LPD in 18 cases (81.8%, non-chemotherapy group), whereas 4 cases required chemotherapy (chemotherapy group). Serum EBVDNA was positive in all patients of non-chemotherapy group, while negative in all of chemotherapy group (p= 0.0003). The positive rate of EBER *in situ* was not significantly different between two groups (61.5 % vs. 50.0%, p=0.682). Age and the duration of MTX treatment were comparable whereas the history of RA was significantly longer in chemotherapy group than in non-chemotherapy group (29 years vs. 13 years, p= 0.0035). After the diagnosis of LPD, they were treated for 37.3 ± 22 months, and the relapse or exacerbation of RA was observed in 13 patients (61.9 %) after 9.2 ± 10 months. Nine patients were treated with various biologic agents, excluding rituximab, for RA relapse. The eight of nine patient sustained LPD remission after treatment with biologic agents; however one case was diagnosed as angioimmunoblastic T cell lymphoma and experienced recurrence of LPD during tocilizumab (TCZ) therapy. She was treated with chemotherapy. TCZ was switched to other biologic

agents, and no recurrence of LPD was observed. There was no difference of the duration of RA and the positive rate of EBER and EBVDNA between patients with and without RA relapse after LPD diagnosis.

Conclusion:

The present study revealed that the positivity of serum EBVDNA was useful to predict the better clinical outcome of MTX-LPD. There was no established evidence of biologic therapies in RA patients with MTX-LPD but they seem to be effective and rather safe for most of RA patients after MTX-LPD diagnosis.

Biologic Therapy Treatment Complications in the Alberta Aboriginal Population with Rheumatoid Arthritis

Background/Purpose: Aboriginal people with rheumatoid arthritis (RA) have more severe disease and an increased number of comorbid conditions, which may result in higher rates of adverse events when using biologic therapy.

Methods: The Alberta Biologics Pharmacosurveillance Program (ABioPharm) is a longitudinal RA cohort study, linked to population-based administrative databases (physician claims and hospitalizations). We calculated incidence rate ratios (IRR) for adverse events comparing Aboriginal to non-Aboriginal groups, including all-cause hospitalization, serious infections, malignancy (lung, breast, colorectal, lymphoproliferative), cardiovascular events (myocardial infarction, congestive heart failure, cerebrovascular disease), thromboembolic events and death, using Poisson regression to adjust for age at biologic start, low socioeconomic status, urban vs rural residence, comorbidities (Deyo-Charlson), number of rheumatologist visits, history of joint replacement surgery, extra-articular features, baseline DAS28, baseline HAQ, number of previous DMARDs, steroids at baseline visit, and standardized for age and sex.

Results: The cohort includes 1,545 patients (n=83 Aboriginal) with a total of 8,145 person-years of follow-up. Aboriginals were younger at initiation of the first biologic (50 vs 55 years), with more comorbidities, higher baseline DAS28ESR scores (mean 6.11 vs 5.19) and slower rates of improvement for tender and swollen joint counts in the first

year of treatment. Aboriginals had a higher risk of all-cause hospitalization (IRR 1.4, 95%CI 1.1 to 1.8, p=0.01), malignancy (IRR 2.6, 95%CI 1.1 to 5.7, p=0.02) and thromboembolic events (IRR 2.7, 95%CI 1.7 to 4.2, p<0.001). They also had higher risk of serious infections (IRR 3.2, 95%CI 2.5 to 4.0, p<0.001), with significantly more episodes of skin and soft tissue infections (IRR 3.8, 95%CI 1.5 to 9.6), osteomyelitis (IRR 6.6, 95%CI 1.8 to 25.1) and pyelonephritis (IRR 8.4, 95%CI 2.0 to 35.3). Aboriginal patients were similar to non-Aboriginal patients in the risk for cardiovascular events (IRR 0.7, 95%CI 0.5 to 1.1, p=0.03). The mortality rate was 0.7 per 100 person-years in the non-Aboriginal group, with no deaths in the Aboriginal group.

Conclusion: Aboriginal patients experience higher rates of all-cause hospitalization, serious infections, malignancy and thromboembolic events, but not cardiovascular events, during treatment with biologic therapy. These findings are important to inform treatment decisions to initiate biologic therapy in Aboriginal patients, and the need for frequent monitoring during therapy.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Given the improved detection of joint injury by MRI than by clinical examination, EULAR recommendations for the use of imaging of the joints in the clinical management of RA states that MRI is useful in monitoring disease activity. However, there are few clinical investigations searching whether MRI findings are even helpful to consider radiographic progression in RA patients who achieved in sustained clinical good response. The present study is to examine whether MRI findings at baseline are useful to predict subsequent radiographic progression in early-stage RA patients who achieves in sustained clinical good response.

Methods: This is a sub-analysis from the 1-year observational study from 76 early-stage RA patients recruited consecutively from Nagasaki University Early Arthritis Cohort in which the subjects received Gd-enhanced MRI of both wrists and finger joints. They gave their informed consent to be subjected to the protocol that was approved by the Institutional Review Board of Nagasaki University. All patients had been received DMARDs during 1 year after entry. The sustained clinical good response was defined by decrement of DAS28 ≥1.2 at 3 months as well as achievement of DAS28 remission through 6 months to 1 year. Synovitis, bone oedema and bone erosion determined by Gd-enhanced MRI were scored by OMERACT-RAMRIS. Plain radiographic damage was studied by Genant-modified Sharp score and the radiographic progression was defined as Δ progression > 0 at 1 year (Δ score > 0). We have investigated whether MRI findings are helpful to predict subsequent radiographic progression in the sustained clinical good responders.

Results: Twenty-four patients were classified as sustained clinical good responders and examined in the present study. Median age, disease duration were 56 y.o, 2.0 months and median DAS28-CRP, CRP (mg/dl), MMP-3 (ng/ml) were 4.40, 0.52 and 87.2, respectively. Rate of ACPA-positive and RF-positive were 91.7 and 83.3%. Median RAMRIS synovitis, bone edema, bone erosion score and Genant-modified Sharp score at baseline were 6, 0.5, 0 and 0, respectively. Among the 24 sustained clinical good responders, five patients developed radiographic progression at 1 year. Multivariate logistic regression analysis has identified that baseline RAMRIS bone erosion score (1 increase, Odds ratio 3.00, 95% C.I. 1.10-8.20, *p*-value 0.032) is the only independent predictor toward the development of radiographic progression at 1 year. In addition, cut-off point 0.5 of baseline MRI bone erosion score showed the best discriminative value toward radiographic progression (sensitivity 100.0%, specificity 73.7%).

Conclusion: Our present data suggest that MRI bone erosion involves in subsequent radiographic progression of early-stage RA even successfully treated by treating RA to target (T2T) strategy. Physicians are recommended to pay attention to the presence of MRI bone erosion in these patients.

Clinical Factors, Anti-Citrullinated Peptide Antibodies and MRI-Detected Subclinical Inflammation in Relation to Progression from Clinically Suspect Arthralgia to Arthritis

H.W. van Steenbergen[1], L. Mangnus[2], M. Reijnierse[3], T. W. J. Huizinga[1] and A.H.M. van der Helm- van Mil[2], [1]Leiden University Medical Center, Leiden, Netherlands, [2]Rheumatology, Leiden University Medical Center, Leiden, Netherlands, [3]Radiology, Leiden University Medical Center, Leiden, Netherlands

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with Clinically Suspect Arthralgia (CSA) have, according to their rheumatologists, an increased risk on rheumatoid arthritis (RA), but their actual outcome is unexplored. This longitudinal study investigated (1) progression from CSA to clinically detectable arthritis and (2) associations of clinical factors, serological factors (among which anti-citrullinated peptide antibodies (ACPA)) and MRI-detected subclinical inflammation with arthritis development.

Methods: 150 CSA-patients were followed ≥6 months. At baseline, clinical and serological data were collected and unilateral 1.5T-MRI of MCP, wrist and MTP-joints was made. MRI-scoring was done according to the RA MRI scoring system. Subclinical MRI-inflammation was defined based on MRI-results of 193 symptom-free persons.

Results: During follow-up (median=75 weeks, interquartile range=40-106 weeks), 30 patients developed clinical arthritis; 87% did so <20 weeks after inclusion. In multivariable analyses, age, localisation of initial symptoms in small and large joints (compared to small joints only), CRP-level, ACPA-positivity and subclinical MRI-inflammation significantly associated with arthritis development; ACPA and MRI-inflammation were most strongly associated (hazard ratio (95% confidence interval) respectively, 6.43 (2.57-16.05) and 5.07 (1.77-14.50)). After 1-year follow-up, 31% of the patients with MRI-inflammation and 71% of the ACPA-positive patients with MRI-inflammation had progressed to arthritis. Forty-three percent of the patients that developed arthritis within 1-year were ACPA-negative; 78% of them had subclinical MRI-inflammation at baseline. When MRI-inflammation was absent arthritis development was infrequent (6% in all CSA-patients and 3% in ACPA-negative CSA-patients).

Conclusion: Subclinical MRI-inflammation precedes clinical arthritis with a few months. Subclinical MRI-inflammation is, independent of other factors such as ACPA, associated with arthritis development.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Despite high clinical disease activity measured by joint counts and global assessments, some patients with active

rheumatoid arthritis (RA) have normal acute-phase reactant (APR) values. This group of patients may have less aggressive disease or may represent earlier phase of the disease, but clinical outcomes of these patients were not previously explored.

We aimed to determine the clinical outcomes of patients with clinically active RA but has normal APR values.

Methods:

Of 2,583 patients with RA enrolled in the KORean Observational study Network for Arthritis (KORONA) registry, 400 patients who had Clinical Disease Activity Index (CDAI) score of >2.8 at baseline, biologic-naïve, and ESR and CRP drawn at both baseline and two-year follow-up visits were identified. Patients were grouped according to baseline APR levels; neither elevated ESR nor CRP (normal APRs), either ESR or CRP elevated (one APR-positive), and both elevated ESR and CRP (both APRs-positive).

Results:

Of patients with active RA, 39% had normal APR; 27% were one APR-positive; only 34% had both APRs-positive. Baseline tender and swollen joint counts, CDAI and HAQ-DI scores were significantly lower in normal APRs group compared with APRs-positive groups ($p<0.0001$). However, mean disease duration was not significantly different between 3 groups. At two-year follow-up, mean DAS28 scores were lower in normal APRs group ($p<0.0001$), and CDAI scores showed trend toward lower values ($p=0.062$). Patients with normal APRs were less likely to use glucocorticoids and biologics. Although remission rate was comparable in 3 groups when measured by CDAI, DAS28 remission rate was significantly in higher normal APRs group.

Conclusion:

Active RA patients with normal APRs have milder disease, better clinical outcomes and require less aggressive treatment compared with APRs-positive patients. Composite disease activity measures which do not include APRs should be considered for monitoring disease activity in patients with normal APRs because disease activity indexes including APRs in its scoring result in underestimation of their disease activity.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: ACR and EULAR published new classification criteria for RA in 2010, aiming for early identification of patients at risk of developing persistent and erosive arthritis. Ultrasonographic examination (US) yields information on inflammation in joints and tendons in RA. Our aim was to investigate whether US inflammation, as well as clinical measures of inflammation, were different in disease modifying anti-rheumatic drug (DMARD) naïve patients fulfilling only the 2010 ACR/EULAR criteria compared to patients fulfilling both the 2010 ACR/EULAR and the 1987 ACR classification criteria for RA.

Methods: RA patients (n=235) who fulfilled the 2010 ACR/EULAR classification criteria were recruited between 2010 and 2013. All patients had symptom duration from first swollen joint < 2 years and were DMARD-naïve with indication for DMARD treatment. US inflammation was evaluated as grey-scale (GS) synovitis and vascularization assessed by power Doppler (PD) in 32 joints by a standardized protocol, with range 0-3 for each joint (1). Clinical inflammation was assessed by 44 swollen joint count, Ritchie Articular Index (RAI), erythrocyte sedimentation rate (ESR) and the Disease Activity Score (DAS). Disease characteristics were compared between the groups using chi-square test, t-test and Mann-Whitney U-test as appropriate.

Results: The 235 patients included had mean (SD) age 51.4 (13.7) years, median disease duration [25, 75 percentiles] 5.7 [2.8, 10.2] months, 62.1% were female, and 81.3% were positive for anti-citrullinated protein antibodies (ACPA). Inflammation assessed by DAS, ESR and US was significantly higher in patients fulfilling both the 1987 and 2010 criteria, compared to patients only fulfilling the 2010 criteria (Table). There was no significant discrepancy in gender distribution, age, disease duration or the proportion of ACPA-positive individuals when comparing the two groups.

Conclusion: Patients with early RA fulfilling only the new 2010 ACR/EULAR criteria had less severe disease, both clinically, biochemically and assessed by ultrasonography, compared to patients fulfilling both the 1987 ACR criteria and the 2010 ACR/EULAR criteria. This may reflect the change in treatment strategies that has occurred over time, with earlier initiation of DMARD treatment. Long-term outcomes of function and morbidity are needed to understand the potential shift in the RA construct caused by the implementation of the new classification criteria.

Table: Disease characteristics in patients fulfilling only the 2010 ACR/EULAR classification criteria versus both the 1987 ACR and the 2010 ACR/EULAR classification criteria.

	Patients fulfilling only the 2010 ACR/EULAR criteria n=77	**Patients fulfilling both the 2010 ACR/EULAR criteria and the 1987 ACR criteria n=158**	***p*-value**

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The window of opportunity concept states that there are superior clinical responses and the potential for remission, when patients with rheumatoid arthritis (RA) are managed earlier and aggressively with disease modifying anti-rheumatic drugs (DMARD). Benefits will be achieved if patients follow prescribed treatment reasonably close. **Objectives** of the study were to investigate whether timing of first non-persistence period and/or duration of persistence with DMARD during the first 4 years of follow-up predicted disease outcomes at the 5th year, in a cohort of early RA patients initiated in 2004 and to identify additional outcome´s predictors.

Methods: Up to February 2015, charts from 107 patients with at least 5 years of follow-up and prospective 6 month-apart assessments of disease activity, of disability and of persistence were reviewed. Non-persistence was defined as omission of at least one DMARD and/or corticosteroids for at least seven consecutive days; regarding methotrexate, one weekly missing dose was considered non-persistence. Persistence was recorded through an interview (up to 2008) and thereafter through a questionnaire; persistence duration was recorded in months. Treatment modifications because adverse events and/or indicated by a physician for any reason were not considered under non-persistent construct. At the 5th year, disease activity was defined according to disease activity score on 28 joints (DAS28) and disability according to health assessment questionnaire (HAQ); both were derived as the mean of corresponding individual scores from all the visits performed during the 5th year. Descriptive statistics and linear and Cox regression analyses were used. All the patients signed informed consent.

Results:

At study entry, patients were more frequently middle-aged (39.1±13.3 years) female (88.8%), with high disease activity and disability; more than 80% had autoantibodies. Over the first 4 year´s follow-up, 54.2% of the patients were indicated oral corticosteroids and all traditional DMARDs. Almost 70% had at least 1 period of non-persistence and their follow-up (median, 25-75 quartiles [25Q-75Q]) to 1st non-persistence period was 13 months (1-31).

Gender, baseline DAS28 and persistence duration predicted DAS28 at the 5th year, and the strongest impact was due to months of persistence. Also, age and persistence duration predicted HAQ at the 5th year. When model were applied in female subpopulation, persistence duration still a predictor of subsequent outcomes.

During the 5th year, 68 patients (56 women) achieved sustained remission (DAS28 below 2.6); in females (N=56, 83%), baseline DAS28 (OR: 0.65, 95% CI: 0.50-0.83, p=0.001) and persistence duration (OR: 1.04, 95% CI: 1-1.08, p=0.05) were its predictors. Also, 84 patients achieved sustained function (HAQ below 0.21) and baseline DAS28 and age were the only predictors. Timing of first non-persistence period did not impact outcomes.

Conclusion: Persistence duration with DMARDs within the first 4 years of the disease predicted subsequent favorable outcomes in early RA patients; additional predictors were younger age, male gender and lower disease activity at diagnosis.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

The 2010 ACR/EULAR classification criteria for rheumatoid arthritis (2010 RA criteria) facilitate early classification of rheumatoid arthritis (RA). The criteria yield a score ranging 0-10, with the cut-off for definite RA set at 6 or more points. In general, diagnostic certainty increases with an increasing number of criteria points. Our objective was to study the 2-year outcome in a cohort of patients (pts) with very early arthritis fulfilling the 2010 RA criteria at baseline, according to the contribution from the 4 different criteria components (joint involvement, serology, acute phase reactants, duration).

Methods:

1118 pts (age 18-75 years) with arthritis of maximum 16 weeks' duration were included in the NOR-VEAC (Norwegian Very Early Arthritis Clinic) study from 2004 to 2010. All pts who fulfilled the 2010 RA criteria at baseline and had follow-up data were included in the current analyses. Two clinical outcome groups were defined: "Persistent disease" (pts prescribed with DMARDs, with a final clinical diagnosis of RA and/or one or more swollen joints at last visit) and "self-limiting arthritis" (no DMARD use ever, final clinical diagnosis not RA and no swollen joints at last visit). The association between the components of the 2010 RA criteria and outcome was examined by univariable and multivariable logistic regression. Additionally, we performed subgroup analyses in the pts with only 6 criteria points.

Results:

Of the 256 pts fulfilling the 2010 RA criteria (age 52.8±13.9 years, 63.3% females, median (25-75 perc.) duration of joint swelling 63.5 (40.0-83.0) days, 57.4% anti-CCP positive, DAS28 5.2±1.3), 36 had self-limiting arthritis. The pts with self-limiting vs persistent disease more often had 5 joint involvement points (77.8 vs 55.9%, p=0.013), 0 serology points (63.9 vs 24.5%, p<0.0005) and 0 duration points (47.2 vs 22.3%, p=0.002). Multivariable logistic regression showed that absence of serology points (OR 4.7, [2.2-10.1]) and duration points (OR 2.4, [1.1-5.1]) were independent predictors of self-limiting arthritis.

A total of 66 pts had only 6 criteria points, and 52.8% (19/36) of the pts with self-limiting arthritis belonged to this group. When the 6 points consisted of 5 joint involvement points and 1 acute phase point, 43.3% had self-limiting arthritis, as opposed to 16.7% for other 6-point combos (p=0.017). Pts with an additional duration point (5 joint involvement points, 1 acute phase point and 1 duration point) less frequently had self-limiting arthritis (19.5 vs 43.3%, p=0.03).

Conclusion:

In this study of 256 pts fulfilling the 2010 RA criteria at baseline, we found that not having a duration point or any serology points were associated with self-limiting arthritis. Pts with 6 criteria points made up by 5 joint involvement points and 1 acute phase point had a high likelihood of having self-limiting arthritis during the 2-year follow-up.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

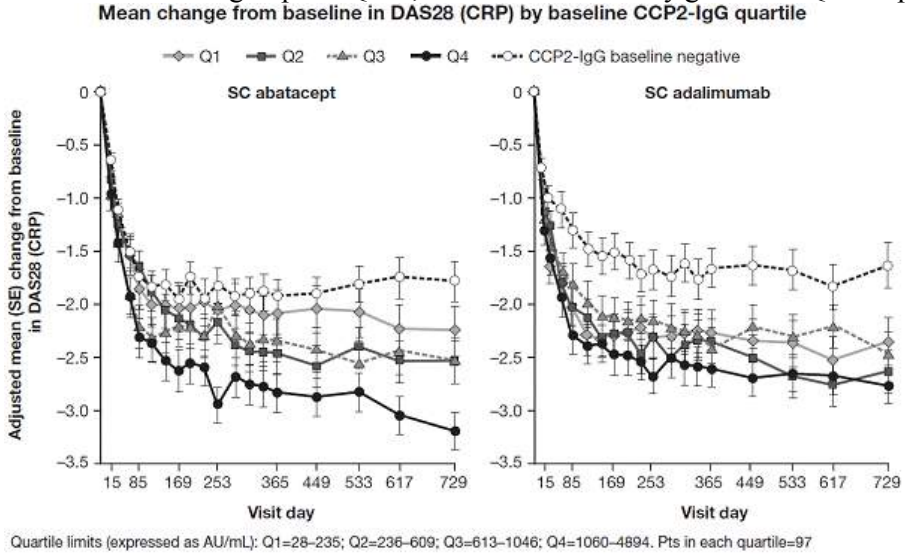
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: In patients (pts) with RA, the predictive value of baseline (BL) titers of anti-citrullinated protein antibodies (ACPA), a known biomarker for RA and disease progression,[1,2] on treatment outcomes is not well understood. In this *post hoc* analysis of the AMPLE study,[3] we assessed the efficacy of SC abatacept (ABA) and adalimumab (ADA) in pts with different BL levels of anti-cyclic citrullinated peptide 2 (CCP2) antibodies (a surrogate for ACPA).

Methods: Pt samples were analyzed by anti-CCP2 immunoglobulin (IgG) ELISA[4] and efficacy outcomes were assessed in positive pts divided into equal quartiles (Q) based on BL titer. Q1–Q4 represent increasing titers of anti-CCP2 antibody. Efficacy outcomes analyzed by Q were: mean change from BL in DAS28 (CRP) and HAQ-DI over time, and remission rates in terms of CDAI, SDAI, and DAS28 [CRP] <2.6-defined remission. Mean change from BL was determined by analysis of covariance, with treatment and DAS28 (CRP) stratification as factors, and BL values as a covariate. Data are also presented for change from BL in DAS28 (CRP) over time in pts who were anti-CCP2 antibody negative at BL. **Results:** There were 97 pts per Q. The numbers of pts per treatment group in each Q were (ABA, ADA): Q1=42, 55; Q2=51, 46; Q3=46, 51; Q4=46, 51. Overall BL characteristics were generally comparable, with no discernible pattern across Qs and treatment groups. For example, pts in ABA Q4 and ADA Q2 had numerically higher DAS28 (CRP) but lower HAQ-DI scores than pts in other Qs. For ABA, mean improvements from BL in DAS28 (CRP) and HAQ-DI were greater in the highest titer anti-CCP2 Q compared with the other Qs. The 95% CI of these measures for the highest and lowest titer Q did not overlap. There was no apparent association between these efficacy measures and BL anti-CCP2 titer in the ADA group. Adjusted mean change from BL in DAS28 (CRP) over time by BL anti-CCP2 Q, including pts anti-CCP2 negative at BL, is shown in the Figure. Reductions in DAS28 (CRP) and HAQ-DI by Year 2 were generally comparable in Q1–3 in both ABA and ADA groups. Remission rates across all indices were broadly similar in ABA and ADA groups in Q1–3, but were numerically greater in Q4 compared with Q1–3 in the ABA group only.



Conclusion: Higher titer anti-CCP2 antibody at BL is correlated with better efficacy in pts from the AMPLE study treated with abatacept, but not with adalimumab.[5]

Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

The current paradigm of optimal clinical management of patients with rheumatoid arthritis (RA) recommends reaching a

state of remission or low activity of the disease, assessed by composite indexes of activity, by means of a tight control and a dynamic adjustment of available therapeutic options, using a "treat to target" strategy. The aim of this work is to assess the level of implementation of the "treat to target" strategy and other parameters of medical quality in clinical records (CRs) of RA patients in Spanish rheumatology departments.

Methods:

Adult RA patients fulfilling 2010 ACR-EULAR criteria for RA and diagnosed between January 1st, 2010 and December 31st, 2013 in Spanish rheumatology departments were included. From every centre, 19 patients were randomly chosen from a computerized anonymized list provided by every department. Independent auditors assessed the CRs, verifying the fulfilling of the quality criteria included in an assessment tool specifically developed for this project. The study was approved by the ethic committees of every participant hospital. Descriptive statistics were used for the presentation of the results.

Results:

A total of 254 CRs from 14 rheumatology departments were included. An explicit assessment of the disease activity as a determinant element considered to choose the therapy was recorded in 32% of the CRs. An optimal escalation of methotrexate dose was registered in 77% of the cases. Use of a composite disease activity score (DAS28, SDAI, CDAI) was reported in 88% of the cases. Disease activity monitoring every 6-8 months after reaching the therapeutic target was recorded in 57% of the cases. In 96 % of the cases, the clinicians had registered patient´s comorbidities and these associated conditions had been considered in planning the therapeutic approach and objective. In only 3.8 % of the CRs, visits every 4 weeks using a composite activity score had been reported during the early stage while trying to reach remission after diagnosis. Starting a DMARD in the first two weeks after diagnosis was recorded in only 30 % of the cases.

Conclusion:

Currently, the implementation of the “treat to target” strategy is scarcely registered in clinical records of patients diagnosed with RA in Spanish rheumatology departments.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I

Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Methotrexate (MTX) use has been associated with reduced cardiovascular morbidity and mortality in patients with rheumatoid arthritis (RA). Although MTX has anti-inflammatory effects, there is little evidence to support additional salutary effects on markers of cardiovascular risk such as blood pressure (BP) and arterial wave reflection (augmentation index, AIx), an indirect marker of arterial stiffness. Observational studies have suggested a lower systolic BP (SBP) in MTX users, approximately 3 mmHg, but it is unknown whether this is independent of anti-inflammatory effects. Thus, the purpose is to investigate associations between MTX, SBP and AIx in RA patients.

Methods: Using a cross-sectional study design, a total of 86 patients with RA (diagnosed using the 2010 American College of Rheumatology criteria) were recruited from rheumatology outpatient clinics at Flinders Medical Centre and Repatriation General Hospital, Adelaide, Australia. Participants were classified according to MTX exposure: MTX and non-MTX (defined as off MTX for >1 year or MTX naïve).

Results: There were 56 MTX (70% female; mean age 61 years) and 30 non-MTX patients (76% female; mean age 63 years). After adjusting for age, mean ±SD clinical SBP was significantly lower in MTX patients (124±1.9 mmHg, $p<0.001$) compared to non-MTX patients (131±2.9 mmHg, $p<0.001$). There were similar differences for central SBP 115 ±1.9 vs. 122 ±3 mmHg, $p<0.001$). MTX use was also associated with lower AIx (28%, 95% CI= 25.7, 29.9 vs. 31%, 95% CI= 27.5, 34.5, $p< 0.001$). Changes in the global inflammatory marker (ESR) and disease activity score (DAS28) and anti-CCP were not significantly associated with clinical SBP ($p=0.80$, 0.79 and 0.65) or AIx ($p=0.86$, 0.76 and 0.051), respectively. Changes in the short-term inflammatory marker CRP were associated with SBP ($\beta=0.42\pm0.17$, $p=0.02$), but not AIx ($\beta=0.86\pm0.1$, $p=0.37$).

Conclusion: Our findings show that the use of MTX is associated with lower systolic blood pressure, which is associated with reduced inflammation. The lower arterial wave reflection in MTX patients was independent of changes in inflammation.

Trends in the Use of Opiates in Rheumatoid Arthritis (RA) Compared to Non-RA: A Population Based Study in 2003-2012

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Opiates are often used to treat difficult to manage pain, however, little is known about the trends of use for opiates in a modern cohort of patients with rheumatoid arthritis (RA). We aimed to evaluate the use of opiates in patients with RA compared to non-RA subjects.

Methods: Retrospective prescription data was examined from 2003-2012 in well-defined population-based incidence cohort of patients with RA by 1987 ACR criteria in 2003-2007 and age/sex matched to non-RA subjects. Any opiate use was defined as one or more prescriptions in the study period and chronic use was defined as 60 days or more of prescribed opiates (at usual dose and usual schedule) in a 6 month period; or those subjects using fentanyl, methadone and controlled/sustained release oxycodone. Disease severity indicators used were RF/ACPA positivity, rheumatoid nodules and erosions in the first year, male sex, and ESR values. Poisson models and age and sex adjusted Cox models were used to examine differences in opiate use between the cohorts.

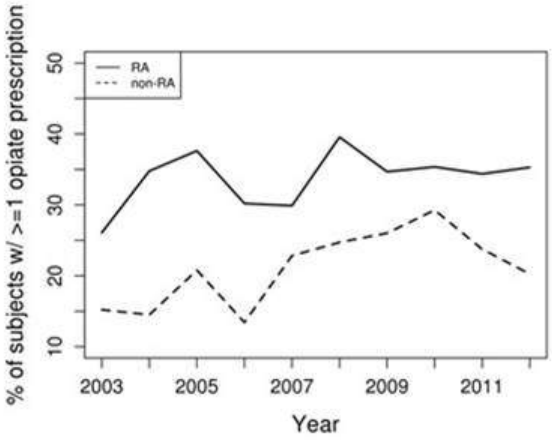
Results: A total of 404 subjects (202 pairs; 69%female) were included in the study with a mean age of 55 ± 15.7 and a mean follow-up date of 6.5 ± 2.4 years. The most frequently prescribed opiate in our study was oxycodone (40%) followed by hydrocodone (20%).

Opiate use (any) was high in both cohorts (35% RA vs 20% non-RA in 2012). Patients with RA had a 54% higher rate of opiate use compared to non-RA subjects (rate ratio {RR}: 1.54; 95% confidence interval {CI}: 1.36, 1.74; Fig. 1a). Chronic opiate use was also common in both cohorts (11% RA vs 7% non-RA in 2012). Patients with RA had a 70% higher rate of chronic opiate use (RR: 1.70; 95% CI: 1.15, 2.53) compared to non-RA subjects (Fig. 1b).

The rate of chronic opiate use increased in both cohorts by 11% per year with no apparent difference in time trends between the cohorts (interaction p=0.46). Women in both cohorts were more likely to be chronic opiate users than men (Hazard ratio [HR]: 1.82; 95% CI: 1.01-3.29). Compared to non-RA subjects, chronic opiate use was higher in younger patients with RA (age 18-49; 3.4% RA vs. 0.5% non-RA), we saw no difference in those over 65 years of age (interaction p=0.007), and a numerically intermediate risk in those 50 to 64. The only marker of disease severity and chronic opiate use was presence of rheumatoid nodules (HR: 1.95; 95% CI: 1.00-3.81).

Conclusion: Opiate use is common. Throughout the study period, rates of any opiate use remained stable but were always significantly higher in patients with RA than those without RA. However, rates of chronic opiate use increased in both cohorts over time and were consistently higher in patients with RA, especially among younger patients and women. In RA, opiate use was generally not related to disease severity indicators suggesting an alternate pain generating pathway.

A. Percentage of rheumatoid arthritis (RA) and non-RA subjects with any opioid prescription according to calendar year



B. Percentage of rheumatoid arthritis (RA) and non-RA subjects with chronic opiate use according to calendar year

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Based on international task force recommendations, the primary goal of rheumatoid arthritis (RA) treatment is to: achieve control of symptoms to greatest extent possible, prevent progression of structural damage, and normalize functional status and social participation (1). A Current definition of comprehensive disease control (CDC) defined as DAS28 (CRP) <2.6, HAQ DI <0.5, D mTSS (modified Sharp score) ≤0.5 has been assessed using data from three clinical trials (DE019, PREMIER and OPTIMA) (2). The objective of this study was to examine the potential incremental benefit of achieving CDC using real world data from Corrona, a large observational RA registry in the USA. Because there were not enough patients who achieved remission but not CDC, data were assessed for patients who achieved CDC compared to those achieving LDA but not CDC, using various measures of LDA.

Methods: RA patients ≥18 years of age in moderate/high disease activity (CDAI>10) with available CDAI, mHAQ and data on new radiographic progression at index visit and at 6m were included, regardless of disease modifying anti-rheumatic drug (DMARD) therapy status. Corrona patients were classified as achieving CDC vs not achieving CDC based on a previously constructed model including age, gender, disease activity index (CDAI), modified health assessment questionnaire (mHAQ) and presence of any new radiographic progression. Patient characteristics at index visit and 6m were compared between predicted CDC achievers and non-achievers but in LDA as defined by other measures like CDAI, DAS28-CRP, mDAS and RAPID3.

Results: There were 1627 patients who met the inclusion criteria of which 20% were CDC achievers (n=331) and 80% non-achievers (n=1296). CDC achievers had significantly lower patient reported pain, fatigue, presence of morning stiffness at baseline, 6m and greater change from baseline. In addition, fewer CDC achievers reported quality of life problems at 6m from baseline compared to cohorts who achieved LDA (defined by CDAI, DAS28-CRP, and mDAS) (**Table**). However same degree of differences in work status, patient pain and fatigue and quality of life measures were not seen in the cohort achieving LDA defined by RAPID3. Patients who achieved LDA (RAPID3) reported lower patient reported pain and fewer patients were disabled at 6m when compared to the CDC achievers. (**Table**).

Conclusion: In this real world analyses, patients who achieved CDC had significant improvement in clinical, structural and functional efficacy outcomes at 6 months compared to the patients who did not achieve CDC but were in LDA defined by CDAI, DAS28-CRP, or mDAS with the exception of RAPID3, where we observed better outcomes for certain patient reported measures. Further studies to assess incremental value of CDC over remission will be valuable.

Clinical Disease Activity Measures Change Substantially and Irregularly over Time in Individual Rheumatoid Arthritis Patients Considered to be in Steady State

Ole Rintek Madsen[1,2] and Emilie Lund Egsmose[3], [1]Department of Reumatology/C, Copenhagen University Hospital Gentofte, Hellerup, Denmark, [2]The DANBIO registry, Copenhagen University Hospital Glostrup Rigshospitalet, Glostrup, Denmark, [3]Department of Rheumatology/C, Copenhagen University Hospital Gentofte, Hellerup, Denmark
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Assessment of clinical markers of disease activity is routine in monitoring patients with rheumatoid arthritis (RA) in daily practice. Changes in clinical measures may reflect natural variation (measurement error) or “real change”. Natural variation is assessed in individuals who are considered to be in “steady state”. We examined natural variation of traditional clinical disease markers in biologically treated patients with stable RA according to EULAR response criteria.

Methods:

233 RA patients treated with a biological agent and with stable disease were identified in the Danish rheumatology registry (DANBIO). According to EULAR response criteria, stable disease was defined as a change in DAS28-CRP ≤ 0.6 between two consecutive visits. Paired data from a single set of such two consecutive visits were extracted for each patient. Data comprised DAS28-CRP and its components, patient global assessment (PaGl), pain, HAQ-DI and physician global assessment (PhGl). Variation of the disease markers on the individual level was expressed as lower and upper 95% limits of agreement (LLoA;ULoA) between two consecutive assessments and changes on the group level as the bias (mean of individual differences) according to the Bland-Altman method. Associations were assessed by Pearson's correlation analyses.

Results:

Male/female ratio was 56/177, mean age 60±15 years, mean inter-visit time duration 22±21weeks, mean DAS28-CRP 3.1±1.2, and mean change in DAS28-CRP 0.0±0.3 (range -0.6 to 0.6) (NS). Results of the variation analyses are shown in the Table. No changes between the repeated tests were found on the group level but limits of agreement in individual patients were wide for all measures. Intra-individual changes was not explained by inter-visit time duration (r = 0.0 to -0.1, NS). Moreover, intra-individual changes of the different measures were not or only weakly inter-correlated (r = -0.3 to 0.1, NS or $p < 0.05$). Changes between the repeated tests were similar for males and females (NS).

Conclusion:

Traditional markers of disease activity varied substantially and irregularly over time in individual RA patients considered to be in steady state. These variations reflect, by definition, measurement errors, and should be taken into consideration when monitoring patients in the daily clinic.

Table. Agreement between two consecutive assessments of clinical measures in RA patients with stable disease activity (change in DAS28-CRP ≤ 0.6).

	Visit 1	Visit 2	bias	p	**LLoA**	**ULoA**

On-Demand Use of Etanercept Only for Disease Flares Reduced the Disease Activity Score and Structural Damage Equivalent to Fully-Use of Etanercept in RA Patients

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Biological disease-modifying antirheumatic drugs (bDMARDs) are essential in the treatment of rheumatoid arthritis (RA). Biological DMARDs are particularly recommended for patients with active RA who may

incur further joint damage. However, in daily clinical practice, some patients with RA do not accept or discontinue bDMARDs because of their high cost. Similar to use of glucocorticoids, the use of bDMARDs may be limited to periods of high disease activity to help reduce patient costs. For this option to work well, the efficacy of a bDMARD should be maintained when restarting the same bDMARDs after several periods of discontinuation, bDMARDs holiday. We conducted a prospective, nonrandomized, non-blinded study (RESUME study: UMIN000008164) to examine the sustained efficacy of etanercept (ETN) after starting and stopping ETN several times in the patients with rheumatoid arthritis.

Methods: Thirty-one bDMARD-naive patients with RA with moderate to severe disease activity (Disease Activity Score 28 [DAS28] of ≥3.2) were enrolled in this study with written consent from 1 January 2011 to 31 December 2012. Their average age was 60 years and average disease duration was 5 years. ETN was administered at 50 mg/week and discontinued when low disease activity (LDA) (DAS28 of <3.2) was achieved. Upon recurrence, the same dose of ETN was administered with observation every 2 months. This strategy was maintained for 2 years. If patients did not achieve LDA within 3 months of ETN administration, other synthetic DMARDs other than glucocorticoids and tacrolimus were administered. If LDA was not achieved within 6 months, the patients were withdrawn from the trial. Clinical measure by DAS28, blood test, radiography (mTSS) was analyzed at baseline, 1 year, and 2year visit. In order to compare the structural damage of this study population, another series of 31 patients with RA treated with fully-use of ETN were evaluated by mTSS.

Results: Thirteen of the 31 patients had an inadequate response to ETN and were withdrawn from the study. Five patients had no flare-up of disease activity after discontinuation of ETN during the observation period. In the remaining 13 patients (8 women), on-demand use of ETN was carried out to maintain LDA. The mean dose of methotrexate in these 13 patients was 10 mg/week, rheumatoid factor was positive in 11 patients, and the mean follow-up period was 20.5 months. All 13 patients achieved LDA at the final follow-up after starting and stopping the ETN several times. The cost-saving calculation was approximately 28% among the five patients who maintained LDA with no need to restart ETN. Structural remission (DmTSS =<0.5) was achieved in 82% of the 13 patients as evaluated by the total Sharp score in 1 year, and 50% in 2 years. Structural remission rate in this study population in 1 year was equivalent to that of full dose use (p=0.464, Fisher's exact probability test).

Conclusion: On-demand use of ETN for disease flares reduced disease activity score and structural damage at low cost.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

The multi-biomarker disease activity (MBDA) score [Vectra] has been evaluated in a number of settings, yet has only limited data evaluating whether it is influenced by comorbidities common to rheumatoid arthritis (RA) patients.

Methods:

Using data from the CORRONA registry through (December, 2014), we conducted a cross-sectional analysis of RA patients who had received at least one MBDA test performed as part of standard of care, concurrent with C reactive protein (CRP) ordered on the same day. Patients were characterized descriptively by MBDA category (low, <=29; moderate 30-44; and high, >= 45) and by CRP, ESR, swollen joint count and CDAI category. LOESS plots of MBDA score by SJC were stratified by common comorbidities (smoking, fibromyalgia, COPD, diabetes, body mass index [BMI]) to visually evaluate the influence of the comorbidity on the MBDA score. Ordinary least squares regression was used to evaluate the association between MBDA score and age, sex, comorbidities and RA-related factors. The comorbidities were considered confounders if adjusting for them changed the MBDA-SJC association by more than 10% (change-in-estimate criterion).

Results:

A total of 585 patients had at least 1 MBDA test concurrent with a CRP performed for standard of care reasons. Patient characteristics were mean (IQR) 65 (54,73) years, 78% female, 66% white, 27% Hispanic. Mean (IQR) BMI was 28.0 (24.5, 32.1); comorbidity prevalence was 10% (diabetes), 3% (COPD), 5% (fibromyalgia); 12% current, 39% former, and 49% never smokers. A total of 72% (n=423) of patients had normal CRP (<10 mg/L); of these, 31% had high, 44% had moderate, and 25% had low disease activity as classified by MBDA (Figure 1).

The MBDA score was significantly associated with SJC (correlation coefficient 0.20, $p < 0.0001$), and was minimally different between patients who did and did not have each of the comorbidities . In bivariate models, there was no significant association between MBDA score and fibromyalgia, diabetes, or COPD, and these factors did not yield confounding between either MBDA score and SJC, nor MBDA and CDAI. CRP alone explained 33% of the variance (R^2) in MBDA score. In the multivariable model, MBDA remained significantly associated with both SJC and CDAI even after adjusting for age, sex, comorbidities, BMI, current steroid use, and other factors.

Conclusion:

In this real-world RA registry, the MBDA score was associated with RA disease activity and was negligibly affected by comorbidities common to RA patients. Approximately one-third of patients with normal CRP levels had high MBDA scores, suggesting the potential that MBDA may provide an opportunity to use an objective lab measure to identify RA patients with active disease even when CRP is normal.

Figures 1: Distribution of CDAI according to MBDA score category for RA patients

with normal CRP (< 10mg/L) [n=423]

How to Recruit Anti-CCP Positive Patients from Primary Care

Jackie L. Nam[1], Laura Hunt[1], Elizabeth M.A. Hensor[1] and Paul Emery[1,2], [1]NIHR-Leeds Musculoskeletal Biomedical Research Unit and Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom, [2]Division of Rheumatic and Musculoskeletal Disease, University of Leeds, Leeds Institute of Molecular Medicine and LMBRU, Leeds, United Kingdom

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Around 1% of the population test positive for anti-cyclic citrullinated peptide (anti-CCP) antibodies. This biomarker predicts progression to rheumatoid arthritis (RA) but over a variable time-frame. To increase its clinical relevance, this study sought to determine (1) if the proportion of anti-CCP positive individuals could be enriched by case selection of people attending primary care with new nonspecific musculoskeletal (MSK) symptoms but without clinical synovitis (CS) and (2) whether these individuals progress rapidly to inflammatory arthritis (IA), in particular RA.

Methods:

In this prospective cohort study, individuals aged ≥18 years with new nonspecific MSK symptoms, without CS, were recruited from primary care in the U.K. Anti-CCP positive individuals were invited for follow-up in the rheumatology department, Leeds. Those who tested negative were sent questionnaires 12 months later.

Results:

2028 individuals were recruited. Of the 2.8% (57/2028) who were anti-CCP positive, 47% (27/57) developed IA [24 RA; 1 undifferentiated IA (UIA); 2 polymyositis]; 92.6% (25/27) within 12 months, [median (IQR) 1.8 (1.0-4.3) months, range 0.3 to 16.1]. Of the anti-CCP negative individuals, 1.3% (20/1559) developed IA (13 RA; 1 UIA; 6 psoriatic arthritis); 75% (15/20) within 12 months. The RR for developing RA within 12 months in the anti-CCP positive group was 66.8 (32.2-138.4, p<0.001); for IA it was 45.5 (95%CI 25.4-81.6, p<0.001).

Conclusion:

Selecting individuals with new nonspecific MSK symptoms without CS enriched the prevalence of anti-CCP positivity to 2.8%. Those who tested positive had a high risk of rapidly developing RA. The cost effectiveness of this approach will need to be determined.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The recent publication of the concerto trial comparing the use of adalimumab in monotherapy versus in association with methotrexate (MTX) at dose varying from 2.5 to 20 mg weekly increased the awareness of the importance of anti-drug antibody in lowering the efficacy of adalimumab in patients with RA. Rhumadata®, a real life clinical database and registry, gives a unique opportunity to compare the two strategies over the very long term. Our objective is to evaluate the impact the combination of MTX over monotherapy on long term retention rate of adalimumab in a population of patients with RA followed at the *institut de recherche en rhumatologie de Montréal* (IRRM) ant the *Centre d'ostéoporose et de rhumatologie de Québec*(CORQ) and entered in the RHUMADATA® Clinical database and registry.

Methods: Data of RA patients who had been prescribed adalimumab (ADA) in any intention on or after January 1st

2002 was extracted. The data included age and gender, disease characteristics, clinical variables, patient and physician specific assessments, and laboratory measures. Composite assessment of disease activity including the DAS28-ESR and the simplified and clinical disease activity indices (SDAI and CDAI) were calculated using readily available formulas. All patients were followed until they discontinued their treatment or June 2, 2015, the date at which the data was extracted from Rhumadata®. Secondary diagnoses and comorbidities established at or before the administration of the biologic agents were coded using the International Classification of Diseases, Ninth Revision, Clinical Modification (ICD-9-CM) codes. Infections occurring while on treatment, biologic status (ongoing or stopped) and the reasons for biologic cessation were also extracted. The 10-year drug retention rates were estimated and compared using Kaplan-Meier survival estimates. Statistical analysis was performed using SAS version 9.4.

Results: The data from 290 patients prescribed ADA (219 in combination therapy and 71 in mono therapy) in any intention were extracted from the RHUMADATA® clinical registry and database. The patients were mostly women (73.1%) and had an average age of 52.6(SD=12.8). The patients had an average disease duration of 7.4 years (SD=7.6) and were exposed to ADA for an average of 3.0 years (SD=3.1) providing 883.3 person-years of treatment. Patients prescribed MTX received an average daily dose of 15.4 mg (SD=6.1). The 10-year retention rates of ADA used in MONO and COMBO therapy were estimated at 13.6% (SD=5.4%) and 22.4% (SD=3.4%) respectively and an overall significant difference in retention rate was observed (log-rank p -value = 0.0107).

Conclusion: Using adalimumab in combination with methotrexate improve significantly the retention rate in patients suffering of RA

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

In early rheumatoid arthritis (RA), initiation of disease-modifying anti-rheumatic drugs (DMARD) within 12 weeks of symptom onset is associated with a significant benefit in long-term disease outcome. Our objective was to determine the proportion of patients with RA in whom DMARD therapy was initiated within the desired time frame.

Methods:

A retrospective chart review of adult patients diagnosed with RA during year 2014 was performed at the rheumatology department of an integrated secondary/tertiary teaching hospital, which provides rheumatology services for a population of more than 500.000 residents. Potential cases were identified by searching the electronic medical records for ICD-10 codes M05.* and M06.* Electronic and paper records of patients were then thoroughly reviewed. Cases fulfilling the 2010 ACR/EULAR classification criteria for RA were included in the analysis. Dates were recorded for onset of inflammatory joint symptoms, initial assessment by a rheumatologist and initiation of DMARD therapy. The percentage of patients treated with DMARD within 12 weeks of symptom onset and the median times for delay were then calculated.

Results:

Between January 1st 2014 and December 31st 2014, 87 new cases of RA were identified at our Department of Rheumatology. Within 12 weeks of symptom onset, 52% of new RA patients were examined by a rheumatologist and 38% of patients were started on DMARD therapy, median time to consultation was 9.9 weeks [IQR 4.4-25.2 weeks], median time to establishment of diagnosis was 12.7 weeks [IQR 5.9-25.9 weeks] and median DMARD treatment delay was 14.4 weeks [IQR 7.6-27.7 weeks]. The preferred DMARD agent was methotrexate (77%), followed by sulfasalazine (9%) and leflunomide (2%). 12% of patients were not prescribed DMARD treatment for various reasons (mainly non-compliance and advanced age).

Table: Demographic data and clinical history	
Gender (female/male) (%)	78/22
Age, years (mean ± SD)	61.5 ± 15.2
Tender joint count (mean ± SD)	9.1 ± 7.6
Swollen joint count (mean ± SD)	8.7 ± 5.8
Erythrocyte sedimentation rate (ESR), mm/h (mean ± SD)	46 ± 23.3
C-reactive protein (CRP), mg/l (mean ± SD)	38 ± 44.0
Positive rheumatoid factor, %	62.1
Positive anti-CCP, %	67.8
DAS28 3v (mean ± SD)	5.4 ± 1.2
Time from symptom onset to first rheumatologist assessment, weeks (median)	9.9 (IQR, 4.4–25.2)
Time from symptom onset to DMARD initiation, weeks (median)	14.4 (IQR, 7.6–27.7)

Conclusion:

38% of new patients with RA were treated with a DMARD within the recommended time frame of 12 weeks. Most of the treatment delay was due to the time elapsed between symptom onset and consultation with a rheumatologist, suggesting the potential additional benefit of improved education of patients and primary care physicians.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Orthopaedic shoes (OS) may help to reduce pain and increase activity participation in rheumatoid arthritis (RA) patients, but should ideally not be needed. We investigated the prevalence and potential risk factors of OS use in RA patients after 10 years of targeted treatment.

Methods: In the 4 treatment arms of the BeSt study, 508 patients with recent onset RA were treated aiming at disease activity score (DAS) ≤2.4. After 10 years, patients were asked if they used OS. Baseline characteristics of users and non-users were compared. Univariable binary logistic regression was performed with OS use as outcome, and baseline total Sharp/van der Heijde score (SHS), foot erosions and foot joint space narrowing (JSN) as continuous and dichotomous variables (cut-off ≥1) as potential predictors. Next, statistically significant predictors ($p<0.1$) were tested in a multivariable model simultaneously with rheumatoid factor (RF), smoking status, anti-citrullinated protein antibodies (ACPA) and DAS. Timing of OS use being unavailable, non-baseline factors were not considered. For highly correlated variables both associated with OS use, only the strongest contributing variable was added to the model. Predictors with statistically significant contribution were kept in the final model. Interaction of each predictor with treatment arm was tested and ruled out.

Results: Of 285/508 patients (56%) information was available regarding OS use at year 10. Responders to the question were younger than non-responders [age mean (SD) 51.3 (12.0) vs 58.4 (14.8) years, $p<0.001$], but were similar regarding gender, smoking status, ACPA, DAS, SHS, JSN and erosions (all baseline). Twenty-one percent (57/273) of the patients reported OS use after 10 years [68.4% female, mean (SD) age 50.3 (11.0) years, DAS 4.6 (0.9), SHS 4.7 (5.3), erosions 1.0 (2.3), JSN 1.0 (1.9), ACPA+ 83.3%, RF+ 77.2%, all baseline]. OS users were more often ACPA+ (77.2% vs 65.8%) and had more erosions [mean (SD) 1.25 (2.4) vs 0.48 (2.5), all $p<0.05$]. Univariable logistic regression showed that only foot erosions contributed significantly to the model as binary (OR 1.95, CI95: 1.1-4.8) but not as continuous variable (OR 1.06, CI95: 0.9-1.2). Neither total SHS nor foot-JSN (binary or continuous) contributed significantly to the model. Multivariable logistic regression showed that baseline foot erosions (binary; OR 1.85, CI95: 1.1-5.3), ACPA+ (OR 4.88, CI95: 2.0-10.6) and DAS (OR 1.72, CI95: 1.2-2.6) were independent predictors of OS use after 10 years. Combining baseline foot erosions, ACPA+ and baseline DAS created the best model.

Conclusion: Despite 10 years of DAS≤2.4 targeted treatment, 21% of recent onset RA patients with available data after 10 years used OS. Presence of foot erosions at treatment start predicts OS use after 10 years; the risk increases for ACPA+ patients and to a lesser extent for patients with higher baseline DAS.

Table 1: Logistic regression models to predict which patients will use orthopaedic shoes within 10 years of treatment start.

	Variable	N patients	Odds Ratio	95% confidence interval	P	Maximum Likelihood R^2
	Univariate predictors					
	SHS yes/no	268	1.99	0.99; 4.00	0.054	0.015
	Erosions foot yes/no	271	2.32	1.12; 4.80	0.045	0.018
	JSN foot yes/no	273	1.50	0.79; 2.86	0.152	0.006
	SHS	268	1.03	0.98; 1.09	0.206	0.006

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Previous reports have demonstrated that malondialdehyde-acetaldehyde (MAA) adducts are produced as a byproduct of oxidative stress and lipid peroxidation and are expressed in RA joint tissues (Thiele GM, Arthritis Rheumatol 2015). Moreover, MAA adducts co-localize with citrullinated proteins and promote robust T cell and antibody responses, the latter being associated with RA disease severity. Whether anti-MAA antibody concentrations predict treatment response in RA is unknown. The objective of this study was to examine the role of anti-MAA antibody isotypes in predicting RA treatment responses in a group of well-characterized patients participating in a randomized controlled trial.

Methods: As part of a secondary analysis of the Rheumatoid Arthritis Comparison of Active Therapies (RACAT) trial, banked serum from baseline, 24, and 48 weeks (n=255) were tested for anti-MAA antibody isotypes (IgA, IgG, IgM) using ELISA. In the 48-week trial, patients with active disease despite methotrexate (MTX) were randomized to receive triple therapy (MTX/sulfasalazine/hydroxychloroquine) or MTX/etanercept. Associations of treatment response with baseline antibody isotype concentrations and changes in antibody concentrations at 24 and 48 weeks were examined using non-parametric Spearman correlations. The primary treatment outcome in this analysis was the change in DAS28-ESR at 48 weeks.

Results: As previously reported (O'Dell JR, N Engl J Med, 2013), patients in the RACAT study had a mean age of ~57 years, 46% were women, and patients had a mean (SD) DAS28 at enrollment of 5.8 (1.9). There were no associations of baseline anti-MAA antibody concentration with treatment response at 24 or 48 weeks. Likewise, there were no associations of change in antibody concentrations with treatment response at 24 weeks. In contrast, changes in IgA and IgG anti-MAA antibody isotype concentrations from baseline to 48 weeks were significantly associated with treatment responses ($r=0.25$; $p<0.001$ for both isotypes) (Figure).

Conclusion: Treatment response in RA over one year of follow-up is strongly associated with declines in both IgA and IgG anti-MAA antibody isotypes, associations that are not apparent after just 6 months. These results and prior studies showing the importance of lipid peroxidation in both MAA adduct formation and RA suggest that anti-MAA antibodies may mediate or act as a marker of RA disease activity promoted through oxidative stress. Further studies will be needed to assess whether this relationship is dependent on specific therapies and to elucidate mechanisms through which reduced anti-MAA antibodies are associated with improved treatment responses in RA.

Race Plays a Role in Influencing the Modest Lipid Lowering Effects of Hydroxychloroquine in Patients with Rheumatoid Arthritis, Independent of Statin Use

Myriam Guevara[1], Bernard NG[1] and Nancy Gove[2], [1]Rheumatology, University of Washington, Seattle, WA, [2]Biostatistics, Seattle Children's, Seattle, WA

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Despite remarkable improvements in RA treatment, there is evidence indicating that the mortality gap between RA patients and the general population is not closing. The increase in mortality in RA is predominantly due to cardiovascular (CV) disease. Literature suggests that important links exist between RA inflammation and atherosclerosis in CV diseases.Dyslipidemia is a well-known risk factor of atherosclerosis. Previous studies have suggested that anti-malarials, chloroquine diphosphate and hydroxychloroquine(HCQ), used in the treatment of autoimmune diseases, have a beneficial effect on the lipid levels. However the studies had small sample sizes. We have analyzed a Veterans Affair (VA) RA cohort of 2925 patients to characterize the effect of 4 months use of HCQ in lipid levels.

Methods: Data for this cohort was obtained from the department of VA administrative data base. All adult (age>=18 years) individuals with a diagnosis of RA (ICD 9 code) at 2 or more outpatient visits from 1999 to 2009 ,were identified. Only patients with at least one lipid level measured at 120-180 days prior to staring HCQ were included. Lipids levels at pre start date of HCQ and post start date of HCQ (120-180 days) were compared using students t-test and then adjusted for age, sex, race, CRP and statin use with multivariable regression (ANOVA/ANCOVA) for the change in different lipid levels. To give equal weight to covariables we conducted an analysis of marginal means for race in each lipid level. All analyses were performed with STATA 11.

Results:

	Yes on Statin	No on Statin	All	Demographics
Gender	402 (15.61%)	2174 (84.39%)	2576	Lipid changes in HCQ users

Male (N/%)			
Age (mean/SD)	69 (9.6)	64(12.20)	
Race White (N/%)	369 (15.50%)	1868 (83.50%)	2237
AA (N/%)	28 (8.26%)	312 (91.74%)	340
Others (N/%)	13 (3.06%)	123 (4.92%)	136
Unknown (N/%)	15 (3.53%)	197 (7.88%)	212
Pre-CRP mg/dl (mean/SD)	16.13 (13.53)	5.16 (12.14)	
Post-CRP mg/dl (mean/SD)	11.22 (37.9)	5.90(17.94)	

	Pre-mean (SE)	Post-mean (SE)	Total Difference	P value
Cholesterol	176.17 (.87)	171.65 (.90)	4.52	0.00
LDL	103.77 (.76)	98.86 (.76)	4.91	0.00
HDL	45.80 (.32)	46.18 (.32)	-0.38	0.06
Non-HDL	130.37 (.85)	125.46 (.86)	4.91	0.00
AI	4.17 (.38)	4.0 (.03)	0.17	0.00

Lipid changes in HCQ users by statin use groups.

	Yes Statins Mean (SD)	No Statins Mean (SD)
Change in Cholesterol	2.32 (37.72)	2.41 (33.18)
Change in LDL	4.76 (30.52)	5.09 (31.78)
Change in HDL	-0.35 (9.78)	- 0.41 (1.09)
Change in non HDL	2.92 (37.069)	5.52 (32.17)
Change in AI	.068 (1.29)	.164 (1.29)

After adjusting for sex, age, race, statin use and post crp values > 10mg/dl using a linear regression, the factor driving the change in the different lipid levels was race (p values for total cholesterol (TC) 0.006,LDL 0.09, non-HDL 0.03, TC/HDL 0.08 and HDL 0.17). When looking at race individually using marginal means analysis the race in the subgroup others was the more influential.

Conclusion: Our results suggest gender and race play a role in the effects of HCQ on lipid profiles in RA patients.Use of HCQ in males is found to be associated with positive changes in the lipid profiles independent from the use of statins. There is a suggestion that whites and African Americans might be less susceptivle to HCQ effect on lipid profiles.

Evaluate the Dose Efficacy Response Relationship of Baricitinib in Patients with Rheumatoid Arthritis

Xin Zhang, Laiyi Chua, C. Steven Ernest II, William Macias, Terence Rooney and Lai San Tham, Eli Lilly and Company, Indianapolis, IN

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I

Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Baricitinib (Bari) is an oral inhibitor of Janus kinases (JAK) selective for JAK 1 and 2. It has demonstrated dose-dependent efficacy in patients with moderate-to-severe rheumatoid arthritis (RA) who have an inadequate response to methotrexate in multiple phase 2 studies. The objective of this analysis was to characterize the dose/exposure-response (D/E-R) relationship of Bari to optimize selection of doses and dose regimens for the phase 3 program.

Methods: Pharmacokinetics (PK) and efficacy data are available in patients with RA from two Phase 2 studies, Study JADA (n=278, Keystone E, et al.) and Study JADN (n=143, Tanaka Y, et al.), respectively. Study JADA used doses of 1, 2, 4, and 8 mg QD for up to 24 weeks and 2 mg BID for 12 weeks, and Study JADN used doses of 1, 2, 4, and 8 mg QD for up to 12 weeks. A Population PK (PopPK) model was developed to characterize plasma concentration-time profiles and identify potential covariates using NONMEM (version 7.2). A semi-mechanistic population PK/pharmacodynamic (PK/PD) model was developed to describe the time course and D/E-R relationship for the key efficacy endpoints, ACR20/50/70 and DAS28-CRP response rates. A placebo effect was accounted for in both PD models. A sequential PK and PK/PD analysis approach was used. The developed PK/PD model was subsequently applied to simulate ACR20/50/70 and DAS28-CRP response rates following various doses and dosing regimens (QD vs BID) to help optimizing dose selection for phase 3 studies.

Results: The models adequately described the PK and the longitudinal dose/exposure-response relationships for ACR20/50/70 and DAS28-CRP for all regimens tested in the phase 2 studies. The mean terminal half-life of BARI was estimated to be approximately 14 hours. Renal function was identified as a significant covariate on the clearance of BARI. No patient factors had a significant impact on the PK/PD relationship. PD steady state was attained approximately 12 weeks after treatment for all endpoints. Based on the dose/response curve, 4 mg approached the maximum effect and offered additional efficacy benefits over 2 mg. Simulations suggested that at the same total daily doses, QD and BID dosing regimens achieved similar average plasma concentrations at steady state. In addition, the efficacy responses were comparable between the QD and BID dosing regimens for all efficacy endpoints at the same total daily doses based on the simulations.

Conclusion: Based on modeling and simulations with phase 2 data over a dose range of 1-8 mg (QD and BID), 4 mg and 2 mg QD were selected for further investigation for the BARI phase 3 studies, with 4 mg QD identified as the preferred phase 3 dose. At the same total daily dose, splitting the dose into a BID regimen does not provide any advantage over QD dosing for any of the efficacy endpoints.

Persistence Among Rheumatoid Arthritis Patients Initiating Intravenous

or Subcutaneous Anti-Tumor Necrosis Factor Therapy in a Large US Registry Cohort

Dennis Parenti[1], Shelly Kafka[1], George W. Reed[2], Jeffrey D. Greenberg[2,3] and Raphael DeHoratius[1,4], [1]Janssen Scientific Affairs, LLC, Horsham, PA, [2]Corrona, LLC, Southborough, MA, [3]NYU School of Medicine, New York, NY, [4]Kimmel School of Medicine, Thomas Jefferson University, Philadelphia, PA

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The objective of this analysis was to examine persistence with intravenous (IV) and subcutaneous (SC) anti-TNF therapies among rheumatoid arthritis (RA) patients (pts) within the US CORRONA RA registry.

Methods: A retrospective analysis from the CORRONA RA registry was used for analyses. Adult RA pts (biologic-naïve and biologic-experienced) with moderate-to-severe RA (CDAI>10) who initiated anti-TNF biologics within the CORRONA registry after June 1, 2009 and had ≥6 months of follow up were eligible. Pts receiving IV anti-TNF therapy were compared with those receiving SC anti-TNF therapy. Propensity scores (PS) were generated to match IV anti-TNF initiators to SC anti-TNF initiators, stratified by line of therapy. Variables used for PS matching were based on characteristics with standardized differences of ≥0.1 including age, gender, duration of RA, work status, smoking status, insurance, prednisone use, monotherapy, prior serious infections, patient global, morning stiffness, year of initiation, time from initiation to 6 month visit, and prior number of biologics to control for population imbalances. Time-varying hazard ratios (HR) comparing persistence in matched IV vs SC through 48 months were estimated and stratified by line of therapy.

Results: A total of 1544 pts were included (772 each for IV and SC therapy). In each treatment group, 387 pts were bio-naïve, 220 had received 1 prior biologic, and 165 had received ≥2 prior biologics. Among all pts, significantly greater proportions of patients receiving IV therapy remained on that agent compared with pts receiving SC therapy (p=0.002) during the first 12 months (HR=0.76 [0.63-0.90]). No significant differences in persistence were observed from 24 – 48 months (HR=1.09 [0.88-1.35], p=0.45) (Figure 1). Similar results were observed for pts who were biologic-naïve (0-12 mons: HR=0.69 [0.52-0.90], p=0.007) and who had received 1 prior biologic (0-12mons: HR=0.80 [0.59-1.10], p=0.17). For pts who had received ≥2 biologics, there was no significant difference in persistence between patients receiving IV or SC anti-TNF therapy.

Conclusion: Within the first 12 months of initiating anti-TNF therapy, pts receiving IV therapy who were biologic-naïve or had received only one prior biologic were more likely to remain on treatment compared with those receiving SC anti-TNF agents. These results may have implications on cost savings, in the first year of treatment, that need to be investigated in further studies.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Disease trajectories in early rheumatoid arthritis (ERA) are characterized by differences in absolute levels of disease activity and rates of improvement, with patients in the worse disease trajectories experiencing worse quality of life outcomes and persistent fatigue. Our objective was to determine if the magnitude of improvements in physical function, as measured by the Health Assessment Questionnaire (HAQ), also vary in the heterogeneous disease trajectories.

Methods: Cluster-based trajectory modeling identified 5 mutually exclusive ERA disease activity trajectories by posterior membership probability using DAS28 over 24 months (described in Table 1). Baseline values and mean changes in the HAQ scores were examined for differences by trajectory group using ANCOVA, with adjustment for covariates (age, sex, number of comorbidities, low income, smoking, race).

Results: The cohort includes 1586 patients (mean 54 years, 181 days of symptoms, 73% female, 82% Caucasian, 18% smokers, 70% seropositive). Half (50%) begin in high disease activity state (DAS), of which only 20% rapidly reach remission (Group 1). Group 5 only achieves moderate disease activity by 24 months, despite higher frequency of use of steroids and biologic therapy. HAQ scores were similar between Groups 1, 4 and 5 at baseline (Table 1). In Group 1 scores improve by 1.08 (SD 0.68) by 12 months but in Group 5 the HAQ fails to reach the minimal clinically important difference for improvement (0.22) and worsens from month 12 to 24 (Figure 1).

Conclusion: Novel strategies are needed to identify which patients are at risk for disparate outcomes so that effective care plans can be enacted to preserve function.

Table 1. Mean (SD) HAQ Scores at Baseline and Change Over 24 Months, by Trajectory Group

	Baseline	Change
Group 1 (HDAS to REM)	1.21 (0.70)	-1.08 (0.68)
Group 2 (MDAS to REM)	0.54 (0.53)	-0.34 (0.51)
Group 3 (MDAS to LDAS)	0.83 (0.62)	-0.34 (0.61)
Group 4 (HDAS to LDAS)	1.39 (0.65)	-0.71 (0.78)
Group 5 (HDAS to MDAS)	1.34 (0.64)	-0.13 (0.66)

Legend: HDAS high disease activity state; REM remission; MDAS moderate disease activity state; LDAS low disease activity state

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The sustainability of any regimen is an important factor to consider when selecting therapy for chronic conditions, such as rheumatoid arthritis (RA). Recent reports suggest that patients (pts) treated with abatacept (ABA) might have better retention rates than those treated with anti-TNFs. We aim to further assess long term retention rates of ABA in comparison with anti-TNFs in the first and second lines of treatment in a real life setting using the Rhumadata database and clinical registry.

Methods: RA patients treated at the *Institut de recherche en Rhumatologie de Montréal* (IRRM) and the *Centre d'Ostéoporose et de Rhumatologie de Québec* (CORQ) with either ABA or an anti-TNF inhibitor, adalimumab (ADA), etanercept (ETA), or infliximab (INF) as first biologic (first cohort) or second biologic (second cohort) after January 1st 2007. Descriptive statistics were used to describe patient characteristics. Characteristics were compared using ANOVA with Bonferroni correction. Kaplan-Meier methods were used to compute the cumulative incidence of treatment discontinuation.

Results: The first cohort included 403 pts (62 ABA, 111 ADA, 195 ETA, and 35 INF) and the second cohort included 189 pts (76 ABA, 47 ADA, 47 ETA, and 19 INF). No clinically significant differences in baseline characteristics were noted between treatment groups. There were no significant differences in retention rates between ABA and anti-TNFs in the first cohort, Figure 1. The estimated 6-years drug retention rates were 52.3% (SD=8.4%) for ABA, 37.8% (SD=4.9%) for ADA, 43.6% (SD=4.3%) for ETA and 45.6% (SD=8.8%) for INF. In the second cohort, in patient with RA having failed a first anti-TNF agent, retention rates with ABA were significantly higher compared to anti-TNFs, Figure 2. For this cohort, the estimated 6-years drug retention rates were 41.2% (SD=7.4%) for ABA, 15.2%

(SD=6.3%) for ADA, 22.7% (SD=7.5%) for ETA and 33.1% (SD=13.1%) for INF. The significantly higher retention rates with ABA in the second cohort were maintained regardless of RF or anti-CCP status or whether the biologics were used as monotherapy or in combination with DMARDs. Lack of efficacy (40.1% and 57.3% in the first and second cohort, respectively) and adverse effects (13.9% and 12.2% in the first and second cohort, respectively) were the most commonly cited reasons for discontinuation.

Conclusion: As a first line biologic, in patient with RA, ABA has similar 6-year retention rates as anti-TNFs. As a second line biologic, in patient with RA, ABA has significantly higher 6-years retention rates compared to anti-TNFs.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Several trials had reported the efficacy and toxicity of methotrexate monotherapy in patients with early rheumatoid arthritis. However, patients outside clinical trials could be more complex and heterogeneous,

with a wide range of comorbidities and clinical characteristics. The aim of our study was to estimate the drug survival and toxicity of methotrexate monotherapy in real life setting.

Methods: We included a cohort of DMARDs naïve patients with diagnosis of early rheumatoid arthritis (RA) of less than 2 years of disease duration. Data was collected every 3 months, including sociodemographic characteristics, functional status, disease activity and medication (dose, treatment strategy and toxicity). The primary outcome was methotrexate monotherapy survival. Time to outcome was assessed from treatment initiation to the end of methotrexate monotherapy (drug suspension or addition of DMARDs/biologics) or last follow-up. Kaplan-Meier product limit method was used to estimate outcome probability. Cox proportional hazards models were fit to determine possible predictors of methotrexate monotherapy survival. A p-value of 0.05 was considered statistically significant.

Results: We included 563 DMARDs (disease-modifying antirheumatic drugs) naive patients with early rheumatoid arthritis. Mean follow-up was 24 ± 16 months. Mean age was 51 ± 14 years, 82% were female and disease duration was 7 ± 6 months. Baseline DAS28 and HAQ were 4.0 ± 1.2 and 0.9 ± 0.6, respectively. Methotrexate (MTX) was the most frequently DMARD used [505 (90%)], followed by Leflunomide [LFN, 193 (34%)], Hydroxychloroquine [HCQ, 105 (19%)] and Sulfazalazine [SFZ, 22 (4%)]. When analyzing treatment strategy, first choice was Methotrexate monotherapy in 384 (68%) of the cases. MTX mean dose was 16 ± 4 mg/week and 44% used MTX doses higher or equal than 20 mg/week. One hundred and fifty patients (40%) had to stop methotrexate monotherapy, with a median survival of 26 months (failure rate = 0.027/patient-months of follow-up). Main reasons for suspension were as follow: addition or substitution of DMARs/biologics due to inefficacy (79%), adverse event (7%) and others (14%). On multivariate analysis, being younger, having a higher disease activity and initial concomitant treatment with prednisone ≥10mg/day, were associated with a higher methotrexate monotherapy survival (Table 1)

Conclusion: In daily clinical practice, 4 out of 10 patients with early rheumatoid arthritis fail to methotrexate monotherapy, being inefficacy the main reason for discontinuation. Only 7% of patients had to stop treatment due to adverse events. Younger age, higher disease activity and initial combination with prednisone ≥10mg/day were associated with a higher methotrexate monotherapy survival.

Table 1. Cox proportional hazard model

Personalizing the Treat to Target Approach in Rheumatoid Arthritis

Eric M. Ruderman[1], Jennifer Beaumont[2], Azra Muftic[2], Arthur M. Mandelin II[1], Amy Eisenstein[2], George J. Greene[2] and David Cella[2], [1]Medicine, Division of Rheumatology, Northwestern University Feinberg School of Medicine, Chicago, IL, [2]Medical Social Sciences, Northwestern University Feinberg School of Medicine, Chicago, IL
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

The treat to target (T2T) approach has become part of the standard of care in RA management. Implicit in this approach is patient involvement in shared decision making, to ensure that treatment decisions meet the needs of the patient as well as the goals of the provider. The Patient Reported Outcomes Measurement Information System (PROMIS) is a validated set of assessment tools to measure patient reported health status across a variety of medical conditions. We sought to learn whether the use of elements from PROMIS could inform the T2T approach, and to understand whether patient reports of disease impact correlate with objective clinical measures. We report here the baseline status of the patients enrolled in the study.

Methods:

Patients with a diagnosis of RA by 2010 criteria were recruited from our academic clinical practice. Patients were stratified at baseline by disease activity (remission or low disease activity, CDAI $\leq$ 10 vs. moderate or high disease activity, CDAI > 10), and we made an effort to balance the 2 groups. Patients will be treated for 1 year, using a T2T approach that recommends consideration of therapeutic escalation when CDAI > 10, with data collected at routine clinic visits. At each visit, we collect standard RA assessments, including joint counts, RAPID3, and CDAI scores. Patients complete a PROMIS assessment quantifying their health status in 5 domains: pain, fatigue, depression, physical function, and social function. Patients are also asked to select priority targets, consisting of 5 items from the domain they deem most important; answers to these questions are also collected at each visit. Table 1 shows the demographics, clinical status and PROMIS measures for the first 94 patients enrolled.

Results:

Compared to the US general population reference values for PROMIS (m=50; SD=10), patients had worse fatigue (m=56.7), pain (m=57.7), and physical function (m=42.3). Baseline scores on depression and social functioning were close to the average of the general US population. Patients with CDAI > 10 scored worse across all domains than those with CDAI $\leq$ 10. When selecting prioritization areas for treatment targets, 38% of patients selected physical function, followed by 35% of participants selecting pain, 16% selecting fatigue, 6% selecting depression, and 4% selecting social function; those with active disease were much more likely to select pain (45% vs. 18%).

Conclusion:

Pain, physical function, and fatigue, the 3 domains in which patients reported worse health status than the general population, were also the areas most frequently selected by patients as priority targets for treatment. Physicians are

informed of the PROMIS scores at each visit, and we will track their impressions of the impact of these data on their treatment decisions. We will also explore, at a patient level, the correlation between PROMIS scores and standard disease activity measures

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: To optimize treatment for rheumatoid arthritis (RA), it is ideal to monitor disease activity on a daily basis such as glucose measurement since RA activity fluctuates over time. Urine can be collected routinely at

home by patients themselves and tested for systemic inflammation. Recently, we had identified 4 urinary biomarker candidates-- gelsolin (GSN), orosomucoid (ORM)1, ORM2, and soluble CD14 (sCD14)-- in RA patients through transcriptomics and proteomics studies.

Methods: Here, we investigated the clinical significance of the aforementioned urinary biomarker candidates in a prospective manner, focusing on their role in predicting RA activity and providing prognosis. Urinary concentrations of the four proteins were determined by enzyme-linked immune-sorbent assay. RA activity and severity were determined by assessing disease activity score 28 and X-rays of hands and feet of patients, respectively.

Results: Urinary ORM1, ORM2, and sCD14 levels were elevated in RA patients. They were positively correlated with the status of the disease activity. In particular, urine determinations of one or two biomarkers (e.g. ORM1+ORM2 or sCD14+ORM2) efficiently represented the presence of high RA activity without the need for blood markers. In parallel, a more rapid radiographic progression in three years was observed in patients with higher ORM2 levels. In multivariate analysis, urinary ORM2 level was an independent risk factor for RA progression. Combination of urinary ORM2 and serum C-reactive protein synergistically increased the predictability for radiographic progression (the adjusted odds ratio: 46·5). *In vitro* functional studies revealed that ORM2 was mainly produced by RA synoviocytes in the joints, directly contributing to proinflammatory responses.

Conclusion: Our urinary biomarkers provide novel candidates for patient-driven measurements of RA activity at home and can shift the paradigm from blood to urine testing in the assessment of RA activity and prognosis in hospitals.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Correct assessment to biologics in rheumatoid arthritis (RA) patients is extremely important regarding future patient management. There is still an open debate about the utility of joint ultrasound (US) parameters and the monitoring of the activity.

Methods:

52 consecutive RA patients on stable RTX treatment administered each 6 months were evaluated. Clinical and US evaluation were performed by two independent assessors, the same day as all laboratory tests. The scanning technique and the settings of the machine (ESAOTE MY LAB70, 15MHz linear probe) were the same for all patients. Examinations were performed by a trained ultrasonographer blinded to all clinical evaluations. US of both hands (dorsal wrist, 2nd to 5th volar metacarpophalangeal and 2nd to 4th volar proximal interphalangeal) was done. All patients were separated in 2 groups according to calculated SDAI, patients having SDAI <3.3 being included in remission group and those with higher SDAI in active disease group.

Results:

86.5% were females, mean age 57.21(11.35) years, mean disease duration 14.12(7.68) years, 82.7% had a csDMARD associated to RTX . Mean DAS28 ESR was 3.12(1.27) and mean SDAI was 7.83(7.75). No significant correlations were found between active synovitis score and VAS (r=0.189, P=0.179), PGA (r=0.251, P=0.073), ESR (r=0.154, P=0.275), nor CRP (r=0.173, P=0.220). Active synovitis score correlated to tender joint count (r=0.368, P=0.007), swollen joint count (r=0.413, P=0.002), SDAI score (r=0.339, P=0.014) and DAS28 score (r=0.348, P=0.011). Boolean remission correlated inversely to number of PD joints (r=-0.416, P=0.002), active sinovitis (r=-0.492, P<0.001). There were significant differences between patients with active disease and RA remission based on SDAI score regarding tender joint count, swollen joint count, ESR, PD joint count, total PD score and active synovitis (see table). SDAI remission correlated inversely to PD joint number (r=-0.383, P=0.005), active synovitis (r=-0.385, P=0.005) and total PD score (r=-0.456, P=0.001). SDAI remission did not correlate to GS joint number (r=-0.039, P=0.785) nor to total GS score (r=-0.140, P=0.324).

	SDAI Remission (SD)	**SDAI Active Disease (SD)**	**P**
DMARD use	0.85(0.37)	0.82(0.38)	
Tender joint count	0.08(0.277)	2.67(3.79)	**0.018**
Swollen joint count	0.00(0.00)	1.95(2.74)	**0.014**
CRP	4.43(5.59)	11.55(17.81)	0.165
ESR	9.15(4.70)	23.41(17.93)	**0.007**
RF	21.57(30.69)	34.01(48.62)	0.409
ACPA	249.41(611.87)	407.92(672.44)	0.471
GS joint number	6.23(3.94)	5.95(2.72)	0.776
PD joint number	1.08(1.75)	2.33(1.51)	**0.016**
Total GS score	8.62(5.37)	10.00(5.29)	0.420
Total PD score	1.08(1.75)	3.23(2.28)	**0.003**
Active synovitis	0.46(0.51)	0.85(0.36)	**0.005**

Conclusion: Total PD score and PR joint numebr, but not GS score or GS joint number, correlates with SDAI remission in RA patients treated with RTX.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I

Session Type: ACR Poster Session A

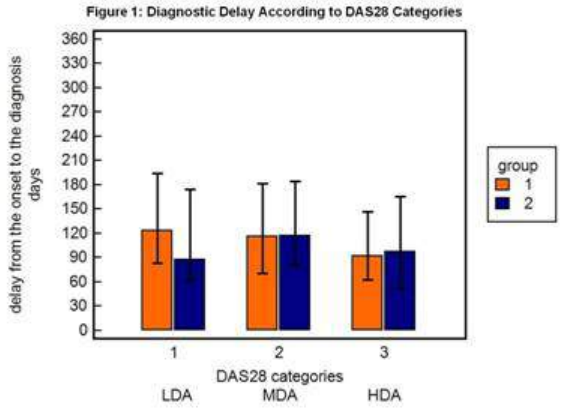
Session Time: 9:00AM-11:00AM

Background/Purpose: In the last 10 years a big effort has been made to reduce the diagnostic delay in patients with early arthritis, in order to start treatment as early as possible and to improve outcomes. The aim of this study is to assess whether diagnostic delay in patients evaluated at our Early Arthritis Clinic (EAC) changed between 2005 and 2014.

Methods: among patients referred to our EAC (disease duration <12 months) between 01/01/2005 to 31/12/2014, those with a diagnosis of rheumatoid arthritis (RA) (according to 1987 and/or 2010 classification criteria) or undifferentiated arthritis (UA) with a complete data-set were recruited. Patients were divided into 2 groups according to the time of diagnosis (group 1: 2005-2009; group 2: 2010-2014). A comparison among demographic and clinical features was performed.

Results: a total of 513 patients were evaluated: 305 patients into the group 1 (74.8% women, mean age 58 ys) vs. 208 patients into the group 2 (73.1% women, mean age 56.5 ys). The time from the onset of symptoms to the diagnosis showed no differences between groups (105 days IQR 66-171 vs. 107 IQR 67-177; p= ns). A total of 42% of the group 1 and 39% of the group 2 had the diagnosis established within 90 days (p= ns); 35.5% vs. 37% between 3 and 6 months (p= ns); 15% vs. 17% between 6 and 9 (p= ns); 7.5 % vs. 7% between 9 and 12 (p= ns). The delay from the referral at our EAC to the visit showed no differences between the groups (20 days IQR 11-31 vs. 20 IQR 13-28; p= ns). At baseline patients in the group 2 showed lower disease activity as for DAS28 (4.97 ± 1.19 vs. 4.57 ± 1.21; p= 0.0003), number of tender joints (7 IQR 3-13 vs. 5 IQR 2-9; p= 0.0009), swollen joints (7 IQR 4-12 vs. 5 IQR 3-8; p <0.0001), ESR (24 IQR 13-42 vs. 21 IQR 10-38; p= 0.0051), VAS-GH (44 IQR 25-50 vs. 50 IQR 30-60; p= 0.0056). In terms of serologic positivity and diagnosis there were no differences (64.6% of RA patients into the group 1 vs. 67.3% of RA patients into the group 2; p= ns).

Comparing DAS28 categories at baseline there were no differences in the diagnostic delay: patients with baseline DAS28 <3.2 had a delay of 124 days (IQR 88-194) in the group 1 vs. 88 (IQR 62-175) in the group 2 (p= ns); patients with baseline DAS28 between 3.2 and 5.1 had a delay of 116 days (IQR 71-182) vs. 117 (IQR 80-184) (p= ns), patients with baseline DAS28 >5.1 had a delay of 92 days (IQR 63-147) vs. 98 (IQR 52-166) (p= ns) (figure 1).



Conclusion: the reduction of disease activity observed during 10 years doesn't depend on a reduced diagnostic delay. Currently, up to the 60% of the diagnosis is still not made within the first 90 days from the onset of symptoms, period conventionally considered a window of opportunity. There is therefore a substantial room for improvement only partially linked to the delay between the referral at EAC and the diagnosis: education programs for patients and primary care physicians in order to reduce the diagnostic delay are still necessary.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: B cell depletion with rituximab (RTX) is an established treatment for RA. It was first introduced at UCL in 1998 and at this centre patients are followed up in a dedicated weekly clinic. Initial treatment protocols included combination with cyclophosphamide, but since 2001 patients are treated with cycles of 2x1g RTX. Initial retreatment strategies based on retreatment at flare evolved in the last 6 years patients to retreatment to avoid flare, based on the duration of response to initial cycles. We aim to characterize RTX drug survival in our cohort and determine 5 years drug retention predictors.

Methods: We conducted a retrospective cohort study of RA patients treated with RTX at UCL between 1998 and 2015. Medical records of 248 RA patients were reviewed; demographic and clinical data was collected. All patients fulfilled 1987 ACR classification criteria. Drug survival data was analysed using Kaplan-Meier estimates. Predictors for 5-years drug retention were determined by a multivariate logistic regression model.

Results: Of the 248 patients included, 81% were female, 80.9% Caucasians. Mean age (SD) was 60.75±15.4yrs and mean age at diagnosis was 39.25±16.2yrs. RF and ACPA were positive in 89% and 84.6% of patients, respectively. History of smoking was present in 59.43%. The most frequent comorbidities were hypertension (30.8%), osteoporosis (20.1%) and thyroid disease (15.43%). Mean follow up duration after RTX initiation was 1737±1206 days (maximum 6055 days). At 2 and 5 years, 78% and 61% patients remained on rituximab (figure 1). Baseline DAS28 was on average 5.93±1.25, CRP 2.2±2.9mg/L. Majority of patients received concomitant therapy with other DMARDs/steroids, MTX 46%, SSZ 21.4%, leflunomide 6.85%, hydroxichloroquine 14.1% and low-dose prednisolone 28.6%. Main reasons for RTX discontinuation were: inefficacy 49 patients (44 primary failures, 6 secondary failures), adverse events 18 patients, pregnancy 1 patient and death 5 patients.

In univariate analysis, current age, disease duration, RF seropositivity, CRP at baseline, number of previous biologics and concomitant use of prednisolone were associated with long-term RTX retention (>5 years). In multivariate analysis, only CRP at baseline kept statistical significance (p=0.014).

Conclusion: Overall, high drug retention rates were observed, independent of concomitant use of conventional DMARDs. In multivariate analysis, higher baseline CRP was associated with long-term drug survival. We found that secondary failures were rare (8% of drop outs) with the current retreatment strategy based on the prevention of flare.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Early diagnosis and treat-to-target strategies with conventional DMARDs in rheumatoid arthritis (RA) have allowed the achievement of remission in a significant percentage of the cases in daily practice. Whether and in which patients

treatments can be suspended with maintenance of health is currently unclear. In this study, we investigated the outcomes of methotrexate (MTX) suspension and predictors of disease recurrence in a real life single centre cohort of early RA patients followed prospectively under DMARD- and glucocorticoid-free conditions.

Methods:

All RA patients included in this current prospective observational study derived from the Pavia's Early Arthritis Clinic and were treated according to a DAS-driven step-up protocol with MTX in monotherapy. Patients achieving stable DAS28 remission and fulfilling the following criteria were eligible for drug suspension: 1) fulfillment of the 2010 ACR/EULAR classification criteria for RA within 12 months from baseline visit; 2) MTX introduced within 12 months from symptoms' onset; 3) ≥24 months of continuative MTX; 4) DAS28 <2.6 for ≥6 months in the absence of glucocorticoids. Patients were followed-up at three-months intervals through complete clinical and ultrasonographic (hands-feet) assessments. Radiographs were repeated annually. Treatment was reintroduced in case of DAS28≥3.2 in a single occasion or 3.2<DAS28≥2.6 for >6 months.

Results:

Seventy RA patients with at least 6 months of follow-up following DMARDs discontinuation were considered. Baseline stratification according to remission stringency showed SDAI remission in 57/70 (81.4%), ACR/EULAR Boolean remission in 52/70 (74.3%) and absence of clinical and ultrasonographic synovitis (SJC44=0 and power Doppler signal in hands-feet=0) in 23/70 (32.9%). Treatment restart due to disease recurrence was observed in 28/70 patients (40%) over 2 years of follow-up, with a median (IQR) time until retreatment of 6 (6-10.5) months. None of the clinical characteristics at the time of diagnosis showed predictive significance. Worsening of disease activity was more likely to occur in patients not in remission according to the SDAI (HR [95% CI] 2.56 [1.15-5.70], p=0.02). Below this threshold, remission stringency failed to show any protective role, with 10/23 (43.5%) patients showing disease recurrence despite absence of clinical and subclinical synovitis at the time of drug suspension. Among patients in SDAI remission, IgG ACPA were the only predictor of relapse, independent of remission duration and the residual inflammatory degree at baseline (HR [95% CI] 4.38 [1.50-12.89], p=0.008). IgG ACPA-IgM rheumatoid factor (RF) double positivity showed increased predictive ability (HR [95% CI] 7.11 [2.38-21.25], p<0.001).

Conclusion:

Despite deep and sustained remission following early treatment and treat-to-target approaches in routine clinical care, DMARD suspension appears a feasible option only in a proportion of RA patients. The autoimmune status is the strongest predictor of disease reactivation in patients achieving stringent clinical and ultrasonographic control of the inflammatory process.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Increased serum lipid levels in patients being treated with tocilizumab (TCZ) is known from several clinical trials[1,2]. It is not known whether additional methotrexate (MTX) alters TCZ's influence on serum lipid levels.

Methods:

Statistical analyses were performed with data from the OPTIMISE trial (EUDRACT No. 2011-001863-39) running in Austria from January 2012 to August 2013. Seventy-seven patients with mild to moderate rheumatoid arthritis (RA) and inadequate response (DAS28 >2.6 and ≤4.5) to a stable dose of MTX (15 - 25 mg/week) were enrolled and received three infusions of TCZ (8 mg/kg) iv every 4 weeks plus MTX. Patients (n = 65) achieving good or moderate EULAR response at week 12 were randomized into Group A (TCZ 8 mg/kg plus MTX) or Group B (TCZ 8 mg/kg plus MTX placebo). Blood was drawn every four weeks and, among other blood parameters, also cholesterol (total, HDL, LDL) and triglycerides were measured. Statistical comparisons were done between the three time points: week 0 (baseline), week 12 (end of therapy TCZ plus MTX) and week 24 (end of TCZ plus MTX or TCZ plus MTX placebo).

Results:

A moderate increase was found in total cholesterol (median of both groups together; 201 mg/dl at baseline, 223 in week 12, 221 in week 24), HDL (63 mg/dl at baseline, 69 in week 12, 66 in week 24) and LDL (118 mg/dl at baseline, 132 in week 12, 130 in week 24). The two groups differed significantly between baseline and week 12. Triglyceride levels did not change significantly. Comparison of the amount of lipid level change from week 12 to week 24 (TCZ plus MTX versus TCZ plus MTX placebo) between the groups was not significant. Only one difference (increase baseline to week 24) revealed a borderline (p = 043; t test) statistical significance between groups.

Conclusion:

RA patients with mild to moderate disease activity show a distinct change in cholesterol levels under successful TCZ and MTX therapy. These lipid levels remained unchanged between week 12 and 24 under continuous therapy with TCZ alone or in combination with MTX. It is unclear as to whether the increase in cholesterol (total, HDL, LDL) is a sign of disease control or a direct effect of TCZ on lipid syntheses.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory disease, predominantly affecting women in their fifth and sixth decades of life. Although population aging increases the mean age of patients with RA, the data in elderly patients are still limited. We aimed to investigate the treatment outcome and the risk factors for poor outcome in elderly patients with RA.

Methods: This cross-sectional study analyzed the data of 1,227 patients with RA who were recruited for KOrean college of rheumatology BIOlogics (KOBIO) registry between 2013 and 2014. The demographic data, drugs, and disease activity were collected for all available participants. We compared the disease status between elderly patients (age ≥ 65) and younger patients (age < 65), and investigated the clinical factors affecting disease activity.

Results: Of 1,227 patients in KOBIO registry, 244 patients with RA were aged 65 or over. The proportion of men was higher ($p = 0.012$), and the duration of disease was longer ($p < 0.001$) in elderly patients compared to younger patients. The prevalence of comorbid condition determined by Charlson Comorbidity Index and Elixhauser's Comorbidity Measures was higher in elderly group ($p = 0.001$). Treatment of methotrexate was more frequent in younger group ($p = 0.004$), while use of other medications was comparable. More patients in elderly group had a high disease activity (disease activity score in 28 joints > 5.1, simple disease activity index > 40, and clinical disease activity index > 22), which was independently associated with longer duration of disease, presence of comorbidity, and non-use of methotrexate ($p = 0.002$, $p < 0.001$, and $p = 0.029$, respectively). Especially, diabetes was closely related with poor treatment outcome.

Conclusion: This study suggests that disease activity might be insufficiently controlled in elderly patients with RA. The meticulous efforts would be required to reach therapeutic target of RA, regardless of age.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: In patients (pts) with rheumatoid arthritis (RA), the non-adherence to therapy may impair the clinical outcomes, being often associated with the disease flare and increased disability. The objectives of this survey were to confirm previous data about the extent of non-adherence to treatment with conventional disease-modifying anti-rheumatic drugs (cDMARDs) alone or with biological DMARDs (bDMARDs) in a larger sample of RA pts in Italy and to identify the profile of cDMARDs non-adherent pts

Methods: This was the second part of a self-reported survey started in 2014 in RA pts treated with cDMARDs in Italy. In the hospital waiting room, pts were asked to fill out an anonymous paper based questionnaire. Fieldwork: December 3rd 2014 – March 6th 2015

Results:

A total of 1,568 RA pts treated with cDMARDs were recruited from 29 Italian centers (females: 72.6%; mean age: 55 years; mean time since RA diagnosis: 9 years; pts already on treatment for other concomitant diseases: 58%): 685 pts (43.7%) were treated with cDMARDs alone and 883 pts (56.3%) were treated in combination with a biologic drug.

Overall, the proportion of pts reporting non-adherence to cDMARDs was 39.2% (n=615): 37.5% (n=257) of pts treated with cDMARDs alone and 40.5% (n=358) of pts treated in combination cDMARD + biologic drug. Among cDMARDs non-adherent pts, 86.3% reported to take “almost always” the cDMARDs treatment, 12% “seldom” and 1.6% “never”, with similar rates for pts treated with cDMARDs alone and in combination with a biologic drug. The main reason given for cDMARDs pts non-adherence was forgetfulness (49.9%); other reasons reported were: side effects fear (25.2%), the feeling they were taking too many drugs (16.6%) and the thought of feeling better (13.5%). Interestingly, 34.5% of the total 615 cDMARDs non-adherent pts did not mention cDMARDs non-adherence to their physician, particularly younger pts (aged ≤ 40 years).

Compared to the overall rate of cDMARDs non-adherence (39.2%), frequency of cDMARDs non-adherence was significantly higher (66.7%) in pts reporting a heavy impact of cDMARDs treatment on their life or an impairment of some aspects of their life, such as social life (55.9%), due to cDMARDs treatment.

Considering pts lifestyle, the rate of cDMARDs non-adherence was higher in pts taking care of family members (non-adherence rate: 43.9%), having an occasional rather than full-time job (49%), rarely practicing sports or hobbies (43.3%), receiving help by family members or caregivers (47.9%), taking also corticosteroids in combination (46.8%)

Conclusion: Results of this second part of the survey confirm that among RA pts cDMARDs non-adherence is quite

widespread (39.2%). Moreover, it is an unrecognised phenomenon in a considerable proportion of non-adherent pts (34.5%), who find difficult to talk to their physician about this issue. cDMARDs non-adherence appears strictly related to the impact of cDMARDs treatment on pts quality of life and is higher in pts treated with cDMARDs in combination with a biologic drug (40.5%), in more severely affected pts and in pts treated with more drugs. Lifestyle appears to be less related to treatment adherence, being more adherent pts with a regular way of life

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Rheumatoid arthritis (RA) patients with anti-citrullinated peptide antibodies (ACPA) need a more aggressive therapy (1). Tocilizumab (TCZ) seems to be the biologic with best response rates when used in monotherapy. It is unclear whether therapeutic response to TCZ monotherapy or TCZ plus methotrexate (MTX) is influenced by ACPA status.

Methods:

Statistical analyses were performed with data from the OPTIMISE trial (EUDRACT No. 2011-001863-39) running in Austria from January 2012 to August 2013. Seventy-six patients with mild to moderate RA and inadequate response (DAS28 >2.6 and ≤4.5) to a stable MTX dose (15 - 25 mg/wk) were enrolled and received three infusions of TCZ (8 mg/kg) iv every 4 weeks + MTX. Patients achieving good or moderate EULAR response at week 12 (n = 65) were randomized into Group A (TCZ 8 mg/kg plus MTX) or Group B (TCZ 8 mg/kg plus MTX placebo). Every four weeks disease activity was estimated with DAS28 (Disease Activity Score with 28 joint counts), SDAI (Simplified Disease Activity Index), CDAI (Clinical Disease Activity Index) and RADAI-5 (Rheumatoid Arthritis Disease Activity Index 5). In both groups patients were assigned to the anti-CCP-positive or -negative group. Group A included 17 patients anti-CCP-positive and 13 patients anti-CCP-negative; Group B 19 patients anti-CCP-positive and 14 patients anti-CCP-negative. Statistical comparisons analyzed three time points (week 0, baseline; week 12, end of therapy TCZ plus

MTX and week 24, end of TCZ plus MTX or TCZ plus MTX placebo).

Results:

In the anti-CCP-positive and the anti-CCP-negative group DAS28, CDAI, SDAI and RADAI-5 changed significantly ($p<0.001$) from baseline to week 12, but did not change from week 12 to week 24. Between-group comparison revealed no significant difference in any disease activity marker at any time point.

Conclusion:

In the anti-CCP-positive and the anti-CCP-negative group DAS28, CDAI, SDAI and RADAI-5 changed significantly ($p<0.001$) from baseline to week 12, but did not change from week 12 to week 24. Between-group comparison revealed no significant difference in any disease activity marker at any time point.

Literature

1. In the anti-CCP-positive and the anti-CCP-negative group DAS28, CDAI, SDAI and RADAI-5 changed significantly ($p<0.001$) from baseline to week 12, but did not change from week 12 to week 24. Between-group comparison revealed no significant difference in any disease activity marker at any time point.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Ofatumumab is a unique anti-CD20 monoclonal antibody with its epitope more proximal and distinct from the epitope recognized by rituximab or by other anti-CD20 monoclonal antibodies. The proximity of this epitope probably accounts for the high efficiency of B-cell killing. The significant role of B-cells in RA and the uniqueness of ofatumumab's epitope resulting in more efficient killing than other B-cell deleting antibodies makes it ideal for use in RA. Our objective was to assess the benefits and harms of ofatumumab in reducing disease activity, pain, and improving function in people with RA.

Methods: We searched multiple databases for eligible studies as well as the websites of the regulatory agencies for

reported adverse events using the search strategy developed by a Cochrane librarian. We included randomized controlled trials comparing ofatumumab alone, or in combination with disease-modifying anti-rheumatic drugs (DMARDs) or biologics, to placebo or DMARDs or biologics alone or in combination with DMARDs, with no restrictions with regard to the dosage.Two authors independently assessed search results, trial quality and risk of bias, and extracted data.

Results: Our search identified three trials with low risk of bias, including 654 patients (383 in ofatumumab group and 271 in control group), for analysis. A stable methotrexate dose was allowed in all patients. Compared with placebo, patients in the ofatumumab group were 3.1 times more likely to achieve an ACR50 (RR 3.12, 95% CI 1.98 to 4.91). The efficacy was noted in patients with (RR, 95% CI: 3.76 (1.47 to 9.59) and without prior TNF-failure (RR, 95% CI: 2.78 (1.6 to 4.84), when given a dose of 700 mg, but not for the 300mg or the 1000 mg dose. The number needed to treat to achieve an ACR 50 response was 6 (95% CI 4 to 7). Patients in the ofatumumab group were 2.3 times more likely to achieve an ACR20 response (RR 2.3, 95% confidence interval (CI) 1.76 to 3.01). Only one trial found improvement in ACR70 response. A significant reduction in disease activity was found in ofatumumab-treated patients compared to placebo. The quality of life was also significantly improved with the ofatumumab treatment , as measured by SF-36 summary score (Mean Difference, 2.48, 95% CI 2.23, 2.73). Total withdrawals and withdrawals due to adverse effects were not statistically different between ofatumumab and placebo. However, withdrawal due to lack of efficacy were significantly lower in the ofatumumab treated patients compared to the placebo group (RR 0.24, 95% CI 0.10 to 0.60). The risk of adverse events was higher in ofatumumab group compared to placebo (RR 1.5, 95% CI 1.37 to 1.72). The incidence of serious adverse events was however not significantly different between ofatumumab and placebo (RR 1.72, 95% CI 0.91 to 3.26). The heterogeneity of the included trials was low (I^2=0%), for all the outcomes.

Conclusion: This systematic review and meta-analysis suggests that ofatumumab is efficacious and safe for the treatment of rheumatoid arthritis compared to placebo. The adverse events profile appears to be acceptable at the present but long-term trials and post-marketing surveillance are required to further assess efficacy and harms.

Change in RF Titers Reflects RA Disease Activity and Predicts Therapeutic Response during TNF Inhibitor Therapy; Patients with a Continuous Reduction of Serum RF Levels Show Good Response

Takayoshi Owada, Kazuhiro Kurasawa, Yuta Takamura, Yumeko Namiki, Ayae Tanaka, Ryutaro Yamazaki, Harutsugu Okada, Satoko Arai, Reika Maezawa, Keiko Hatanaka and Yoshiki Ishii, Clinical Immunology, Dokkyo Medical University, Mibu, Tochigi, Japan

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Serum RF was detected in 26-90% of RA patients, and high-titer RF has been shown a poor prognosis factor in RA and predictor of resistance to RA therapy. Several reports have shown that tumor necrosis

factor (TNF) inhibitors decrease serum RF levels. However, it remains unclear whether changes in serum RF level during TNF inhibitors therapy reflects RA disease activity and predicts therapeutic response.

Methods: Subjects were 61 RA patients who filled ACR RA criteria 1987, were biologics-naïve, were treated with TNF inhibitors, and had moderate to high disease activity (DAS28-CRP≧2.7) and high titer of serum RF (≧100IU/ml). Their medical records were reviewed retrospectively. Serum RF titers were measured every visit t during TNF inhibitors treatment by using immunonephelometry, and more than 10% of changes in RF levels was judged as significantly. RA disease activity was measured by DAS28-CRP. Treatment responsiveness was assessed by EULAR response criteria.

Results: Subjects were 61 patients with 13 male and 48 female, 55.5 years (average) of age and 5.9 years (median) of disease duration. TNF inhibitors were 23 of infliximab, 32 of etenercept, 5 of adalmumab and 1 of golimumab. MTX were given to 40 patients with 7.7 mg (average) /week. At baseline serum RF levels were 386+415 U/ml (average +SD) and 221U/ml (median), and DAS28-CRP were 4.54 (average). Three months after TNF inhibitor therapy, RF titers were decreased in 87% of cases (347 at baseline and 135 U/ml at 3month, reduction rate; 61%), while 13% failed to reduce RF levels (751 at baseline and 830 U/ml Reduction rate; -10.5%). DAS28-CRP of patients without RF reduction (n=6) were 4.05 at baseline, 3.06 at 3 month at 3month and 2.83 at 12 month. Only 1 (17%) and 1 cases (17%) achieved clinical remission and low disease activity by DAS28-CRP at 12 month, and 2 cases (33%) satisfied good response by EULAR response criteria at 12 month. Among patients with RF reduction at 3month, 48% of cases showed re-elevation of RF titers (379 at baseline, 156 at 3month and 226 U/ml at 12 month) and others revealed continuous reduction of the titers (318 at base line, 117 at 3month and 63 U/ml at 12 month). DAS28-CRP of patients with RF re-elevation after 3month (n=26) were 4.58 at baseline, 2.80 at 3 month, 2.92 at 12 month. Among them clinical remission and low disease activity by DAS28-CRP were achieved in39% and 12%, respectively, and 46% of patients showed good response. DAS28-CRP of patients with RF continuous reduction (n=29) were 4.62 at baseline, 2.37 at 3 month, 2.08 at 12 month. Among them clinical remission and low disease activity by DAS28-CRP were achieved in 58% and 21%, respectively, and 79.3 % of patients showed good response, which was significantly high compared to those without RF reduction and those with re-elevation.

Conclusion: Three month after TNF inhibitors RF titers were reduced in 90% of patients. Those who failed decrease RF titers showed poor response to the therapy. Among patients with RF reduction at 3 month, 50% of them showed re-elevation of RF titers and others revealed continuous reduction of RF. Approximately 80% of patients with a continuous reduction of RF levels shows good response. Therefore, change in RF titers predicts therapeutic response of RA.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: TNF is a key pro-inflammatory cytokine in normal immune responses and pathologically in the rheumatoid arthritis (RA) synovium, thus representing a key treatment target but one where potential negative effects on responses to natural infection and vaccination must be balanced. We hypothesized that some of the clinical efficacy of TNF blockade in RA may be mediated by effects on the B cell compartment and have previously reported that RA patients on anti-TNF (etanercept) have a disruption of germinal center (GC) reactions in peripheral lymphoid tissue (Anolik, J Immunol., 2008, 180: 688). Here, we characterized vaccine responses in RA patients recently started on TNF blockade.

Methods: We randomized subjects in a 2:1 ratio to receive standard dosing regimens of etanercept or adalimumab for 24 WK. The subjects met the 1987 ACR criteria for RA, clinically active (DAS28>4.4), and were on MTX. Disease activity and response was assessed based on DAS28-CRP. Twenty eight of 63 randomized subjects participated in a vaccine sub-study receiving vaccination with Hepatitis A (accelerated 12 and 16 WK), Hepatitis B (accelerated 20 mg at 12, 16, 20 WK), diphtheria/tetanus (dT) booster (12 WK) or combination. Response to Hep B was defined as an antibody titer ≥12 up to 36 WK after randomization. Response to Hep A was defined as a detectable antibody at any point after immunization (to 20 WK). dT booster responder was defined as a titer > 1.0 IU/mL and a ratio to pre-boost of > 3.0. Flow cytometry of B cells was performed at baseline and at 12 and 24 WK. Expression of CD19, IgD, CD27, CD38 and CD24 were used to identify B cell subsets.

Results: A surprisingly high fraction of patients receiving Hep B vaccination were non-responders (NR) (78%, n=18/23). All 5 patients who responded to Hep B were receiving etanercept. Responses to Hep A were higher (48%, n=10/21). Two out of 5 patients who received dT vaccine were responders. For patients who received both Hep A and Hep B vaccinations (n=14), 21% responded to both (n=3), 14% responded to Hep A vaccine alone (n=2), and 64% of patients did not respond to either vaccines (n=9). In the group receiving both vaccines, we analyzed the B cell compartment by flow cytometry. There were no significant differences in the % of core B cell subsets: switched memory, double negative memory, un-switched memory, and naïve B cells at baseline and 12 and 24 WK after anti-TNF treatment between those responding to at least 1 vaccine (R) and those not responding (NR). The mean % (SE) of germinal center-like B cells in the R group was significantly higher than the NR group over all visits (GC like: CD19+IgD-CD27-CD38++CD24-) (R: baseline 2.3±0.66, WK12 1.9±0.50, WK24 2.2±0.44 vs. NR: baseline 0.9±0.49, WK12 0.8±0.39, WK24 0.6±0.33; p=0.04 overall mean, 0.01 WK24).

Conclusion: These data suggest that the *in vivo* generation of B cell memory in response to the T dependent neoantigens hepatitis B and hepatitis A is impaired in RA patients treated with anti-TNF. The % GC B cells in the periphery may correlate with responses to vaccination.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Early and intensive treatment with DMARDs are essential for remission induction in newly diagnosed RA patients. However, demographic, psychosocial and disease related factors may play a role as well.

Objectives:

To investigate which demographic, psychosocial and disease related factors are associated with attaining remission at two consecutive visits in early RA patients treated in a treat-to-target manner

Methods:

We used 2 years follow-up data from patients participating in the tREACH trial[1,2] in which induction therapy strategies were compared: (A) combination high dose conventional therapy ((MTX + sulfasalazine + hydroxychloroquine or (B) MTX. Both groups had glucocorticoid (GCs) bridging. Disease activity (DAS) was assessed every 3 months. Remission was defined as DAS<1.6 at 2 consecutive visits (3 months). Univariate and multivariate logistic regression analyses were performed including demographic, disease related and psychosocial factors evaluated at baseline as predictors for attaining remission during 24 months of follow-up.

Results:

281 patients (68% female; mean DAS 3.4, median HAQ 1.00) were included. During 2 years of follow-up, 139 of 281 (49%) patients (group A: 93 (51%), group B: 46 (47%)) attained remission at 2 consecutive visits. Univariate analysis revealed that older age and female sex were associated with a lower chance of attaining remission (demographic factors). Similar relations were observed for higher DAS, HAQ and worse physical functioning (disease factors) and higher levels of anxiety, depression, fatigue and passive coping with pain (psychosocial factors). In multivariate analysis within blocks of covariates, age and sex maintained significance in the block of demographic factors, DAS and ACPA positivity in the block of disease factors and fatigue in the block of psychosocial factors. In the final model combining the independent block predictors, age, sex and fatigue remained significant.

Conclusion:

In the tREACH trial, 50% of early RA patients attained remission within 2 years of follow-up. Older age, female sex, higher baseline DAS, ACPA positivity and fatigue were important predictors for not attaining remission, but in the final model only age, sex and fatigue remained. Results suggest that high levels of fatigue may prevent patients from attaining remission despite treatment according to a tight control and treat-to-target strategy.

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Periodic measurement of disease activity using validated tools such as the Clinical Disease Activity Index (CDAI) is considered an important aspect of care for patients with rheumatoid arthritis. Treat to target strategies mandating changes in therapy to achieve low disease activity measures have been well studied. However, much less is known about the use of these measures and the influence on physician behavior in routine clinical practice.

Methods: Seventy nine rheumatologists from 35 practices in the mid-Atlantic participated in a payer sponsored rheumatologist developed RA treatment clinical pathway which required CDAI measurement at each visit. To be considered compliant with the pathway, practices were required to enter all RA patients insured by the payer into Pathway Compliance Software, utilize oral DMARDs for at least 3 months prior to use of a biologic agent, prescribe the biologic agent at the lowest approved dose and increase dose according to the package guidelines. Patients were not required to change biologics for ongoing disease activity, but biologics could not be initiated, switched or increased if the patient was in CDAI remission. Practices achieving 80% compliance with the program were offered increased reimbursement to offset the cost of data collection and program compliance.

Results: From 1/1/12 to 12/31/2013, 3,200 patients were enrolled in the pathway and had at least 2 physician encounters. Of these patients, 586 patients started a new biologic(s) in the study period: 137 started their first biologic and 449 switched to another biologic(s), 301 patients were evaluated based on availability of follow up CDAI scores. Mean CDAI scores at the visits during which biologic therapy was initiated or changed was 13.1 and 12.2 respectively. Mean CDAI scores for each of the groups in 3 months since biologic initiation or switch were 10.4 and 11.3 respectively and improved by 27% in biologic naïve group and 7% in biologic switch group. Of the total 4,048 visits with CDAI scores, 587 visits were associated with high CDAI scores, 333 of them (57%) resulted in therapy modification. In patient visits with CDAI scores showing high disease activity (CDAI>22), but without change in therapy to a first time biologic or a second biologic, mean CDAI, PGA (Patient's Global Disease Activity), EGA (Evaluator's Global Disease Activity), SJC (swollen joint count) and TJC (tender joint count) scores were 34.7, 6.0, 5.2, 7.5, and 15.3 compared to patients who switched at high disease activity with the mean CDAI, PGA, PhGA, SJC, and TJC of 36.8, 5.5, 5.4, 9.3, 15.8 respectively (p>.05).

Conclusion: Starting biologic therapy positively impacts clinical outcomes as measured by CDAI score; however CDAI scores do not seem to always impact the decision to start or switch the biologic. More research is needed to fully elucidate the decision drivers having the highest impact on the decision to switch therapy.

Comparative Effectiveness and Time to Response Among Abatacept, Adalimumab, Certolizumab, Etanercept, Infliximab, Rituximab and Tocilizumab in a Real World Routine Care Registry

Yusuf Yazici[1], Hannah Bernstein[1] and Christopher Swearingen[2], [1]Department of Medicine, Division of Rheumatology, New York University School of Medicine, New York, NY, [2]Pediatrics & Biostatistics, University of Arkansas, Little Rock, AR

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: With the availability of multiple biologic agents, each with different modes of action, use of real world registries provide the manner in which to examine comparative effectiveness in the absence of head-to-head clinical trials inform physicians how they might be used for the treatment of rheumatoid arthritis

Methods: Arthritis Registry Monitoring Database (ARMD) has been collecting prospective patient data since 2005 in all patients seen in routine care. Each patient in this setting (with any diagnosis) completes a 2-sided, 1-page MDHAQ (multidimensional health assessment questionnaire) at every visit while waiting to see the physician in the infrastructure of clinical care. The MDHAQ includes scales for physical function, pain, patient global estimate (PATGL), fatigue, and a self-report RADAI painful joint count. Usage of the biologic medications abatacept, adalimumab, certolizumab, etanercept, infliximab, rituximab and tocilizumab along with self-reported disease activity and clinic measures were

abstracted. Treatments were considered to be independent of each other as no individual received biologic medications in combination. Time to first response defined as an improvement in RAPID3 of at least 3.6 was calculated; change from biologic medication initiation to first response for self-reported disease activity and clinic measures was estimated. For those individuals with no response, time to last follow-up was calculated and this was defined as lack of efficacy. Differences in time to first response between biologic medications versus lack of efficacy were estimated using competing risks proportional hazards model, adjusting for age, duration of disease, baseline RAPID3.

Results: 4217 encounters were reviewed for this analysis. A total of 1789 treatment observations were abstracted in 316 subjects. For those subjects with a baseline RAPID3 ≥ 3.6, average age of the cohort was 51.5 years (±14.5), average duration 9.3 years (±9.3), 213 (85%) were female, and average baseline RAPID3 was 14.8 (±6.3). Using infliximab as a reference, improved efficacy was estimated with abatacept (SHR = 1.5), etanercept (SHR = 1.6) and rituximab (SHR=2.3) adjusting for age, duration and baseline RAPID3. Increased age led to a decreased likelihood of response (SHR=0.99, P=0.045). As expected, the higher the baseline RAPID3, the likelihood of a positive treatment response also increased (SHR=1.09, P<0.001). Adalimumab and tocilizumab had some improved efficacy, while certolizumab had decreased efficacy compared to infliximab.

Conclusion: Our data suggest that there are no major differences in efficacy of adalimumab, abatacept, etanercept and infliximab and time to response when treating RA patients. With no difference in clinical outcomes, most treatment decisions may be based on ease of use and safety data of respective biologics agents when they are being considered for RA treatment.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Use of biologic agents for the treatment of rheumatoid arthritis continues to grow rapidly, with the cost of these agents putting a significant strain on health care budgets. Although rheumatologists and third party payers share the goal of ensuring quality of care for RA patients, rheumatologists fear potential limitation of access to biologics due to cost while third party payers are concerned about the rising expenses associated with the use of these agents. Treatment pathways have been suggested as a tool to address these issues.

Methods: Seventy nine rheumatologists from 35 practices in the mid-Atlantic region participated in a payer-sponsored, rheumatologist-developed RA treatment clinical pathway. To be considered compliant with the pathway, practices were required to enter all RA patients insured by the payer, utilize oral DMARDs for at least 3 months prior to use of a biologic agent, prescribe the biologic agent at the lowest approved dose, and increase dose according to package guidelines. Initial biologic therapy could include any of the TNF, abatacept (SC or IV) or tocilizumab (SC or IV). Rituximab or tofacitinib were reserved for previous biologic failures. Patients were not required to change biologics for ongoing disease activity, but biologics could not be initiated, switched or increased in dose if the patient was in Clinical Disease Activity Index (CDAI) remission. Persistence and mean CDAI were calculated and evaluated at 6 and 12 months for patients on TNF and non-TNF agents.

Results: From 1/1/12 to 12/31/2013, Of 3200 patients on the pathway, 586 patients started a new biologic(s) in the study period, 137 started their first biologic and 449 switched to another biologic. 301 patients were analyzed at treatment initiation based on their CDAI score availability of which 159 initiated TNF agents and 142 initiated non TNF- agents. Of these patients, 65% were persistent on therapy at 6 months on TNF agents and 84% on non-TNF agents; at 12 months, 52% were persistent on TNF agents and 65% on non-TNF agents. The mean CDAI scores at 6 months were 7.7 for TNF group versus 10.2 for non-TNF group (p=.010); while at 12 months the mean CDAI scores were 8.6 in TNF and 10.7 in non-TNF group respectively although the difference was not statistically significant as assessed by t-test (p=.23). Overall the mean CDAI score for patients who initiated a biologic was 12.6, while the mean CDAI score for patients who persisted on their biologic for a year was 9.7.

Conclusion: Persistence decreased over time in both TNF and non-TNF patients with higher rate of drop off occurring in patients on TNF. Patients exhibit improvement in CDAI scores, while participating in the Pathway program. Guideline-driven care is taking into consideration both efficacy and costs and has no negative impact on patient reported outcomes.

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Adalimumab (ADA) plus methotrexate (MTX) and MTX treatments for rheumatoid arthritis (RA) have been assessed in phase 2–4 clinical trials. This meta-analysis used 5 such studies to create a maximum efficacy (Emax) model describing the time course of the change from baseline in the 28-joint Disease Activity Score (DAS28) based on C-reactive protein (CRP).

Methods: DAS28(CRP) is a validated, continuous clinical efficacy endpoint for assessing signs and symptoms in RA patients (pts); change from baseline was modeled using a 3-parameter, nonlinear Emax model of ADA+MTX or MTX efficacy over time (up to 52 wks). Emax models for the DAS28(CRP) time course for each treatment and each study were built using data from pts with early (n=3 studies) and established (n=2) RA. Contributions of baseline covariates were assessed using the least absolute shrinkage and selection operator (LASSO) penalized linear regression model.

Results: Emax model estimates for DAS28(CRP) responses to ADA+MTX and MTX treatments are in **Table 1**. Visual inspection confirmed that modeled time courses for DAS28(CRP) responses to ADA+MTX and MTX treatments were consistent with observed mean and median values of the combined studies; residual variability for DAS28(CRP) change was 1.1 in both groups. The modeled DAS28(CRP) response to MTX appeared to develop more slowly vs response to ADA+MTX (9.4 vs 3.1 wks for 50% effect). The effects of RA duration on DAS28(CRP) responses were estimated by modeled time courses for ADA+MTX and MTX in pts with early (duration=0.4 y, no prior DMARD use) and established (duration=5 y, prior DMARD use) RA; all other covariates were fixed. The DAS28(CRP) responses to MTX and ADA+MTX were greater in pts with early vs established RA **(Figure 1)**. When the covariate for baseline disease activity was set to DAS28(CRP)=5.5 (less active RA) vs 6.5 (more active RA), the model predicted greater responses to either treatment in pts with more active RA **(Figure 2)**.

Conclusion: Time courses of DAS28(CRP) responses to ADA+MTX and MTX treatments over 52 wks were well characterized by Emax models incorporating baseline covariates. The models predicted the greatest treatment differences between ADA+MTX and MTX during the first 24 wks and greater DAS28(CRP) responses to either treatment in pts with early RA and more active RA at baseline.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Disease activity measurement is a cornerstone of the Treat to Target strategy. However, all currently used measures include a Patient Global Score (PtGLB) as one of the components. We assessed disparities in Patient Global Scores in White vs. Black patients in a community based practice and its impact CDAI.

Methods: Data from random visits of 236 RA patients was obtained. Data regarding patient demographics, as well as other measures of clinical status were evaluated. Regression analysis was used to determine impact of race on PtGLB, controlling for age, sex, disease duration, education level, swollen joint count, and Fibromyalgia co-diagnosis. CDAI was calculated by using standard measures and, also, corrected for ethnicity.

Results: 236 patients with RA, 198 Caucasian and 38 of African descent were analyzed. Two sample t-test to compare the two racial groups revealed no significant differences in age, duration of disease, education level, Fibromyalgia co-diagnosis, and swollen joint count (all p-values >0.05). Statistically significant differences were found in gender and PtGLB, with a higher proportion of female patients and higher PtGLB in the black population (mean of 5.09, 95% CI 4.15 – 6.04 vs. 3.62, 95% CI 3.23 – 4.02) (p=0.004). Higher Provider Global Scores were seen in the black population vs. the white population (1.92, 95% CI 1.09 – 2.75 vs. 1.27, 95% CI 1.04-1.50) (p=0.04).

After controlling for age, sex, duration of disease, education level, Fibromyalgia co-diagnosis, and swollen joint count, it was found that the average patient-reported global assessment score was 3.83 in the white population vs. 5.17 in the black population (D= 1.34).

When CDAI scores were calculated without correcting for influence of race on PtGLB, the mean CDAI score in whites were lower than in the blacks (10.97, 95% CI 9.59 – 12.36 vs. 14.35, 95% CI 10.05 – 18.64). 57% (112 of 198 patients) of whites were in low disease activity or remission state vs. 37% (14 of 38 patients) of the black population. (p=0.033)

After correcting for the influence of race, the percentage of patients in remission/low disease state in the black population increased to 47% (18 of 38 patients). After correction thee was no statistically significant differences between the two groups. (p=0.374)

Conclusion: African-American patients on average have higher self-reported global disease activity levels. This may lead to misclassification of patients as being outside of the remission/low disease activity range, which may lead to over-treatment of patients who would otherwise have no changes made to their management plan.

Further studies with larger numbers of patients and inclusion of additional racial/ethnic groups to substantiate the results of this study are required.

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Advancements in RA treatment approaches with DMARDs and biological agents have enabled disease remission goals that were previously considered unattainable. The concept of "tight control" strategies tailored to individual patients defines specific clinical targets for DAS remission, reduction of CRP and ESR to normal measures and the halting of joint damage within a reasonable time frame. 14-3-3η is normally a ubiquitous intracellular protein that in RA, is released into the extracellular space where it acts as a ligand that potently induces MMPs, RANKL as well as TNFα and IL-6. 14-3-3η is available as a highly specific diagnostic blood test for RA and is modifiable over the disease course, lending itself well to serial testing for disease monitoring to healthy, negative levels. The aim of this study was to examine whether seroreversion of 14-3-3η to negative levels at 18 months is associated with a better radiographic outcomes at 30 and 42 months in RA patients.

Methods: Serum 14-3-3η levels were measured at baseline (BL) in 331 patients with recent onset polyarthritis (Sherbrooke EUPA), in which tight control was applied and 60 months follow-up completed. 14-3-3η positivity was defined as ≥0.19 ng/ml. Mean age was 60 years, 62% were female, and median (IQR) duration of symptoms was 4 (1.7-5.7) months. At 18 and 30 months, radiographic follow-up data was available for 320 and 310 patients, respectively. ANOVA analysis was performed to assess the significance of differences in radiographic outcomes from BL to 18 months based on 14-3-3η positive status at BL and 18 months. DAS remission at 18 months was defined as <2.6. Differences in mean ΔSHS from 18 to 30 and 42 months based on 18 month 14-3-3η positivity was assessed using the Student t-test.

Results: Out of 320 patients, 147 (46%) patients were 14-3-3η positive at BL. At 18 months, 126 (86%) remained positive (RP) and 21 (14%) became negative (BN). Of the 173 (54%) that were negative at BL, 154 (89%) remained negative (RN) and 19 (11%) became positive (BP). In evaluating radiographic progression from BL to 18 months, ANOVA analysis revealed that the mean (SD) ΔSHS was lowest in those patients that BN for 14-3-3η [2.7 (3.9)] or RN [2.5 (4.8)] versus patient groups that RP [4.3 (5.7)] or BP [6.0 (10.5)], p=0.009. Sub-grouping of patients according to DAS28 remission revealed despite achieving a DAS28 <2.6, patients that were 14-3-3η positive at 18 months had significantly higher ΔSHS from 18 to 30. Similar observations were apparent in non-remitters (table).

		14-3-3η at 18 mo	N	Mean	Std. Dev	p-value
Not in remission at 18 mo	ΔSHS from 18-30	positive	67	4.9403	8.37724	0.002
		negative	73	1.5616	4.00689	
	ΔSHS from 18-42	positive	67	8.9254	14.70963	0.006
		negative	76	3.6447	6.98895	
Remission at 18 mo	ΔSHS from 18-30	positive	70	3.1714	4.66865	0.002
		negative	95	1.4211	2.4779	
	ΔSHS from 18-42	positive	68	3.7941	8.39609	0.136
		negative	92	2.3261	3.65883	

Conclusion: Patients with early polyarthritis who are 14-3-3η seronegative and remain negative or revert from positive to negative levels at 18 months, have less radiographic progression at 30 and 42 months. Aiming for negative 14-3-3η levels as part of treat-to-target strategies may assist clinical efforts to halt joint damage progression.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with established RA undergoing total joint arthroplasty (TJA) frequently experience a disease flare within 6 weeks of surgery. This study aims to determine which histopathologicfeatures indicating active synovial inflammation in tissue obtained during TJA was associated with patients who experience post-op flare.

Methods: Synovial tissue obtained at the time of TJA from a cohort of well-characterized RA patients was examined by 2 experienced musculoskeletal pathologists for features known to be associated with rheumatoid arthritis. Significant previously described synovial pathologic features selected by unadjusted logistic regression included synovial lymphocytic and plasma cell infiltration, sclerosis/fibrosis, synovial lining hyperplasia, vascularity, and mucoid change were combined as a limited pathology score. Patient's summary scores were compared to clinical status, including flare yes/no whether in the 6 week postoperative course. Inter-pathologist reliability, along with disease characteristics and flare status correlations, were assessed using Spearman's correlation coefficient. Flare was classified using patient self-report and MD agreement based on chart review. Immunohistochemicalstaining for Rho Kinase pathway markers was performed.

Results: Baseline and disease characteristics from 37 RA patients showed no differences in those who reported flare (n=23) vs. those who did not (n=14) (**Table 1**). Pathologist scoring of summed synovial inflammatory features were highly correlated between (Spearman's rho=.55, p-value=0.01) and within (Spearman's rho=0.7, p<0.01) readers. While there was no correlation between the summary pathology score and baseline disease characteristics (DAS28CRP/flare: rho=0.2, CRP/ flare: rho=0.2) **,** flare was associated with synovial lymphocytic infiltration (OR 4.2, 95% CI 1.2-14.9, p=0.03), and plasma cell infiltration (OR 6.3, 95%CI 1.7- ∞, p<0.01). Sclerosis/fibrosis was not significantly associated with flare (OR 0.9, 95%CI 0.4-2.2, p=0.78) (**Table 2)**. The pERM staining (surrogate marker for ROCK activation) could be observed in different cellular components but the staining pattern did not differentiate flarers.

Conclusion: Inflammatory histological features in synovial tissue at the time of surgery are associated with a higher risk for post-operative flare. The notion that RA at the time of arthroplastyrepresents "burnt-out disease" should be re-evaluated.

This study was supported by the Clinical Translational Science Center (CTSC) (UL1-TR000457-06)

Pretreatment Prediction of Response to Anti-Cytokine Therapy Using Serum Cytokine/Chemokine/Soluble Receptors in Individual Rheumatoid Arthritis Patient

KAZUYUKI YOSHIZAKI, Organic Fine Chemicals, The Institute of Scientific and Industrial Research, Osaka University, Suita, Japan
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: In clinical practice in rheumatoid arthritis (RA), it has been noted that each anti-rheumatic therapy delivers a different outcome for individual RA patients and this makes it difficult to prescribe the most efficacious treatment for them. Being able to predict a patient's response/outcome before they are treated would allow doctors to prescribe the cytokine therapy that is the most efficacious for each RA patient. It is critical to identify molecular biomarkers that can predict patient response to anti-TNF-a or anti-IL-6 based therapies before patients are treated so that non-effective therapies are eliminated and more effective ones can be prescribed for patients at an earlier stage. We believe that identifying reliable predictive biomarkers will make it easier to follow EULAR's treat-to-target recommendation by allowing clinicians to know in advance if a treatment strategy will achieve the treatment goal (target) that has been pre-determined for each RA patient.

Methods: We enrolled 138 RA patients (naïve and non-naïve to anti-cytokine therapy) and measured 31 cytokines/chemokines/soluble receptors in their serum before administering tocilizumab or etanercept for 16 weeks. We selected parameters that correlated with patient's week 16 DAS28-CRP score by multiple linear analyses and identified biomarkers that could predict if patients would experience complete remission or non-remission by multiple logistic analyses.

Results: Multiple linear regression analysis based on patients' week 16 DAS28 revealed that sgp130, logIL-6, logIL-8, logEotaxin, logIP-10, logVEGF, logsTNFR-I and logsTNFR-II serum levels before therapy were potential biomarkers to predict biologic naïve patients' week 16 DAS28. Sgp130, logIP-10, logsTNFR-II and logIL-6 were predictive of complete remission or non-remission to tocilizumab therapy by multiple logistic analyses. A high sgp130 level was the most reliable predictor of patients' outcome. Additionally, we found logIL-9, logVEGF and logTNF-a to be less reliable at predicting the week 16 DAS28 score in naïve etanercept patients. Most of these biomarkers, especially sgp130, are involved in RA pathogenesis and IL-6 signal transduction, which further suggests that they are highly reliable.

Conclusion: We discovered reliable biomarkers that can predict clinical disease activity and outcome before RA patients undergo anti-IL-6 and anti TNF-a therapy. Most of the predictive biomarkers are involved in RA pathogenesis. Predicting treatment disease activity and outcome for anti-IL-6 reagent can assist doctors to more effectively pursue EULAR's treat-to-target approach by identifying in advance if IL-6 blockades will allow individual RA patients to reach their treatment target.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: HAQ (Health Assessment Questionnaire) assesses functional disability in rheumatoid arthritis (RA) patients. Correlation between HAQ and disease activity might change according to the length of the disease. The purpose of our study was to assess this correlation in RA patients according to disease duration

Methods: RA patients ≥18 years (ACR/EULAR 2010 criteria) seen between March and May 2014 were included. At the inclusion visit: age, gender, disease duration, tender and swollen joint count (28 joints), disease activity by CDAI (Clinical Disease Activity Index) and physical function (HAQ-A, argentine Spanish validated version) were recorded. Patients were divided in two groups according to disease duration (≤ or >5 years). Variables were compared between both groups. Spearman correlation between CDAI and HAQ was calculated in each subgroup. Receiver Operating Characteristic (ROC) curve was used to assess the discriminating power of HAQ in patients in clinical remission (by CDAI), for the whole group and in the different age subgroups

Results: 104 patients, 91 females (88%), mean age of 60 years were included. Table 1 shows patients demographics and clinical features, by age group. While there were no significant differences in disease activity measurements, patients with longer disease duration had significantly worse HAQ-A. There was a significant correlation between HAQ-A and CDAI ($r=0.50$ $p<0.001$) for the total group. In patients with<5 years of disease duration (n=38) the correlation was $r=0.69$ ($p<0.0001$), whereas a lower correlation was found ($r= 0.48$ $p<0.001$) in patients with >5 years of disease duration (n=66). Patients on CDAI remission had significantly lower HAQ-A values than patients not in remission in both disease duration groups. However independently of remission status, patients with longer disease duration had significantly higher HAQ-A values than patients with short disease duration (table 2). The best cutoff value for HAQ–A to discriminate patients in remission (CDAI) using the ROC curve, in patients with shorter disease (≤5 years) was 0.125(AUC:0.85; 95% CI:0.74-0.96; Sensitivity (Se):76%; Specificity (Sp):92% and 0.875(AUC:0.81; 95% CI: 0.69-0.92 Se:59% Sp:90%) in patients with longer disease duration(>5 years)

Table 1

Characteristics	**Total group (N= 104)**	**Disease duration < 5 years (n=38)**	**Disease duration > 5 years (n=66)**	**P value**
Mean age (DS)	60 (14)	58.7 (16.7)	60.2 (11.7)	0.608
Females, n (%)	91 (88)	33 (87)	58 (88)	0.878
Mean years of Disease duration (SD)	10.1 (10.6)	1.3 (0.98)	15 (10.2)	<0.0001
Rheumatoid Factor positive, (n=96), n (%)	62 (65)	24/37 (65)	38/59 (64)	0.964
Anti-CCP positive, (n=87), n (%)	71 (82)	26/34 (76.5)	45/53 (85)	0.322
Mean CDAI (DS)	8,9 (10)	9.7 (12.2)	8.4 (8.4)	0.5320
Mean HAQ (DS)	0,64 (0,73)	0.37 (0.6)	0.8 (0.8)	0.0040
Mean pain VAS (DS)	29 (26,3)	27.3 (25.3)	29.7 (27.1)	0.6573
Mean VAS PGA (DS)	27 (27)	27.1 (27.2)	26.9 (27.3)	0.9644
Mean VAS PhGA (DS)	22 (20)	21.7 (20.6)	22.9 (20.2)	0.7862
On Methotrexate, n (%)	83 (80)	33 (87)	50 (76)	0.175
On Biologics, n(%)	33(32)	1 (2.6)	32 (49)	<0.0001
On Steroids, n(%)	25(24)	12 (32)	13 (20)	0.175

Table 2

	CDAI remision (n=33)	CDAI no remision (n=71)	P value
Mean HAQ-A, (SD), Patients < 5 years disease duration	(n=13) 0,03 (0,1)	(n= 25) 0,55 (0,7)	0,0105
Mean HAQ-A, (SD), Patients > 5 years disease duration	(n=20) 0,3 (0,5)	(n= 46) 1 (0,8)	0,0002
P value	0.0264	0.0078	

Conclusion: Correlation between disability measured by HAQ-A and disease activity measured by CDAI was better in patients with shorter disease duration.Patients with longer disease duration had higher functional disability independently of disease activity. Different HAQ-A values might need to be chosen as treatment targets for patients with different duration of disease

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Genealogical and genetic association studies have suggested that joint damage in rheumatoid arthritis (RA) may be heritable. We and others have found a number of specific genetic variants associated the extent of rheumatoid joint damage. Here, we estimate the cumulative association of single nucleotide polymorphisms (SNPs) associated with joint damage in a cohort of Mexican Americans (MA) and European Americans (EA) with RA.

Methods:

We recruited MA and EA patients with RA from rheumatology practices, and followed them over time. We used the Immunochip array to identify single nucleotide polymorphisms associated with the extent of radiographic joint damage on the latest available radiograph, quantified by inverse normal Sharp scores. Association analyses were conducted using PLINK, adjusting for age at RA onset, sex, RA duration and the first two ethnic principal components to adjust for population stratification. Association analyses were stratified by ethnic group. We excluded SNPs with call rates below 95% or minor allele frequencies below 1%, and patients with admixture or cryptic kinship relationships. We used the six SNPs with the strongest association with joint damage in each ethnic group as defined by a P-value $\leq 10\text{-}5$, to construct a cumulative scale by summing the number of damage-associated alleles in each patient. We examined the association of the cumulative SNP scale with joint damage progression over the duration of the study using scale x RA duration product terms in generalized estimating equations adjusted for age at RA onset, sex and ethnic group.

Results:

Genotypic and joint damage data were available for 675 MAs and 410 EAs. These patients had 3,186 Sharp scores available, covering a period of 4,149 patient-years (mean 3.8 years per patient, range 0 to 19). The Sharp score increased by 4.1 per year of disease (95% C.I. 3.98, 4.35), without difference between ethnic groups. The mean number of damage-associated SNPs in each patient was 4.4 (range 0 to 12), each additional SNP associated with an increase Sharp progression rate of 0.2 per year (95% CI 0.1, 0.3; $P \leq 0.001$). Among patients with 3 or less risk alleles, Sharp increased by 3.6 per year (3.4, 3.9); among patients with 4 to 6 alleles, Sharp increased by 4.1 per year (3.9, 4.3), and among patients with 7 or more alleles, Sharp increased by 4.9 per year (4.5, 5.3). The figure plots Sharp score over disease duration, according to the number of damage associated SNPs.

Conclusion:

Genetic variants associated with joint damage display a cumulative association, patients with a greater number of SNPs displaying greater joint damage. These findings may provide insights into the biology of joint damage in RA and if validated in other populations, could be of use for the early identification of RA patients at risk for joint damage.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: To clarify whether MRI bone oedema predicts the development of rapid radiographic progression (RRP) in Nagasaki University Early Arthritis Cohort patients with early-stage rheumatoid arthritis (RA).

Methods: Early-stage RA patients (n=76) were enrolled and underwent Gd-enhanced MRI of both wrists and finger joints. Synovitis, bone oedema and bone erosion were evaluated using the Rheumatoid Arthritis Magnetic Resonance Imaging score (RAMRIS). RRP was defined as an annual increment > 3 at 1 year by plain radiographs and the Genant-modified Sharp score. A multivariate logistic regression analysis was performed to establish the risk factors for RRP, using patients' characteristics, serum variables, MRI findings, therapeutic responses and regime.

Results: The patients' median age was 54.5 yrs, and their median disease duration at enrollment was 3 months. RRP was found in 12 of the 76 patients at 1 year. A univariate analysis revealed that matrix metalloproteinase-3, RAMRIS bone oedema score and RAMRIS bone erosion score were associated with RRP. Multivariate logistic regression analyses demonstrated that the RAMRIS bone oedema score at enrollment (5-point increase, OR 2.18, 95%CI 1.32–3.59, p=0.002) is the only independent predictor of the development of RRP at 1 year. An ROC analysis identified the best cut-off value for RAMRIS bone oedema score as 5.

Conclusion: Our findings suggest that MRI bone oedema is closely associated with the development of RRP in early-stage RA patients. Physicians should carefully control the disease activity when MRI bone oedema is observed in early RA patients.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: The presence of rheumatoid factor (RF) and antibodies against citrullinated peptides (ACPA) is associated with progression of joint damage in patients with rheumatoid arthritis (RA). RF and ACPA levels may change during the course of therapy, but it not clear, if such changes in autoantibody levels also reflect a change in prognosis of RA. Here, we aimed to investigate whether changes of RF and ACPA reflect a true change in prognosis of RA.

Methods: A cohort of 450 RA outpatients was identified based on classifiable RA by the 2010 ACR/EULAR classification criteria, the presence of at least 2 available radiographs of hands and feet 3 years (30 to 42 months) apart, as well as availability of serological tests for RF and ACPA taken within 3 months prior or after each radiograph. Radiographic images were scored using the modified Sharp/van der Heijde (SvH) method.

Logistic regression analysis was used to examine the effect of RF and ACPA at baseline and after 3 years on significant damage progression (defined as increase of >=5 on the SvH score); results were adjusted for disease activity, expressed as Simplified Disease Activity Index (SDAI).

Results: At baseline, RF and ACPA were positive in 60.2% and 61.6%, respectively, of patients. Mean (SD) RF levels were 183.6 (517.2) IU/ml at baseline and 111.2 (247.2) IU/ml after 3 years; ACPA levels were 187.2 (232.6) IU/ml and 145.3 (169.5) IU/ml, respectively. Over the 3-year course, RF levels changed by a mean (SD) of 72.4 (409.7) IU/ml ($p<0.001$) and ACPA levels by 41,9 (120.8) IU/ml ($p<0.001$). SDAI levels at baseline and after 3 years were 13.8 (11.3) and 8.7 (8.8), respectively.

Univariate logistic regression showed a clear association of radiographic progression with higher levels of RF at baseline (p=0.039), but not

after 3 years (p=0.515). When adjusting these effects for time-integrated levels of disease activity, they essentially remained unchanged (p=0.052 and p=0.513, respectively; table), despite the expected highly significant association of disease activity and progression. Similarly to RF, the effect of ACPA on radiographic progression was significant at baseline before and after adjusting for disease activity, but in contrast to RF, remained so also after three years (table).

Conclusion: RF levels seem to comprise reversible and irreversible components. RF is associated with progression of RA, although removal of the reversible component also eliminated this association. This association was independent of disease activity during the observed period. ACPA is poorly reversible and the association with progression remained unchanged from baseline to year 3.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Remission is the key treatment goal in rheumatoid arthritis (RA). Although clinical remission is increasingly achieved, many patients progress both structurally and functionally. We currently do not routinely assess immunological markers or perform ultrasound imaging to define remission.

We aimed to document the variability of clinical, patient-reported, imaging and immunological characteristics of RA patients in clinical remission and to correlate these with outcomes.

Methods: In a retrospective, observational study patients with an RA diagnosis (1987 or 2010 ACR/EULAR criteria) were selected from our early inflammatory arthritis database; the lowest observation of 3-variable DAS28CRP≤3.2 after diagnosis was chosen as the index visit. We defined flare as loss of index visit state [remission (<2.6) or low disease activity (LDA; 2.6-3.2)]. We collected clinical data, patient-reported outcomes and ultrasound Power Doppler (PD) and Grey Scale (GS) findings. Frequencies of naïve $CD4^+$T-cells, Inflammation related cells (IRC), regulatory T-cells (Treg) measured and analysed by advanced 8-colour flow-cytometry were compared with reference range values obtained from 120 healthy controls.

Results: We included 633 patients (69% female; mean age 57.6 years) with a minimum DAS28CRP≤3.2 (mean 1.87/SD 0.68). Of these, 513 were in DAS-defined clinical remission. The majority (75%) were taking conventional synthetic DMARD therapy only, 45% as monotherapy. Inflammatory markers, joint counts and levels of disability/function and life impairment were generally low, as expected.

Positive PD signal was present in 43% (141/326) of patients in remission; 76% (248/326) had evidence of GS changes >1 in ≥1 joint. In LDA, PD and GS changes were 64% (46/72) and 85% (61/72) respectively.

In remission, abnormal T-cell numbers were seen in 9% (4/46), 26% (12/46) and 50% (23/46) for naïve, IRC and Treg's respectively. For LDA, the figures were 40% (2/5), 60% (3/5) and 100% (5/5).

15% (85/559) of patients flared within 6 months of the index visit. Odds of flare were higher in females, those with higher DAS28, longer disease and/or remission duration and evidence of PD synovitis (Table 1).

Conclusion: Despite being in DAS-defined clinical remission, a substantial proportion of patients exhibit PD synovitis on ultrasound and have evidence of T-cell abnormalities. Current remission criteria are composite scores and do not measure inflammation directly. Validation of imaging techniques and identification of remission biomarkers could lead to a better understanding of what constitutes true remission, with relevance for disease stability. Further work is required to assess the predictive value of T-cell abnormalities for flare.

		% (n) flared within 6 months	Odds ratio (95% CI), *P* value

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Biologic therapy is now a cornerstone of RA management, but treatment response is variable, failing in up to 40% of patients. To direct appropriate treatments towards those patients most likely to benefit, reliable predictors of treatment response must be identified. Response is usually measured using DAS28, using clinical, biochemical, and patient-reported data. It has recently been shown that psychological factors influence individual DAS28 components, notably tender joint count and patient visual analogue scale (VAS) (*Arthritis Care Res 2014,* 66:861-868).

We hypothesised that psychological factors also influence change in DAS28 after biologic therapy, and that individual components of DAS28 would be affected disproportionately.

Methods:

Data from the BRAGGSS cohort was used: a multicentre, observational study of RA patients with severe active disease according to NICE criteria and undergoing biologic therapy.

Clinical and demographic data were collected from patients about to commence a biologic drug, then at three and six months. Illness beliefs, treatment beliefs, and mood were assessed at the same timepoints using validated measures: the Brief Illness Perceptions Questionnaire (B-IPQ), the Beliefs about Medications Questionnaire (BMQ), and the Hospital Anxiety and Depression Scale (HADS), respectively.

The relationships between psychological factors at baseline and 3- and 6-month change in DAS28 components were analysed using linear regression.

Results:

At baseline, 75.5% of 1847 patients were female, with a mean age of 58.4, DAS28 of 5.74 and HAQ of 1.74. 73.1% patients received anti-TNF drugs. There were significant associations ($p<0.05$) between nine of the 12 psychological factors with patient VAS, and six psychological factors with tender joint count. Three B-IPQ items and HADS depression were associated with CRP ($p<0.05$). At six months, no associations between baseline B-IPQ scores and changes in composite DAS28 were observed but BMQ and HADS anxiety scores showed a significant association ($p<0.05$). Interestingly, an association was found between baseline illness beliefs and changes in CRP, indicating that with lower baseline psychological scores inflammation was more reduced; for example, personal control ($\beta=-0.786$, $p=0.05$), treatment control ($\beta=-1.48$, $p=0.005$) and coherence ($\beta=-1.623$, $p=<0.001$). This was true at both three and six months follow-up.

Conclusion:

This study confirms earlier findings suggesting that baseline psychological factors affect baseline DAS28, especially patient-reported measures. Interestingly, psychological factors were significantly correlated with change in CRP at both 3 and 6 months, suggesting psychological state may be a driver of inflammation in RA and that the most appropriate approach for some patients may include addressing psychological wellbeing.

Overall, psychological factors were associated disproportionately with individual components of DAS28, but not with change in composite DAS28 score. This illustrates that reporting of individual DAS28 components may highlight individual patients' differing needs despite superficially similar composite scores.

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Rheumatoid arthritis (RA) is characterized by autoimmunity to citrullinated proteins. *Porphyromonas gingivalis* (*Pg*) has been proposed as an epidemiologic link between RA and periodontitis (PD) and expresses peptidylarginine deiminase (PPAD). In addition to catalyzing citrullination, PPAD itself can be citrullinated. Reports have demonstrated a heightened immune response to cit-PPAD that is specific to RA and that might serve as a potential mechanism for breaching immunologic tolerance. There have been no studies examining the association of anti-cit-PPAD antibody with RA risk factors or measures of disease severity. The objective of the present study was to examine the association of anti-cit-PPAD antibody with known RA risk factors and disease severity.

Methods:

Patients with RA (n=285) were studied in a post-hoc analysis of a case-control study that included standardized full-mouth examination to assess PD status. ACPA specific to CCP, cit-enolase, and cit-H2A (histone) and antibody to the immunodominant peptide of cit-PPAD (CPP3) were measured using ELISA. Anti-CPP3 was defined as concentrations ≥2.5 SD above the mean in 330 osteoarthritis controls, while anti-cit-enolase and anti-cit-H2A were defined as concentrations ≥2 SD above the control mean. Associations of RA risk factors (smoking, PD, and HLA-DRB1 shared epitope [SE]) with anti-CPP3 positivity were examined using the chi-square test; associations with disease activity and radiographic severity (hand films and oral panoramic films) were examined using Wilcoxon rank-sum tests. Associations of anti-CPP3 with ACPA concentrations were examined using Spearman rank correlations.

Results:

Anti-CPP3 positivity was observed in 100 RA cases (35%) with positivity nearly exclusive to anti-CCP antibody positive RA; only 3 of 43 anti-CCP negative RA cases were positive for anti-CPP3. Associations of anti-CPP3 antibody with patient factors and RA disease severity measures are shown in Table 1, with significant associations between anti-CPP3 antibody and HLA-DRB1 SE status, erosion score on hand films, alveolar bone loss, and RF. There were significant correlations of anti-CPP3 antibody concentrations with ACPA concentrations including anti-CCP (r 0.54; $p < 0.001$), anti-cit-enolase (r 0.63; $p < 0.001$), and anti-cH2A (r 0.41; $p < 0.001$).

Conclusion:

As previously observed with ACPA, antibody to citrullinated PPAD is increased in RA and is associated with worse oral and joint radiographic damage in RA in addition to HLA-DRB1 SE and higher titers of RF. Moreover, anti-CPP3 antibody is strongly correlated with circulating ACPA, supporting a potential pathogenic role for *Pg* expressed PPAD in RA disease pathogenesis and progression.

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Complement activation, a key component of innate immunity and activator of adaptive immunity has been linked to RA pathogenesis. Anti-citrullinated peptide antibody (ACPA) and rheumatoid factor (RF) may cause complement activation. We examined the association of the terminal complement component C5 and its breakdown product C5a with ACPA in a preclinical Indigenous North American (INA) population at high risk for severe RA.

Methods: C5, C5a, and ACPA were examined by enzyme-linked immunosorbent assay ELISA, RF by nephlometry, in 267 sera from INA with RA (n=43), first degree relatives (FDR) (ACPA positive n=16; ACPA negative n=64) and FDR who later developed synovitis (FDR-S; n=10). Samples were spun and stored at -20C. ACPA positive FDRs samples were matched to one or two ACPA negative FDR samples based on date of sample collection. Levels were correlated with sample storage duration to assess for *in vitro* complement activation. Associations between C5, C5a, ACPA, and subject group were determined using Chi squared, Mann Whitney U tests and Wilcoxon signed ranks tests for paired samples. Correlations were tested by Spearman correlation. Multivariable models controlling for time stored, ACPA, RF, visit sequence and sex were generated to determine the independent influence of ACPA on C5 and C5a serum levels. Data are reported as median (interquartile range (IQR)) and B with 95% confidence limits (CL).

Results: C5a levels increased with increasing time stored (rho=0.69; p<0.0001); C5 levels decreased (rho= -0.33;p=0.002); median (IQR) time stored 6.3(5.5) years). This presumed *in vitro* activation was most important for samples stored over 5 years. In FDR samples matched for time stored, C5a and C5 levels were similar between FDR persistently ACPA positive vs ACPA negative (C5a 17.8 (6.3) vs 17.0 (6.7) ng/ml; p=ns; C5 135.2 (81.7) vs 130.8 (87.5) µg/ml; p=ns). Comparing all samples from FDRs, C5 levels were higher in ACPA positive vs ACPA negative samples (135.2 (46.6) vs 71.2 (75) µg/ml; p<0.001). Using linear regression to determine predictors of C5 levels in 153 samples from 80 FDR, the presence of ACPA independently predicted higher C5 level (B (CL) 42 (17-71)) after correcting for duration of time sample stored, visit sequence, sex and RF (titre > 40 U/ml being positive). This association with ACPA was not seen for C5a. In FDR-S (n=10), ACPA titers increased prior to synovitis. FDR-S had higher C5a levels than FDR (238 (225) vs 133 (362) ng/ml; p<0.0001) an association that was significant after correcting for duration of storage, visit sequence, ACPA, RF and sex (B=95(16-174); p=0.02).

Conclusion: In vitro complement activation may occur with prolonged sample storage and must be considered in any analysis of stored samples. C5 level is independently predicted by ACPA in FDR in an INA prospective cohort suggesting decreased activity of the terminal complement cascade in the presence of ACPA. Those who transitioned to synovitis showed evidence of increased complement activity and prior to onset of synovitis showed expansion of ACPA. ACPA related complement cascade activation in imminent synovitis cannot be confirmed based on this data.

Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Periodontitis (PD) has been implicated as an etiologic risk factor in rheumatoid arthritis (RA), an association that is speculated to be related to the oral pathogen *Porphyromonas gingivalis* (Pg). Among prokaryotes, Pg has the unique ability to citrullinate antigens, and anti-Pg immunity in established RA has been linked to the expression of anti-citrullinated protein antibody (ACPA). To date, no studies have investigated whether an association exists between anti-Pg antibody and pre-clinical ACPA expression or the future development of RA. The objective of this study was to evaluate the association between anti-Pg antibodies and development of RA as well as RF and anti-CCP2 antibodies in preclinical RA.

Methods:

A longitudinal case-control design was used to study 73 U.S. military personnel who eventually developed seropositive RA and 73 controls, matched on age at diagnosis, sex, race, number of samples available, duration of sample storage and enlistment region. Stored serum samples taken prior to RA diagnosis were tested for RF (isotypes and nephelometry), anti-CCP2 antibody, and antibody to Pg outer membrane antigen. Generalized estimating equations (GEE) were used to determine the association of anti-Pg antibody with RA case status. In secondary analysis, mixed effects linear regression was used to determine the association between anti-Pg antibody and autoantibody concentrations in preclinical RA. All antibody levels were log-transformed for analysis.

Results:

At the time of diagnosis, RA cases had a mean (±SD) age of 40 (10) years, 59% were men, and a majority were Caucasian (67%). Cases and controls had a mean of 3.5 (1.3) samples available for analysis (2.9 ± 1.3 pre-diagnosis among cases) with a median of 1.4 (IQR 0.8-2.7) years from the last sample prior to diagnosis to diagnosis. As shown in the Table, there was no association of pre-clinical anti-Pg antibody and RA case status (p=0.32). Among cases, there was no association between anti-Pg and anti-CCP2 antibody concentrations (p=0.63). However, anti-Pg antibody levels were significantly associated with RF measured by nephelometry (p=0.009). Although not reaching statistical significance, isotype analysis demonstrated the strongest association between anti-Pg antibody and RF IgM concentration.

Conclusion:

There was no evidence in this study to support an association of anti-Pg antibody with the risk of developing seropositive RA nor was anti-Pg antibody associated with circulating ACPA during the pre-clinical period. The association of anti-Pg antibody with RF warrants further investigation, particularly in light of recent work demonstrating that RF acts synergistically with ACPA in promoting inflammation in RA.

Table Associations of anti-*P. gingivalis* (Pg) antibody levels) with RF and anti-CCP2 in preclinical samples from RA cases

	Coefficient	p-value
RF nephelometry, IU/ml	0.34	0.009
RF isotypes, IU/ml		
IgM	0.33	0.13
IgA	0.18	0.29
IgG	-0.04	0.89
Anti-CCP2, U/ml	0.16	0.63

* Linear mixed effects models include fixed effects for differing slopes over time before and after 1250 days prior to diagnosis. The models included random intercepts to take into account individual variation in RF or anti-CCP levels; all antibody concentrations log-transformed

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The protein/peptide citrullination is a post-translational modification and the citrullinated peptide epitopes are recognized by anti-citrullinated protein/peptide antibody (ACPA), which is a major diagnostic or prognostic marker for rheumatoid arthritis (RA). Together with ACPA, specific citrullinated endogenous protein/peptide autoantigens in the major inflammatory lesions of RA (e.g, synovial fluid) may provide valuable information for the development of early diagnosis and therapeutic intervention.

Methods: Synovial fluids obtained from RA (n=4) and osteoarthritis (OA) (n=4) patients were pooled, separately. Peptides in each pooled synovial fluid were extracted using centrifugal filtration and solid phase extraction, and then analyzed by a Q-Exactive mass spectrometer. ScaffoldPTM (v.2.1.3) was used to validate peptide identification and citrullination site mapping. Elevated levels of RA-specific citrullinated peptides are validated by targeted MS/MS analysis with synovial fluids from RA (n=30), OA (n=15), and ankylosing spondylitis (AS) (n=5).

Results: We have identified total 1094 endogenous peptides originated from 120 proteins using LC-MS peptide profiling experiment with pooled RA and osteoarthritis (OA) synovial fluids, separately. Among them 121 peptides derived from 9 proteins (FGA, FGB, SAA1, HMGN2, PTMA, SRGN, COL5A3, PRG4, and APOBR) were found to be citrullinated. The majority of citrullinated peptides were detected only in RA synovial fluid where some identified FGA citrullinated peptides are previously known citrullination sites of FGA, which validate our experiment. We also identified an RA unique citullinated peptide, which has not been reported in the past. To verify RA specific citrullinated peptides, targeted MS/MS analysis of selected citullinated peptides with synovial fluids from RA (n=30), OA (n=15), and ankylosing spondylitis (n=5) patients is being conducted.

Conclusion: We have identified unique citrullinated peptides present in RA synovial fluid. To validate representing citrullinated peptides in RA, we have undertaken targeted MS/MS analysis of selected citrullinated peptides using RA, OA, and AS synovial fluids. The eventual results from the independent cohort studies will confirm unique citullinated peptide markers present in RA synovial fluid, which may provide their diagnostic or therapeutic values for RA.

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: We previously showed that bone marrow (BM) CD34+ cells from rheumatoid arthritis (RA) patients have abnormal capacities to respond to tumor necrosis factor alpha and to differentiate into fibroblast-like cells producing MMP-1, resembling type B synoviocyte. In addition, we have recently demonstrated that the mRNA expression of nuclear factor kappa B1, Krüppel-like factor 5 and FK506-binding protein 5 in BM CD34+ cells is significantly higher in RA patients than osteoarthritis (OA) patients. Antibodies directed to citrullinated proteins are extremely specific for RA. Citrullination is catalyzed by a group of peptidylarginine deiminase (PAD) enzymes. PAD family members are categorized into five isoforms (PAD1, 2, 3, 4 and 6). Several studies have disclosed that PAD2 and PAD4 are expressed in rheumatoid synovial tissue or in mononuclear cells of rheumatoid synovial fluid. Moreover, Sp1 has been shown to regulate transcription of these PADI genes. The current study therefore examined the mRNA expression of PADI2, PADI4 and Sp1 transcription factor in BM CD34+ cells from RA patients.

Methods: BM samples were obtained from 48 patients with RA (6 males and 42 females: mean age 58.8 years) and 30 patients with OA (3 males and 27 females: mean age 71.1 years), who gave informed consent, during joint operations via aspiration from iliac crest. CD34+ cells were

purified from the BM mononuclear cells by positive selection with magnetic beads. The expression of mRNA for PADI2, PADI4 and Sp1 was examined by quantitative reverse transcription PCR and is shown as the ratio of the copy numbers to those of b-actin mRNA.

Results: The expression of mRNA for PADI2 was significantly higher in RA BM CD34+ cells than OA BM CD34+ cells (Fig. A). Compared to OA BM CD34+ cells, PADI4 and Sp1 gene expression levels of RA BM CD34+ cells manifested no statistically significant increase (Fig. B and C). The mRNA expression levels of PADI2, PADI4 and Sp1 were not correlated with serum C-reactive protein or with the administration of methotrexate or oral steroid. PADI2 gene expression was significantly correlated with PADI4 ($p<0.0001$, $r=0.7143$) and Sp1 ($p<0.0001$, $r=0.7954$) gene expression in RA BM CD34+ cells.

Conclusion: These results indicate that the enhanced expression of PADI2 mRNA in BM CD34+ cells plays a pivotal role in the pathogenesis of RA, and might be closely associated with mRNA expression of PADI4 or Sp1.

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Chronic periodontitis has been associated with rheumatoid arthritis (RA), and *Porphyromonas gingivalis* has been proposed as the mechanistic link, due to its unique property among pathogens to express a citrullinating enzyme (denoted *P.* PAD). We have recently demonstrated elevated anti-*P. gingivalis* antibody levels in patients with anti-citrullinated protein antibody (ACPA) positive RA compared to controls. To investigate this aetiological hypothesis further, we have analysed the anti-*P. gingivalis* antibody response in pre-RA individuals in relation to the development of the ACPA response.

Methods: Incident cases of RA were identified among participants (n=30447) in a community based health survey linked to local and national registers, followed by a structured review of the medical records. One control from the health survey, matched for age, sex and year of inclusion, was selected for each validated case. Anti-CCP2 antibody status was determined by the standard commercial ELISA method (Euro-Diagnostica AB). Anti-*P. gingivalis* IgG were detected by in-house ELISAs, using a citrullinated peptide derived from *P.* PAD (CPP3) and the arginine-containing equivalent (RPP3), or purified arginine gingipainB (RgpB) protein, as coating antigens. Cut off values for these antibodies were set at the 98th percentile among the controls. Analyses were stratified by time from inclusion in the health survey to RA diagnosis (1-5 and 6-13 years, respectively).

Results:

Serum was available from 166 cases (78% women), diagnosed with RA at a median of 5 years (IQR 3-8; range 1-13) after inclusion in the health survey. Anti-CPP3 and anti-RPP3 antibodies were detected in 6.0% and 5.4% of the pre-RA cases, respectively, whereas anti-CCP2 was positive in 22.3% of pre-RA cases. Positive anti-CPP3 antibodies were more frequent among anti-CCP2 antibody positive pre-RA cases (13.5 % *vs.* 3.9 %; p=0.04), whereas there was no such difference for anti-RPP3 IgG. Anti-CCP3 and anti-RPP3 antibodies occurred 1-5 years before RA diagnosis (7.2 % for both antibodies) as well as among those investigated 6-13 years before RA diagnosis (4.8% and 3.6%, respectively). Among anti-CPP3 positive pre-RA cases, levels of anti-CPP3 IgG were higher in those sampled ≤5 years before diagnosis (median 22.6 AU/ml (interquartile range (IQR) 17.0-29.2) *vs.* median 13.7 AU/ml (IQR 12.7-14.7; p=0.001), whereas there was no such difference for anti-RPP3 IgG (median 5.7 AU/ml; IQR 3.5-8.7 *vs.* median 4.2 AU/ml; IQR 3.9-14.6; p=0.71). Anti-RgpB IgG levels were not significantly different in pre-RA cases compared to controls (median 110.4 AU/ml;IQR 53.0-233.5 *vs.* median 94.4 AU/ml IQR 45.5-194.1; p=0.15).

Conclusion: Antibodies to *P.gingivalis* antigens occur years before RA diagnosis in a subset of pre-RA individuals. Presence of anti-CPP3 antibodies is associated with anti-CCP2 antibody positivity in the pre-clinical phase of RA, suggesting that the antibody response to citrullinated *P.*PAD in the context of chronic periodontitis could be one mechanism through which the early RA-specific immune phenotype can develop.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Chronic periodontitis has been considered as an important determinant in both occurrence and severity of rheumatoid arthritis (RA). It has been hypothesized that citrullination by the periodontal pathogen *Porphyromonas gingivalis* may play an important role in the development of RA-specific autoimmunity, by breaking immune tolerance to citrullinated proteins and trigger the production of anti-citrullinated protein antibodies (ACPA). In support of this hypothesis, we have recently demonstrated elevated anti-*P. gingivalis* antibody levels in RA compared to controls, specifically in ACPA+ RA. The aim of the present study was to further investigate the role of *P. gingivalis* in RA aetiology, by analysing the anti-*P. gingivalis* antibody response in plasma samples collected before the onset of RA.

Methods: A case-control study was preformed within the Medical Biobank of Northern Sweden. The study included 251 individuals who donated in total 422 plasma samples predating the onset of clinical symptoms of RA, and 198 population-based controls from the same cohort. The median (IQR) predating time until onset of RA was 5.2 (6.2) years. For 192 individuals diagnosed with RA, plasma was available from the time point of RA diagnosis, and 152 of these patients had also donated plasma before the onset of symptoms. All samples were analysed by in-house ELISAs for the presence of antibodies to virulence factor arginine gingipainB (RgpB) purified from *P. gingivalis*, and a citrullinated peptide (denoted CPP3) derived from the *P. gingivalis* PAD enzyme. Based on ROC curve analysis on RA patients and controls, a cut-off for anti-CPP3 IgG positivity was set at the 96th percentile. The anti-*P. gingivalis* antibody data was evaluated in relation to the development of the classical ACPA response.

Results: The concentration of anti-RgpB IgG levels was significantly increased in RA patients (mean±SEM; 114.4±16.9 AU/ml), and importantly also in the pre-symptomatic individuals (152.7±14.8 AU/ml), when compared to controls (82.2±12.1 AU/ml, $p < 0.001$ for both). Antibodies against CPP3 were detected in 8% of the RA population, and in 5% of pre-symptomatic individuals, with elevated levels in both RA patients (9.29±1.81 AU/ml) and in pre-symptomatic individuals (4.33±0.59 AU/ml), compared to controls (2.36±0.58 AU/ml, $p < 0.001$ for both). The anti-CPP3 antibody response followed the classical ACPA response, with increasing antibody levels over time, whilst the anti-RgpB IgG response was stable in pre-symptomatic individuals during the pre-dating time and (if anything) showed a trend towards lower levels after RA diagnosis, potentially as a result of anti-inflammatory treatment.

Conclusion: Antibody levels against *P. gingivalis* were significantly increased in RA patients compared to controls, and more importantly, these

antibodies were detected years before onset of symptoms of RA, supporting an aetiological role for *P. gingivalis* in the development of autoimmunity and autoimmune disease in a subset of RA patients.

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

We previously showed that anti-CCP2 antibodies are associated with parenchymal lung abnormalities in patients with early RA[1]. This study aims to examine the association between ACPA fine specificities and parenchymal lung changes in an early RA cohort.

Methods:

Patients with newly diagnosed RA according to the ACR 1987 classification criteria and naïve to treatment with oral glucocorticoids or DMARDs were eligible for the study. High-resolution computed tomography (HRCT) was performed in order to assess the presence of parenchymal lung changes (ground glass changes, nodules, infiltrates or fibrosis). ImmunoCAP was used to detect RF IgA, RF IgM, anti-CCP2 IgA, anti-CCP2 IgG and ISAC microarray system[2]was used to detect antibodies against 10 citrullinated (Cit) peptidic antigens: CCP-1 (Filaggrin), CEP-1 (α-enolase), Vim 2-17, Vim 60-75 (Vimentin), Fib β 36-52, Fib α 573, Fib α 591, Fib α 36-50, Fib β 60-74, Fib α 621-635 (Fibrinogen).

Logistic regression analysis was performed to examine possible associations between parenchymal lung changes at the time of RA diagnosis and autoantibodies, adjusted for age and sex. Due to the potential risk for effect modification of smoking and the strong association between smoking and Cit peptides, we stratified the cohort according to ever vs. never smokers.

Results:

A total of 106 patients with available HRCT were included in the analysis. The mean (SD) age was 57 (14) years. The majority were females (69%); 73% were ever smokers while 29% were current smokers; 70% were positive for RF and 69% were positive for anti-CCP2. Parenchymal lung changes were found in 58 patients (54.7%). Higher age, RF IgA, CCP2 IgG, ever smoking and pack-years above 24 were significant predictors of parenchymal lung changes (table 1). Some ACPA fine specificities, especially against Cit Fib and Cit Vim peptides, were associated to parenchymal lung changes in ever smokers (table 2). The risk of having parenchymal changes increased parallel to the increase of the number of ACPA specificities (table 2). Having five or more ACPA specificities at the time of diagnosis increased the risk of having lung abnormalities in ever smokers by 6.6 times (OR=5.8, 95% CI=1.6-27.3).

Conclusion:

The presence of RF IgA, anti-CCP2 IgG, antibodies to Cit Fib and Cit Vim peptides were strongly associated to parenchymal lung changes in ever smokers with early RA. The more ACPA fine specificities, the higher the risk of having parenchymal lung changes at the time of RA diagnosis.

Citrullinated Fibrinogen Promotes Bone Marrow Mesenchymal Stem Cells to Assume a Proinflammatory Phenotype

Yue Sun, Wei Deng, Weiwei Chen, Genhong Yao, Xuebing Feng and **Lingyun Sun**, Department of Rheumatology and Immunology, The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Mesenchymal stem cells (MSC) are not only immune-inhibitory cells, and may act as pro-inflammatory cells due to lack of a proper “licensing”. The role of MSC in autoimmune settings of rheumatoid arthritis (RA) has remained to be elucidated. Citrullinated fibrinogen (cfb) has been considered as one of the important autoantigens in RA and contributes to perpetuate the disease. Our study aimed to analyze the responses of bone marrow derived MSC (BMSC) to cfb.

Methods: BMSC were isolated from RA and osteoarthritis (OA) patients and exposed to cfb or native fibrinogen (fb). Proinflammatory cytokines stimulated by cfb were determined by quantitative PCR and ELISA. To evaluate the role of the toll like receptor 4 (TLR4)-NFκB pathway in the induction of cytokines by cfb, parallel experiments were performed using inhibitors of TLR4 or NFκB pathway. To investigate whether BMSC retain their immunosuppressive properties after exposure to cfb, we detected the effects of cfb primed BMSC on proliferation of peripheral blood mononuclear cells (PBMC).

Results: The autoantigen cfb increased the gene expression and protein production of IL-6, IL-8 and CCL2 in BMSC from both RA and OA patients. However, the production of IL-1β and TNFα were unaffected by cfb. Compared with fb, cfb induced significantly higher expression of the pro-inflammatory cytokines (IL-6, IL-8 and CCL2) in these cells. Blocking experiments showed the participation of TLR4-NFκB pathway in the induction of these cytokines. The autoantigen cfb also compromised the ability of BMSC to inhibit PBMC proliferation, as well as, impaired the potency of BMSC to produce the key immunomodulatory molecule indoleamine dioxygenase (IDO).

Conclusion: Our results suggest that cfb promotes pro-inflammatory responses in BMSC and negatively affects their immunomodulatory functions. Citrullinated fibrinogen may act as a dangerous “licensing” for BMSC and thereby contributing to the propagation of inflammation in RA.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: It has been hypothesized that *Porphyromonas gingivalis* - the only known pathogen to express a citrullinating enzyme (called *P.*PAD) - is etiologically linked to the development of anti-citrullinated protein antibody (ACPA) positive RA, via citrullination of its own as well as human proteins, generating autoantigens and the subsequent production of ACPA. In support of this hypothesis, it was recently shown that *P.*PAD can auto-citrullinate and that a subset of RA patients has elevated antibody levels towards citrullinated *P.*PAD. In the present study, we have characterized this antibody response in more details.

Methods: The antibody response to a citrullinated *P.*PAD-derived peptide denoted CPP3 (and the arginine-containing equivalent RPP3) was analysed in the Swedish population-based case-control cohort EIRA (n=2,859 RA cases; n=373 controls) using the ImmunoCAP ISAC microarray system (PhaDia Multiplexing Diagnostics). ACPA status, smoking habits, genetics, CRP levels and DAS28 data were retrieved from the EIRA database. Unconditional logistic regression analysis was used to calculate odds ratios (OR) with 95% confidence intervals (CI) for the association of different risk factors with different RA subsets.

Results:

With 98% specificity, using the EIRA control population to set cut-off, 10.4% of EIRA RA cases had antibodies to CPP3, and interestingly, 5.4% had antibodies to RPP3. In the same cohort, 65% were anti-CCP2 antibody positive. The majority of anti-CPP3 antibody positive patients were confined to the CCP2 positive population, and anti-CPP3 antibody levels correlated strongly with other ACPA fine-specificity levels (r = 0,99; p < 0,0001). When comparing CCP2+ / CPP3+ patients with CCP2+ / CPP3- patients, a significantly stronger association was found between smoking and the double positive subset (OR=2.88; 95% CI: 2.11-3.92) than between smoking and the CCP2 single positive subset (OR=1.75; 95% CI: 1.54-1.99) (p<0.0012), while we could not detect any significant difference with respect to the association of *HLA-DRB1* shared epitope and the two different subsets of RA (OR=7.27; 95% CI: 4.82-10.97 and OR=5.52; 95% CI: 4.58-6.64, for CCP2+ / CPP3+ and CCP2+ / CPP3- RA, respectively, p=0.32). As with the ACPA response in general, there was only a weak correlation between anti-CPP3 antibody positivity and baseline DAS28 and CRP levels.

Conclusion:

Conclusions: A small subset of RA (10.4%), mainly anti-CCP2+ RA, had an antibody response to CPP3. This antibody response associated with the ACPA response and showed similar characteristics as other ACPA fine-specificities, in relation to RA risk factors and disease activity scores. However, a subset of RA patients also had an antibody response to the arginine-containing RPP3 peptide (5.4%), which is not the case for most arginine-containing epitopes. Contrary to the other ACPA targets, CPP3 is a bacterial peptide sequence, and in a subset of patients, this antibody response could represent an aetiological link between *P. gingivalis* infection and ACPA+ RA development.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Antibodies against citrullinated proteins (ACPAs) are the autoimmune hallmark of rheumatoid arthritis (RA), and can precede the onset of symptomatic disease by years. By introducing neo-epitopes into self-proteins, posttranslational protein citrullination is thought to break immune tolerance and drive autoimmunity in RA. While many RA autoantigens are recognized in a citrulline-dependent context, some antigens are targeted as native (unmodified) proteins in RA, including Fc-gamma (targeted by rheumatoid factor), hnRNP A2/B1 (RA33), peptidylarginine deiminase type 4 (PAD4) and calpastatin among others. How these antibody systems fit into the current paradigm of autoantigen citrullination in RA is not known.

Methods:

Synovial fluid (SF) cell samples from patients with RA were analyzed by mass spectrometry (MS) and immunoblotting. HnRNP A2/B1/A2b/B1b (RA33) was cloned from RA SF cell cDNA, and expressed as recombinant proteins in an *E coli* system. Purified RA33 splicing variants were citrullinated in vitro using human rPAD4. Patients with RA (n=196 from the baseline visit of a prospective cohort study) and healthy controls (n=56) were assayed in parallel for antibodies against native and citrullinated hnRNP B1b by quantitative ELISA. Patients fulfilled the American College of Rheumatology 1987 revised criteria for the classification of RA. Antibody specificity against native and citrullinated RA33 was further analyzed by immunoblotting and immunoprecipitation (IP) using in vitro transcribed-translated, radiolabeled RA33.

Results:

We found that RA33, a classic native autoantigen in RA, is citrullinated in the rheumatoid joint. MS analysis of RA SF cells and in-vitro citrullinated RA33 confirmed citrullination in 16/25 arginine residues of the full-length protein. Using native and citrullinated antigen, we demonstrated that RA33 is targeted by patient sera in three ways: only as a native protein; both as a native and as a citrullinated protein (double-reactive sera); and only as a citrullinated protein. These distinct patterns of reactivity were confirmed by IP, immunoblotting and competition assays. Anti-(native) RA33 antibodies were almost exclusively detected in early RA (Figure A). In contrast, anti-citRA33 antibodies were positively associated with disease duration, and most commonly detected in patients with long established disease (>18 years post diagnosis). The unique subset of double-reactive patients appeared to identify a transitional disease phase in the evolution of an exclusively anti-native to a mature anti-citrullinated protein antibody response in RA.

Conclusion:

The study of RA33 suggests that native and citrullinated proteins targeted by autoantibodies in RA are part of a single antibody system, which appears to evolve with disease duration. This challenges the paradigm of citrullination as the inciting principle underlying loss of tolerance in RA.

Immunoglobulin-a and Immunoglobulin-G Isotypes of Anti-CCP Antibodies Are Present in the Sputum of Subjects at Risk for Future Development of RA

Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

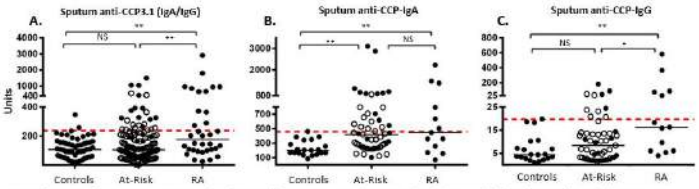
Background/Purpose: Serum elevations of anti-CCP prior to inflammatory arthritis (IA) in RA suggest that anti-CCP is generated at a site outside of the joints. Data suggest this site is likely a mucosal surface. To test the hypothesis that anti-CCP is generated in the lung mucosa, we examine levels of specific anti-CCP isotypes in the sputum of subjects at risk for future development of RA.

Methods: From the Studies of the Etiology of RA (SERA) we studied 34 serum anti-CCP3.1(+) patients with RA (2010 criteria), 142 subjects without IA but At-Risk for future RA based on serum CCP3.1 positivity (N=43) or family history of RA (N=99) and 56 serum CCP3.1(-) healthy controls. Simultaneously collected serum and induced sputum were tested by ELISA for anti-CCP3.1 (IgG/IgA Inova Diagnostics). Sputum from a subset of subjects was also tested for isotype-specific anti-CCP-IgA and CCP-IgG (Inova Diagnostics, research use only). For each CCP, sputum positivity was set based on levels present in <5% of controls.

Results: Sputum anti-CCP3.1 levels were elevated in RA and At-Risk subjects and highest in RA (Figure Panel A, $p<0.01$). In At-Risk subjects, 25/142 (18%) were sputum anti-CCP3.1(+) of whom 13 were serum CCP3.1(-) (Figure A). Furthermore, anti-CCP3.1/total IgG+IgA ratios were

higher in sputum than serum ($p<0.01$) supporting local lung generation and not serum translocation. For CCP isotypes, sputum anti-CCP-IgA levels were elevated and similar between RA and At-Risk subjects (Figure B, p=0.66). In contrast, sputum anti-CCP-IgG levels were higher in RA than At-Risk subjects (Figure C, p=0.02). Also, At-Risk subjects had higher rates of sputum anti-CCP-IgA positivity compared to IgG (42 *vs.* 19%, p=0.02), while in RA sputum anti-CCP-IgA and IgG positivity was similar (46 *vs.* 38%, p=1.0). Finally, in At-Risk subjects, sputum anti-CCP3.1 positivity was not affected by age or sex, but subjects with serum CCP3.1(+) and >10 pack-years of smoking had higher rates of sputum CCP3.1 positivity (Table).

Conclusion: Sputum testing identifies anti-CCP generation in the lung in a portion of individuals At-Risk for RA. Furthermore, sputum anti-CCP-IgA are more prevalent than IgG in At-Risk subjects which is in contrast to anti-CCP-IgA and IgG positivity rates in established RA which are similar. These findings suggest that in some subjects, anti-CCP-IgA generation in the lung may be an important factor in early loss of tolerance. Moreover, the development of sputum anti-CCP-IgG may be an important aspect of transition to articular RA. Longitudinal studies are needed to explore factors (including smoking) that may directly influence the development of mucosal autoimmunity in RA.



Distribution of Sputum anti-CCP levels. Median sputum anti-CCP3.1 levels were highest in RA (Panel A). Sputum anti-CCP-IgA levels were not significantly different between At-Risk and RA subjects (Panel B), but sputum anti-CCP-IgG was significantly higher in RA compared to At-Risk subjects (Panel C). — Median level; - - - Cut-off for positivity; ○ Serum CCP3.1 (-); ● Serum CCP3.1 (+); ** p<0.01; * p<0.05; NS – non-significant

Table. Subject demographics and prevalence of positivity for sputum anti-CCP

	Controls (N=56)	At-Risk (N=142)	RA (N=34)	P-Value[1]
Age, Mean ± SD	36 ± 13	52 ± 15	53 ± 10	<0.01
Female (%)	88%	67%	59%	<0.01
Non-Hispanic white (%)	70%	75%	59%	0.36
Ever smoker (%)	21%	32%	47%	0.09
>10 pack-years smoking (%)	0%	11%[2]	41%	<0.01
Self-reported history of lung disease (%)	13%	25%	29%	0.26
Serum CCP3.1 (+), N (%)	-	43/142 (30%)[3]	34/34 (100%)	<0.01
Sputum CCP3.1 (+), N (%)	-	25/142 (18%)	12/34 (35%)	0.02
Sputum CCP-IgA (+), N (%)	-	22/53 (42%)[4]	6/13 (46%)[5]	0.76
Sputum CCP-IgG (+), N (%)	-	10/53 (19%)[4]	5/13 (38%)[5]	0.14

1. For demographics, P-value is comparing all 3 groups using ANOVA and chi-square testing. Controls were younger and more often female. RA subjects were more often smokers. For serum/sputum CCP positivity, P-value is comparing At-Risk and RA subjects using chi-square testing.
2. At-Risk subjects with a >10 pack-year smoking had higher sputum anti-CCP3.1 positivity rates compared to subjects without a >10 pack-year smoking history [6/15 (40%) vs. 19/127 (15%), p=0.02]
3. At-Risk subjects with serum anti-CCP3.1 positivity had higher sputum CCP3.1 positivity rates compared to serum anti-CCP3.1(-) At-Risk subjects [12/43 (28%) vs. 13/99 (13%) p=0.04]
4. In At-Risk subjects, sputum anti-CCP-IgA positivity rates were higher compared to anti-CCP-IgG positivity [22/53 (42%) vs 10/53 (19%), p=0.02].
5. In RA subjects, sputum anti-CCP-IgA and IgG positivity rates were similar [6/13 (46%) vs. 5/13 (38%), p=1.0]

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Citrullinated peptides are major targets of disease-specific autoantibodies in rheumatoid arthritis (RA).

We generated a multi-epitope citrullinated peptide (Cit-ME), derived from major prevalent citrullinated autoantigens (citrullinated filaggrin, β-fibrinogen, vimentin and collagen type II).

Our aim was to test the ability of the Cit-ME peptide to immunomodulate cytokines gene expression and to alter the Treg subset in culture when incubated with peripheral blood mononuclear cells (PBMC) derived from newly diagnosed RA patients

Methods:

Naïve RA-patient's derived PBMC were incubated in the presence of either the Cit-ME or citrullinated-β-fibrinogen peptide derived from a single prevalent citrullinated autoantigen (1.25µg/ml). Immunomodulation by the peptides was compared to matched non-citrullinated peptides and to traditional biological therapies as Infliximab and Tocalizumab. Following incubation of 24-72 hours with the experimental components we analyzed immune-modulation of cytokines by real-time PCR and analysis of T regulatory population by flow cytometry.

Results:

We found that PBMC from RA patients, incubated in the presence of either Cit-ME or citrullinated-β-fibrinogen, elicited up-regulation of the TGF-β gene expression (16% and 8%, respectively) as compared to the medium control. The Cit-ME elevated the frequencies $CD4^{+}FoxP3^{+}$ T cells (18%) as compared to the medium. In addition, both citrullinated peptides were shown to down-regulate the mRNA expression of the pathogenic cytokines TNF-α and IL-1β. Furthermore we found that the citrullinated peptides were more effective in downregulating the inflammatory state of the PMMC as compared to the effect of the biological agents.

Conclusion:

Citrullinated autoantigens can immunomodulate the inflammatory response in PBMC of patients with RA in culture.

Immune Responses to Mycobacterium Heat Shock Protein 70 Accompany Self-Reactivity to Human Bip in Rheumatoid Arthritis

Hirofumi Shoda[1], Shuji Sumitomo[1], Keishi Fujio[2] and Kazuhiko Yamamoto[1], [1]Department of Allergy and Rheumatology, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan, [2]Department of Allergy and Rheumatology,Graduate School of Medicine, The University of Tokyo, Tokyo, Japan

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Molecular mimicry is believed to be an important mechanism of autoimmunity development. We previously demonstrated that imbalance between effector and regulatory T cells specific for BiP, a member of heat shock protein 70 family, induced autoimmne responses in rheumtaoid arthritis (RA). However, the reason why BiP-specific effector T cells developed in RA remains unclear. Here, we examined the immunological linkages between human heat shock proteins (HSPs) and Mycobacterium (Myc) HSPs in RA because the sequences of HSPs are preserved through the species.

Methods: Serum antibodies to bacteria (Mycobacterium and E.Coli) and human HSPs (HSP10, HSP40, HSP60, HSP70) in RA were measured by ELISA. Proliferation of peripheral blood mononuclear cells (PBMCs) from HLA-DR4-positive RA patients in response to MycHSP70-derived and BiP-derived peptides was examined using ^{3}H-thymidine uptake. The effect of immunity on MycHSP70, was evaluated by immunizing HLA-DR4-trangenic mice with MycHSP70 and CFA, and measuring serum antibodies by ELISA. $CD4^{+}$ T cell proliferation in response to MycHSP70 and BiP epitopes was measured by ^{3}H-thymidine uptake. MycHSP70-derived peptide was orally administered to collagen-induced arthritis (CIA) and scores were observed.

Results: Serum titers of antibodies against MycHSP70 were significantly elevated in RA patients and correlated with serum anti-BiP and anti-ciurullinated BiP antibody titers. A MycHSP70-derived HLA-DR4 major epitope was identified using proliferative capasity of RA PBMCs as an indicator. The major T-cell epitope, $MycHSP70^{287-306}$, was located at the corresponding position in the major epitope for human $BiP^{336-355}$, and PBMC proliferations in response to $MycHSP70^{287-306}$ and $BiP^{336-355}$ were highly correlated. These two peptides shared the common amino acid sequences which were important for HLA-DR4 binding. Immunization with MycHSP70 induced BiP-specific T cell proliferation, and development of anti-BiP antibodies. Moreover, oral administration of $MycHSP70^{287-306}$resulted in amelioration of CIA and inhibition of BiP and collagen-specific T cell proliferations .

Conclusion: Immune responses to MycHSP70 were associated with adaptive immunity against BiP in RA. Mycobacterium exposure in the daily environment could trigger the immune responses. Further examination of the immune response against BiP could reveal a mechanism for the development of related autoantibodies including ACPA upon exposure to a certain spectrum of microbes.

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is an inflammatory disease that leads to bone erosion. Bone morphogenetic proteins (BMPs) have favourable effects in the recovery of bone damage by stimulating the differentiation of osteoblasts. The effect of BMPs and their inhibitors in the mechanism of bone destruction has not been identified yet. The plasma levels of BMP 2, 3, 4, 5, 6, 7, 9, 14, noggin, sclerostin in RA patients and healthy volunteers were compared and correlated with the disease activity, clinical and radiographic progression.

Methods: In this prospective cohort study, 138 RA patients fulfilling the 1987 ACR criteria and 80 healthy volunteers aged 18-65 years were recruited. Group 1 consists of 85 patients using non-biologic disease-modifying antirheumatic drugs (DMARD) and group 2 consists of 53 patients using anti-TNFa. Control group was identified as Group 3. All groups were matched on age and sex. Tender/swollen joint, erythrocyte sedimentation rate (ESR), c-reactive protein (CRP), DAS28-ESR, DAS28-CRP, pain and health assessment questionnaire (HAQ) were evaluated

clinically. Structural damage was measured by using van der Heijde modified total Sharp scoring method (mTSS). Blood samples were collected. The plasma levels of BMPs, noggin and sclerostin were measured by ELISA method. In all groups, the plasma levels of BMPs and their inhibitors were analyzed by Kruskal-Wallis one-way analysis of variance. Differences between group 1 and group 2 were compared by chi square test and Mann-Whitney U test. P value of 0.05 was considered statistically significant.

Results: Baseline characteristics of group 1 and 2 were shown in table 1 and the comparison of the plasma levels of BMPs in all groups was shown in table 2. The correlation between HAQ and BMP 2, 5,7,14, sclerostin (r=-0,290 p=0,008, r=-0,219 p=0,046, r=0,229 p=0,037, r=-0,273 p=0,013, r=-0,388 p<0.001); between DAS28-ESR and BMP 2, 5,14, sclerostin (r=-0,236 p=0,03, r=-0,259 p=0,017, r=-0,216 p=0,047, r=-0,358 p=0,001); between DAS28-CRP and BMP 2, 5, sclerostin (r=-0,257 p=0,018, r=-0,236 p=0,03, r=-0,330 p=0,002) were statistically significant in DMARD group. There was no correlation in anti-TNF group.

Conclusion: The plasma levels of BMP 2, 4, 5, 6, 7, 9, 14 are increased, whereas BMP subgroup inhibitors which are BMP 3, noggin and sclerostin are decreased and the differences between the results of RA patients using anti-TNFa and healthy volunteers were statistically significant. In this 1-year follow-up study, the plasma levels of BMPs and their inhibitors, HAQ, mTSS and clinical evaluation will be repeated one year later.

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: An interferon-α gene signature (IGS) has been demonstrated in a number of rheumatological conditions, including rheumatoid arthritis (RA) where it is present in about 20-30% of patients. In established RA the IGS does not correlate with any disease activity parameters however ongoing immunomodulatory treatment may mask any underlying associations. We therefore wished to investigate any association between the IGS and disease activity in early RA patients prior to administration of any disease modifying therapy.

Methods: Disease modifying drug naïve patients fulfilling the ACR/EULAR criteria for a new diagnosis of RA were recruited from the Early Arthritis Clinic at the Freeman Hospital, Newcastle-upon-Tyne, UK. Clinical parameters included sex, age, swollen joint count (SJC), tender joint count (TJC), patient reported visual analogue scale of disease severity (VAS), disease activity score (DAS-28), inflammatory markers (CRP, ESR), autoantibody status (seropositive defined as either rheumatoid factor and/or anti CCP antibody positive) and symptom duration. In addition whole blood RNA was collected in Tempus Blood RNA tubes at diagnosis and following RNA extraction the expression of 5 interferon-α response genes (MXA, IFI6, OAS-1, ISG-15 and IFI-44L) was quantified using TAQMAN real-time PCR. Using the whole blood expression of these genes in an independent healthy control population an interferon gene score was calculated as previously published (Feng et al., Arthritis and rheumatism. 2006; 54(9):2951-62). Statistical tests were performed using GraphPad prism v5 (GraphPad Software, Inc) and included linear regression and Mann-Whitney U tests. Significance was taken when $p<0.05$.

Results:

We recruited 36 early RA patients. Median age was 59 years [range 30-91] and male:female ratio was 1:2. The healthy control population (n=17) had a median age 33 [range 23-57] and a male:female ratio 1:1. Notably age and sex had no significant association with the IGS within our early RA cohort ($p=0.549$ and $p=0.513$ respectively, linear regression). We found no significant difference in IGS score between our early seropositive RA and seronegative RA ($p=0.925$, Mann=Whitney U). Furthermore there was no association between any of the disease activity parameters measured (SJC, TJC, VAS, DAS-28, symptom duration, ESR and CRP) and the interferon gene score or individual gene expression ($p>0.05$ for all, linear regression).

Conclusion:

We demonstrate the novel finding that in early, drug naïve RA the IGS does not associate with markers of disease activity. This is similar to what has been shown in established RA. We know however that a high IGS score may predict poor response to certain therapies therefore, rather than reflecting inflammation/disease activity, interferon-α exposure may represent a distinct pathological process within a subset of RA patients. We propose that understanding this heterogeneity further is likely to assist in the development of novel therapeutic pathways for a subset of RA patients.

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Malondialdehyde-acetaldehyde (MAA) adducts are expressed in synovial tissues in rheumatoid arthritis (RA). Post-translational MAA modifications are pro-inflammatory, promoting robust anti-MAA antibody responses that are correlated with markers of RA disease severity. Whether anti-MAA antibodies are produced locally in affected joint tissues is not known. If present in higher concentrations in synovial fluid (SF) than in sera, this would support a potential pathogenic role of these antibodies in RA. The objective of this study was to evaluate the expression of anti-MAA antibody isotypes in paired SF/serum samples of patients with RA and OA to better understand the relationship of circulating antibody with antibody expressed locally in joints.

Methods: Paired serum/SF samples were examined, drawn from 29 RA patients and 13 OA patients on the same day, banked, and frozen at -70^{0}C until analysis. Anti-MAA antibody isotypes (IgA, IgG, and IgM) were measured in arbitrary units (AU) using ELISA and examined as means ± SEMs. Paired t-tests were used to compare anti-MAA antibody concentrations in SF vs. serum, while RA/OA comparisons were made separately for SF and serum using a Student's t-test.

Results: Anti-MAA antibody concentrations were numerically higher in RA-SF vs. OA-SF for IgA and IgM, a difference that reached statistical significance for the IgG isotype (p=0.008) (Figure 1). There were no significant RA-OA differences for any of the circulating anti-MAA antibody isotypes. In analyses of paired RA samples, IgG (663±121 vs. 219±76 AU, p<0.001) and IgM (1148±328 vs. 464±115 AU, p=0.033) anti-MAA antibody isotypes were significantly higher in the SF vs. serum. IgA anti-MAA antibody concentrations in RA SF did not differ significantly from paired sera (Figure 2). There were no differences in anti-MAA antibody concentrations in paired SF/serum samples from OA patients.

Conclusion: These results complement a previous report demonstrating that MAA adducts are expressed in inflammatory joint tissues in patients with RA. For the first time, these results show that anti-MAA antibodies, particularly the IgM and IgG isotypes, are also present in significantly higher concentrations in the joint compared to the circulation. It is possible that anti-MAA antibody may be produced locally or alternatively that these antibodies accumulate in joint tissues. Taken together, these results suggest that anti-MAA antibody could play an important pathogenic role and that its detection in SF could serve as an informative RA biomarker.

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To identify a serum biomarker for prediction of the response to biologics (Bio) in patients with rheumatoid arthritis (RA), we performed serum metabolomics analysis in RA patients before and after Bio treatment.

Methods: We collected the fasting serum samples of RA patients prior to starting or switching Bio treatment due to increased disease activity despite prior treatment with DMARDs or Bio. Twenty-seven patients were included (TNF-α inhibitors (TNFi) 13, tocilizumab (TCZ) 6, abatacept (ABT) 8). The average age was 60.1 (42-74) years old. There were 3 non-responders in TNFi group, and 1 in ABT. We also collected fasting serum samples from 12 healthy volunteers, and used as healthy controls (HC). We performed metabolome analysis using a Gas Chromatograph Mass Spectrometer (GCMS-QP2010 ultra). Multivariate statistics was carried out by using Simca P+ software.

Results: We detected 99 metabolites from the serum samples. The level of 44 of them was significantly different in RA patients (before Bio treatment) compared to HC. The 2D-plots of the principal component analysis (PCA) scores for all 99 metabolites showed distinct clustering for the two subject group. We have identified several metabolites which greatly contributed to the observed separation of the metabolomics profiles of the RA patients and HC by the corresponding 2D-PCA. Regarding prediction of response to biologics treatment, we revealed that patients with low serum levels of taurine at baseline showed good response to Bio treatment. The ROC analysis of taurine revealed an area under the curve of 0.900, with a specificity of 83.3% and sensitivity of 93.3% at the cutoff level of 0.00056 (P<0.001). In addition, we demonstrated that the serum levels of asparagine was significantly correlated with the DAS28-CRP (P<0.01, r^2=0.269), and significantly increased after Bio treatment (P<0.05).

Conclusion: Our present findings indicate that the pathogenesis of RA is accompanied by variations in the serum levels of low molecular weight metabolites, which supports the potential for using GCMS-based metabolomics as a diagnostic and monitoring tool for RA, and taurine may be a novel biomarker to predict the therapeutic response to Bio in RA.

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Recently, three different subsets of circulating monocytes: $CD14^{bright}CD16-$ (classical), $CD14^{bright}CD16+$ (intermediate) and $CD14^{dim}CD16+$ (nonclassical) monocytes have been defined. It has been reported that circulating intermediate subset increased in coronary artery disease and inflammatory disease such as infection and auto-inflammatory disease. However, the pathogenesis of increase of intermediate monocytes in inflammatory condition is still unclear and the relationship between cytokines and intermediate monocytes is unknown particularly in rheumatoid arthritis (RA). The purpose of this study is to investigate influence on intermediate monocytes by anti-cytokine treatment in patients with RA.

Methods: 32 RA patients and 14 healthy control subjects (HC) were enrolled in this study. All patients had never received a treatment with methotrexate (MTX) or biological agents. Peripheral blood samples and clinical records of the patients were obtained at the time of 0, 12 and 24 weeks after treatment. Peripheral blood samples were also obtained from HC. The expression levels of CD14 and CD16 on monocytes were measured by flow cytometry (FCM).

Results: 8 patients received anti-IL-6 receptor antibody, tocilizmab (TCZ) treatment alone, 12 patients received anti-TNF-a antibody, adalimumab (ADA) with MTX treatment and others received only MTX treatment. FCM analysis revealed that the proportion of intermediate monocytes significantly increased in patients at baseline compared with HC. The proportion of intermediate monocytes significantly decreased after TCZ and ADA treatment ($p=0.029$ and $p=0.012$, Fig 1). The proportion of intermediate monocytes were significantly and positively correlated with DAS28-ESR score ($r=0.47$, $p<0.01$) and DAS28-ESR score decreased in accompany with the proportion of intermediate monocytes after inhibition of inflammatory cytokine signal.

Conclusion: We showed that $CD14^{bright}CD16+$ intermediate monocytes significantly decreased with the change of disease activity by key cytokines, IL-6 or TNF-a signal blockade in RA. This result indicates that the proportion of circulating monocytes is controlled by IL-6 and TNF-a axis and is important for reflecting disease activity in RA.

Fig 1) The proportion of intermediate monocytes significantly decreased after TCZ and ADA treatment.

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

In rheumatoid arthritis (RA) patients, bone marrow edema (BME)-scores are associated with development of erosions. However, little is known on the course and outcome of BME at bone level. Therefore this study determined the association of BME and MRI-synovitis in the same bone longitudinally.

Methods:

1,947 bones of MCP, wrist and MTP-joints of 59 patients presenting with rheumatoid or undifferentiated arthritis were studied using 1.5T MRI at baseline, after four and twelve months. Scanning and scoring of BME, synovitis and erosions were performed according to RAMRIS. The relation of the course of BME and synovitis to erosive progression at bone level during 1-year was evaluated.

Results:

Of the bones showing BME at baseline (n=203), BME persisted in 56%, disappeared in 39%, and disappeared-reappeared seldom (5%). Stratified analyses at baseline revealed that BME was associated with erosive progression, in presence and in absence of local synovitis (ORs 7.5 95%CI 3.8-14.9 and 6.9 95%CI 1.9-25.6). Local synovitis, however, was not associated with erosive progression (OR 2.0 95%CI 0.6-7.0 in presence of BME and 1.9 95%CI 0.8-4.1 in the absence of BME). In multivariable GEE-analyses, persistent BME was strongly associated with erosive progression (OR 60 95%CI 17-318), in contrast to persistent synovitis (OR 1.4 95%CI 0.4-5.3).

Conclusion:

BME frequently persists during the first year. Persistent BME was strongly associated with erosive progression in the same bone, independent of local synovitis. No independent association was observed for persistent synovitis. These findings are relevant for the comprehension on the development of erosions in RA.

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: A large fraction of patients with RA does not respond to treatment with glucocorticoids (GCs) and disease-modifying anti-rheumatic drugs (DMARDs), or becomes resistant in time. Multidrug resistance may underlie the lack of response, but markers to predict or monitor drug resistance in RA are lacking. In this study, drug efflux capacity and multidrug transporter expression were investigated on various lymphocyte populations in relation to combined DMARD/GC therapy response.

Methods: Peripheral and/or synovial lymphocytes were obtained from: healthy individuals, established inflammatory arthritis patients and DMARD/GC therapy responders and non-responders at baseline and after 6 months of therapy. Drug efflux capacity, indicated by rhodamine-123 (Rh123) and calcein transport, and MDR1, MRP1 and ABCG2 expression were analysed for total lymphocytes, as well as for B, CD4+ T, CD8+ T and natural killer (NK) cells.

Results: Compared to healthy individuals, lymphocytes from patients with inflammatory arthritis showed a higher drug efflux capacity and expressed higher MDR1 and MRP1 levels. DMARD/GC non-response was associated with lower MDR1 expression and Rh123 efflux by naïve CD8+ T cells at baseline and increased MRP1 expression and calcein efflux after 6 months of treatment. Blocking MRP1 activity partially inhibited calcein efflux by peripheral and synovial lymphocytes, indicating additional MRP1-independent drug resistance.

Conclusion: Multidrug resistant lymphocytes are present in RA. In addition, MDR1 expression and activity in naïve CD8+ T cells was identified as a marker to distinguish DMARD/GC therapy responders from non-responders at baseline. Moreover, increased calcein efflux capacity by lymphocytes during DMARD/GC treatment is associated with the lack of response on this treatment. Implementation of these findings in current diagnostic and treatment protocols might lead to improved personalized RA treatment strategies.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with established Rheumatoid arthritis (RA) present evidence for an exhausted immune system. It is not known whether patients seen at the Early inflammatory PolyArthritis (EPA; 1-12 month symptom duration) stage already present with immune exhaustion. Quantification of T-cell receptor excision circles (TREC) in peripheral blood is a readily available measure of T cell thymic output.

Objective. To explore if low TREC numbers in EPA patients are associated with poorer disease outcomes.

Methods: Variables allowing calculation of disease activity indices (DAS-28 and SDAI), hand and feet X-rays scored using the modified Sharp method (SHS) and DNA from peripheral blood were serially collected at inclusion and at pre-specified times during follow up from consecutive EPA patients from the Early Undifferentiated PolyArthritis (EUPA) cohort and from healthy controls with similar sex and age distribution. TREC numbers per 10^5 nucleated cells in peripheral blood were estimated by quantitative polymerase chain reaction (qPCR) using the method described by Cheynier et al **(***Methods Mol Biol* 2007;**380:**197-213**)**. The effect of sex and increasing age on log-transformed TREC numbers were analyzed using Pearson correlations and repeated measures ANOVA. Receiver Operating Characteristics (ROC) curves using baseline TREC numbers were drawn to determine the best cut-off to predict significant joint damage (SHS ≥5) at 30 months. Levels of TREC at baseline and outcomes over time were correlated using linear regression, repeated measures ANOVA or generalized estimating equations for binary outcomes (GEE).

Results: We report on 73 EPA patients (93% RA; median duration 4.7 months; 48 women; mean 54.8 years) and on 98 healthy controls with similar age and sex. The median (IQR) number (per 10^5 nucleated cells) of TREC at inclusion was 88.6 (25.1-269.1) for EPA patients and 129.3 (45.4-289.4) for controls (p=0.112). In both patients and controls, TREC numbers decreased with increasing age, and women as a group had higher numbers. TREC numbers at baseline inversely correlated with disease activity but this correlation was lost during follow up. At baseline, ROC curves revealed that a value of < 128 TREC per 10^5 nucleated cells best identified patients with SHS ≥5 at 30 months (AUC = 0.613; sensitivity = 0.600; specificity = 0.731; RR (95% CI) = 1.91 (1.01-3.31), p=0.024). TREC < 128 also associated with SHS ≥ 5 at baseline (AUC = 0.716; sensitivity = 0.786; specificity = 0.678; RR (95% CI) = 3.77 (1.64-8.66), p<0.001). There was a trend between TREC levels < 128 at baseline and radiographic progression (ΔSHS ≥ 5) from baseline to follow up: RR (95%CI) = 2.24 (0.92-5.50); p=0.077.

Conclusion: Our age and sex results in healthy controls parallel published results. In EPA patients, baseline TREC numbers were correlated with initial but not subsequent disease activity. Low baseline TREC levels were associated with more joint damage at baseline and trended to predict more progression during follow up. Measurement of TREC numbers represents a novel promising biomarker in EPA patients, potentially identifying patients who already have developed the exhausted RA phenotype, those most likely to develop severe joint damage.

Clinical Relevance of Etanercept Levels and Anti-Etanercept Antibodies in Long-Term Treatment of Rheumatoid Arthritis Patients

Susanne Drynda and **Jörn Kekow**, Univ of Magdeburg, Clinic of Rheumatology, Vogelsang-Gommern, Germany
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Biological compounds have belonged to the therapeutic options for the treatment of rheumatoid arthritis for about 15 years. The application of biological substances is subject to a risk of developing antibodies against these structures, causing adverse events or loss of efficacy. It was the aim of the study to analyse the clinical relevance of anti-drug antibodies and drug levels in the course of a long term treatment of patients with rheumatoid arthritis with etanercept (ETN).

Methods:

In this retrospective analysis, 508 serum samples from 102 RA patients (84 female/18 male, mean age 50.8±1.5 years, mean disease duration 10.8±0.8 years) were obtained after 6, 12, 24, 36 and 48 months of treatment with ETN, and selected for determination of anti-ETN antibodies and drug levels. If available, serum samples obtained at least 2 weeks after discontinuation of ETN treatment (due to side effects, non-response, remission or surgery) were used for analysis to exclude any interference of high drug levels with the anti-drug antibody assay. For the determination of anti-ETN and ETN levels, Promonitor® - assays (Proteomika, Spain) were used according to the manufacturer's instructions.

Results:

Mean baseline disease activity (DAS28) of 5.77±0.11 decreased to 3.72±0.14, 3.46±0.12, 3.43±0.15 and 3.16±0.15 after 6, 12, 24 and 48 months of ETN treatment. No anti-ETN antibodies were found at any time point, neither in the course of treatment nor in samples from 72 of these patients obtained at least two weeks after discontinuation of ETN treatment (mean 51±3.9 months, range 18-120 months).

Mean ETN serum levels were 3.58±0.17µg/ml, 4.33±0.24µg/ml, 4.22±0.29µg/ml, 4.21±0.27 and 4.66±0.42µg/ml after 6, 12, 24, 36 and 48 months respectively. ETN levels remained stable in most patients, mean levels between individual patients ranged between 0.9 and 9.91µg/ml. In the lower quartile of patients with mean ETN level <2.5µg/ml, the DAS28 decreased from 5.46±0.26 to 3.79±0.19 (-1.67), 4.06±0.45 (-1.40), and 3.74±0.40 (-1.72) after 6, 24 and 48 months. A stronger DAS28 improvement was found in the upper quartile >5.07µg/ml from 6.10±0.21 to 3.74±0.33 (-2.36), 3.19±0.23 (-2.91), and 3.03±0.19 (-3.07) respectively.

Conclusion:

Our study confirms the lack of anti-drug antibodies in a large cohort of RA patients in the course of a long-term treatment with ETN. The absence

of anti-ETN antibodies in serum samples after discontinuation of therapy confirms this result by exclusion of false negative results resulting from interference with high ETN levels in the course of treatment.

ETN serum levels are subject to strong variations between individual patients. A significant reduction of disease activity was found in each quartile, the greatest mean reduction was observed in the group with the highest ETN serum levels.

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: MicroRNAs (miRNAs) are small non-coding RNAs that function as negative regulators of gene expression at posttranscription level and play a significant role in rheumatoid arthritis (RA) (1). The expression of TNF-α, a key pro-inflammatory cytokine of RA pathogenesis, is negatively regulated by miR-125b (2). Therefore, the aim of this study was to evaluate the expression of miRNA-125b in peripheral blood mononuclear cells (PBMCs) and its association with disease activity and achievement of remission in early RA patients.

Methods: A total of 60 patients (44 females; mean age 54.1 years) with early rheumatoid arthritis were studied. Total RNA was isolated from PBMCs collected from patients before and three months after the start of glucocorticoids and disease modifying antirheumatic drugs. The expression of miRNA-125b was determined by quantitative PCR. Small nucleolar RNA RNU44 was used for normalization. Relative expression was calculated as 2^{DCt}. Disease activity of RA patients was assessed according to the 28-Joint Count Disease Activity Score (DAS28), the Simplified Disease Activity Index (SDAI) and Clinical Disease Activity Index (CDAI).

Results: We found an inverse association between miRNA-125b expression and disease activity as assessed by DAS28 (r= -0.404; p= 0.001), SDAI (r= -0.334; p= 0.009) and CDAI (r= -0.263; p= 0.043) at baseline. The expression of miRNA-125b was significantly up-regulated three months after the start of treatment in all RA patients (p=0.005). The up-regulation of miRNA-125b after the three months of treatment was particularly observed in patients who achieved DAS28 defined remission compared to those who did not achieve the treatment target after 12 months. Age, sex, autoantibodies (RF-IgM, anti-CCP) and smoking did not affect miRNA-125b expression in PBMC.

Conclusion: The up-regulation of miRNA-125b in PMBCs following treatment initiation may represent potential biomarker predicting achievement of remission in early RA patients.

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Synovial fibroblasts (SF) from the joints of RA patients display an activated and invasive phenotype. They produce a number of pro-inflammatory cytokines and proteolytic enzymes and in consequence play a crucial role in perpetuating inflammation and mediating local damage in RA. Several microRNA are known to be involved in the aggressive phenotype of RASF, therefore, we set out to identify microRNA which were differentially expressed in these cells at a very early stage of disease.

Methods: SF were obtained from patients with undifferentiated arthritis (symptom duration <3 months). Patients were classified as resolving arthritis or very early RA depending on whether they fulfilled the ACR criteria for classification within the subsequent 18 months. microRNA expression was measured by TaqMan low density array (TLDA). For functional experiments SF were isolated from RA patients undergoing joint replacement surgery. SF were stimulated with IL-1β (1 ng/ml), TNFα (10 ng/ml), TGFβ (10 ng/ml), BLP (300 ng/ml), poly I:C (10 µg/ml) or LPS (100 ng/ml) for 24h. For long term stimulations cells were cultured with TGFβ (10 ng/ml) for 72h, or TNFα (10 ng/ml) for 7 days. Endogenous miR-204 was down regulated using Lipofectamine transfection with specific miRNA inhibitors. Total RNA was isolated, and miR-204 expression quantified by Taqman qPCR. The concentrations of IL-6, IL-8, MMP1 and MMP3 were measured in cell culture supernatants by ELISA. Adhesion and proliferation of cells were all quantified using the xCELLigence system.

Results: TLDA analysis identified miR-204 as an interesting candidate which was down regulated in SF from very early RA patients. PCR in additional samples confirmed that miR-204 was significantly lower in SF derived from very early RA patients compared to those from patients with resolving arthritis ($p<0.05$) or healthy controls ($p<0.001$). miR-204 expression was also reduced in SF following stimulation with poly I:C (x-fold: 0.63 ± 0.04, $p<0.05$), and after prolonged exposure to TGFβ (x-fold: 0.58 ± 0.06, $p < 0.001$) or TNFα (x-fold: 0.64 ± 0.11, $p<0.05$). Compared to transfection with a control inhibitor, inhibition of miR-204 in SF resulted in a significant increase in the production of IL-6 (1332 ± 173.6 vs 2087 ± 274.5 pg/ml), IL-8 (78.26 ± 22.76 vs 212.4 ± 38.33 pg/ml), MMP1 (127.8 ± 21.47 vs 360.6 ± 92.94 pg/ml) and MMP3 (129.4 ± 62.29 vs 518.4 ± 78.6 pg/ml). We were also able to show that miR-204 inhibition results in decreased attachment and proliferation of SF.

Conclusion: The reduced miR-204 expression observed in SF from very early RA patients suggests that this microRNA is not altered as a consequence of chronic inflammation, but instead represents an early change in the development of RA. This novel finding, together with the increase in basal cytokine and MMP production observed following miR-204 inhibition, suggest an important functional role of this microRNA in regulating SF activation. We therefore hypothesize that miR-204 targets a master regulator of inflammatory pathways in SF and its down regulation in early RA contributes to the activated and aggressive phenotype observed in RASF.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Rheumatoid arthritis (RA) is often characterized by the presence of rheumatoid factor (RF), anti-citrullinated protein antibodies (ACPAs) and bone erosions. Successful treatment can compromise the normal immune response, increasing the risk of infections. The interleukin 20 receptor (IL-20R) axis comprising IL-19, IL-20, and IL-24 ("the IL-20R cytokines") and their shared receptors activates tissue homeostasis processes but not the immune system (Figure 1A). Consequently, modulation of the IL-20R axis may not lead to immunosuppression, making it an interesting drug target. The objective of this study was to determine the role of the IL-20R axis in early RA with focus on associations of the three cytokines with clinical disease activity and prognosis.

Methods:

The IL-20R cytokines were measured in plasma samples from treatment naive early RA patients during 24 months treatment with methotrexate, adalimumab/placebo and intra-articular glucocorticoid injections (the OPERA trial) (n=152) and healthy controls (n=88). IL-20R1 and IL-22R expression was studied in paired peripheral blood and synovial fluid cells from RA patients (n=15) with at least one swollen joint (for obtaining synovial fluid) with flow cytometry and confocal microscopy. Heat aggregated human gamma globulins (HAGGs) and immune complexes containing citrullinated fibrinogen (cFb-ICs) were used to stimulate macrophages. Osteoclasts (OCs) derived from synovial fluid cells were used to assess the effect of the IL-20R cytokines.

Results:

The plasma concentrations of IL-20 and IL-24 (but not IL-19) were increased in early RA patients compared with healthy controls (both $P<0.002$) and decreased after 6 months of treatment (both $P<0.0001$). The expression of IL-22R (but not IL-20R1) was increased on monocytes from RA synovial fluid compared with monocytes from both RA and healthy control peripheral blood. The plasma concentrations of IL-20 and IL-24 were increased in RF and ACPA positive compared with negative early RA patients (all $P<0.0001$). HAGGs and cFb-ICs stimulated the production of the IL-20R cytokines by myeloid cells. Increased baseline plasma concentrations of IL-20 and IL-24 were associated with Sharp-van der Heijde score progression after 24 months (SpearmanÕs rho=0.19 and 0.26, both $P<0.05$) in the early RA patients. The IL-22R was expressed by OC precursors and in multinucleated OCs and these cells were activated by IL-20 and IL-24.

Conclusion:

This study suggests that IL-20 and IL-24 link RA-associated autoantibodies with activation of OCs and radiographic progression via the IL-22R1 (Figure 1B). Modulation of this axis holds promise as feasible anti-erosive treatment modalities in seropositive RA.

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: We reported that human T-lymphotropic virus type 1 (HTLV-1) positive patients with rheumatoid arthritis (RA) had higher inflammation and greater resistance to anti-TNF treatment than HTLV-1 negative patients. The levels of plasma IL-6 and CCL20 in HTLV-1 positive RA patients was significantly higher than in HTLV-1 negative patients. The objectives of this present study are to investigate the efficacy and safety of anti-IL-6 receptor antibody, tocilizumab (TCZ) treatment to HTLV-1 positive RA who were who were not responsive to anti-TNF therapies. In addition, we investigated whether HTLV-I infected cells modulates the expression of cytokine, chemokine, and matrix metalloproteinase in RA synovial fibroblast (RASF) in vitro.

Methods: We identified 5 of 6 HTLV-1 positive RA patients, who were not responsive to anti-TNF therapies, were administered TCZ treatment as their secondary biologics in our biologics cohort study. Therapeutic response at 3 months after beginning of treatment with TCZ was evaluated using EULAR response criteria. We also analyzed the changing of C-reactive protein (CRP), erythrosedimentation rate (ESR), disease activity score in 28 joints (DAS28) and clinical disease activity score (CDAI). As secondary endpoints, discontinuation rate of TCZ treatment and safety, especially the development of adult T-cell leukemia (ATL), were evaluated over a one-year period. HTLV-1 infected (MT2 or Hut102) or non-infected (Jurkat) cell-lines were co-cultured with RASF for 48h. To avoid direct-interaction between these cells, we setup transwell co-culture system using inserts with 0.4um pore membrane. The levels of 25 cytokines in cell culture medium were measured using multiplex cytokine assay (Luminex, Millipore). The level of soluble IL-6 receptor (sIL-6R) in culture medium was measured using ELISA. The phosphorylation of NF-kB p65 in RASF co-cultured with HTLV-1 infected or non-infected cells were determined by immune blotting. The expression of IL-6, CCL20,

VEGF, and MMP1 mRNA in RASF was measured using real-time quantitative PCR.

Results: According to EULAR response criteria, the rate of good, moderate and no response after treatment with TCZ in HTLV-1 positive RA patients was 60, 40, and 0%, respectively. The rate of low disease activity was 60 %. The levels of CRP, ESR, DAS28, and CDAI were significantly decreased after treatment with TCZ. The efficacy of TCZ treatment sustained for at least one-year period. During the one-year observation period, no patients developed ATL. The protein levels of IL-6, CCL20, IFN-γ and sIL-6R in mono-culture medium of HTLV-1 infected cell lines was higher than in that of Jurkat cell. The phosphorylation of NF-kB p65 was increased in RASF co-cultured with HTLV-1 positive cells. The expression of IL-6, CCL20, VEGF and MMP1 mRNA increased in RASF co-cultured with HTLV-1 infected cells, but not with Jurkat cell.

Conclusion: TCZ improved response to therapy in HTLV-1 positive RA who were who were refractory to anti-TNF therapies. In vitro study showed that HTLV-1 infected cells induced the expression of IL-6, CCL20, VEGF and MMP in RASF. Taken together, these results suggested that IL-6 may play an important role in the pathogenesis of HTLV-1 positive RA patients.

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster I

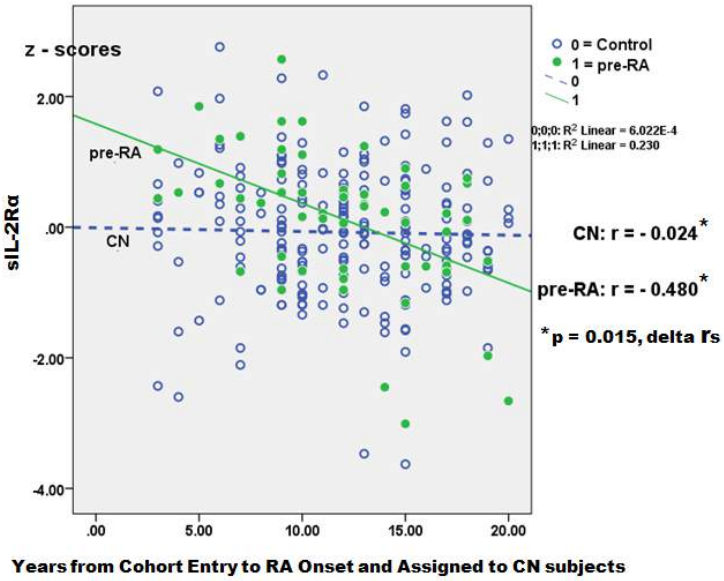
Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Baseline sIL-2Rα levels predicted total mortality in both pre-RA and matched CN subjects, in a preceding prospective cohort study (A&R 2010; 62:S19). Now, the trend of serum sIL-2Rα levels is analyzed over a 20-year interval between cohort entry to incident RA onset, in pre-RA and matched CN subjects.

Methods: The community-based cohort (N = 21,061 adults) was enrolled in 1974, yielding 54 new onset RA cases, 3 to 20 (mean 12) years after entry (1977 – 1994). Cohort CN subjects (n = 216) were matched on 1974 entry criteria (4 CN**:** 1 pre-RA). Stored (-70ºC) sera were assayed (ELISA) "blindly", using R & D Systems high sensitivity kits for: sIL-2Rα; sTNF-R1; 3 inflammatory cytokines; and 2 acute phase protein levels. Natural log and z-score transformations were performed on all continuous baseline assay variables. Matched CN subjects were assigned the intervals to RA onset, within 54 separate sets. Partial (age-adjusted) correlations of intervals (X-axis) and baseline serum biomarker levels (Y-axis) were compared in study groups. Independent predictors of baseline sIL-2Rα levels (interval from cohort entry to RA onset and other variables of interest) were identified by multiple regression (MR) models.

Results: Baseline sIL-2Rα and sTNF-R1 levels correlated strongly in total 270 subjects ($r = 0.464$, $p < 0.001$) and in each study group (54 pre-RA, $r = 0.473$, $p < 0.001$; 216 CN, $r = 0.470$, $p < 0.001$). In pre-RA, sIL-2Rα levels increased significantly with decreased interval from 1974 cohort entry to RA onset ($r = -0.480$, $p < 0.001$), not found in CN ($r = -0.025$, $p = 0.744$), the difference being significant ($p = 0.001$) (Fig). In a MR model of pre-RA, baseline sIL-2Rα levels were significantly predicted by (1) interval (yrs) from cohort entry to RA onset (beta = -0.372, $p = 0.002$) and (2) sTNF-R1 levels (beta = 0.376, $p = 0.002$), but not by: entry age; sex; cigarette smoking; or 2013 survival status. In 216 CN, sIL-2Rα level was predicted only by sTNF-R1 (beta = 0.434, $p < 0.001$), not by the pre-RA interval (beta = -0.011, $p = 0.862$) or other variables in the model (Table).



Predictors of Baseline sIL-2Rα Levels in pre-RA vs CN

Independent Variables in Multiple Regression	pre-RA (n = 54)		Control (n = 216)	
	beta	p	beta	p
Cohort Entry to RA Onset (yrs) *	- 0.372	0.002	- 0.011	0.862
Baseline sTNF-R1 Level	0.376	0.002	0.434	< 0.001
Age at Cohort Entry	- 0.121	0.345	- 0.031	0.667
Sex	- 0.215	0.072	0.091	0.153
Cigarette Smoking (7-scale)	0.082	0.486	0.116	0.077
Surival Outcome in 2013	- 0.004	0.977	0.073	0.322

*p = 0.015, difference in beta correlations of pre-RA (-0.372) vs CN (-0.011)

Conclusion: The novel temporal trend of sIL-2Rα levels may reflect multi-year immunological up-regulation before clinical onset of RA and deserves further study for confirmation.

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

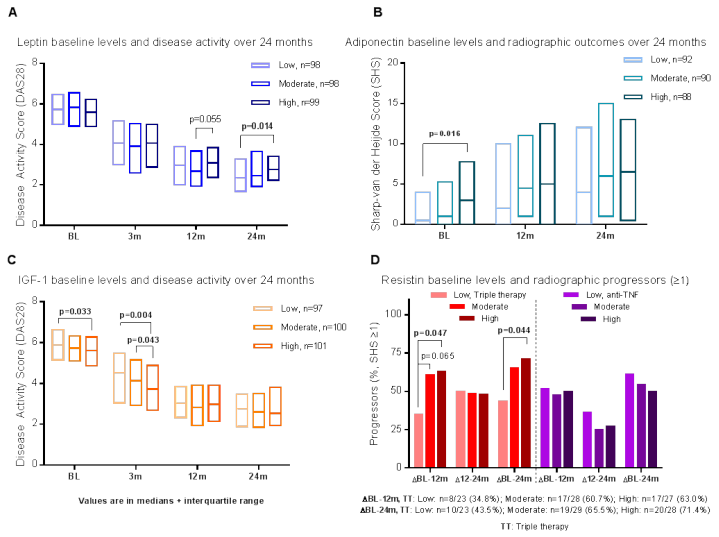
Background/Purpose: Adipokines are cytokines/hormones primarily synthesized in white adipose tissue. In rheumatoid arthritis (RA), some

adipokines have been associated with worse outcomes (1-3). The aim of this study was to determine whether adipokine or insulin-like growth factor 1 (IGF-1) serum measurement at baseline (BL) could predict future disease activity and radiographic outcomes in patients with early RA.

Methods: Serum levels of adiponectin, leptin, IGF-1, and resistin at RA diagnosis were analyzed in 330 patients enrolled in the Swedish pharmacotherapy (SWEFOT) trial (207 with Body Mass Index (BMI)). All patients received methotrexate (MTX) for 3 months. Thereafter, responders (DAS28≤3.2) remained on MTX, while non-responders were randomized to triple therapy (MTX+sulfasalazine+hydroxychloroquine) or anti-TNF add-on (MTX+infliximab). The biomarker levels were divided into tertiles for further analyses, after adjustment for known level differences to due sex (adiponectin and leptin) and age (IGF-1 SD score). Disease activity (DAS28) and radiographic damage (Sharp-van der Heijde Score, SHS) were evaluated over 24 months.

Results: Adiponectin and leptin levels – but not IGF-1 or resistin – were inversely and directly proportional, respectively, to BMI, which was associated with worse DAS28 over 24 months. Disease activity did not differ between tertile groups of leptin at BL (diagnosis), but patients with high BL leptin had significantly higher DAS28 at 24 months (Figure A). On the other hand, among initial MTX responders, high/moderate (n=54) vs. low BL leptin (n=27) was associated with less rapid radiographic progression from BL-12 months (ΔSHS≥5, 7.4% vs. 29.6%, p=0.036). Disease activity did not differ significantly between adiponectin groups, however, they were directly proportional to BL SHS with a numerical trend over time (Figure B).

Patients with low BL IGF-1 had higher DAS28 up until 3 months, but it was not significant thereafter (Figure C). In addition, more radiographic progressors were observed between those with low vs. high IGF-1 among initial MTX responders (BL-12 months, n=19 vs. 31, respectively: ΔSHS≥1, 68.4% vs. 32.3%, p=0.013; BL-24 months, n=21 vs. 32: 81.0% vs. 50.0%, p=0.023). For resistin, there were more progressors among those with high BL levels among triple therapy-treated patients (Figure D), which was not observed among the anti-TNF or MTX responder groups.



Conclusion: Differences in certain adipokines and IGF-1 were associated with clinical and radiographic outcomes within specific treatment groups. Thus, they may be useful predictors and may give insight into pathogenic mechanisms influencing RA outcomes such as high BMI and disease activity.

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Abatacept (ABT) is very effective in treating rheumatoid arthritis(RA)[1]. Patients with RA have an increased risk of cardiovascular disease (CVD), and rheumatologists need to develop primary prevention strategies for CVD in RA patients[2, 3]. For example, some biologics used to treat RA also reduce subclinical atherosclerosis and may improve morbidity in CVD[4, 5]. There is no evidence that ABT effect subclinical atherosclerosis. To examine the effect on subclinical atherosclerosis in disease modified anti-rheumatic-drugs (DMARDs) resistant RA patients in a cohort study design.

Methods: 75 RA patients with moderate to severe active disease despite DMARDs treatment (disease activity score: DAS28>3.2) were received ABT (125mg every week subcutaneously). Subclinical atherosclerosis was assessed with cardio-ankle vascular index (CAVI) and augmentation index corrected for a heart rate of 75 beats per minute (AIx@75) at baseline and 24 weeks follow-up. Clinical data were collected at regular visits. CAVI is combined pulse wave velocity (PWV) and **flow mediated dilation**, and CAVI measures arterial wall stiffness independent of blood pressure and it is superior to brachial ankle PWV as an index of atherosclerosis. No new all treatments (stating, low lipids drug, and etc.) were allowed.

Results: 65 patients completed this study. There were no changes in CAVI(12.68 ± 1.76 and 12.71± 2.11; p = 0.96) and AIx@75(32.45 ± 9.8, 33.21 ± 12.6; p = 0.87) from baseline to 24 weeks follow up.DAS 28-ESR score improved significantly from baseline to 24 weeks(5.87±2.15, 2.57±1.32: p=0.01). There were no There was no change in systolic and diastolic blood pressure Total cholesterol/LDL cholesterol ratio, atherogenic index and triglycerides. Changes of CAVI and AIx@75 were not correlated with changes of disease activity from baseline to 24 weeks follow up. (CAVI: p=0.75, AIx@75: p=0.81).No patients suffered from new CV disease.

Conclusion: These findings suggest that ABT did not improve subclinical atherosclerosis after 24 weeks follow up despite good control of disease activity in rheumatoid arthritis.

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: The individual response to anti-TNFs etanercept (ETA), infliximab (INF) and adalimumab (ADA) in rheumatoid arthritis (RA) may vary. Options for managing inadequate response include dose escalation of the anti-TNF agent and/or intensification of co-therapy, which can lead to higher drug costs, patient inconvenience and greater risk of adverse events. The Canadian Drug Utilization in Rheumatoid Arthritis (CADURA) study compared dose escalation, intensification of DMARDS and steroids, and switches to another biologic between patients with RA initiating ETA, ADA or INF.

Methods: This was a retrospective chart review of RA patients treated in 11 clinical practices across Canada. Patients were 18 years or older who initiated an anti-TNF between January 1, 2006 and December 31, 2012, with no prior use of biologic DMARD. Outcomes were assessed over 12 and 18 months. For the 12- month analysis, patients were required to have ≥3 physician visits following initiation and ≥1 visit during months 9-15; the 18 month analysis also required ≥ 1 visit during months 15-21. Dose-escalation of anti-TNF was defined as the first occurrence of any upward adjustment in dose or dosing frequency of the anti-TNF from the label indication: ETA, 25 mg twice weekly or 50 mg once weekly; ADA, 40 mg once every other week; INF, 3mg/kg every 8 weeks after the 3rd infusion. Additional outcomes were: 1) anti-TNF dose-escalation and/or DMARD intensification and 2) anti-TNF dose-escalation and/or DMARD and/or steroid intensification. Intensification included any increase in dose or dosing frequency, any addition, any switch from oral to subcutaneous injection (DMARD), or any intramuscular or intra-articular injections (steroid) 3 months after initiation of the anti-TNF.

Results: The 12-month analysis included 314 patients (mean age 56.3 years [range: 21-90 yrs]; 77% female; mean RA duration 9.0 yrs [range: 2-26 yrs]). Among patients initiating ADA, 83% had concomitant DMARD vs 72% of patients initiating ETA and 75% initiating INF. There were 217 patients in the 18-month analysis. No dose escalation occurred with ETN over 12 and 18 months, vs 38% and 32% for INF (p<0.001) and 2% and 2% for ADA (p=0.199, p=0.218). Over 18 months, dose escalation and/or DMARD and/or steroid intensification was less frequent among ETA (16%) vs INF (44%, p=0.005) and ADA (34%, p=0.004). By 18 months, 22% of patients initiating ADA had switched to another biologic compared with 6% of ETN patients (p=0.001).

Conclusion: Physicians more frequently used dose escalation when treating with INF, and DMARD and/or steroid intensification when treating with ADA. Patients treated with ETN had no dose escalation, were less likely to have DMARD and/or steroid intensification than patients initiating INF or ADA over 12 and 18 month, and were less likely to switch to another biologic over 18 months than patients initiating ADA.

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Calprotectin (MRP8/MRP14, S100A8/A9) is a protein abundant in cytosol of granulocytes and monocytes/macrophages and released during cell activation. It reflects clinical disease activity in patients with rheumatoid arthritis (RA). Ultrasonography (US) is sensitive for detecting synovitis (grey scale, GS) and vascularization (power Doppler, PD). There is only published one small study showing associations between calprotectin and US in RA patients.

To study the associations between calprotectin and a comprehensive US examination as well as clinical/laboratory variables and to explore the responsiveness of calprotectin to biologics in a large cohort of RA patients.

Methods:

A total of 141 patients with RA (mean (SD) age of 50.3 (13.3) years and disease duration 9.9 (8.6) years, 81% women, 77% anti-CCP positive) starting different biologic medication (including 66,7% anti-TNF) were examined at baseline and after 1, 2, 3, 6 and 12 months for calprotectin, CRP, ESR, clinical variables as well as US of 36 joints and 4 tendons (wrist (incl. RU, IC, RU), MCP 1-5, PIP 2-3, elbow, knee, ankle, MTP 1-5, ECU and tib.post. tendons bilaterally). Both GS and PD pathology were scored semi-quantitatively 0-3 by one sonographer (HBH) (Siemens Antares Excellence version, 5-13MHz probe, PRF 391Hz, no updates during the study). At each examination EDTA-plasma was frozen at -80 degrees, and all calprotectin concentrations were analyzed at the same time (normal levels ≤ 900 µg/L). Changes from baseline were assessed by Wilcoxon T-test, differences between groups by Mann-Whitney and correlations by Spearman's rank.

Results:

All variables decreased significantly from baseline (table 1) ($p<0.001$). Calprotectin had higher correlations with CRP during the study (range r=0.46-0.76), than with ESR (range r= 0.31-0.56), while the correlations between ESR and CRP was 0.47-0.69 (all correlations $p<0.001$). Prednisolone users at baseline (55%, median 7.5 mg) had higher levels of calprotectin ($p=0.006$), sum score GS ($p=0.02$) and number of swollen joints ($p=0.02$), while no differences were found between the groups for ESR, CRP or the other variables. Calprotectin was highly associated with US scores during the study, with higher correlations than ESR or CRP (table 2).

	Baseline	1 month	2 months	3 months	6 months	12 months
Calprotectin µg/L	1149 (698-1949)	739 (501-1223)	659 (436-1105)	673 (443-1122)	653 (409-982)	637 (453-954)
ESR mm/h	22 (11-35)	14 (7-26)	14 (8-28)	16 (7-24)	14 (7-21)	14 (7-21)

Assessor's global VAS (study nurse)	27 (18-38)	20 (10-30)	17 (11-26)	15 (10-25)	13 (8-20)	13 (8-20)
DAS28	4.4 (3.1-5.4)	3.6 (2.7-4.7)	3.2 (2.6-4.4)	3.2 (2.3-4.2)	2.9 (2.3-3.7)	2.8 (2.1-3.9)
Number of swollen joints (of 32)	6 (3-11)	4 (2-9)	4 (2-7)	3 (1-7)	2 (0-5)	1 (0-4)
Number of tender joints (of32)	4 (2-11)	4 (1-9)	3 (0-7)	3 (0-7)	1 (0-4)	1 (0-5)
Patient's global VAS	46 (20-67)	25 (10-46)	22 (8-36)	19 (5-37)	16 (5-33)	19 (6-33)

	Sum score Grey scale 36 joints and 4 tendons						**Sum score power Doppler 36 joints and 4 tendons**					
	Baseline	1 month	2 months	3 months	6 months	12 months	Baseline	1 month	2 months	3 months	6 months	12 months
Calprotectin	0.59**	0.51**	0.50**	0.37**	0.48**	0.25*	0.62**	0.53**	0.53**	0.46**	0.47**	0.31**
ESR	0.19*	0.04	0.06	0.01	0.19*	0.01	0.30**	0.14	0.15	0.12	0.21*	0.15
CRP	0.41**	0.21*	0.30**	0.18*	0.33**	0.20*	0.47**	0.23*	0.33**	0.26*	0.35**	0.30**

Conclusion:

In this first large study exploring calprotectin and US, calprotectin was found to be highly associated with both sum GS and PD scores. In addition, calprotectin was not suppressed by use of prednisolone like CRP/ESR and it was highly responsive to biologic medication. These findings support the use of calprotectin as an inflammatory marker in RA patients.

Can Anti-TNF-Induced Autoantibody Conversion be Reversed By Switching to Abatacept Therapy in Patients with RA on Background MTX?

Maya H. Buch[1], A Johnsen[2], DA Wong[2] and M Schiff[3], [1]University of Leeds and Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom, [2]Bristol-Myers Squibb, Princeton, NJ, [3]University of Colorado, Denver, CO

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-TNF therapy for RA is associated with antinuclear (ANAs) and anti-double-stranded DNA (anti-dsDNA) autoantibodies.[1,2] The effect of biologics on autoantibody-positive patients is unknown. We explored ANA and anti-dsDNA antibody development during abatacept (ABA) and anti-TNF treatment (ATTEST/AMPLE trials) and effects of switching to ABA in patients with ANA/anti-dsDNA (ATTEST). **Methods:** All patients had active RA, were biologic naïve and MTX inadequate responders. ATTEST: patients were randomized to IV ABA (～10mg/kg q4w), infliximab (IFX; 3mg/kg q8w) or placebo, on background MTX. At Month 6, placebo-treated patients started ABA (blinding maintained); ABA- and IFX-treated patients continued treatment. Patients completing the 1-year DB period were eligible to receive ABA (open-label long-term extension [OLE]). AMPLE (2-year head-to-head trial): patients were randomized to SC ABA (125mg weekly) or SC adalimumab (ADA; 40mg biweekly), on background MTX. Serum ANA and anti-dsDNA were measured at baseline, Month 6, Year 1 and 2 in ATTEST, and at baseline, Year 1 and 2 in AMPLE.

Results: In the ATTEST DB period, 156 patients received IV ABA and 165 received IFX; 132 and 136 patients received IV ABA in the OLE, respectively. In AMPLE, 318 patients received SC ABA and 328 received ADA. At baseline in ATTEST, 69 patients (32 IV ABA/37 IFX) were ANA+ and 26 (11 IV ABA/15 IFX) were anti-dsDNA+; AMPLE: 166 were ANA+ (72 SC ABA/94 ADA) and 6 anti-dsDNA+ (1 SC ABA/5 ADA). In both studies, a higher percentage of patients seroconverted (negative–positive, baseline–Year 1) with anti-TNFs versus ABA (Table); this difference continued during AMPLE Year 2. In ATTEST, 48.5% (ANA) and 48.3% (anti-dsDNA) of IFX-treated patients who entered the OLE seroconverted (negative–positive, baseline–Year 1), falling to 22.4% and 13.3%, respectively, at Year 2 after switching to ABA. The percentage of patients who seroreverted (baseline positive–negative) increased from 12.1% to 20.6% on switching from IFX to ABA (Table).

		Year 2	0 (0/248)	12.2 (29/237)	100.0 (1/1)	75.0 (3/4)

Data are % (n/N). *ITT population; †only pts who entered the OLE; ‡pts switched to IV ABA + MTX; ANA=antinuclear antibodies; Anti-dsDNA= anti-double-stranded DNA; DB=double blind; OLE=open-label long-term extension

Conclusion: In ATTEST, switching from infliximab to abatacept seemed to reverse autoantibody induction observed with anti-TNF treatment. In both trials, anti-TNF therapy was associated with greater autoantibody induction than abatacept. These data imply an effect of T-cell co-stimulation blockade on B-cell function and autoantibody production.[3]

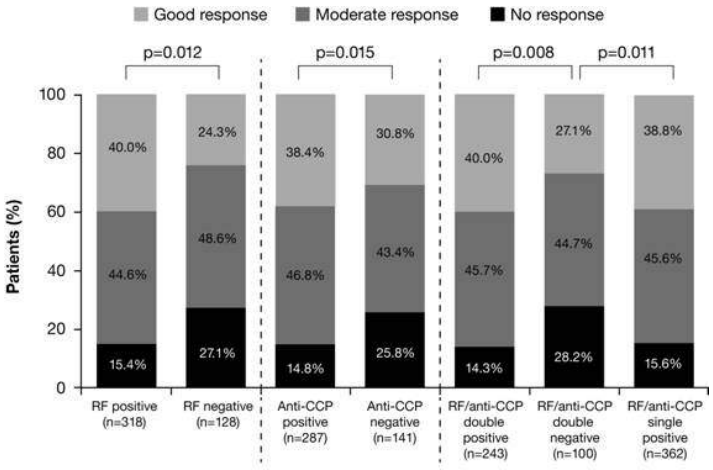
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: In a recent meta-analysis, neither rheumatoid factor (RF) nor anti-cyclic citrullinated peptide (anti-CCP) antibody status were associated with clinical response to treatment with anti-TNF agents.[1] In contrast, anti-CCP positivity may be associated with increased abatacept efficacy in patients (pts) with prior biologic failure[2,3] and in biologic-naïve pts.[4] In this analysis, the efficacy of abatacept after 6 months' follow-up in biologic-naïve pts enrolled in the ACTION study was compared in RF/anti-CCP-positive versus -negative pts. **Methods:** ACTION is a 2-year, international, multicenter, prospective, observational study evaluating retention and effectiveness of IV abatacept in pts with RA. Baseline characteristics and clinical outcomes were evaluated at 6 months and compared for anti-CCP/RF-positive and -negative pts who were biologic naïve using analysis of variance on ranks for quantitative variables and Fisher exact tests for qualitative variables. EULAR response was based on DAS28 (ESR or CRP) and derived from individual core components, as were mean CDAI and Boolean remission. **Results:** In 672 biologic-naïve pts, RF status was reported in 577 (86%) pts (412 [71%] positive) and anti-CCP antibody status in 552 (82%) pts (364 [66%] positive); 308/511 (60%) pts were double positive and 127/511 (25%) pts were double negative. Clinical outcomes at 6 months were more beneficial for pts who were RF or anti-CCP positive versus negative, including EULAR good or moderate response versus no response (Figure); mean (95% CI) CDAI (calculated) (RF: 10.8 [9.8, 11.8] vs 15.3 [13.4, 17.2]; p<0.001; anti-CCP: 10.9 [9.8, 12.0] vs 14.3 [12.4, 16.2]; p=0.002) and Boolean remission (RF: 13.3% vs 4.0%; p=0.008; anti-CCP: 12.5% vs 6.3%; p=0.096). Similarly, significant differences in clinical outcomes were observed for pts who were RF/anti-CCP single positive or double positive versus double negative, respectively, including EULAR good or moderate response versus no response (Figure); mean (95% CI) CDAI (calculated) (11.1 [10.2, 12.1] and 10.5 [9.3, 11.6] vs 14.5 [12.3, 16.7]; p=0.003 and p=0.001, respectively) and Boolean remission (12.3% and 13.8% vs 3.8%; p=0.025 and



P value for likelihood of a good/moderate EULAR response versus no response based on DAS28 (ESR or CRP)

p=0.013, respectively). **Conclusion:** These are the first prospective real-world data showing superior efficacy of abatacept in biologic-naïve pts who are RF and/or anti-CCP positive versus negative, even when using stringent remission criteria. The association between autoantibody status and clinical outcomes with abatacept may be linked to the mechanism of action. 1. Lv Q, et al. *PLoS One* 2014;**9**:e89442. 2. Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Combination treatment of rheumatoid arthritis (RA) with methotrexate (MTX)+adalimumab (ADA) has been shown to be more effective than ADA monotherapy. However, MTX is associated with known toxicity. Here we assessed the relationship between MTX-related toxicity and achieved efficacy of ADA+MTX treatment.

Methods: Data were from 2 randomized controlled trials. In CONCERTO[1], early RA patients (pts) initiated ADA + 2.5, 5, 10 or 20 mg/week (wk) MTX for 26 wks. In MUSICA[2], pts with moderate-severe RA and an inadequate response to MTX initiated ADA + 7.5 or 20 mg/wk MTX for 24 wks. Efficacy was assessed by ACR50. MTX toxicity was assessed by collecting information from pts at each visit on 18 pre-specified MTX- related adverse events (AE) reported in the MTX product label: abnormal hair loss or sweating, chronic dry cough, conjunctivitis,

dizziness, excessive fatigue/malaise, fever and/or chills, infection, nausea and/or vomiting, oral ulcers, skin pigment changes, rash/hives, stomach discomfort, tinnitus, unexplained visual changes/diarrhea or weight loss. The observed efficacy of initiated ADA+concomitant MTX, and MTX-related AE are reported.

Results: In CONCERTO, pts were MTX–naïve. During the study, the mean duration of MTX exposure was 174.6 days. Overall, 113/395 pts (28.6%) reported 345 MTX-related AEs, including 1 serious AE (SAE, excessive fatigue and/or malaise); 10 events (in 2 pts) led to discontinuation. Pts in the 10/20 mg MTX groups reported the most AE. Pts in the 20 mg MTX group had both, the highest ACR response rate, and MTX-related AE. For each MTX dosage group, AE rates remained steady, whereas ACR50 response rates to ADA + MTX increased over time (Fig 1A). At Wk 26, the ACR50 response rates ranged from 54- 68%; MTX-related AE rates ranged from 2.4-17.8%. In MUSICA, the mean duration of prior MTX exposure was 1.5 yrs; mean prior MTX dosage was 17.3 mg/wk. During the study, the mean duration of MTX exposure was 157.5 days. Overall, 71/309 pts (23%) reported 185 MTX-related AEs; including 5 SAEs (4 infections and 1 fever and/or chills); 6 events (in 4 pts) led to discontinuation. MTX-related AE were reported at similar rates for both MTX dosage groups and peaked at Wk 4, whereas ACR50 response rates increased with time for both groups (Fig 1B). At Wk 24, the ACR50 response rates were 32.3% and 37.5% while the MTX-related AE rate was 6.5%.

Conclusion: In pts with early and established RA initiating ADA in combination with MTX, treatment efficacy was achieved despite reported MTX-related toxicity. Most MTX-related AE were mild and led to study discontinuation in 0.5% and 1.3% pts in CONCERTO and MUSICA respectively. While rates of MTX -related AE remained steady, efficacy of ADA+MTX increased during both trials.

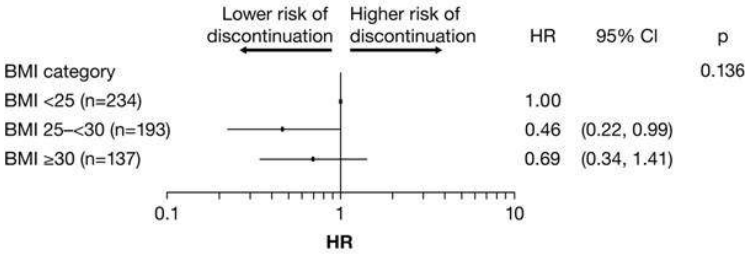
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: In RA, obesity may negatively affect clinical response to anti-TNF agents.[1] In contrast, real-world data show abatacept efficacy and retention are unaffected by BMI in patients (pts) with prior biologic failure.[2,3] Here, response to abatacept was assessed after 6 months, according to BMI, in biologic-naïve pts enrolled in the ACTION study. **Methods:** ACTION is a 2-year, international, multicenter, prospective, observational study evaluating retention and effectiveness of IV abatacept in pts with RA. In this 6-month analysis of biologic-naïve pts enrolled in ACTION, baseline characteristics and clinical response were compared by BMI subgroup: underweight/normal (<25 kg/m^2), overweight (25–<30 kg/m^2) and obese (≥30 kg/m^2). Time to abatacept discontinuation (overall and due to efficacy and safety) was estimated using Kaplan–Meier survival analysis and compared using log-rank tests. **Results:** BMI was reported in 643/672 (96%) pts: 264/643 (41%) were underweight/normal, 224/643 (35%) overweight and 155/643 (24%) obese. Higher baseline BMI was associated with more active disease (mean [95% CI] DAS28 [CRP] [derived] 4.6 [4.5, 4.7], 4.8 [4.7, 5.0] and 5.1 [4.9, 5.2] for BMI <25, 25–<30 and ≥30 kg/m^2, respectively), possibly due to a relation between fat tissue and chronic inflammation[4], and numerically more women (74, 66 and 81%), more metabolic disorders (22, 29 and 46%) and fewer RF positive (77, 68 and 67%) and anti-cyclic citrullinated peptide positive (71, 63 and 63%) pts (for BMI <25, 25–30 and ≥30 kg/m^2, respectively). Overall retention rates at 6 months (Kaplan–Meier analysis) did not differ across groups (84, 89 and 87%, for BMI <25, 25–<30 and ≥30 kg/m^2, respectively; log-rank p=0.290); no significant differences between groups were observed in discontinuation rates due to safety (log-rank p=0.683) or efficacy (log-rank p=0.516). After adjustment for baseline characteristics, BMI was still not significantly associated with risk of discontinuation (reference BMI <25 kg/m^2; HR [95% CI] 0.46 [0.22, 0.99] and 0.69 [0.34, 1.41] for BMI 25–<30 and ≥30 kg/m^2, respectively; figure). No significant differences in the percentage of pts in EULAR moderate or good response and no response were observed by BMI (80.7, 86.1 and 77.0% and 19.3, 13.9 and 23.0% of pts with BMI <25, 25–<30 and ≥30 kg/m^2, respectively; p=0.178).

Figure. Adjusted risk of discontinuation by BMI group (adjusted for baseline characteristics)



HR=Hazard ratio

Conclusion: BMI does not impact abatacept retention or clinical response in biologic-naïve pts with RA. Unlike anti-TNFs, obesity is not a risk factor for reduced efficacy of abatacept. These results are similar to those observed in real-world studies in pts with prior biologic failure.[2,3]

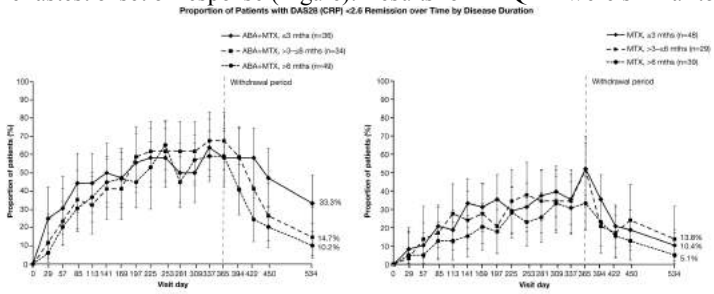
Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with RA and longer disease duration generally do not respond as well to treatment with DMARDs as patients with a shorter duration of disease. Earlier use of biologic DMARDs can improve disease control.[1,2] The AVERT trial provides the opportunity to examine outcomes in patients with varying degrees of early disease duration in which the definition for disease duration is well defined across groups. **Methods:** Patients with early active RA (clinical synovitis in ≥2 joints for ≥8 weeks, persistent symptoms for ≤2 years and DAS28 [CRP] ≥3.2), and who were anti-cyclic citrullinated peptide-2 positive, were randomized to SC abatacept (ABA) 125 mg/week + MTX, SC ABA 125 mg/week alone or MTX alone for 12 months. All RA treatment was removed after 12 months in patients with DAS28 (CRP) <3.2.[3] In this *post hoc* analysis, proportions of patients achieving protocol-defined remission (DAS28 [CRP] <2.6) or improvement in HAQ-DI (≥0.3 units from baseline) were assessed by ≤3 months', >3 to ≤6 months' or >6 months' disease duration (defined as the duration of persistent symptoms at baseline) and treatment group. Adjusted mean changes from baseline in HAQ-DI were also evaluated by disease duration. **Results:** Patients were randomized and treated with ABA+MTX (n=119) or MTX (n=116): 36 and 48 with ≤3 months'; 34 and 29 with >3 to ≤6 months'; 49 and 39 with >6 months' disease duration, respectively. No systematic differences were seen in baseline demographics and clinical characteristics for patients grouped by disease duration. Irrespective of baseline disease duration, a higher proportion of ABA+MTX-treated patients achieved Month 12 and sustained (Month 18) remission, compared with MTX alone. A higher proportion of ABA+MTX-treated patients with disease duration ≤3 months maintained remission following all treatment withdrawal compared with longer disease durations and MTX alone (Figure). ABA+MTX-treated patients with ≤3 months' disease duration also had the fastest onset of response (Figure). Results for HAQ-DI were similar to the overall population, regardless of baseline disease duration.



Conclusion: Disease duration of ≤3 months was associated with faster onset of clinical response and the ability to achieve higher rates of drug-free remission following treatment with abatacept+MTX in AVERT.[4]

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with RA are often treated with anti-tumor necrosis factor (TNF) agents. However, patients with a stable response to anti-TNF therapy may discontinue or switch treatments for non-medical reasons such as cost reduction. We evaluated real-world clinical outcomes associated with non-medical switching of anti-TNF therapies among patients with RA in the USA.

Methods: A rheumatologist-administered chart review collected online data (from 1/2011 through 4/2014) on patients with a diagnosis of RA who had a physician-reported stable response to an anti-TNF therapy for ≥6 months (baseline period). Patients who maintained response and either discontinued or switched for non-medical reasons from the anti-TNF (discontinuers) were matched to a patient visiting the same rheumatologist within a 60 day period who did not switch/discontinue therapy for non-medical reasons (continuers). Non-medical reasons for switching/discontinuing therapy included increased copay, change of insurance, job loss, or other economic factors that limited affordability of medication. Switchers/discontinuers were followed for 12 months from the date of discontinuation; continuers were followed for 12 months from the date of an office visit within 2 months of a matched switcher/discontinuer's discontinuation date. Differences between cohorts in baseline sociodemographic characteristics, disease severity (categorized as mild, moderate, or severe), comorbidities, medication use (anti-TNF and other RA-related drugs), and resource utilization were assessed with descriptive statistics. Generalized linear models were used to compare disease flares, disease control, and use of medical services between groups during the follow-up period, after adjustment for baseline characteristics.

Results: 83 matched pairs of switchers/discontinuers (69.9% switchers/30.1% discontinuers) and continuers were analyzed (N=166). Switchers/discontinuers were more likely than continuers to be Hispanic (27.7% vs 15.7%, *P*=.041); otherwise, there were no significant differences between cohorts in baseline sociodemographic and disease characteristics, comorbidities, medication use, or resource utilization. In the follow-up period approximately 48% of switchers/discontinuers had well-controlled disease symptoms as assessed by the rheumatologist, a significantly lower rate (adjusted odds ratio=0.15, *P*<.001) than continuers (84%). Compared with continuers, switchers/discontinuers had a significantly greater risk of flares and more frequent flares across all disease severity levels; they also had an increased risk of emergency department visits and more repeat emergency department visits (both *P*<.05; **Table**).

Conclusion: In this real-world study of patients with RA, discontinuation of an anti-TNF therapy for non-medical reasons was associated with significantly worse clinical outcomes and increased health care resource use.

Table. Treatment Response and Health Care Resource Utilization Among Patients with RA				
	Odds Ratio/Incidence Rate Ratio (Anti-TNF Switchers/Discontinuers vs Continuers[a])			
	Unadjusted	*P*-value	Adjusted	*P*-value
Likelihood of ≥1 Flare	3.29	<.001*	3.63	<.001*
Mild RA[b]	1.90	.018*	2.26	.005*
Moderate RA[b]	5.78	<.001*	5.76	<.001*

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I

Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: The goal of rheumatoid arthritis (RA) treatment is remission or, when not achievable, low-disease-activity (LDA). Initial combined therapy with MTX + anti-TNF achieves these goals more often but at a high cost. Some trials have therefore used the combined treatment for a limited time only ("induction-maintenance"). However, it has remained unclear if the benefits from the induction phase are sustained during maintenance, and individual trials may not have been sufficiently powered to resolve this issue. Therefore, we performed a meta-analysis of trials using the initial combination of MTX+Adalimumab in DMARD-naïve early RA-patients.

Methods: A systematic literature search was performed for induction-maintenance randomized controlled trials where initial combination therapy was compared with MTX-monotherapy in patients with clinically active early RA. Our primary outcome was the proportion of patients who achieved LDA (DAS28≤3.2) and/or remission (DAS28<2.6), at 12-52 weeks of follow-up comparing patients who started with MTX+ADA to those who started with MTX alone. A random effects model was used to pool the risk ratio (RR) for clinical remission and LDA.

Results: The literature search identified 2810 studies that matched the predefined search terms. We identified four published randomized trials (Table 1), where MTX+ADA was given as initial therapy and where ADA was withdrawn in a subset of patients after LDA/remission had been achieved. For two of these trials (Guépard and Hit-Hard) original data were re-examined, for the other two (Optima and Opera) only published data were available. As expected, the RR of achieving clinical remission or LDA with combination therapy was significantly greater than with MTX monotherapy; 1.76 (95%CI 1.51-2.06) and 1.45 (95%CI 1.03-2.08), respectively. Most importantly, the pooled RRs for achieving clinical remission and LDA at follow-up after discontinuation of ADA were 1.30 (95%CI 0.90-1.87) and 1.22 (95%CI 0.95-1.58), respectively, with significant heterogeneity between trials. Opera featured consistent use of intra-articular glucocorticoid-injections as a treat-to target strategy and therefore a sensitivity analysis excluding Opera was performed where the pooled RR for achieving clinical remission and LDA, at follow-up after discontinuation of ADA, were 1.56 (95%CI 1.21-2.00) and 1.37 (95%CI 1.09-1.72), respectively, without significant heterogeneity (Figure 1).

Conclusion: This meta-analysis supports the hypothesis that in early RA, initial therapy with MTX+ADA is associated with a higher chance of retaining LDA and/or remission even after discontinuation of ADA.

Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Predicted vs. Observed Radiographic Progression in early Rheumatoid Arthritis (POPeRA) is a method that has previously confirmed the relative radiographic efficacy of synthetic disease-modifying antirheumatic drugs (DMARDs) and anti-TNF treatment (1, 2). Here, we applied the POPeRA technique to the randomized Finnish Rheumatoid Arthritis Combination trial (3) (FIN-RACo, combination vs. single) as well as the NEO-RACo trial (4) (combination+anti-TNF vs. combination+placebo) in order to demonstrate how various treatment modalities affect radiographic progression.

Methods:

POPeRA utilizes the baseline radiographic score divided by the patient-reported symptom duration in months before baseline to predict radiographic outcomes over time, and simulates how patients would progress as if not on treatment. It was applied to 144 and 90 patients with eRA from the FIN-RACo and NEO-RACo trials, respectively. The Larsen score (FIN-RACo) and Sharp-van der Heijde score (SHS) (NEO-RACo) was available at baseline, 2, and 5 years. For FIN-RACo, patients were randomized either to a single DMARD (all starting with sulfasalazine; 60% had prednisolone in accordance to the physician's judgment) or to more intensive DMARD combination therapy (all starting with triple therapy: methotrexate+sulfasalazine+hydroxychloroquine with prednisolone). In NEO-RACo, all patients were assigned to FIN-RACo combination protocol plus a randomized 6-month induction of either placebo or anti-TNF treatment (infliximab). For both trials, treatment became unrestricted after 2 years.

Results:

In FIN-RACo, combination vs. single therapy resulted in superior outcomes in the change from predicted progression over 2 and 5 years (mean 35.7% reduction vs. -32.9%, a worsening from predicted, p=0.001; 34.2% vs. -17.8%, p=0.003, n=72, respectively). Patients positive for rheumatoid factor (RF) (n=102) had significantly worse changes from predicted at 2 and 5 years than RF-negative patients (n=42) (-13.6 vs. 38.1, p=0.035; -6.7 vs. 44.3, p=0.002, respectively). Superiority for combination vs. single therapy was observed in both RF-positive and RF-negative patients.

In NEO-RACo, combination+6-month anti-TNF therapy (n=44) led to significantly greater reductions from predicted progression than combination+placebo (n=46) both at 2 and 5 years of follow-up (98.5% vs. 83.4%, p=0.005; 92.4% vs. 82.5%, p=0.027, respectively). However, anti-TNF add-on treatment was superior only among RF-positive patients (n=67).

Conclusion:

These results confirm that conventional combination therapy in eRA has a

long-term radiographic benefit versus monotherapy. Using the POPeRA method, the addition of anti-TNF induction therapy for 6 months was shown to further increase the long-term radiographic benefit in RF-positive patients.

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Tuberculosis (TB), a reportable disease world-wide, is rare in the US (2013 incidence rate [IR]: 3 cases per 100,000 persons)[1] and is an event of interest in patients (pts) receiving biologic (b)DMARDs. Large healthcare claims databases are useful in assessing rare events, but confirmation of TB in the absence of information on culture results can be challenging. Typically, an International Classification of Diseases, Ninth Revision (ICD-9) code is used to identify an event, although these codes may be limited by varying sensitivity and poor positive predictive value.[2] In a published study by Calderwood et al., combinations of diagnostic codes, dispensed anti-TB medications and procedure codes (e.g. chest radiographs or sputum staining for acid-fast bacteria) detected TB cases with high sensitivity. Dispensing of two or more anti-TB medications was the most sensitive criterion, with a sensitivity of 89%.[3] The present analysis compares TB risk in pts using abatacept or other bDMARDs via these two methods. **Methods:** Adults diagnosed with RA in the MarketScan® Commercial and Supplemental Medicare databases who initiated treatment with abatacept or another bDMARD between July 1, 2006 and July 31, 2012 were included in the analysis. Included pts had at least 180 days of continuous health plan enrollment prior to and ≥1 day following initiation of the qualifying RA treatment. TB cases were defined using two methods: 1) at least 1 claim for an ICD-9 code indicating TB after initiation of a bDMARD and 2) applying the algorithm described by Calderwood et al.[3] IRs (per 1000 person-years) were calculated using both methods. A Cox regression analysis, adjusted for propensity score and prior bDMARD use, was conducted to compare the 2 cohorts. **Results:** Using the first method, there were 22 cases of TB among 10,898 abatacept initiators vs 63 cases among 37,441 initiators of other bDMARDs, corresponding to an IR (95% CI) of 2.65 (1.66, 4.01) vs 1.99 (1.53, 2.55), respectively. Using the second method, there were 3 cases of TB among abatacept initiators vs 5 cases among initiators of other bDMARDs, corresponding to an IR (95% CI) of 0.36 (0.07, 1.05) vs 0.16 (0.05, 0.37), respectively. The adjusted hazard ratio (95% CI) comparing abatacept initiators with initiators of other bDMARDs was 2.38 (0.95, 5.98) using method 1 and 1.00 (0.06, 15.99) using method 2.

Conclusion: Although we are unable to determine true positive or negative cases of TB in the claims-based data, applying the Calderwood algorithm provided estimates consistent with published rates of TB among pts with RA.[4] These results are also consistent with previous research demonstrating that TB diagnostic codes alone have poor positive predictive value. Validated algorithms are important when using claims-based data to evaluate TB events among pts with RA and in studies assessing the relationship between TB and treatment for RA.

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with RA are at increased risk for herpes zoster (HZ). Tofacitinib is an oral Janus kinase inhibitor for the treatment of RA. Treatment with tofacitinib appears to increase the risk of HZ.[1] However, it is unclear whether the use of concomitant nonbiologic DMARDs or glucocorticoids (GCs) further increases HZ risk in patients with RA using tofacitinib.

Methods: We identified reports of serious and non-serious HZ from Phase (P)1/P2/P3 and long-term extension (LTE) studies of tofacitinib in RA patients (data cut April 3, 2014; one LTE study still ongoing; database unlocked), and calculated crude incidence rates (IRs) for all HZ (serious and non-serious; unique patients with events per 100 patient-years [py]) with 95% confidence intervals (CIs). Patients were censored at study withdrawal, first HZ event, or death. Within P3 studies we described HZ rates in stratified fashion according to concomitant nonbiologic DMARDs and baseline GC use. To evaluate risk factors for HZ, we used pooled P1/P2/P3/LTE data and performed univariate and multivariable analyses using logistic regression. Stepwise selection with an entry and stay criterion of α=0.1 was used to form the final multivariable model.

Results: In 19 pooled P1/P2/P3 and LTE studies (total: 6192 patients; 16,839 py of exposure) HZ was reported in 636 tofacitinib-treated patients: IR 4.0 (3.7, 4.4). IRs for HZ varied widely across regions of enrollment, being lowest in Eastern and Western Europe (2.4 [2.0, 2.9] and 3.3 [2.4, 4.4], respectively) and highest in Japan/Korea: IR 8.1 (7.0, 9.4). The IR for United States/Canada/Australia was 4.3 (3.7, 5.1). Within P3 studies, IRs varied according to tofacitinib dose, background nonbiologic DMARDs (92% of patients using DMARDs were using MTX), and baseline GCs: IRs per 100 py were lowest for tofacitinib 5 mg twice daily (BID) monotherapy without GCs (IR 0.6 [0.1, 2.0]) and highest for tofacitinib 10 mg BID with DMARDs and GCs (IR 5.4 [3.7,7.7]) (Figure). Multivariable analysis showed that age, baseline GC use, concomitant DMARD use, tofacitinib dose (10 mg BID vs 5 mg BID), smoking history and region were likely predictors of HZ (Table).

Conclusion: Among patients with RA using tofacitinib, concomitant use of nonbiologic DMARDs or GCs appears to increase the risk and overall IR per 100 py of HZ from 0.56 to 4.82 with 5 mg BID. Limiting the use of GCs or MTX could potentially mitigate HZ risk.

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Response to therapies may vary based on anti-citrullinated protein antibodies (ACPA) status. We compared treatment response to abatacept in ACPA-positive versus -negative RA patients (pts) in a US national observational cohort. **Methods:** Using the Corrona RA registry, we identified new initiators of abatacept between February 2006 and January 2014. ACPA testing (ELISA assay for cyclic citrullinated peptide 2 seropositivity) was performed within 6 months of initiation. Disease activity was assessed using CDAI at both initiation and at a follow-up visit at 1 year (±3 months). The primary outcome was change in CDAI from baseline, with a secondary outcome examining achievement of low disease activity (LDA; CDAI ≤10) among those who initiated abatacept when in moderate or high disease activity, and

achievement of remission (CDAI ≤2.8) when initiated with low, moderate or high disease activity. Multivariable linear and logistic models were performed. Additionally, at 1 year we evaluated the proportion of ACPA-positive and -negative pts who remained on abatacept, switched to another biologic, or discontinued abatacept without initiating another biologic. **Results:** We identified 149 abatacept initiators who met inclusion criteria (64 with ACPA <20 units/mL [considered negative] and 85 with ACPA ≥20 units/mL [considered positive]). Most pts were female, Caucasian, aged 55.9–57.5 years, with moderate disease activity and a median disease duration of 4–6 yrs (Table 1). The majority (77.9%) of pts had prior exposure to at least 1 biologic or small molecule. Treatment with abatacept was associated with a mean change (95% CI) in CDAI of –5.24 (–8.42, –2.06) in the ACPA-negative group compared with –7.99 (–10.71, –5.27) in the ACPA-positive group (Table 2). Achievement of LDA occurred in 24.5% (95% CI 12.9, 36.1) of ACPA-negative patients vs 35.2% (24.1, 46.3) in the ACPA-positive group. Similarly, achievement of CDAI-defined remission occurred in 3.2% (95% CI 0, 7.5) of ACPA-negative patients vs 17.1% (8.9, 25.2) in the ACPA-positive group. Among the respective ACPA-negative and ACPA-positive pts, at 1 year 54.5% vs 72.9% remained on abatacept, 28.1% vs 16.5% switched to another biologic and 17.2% vs 10.6% discontinued the drug without initiating another biologic.

Conclusion: There was a suggestion of a greater response in ACPA-positive abatacept users compared with ACPA-negative users although not significant. The analyses were limited by sample size, warranting further evaluation.

Table 1. Baseline characteristics

Improvement in Disease Activity and the Long-Term Risk of Serious Infectious Events in Rheumatoid Arthritis Patients Treated with Certolizumab Pegol

Jeffrey R. Curtis[1], Marc de Longueville[2], Cathy O'Brien[2] and Boulos Haraoui[3], [1]University of Alabama at Birmingham, Birmingham, AL, [2]UCB Pharma, Brussels, Belgium, [3]Department of Medicine, Centre Hospitalier de l'Université de Montréal, Montréal, QC, Canada

Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Anti-TNF drugs are an effective treatment option for rheumatoid arthritis (RA) patients (pts) but have been associated with an increased incidence of serious infectious events (SIEs). High disease activity has been suggested to be a predictor of SIEs in RA. Here we examine whether improvement in disease activity over time is associated with a reduced risk of SIEs in certolizumab pegol (CZP)-treated RA patients.

Methods:

CZP safety data from bio-naïve patients were pooled from the RAPID1 and RAPID2 randomized clinical trials (RCTs; NCT00152386/NCT00160602) and their open-label extensions (OLEs; NCT00175877/NCT00160641). Post-hoc analyses included all SIEs with onset after the first CZP dose and up to 84 days after the last CZP dose or withdrawal. A multivariate Cox proportional hazards model (selection criteria: entry $p \leq 0.2$, stay $p \leq 0.25$) was used to estimate the relative risk (hazard ratio [HR]) of baseline (BL) and time-dependent pt covariates to SIEs. BL covariates selected by the final Cox model were age (<65; ≥65 yrs) and medically-treated comorbidity (diabetes, COPD, cardiac disorder hypertension, hyperlipidemia, transient ischemic attack or cerebrovascular disorder). Time-dependent covariates were measured at each pt visit (≤12 week intervals) and included DAS28(CRP), HAQ-DI and flare (increase >1.2 in DAS28[CRP] between visits). Pts were categorized by decrease in DAS28(CRP) between specific time points and the assessment performed before the first CZP dose (absolute decrease: <0.6; 0.6–1.2; 1.2–2.6; ≥2.6); pts with >1 DAS28(CRP) assessment in a time interval were categorized using the largest decrease in that interval. Incidence rates (IRs) of SIEs were calculated per 100 patient-years (PY), with 95% confidence intervals (CIs).

Results:

1506 bio-naïve CZP pts were included, with a total exposure of 5778.6 PY (max pt exposure: 6.40 PY; median exposure per pt: 4.79 PY). In total, 201 pts reported ≥1 SIE (IR 3.66/100 PY [3.17–4.21]) over ~6 yrs of CZP treatment. According to the Cox model, pts experiencing a flare had more than double the risk of SIEs (HR 2.21 [1.41–3.47]); also, an increment of 0.125 in HAQ-DI was associated with a 27% increase in the risk of SIEs (HR 1.27 [1.03–1.56]). By contrast, a one unit decrease in DAS28(CRP) was associated with a 17% reduction in the risk of SIEs (HR 0.83 [0.75–0.92]). Furthermore, the observed incidence of SIEs over time was generally lower among pts with an absolute decrease ≥2.6 in DAS28(CRP) (Table).

Conclusion:

Over time, lower disease activity was associated with a reduced risk of SIEs in CZP-treated RA pts and, conversely, flare was associated with increased risk. This study suggests that, in line with current treat-to-target guidelines, reducing disease activity may help to decrease the long-term risk of SIEs associated with anti-TNF drugs.

Table: Observed incidence of SIEs over time in patients categorized by absolute decrease in DAS28(CRP) since the first CZP dose

		Absolute decrease in DAS28(CRP) [a]			
		<0.6	0.6–1.2	1.2–2.6	≥2.6

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: TNF inhibitors have been used as a treatment for moderate to severe RA patients. However, reliable biomarkers that

predict therapeutic response to TNF inhibitors are lacking. In RA, Th1 cells stimulate macrophage activation via IFNγ and lead to secretion of TNF. Th17 cells are another pro-inflammatory Th subset which secrete IL17 and have also been involved in the pathogenesis of RA. In this study, we investigated whether Th1- and Th17- associated chemokines may represent useful prognostic biomarkers for TNF inhibitor treatment in RA.

Methods: We recruited RA patients from the Cooper University Hospital Rheumatology Clinic. The inclusion criteria for this study were: 1. diagnosis of RA by ACR criteria, 2. active RA defined by DAS >4.4, 3. clinical indication for initiating adalimumab or etanercept treatment. The exclusion criteria were: 1. diagnosis of other connective tissue diseases, 2. diagnosis of chronic infection. We obtained complete medical history and physical exam, demographic information, medications and laboratory data. At baseline and 14 weeks after TNF inhibitor therapy, we assessed DAS28 ESR and measured serum levels of Th1-associated chemokines (CXCL9, 10, 11) and Th17-associated chemokine (CCL20) using commercial ELISA kits. Responders and non-responders were defined as patients who had good/moderate response and no response at week 14 by EULAR response criteria. Wilcoxon two sample test was performed to compare chemokine levels.

Results: We assessed 16 RA patients who started either adalimumab or etanercept. Their baseline characteristics, summarized in Table 1, show no significant differences between responders (n=9) and non-responders (n=7). Responders showed a trend toward higher levels of baseline Th1 chemokines compared to non- responders (Fig 1). CXCL10 levels were significantly higher in responders (437 ± 354 vs 144 ± 45 pg/ml, p=0.04) while CXCL9 (2266 ± 1517 vs 1126 ± 452 pg/ml, p=0.16),and CXCL11 (887 ± 1114 vs 515 ± 853 pg/ml, p=0.25) differences did not reach statistical significance. There were significant correlations between CXCL9 and CXCL10 (r =0.61, p=0.01) and between CXCL9 and CXCL11 (r=0.66, p=0.01). CCL20 levels were lower in responders but were not significantly different (15.6 ± 12.0 vs 33.8 ± 41.8 pg/ml, p=0.63).

Conclusion: Elevated baseline levels of Th1 cytokines including CXCL9, 10 and 11 appear to be associated with favorable responses to TNF inhibitors whereas Th17 chemokine, CCL20, may be associated with unfavorable responses.

Table 1. Baseline characteristics of RA patients

	Responders (n=9)	Non-responders (n=7)	p value
Age (years)	45.6	50.6	0.43
Gender (female %)	89	86	1.00
Duration (years)	5.3	5.8	0.87
RF or CCP positivity (%)	56	43	1.00
DAS28 ESR	6.1	6.8	0.23
ESR (mm)	31	31	1.00
Concomitant MTX (%)	78	100	0.57

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Assessing Very Early Rheumatoid arthritis Treatment (AVERT) was a Phase IIIb, randomized, active-controlled study to evaluate the efficacy and safety of abatacept (ABA) treatment in three phased periods: during treatment, following withdrawal of all therapies and during re-exposure. Here, we present data from the withdrawal and re-exposure periods.

Methods: MTX-naïve, anti-cyclic citrullinated peptide 2-positive patients (pts) with early RA (active synovitis in ≥2 joints for ≥8 wks, DAS28 [CRP] ≥3.2 and onset of symptoms within ≤2 yrs) were initially randomized to 12 months of weekly SC ABA 125 mg + MTX, ABA 125 mg monotherapy or MTX alone (treatment period). Pts with DAS28 (CRP) <3.2 at Month 12 then entered a 12-month withdrawal period with no treatment. All pts with protocol-defined flare after Month 15 could receive open-label ABA + MTX (re-exposure period) for 6 months.

Results: Most pts could not remain treatment-free after complete treatment withdrawal, due to worsening disease activity (172/225; 76.4%) during the 12-month withdrawal period. Of those who entered the withdrawal period, rates of pts maintaining DAS28 (CRP) <2.6 free of all drugs at 24 months were 14.0, 12.3 and 11.3% for ABA + MTX, ABA mono and MTX alone, respectively. Rates of pts ever achieving a major clinical response (MCR) at 24 months were 40.3, 25.9 and 15.5% for ABA + MTX, ABA mono and MTX alone, respectively. A total of 146 pts entered the re-exposure period and 140 completed. Their baseline demographics and disease characteristics were similar to those of pts at study entry (mean RA duration ~0.5 yrs). The mean (SD) DAS28 at re-exposure period entry was 5.47 (1.27) and, at the end of the re-exposure period, was 2.43 (0.95). A total of 62% (78/126) of evaluable pts were in DAS28 (CRP) remission on re-exposure period Day 169. The mean (SD) HAQ at re-exposure period entry was 1.45 (0.64) and, at the end of the re-exposure period, was 0.63 (0.57). Over 12 months of the withdrawal period, the numbers (%) of serious AEs were 2 (2.4), 0 (0) and 5 (6.7), respectively, and only 1 serious infection was reported in the MTX alone arm (pyelonephritis; 337.4 pt-yrs). In the re-exposure period, no pts discontinued due to AEs and no serious infections were reported (292.2 pt-yrs). The overall rates of infections were 8.9 and 16 (incidence rate/100 pt-yrs) in the withdrawal and re-exposure periods, respectively (overall rates were 110.7 and 72.8 in the first and second 6 months of the initial treatment period). Multivariate analysis to identify predictors of time to flare and achieving DAS28 (CRP) <2.6 in the re-exposure period will be presented.

Conclusion: Re-treatment with abatacept + MTX can effectively recapture prior remission following flare after complete withdrawal of therapy. The likelihood of ever achieving a MCR was more likely in pts in the abatacept + MTX arm (> abatacept > MTX). There were far fewer infection events in the combined withdrawal period and re-exposure period than in the initial treatment period and only 1 serious infection was reported in the combined withdrawal period and treatment period suggesting re-treatment is well tolerated.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Therapeutic target in rheumatoid arthritis (RA) aims at achieving remission or low disease activity. Among the known poor prognostic factors are anti–citrullinated protein antibody (ACPA) and rheumatoid factor (RF). Clinical significance and therapeutic implications of the positivity of antinuclear antibodies (ANA) in serum of RA patients before starting the biological treatment is still under debate.

Purpose: The implications of ANA positivity, as a prognostic factor, in the therapeutic response to biologic therapy in RA, as measured by DAS28 score.

Methods: observational study; all data were gathered from the electronic database of Romanian Registry of Rheumatic Diseases (RRBR) which comprises all RA patients following biological treatment in the country. There were included only RA patients who were evaluated for the presence of ANA, before initiating any biologic therapy.

Results: 740 RA patients were included in the study, mean age 56.50 years (± 12.59), 84.5% women, mean disease duration 12.54 years (± 7.67). At baseline (prior to any biologic start), 26.9% patients were positive for ANA, 89.8% for RF, 37% for ACPA, 35.1% were double seropositive (for RF and ACPA) while 13.1% were triple seropositive (RF, ACPA, and ANA) and the mean DAS28 was 5.09 ± 2.35. 72.4% patients were treated with TNF-alpha blockers, while 27.6% with anti-CD20 drugs. During evolution, 22% of subjects required switch of therapy. Biologics persistency (the duration of therapy under one drug) was 31.70 (± 29.95) months and the latest DAS 28 score was 2.90 ± 1.41. There were statistically significant differences between DAS28 values at all assessments, depending on the presence of ANA. At biological start, DAS28 score in ANA positive group was 5.70 ± 2.06, while in ANA negative group was 4.86 ± 2.41 ($p < 0.001$). Concerning efficacy, assessed by the latest DAS28, ANA positive group had a score of 3.32 ± 1.61, compared to 2.74 ± 1.30 in ANA negative patients ($p < 0.001$). The drug persistence in ANA positive patients was 22.65 ± 25.68 months, versus 34.86 ± 30.71 months in ANA negative group ($p < 0.001$). For patients who required switch of therapy, DAS28 score at switch time was 5.42 ± 1.52 in ANA positive group, versus 4.79 ± 1.80 in ANA negative group ($p = 0.05$). There is a poor positive association between ANA positivity and DAS28 at all assessments ($r = 0.2$, $p < 0.01$) and ACPA positivity ($r = 0.2$, $p < 0.01$) and a negative correlation between ANA positivity and drug persistence ($r = -0.2$, $p < 0.01$). Linear regression showed that the best predictor of the current value of DAS28 is ANA positivity, independent of the presence of RF, ACPA, double or triple seropositivity ($t=2$, $p<0.05$).

Conclusion: ANA positivity in patients with RA, before starting any biological therapy, may be a poor prognostic factor for the therapeutic efficacy, as well as for the drug persistence. More studies are needed to confirm these observations.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

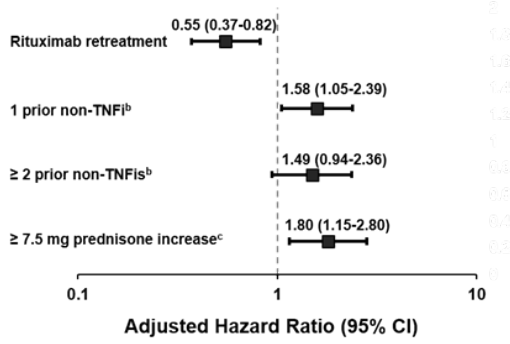
Background/Purpose: The goal of treatment for patients with rheumatoid arthritis (RA) is to achieve and maintain low disease activity (LDA) or remission. Little information is available on the likelihood and predictors of sustained response following LDA/remission among patients receiving rituximab. The objective of this analysis was to examine factors associated with sustained response in patients with RA treated with rituximab in the Corrona registry.

Methods: Corrona is a US-based, prospective, observational cohort of nearly 40,000 patients with RA. Patients with moderate or high disease activity (Clinical Disease Activity Index [CDAI] > 10) who initiated rituximab and who achieved LDA/remission (CDAI ≤ 10) within 12 months of their last rituximab infusion were included. Patients were followed until loss of response (CDAI > 10), initiation of another biologic or small molecule or exit from the registry. Covariates ascertained at the time of rituximab initiation included functional status, CDAI and patient-reported pain. Covariates examined at LDA/remission were demographic and clinical characteristics, prior medications and concomitant steroid and conventional synthetic disease-modifying antirheumatic drug (csDMARD) use. Time from rituximab initiation to LDA/remission was estimated. Time-varying covariates included rate of rituximab retreatment, number of prednisone dose increases and csDMARD initiations over time. Survival analyses and Cox proportional hazard regression models estimated the likelihood of sustained response following rituximab treatment and associations between covariates of interest and sustained response.

Results: Of the 1184 patients who initiated rituximab and had ≥ 1 follow-up appointment, 306 patients achieved LDA/remission within 12 months of their last rituximab infusion (median [IQR] time to LDA/remission, 5 [3-10] months). Most patients were female (76%) with a median (IQR) age of 60 (52-68) years; over 84% of patients had received ≥ 2 prior biologics. Of these patients, 34% received rituximab retreatments at a median (IQR) rate of 1.01 (0.71-1.36) retreatments per year. Twelve months after achievement of LDA/remission, 49% of patients maintained their response. In adjusted models (**Figure**), rituximab retreatment was associated with a significantly increased likelihood of sustained response, while prednisone dose increases ≥ 7.5 mg and use of 1 prior non–tumor necrosis factor inhibitor (TNFi) biologic were associated with increased likelihood of loss of response.

Conclusion: In this cohort of patients with refractory disease and use of several prior biologics who achieved LDA/remission following rituximab treatment, rituximab retreatment was associated with significantly greater sustained response. Increased prednisone doses and prior non-TNFi biologic use, factors that are likely surrogate markers of more severe disease, were associated with shorter sustained response.

Figure. Adjusted Analysis of Key Factors Associated With Loss of Sustained LDA/Remission in Patients Treated With Rituximab[a]



CDAI, Clinical Disease Activity Index; LDA, low disease activity; mHAQ, modified Health Assessment Questionnaire; RA, rheumatoid arthritis; TNFi, tumor necrosis factor inhibitor.
[a] Adjusted analysis includes all significant covariates from the unadjusted analysis (rituximab retreatment, BMI, mHAQ, classification of global functional status in RA and prednisone dose) as well as covariates defined a priori as those factors previously shown to influence likelihood of sustained LDA/remission (age, sex, disease duration, no. of prior TNFis and disease activity at the time of rituximab initiation).
[b] Zero prior TNFis is referent.
[c] No prednisone dose increase is referent.
[d] Other factors assessed that were not significant (not shown) included age, sex, BMI, duration of RA, baseline CDAI, mHAQ, functional status, no. of prior TNFis and prednisone dose increases < 7.5 mg.

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor for the treatment of rheumatoid arthritis (RA). Rates of herpes zoster (HZ) were higher than observed with other agents used to treat RA in tofacitinib RA development program, especially in Japan and Korea.[1] Higher than expected HZ rates were also recognized in the tofacitinib psoriasis (PsO) studies in Japan. It is important to identify mechanisms of increased risk of HZ infection for patients receiving tofacitinib. The objectives of this study were to determine if the increased risk of HZ seen with tofacitinib are associated with genetic risk factors, and whether the genetic risk factor can inform the mechanisms of increased HZ rate under tofacitinib that varied across ethnicities.

Methods: We performed a trans-ethnic and trans-indication meta-analysis of genome-wide association study in a total of 5,246 tofacitinib-treated subjects in RA, PsO Phase 2, 3 and long-term extension (LTE) studies (data cut-off April 2014; LTE ongoing, database not locked), by evaluating ~8 million genetic variants on HZ event (case vs control) and time to HZ event via logistic and Cox regression, respectively.

Results: After adjusting for age, baseline absolute lymphocyte count, genetically defined ethnicity and concomitant methotrexate use (RA only), we identified five loci associated with either increased HZ event rate and/or shorter time to HZ event at genome wide significance ($P < 5 \times 10^{-8}$). Two associations were noteworthy based on biological plausibility. A SNP near *CD83* (and *LINC01108*) was associated with increased risk of HZ events (meta-analysis OR = 3.7, $P = 2.1 \times 10^{-8}$). The frequency of the risk allele was low in Caucasians (<3%) and rare in Japanese (<0.1%). CD83 is expressed on multiple immune subsets, is a marker of dendritic cell maturation and B cell activation and is down-regulated in dendritic cells by VZV infection suggesting a plausible mechanism. The second association was near *IL-17RB*, and this SNP was associated with faster rate of HZ onset (meta-analysis HR = 3.6, $P = 7.6 \times 10^{-10}$). This association was driven by a risk allele common in Japan (~17% in the general Japanese population) but <0.2% in Caucasians. *IL-17RB* is highly expressed on iNKT2 and iNKT17 cells, whereas iNKT1 cells are *IL-17RB* negative and dependent on JAK-dependent IL-15. iNKT cell deficiency with low production of interferon gamma by iNKT cells is linked to disseminated varicella in response to vaccination in two case reports, despite a generally intact immune system. Overexpression of IL-25, the ligand for *IL-17RB*, also leads to recurrence of varicella, suggesting that the ratio of iNKT1 to iNKT2 and 17 cells is important.

Conclusion: Genetic analysis of ~5,300 individuals treated with tofacitinib has identified multiple loci that are associated with increased risk of HZ. The risk allele of one of these polymorphisms is significantly more prevalent in the Japanese population. A possible iNKT cell skewing mechanism is suggested that will be evaluated in future studies.

Rituximab Associated Late Onset Neutropenia – a Rheumatology Case Series and Review of the Literature

William Monaco[1], William F.C. Rigby[2] and Jonathan Jones[3], [1]Internal Medicine, Dartmouth-Hitchcock Medical Center, Lebanon, NH, [2]Geisel School of Medicine at Dartmouth, Lebanon, NH, [3]Rheumatology, Dartmouth-Hitchcock Medical Center, Lebanon, NH

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rituximab (RTX) has been associated with late onset neutropenia (LON), defined as an absolute neutrophil count (ANC) < 1.5 x 10^9/L at least 4 weeks after the last infusion. Reports of LON are primarily found in the hematology literature. We determined the incidence of LON in patients with rheumatic disease at a single tertiary medical center, ascertained patient characteristics, and performed a literature review.

Methods: We performed a retrospective study of patients at Dartmouth-Hitchcock Medical Center that received RTX for a rheumatologic disease between 2006-2014 and developed LON. In addition, we reviewed 4 case series of LON after RTX was given for rheumatologic disorders.

Results: We found 11 patients who developed LON (6 male and 5 female, average age 63), which was 6.5% of 168 patients receiving RTX. The most common diagnosis was RA (9 LON patients and 73% of all patients who got RTX). The average time to LON after RTX therapy was 90 days (range of 40 to 198 days). The average ANC nadir was 0.5 x 10^9/L, and while 3 patients received granulocyte colony-stimulating factor (G-CSF), all patients' neutrophil counts normalized. The median total dose of RTX prior to LON was 5 gms. 4 patients presented with an infection (biliary sepsis, pneumonia, cellulitis, and perirectal abscess), 2 presented with fever without an infectious etiology, 1 patient complained of abdominal pain, and 4 cases were found with routine blood work (1 of these patients was hospitalized with a large bowel obstruction). 8 of the 11 patients were given a repeat infusion of RTX after recovery of their neutrophil count; none went on to re-develop LON. Bone marrow biopsies from 4 patients had the predominant cell line as lymphocytes, comprising an average of 41% (range 24-50%) of the cellular aspirate followed by monocytes (16%), promyelocytes (12%), and neutrophils/bands (8%).

From the literature, we identified 36 patients (8 male and 28 female, average age 55) who developed LON after RTX therapy. Again, the most common diagnosis was RA (58% of patients). Compared to our cohort, these patients had similar times to LON, ANC nadir, and average RTX dose prior to LON. Most patients presented asymptomatically and all survived. Neutrophil counts recovered in all patients spontaneously or with G-CSF. If patients received G-CSF, the only difference was time to recovery of neutrophil counts: 6.4 ± 3.2 days with G-CSF vs 11.2 ± 6.3 days without G-CSF (p=0.04). There were no reported cases of LON recurrence when patients were given RTX after recovery of neutrophil counts.

Conclusion: LON is a rare complication of RTX affecting approximately 5% of patients. While these patients can present with infection, they typically recover without serious sequelae. Among reported cases, RTX rechallenge does not lead to recurrence of neutropenia. Though the etiology of LON is unknown, there is some evidence that LON is caused by an imbalance of lymphopoiesis and granulopoiesis and/or maturation arrest at the promyelocyte stage.

Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Treat-to-target (T2T) of remission strategies has been widely accepted as the standard of care for patients with Rheumatoid Arthritis (RA). In early RA, implementation of T2T in daily clinical practice has been shown to provide earlier clinical improvement. However, the optimal treatment protocol is still not clear.

The objective of this study is to compare the effectiveness of two T2T strategies: a step up approach starting with methotrexate (MTX) monotherapy (cohort I) versus an initial combination approach (cohort II) starting with high dose of MTX, hydroxychloroquine (HCQ) and an optional intramuscular triamcinolone acetonide (TCA) injection in early RA patients.

Methods: Baseline demographics, clinical and patient-reported outcome measures and one-year follow-up data were used. A total number of 128 patients from cohort II were case-control matched with 128 patients from cohort I on gender, age and baseline disease activity. Twelve month follow-up data were available for 121 patients in both cohorts. The primary outcome was the proportion of patients having reached at least one DAS28 <2.6 (DAS28 remission) after 1 year. Secondary outcomes were time to achieve remission and mean-changes in DAS28 scores at 6 months and 1 year. **Results** were analyzed using chi-square tests for proportional differences, t-tests for mean differences and Kaplan-Meier survival analysis for between-group differences in time to achieve remission. The course over time was compared between groups by specifying a linear mixed model with strategy and time as fixed factors. An ante-dependence structure was used as a model for the covariance matrix, since it gave the best fit to the data. Post-hoc ANCOVA analyses were performed with baseline DAS28 score as a covariate.

Results: After one year of follow-up, remission was reached at least once in 77.3% of the patients in cohort II versus 71.9% in cohort I (p=0.391). Median time to first remission was 17 weeks in cohort II versus 27 weeks in cohort I (p=0.044). A significant time by strategy interaction was found. Post-hoc analysis revealed a significant difference between strategies at 6 months (p=0.04, mean difference = 0.295, 95% CI= 0.01 - 0.58) but not at 12 months (p=0.36, mean difference = 0.128, 95% CI= -0.14 - 0.4).

Conclusion: In patients with early RA treated according to the T2T principles, the initial combination therapy with MTX and HCQ and optional TCA resulted in significantly quicker remission and lower disease activity at 6 months than the step up strategy starting with MTX monotherapy. At 12 months, no significant differences remained in mean DAS28 scores or the proportion of patients in remission.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Tocilizumab, an interleukin-6 (IL-6) receptor antagonist, is an effective drug for the treatment of rheumatoid arthritis (RA). During administration of tocilizumab, previous studies have shown that the levels of erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP), classic acute phase reactants, might not be elevated even in RA patients with high inflammatory activity due to infection. Therefore, we evaluated whether neutrophil–lymphocyte ratio (NLR), which has been recently introduced as a useful parameter for monitoring the disease activity in systemic inflammatory diseases, reflect treatment response to tocilizumab therapy better than ESR and CRP in patients with RA.

Methods: A total of 72 RA patients treated with tocilizumab in a single tertiary referral hospital from Jan 2013 to Dec 2014 were initially included in our study. We excluded 30 patients due to infection (n=9), administration less than six months (n=8), adverse event (n=6), violation of interval (n=5), pregnancy (n=1), and combined malignancy (n=1). Out of the remaining 42 patients, 14 experienced flare-up during tocilizumab therapy. Flare-up was defined as events that needed either dose escalation of steroid, intra-articular steroid injection or switch tocilizumab to another biologic agent. The data were retrospectively reviewed with the electronic medical records. We compared levels of inflammatory markers including leukocyte count, ESR, CRP and NLR at flare-up and stable state before flare-up. Moreover, 28 patients with stable RA after tocilizumab administration were also evaluated. The levels of inflammatory markers were compared at three and six months after initiation of tocilizumab.

Results: In the group of patients who experienced flare-up during tocilizumab treatment, the levels of CRP were not significantly different between those measured at stable state and flare-up (0.32 ± 0.45 vs 0.73 ± 1.03 mg/dL, p=0.110). The levels of ESR and the values of NLR were

significantly different between those measured at stable state and flare-up (14.9 ± 15.8 vs 24.3 ± 23.3 mm/hr, p=0.041 and 1.98 ±1.01 vs 4.05 ± 3.42, p=0.002). The levels of ESR and CRP measured at flare-up ranged within the normal limit in eight and nine patients each, and four and three patients each had decreased levels of ESR and CRP at flare-up compared with those at stable state. However, the values of NLR in all patients except one patient increased significantly at flare-up compared to stable state, and the percentage of increment ranged from -13 to 437%(105 ± 42). In the group of patients who were stable during tocilizumab treatment, the levels of NLR did not change between those measured at three and six months after initiation of tocilizumab (1.47 ± 0.70 vs 1.30 ± 0.69, p=0.233).

Conclusion: The levels of CRP did not reflect treatment response to tocilizumab administration in RA patients, whereas the values of NLR were significantly increased in the flare group. The values of NLR were more associated with treatment response to tocilizumab than the levels of ESR. Thus, our present findings suggest that NLR is more valuable for evaluating the disease activity in patients with RA during tocilizumab therapy.

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Granulocyte macrophage-colony stimulating factor (GM-CSF) mediates a range of immunological and inflammatory processes, and plays a role in a variety of inflammatory diseases. Namilumab (AMG203), a human immunoglobulin G1 (IgG1) monoclonal antibody with high affinity for the GM-CSF ligand, is under investigation in rheumatoid arthritis (RA) and psoriasis. Selection of an appropriate dosing schedule using modelling and simulation for proof-of-concept (PoC) studies is a key step in drug development. The objective of this analysis was to integrate clinical and non-clinical pharmacokinetic (PK) and pharmacodynamic (PD) data to identify an appropriate subcutaneous dosage for namilumab PoC and traditional Phase II studies.

Methods: A range of data was used to build the fundamentals of the analysis. Initially, the effective concentration of 22E9, a surrogate mouse antibody of namilumab, in a collagen-induced arthritis (CIA) mouse model was combined with the outcome of an ex-vivo cellular inhibition assay for namilumab in order to suggest an efficacious concentration range (22E9 and namilumab have similar neutralising potencies against murine and human GM-CSF, respectively). In addition, PK and PD similarities and differences between namilumab and anti-TNF-α antibodies, as well as known cytokine levels in joints of patients with RA, were used to support the predicted efficacy range of namilumab. These concentrations were translated into human doses using a population PK model developed based on data from two Phase I studies of namilumab in healthy volunteers (single ascending intravenous doses up to 8 mg/kg) and patients with mild-to-moderate RA (repeated subcutaneous doses of 150 or 300 mg; PRIORA, NCT01317797).

Results: The EC_{50} for namilumab was calculated as 11 µg/mL in the CIA mouse model, which was supported by results of the ex-vivo blood assay. In addition, the observation of similar affinities of anti-TNF-α antibodies (12–90 pM) and namilumab (46 pM), in conjunction with target expression in the synovium in similar ranges of magnitude, indicated that targeting clinical concentration ranges seen with anti-TNF-α antibodies should translate into clinical efficacy. Next, a population PK model was applied to translate clinical concentration ranges into dosing schedules. Doses from 20 to 150 mg were selected with the intent to cover low, medium and high efficacious exposures in RA and psoriasis. In addition, a loading dose was suggested for a selected Phase II trial.

Conclusion: Integration of preclinical and clinical PK and PD data for namilumab and combination of these with data from anti-TNF-α antibodies was essential to determine the appropriate namilumab dose schedule for evaluation in Phase II studies.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor for the treatment of rheumatoid arthritis (RA). In the global tofacitinib RA clinical program, rates and types of malignancies remained stable over time with increasing tofacitinib exposure; the overall malignancy incidence rate (IR) (excluding non-melanoma skin cancer [NMSC]) was 0.85 (95% CI, 0.70-1.02) events per 100 patient-years (pt-yrs); age- and sex-adjusted standardized incidence ratio (SIR) vs. US SEER database was 1.17 (95% CI, 0.96-1.41).[1] This analysis evaluated malignancy (excluding NMSC) in Japanese RA (JRA) pts in the tofacitinib clinical program, compared with JRA and Japanese general populations (JGP).

Methods: Malignancy data were pooled from 2 Phase (P) 2, 1 P3 and 1 open-label long-term extension (LTE) RA studies conducted in Japan (April 2014 data cut). Pts received tofacitinib 5 or 10 mg twice daily (BID) in P3 and LTE; also 1, 3, and 15 mg BID in P2.

Malignancy data were also obtained for: JGP aged 16-<75 yrs (2010 data from the Cancer Information Service, National Cancer Center, Japan)[2]; Japan Medical Data Center (JMDC) RA population aged 16-<75 yrs (Jan 2005 to Oct 2013).

Results: 556 JRA pts (1705 pt-yrs of exposure) received tofacitinib in P2/P3/LTE studies; 22 pts had malignancies. From JMDC (23,481 pts in total), 14,728 pts received any treatment for RA; 2,317 pts received nonbiologic or biologic DMARDs.

Cumulative IRs for malignancy (excluding NMSC) in tofacitinib-treated JRA pts in clinical trials are shown in the Figure; SIRs (95% CI) for malignancy (excluding NMSC) were 2.13 (1.33-3.22) vs. JGP, 1.21 (0.76-1.83) vs. JMDC population receiving any treatment for RA, and 0.87 (0.55-1.32) vs. JMDC population receiving nonbiologic or biologic DMARDs (Table).

Conclusion: Following numerically lower incidence rates over months 0-12 with possible effect of pre-randomization screening, the risk of all malignancies (excluding NMSC) among JRA pts exposed to tofacitinib appears stable with increasing exposure to tofacitinib. The overall malignancy rate in the tofacitinib-treated JRA population was similar to the JMDC RA populations, and was increased compared with the JGP. Given the limited pt-yrs accrued to date in Japan, ongoing post-marketing surveillance will further evaluate malignancy among JRA pts exposed to tofacitinib.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Previous studies have shown differences in treatment retention between anti-TNF agents. Furthermore, although inconsistent, data from the literature suggest that some factors (e.g. concomitant methotrexate use) may be associated with improved retention of certain anti-TNF agents. The aim of this analysis was to compare the long-term retention of infliximab (IFX) and golimumab (GLM) and to identify independent predictors of retention in patients with rheumatoid arthritis (RA) followed in Canadian routine practice

Methods:

BioTRAC is an ongoing, prospective registry of patients initiating treatment for RA, ankylosing spondylitis, or psoriatic arthritis with IFX or GLM. Eligible people for this analysis included RA patients treated with IFX who were enrolled since 2002 or with GLM enrolled since 2010; patients not discontinued who had a follow-up of <18 months were excluded. Independent predictors of long-term retention, defined as ≥18 months, were assessed with multivariate logistic regression using backwards variable selection. Receiver operator curve (ROC) analysis was used to determine the optimal cut-off points of CDAI for long-term retention

Results:

A total of 972 patients (76.3% female) were included with mean (SD) age of 55.9 (13.8) years and disease duration of 8.6 (9.1) years at baseline. The majority were biologic naïve (94.5%), treated with IFX (84.8%), and received a concomitant DMARD (88.5%) at baseline; 35.9% were treated with a corticosteroid (CS). Mean (SD) disease parameters at baseline were: CDAI: 35.3 (17.5); HAQ: 1.6 (0.7); swollen joint count (0-28): 10.3 (6.8); tender joint count (0-28): 12.0 (7.9); patient global (VAS cm): 6.0 (2.5); physician global (0-10 NRS): 6.4 (2.1).

Six hundred (61.7%) patients received treatment for ≥18 months. In univariate analysis, age [OR (95% CI): 0.99 (0.98-1.00)], disease duration [0.97 (0.95-0.99)], enrolment year [1.10 (1.06-1.15)], male gender [0.68 (0.50-0.94)], GLM vs. IFX use [2.24 (1.58-3.19)], biologic naiveté [0.58 (0.33-1.01)], and baseline DMARD use [0.54 (0.36-0.80)] were identified as potential predictors of retention (P<0.100). Baseline CS use [0.86 (0.66-1.13)], CDAI [1.00 (0.99-1.00)], and HAQ [0.98 (0.81-1.17)] did not have an impact. Upon multivariate adjustment, older age [0.98 (0.97-1.00)] and male gender [0.50 (0.29-0.85)], were associated with significantly lower odds of discontinuation, while more recent enrolment year was associated with higher odds [1.36 (1.20-1.54)].

Lower disease activity (CDAI remission vs. low vs. moderate vs. high) at 6 or 12 months was associated with significantly (P<0.001) higher probability of long-term retention. ROC curve analysis identified a CDAI score at 6 months ≤15.7 (AUC=0.652; P<0.001) and a score at 12 months ≤14.6 (AUC=0.679; P<0.001) as most accurately predicting long-term retention

Conclusion:

The results of this analysis have shown that treatment retention of IFX and GLM in real-world are comparable. Age, gender, and enrolment year, possibly signifying differences in patient preferences or changes over time in clinical practice, as well as CDAI score of 15 or less at 6 or 12 months were identified as significant independent predictors of long-term retention

Association Between Three Measures of Oral Glucocorticoid Exposure and Potential Adverse Events Among Patients with Rheumatoid Arthritis

Jennie Best[1], Amanda Farr[2], Gregory Lenhart[2], Khaled Sarsour[1], Marni Stott-Miller[2] and Yong Gil Hwang[3], [1]Genentech, South San Francisco, CA, [2]Truven Health Analytics, Cambridge, MA, [3]Department of Medicine, University of Pittsburgh, Pittsburgh, PA

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Oral glucocorticoids are commonly used to treat rheumatoid arthritis (RA). However, their use may be associated with potential adverse events. Therefore, the objective was to evaluate the association between exposure to oral glucocorticoids and incident adverse events, using three different measures of oral glucocorticoid exposure.

Methods: This retrospective cohort study utilized two large administrative claims databases. Patients with RA aged 18 years and older with at least one prescription claim for an oral glucocorticoid between 1/1/2010-12/31/2013 (index date) were identified. Patients were required to be continuously enrolled for 12 months prior to index date with no claims for oral glucocorticoids, to be continuously enrolled for 1 month after index date and have no diagnoses for other autoimmune conditions. Oral glucocorticoid use was measured in monthly panel periods after the index date. The following measures were captured: cumulative dose in prednisone-equivalent milligrams, months on therapy, and months since last use. Presence and time from index date to any potential adverse event assessed (osteoporosis, fracture, aseptic necrosis of bone, hospitalization for pneumonia or infection, hospitalization for myocardial infarction or stroke, type 2 diabetes, ulcer/gastrointestinal bleed) were measured. Cox proportional hazards models with time-fixed and time-varying covariates were fit to the data.

Results: There were 36,502 RA patients identified; average age 58.2 years and 78.3% female. Patients were followed for a total of 60,663 years. During follow-up, 17,512 patients (48.0%) had at least 3 months with oral glucocorticoid exposure. Mean cumulative dose/month was 59 mg. 7,358 (20.2%) patients had evidence of a potential adverse event. Unadjusted incidence rates are presented in Figure 1. Results from time-varying models are presented in Table 1. Higher cumulative dose and more months of treatment were associated with a significantly increased risk of adverse event, while an increase in the time since last glucocorticoid use was associated with a significantly decreased risk of adverse event. These trends were noted in individual models and in models including all three exposure measures.

Conclusion: Among patients with RA, greater exposure to oral glucocorticoids, operationalized as higher cumulative dose and more months of treatment, was associated with increased risk of experiencing an adverse event. Greater time since last exposure was associated with a decreased risk. It is important for clinicians to consider steroid-sparing treatments for RA patients.

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: We hypothesized that characterization of patients' metabolic profiles, utilizing both high-resolution ^{1}H-nuclear magnetic resonance (NMR) and mass spectrometry (MS), might help predict response to rituximab therapy in rheumatoid arthritis (RA).

Methods: 23 active seropositive RA patients on concomitant methotrexate were treated with rituximab (1g intravenously; days 0 and 14; without peri-infusional steroids). Clinical outcome was determined 6 months after treatment. Patients were classified as responders or non-responders according to the ACR20 responses. Blood was collected before (baseline) and at 6 months after rituximab therapy. A Bruker Avance 700 MHz spectrometer and a Thermo Scientific Q Exactive Hybrid Quadrupole-Orbitrap Mass Spectrometer were used on ultrafiltered peripheral blood samples at baseline and 6 months after rituximab therapy. Data processing and statistical analysis were performed in the MATLAB programming environment. Pathway analysis was performed using VANTED software. Significantly different metabolites were identified and the relationship between metabolites and clinical outcome was studied.

Results: Multivariate statistical analysis of the ^{1}H-NMR baseline spectra successfully discriminated between RA patients classified as rituximab responders (n = 14) and non-responders (n = 9), at baseline and 6 months after rituximab treatment. A two sample t-test produced p-values of less than 0.05 for seven metabolites which were decreased in responders: phenylalanine, 2-hydroxyvalerate, succinate, choline, glycine, acetoacetate, and tyrosine. Lipids analysis by MS also discriminated between RA patients. Prior to treatment, most observed classes of glycerophospholipids were downregulated in rituximab responders, including phosphatidylethanolamines, phosphatidylserines, and phosphatidylglycerol. Opposite trend was observed in phosphatidylinositols. Following treatment with rituximab, several of these trends were reversed in responders, suggesting that response to rituximab is related to shifts in phospholipid composition in responders.

Conclusion: The relationship between blood profiles and patient response to rituximab therapy suggests that the application of ^{1}H-NMR and MS profiling may be a promising clinical tool for RA therapy optimization. Additional metabolic profile studies are needed to determine if metabolic profiling can predict response to this and other biological therapies in RA patients**.**

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: : Currently, there is no clarity regarding which biologic to switch to when patients fail to respond to TNF inhibitors (TNFis). Detailed information for predicting long-term outcomes when switching from TNFis to ABT would be helpful in clinical practice. This study aimed to identify predictive factors for achieving low disease activity (LDA) in rheumatoid arthritis (RA) patients switching from tumor necrosis factor inhibitors to abatacept (ABT).

Methods: Patients who were registered in the multicenter observational cohort study in Japan were enrolled in this study. Predictive factors for LDA achievement at each time point were determined by univariate and multivariate logistic regression analyses. The cut-off of DAS28-CRP and DDAS28-CRP from baseline up to 24 weeks for LDA achievement at 52 weeks were explored using receiver operating characteristic (ROC) curves.

Results: Of 2,771 RA patients registered until 2013, 76 with moderate or high disease activity were selected. Fifty-three percent of patients received ABT with MTX (mean dose; 7.8 mg/week), and 26% achieved LDA. In total, the drug retention rate at 52 weeks was 76.3%. Multivariate analysis confirmed that DAS28-CRP at 12 weeks and DDAS28-CRP from baseline to 12 weeks were independent factors for LDA achievement at 52 weeks [OR: 0.26, 95% confident interval (CI): (0.12-0.56), OR: 0.25, 95% CI: (0.11-0.57), respectively]. DAS28-CRP at

baseline was not the factor.

We confirmed the association between DAS28-CRP at each time point and LDA achievement at 52 weeks based on ROC curves. DAS28-CRP at 4, 12, and 24 weeks was associated with LDA achievement (AUC at 4 weeks, 0.74; 12 weeks, 0.86; 24 weeks, 0.83) (Fig. A), and that between DDAS28-CRP from baseline to each time point (AUC from baseline to 4 weeks, 0.66; to 12 weeks, 0.75; to 24 weeks, 0.70) (Fig. B).

The best cut-off values of DAS28-CRP at 12 weeks and DDAS28-CRP from baseline to 12 weeks for LDA at 52 weeks were 3.9 (sensitivity: 0.85, specificity: 0.78) and -0.97 (sensitivity: 0.70, specificity: 0.70), respectively. Seventy-one percent of patients who achieved both of these cut-off values at 12 weeks achieved LDA at 52 weeks.

Conclusion: We examined the effectiveness of switching from TNFis to ABT in clinical practice. Our findings suggest the need to consider the clinical course up to 12 weeks in order to predict long-term outcomes. These findings should be useful and applicable to the "treat to target" strategy in real-world clinical settings.

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Biologics constitute an important drug category in the pharmacological treatment of rheumatoid arthritis (RA). Drug-free remission (REM) may also be achievable if the condition is responsive to treatment. In RA patients who had been treated with tocilizumab (TCZ) and whose disease activity was well-controlled, the administration interval of TCZ was extended, and a follow-up observation was carried out.

Methods:

The study was conducted on 101 RA patients treated with TCZ, who could be followed up for 52 weeks or longer. The cases were analyzed by dividing into two groups: a group of 41 patients whose administration interval was extended after achievement of a state of low disease activity (LDA) (extended-interval administration group, E-group), and a group of 61 patients for whom the doses continued to be administered at 4-week intervals in accordance with the package insert (standard-administration group, S-group). Evaluation of disease activity was conducted by using DAS28-ESR.

Results:

Comparison between S-group and E-group showed significant differences ($p<0.05$) in the following background items at the time of introduction of TCZ therapy: swollen joint count (SJC): 18.7±7.6 and 15.6±8.4, CRP (mg/dl): 2.77±3.01 and 1.81±2.56, DAS28-CRP: 6.1±1.5 and 5.6±1.4, CDAI: 51.7±16.6 and 43.6±17.5, and SDAI: 50.0±18.4 and 49.8±18.5. In E-group, extension of the interval was attempted at an average of 31.6 weeks (11 weeks to 101 weeks) after initiation of the introduction of TCZ therapy. In average, the duration of persistence of LDA until initiation of the extension of administration intervals was 23.1 weeks (4 weeks to 78 weeks). The changes in DAS28-ESR scores were examined after initiation of the extension of the administration interval; and the findings showed that the scores were 2.00±0.93 at the time of the initiation of the extension, 2.02±0.92 at 12 weeks, 2.11±1.13 at 24 weeks, 2.16±1.00 at 36 weeks, and 2.06±1.00 at 52 weeks. The REM rate was 70.7% at the time of the initiation of the extension, 65.9% at 24 weeks, and 61.0% at 52 weeks. In 7 patients (17.1%), relapse developed within 52 weeks following the extension of the administration interval of TCZ, and in all cases, resetting the administration interval back to 4 weeks led to an improvement of the patients' condition and an achievement of LDA within 24 weeks. The patients who relapsed showed significant differences in terms of the duration of the persistence of LDA until initiation of the extension, as well as in terms of ESR and DAS28-ESR scores at the time of the initiation of the extension ($p<0.05$). Based on the ROC curve, the DAS28-ESR at the time of initiation of the extension of the administration interval showed an AUC of 0.732 with a cut-off value of 1.81 weeks; and the duration of the persistence of LDA until initiation of the extension of the administration interval showed an AUC of 0.735 with a cut-off value of 14.0 weeks.

Conclusion:

Extension of administration intervals was carried out in 40% of RA patients treated with TCZ. For 82.9% of the cases, disease activity was maintained at a good level for a period of 52 weeks or longer.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Our previous analyses using the national administrative database from Veteran Health Administration showed that RA patient who were switched from oral to subcutaneous MTX due to intolerance or lack of response were more likely to stay on methotrexate monotherapy longer. We seek to determine if RA patients who were on multiple traditional DMARD stay longer on traditional DMARD when subcutaneous MTX was used. We also compare the occurrences of liver enzymes abnormalities between those on subcutaneous MTX with those on oral therapy.

Methods: The duration of multiple traditional DMARD therapy, defined as the time between starting the use of a multiple traditional DMARD regimen that includes methotrexate and the switch to or addition of biologics, is compared between those on oral methotrexate and those on subcutaneous methotrexate for at least 30 days using a Wilcoxon-Matt-Whitney test. Factors that could potentially influence the duration of multiple traditional DMARD use include: gender, age, race, and maximum MTX dose. These factors were assessed using a log-rank test and Kaplan-Meier curves; Cox regression models were run to correct for patient variables. Liver enzyme abnormalities were compared between patients on subcutaneous and oral MTX who received MTX monotherapy for >30 days; abnormal alanine aminotransferase (ALT) levels and aspartate aminotransferase (AST) levels were defined as exceeding twice the upper limit of normal.

Results: Of the 13,254 patients who were treated with a DMARD for at least 90 days, 6541 were on more than one DMARD at any point in time, and in 3586, MTX was included in the multiple DMARD regimens. There were 1837 biologic starts among these 3586 patients (1604 were treated with oral MTX, 197 with subcutaneous MTX). Patient treated with oral MTX remained on multiple traditional DMARD for a mean (SD) of 683 (650) days compared with 580 (595) days for patients treated with subcutaneous MTX (P=0.014). Based on log-rank tests (see figure), the use of subcutaneous MTX was associated with significantly shorter duration of traditional multiple DMARD therapy use (P=0.025). After adjustment for patient variables using Cox regression models, the association of subcutaneous MTX use with the duration on multiple traditional DMARD therapy was no longer significant (P=0.107). Age and race remained significantly associated after corrections. Of the patients treated with MTX who had ALT and/or AST levels assessed, the rates of abnormal ALT and AST levels were not significantly different between those receiving oral and subcutaneous MTX (P=0.090 and P=0.924, respectively).

Conclusion: Unlike the duration of MTX monotherapy, the duration of multiple traditional DMARD use was not significantly associated with use of subcutaneous MTX. Among those using MTX for >30 days, there was no significant differences in liver enzyme abnormalities between patients treated with subcutaneous MTX and oral MTX.

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

The production of autoantibodies, such as anti-nuclear antibodies (ANA) and anti-ds DNA antibodies (anti-DNA), is commonly observed in patients who have been treated with tumor necrosis factor (TNF) inhibitors. We had reported that accelerated anti-DNA production was predominantly observed in patients treated with infliximab (IFX), and this occurred more frequently in anti-Ro/SS-A antibodies (anti-Ro) positive rheumatoid arthritis (RA) patients. The purposes of this study were to examine whether the positive rate of ANA and anti-DNA before and after commencement of treatment is different among TNF inhibitors and to compare the positive rates between anti-Ro-positive and -negative patients. Moreover, we investigated the relationship between the production of such autoantibodies and clinical response.

Methods:

We examined 246 patients with RA treated with TNF inhibitors as the first biologics DMARDs: IFX; 116, etanercept (ETN); 64, adalimumab (ADA); 36, and golimumab (GLM); 30 and studied positive rate of ANA and anti-DNA before and after commencement of each TNF inhibitors. ANA was tested using an indirect immunofluorescent assay on fixed HEp-2 cell substrate. Anti-DNA was measured using a radioimmunoassay (RIA). A part of anti-DNA positive patients were tested anti-DNA isotype of IgG, IgM, and IgA by enzyme-linked immunosorbent assay. We compared the positive rate of ANA and anti-DNA between anti-Ro-positive and -negative patients. Clinical response was evaluated by EULAR response using disease activity score (DAS) 28/CRP.

Results:

The positive rate of ANA before and after commencement of IFX, ETN, ADA, and GLM were 63.8% to 89.7%, 56.3% to 68.8%, 72.2% to 75.0%, and 66.7% to 63.3%, respectively. Sixty-five patients (26.4%) were anti-DNA positive after TNF inhibitors, and anti-DNA titers increased from baseline after IFX, ETN, ADA, and GLM were 4.3% to 41.4%, 1.6% to 10.9%, 8.3% to 25.0%, and 0.0% to 3.3%, respectively. Both ANA and anti-DNA were significantly elevated after treated with IFX than other TNF inhibitors ($p<0.001$ and $p<0.001$, respectively). Moreover, the positive rate of anti-DNA in patients treated with IFX and ADA was notably increased in anti-Ro-positive patients compared to anti-Ro-negative patients (68.2% vs 35.1%; $p=0.009$, 66.7% vs 16.7%; $p=0.039$, respectively). On the other hand, only one patient was anti-DNA positive after treated with GLM and there was no anti-Ro-positive patient who anti-DNA was detected after treated with GLM. In 38 patients with positive anti-DNA by RIA, isotype of IgM was found in 34 cases (89.5%) after treatment, while IgG and IgA was positive in few patients. Furthermore, 35 of 65 patients increased anti-DNA after treated with TNF inhibitors were stopped or switched biologics because of inefficacy and this observation was found in most of the patients with anti-Ro (71.4%).

Conclusion:

The production of anti-DNA after treated with TNF inhibitors was frequently increased in anti-Ro-positive patients and it was suggested to relate to the lesser clinical response and to decrease the continuation rate. In addition, the production of autoantibodies was different among TNF inhibitors and it might be considered to select the treatment of TNF inhibitors.

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is associated with reduction of bone mineral density (BMD) and increased risk of peripheral and axial fractures. Methotrexate is the first-line treatment in this disease. MTX has been suspected to play a noxious role on bone of patients treated for leukemia or RA. We aimed to assess the effect of MTX on BMD after 1 year of treatment, in patients with RA.

Methods: We performed a systematic review and a meta-analysis of the literature. Two authors (RK and YD) independently screened PubMed-Medline, the Cochrane library and Ovid journals databases. Key words were: "rheumatoid arthritis" AND "methotrexate" AND ("mineral densityÓ or "remodeling markers" or "formation" or "resorptionÓ or "boneÓ). Data, including BMD variation, were extracted using a predetermined form. We selected all prospective studies, with assessment of baseline and 1-year lumbar spine, femoral neck or hip BMD, in patients treated by methotrexate monotherapy. This screening was supplemented by hand searching of relevant references in selected papers. Studies were limited to those concerning human species, published in English, before March 2015. Pooled BMD variation was computed by meta-analysis.

Results: We identified 433 articles in PubMed database and 7 in Cochrane or Ovid databases. We selected 5 eligible references for the systematic review and 4 relevant for meta-analysis. We analyzed 144 patients. 106 were women, 94 displayed early arthritis (<1 year), they had active RA. Two studies included in the meta-analysis contained possibility of bisphosphonates treatment and steroids therapy (Table 1). Meta-analysis concerning 1-year lumbar BMD variation did not show a significant variation: 0.00 g/cm^2, 95% confidence interval (95%CI) [-0.02, 0.02] (Figure 1a). Meta-analysis concerning 1-year femoral neck BMD variation showed a non-significant variation: -0.01 g/cm^2, 95%CI [-0.04, +0.01] (Figure 1b). Meta-analysis was not possible for 1-year total hip BMD variation. Estimated heterogeneity of studies was high.

Table 1. Main characteristics of the studies included in the meta-analysis

Reference	Study type	MTX Population	Age, mean +/- SD	Disease duration (year)	Percentage female	Corticotherapy (Prednisone ³10_mg/day)	Bisphosphonates	DAS 28 +/- SD
Van Der Goes, 2013	Randomized, placebo-controlled, double-blind	84	52 +/- 13	< 1	65	Yes	Yes	3.2 +/- 1.1
Haugeberg, 2009	Randomized, placebo-controlled, double-blind	10	53.1 +/- 13.7	< 1	70	Yes	Yes	7 +/- 0.9
Marotte, 2007	Case-control	99	53.9 +/- 15.9	10.9 +/-8.9	79	No	Yes	5 +/- 1.15
Minaur, 2002	Non- randomized, longitudinal	28	62.6 +/- 8.9	6.6	79	No	No	5.27 +/- 1
Mazzantini, 2000	Non-randomized, longitudinal	22	59 +/- 9	9 +/- 9	100	No	No	-

Figure 1a. Lumbar BMD meta-analysis

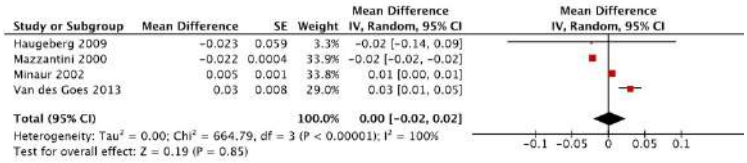

Figure 1b. Femoral BMD meta-analysis

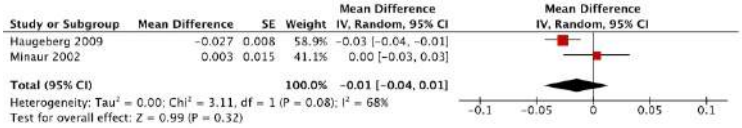

Conclusion: We did not observed a significant variation of 1-year lumbar and femoral neck BMD in patients treated by MTX, thus suggesting a neutral effect of MTX on BMD in RA.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: It is a well-known fact the decline of life expectancy in Rheumatoid Arthritis (RA) being the increased mortality in these patients a constant concern in Rheumatology. This increment in mortality has been linked to multiple factors such as disease activity and treatment. The purpose of our study was to assess the mortality rate and to evaluate the mortality risk in a cohort of RA patients with and without Biologic Agents (BA). Other factors associated to mortality risk were also investigated.

Methods: An inception cohort of RA patients diagnosed between January 2000 and December 2004, were recruited from a Rheumatology outpatient clinic of a tertiary Hospital in Madrid, Spain, and followed for up to 13.5 years after diagnosis. Dependent variable was death (obtained from the National Death Index) and independent variable was use of BA. Covariables: sociodemographic (age, sex, level of studies), clinical (DAS-28, HAQ, hospital admissions, comorbidity, rheumatoid factor [RF]) and therapy (concomitant corticoids, Disease Modifying Antirheumatic Drugs [DMARDs] and BA). Survival techniques were used to estimate the mortality rate (MR) in our cohort, expressed per 1,000 patient-years with their respective confidence interval [95 % CI]. They were follow-up until lost of follow-up, death or end of the study. The influence BA on mortality rate was analyzed using multivariable Cox proportional hazards models adjusting by age, sex, disability, comorbidity, calendar year, disease severity and other variables. BA were used in a time-dependent manner. **Results** were expressed by hazard ratio (HR) and 95% CI.

Results: We included 576 patients and 711 courses of therapy. 75% were women with a mean age at diagnosis of 59±years. The mean DAS and HAQ at diagnosis were 3.8±1.2 and 0.7±0.6 respectively. 68% patients were taking corticoids, 113 (19.6%) BA and 86% DMARDs (median [p25-75]: 2 [1-3]), being MTX the most prevalent (70%). There were 133 deaths per 5,441 person-years at risk in the total cohort. MR was estimated in 27 [22.5-31.6]. MR for BA was 12.6 [6-26] and for the rest 28.4 [23.8-33.8]. The unadjusted HR of mortality in BA was 0.37 [0.17-0.8] (p=0.011). Controlling by confounders (age, gender, calendar time, comorbidity, disease activity, quality of life), the HR for death in those treated with BA was 0.72 [0.3-1.6], p=0.4) versus those not treated. Other variables independently associated with death were: age at diagnosis (HR: 1.09 [1.07-1.11]), positive RF (HR: 1.94 [1.3-2.8]), hospital admissions (HR: 1.19 [1.12-1.25]), HAQ > 1.5 (HR: 1.98 [1.07-3.6]) and MTX use (HR: 0.4 [0.29-0.66]).

Conclusion: This study describes mortality rate in real-life conditions in an inception cohort of RA patients. After controlling by factors that influence mortality, we found that survival in patients receiving BA is not different than those receiving other classic DMARDs. We have assessed the role of other variables in the risk of mortality.

Optimization of Treatment Intervals of Tocilizumab and Golimumab By Measuring Serum Trough Levels in Rheumatoid Arthritis Patients

Yoshinobu Matsuura[1], Masashi Narazaki[2], Masayuki Nishide[2], Yasuhiro Kato[2], Hideki Yorifuji[2], Toru Hirano[3], Yoshihito Shima[3], Toshio Tanaka[2], Atsushi Ogata[4] and Atsushi Kumanogoh[3], [1]Internal Medicine, Allergy and Rheumatic diseases, Osaka University Graduate School of Medicine, Suita, Japan, [2]Osaka University Graduate School of Medicine, Suita, Japan, [3]Respiratory Medicine, Allergy and Rheumatic Diseases, Osaka University Graduate School of Medicine, Suita, Japan, [4]Osaka University Graduate School of Medicine and NTT West Osaka Hospital,

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Biologic agents have dramatically improved the outcome of rheumatoid arthritis (RA) patients. However, the administration dose and treatment intervals of these agents are usually fixed for individual patients. Hence, patients displaying disease remission receive an unnecessary high dose of medication. The immunosuppressive action of biologics in this medication strategy exposes patients to a high risk to gain infectious diseases and causes increased medical costs. In this study, we optimized the treatment intervals of the biologics tocilizumab and golimumab by monitoring their serum trough levels in individual patients.

Methods:

Japanese RA patients were treated either with intravenous tocilizumab (TCZ) 8mg/kg or subcutaneous golimumab (GLM) 50mg every 4 weeks (n=49 or n=20, respectively) and enrolled to analyze their serum trough levels of the respective biologics. Recombinant human soluble IL-6 receptor or human TNFα was coated on ELISA plates and bound TCZ or GLM in patient sera was detected with anti-human IgG1 antibody. The disease activity was evaluated with DAS-CRP. Treatment intervals were prolonged for patients with low disease activity displaying tocilizumab or golimumab serum trough levels>1μg/ml.

Results:

We monitored significant differences of the serum trough levels of the respective agent among individual patients. TCZ ranged from 0.25μg/ml to 52μg/ml (17.4 ± 10.4μg/ml), while GLM ranged from 0.25μg/ml to 10.9μg/ml (3.34 ± 3.13μg/ml). A positive correlation between age and serum trough levels was found in the TCZ group (P=0.0101, r^2=0.3863). However, we did not find any correlation between the disease activity and serum trough levels of the biologics in both TCZ and GLM groups. In the TCZ group, the mean trough level was 16.8μg/ml ± 8.1μg/ml at 4-weeks and was reduced to 11.1μg/ml ±9.0μg/ml after 5-weeks and 3.09μg/ml ±3.29μg/ml after 6-weeks. 24 patients with low disease activity displaying serum trough level >1μg/ml of TCZ agreed to prolong treatment intervals. 13 of the 24 patients showed a TCZ serum level >1μg/ml even after prolongation of medication without any disease exacerbation. However, 11 of 24 patients displayed a decreased TCZ serum trough level <1μg/ml. In this group 3 patients had a increased DAS-CRP score whereas in 8 patients the disease activity was not affected. In the GLM group, the mean trough serum level was 3.34μg/ml ± 3.13μg/ml after 4-weeks and was reduced to 2.85 μg/ml ± 2.51μg/ml after 5-weeks and 1.41μg/ml after 6-weeks. The disease activity didn't change after modification of the medication interval.

Conclusion:

Significant difference of serum trough levels of biologics was observed among RA patients treated with TCZ or GLM. Maintenance of a certain serum trough levels by monitoring concentration of biologics may allow optimization of treatment intervals without increasing the disease activity and may lead to decrease medical costs.

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Last years, biological dose tapering in patients with inflammatory diseases has become a routine clinical practice. Since 2011 we are applying a dose reduction protocol in our biological monographic consultation and our day hospital : etanercept dosage from 50 mgrs to 25 mgrs subcutaneous weekly injection, adalimumab 40 mgrs subcutaneous injection administration spacing of 2 to 3 weeks, tocilizumab, dose reduction from 8 mgrs/kg to 6 mgrs/kg. Thus we have achieved optimization rates in our patients close to 40% at the end of 2013.

The aim of this study is to analyze baseline characteristics and course of the disease in these optimized patients, in order to improve our treatment protocols if possible.

Methods: : Retrospective analysis of data from clinical records and database of 115 patients under therapy with etanercept, adalimumab and tocilizumab, with at least two year evolution of dose reduction or withdrawal. We consider baseline features, drug, time of dose tapering, including frecuency, time and course of flares if happened. We used SPSS 21.0 for statistical analysis

Results:

115 patients (59 female and 56 male), 34% with rheumatoid arthritis (RA), 62.6% with axial or peripheral spondylitis (SPa), including psoriatic arthritis, and 3.5% juvenile idiopatic arthritis (JIA), most of them with longstanding disease (148.47 months, range 18-638), and long time disease remission at optimization (33.46 months, range 6-134). 26 patients stopped biological treatment, but most of them (22) for other clinical conditions (surgery, infection, poor adherence, adverse events, malignancy). Optimized patients kept in remission for 34,24 months (range 10-77).

32.2% of patients flared, 46,2% suffering from RA and 26.4% with SPa, which means statistically significant difference (chi square 4.45, p=0.035). There was no significant difference among biological drugs analized in terms of flare at any indication, or when you considered SPa, but the differences reached significance when you compare flared RA patients under adalimumab (18.8%) and etanercept (46.3%), Chi square: 16.5; p<0,001.

RA patients flared earlier than SPa patients, with statistical significance (Log Rank test p: 0,027), and this was not influenced by concomitant therapy or the use of metotrexate, but by the biological drug used: RA patients under etanercept flared earlier than SPa (difference in survival curve). This did not occur among patients under adalimumab.

Extraarticular disease (psoriasis, uveitis, diarrhea) was the main manifestation of flare in 42% of our SPa patients.

Conclusion: In our experience dose reduction of biological therapies is safe and cost effective, even withdrawall is possible in selected cases. Concerning therapy with etanercept, we must consider a most conservative dose reduction protocol, at least in our RA patients. In SPa patients we must pay close attention extraarticular manifestations specially when dose tapering.

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Protease activity, especially MMP3, is known to be increased with arthritis, such as rheumatoid arthritis. MMP3 is mainly expressed by fibroblasts; a key cell in arthritis. In RA, Serum levels of MMP3 isassociated with structural progression and elevated compared to OA. The present methods for assessing MMP3 is ELISA of total MMP3 (tMMP3) or the activity by using a substrate. However, neither of these approaches provide serological information about the level of the active form of MMP3 (acMMP3). In this study we used a serological biomarker detecting acMMP3, to investigate if this biomarker was a biomarker of treatment efficacy (Tocilizumab; TCZ), aid in dose-finding and if it was related to radiographic progression.

Methods: LITHE biomarker study (n=585) was a 1-year phase III, double-blind, placebo (PBO)-controlled, parallel group study of 4 or 8 mg/kg every 4 weeks, in RA patients on stable doses of methotrexate (MTX). acMMP3 was tested in serum from baseline (BL) and week 4, 16, 24 and 52 and tMMP3 in serum from BL and week 4 and 16. Patients not reaching ACR20 remission at week 16 or 24 received rescue treatment (escape); 4mg/kg patients received 8mg/kg for the rest of the study. Spearman's correlation was analysed between BL level of acMMP3 (log transformed) and clinical measures. Associations between BL acMMP3 and change in JSN and mTSS were investigated in the PBO group was assessed by Spearman's correlations. Change in acMMP3 levels were studied as a function of time and treatment. Relation to radiographic progression was assessed t-test when segregating the treated population into 2 group; more or less than 35% change in acMMP3 at week 16 .

Results: At BL tMMP3, but not acMMP3, was correlated with radiographic change (erosion rho 0.22 and modified total sharp score rho: 0.21) at 1 year and HAQ (rho -0.19) at 24 weeks and acMMP3, and tMMP3 were correlated to each other (rho 0.15). Percentage change in acMMP3 at week 16 in the TCZ groups was negatively correlated to change in radiographic change at 1 year (erosion rho -0.20 and modified total sharp score rho -0.20), but for joint space narrowing only in the 4mg/kg group (rho -0.27). Percentage change in tMMP3 at week 16 in the 4mg/kg group was correlated to disease activity measures (DAS rho 0.21, HAQ rho 0.20, VAS pain rho 0.21). acMMP3 was dose-dependently decreased by TCZ (p=0.026) already at week 4, whereas tMMP3 was decreased by treatment (p=0.0001) without dose-differentiation. Furthermore, acMMP3 was decreased in escapers compared to non-escapers at 1 year.

Conclusion: Serum acMMP3 and tMMP3 were efficacy biomarkers of TCZ at week 4 and acMMP3, but not tMMP3, differentiated doses. The change in acMMP3 at week 16 was inversely associated with radiographic change at 1 year, whereas the change in tMMP3 was associated with disease activity. This study illustrates that the activity of a protease can assess early, who will benefit from TCZ.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Abatacept (ABT) is a biologic drug and has been available for rheumatoid arthritis (RA) patients since 2010 in Japan. There have still been few reports describing the association of rheumatoid factor (RF) with the short- and long-term clinical results of ABT. The aim of this study is to demonstrate whether the positivity for RF is associated with the short-term (52 weeks) clinical response to ABT and the long-term (4 years) drug retention rate of ABT using data from a Japanese multicenter registry system for RA patients treated with biological DMARDs.

Methods: Participants were consecutive 508 patients with RA who were prospectively registered in the Tsurumai Biologics Communication Registry and treated with ABT. Demographic data and the following parameters of disease activity were collected; TJC, SJC, patient global assessment, ESR, and serum CRP at baseline, 4, 12, 24, and 52 weeks. The last observation carried forward (LOCF) method was used in each analysis. Survival analysis was performed with the Kaplan-Meier method and log-rank test. We compared these clinical indices between the patients with and those without RF positivity.

Results: At baseline, mean age was 65.1 years, disease duration was 13.1 years, and DAS28-CRP was 4.36. Of the 508 patients, 78.8% was female, 77.5% was RF positive (>20 mg/dl), and 42.7% had prior biologics history (Bio-switch). Percent change of DAS28-CRP was significantly greater in the RF positive group from 4 weeks throughout 52 weeks ($p < 0.05$) (Fig. 1a). The proportion of patients that achieved EULAR moderate response was also greater in the RF positive group from 4 to 52 weeks ($p < 0.01$) (Fig. 1b). Overall drug retention rate was 60.0% in the RF negative and 77.5% in the RF positive group at 4 years (Fig. 2a). Discontinuation rate due to insufficient efficacy (Insufficiency) was 27.2% in the RF negative and 15.3% in the RF positive group (Fig. 2b). Discontinuation rate due to adverse events was similar between the groups (Fig. 2c). Within the bioswitch patients, the RF negative group demonstrated significantly higher discontinuation rate due to secondary failure (40.8 vs 11.0%) (Fig. 3b). The hazard ratio (HR) for secondary failure, adjusted for sex, age, disease duration, concomitant MTX and PSL, and baseline DAS28-CRP, was 4.17 (95%CI 1.20-14.45) for RF negative versus RF positive. On the other hand, RF positivity did not affect the discontinuation rate in the Bio-naïve patients (Fig. 3a).

Conclusion: We found that RF positivity was associated with better short-term response to ABT. We also found that RF positivity significantly improve the long-term incidence rate of discontinuation due to secondary failure in the bio-switch patients. It is necessary to establish the strategy for additional therapeutic intervention, such as concomitant drugs, in this patients group to improve the short- and long-term clinical results of ABT.

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I

Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Tumor necrosis factor inhibitors (TNFi) have helped patients achieve remarkable outcomes as in improving synovitis and halting structural damages in severe cases of rheumatoid arthritis (RA). Nowadays academic interests lie towards strategies of 'tapering' or 'discontinuing' biological therapy, especially in cases where patients are being maintained in clinical remission for an adequate period. However, not many studies have traced the outcomes after discontinuing TNFi.

Methods: The 'Investigation of outcomes after Golimumab discontinuation' or GOLD study, is an observational study participated by 10 centers nationwide, following up clinical data of Korean RA patients who were enrolled in the 5-year extension study of GO-BEFORE and GO-FORWARD. Medical records of the 2-year post-golimumab period were reviewed and pertinent clinical data including DAS scores, prescriptions, comorbidities, laboratory findings, as well as radiographic images were analyzed.

Results: The 60 RA patients (male 5, female 55) had the following mean values at discontinuation (baseline); age of 51.0 years, disease duration of 16.5 years, and a DAS28-CRP score of 2.71. At the 2-year time point, 9/60 (15%) patients had restarted biologics. The mean period restarting biologics was 18.7 months (range 4~28) after discontinuation. Baseline characteristics of the 'biologic restarters' and 'non-biologic users' are depicted in the table. New joint damage was discovered only in non-biologic users (4/51 patients) at 2 years.

Conclusion: The GOLD study based on 'deliberate' discontinuation of TNFi in RA patients with low disease activity shows that patients with higher swollen joint counts, physician's global assessment score at the time point of discontinuation tend to restart biologics in the near future. New joint damage ensued only in those off biologics.

Table. Baseline characteristics between the 2 groups at discontinuation*

	Biologic Restarters (n= 9)	Non-biologic Users (n= 51)	*P* value
Age, years	49.9	51.2	0.73
ACR20, %	66	82	0.27

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Anti-citrullinated protein antibody (ACPA) has been an important marker in diagnosing rheumatoid arthritis (RA). Its predictive value remains unclear; therefore, here we investigated whether the pre-treatment ACPA titer is able to predict the treatment efficacy of first biological treatments in RA.

Methods:

Records of relevant patients with RA were collected from the Tsurumai Biologic Communication Registry, wherein the department of Nagoya University and 20 affiliated hospitals in Japan are enrolled. The relevant data of a total of 388 patients with RA who met the 2010 ACR–EULAR classification criteria for RA were completely recorded in regard to DAS28ESR before and after biological treatment. The ACPA status was divided into three categories: negative (0–4.4 U/ml), low-positive (4.5–13.5 U/ml), and high-positive (>13.5 U/ml). The 154 ACPA low-positive patients and 172 ACPA high-positive patients were compared with regard to the effect of ACPA titer on biological treatment. Only bio-naïve patients were included in this study, whereas patients who received second or latter biological treatment were excluded. We analyzed the relevant data using analysis of covariance (ANCOVA) with pre-treatment DAS28ESR as covariant.

Results:

The demographic characteristics of each group at baseline are presented in Table 1. Pre-treatment DAS28ESR was significantly associated with DAS28ESR improvement, where the higher pre-DAS28ESR, the larger DAS28ESR improvement ($p < 0.01$; Figure 1). Pre-treatment DAS28ESR was 5.11 in ACPA low-positive patients and 5.25 in ACPA high-positive patients, and DAS28ESR improvement in the two groups was 2.49 and 2.22, respectively. Compensating each DAS28ESR according to the pre-biological treatment value using ANCOVA as the whole mean value, which is 5.19, DAS28ESR improvement was 2.54 in ACPA low-positive patients and 2.17 in ACPA high-positive patients, respectively, and the difference was significant ($p < 0.05$; Table 2).

Conclusion:

The ACPA titer significantly affected DAS28ESR improvement after first biological treatment. In addition, the efficacy of first biological treatment was inferior in ACPA high-positive patients compared with that in ACPA low-positive patients with RA.

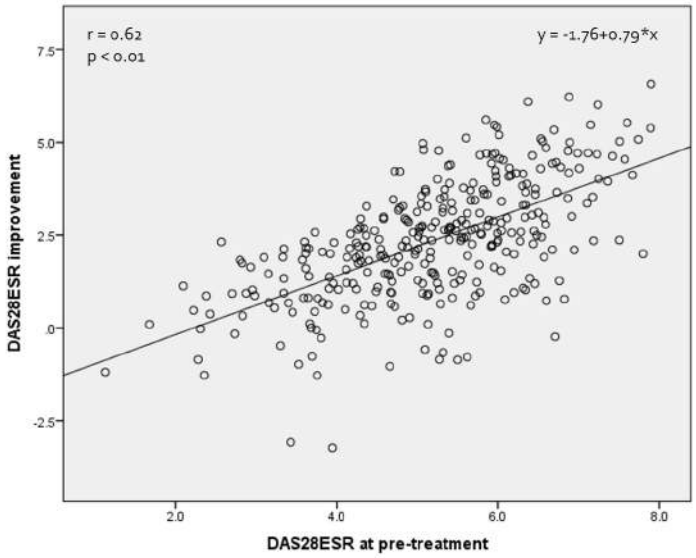

Figure 1. Relationship between DAS28ESR at pre-treatment and DAS28ESR improvement

Table 1. Characteristics of ACPA low-positive and high-positive, as measured at baseline.

	ACPA low-positive (n = 154)	ACPA high-positive (n = 172)	p
Age, Mean ± SD years	57.2 ± 14.3	56.7 ± 14.2	0.73
Sex, % female	79.2	79.7	1

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Glucocorticoids (GC) are used to treat a wide range of inflammatory diseases including rheumatic and musculoskeletal diseases. EULAR recommendations on GC therapy are up to date but uncertainty about the benefit-risk ratio of GC persists. To address this issue, a multidisciplinary EULAR task force was assembled. Bearing in mind the known beneficial effects of GC, the primary aim was to achieve consensus when formulating conditions under which these drugs have an acceptable low level of harm, based on systematic evaluation of available evidence on adverse effects (AE).

Methods: Focussing on the four most worrisome AE of GC (cardiovascular disease (CVD), effects on bone, GC-induced hyperglycaemia & diabetes mellitus and infections), a systematic literature review was performed and discussed in the expert group. One breakout group per AE discussed the relevant evidence in detail and presented their results to the other group members following a structured questionnaire for final discussion. The questions addressed dose-harm relationships, relevant patient characteristics, co-morbidities, co-medications and both preventive and therapeutic measures with regard to the AE mentioned above.

Results:

The common basis for the group´s work was (i) an initial agreement with current guidelines stating there is convincing evidence for the beneficial effects of GC also at low dosages and (ii) the view that data on AE are limited (e.g. in terms of duration of GC use), sometimes both contradictory and biased. As a result of the critical appraisal of available evidence, the task force members agreed that for the majority of patients:

- at **dosages of ≤5mg/d**prednisone equivalent the benefits are greater than the risks with the exception of patients at high risk for CVD who may require preventive measures

- **at dosages of >10mg/d**the risks are greater than the benefits, with the exception of patients with (partial) GC resistance

At **dosages between >5 and ≤10mg/d**, the level of harm depends on patient-specific characteristics such as disease activity, presence of additional risk factors, and preventive measures. In general, an early diagnosis, low disease activity, low cumulative GC dosage, healthy life style (including appropriate exercise) and both, monitoring and treatment of risk factors and co-morbidities, respectively, represent factors which reduce the risk of harm. For each AE of GC, specific factors can affect the risk and, therefore, the level of harm in both directions. Moreover, for some GC induced AE (i) specific patient groups are at higher risk, (ii) certain co-morbidities increase the risk and (iii) the genetic background and (iv) specific disease characteristics may have impact on the risk of harm. Thus, the level of harm varies between individuals, and consequently our consensus is valid for the majority of patients rather than every individual patient.

Conclusion: There is no absolute condition or conditions under which GC always have an acceptable low level of harm. However, based on currently available evidence, our consensus provides the rationale to accomplish a relatively safe use of GC in the majority of patients.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I
Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Tocilizumab (TCZ) is clinically effective against rheumatoid arthritis (RA) and over 50% of RA patients who had completed 5 years of TCZ treatment maintained remission[1)]. However, long-term treatment of biologics is often the cause of economic burden and restriction of treatment options. Although there are some trials to stopping biologics for patients in remission[2)], efficacy and tolerability of extended dosing interval with TCZ is not known. Objective of this study is to evaluate the efficacy and tolerability of 6-week extended dosing interval with TCZ in RA patients in remission.

Methods: Eligible patients were those who met the 2010 ACR/EULAR classification criteria. Consecutive patients at our institute who had received over 6 times of TCZ injection in remission maintained over 3 months with their informed consent between December 2013 and December 2014. The cut-off value of remission was DAS28-ESR <2.6. Last observation carried forward method was used for consecutive analysis.

Results: Fifteen patients were enrolled. At baseline, mean age was 52.0 ± 13.9 year-old, and the percentage of female was 78.6%. Mean disease duration was 11.0 ± 10.8 years. 21.4% and 7.1% of patients used concomitant methotrexate and glucocorticoids, respectively. 35.7% of patients previously used biologics. Mean duration until beginning the extension of dosing interval from starting TCZ was 38.6 ± 22.1 months. Mean duration until achieving remission from starting TCZ was 1.96 ± 2.56 months. Mean DAS28-ESR was 0.98 ± 0.74 at baseline. 77.8% of patients were seropositive. Thirteen (86.7%) patients have completed TCZ with 6-week extended dosing interval until Week 24, and all of them maintained in remission, though DAS28-ESR mildly increased to 1.55 ± 0.21 at Week 24 (p=0.026, baseline *vs* Week 24). CRP and ESR also tended to increase until Week 6 (p=0.071 and p=0.220, respectively), but did not change between Week 6 and Week 24 (p=0.842 and p=0.661, respectively). The change in DAS28-ESR at Week 24 did not correlate with the baseline parameters including age, sex, disease duration, CRP, ESR, MMP-3 and the seropositivity. The patients whose durations until achieving remission from starting TCZ were shorter tended to maintain lower disease activities (Spearman's rho=0.49, p=0.072). One patient dropped from the study because of the RA flare and returned to 4-week interval at Week 18. Five adverse events were noted in 5 patients. TCZ was discontinued due to the recurrence of lymphoproliferative disorder in one patient at Week 12. The other 4 events (2 mild upper respiratory infections, the fracture of humerus by falling accident and ureterolithiasis) did not lead to cessation of TCZ.

Conclusion: This trial suggested that 6-week extended dosing interval with TCZ therapy is effective and tolerable in RA patients as remission maintenance in daily clinical practice.

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Anti-drug antibodies (ADAb) in patients treated with adalimumab have been associated with decreased adalimumab concentrations and loss of clinical response, and therefore treatment discontinuation. A large proportion of patients is immunized against adalimumab, but not in every

patient ADAb are detectable due to drug interference. Formation of ADAb at initiation is possibly triggered by low drug levels in the patient and vice versa higher drug levels could possibly leed to tolerance in the patient. Since the presence of ADAb is associated with decreased adalimumab concentrations and treatment discontinuation, these concentrations may give an estimation of the presence of ADAb, however, no cutoff concentration has been investigated yet. This study aimed at determining a cutoff value for adalimumab trough concentration for treatment discontinuation due to the presence of ADAb.

Methods:

This study was conducted in a prospective observational cohort study of 272 consecutive rheumatoid arthritis (RA) patients treated with adalimumab at the Department of Rheumatology, Jan van Breemen Research Institute | Reade, Amsterdam, the Netherlands. Patients were treated with adalimumab 40 mg every other week. The dosing schedule was increased to 40 mg every week in patients with an inadequate response, (22 patients before 16 weeks). Blood samples were collected before next injection after 4, 16, 28, 40 and 52 weeks of treatment to measure adalimumab concentrations and to detect the presence of ADAb using an ELISA and RIA (radioimmunoassay, Sanquin, Amsterdam). Patients were followed during one year.

Data were analyzed using ROC curve analysis. Youden index was used to estimate the cutoff value for adalimumab concentration which predicts discontinuation within one year due to ADAb presence *versus*patients not discontinuing treatment (ADAb+ and ADAb-) and patients discontinuing treatment for which no ADAb were detected (ADAb-).

Results:

The area under the ROC curve (AUC) is 0.8968 (95% CI 0.8391 to 0.9546, $p<0.0001$). The cutoff concentration which maximizes Youden index is 5.0 mg/L with sensitivity of 77,5%, specificity of 90,9%, a positive predictive value of 30.3% and negative predictive value of 98.8%.

Conclusion:

Patients who have adalimumab concentrations lower than 5 mg/L at 16 weeks after start of treatment, have a higher risk of treatment discontinuation within one year due to ADAb formation than patients who have higher concentrations at that time point. A patient whose adalimumab concentration is below 5 mg/L at week 16 has a 30% chance to form detectable antibodies against adalimumab, whereas for a patient above this cutoff value, this chance is only 1.2%.

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with Rheumatoid arthritis (RA) have a variety of therapeutic options however tools to predict individual patients' response are limited. The purpose of this study is to evaluate the ability of a Genefron diagnostic kit to predict RA patient response to TNF α blockers or rituximab

Methods:

Sixteen RA patients were assessed before starting a biologic agent: TNFα blockers (n=10) or rituximab (n= 6). Patients were re-evaluated 3

months after starting treatment. Assessment included swollen joint count (SJC), tender joint count (TJC), patient assessment of disease activity and pain by VAS, physician assessment of disease activity by VAS and health assessment questionnaire (HAQ). Genefron personal diagnostic kits measure the expression level of selected genes (IFN related genes, ubiquitin, genes activating the innate system) by quantitative real time PCR (qRT PCR) aiming to predict treatment outcome for each patient. Blood samples were obtained from each patient before administration of the biologic agent (T_0) and 20-24 hours later (T_{24}). RNA was extracted from PBMC samples and cDNA was transcribed from the RNA samples by high capacity cDNA reverse transcription. qRT PCR results were obtained using selected gene probes.

Results:

The TNFα blocker group included 9 females/1 male with a median age of 62±10 years and a disease duration of 9.5±16.2 years. A significant decrease in disease activity was observed after 3 months of treatment. Five patients achieved an ACR 20 response. Mean DAS 28 decreased from 5.6±0.9 to 4.3±1.4. The Genefron diagnostic kit predicted the response in 9 of 10 patients, resulting in a prediction accuracy of 90%, sensitivity of 75% and specificity of 100%. The rituximab group included 5 females/1male with a median age of 68±9.3 years and a disease duration of 9±8.5 years. Three patients achieved an ACR 20 response. The Genefron diagnostic kit predicted the response correctly in all 6 patients.

Conclusion:

In this small group of patients, the Genefron diagnostic kit predicted the response to TNFα blockers and rituximab in a high percentage of patients. These preliminary results require further confirmation in large scale studies to assess whether this kit may possibly aid in the selection of a suitable biological drug for the individual RA patient.

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Endothelial dysfunction is an early step in the formation of atherosclerotic lesions and can be quantified by the degree of flow mediated vasodilation (FMD) of the brachial artery. FMD is a predictor of cardiovascular (CV) events in the general population and is lower in patients with inflammatory joint diseases (IJD) compared to the general population. Restoration of endothelial function to normal levels has been proposed as an important factor in the process of atherosclerotic plaque regression. Our aim was to investigate the effect of long-term rosuvastatin therapy on FMD in patients with IJD and carotid artery plaque(s) (CP). Furthermore, we evaluated associations between change in FMD (ΔFMD) and change in CP height, arterial stiffness [aortic pulse wave velocity (aPWV) and augmentation index (AIx)], lipids, rheumatic disease activity and inflammatory variables.

Methods: Eighty-five statin naïve patients with IJD and ultrasound verified CP (rheumatoid arthritis: 53, ankylosing spondylitis: 24, psoriatic arthritis: 8) received rosuvastatin treatment for 18 months to obtain low density lipoprotein cholesterol goal <1.8 mmol/L. All patients underwent assessment of FMD, aPWV, AIx and carotid ultrasound at baseline and at study end. Change in FMD from baseline to study end was analyzed using paired-samples t-test. Furthermore, multiple linear regression analyses, adjusted for age, gender and use of biologic disease-modifying anti-rheumatic drugs, were applied to evaluate associations between DFMD and change in CP height, aPWV, AIx, lipids, disease activity/inflammatory variables and medication. In addition, the mean diameter of the brachial artery as a result of FMD was plotted against time at baseline and 18 months.

Results: The patient cohort had 60% females and the median (IQR) age and disease duration was 61.0 (56.0-67.0) and 18.0 (8.3-26.0) years,

respectively. The mean ±SD FMD was significantly improved from 7.10 ±3.14 % at baseline to 8.70 ±2.98 % at study end (p<0.001). Multiple linear regression analyses revealed that the FMD improvement was linearly associated with the improvement in arterial stiffness as measured by AIx: β (CI): -0.09 (-0.18, 0.00) (p=0.05) and CP height regression: β (CI): -3.10 (-4.95, -1.25) (p=0.001). DFMD was not associated with changes in lipid levels, disease activity, inflammatory variables or medication. The mean diameter of the brachial artery as a result of FMD was plotted against time at baseline and 18 months is shown in figure.

Conclusion: Long-term lipid lowering with rosuvastatin improved endothelial function measured by FMD in IJD patients with atherosclerotic disease. The statin-induced improvement in endothelial function was linearly associated with reduced arterial stiffness and CP regression. Our results support the hypothesis that restoration of endothelial function plays an important role in the process of atherosclerotic regression.

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

It has previously been shown that current smoking is a predictor of poor response to methotrexate or anti-TNF treatment in rheumatoid arthritis (RA). The impact of smoking for response to biologic DMARDs (bDMARDs) with different modes of action is not known. The objective of this

study was to investigate the effect of smoking on the effectiveness of abatacept (ABA) in patients (pts) with RA.

Methods:

This is a pooled observational database analysis of 9 European RA registries (ARTIS-SE, ATTRA-CZ, BIOBADASER-ES, DANBIO-DK, GISEA-IT, NOR-DMARD-NO, ORA-FR, SCQM-CH, Reuma.PT). Inclusion criteria for this analysis were a diagnosis of RA, initiation of ABA and available information on current smoking status. The primary endpoint was ABA drug retention. A secondary endpoint was EULAR good or moderate response rate at one year, estimated by longitudinal interpolation (mixed linear model) and corrected for drug retention (Lundex[1]).Time to discontinuation was defined as the time between drug initiation and last administration plus one dispensation interval. Drug retention was analyzed using a Cox proportional hazards model, adjusting for potential confounders, including calendar year of treatment initiation, patient demographics, country of origin and disease characteristics.

Results:

We identified 4476 pts initiating ABA with 7881 pt-years (PY) of follow-up, of whom 721 (16%) were current smokers, and 3755 were non-smokers. Smokers were significantly younger (mean age 55.2 versus 58.4 yrs, $p<0.001$), with shorter disease durations (10 vs 13 yrs, $p<0.001$), more often RF-positive (78% vs 73%, $p=0.03$), more commonly males (27.5% vs 17.8%, $p<0.001$), with lower disease activity at baseline (DAS28 4.6 vs 4.8, , $p<0.01$) and less prior bDMARD exposure (median number of past bDMARDs 1 vs 2, $p<0.001$). Smoking was associated with an increased risk of ABA discontinuation for any reason (crude median survival time of 1.67 yrs vs 1.99 yrs for non smokers, $p=0.04$, hazard ratio (HR) (95% CI): 1.12, (1.01-1.32)), even after adjusting for potential confounding factors (HR (95% CI): 1.17 (1.01-1.35), $p=0.03$). When examining the role of current smoking on specific causes of drug discontinuation, only discontinuations due to ineffectiveness were associated with smoking (crude HR: 1.17, $p=0.03$; adjusted HR 1.17, $p=0.10$), but not discontinuations due to adverse events (crude HR: 1.03, $p=0.80$; adjusted HR 1.17, $p=0.38$). The EULAR good or moderate response rates at one year were lower in smokers than in non-smokers (73% versus 84%) ($p<0.001$). The Lundex based on EULAR good or moderate response rates were also lower in smokers then in non-smokers (48% versus 56%). The effect of smoking on ABA effectiveness was not modified by country of origin.

Conclusion:

Data from this Pan-European registry analysis suggest that smoking is associated with a decreased effectiveness of ABA, with higher discontinuation rates and lower response rates, as has previously been reported for methotrexate and anti-TNF agents. The difference in drug retention was modest and mainly due to discontinuations related to ineffectiveness. The mechanisms underlying this association remain to be elucidated and unmeasured confounding cannot be ruled out.

Predicting the Need for Additional Treatment in Early Rheumatoid Arthritis Patients Treated to Target on Methotrexate Monotherapy

Xavier Teitsma[1], Johannes Jacobs[2], Paco Welsing[3], Thasia Woodworth[4], Attila Pethö-Schramm[5], Michelle Borm[6], Corrado Bernasconi[5], Floris Lafeber[1] and Johannes W J Bijlsma[7], [1]Department of Rheumatology and Clinical Immunology, University Medical Center Utrecht, Utrecht, Netherlands, [2]Rheumatology & Clinical Immunology, University Medical Center Utrecht, Utrecht, Netherlands, [3]Department Rheumatology and clinical immunology, University Medical Center Utrecht, Utrecht, Netherlands, [4]Medicine, Division of Rheumatology, David Geffen School of Medicine, Los Angeles, CA, [5]F. Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Joint damage and functional disability can be reduced by intensive treatment of newly diagnosed rheumatoid arthritis (RA) patients during the "window of opportunity". Although methotrexate (MTX) is considered the anchor disease-modifying anti-rheumatic drug (DMARD) for initial RA treatment, the majority of patients need additional treatment due to inefficacy or MTX-associated adverse events. Predictors of the need to add another treatment to MTX may identify patients who can benefit from intensive treatment. Starting combination treatment in such patients earlier can improve the likelihood of timely RA control.

Methods:

In U-ACT-EARLY, a double blind, placebo-controlled treatment strategy trial, 108 patients with newly diagnosed RA (1987 or 2010 criteria) were randomized to initiate MTX monotherapy according to treat-to-target principles. MTX was increased to 30 mg/week (or maximum tolerable dose) until remission (DAS28-ESR <2.6 with SJC < 4) was achieved. In the absence of remission at maximum MTX dose (~20 weeks), hydroxychloroquine (HCQ) 200 mg bid was added. If after 12 weeks, remission still was not reached, tocilizumab (TCZ) was added to MTX-HCQ. Baseline demographic, clinical, laboratory, and functional assessment data were evaluated; missing data were imputed using multiple imputation. Multivariate logistic regression with univariate preselection was used to identify factors predictive for patients requiring additional treatment.

Results:

Patients had mean disease duration ~4 weeks and high DAS28-ESR (Table 1). Fifty-six of 108 patients (51.9%) added TCZ to MTX-HCQ due to inefficacy (n=52) or adverse events (n=4) (fig.1). Multivariate logistic regression analysis identified higher DAS28-ESR (p<.001) and smoking (p=.067) as main baseline predictors for addition of TCZ. Model discrimination was reasonable with an area under the receiver operating characteristic (ROC) curve of 0.72 (95% CI: 0.63-0.82). Table 2 shows the observed probability of adding therapy for the 2 predictor categories.

Conclusion:

The majority of very early RA patients initiating MTX monotherapy in a treat-to-target strategy required addition of TCZ to achieve remission. Patients actively smoking with higher baseline DAS28-ESR scores were more likely to require additional treatment.

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

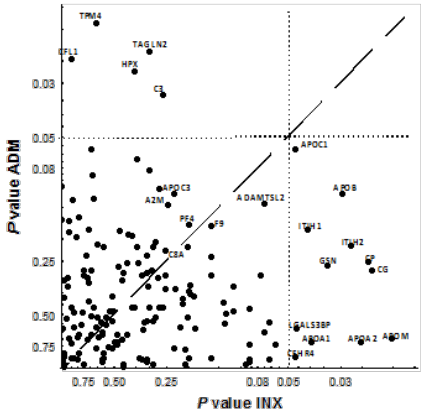
Background/Purpose:

Biomarkers of response to treatment in rheumatoid arthritis (RA) are sorely needed given the large inter-individual variability in efficacy of the available drugs. However, some authors think it will be difficult to distinguish between response to the different drugs. The doubts on biomarkers

are based in the broadly similar efficacy of all bDMARDs and the lack of validated biomarkers to date, although the best-established, as seropotivity, show clear drug-specific association. **Methods:**

Discovery of biomarkers of response to adalimumab (ADM) was based in combined depletion of the most abundant serum proteins, 8-plex iTRAQ labeling, two-dimensional LC fractionation, protein identification and relative quantification with a hybrid Orbitrap mass spectrometer. The results were compared and combined with an identical study of response to infliximab (INX) (1). **Results:**

262 proteins were identified in all the samples with at least 2 peptides and 95% confidence. Nine proteins presented differences between non-responders (NR) and responders (R) ($P < 0.05$), representing candidate biomarkers of response to ADM. None of them was coincident with the previously identified 14 candidate biomarkers of response to INX. In addition, the NR/R differences in response to ADM and to INX were not correlated ($r_{spearman}$= 0.07; P= 0.40), and were inversely correlated when only the significant proteins were considered ($r_{spearman}$= -0.69; P= 0.0023) as shown in Fig. 1.



The combined analysis of response to ADM and to INX, however, identified eight proteins (ADAMTSL2, A2M, APOB, APOC3, F9, C3, C8A and PF4), showing that discordance was not universal. **Conclusion:**

Potential biomarkers of response to ADM were identified. This panel was independent of the previously obtained in response to INX. The pathways highlighted in the two studies were also different. These results suggest that mechanisms of inter-individual variability are partly drug-specific, and that it will be possible to obtain biomarkers orienting the election of drugs.

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Treat-to-target (T2T) in early Rheumatoid Arthritis (RA) has been successfully implemented in daily clinical practice. Patients achieve remission very early and during a follow-up of three years T2T leads to persistent low disease activity in most patients and high remission rates. Unfortunately, some patients do not respond to this approach and remain in - or return to - moderate or high disease activity. These patients should be recognized early, as they might benefit from alternative therapeutic approaches. The aim of this study is to describe the five year clinical outcome of implementation of a T2T strategy in early RA. We aim to identify subgroups of patients with distinct long-term trajectories of disease activity.

Methods: In DREAM remission induction cohort I, patients with newly diagnosed RA were treated according to a T2T step-up strategy aiming at remission. Treatment consisted of methotrexate, followed by the addition of sulfasalazine and subsequently exchange of sulfasalazine with a tumor necrosis factor inhibitor in case of persistent disease activity. The mean change in the disease activity score in 28 joints (DAS28) was analysed with a linear mixed model. Subgroups of patients with distinct trajectories of disease activity were described and predictors will be identified.

Results: Data of 229 patients were used (63% female, mean age 57 years, 78% fulfilling the ACR 1987 criteria). Remission rates at 12 weeks, 24 weeks, 1 year, 3 years and 5 years were 31.1%, 48.8%, 60.6%, 63.6% and 63.2%, respectively. Mean DAS28 improved from 4.93 (95% CI 4.79 – 5.07) at baseline to 2.44 (95% CI 2.28 – 2.60) after five years (p<0,0001). Four subgroups with distinct trajectories of disease activity could be identified. A very small group (2.2%) could be classified as non-responders: they did not achieve remission at any moment during the first five year of follow-up. The second group (21.4%), the poor-responders, reached remission only after the first year. The third and largest group (68.1%), the responders, achieved remission within the first year and then had a varied course of disease activity. Finally, the fourth group with the best outcome (8.3%) achieved remission in the first year and remained in remission during the whole follow-up. Analysis of predictors will follow.

Conclusion: Implementation of a treat-to-target per-protocol treatment strategy leads to high long-term remission rates in daily clinical practice. Four groups with distinct trajectories of disease activity could be described. Predictors will be identified and presented during the 2015 ACR annual meeting.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Connective tissue degradation and formation is markedly increased in rheumatoid arthritis (RA). Increased tissue formation may result in fibrosis, whereas increased degradation may result in joint and tissue destruction. Different interventions such as anti-TNF-Î±, Anti-IL6R and JAK may provide both similar and different responses on key tissues.

Quantification of circulating levels of specific neo-epitopes of the extracellular matrix may act as biomarkers of connective tissue turnover and thereby may be used as objective tools for monitoring treatments effects in RA. Type II collagen formation (PRO-C3) has been demonstrated to be both a diagnostic marker for the presence of liver fibrosis and in addition to provide prognostic information on progression.

The aim of the study was to investigate the effect of fibrogenesis biomarkers in RA patients as an effect of methotrexate (MTX) combined with either tocilizumab (TCZ, anti-IL-6R), tofacitinib (TOFA, JAK inhibitor), adalimumab (ADA, anti-TNF-Î±) or given as a monotherapy.

Methods: 149 RA patients were included at the time of initiating one of the following treatments: 1) MTX; 23, 2) ADA+MTX; 49, 3) TOFA+MTX; 27, and 4) TCZ+MTX; 50. Serum samples were drawn along with Sharp-vdH score (SHS) and other clinical data at baseline and again 1 year after initiation of treatment (follow-up). Type III collagen formation, PRO-C3, ASAT, and ALAT were measured in the serum samples. Wilcoxon matched-paired rank test was performed. Error bars are shown as SEM.

Results: Anti-TNF-Î±, and anti-IL6-R resulted both in statistical increase in the liver enzymes ASAT and ALAT, whereas JAK intervention did

not. Interestingly, the PRO-C3 marker was significantly (P<0.05) inhibited by JAK inhibition in the TOFA group from 19.9ng/ml on average at baseline to 16.4ng/ml at follow-up, whereas the other treatments did not affect PRO-C3 significantly. Also, although serum EGF levels were decreased by anti-TNF and anti-IL-6, they are increased by TOFA.

Conclusion: Increased tissue remodeling is a characteristic of rheumatoid arthritis, in which both formation and degradation is affected. JAK inhibition resulted in a significant attenuation of a marker of fibrogenesis and could be involved in mesenchymal-epithelial transition, which warrant further investigation of the effect if JAK inhibition compared to that of anti-TNF-Î± and anti-IL6R.

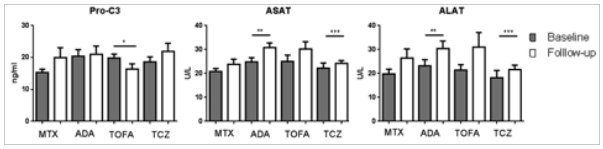

*Figure 1, Evaluations of ASAT, ALAT and Pro-C3 at baseline and follow-up. Difference between baseline and Follow-up was evaluated by mean of Wilcoxon match pairs signed rank test. *p<0.05, ** p<0.01, ***p<0.001. Error bars are illustrated as SEM.*

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To evaluate the economic impact of adalimumab (ADL) and etanercept (ETN) dose reduction (by decreasing treatment frequency) and drug monitoring in patients with rheumatoid arthritis (RA) in clinical remission.

Methods: ADL, ETN and anti-drug antibody levels were measured using Promonitor-ADL, Promonitor-ETN, Promonitor-Anti-ADL and Promonitor-Anti-ETN ELISA kits (Progenika, Grifols, Spain), respectively, during 2013-2014. Cut-points for ADL and ETN levels were 0.024 and 0.035 mg/L, respectively, and for Anti-ADL and Anti-ETN antibodies 3.5 and 132 AU/mL, respectively. Sera were drawn immediately before each injection. Clinical remission was defined as sustained DAS28-ESR≤2.6 during 6 consecutive months. The following was collected: RA progress, time on biologic treatment, reason for drug withdrawal or for resuming the conventional frequency, ultrasound activity index (Doppler) in 12 joints, and basal (ADL every 14 days; ETN every 7 days) and decreased (ADL every 18-21-28 days; ETN every 10-14 days) frequencies. Annual doses avoided were calculated for the modified frequency of ADL (every 18 days: 5.8 doses; every 21 days: 8.7 doses and every 28 days: 13 doses) and ETN (every 10 days: 15.5 doses and every 14 days: 26 doses). Savings during the two years, and the theoretical number of patients that could have been treated with costs saved were calculated (ADL and ETN dose prices were 500€ and 250€, respectively).

Results: Drug and anti-drug antibody levels were measured in 45 RA patients accounting for a total of 94 tests. 87% of patients were women, average age of 60.5±18 years. Average disease duration was 15±9.8 years and average ADL and ETN treatment durations were 5.2±1.3 and 5.1±1.8 years, respectively. Average time of decreased treatment frequency for both drugs was 1.2±0.7 years. ADL and ETN was the first line biological drug in 73% and 37% of patients, respectively. Synthetic DMARDS were given in 100% and 78% of patients on ADL and ETN, respectively. 87% of patients with a modified dosing frequency maintained clinical remission. Two ADL patients (7%, those treated every 18 days) resumed the conventional frequency and 4 ETN patients (22%, 3/75% treated every 10 days and 1/25% treated every 14 days: average of 6

months on modified frequency). Anti-drug antibodies were not detected in any patient after 1 year follow up. Table 1 summarizes clinical, drug monitoring and impact of savings data. During 2013 and 2014 22 RA patients started biologic therapy. Cost savings consequence of optimization allowed treatment of 22 new patients during 1 year.

Conclusion: Decreasing ADL and ETN dosing frequency with sustained clinical activity is possible in RA patients in remission by monitoring disease activity and serum drug levels. Dose optimization enables significant savings. Antibodies are not detected in patients with a decreased treatment frequency. It is likely that patients with a long term remission require less drug level.

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Limited data are available about infliximab(IFX) dose escalation. This analysis examines the frequency of dose escalation among IFX patients using data from the US CORRONA RA registry and describes the characteristics of patients who dose escalate vs those who do not.

Methods: RA patients initiating IFX at a dose of ≤5 mg/kg on or after 6/1/2009 with at least 1 follow-up visit with dose information were eligible for analysis. Subgroup analysis was performed among patients with follow-up at 1yr to compare characteristics between those who dose escalated vs those who did not. Dose escalation was defined as an increase of >1mg/kg in dose and/or a decrease in the frequency of dosing by at least 1 wk (e.g. q 8 wks to q7 wks). Censoring occurred if patients switched to another biologic or left the registry. Descriptive statistics were used to compare baseline characteristics of infliximab patients stratified by number of biologics, and also comparing those who dose escalated vs

those who did not within the 1st yr after initiating therapy.

Results: A total of 716 patients initiated IFX after June 2009. Common characteristics included mean age (61yrs), women (78%), mean weight (83kg), RF + (70%) and CCP+ (67%), baseline CDAI (22.5), and insurance status (Medicare 46%, Medicaid 6%). Differences between those who initiated IFX as their 1st, 2nd, or 3rd biologic included RA duration (7.0, 9.6, 11.0 yrs, respectively, $p < 0.001$), college education (50, 61, 66%, respectively, $p = 0.002$), number of prior DMARDs (1.6, 1.8, 2.0; $p < 0.001$), proportion receiving monotherapy (12, 15, 26%), and prednisone use (31, 29, 35%).

Over 3yrs follow-up, the proportions of patients escalating IFX significantly differed, ranging from a low of 21% at 1 yr for patients using IFX as 1st line to a high of 81% at 3yrs for patients using it as 3rd line (Table, $p = 0.0024$ for between-group differences). In patients with follow-up data at 12mo (n=608), there were some baseline characteristics associated with dose escalating vs not in the 1st yr of therapy including shorter RA duration($p = 0.03$), greater number of prior biologics ($p=0.04$), monotherapy ($p = 0.03$), greater prednisone use ($p=0.01$), and higher CDAI ($p=0.04$) and related disease activity measures.

Conclusion: Dose escalation of IFX is relatively frequent over time. Patients with more severe RA undergo dose escalation more commonly than those with less severe disease. Understanding long term benefits and persistence and related factors following dose escalation may help optimize dose escalation as a treatment strategy compared to switching.

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Tocilizumab (TCZ) is a humanized anti-IL-6R monoclonal antibody approved for the treatment of active rheumatoid arthritis (RA) (EMA: 8mg/kg q4w). Response to treatment may depend on the dose as well as on the achieved seric levels.

Purpose

To analyze the serum levels of TCZ in two cohorts of RA patients on chronic treatment with IV TCZ and its relationship with disease activity and disease remission. To establish a cut-off point of TCZ serum levels with high discriminative capacity for disease remission.

Methods:

Cross-sectional study of 2 cohorts (Barcelona, Spain and Lausanne, Switzerland) that included all RA patients on chronic treatment with **IV**TCZ. Demographic, disease activity, serum markers, TCZ trough levels (detectable levels > 1 µg/ml) (LISA TRACKER Tocilizumab Theradiaag, France) and IL6 levels (ELISA) were analyzed. Samples were collected just before treatment infusion. TCZ levels were correlated with different clinical and serological parameters. Multivariate logistic regression was calculated to determine variables associated with remission (DAS28 ≤2.6). ROC curve analysis was performed to study the discriminatory capacity of the area under the curve (AUC) of TCZ levels associated with remission.

Results:

77 RA patients were included (40 Barcelona Cohort, 37 Lausanne Cohort). 89.6% were women, with a mean age of 55.17 ± 13.4 years and a disease duration of 13.8 ± 8.4 years; 70.1% were FR and/or anti-CCP positive. 42.9% of patients were on monotherapy, 40.3% were receiving low dose glucocorticoids and 22.1% were on reduced dose of TCZ (6 or 4 mg/kg q4w). 43 patients (56.6%) were on remission. Swiss patients had lower disease activity and were more frequently on remission, and used corticosteroids and DMARD combination therapy less frequently. 20 patients (26%) had undetectable levels of TCZ (<1 µg/ml). This situation was associated with significantly higher levels of CRP, lower levels of IL-6 and higher DAS28; but there were no differences in tender and swollen joint count (Table). Patients in remission had higher levels of TCZ and had more frequently detectable levels of TCZ in comparison with those patients that were not in remission. The cut-off point of 3.48 µg/ml had the greatest discriminative capacity for clinical remission (AUC 0.724; 95% CI: 0.607-0.840; p=0.001) with a sensitivity of 79.5% and a specificity of 67%. In the multivariate analysis the presence of levels ≥ 3.48 µg/ml of TCZ and the use of corticosteroids were independently associated with clinical remission.

Conclusion: Detectable levels of TCZ (≥1 µg/ml) in RA patients in chronic treatment with TCZ were associated with a lower CRP values. The cut-off point of serum TCZ with best discriminative capacity for clinical remission was 3.48 µg/ml. Serum levels of TCZ ≥ 3.48 µg/ml may be more adequate to achieve clinical remission or low disease activity.

Table. Patients with detectable and undetectable serum levels of TCZ.

	Undetectable Serum trough levels <1µg/ml (n=20)	**Detectable Serum trough levels ≥1µg/ml (n=57)**	***p***

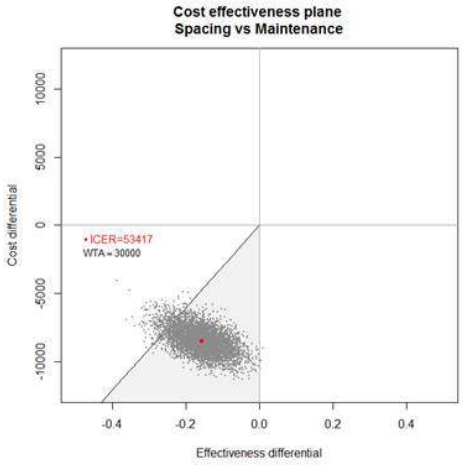
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Once remission is achieved for patients with rheumatoid arthritis (RA), treatment down-titration should be attempted, for safety issues or economic reasons. One of the proposed strategies, recently tested in the STRASS trial*, is to progressively space injections of TNF-blockers. The objective was to assess the Incremental Cost-Effectiveness Ratio (ICER) of a strategy of progressive spacing of TNF-blocker injections (S-arm) over another maintaining them at full-dose (M-arm) in RA patients in stable remission.

Methods: The study was a French multi-centre 18-month equivalence randomized open-label controlled trial. It included patients receiving etanercept (ETA) or adalimumab (ADA) at stable dose for ≥ 1 year; in remission on 28-joint Disease Activity Score (DAS28) for ≥ 6 months; and with stable joint damage. In the S-arm, the interval between 2 subcutaneous injections was increased every 3 months by 50% in 4 steps, to a complete stop at step 4. If remission was not maintained, spacing was suspended or reversed to the previous interval. Costs engaged within the study-period (medical costs (drugs, consultations and medical tests, use of emergency room and hospitalizations) and costs relative to sick leave) measured in euros were assessed. Utilities values used to compute Quality Adjusted Life Years (QALYs) were derived from the French EQ-5D, assessed at baseline and every 6 months. The ICER was estimated. A probabilistic sensitivity analysis was performed by computing 5000 ICERs (bootstrap). The probability of cost-effectiveness (p of CE) of the spacing strategy was computed for different Willingness to Accept (WTA) compensation for QALY loss thresholds. The impact of missing data was investigated.



Results: Analyses were performed on 44 patients in the S-arm and 54 in the M-arm with complete data. In the S-arm, TNF-blockers were stopped for 34.1% of the patients, tapered for 43.2%, maintained at full-dose for 18.2%. After 18 months of follow-up, patients in the S-arm gained 1.106 QALYs while it was 1.264 in the M-arm (mean differences in QALYs of -0.158). After 18 months, total mean cost was 12 452 euros in the S-arm and 20 892 euros in the M-arm (mean cost difference of -8440 euros). The estimated ICER was 53 417 euros saved per QALY lost. The p of CE of the spacing strategy was 0.94 and 0.59 for WTA thresholds at 30 000 and 50 000 euros respectively.

Conclusion: The spacing strategy was found to be less efficient in terms of QALY gains. Nonetheless, the spacing strategy is associated to substantial cost reduction. The acceptability of such a QALY loss reported to the cost avoided remains to be determined, since no consensual threshold has been determined for WTA compared to willingness-to-pay.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Rituximab is an anti-CD20 antibody that represents a therapeutic alternative for the patients with rheumatoid arthritis. It has been proven that rituximab at a dose of 2 gm is very effective in patients with DMARD and antiTNF failures. But the cost of this therapy is high and increases the economic burden. Limited data has shown that B cell is possible even with lower dosage to what is recommended.

Methods: In this open label, prospective, observational study at tertiary care center sero positive RA patients who responded inadequately to combination of DMARD, were given single dose of 100 mg of rituximab. B cell numbers in the peripheral blood was assessed by Flow cytometry and B cell depletion was defined as B cell numbers < 0.01 %.Efficacy was evaluated using B cell depletion after 2 weeks and disease activity score in 28 joints (DAS28) on monthly bases. Those patients who did not achieve EULAR moderate response were given second dose of rituximab 500mg.

Results: : 14 patients(12 females and 2 males; mean age 47 ± 7.1years) were included in the study. Mean duration of the disease was 8 ± 6.8 years .RF was positive in 13 out of 14 and Anti CCP antibody was positive in all patients. At baseline mean DAS score was 6.2 ± 0.79 and mean CD 19 % was 11.03 ± 4.53%. After 2 weeks of rituximab, B cell depletion was achieved in 11 patients (79%) and mean DAS28 was 2.86 ± 0.84 at the end of 24 weeks. Two patients were given second dose of 500mg rituximab after 8 weeks of first dose. Out of 14 patients, 8 achieved good EULAR response and 6 achieved moderate EULAR response. At 24 weeks ,7 (50%) patients were in remission.

Conclusion: : Early results from this study are very promising and show that low dose rituximab is effective in treating RA patients with inadequate response to DMARD.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Seronegative RA patients have inferior clinical response to rituximab [1]. However, there is significant heterogeneity in this group of patients for baseline clinical features (e.g. radiographic erosion, or alternative markers of B cell dysfunction such as ANA or hypergammaglobulinaemia), as well as for clinical response to rituximab. These features may help to predict response [2]. Objective: To identify clinical predictors of response to rituximab in seronegative RA as a means to select patients suitable for B cell targeted biologics

Methods:

Baseline demographic and clinical characteristics will be extracted from RF and CCP2 negative patients in the following clinical trials: REFLEX, DANCER, IMAGE, SERENE and SUNRISE (which recruited 376 RF-CCP- patients). This preliminary analysis includes data on 88 patients from rituximab-treated arms of SERENE and IMAGE with complete data, but does not include analysis of erosions or ANA. We used 6 month DAS28, adjusted for baseline DAS28 as our primary response outcome, and tested each variable using univariate linear regression.

Results:

Table 1 shows the result of univariate analysis of each potential predictor. Positive coefficients indicate increase in adjusted 6-month DAS28 for presence (categorical variables) or unit increase (continuous variables) in the characteristic. Negative coefficients indicate characteristics

associated with a reduction in in 6-month adjusted DAS28.

Characteristic	Coefficient (95% CI)	*P* value
Age, per year	0.01 (-0.01, 0.04)	0.233
Female	0.47 (-0.27, 1.21)	0.208
BMI, per unit	0.04 (0.00, 0.08)	0.046
Total IG (ln-trans)*, per unit	-0.67 (-1.65, 0.31)	0.176
IGA (ln-trans)*, per unit	-0.34 (-0.91, 0.23)	0.237
IGG (ln-trans)*, per unit	-0.62 (-1.55, 0.30)	0.185
IGM (ln-trans)*, per unit	-0.03 (-0.64, 0.58)	0.922
Smoker Ex	0.67 (-0.09, 1.41)	0.082
Current	0.11 (-0.72, 0.94)	0.795
Disease duration (ln-trans)	-0.01 (-0.29, 0.28)	0.959
N previous DMARDs 1-2	0.13 (-0.49, 0.76)	0.671
>2	0.26 (-1.23, 1.75)	0.729
Oral glucocorticoid at baseline	-0.68 (-1.28, -0.08)	0.028
DAS28, per unit	0.49 (0.20, 0.77)	0.001
HAQ-DI, per unit	0.19 (-0.32, 0.71)	0.459

Conclusion: Response to rituximab in seronegative RA is associated with lower BMI and use of oral glucocorticoids, with a trend to association with never smoking in univariate analyses. Our data were consistent with a previously-reported association of response with hypergammaglobulinaemia but we cannot confirm clinical utility of IgG as predictor in this analysis. Final analysis will include data from 376 patients using comprehensive multivariable modelling, including erosion and ANA data.

Calprotectin and TNF Antagonist Serum Trough Levels Identify Active Ultrasound Synovitis in Rheumatoid Arhritis and Psoriatic Arthritis Patients in Remission or Low Disease Activity

Jose Inciarte-Mundo[1], Julio Ramírez[1], Virginia Ruiz-Esquide[1], M. Victoria Hernández[1], Oscar Camacho[1], Sonia Cabrera-Villalba[1], Andrea Cuervo[1], Mariona Pascal[2], Jordi Yagüe[2], Juan D. Cañete[1] and Raimon Sanmarti[1], [1]Rheumatology Department, Hospital Clinic i Provincial, Barcelona, Spain, [2]Immunology Department, Hospital Clinic i Provincial, Barcelona, Spain

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I

Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

An accurate assessment of disease activity is needed in Rheumatoid arthritis (**RA**) and Psoriatic Arthritis (**PsA**) patients in remission or low disease activity for clinical decision-making. Calprotectin a major S100 leukocyte protein and TNF antagonist (**TNFa**) serum trough levels are associated with disease activity. Residual power Doppler ultrasound synovitis (**PDUS**) is *predictive* of clinical *flare* in this group of patients.

Objectives:

To analyze the relationship between PDUS with calprotectin and TNFa serum trough levels in RA and PsA patients in clinical remission or low disease activity. To correlate calprotectin levels with serum trough levels of TNFa.

Methods :

Cross-sectional analysis from a prospective cohort study of RA (ACR 1987) and PsA patients (CASPAR) treated with TNFa [etanercept (**ETN**), adalimumab (**ADA**), and infliximab (**IFX**)] for ≥ 3 months in clinical remission (DAS28-ESR<2.6) or low disease activity (DAS28-ESR<3.2) in ≥2 consecutive visits. The patients underwent clinical, laboratory, and PDUS assessment at visit 4 (12 months of follow-up). Calprotectin serum levels (using kits from Calpro AS) and TNFa serum trough levels (using kits from Promonitor®, Progenika) were determined. A rheumatologist experienced in musculoskeletal ultrasound and blinded to clinical and laboratory data performed US assessment with a high sensitivity equipment (MyLabTwice®, Esaote, Italy. 8-14 MHz linear probe). 22-joint B-mode synovial hypertrophy (**SH**) and PDUS signal were scored from 0-3 at each joint. Global indices for SH and PDUS signal were calculated. Ultrasound active synovitis (**UAS**) was defined as intraarticular synovitis detected with power Doppler signal.[1]

Results :

Ninety-two patients (42 RA, 50 PsA) out of 100 patients included at study entry completed the follow-up at 12 months (visit 4). 43 patients had UAS (27 RA and 16 PsA). UAS patients showed higher disease activity, higher calprotectin levels and lower drug serum trough levels, even when analyzed by diagnostic (RA or PSA) (**table 1**). When a more stringent UAS criteria were apply (SH grade 2+PDUS)[2], only calprotectin can distinguish between them [active (*n*=15) 3.48(0.2-5.5) *vs*. inactive (*n*=77) 1.47(0.06-4.8), *p*=<0.001]. Calprotectin and serum trough levels inversely correlated with PDUS score in ADA (rho=-.591, p=<0.001 and rho=-.842,p=<0.001,respectively) and ETN (rho=-.313,p=0.039 and rho=-.649,p=<0.001,respectively). Calprotectin serum levels inversely correlated with ADA serum trough levels (rho=-.461, *p*=0.008), non-significant correlations were observed with ETN and IFX.

Conclusion :

Calprotectin and TNFa serum trough levels may help to identify ultrasound active synovitis in RA and PsA patients in clinical remission/low disease activity.

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Tocilizumab (TCZ) is an interleukin 6 (IL-6) inhibitor that is used in Rheumatoid Arthritis (RA) treatment (1). Due to the role played by IL-6 in viral immunosurveillance, we studied the effect of TCZ on the viral load for the Epstein Barr Virus (EBV), Cytomegalovirus (CMV) and Varicella Zoster Virus (VZV) in patients with RA.

Methods:

This was a prospective monocenter study of RA patients taking TCZ. All patients satisfy the 2010 ACR-EULAR classification criteria for RA. Demographic, clinical and laboratory data were collected on each patient. Viral loads (VL) were determined in whole blood (using the Biomerieux EBV and VZV R-gene quantification kit, Abbott Real Time CMV kit) at TCZ initiation and during treatment follow-up. A difference between two viral loads of 0.5log10 copies/ml of whole blood was considered significant.

Results:

22 patients were evaluated. There were 20 (91%) women of a mean age of 57.8 + 11.2 with seropositive and erosive (74%). RA that had been progressing for a mean of 11.3 + 9.7 years. TCZ was administered alone (36.7%) or in combination with methotrexate (MTX) (50%).

When TCZ was introduced, the EBV VL was positive in eight patients with a mean VL value of 1777.2 + 3518.3 (3.5 + 0.4 log10) copies/ml. Only one patient had a positive CMV VL. The VZV VL was negative in all patients. After 9.2 + 4.8 months had lapsed, EBV VL and CMV VL became negative in six of eight patients (p=0.02) and did not significantly vary in the remaining two patients. No VL (EBV, CMV, VZV) became positive. A positive EBV VL did not correlate with RA activity (DAS28ESR, DAS28CRP) or with inflammatory biomarkers (ESR and CRP). RA activity significantly declined after six months of TCZ treatment (DAS28ESR after six months 2.8 + 1.1 vs. 5.14 + 0.9 [p<0.001]).

The treatments of positive EBV patient were collected among 6 patients with EBV VL become negative after TCZ perfusions and 50% of patients did not take any DMARDS.

Conclusion:

In our study, TCZ did not increase the VL of EBV, CMV or VZV. This is the first report on the influence of TCZ on the VL of EBV, CMV and VZV in RA patients. Our EBV results are identical to those that we reported on anti-TNF, which were found by other teams as well (2, 3). Nevertheless, although we did not demonstrate any changes in CMV or VZV VL in patients taking TCZ, but there were reported several cases of severe infection (4;5;6;7). Most of RA patient have still glucocorticoid which can also influence the immunosurveillance for virus (8). Studies involving larger patient populations are necessary.

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Methotrexate (MTX) and leflunomide are categorized as DMARDs of first choice in treating rheumatoid arthritis patients. MTX should be used cautiously in patients with impaired kidney function, but treatment with MTX may also show an increased effectiveness in these patients, because of accumulation. If MTX is contraindicated, for instance because of more severely impaired kidney function, leflunomide can be used without dose adjustment. We aimed to explore the role of the kidney function for the 6 month treatment response to either methotrexate or leflunomide in RA patients.

Methods:

We selected patients from a longitudinal RA database, who started MTX monotherapy or leflunomide treatment and had clinical follow ups over at least 6 months. In a multivariable regression analyses, we used change in the simplified disease activity index (SDAI) after 6 months as dependent variable, and baseline SDAI, creatinine (or glomerular filtration rate), and MTX dose as independent variables.

Results:

We identified 256 patients starting MTX (80% female, 59% rheumatoid factor, RF, positive; mean±SD: SDAI: 17.2±12, creatinine: 0.83±0.14 mg/dl, glomerular filtration rate (GFR): 83±22 ml/min, end MTX dose: 20.6±6.1) and as comparator group 80 patients starting a treatment of at least 6 months with leflunomide (86% female, 57% RF positive, mean±SD SDAI: 13.6±8.8, creatinine:0.85±0.23, GFR: 88±53).

Regression analyses in the MTX cohort showed that that, after adjusting for MTX dose, higher creatinine was associated with higher SDAI response after 6 months of treatment (p=0.029). Analogously, in a separate analysis lower GFR was also significantly associated with larger clinical improvement (p=0.04) (**Figure).** SDAI response in patients with impaired kidney function and lower MTX dose (GFR <75ml/min and <20mg of MTX, respectively) was similar to patients with normal kidney function and higher MTX dose (GFR >75ml/min and ≥25mg of MTX). In patients treated with leflunomide, creatinine as well as GFR were not associated with SDAI change after 6 months of treatment (p=0.585, p=0.962, respectively).

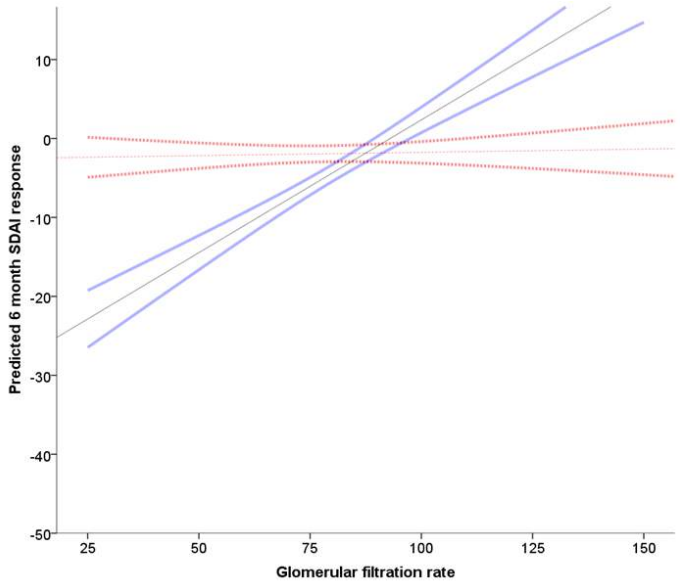

Figure: Regression splines for SDAI response at 6 months of MTX treatment (blue with confidence intervals) and leflunomide (red dotted with CI) predicted by glomerular filtration rate

Conclusion:

We demonstrated here that patients with impaired renal function seem to benefit in terms of SDAI response during treatment with methotrexate. This was not found in patients treated with leflunomide. Higher treatment responses in patients with impaired kidney function indicate increased clinical benefit. This could also indicate room for higher MTX doses, which are historically limited to 25mg/week, in patients with normal kidney function and accompanied folate substitution.

Serum Progranulin (PRGN) Level Is Not a Biomarker for Responsiveness to Tumor Necrosis Factor (TNF)-Antagonist Therapy in Rheumatoid Arthritis (RA) Patients

Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: PRGN is a growth factor that binds TNF receptors without triggering TNF-like activity, thereby serving as a naturally-occurring antagonist of TNF -mediated inflammatory signaling. In multiple mouse arthritis models, PRGN inhibits TNF-activated intracellular signaling and development of joint inflammation. We hypothesized that endogenous PRGN levels may affect responsiveness to TNF-antagonist therapy in RA patients. Accordingly, we conducted a pilot observational study in RA patients to assess whether serum PRGN levels would either predict and/or reflect responsiveness to TNF-antagonist therapy. TNF may play a greater role in driving disease in RA patients who bear low PRGN levels (PRGN-low) than in RA patients who bear high PRGN levels (PRGN-high). If correct, then PRGN-low would be more responsive to TNF-antagonist therapy than PRGN-high.

Methods: We enrolled 40 Hispanic RA patients who had never received TNF-antagonist therapy and who, in the judgment of their respective

physicians, were candidates for TNF-antagonist therapy. Prior to initiation of TNF-antagonist therapy and at regularly scheduled visits for 12 months following initiation of such therapy, disease activity was assessed by DAS28-CRP, and blood samples were collected for serum PRGN levels (measured by ELISA). Assignment of level of disease activity (high, moderate, low) and degree of clinical response (no, moderate, good, remission) was based on EULAR criteria.

Results: Of the 40 RA patients enrolled. 34 were female and 6 were male: median (range) age, 53 (22-75) years; median (range) years of symptoms, 4 (1-29); median (range) tender joints, 16 (0-28); median (range) swollen joints , 7 (0-25); median (range) ESR, 43 (7-105); median (range) CRP, 12 (1-195); median (range) DAS28-CRP, 5.59 (3.28-8.04). 31 patients had high disease activity, and 9 had moderate disease activity. 20 patients had radiographic erosive disease; 23 were taking methotrexate; 3 were taking corticosteroids; 29 were taking hydroxychloroquine; 2 were taking leflunamide; and 19 were taking sulfasalazine. Based on the distribution of baseline serum PRGN levels, 9 RA patients were classified as PRGN-high, and 31 patients were classified as PRGN-low. No statistical differences were noted in baseline parameters between PRGN-high and PRGN-low.

Of the 40 patients, 35 initiated TNF-antagonist therapy (8 PRGN-high, 27 PRGN-low). At the last follow-up visit, 19 achieved clinical remission, 4 achieved a good response, 8 achieved a moderate response, and 4 had no response. As determined by log-rank analysis, there were no differences in achievement of moderate/good responses, good responses, or clinical remission between PRGN-high and PRGN-low. Post-initiation visits were divided into 4 intervals (1-91 days; 92-182 days; 183-273 days: ≥274 days); there were no differences in DAS28-CRP between PRGN-high and PRGN-low at any interval. Serum PRGN levels declined following initiation of TNF-antagonist therapy, but changes in serum PRGN levels did not correlate with changes in DAS28-CRP.

Conclusion: Serum PRGN levels neither predict nor reflect clinical responsiveness to TNF-antagonist therapy in RA patients.

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: The aim of this study was to investigate the frequency and risk factors of postoperative complications in rheumatoid arthritis (RA) patients treated with abatacept in routine care.

Methods: The ORA registry is a French nationwide prospective cohort which recruited 1032 patients receiving abatacept for RA according to ACR criteria in routine care. Data for patients who underwent surgery while treated with abatacept (including the 4 months following last infusion) were reviewed to describe the frequency of postoperative complications. Characteristics of patients and surgeries were compared

between patients with and without complications to identify factors associated with complications. Quantitative variables were compared by the Mann-Whitney test, and qualitative variables were compared by the Fisher's exact test.

Results: We identified 215 (20.8 %) patients who underwent 284 surgeries between June 2008 and December 2012, including 189 (66.5%) orthopedic surgeries and 35 (12.3%) abdominal surgeries. Twenty (7.0%) surgeries, in 20 patients (9.3%), entailed complications, of which 11 infections (3.9% of surgeries) and 6 delayed healing (2.1% of surgeries). Abatacept was discontinued after 3 (15.0%) surgeries in the complicated group versus 28 (10.6%) in the group without complications, and this difference was not significant (p=0.467). No death was reported. Characteristics of patients and surgeries with and without complications are shown in table 1. Co-morbidities and associated treatments were not different between both groups. The median time between the last infusion of abatacept and surgery was 5.9 weeks (interquartile range [IQR] 3.8-8.8 weeks), with no difference between patients with and without complications (5.1 vs 6.0 weeks, p=0.14). The median time between the initiation of abatacept and surgery was significantly shorter in the complicated group (9 [IQR 2-19] vs. 16 months [IQR 8-26], p=0.0065), while DAS28 score at the time of surgery was similar between both groups (3.86 vs 3.43, p=0,25). Orthopedic surgeries were associated with a higher rate of postoperative complications (9,5% vs. 2,1%, p=0,025), but no difference was found in each subgroup of orthopedic procedures (i.e. hand/wrist, foot/ankle, spine surgeries or arthroplasty).

Conclusion: In real life RA patients treated with abatacept and undergoing surgery, there is no specific predictive factor of complications except an orthopedic vs non-orthopedic procedure (like in every RA patient) and a shorter time after initiation of abatacept. The latter factor, also found in our rituximab AIR registry (Godot et al, Arthritis Care Research 2013), is probably a bias due to the healthy drug survival effect. Interestingly, the median time between the last infusion of abatacept and the surgery was short: 5 to 6 weeks and did not influence the rate of post-operative complications.

Table 1. Characteristics of patients and surgeries and univariate analysis of predictive factors of postoperative complications after surgery for RA patients treated with abatacept. IQR = interquartile range ; ABA = abatacept ; DAS28 = Disease Activity Score in 28 joints using the erythrocyte sedimentation rate.

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The mechanism of methotrexate in rheumatoid arthritis (RA) is complex. It may increase adenosine levels by blocking conversion to of xanthine to uric acid (UA). This study was done to determine if methotrexate lowers UA in early RA (ERA).

Methods: Data were obtained from CATCH (Canadian Early Arthritis Cohort), an incident ERA cohort. All ERA patients with serial UA measurements were included comparing those with methotrexate use vs. no methotrexate (controls). Analyses were exploratory. Patients with concomitant gout or taking uric acid lowering therapies were excluded.

Results: Forty-nine of 2524 ERA patients were identified with data available for both pre-methotrexate UA levels vs. post-methotrexate UA levels (300 µmol/L vs. 273 µmol/L respectively (p=0.035)). The control group not taking methotrexate had a mean baseline uric acid level of 280 µmol/L and a follow-up level of 282 µmol/L (p=0.448); mean change in UA with methotrexate was -26.8 µmol/L, vs. 2.3 µmol/L in no methotrexate group (p=0.042). Methotrexate users with a decrease in UA had a mean lower DAS28 score of 2.37 vs. controls (3.26) at 18 months (p=0.042). Methotrexate users who decreased UA had a lower SJC of 0.9 at 18 months vs. methotrexate users without lowering of UA who had a SJC of 4.5 (p=0.035). Other analyses were not significant.

Conclusion: Methotrexate response is associated with lowering of uric acid in ERA compared to non-users, and may be due to changes in adenosine levels. Methotrexate response is associated with lower UA and fewer swollen joints compared to non-responders.

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) are at increased risk for herpes zoster (HZ) infection. RA treatment including

immunosuppressant medications could further exacerbate the risk. The aim of this study was to investigate the effects of conventional (cDMARDs) and biologic disease-modifying antirheumatic drugs (bDMARDs) on the risks of HZ infection in RA patients.

Methods: In this retrospective cohort study, a total of 277 RA patients were enrolled, who ever received bDMARDs at Seoul National University Hospital between August 2003 to February 2015. Among the enrolled patients, 718 treatment episodes of cDMARDs and bDMARDs were identified, which included infliximab, etanercept, adalimumab, golimumab, rituximab, abatacept, and tocilizumab. Baseline information included demographics, disease duration, comorbidity, smoking history, rheumatoid factor, anti-CCP antibodies, erythrocyte sedimentation rate, C-reactive protein, and concomitant cDMARDs at initiation of treatment. After identifying all episodes of HZ infection, crude incidence rates of HZ per 100 patient-years (95% confidence intervals [CI]) were calculated.

Results: Among 718 treatment courses, 277 (38.6%) used cDMARDs, 66 (9.2%) infliximab, 175 (24.4%) etanercept, 95 (13.2%) adalimumab, 9 (1.3%) golimumab, 41 (5.7%) rituximab, 31 (4.3%) abatacept, and 24 (3.3%) tocilizumab. A total of thirty-one episode of HZ occurred, sixteen occurred in cDMARDs treatment courses and twenty-one occurred in bDMARDs, 2 infliximab, 8 etanercept, 5 adalimumab, 3 rituximab, and 3 abatacept. The crude incidence rate per 100 patient-years was 2.4 (95% CI, 1.4-3.9) for cDMARDs, 2.2 (0.3-7.9) for infliximab, 1.8 (0.8-3.6) for etanercept, 3.7 (1.2-8.4) for adalimumab, 3.9 (0.8-11.0) for rituximab, and 8.5 (1.8-23.1) for abatacept (Table 1).

Conclusion: bDMARDs do not always increase the risk of HZ infection in RA patients, although HZ infection rates vary between different bDMARDs.

Table 1. Crude incidence Rates of Herpes Zoster Events per 100 patient-years

	Observed patient-years	Herpes zoster Events number	100 patient-years	95% CI
Total (n=718)	1470.2	37	2.5	1.8-3.5
cDMARDs (n=277)	662.1	16	2.4	1.4-3.9

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Methotrexate (MTX) is standard treatment in RA. Absorption is better in subcutaneous MTX (scMTX), which may impact speed of onset. In RA, earlier time to remission improves long-term results. Objectives were to determine the speed of onset of scMTX with optimal care in early rheumatoid arthritis (ERA).

Methods: Patients with ERA were studied for outcomes at baseline, 6 weeks and 12 weeks comparing the interval change in DAS28 from 0 to 6 weeks (early period) and 6 to 12 weeks (late period) to see if more benefit was observed in very early treatment with scMTX. Repeated measures ANOVA analyses were performed. The proportion of patients achieving CDAI, SDAI, DAS28 remission and/or low disease activity across time was compared.

Results: 103 patients were included from a single site inception cohort between 2008 to 2014: age 56.2+16.0; 64% female; 57.3% ever-smokers; 59% RF+; mean disease duration 5.3+3.5 months; 83% met ACR 2010 criteria for RA. All included patients received MTX (98.0% scMTX, 98% 25mg/week). Few patients reported headache (3%), nausea (4%), and gastrointestinal symptoms (1.0%), with no dropouts secondary to MTX intolerance in the first 3 months. The mean change in outcomes between the early and late time periods are demonstrated in Table 1, with significantly greater change seen in the early period for several outcome measures. There were a larger proportion of patients achieving SDAI, CDAI and DAS28 remission and/or low disease activity state in the early versus late period, as shown in Table 2. There was a significant improvement when using combination DMARD therapy with sc MTX compared to MTX alone at each time point for many disease measures (TJC, CRP, DAS28, CDAI, SDAI and HAQ), however combination DMARD cohort size was small (n=9). Co-medication with steroids included 33% intra-articular, 14% oral, 14% intra-muscular, and 20% combination steroids. The use of intra-articular steroids with MTX yielded the most disease measures that improved significantly in the early group (0-6wks) vs. later (6-12wks).

Conclusion: ScMTX is rapid, as the change in many disease activity scores was significantly greater between 0-6wks compared to 6-12wks. The use of combination therapy with DMARDs gave added value over methotrexate monotherapy, although generalizability is limited by sample size in the combination cohort. Intra-articular steroid injections may contribute to the early effect of treatment in the first six weeks, supporting early effective combination therapy with scMTX including joint injections as best practice for rapid improvement.

Disease Measure	N	Mean Difference in Disease Activity Score		Mean Difference Early vs. Late	Significantly greater change in early period?	p
		Early Period (0–6 wks)	Late Period (6-12 wks)

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Treatment of rheumatoid arthritis (RA) with anti-Tumor Necrosis Factor (TNF) such as adalimumab may result in some patients (pts) developing anti-adalimumab antibodies (AAA). Findings from a case control study suggest that occurrence of thromboembolic events is higher in pts treated with adalimumab, who developed AAA, compared to those who did not[1]. The objective was to determine if thromboembolic events occur at a higher frequency in pts positive for AAA (AAA+) compared to pts who did not have AAA (AAA-) across several RA clinical trials.

Methods: This was a post hoc analysis of data from the following clinical trials of adalimumab in pts with RA: DE001, DE004, DE005, DE007, DE009 (ARMADA), DE010, DE011, DE013 (PREMIER), DE019, DE035, DE037, M02-575 (CHANGE), M06-859, M10-261, M12-071 (MUSICA), M12-073 (CONCERTO), and M13-390. Pts with RA who received any adalimumab dose were included in the analysis. The incidence rate of treatment-emergent thromboembolic events which occurred up to the last measurement of AAA, were summarized for AAA+ and AAA- pts as events/ 100 patient years (E/100PY). Preferred terms of the Medical Dictionary for Regulatory Activities (MedDRA) system organ class (17.1) were used to code the events. Arterial events such as transient ischemic attack (TIA), cardiovascular accident (CVA), myocardial infarction (MI), and venous events, such as deep vein thrombosis (DVT) with or without pulmonary embolism, superficial vein thrombosis, and thrombosis at unusual sites were included.

Results: A total of 3995 pts were included; 367 were AAA+ with 276.6 patient years (PY) of adalimumab exposure and 3628 were AAA-, with 2255.7 PY of adalimumab exposure. One out of 367 (0.3%) pts who was AAA+ and 29/3628 (0.8%) pts who were AAA- reported a thromboembolic treatment- emergent adverse event (AE) **(Table)**. In the AAA+ pts, the incidence of AE was 0.4 E/100PY (1 event, a cardiac disorder which did not lead to adalimumab discontinuation). In the AAA- pts, 1.4 E/100PY were reported; <0.1 E/100PY (1 cerebrovascular accident and 1 DVT) led to adalimumab discontinuation. Incidence of serious AEs was 0.4 E/100PY in the AAA+ pts and 0.7 E/PY in the AAA- pts.

Conclusion: Across multiple clinical trials of adalimumab in pts with RA, the incidence rate of embolic and thromboembolic events including DVT was not found to be greater in pts with AAA compared to pts who did not develop these antibodies.

Treatment – emergent thromboembolic events occurring up to last AAA measurement date

	All treatment-emergent thromboembolic events E (E/100 PY)		Treatment-emergent thromboembolic events leading to discontinuation E (E/100 PY)

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Despite their profound inhibitory effects on inflammation and bone destruction, it remains unclear whether biological therapies can improve the long-term prognosis of patients with rheumatoid arthritis (RA). Enhanced risk of atherosclerotic cardiovascular (CV) disease is a key feature of RA. Oxidative stress is closely associated with the process of atherosclerosis. In the present study we have investigated the correlation between efficacy of 52-week treatment with tocilizumab (TCZ) and levels of oxidative stress markers in patients with RA.

Methods: Patients treated with TCZ were prospectively studied with informed consent. Efficacy of TCZ and levels of 8-OHdG and 8-iso-PGF2a in urine were evaluated by enzyme immunoassay and enzyme-linked immunosorbent assay, respectively, at baseline and 52 weeks.

Results: Thirty out of 82 patients with RA (mean age 61.0 years old; mean disease duration 7.5 years; concomitant MTX 60%) were studied at the 52-week analysis. The rate of DAS28 (ESR) and CDAI remission at 52 weeks was 76.7% and 33.3%, respectively. In all patients levels of 8-OHdG in urine were decreased (at baseline, 12.5 ng/mg Cr; at 6 months, 9.5 ng/mg Cr), while levels of 8-iso-PGF2a in urine were not altered (at baseline, 355.4 pg/mg Cr; at 6 months, 387.4 pg/mg Cr). Intriguingly, however, levels of 8-OHdG and 8-iso-PGF2a were both decreased in a subgroup of patients with RA who took concomitant MTX, at an early stage of disease, or achieved CDAI remission.

Conclusion: Efficacy of 52-week treatment with TCZ correlated with reduced levels of oxidative stress markers in RA patients. This trend was noted in a subpopulation of patients with RA who took concomitant MTX, at an early stage of disease, or achieved CDAI remission. Together, these findings suggest that treatment with TCZ improves the long-term prognosis of patients with RA by lowering the risk of CV events.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Drug immunogenicity is one of the main mechanisms behind therapeutic failure in rheumatoid arthritis (RA) patients. Our aim was to follow for 2 years RA patients treated with anti TNF agents and to analyze whether the duration of efficacious anti TNF treatment is correlated to their serum drug level at the moment of disease flare, immunogenicity and csDMARD association.

Methods: Ninety two RA patients already treated with anti TNF agents (infliximab, adalimumab, etanercept) were included in a prospective study for 2 years. The clinical activity was measured by DAS28-ESR and SDAI scores. Patient's follow-ups were done every 2 months for infliximab (IFX) and every 3 months for etanercept (ETN) and adalimumab (ADL). At the moment of first sign of treatment failure, serum samples were obtained before anti TNF drug administration. Serum drug and anti-drug antibodies levels were measured by ELISA.

Results: Sixty five patients experienced signs of treatment failure and consequently they were tested for serum drug and anti-drug levels. Eighteen patients were excluded from final analysis due to changes in therapy that could affect serum drug level and immunogenicity, as increase in anti TNF agent dose and a new csDMARD association. Twenty patients treated with IFX experienced loss of response. Eleven patients had undetectable IFX serum level and 9 patients - detectable IFX serum level. The mean IFX treatment duration until the disease flare was not different in these 2 groups: 29.36±17.56 months vs. 40.66±36.96 months (P=0.379). Efficacious treatment duration did not correlate to IFX drug level (r=0.176, P=0.458) at the moment of disease flare, nor with combination therapy with csDMARD (r=-0.045, P=0.852). Nine patients had anti IFX antibodies, but their presence did not correlate to IFX efficacious time (r=0.302, P=196). Serum ETN drug and anti ETN antibodies levels were measured in 18 patients. Only 3 patients had undetectable ETN level. The mean ETN efficacious treatment duration was not significantly different between patients with detectable vs. undetectable ETN serum level (47.8±38.5 months vs. 57.67±23.75 months, P=0.679). Treatment duration did not correlate to ETN serum level(r=-0.244, P=0.328), nor to csDMARD association(r=-0.012, P=0.962). Nine patients treated with ADL for mean 45.56±23.88 months experienced first signs of loss of response. Only one patient had undetectable drug level being on efficacious treatment with ADL for 36 months. The mean efficacious treatment duration in patients with detectable ADL serum level was 46.7±25.2 months. Treatment duration did not correlate to ADL serum level (r=0.377, P=0.318), nor with csDMARD association (r=0.413, P=0.270).

Conclusion: The efficacious treatment duration of anti TNF agents in RA patients seems not to correlate to serum drug level at the moment of first signs of loss of response and may not be influenced by csDMARD association.

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

CD19 is a membrane glycoprotein of the immunoglobulin superfamily and part of the hetero-oligomeric complex comprising the complement receptor type 2, which positively regulates BCR activation. In the tight skin (TSK/+) mouse model for human SSc it has been demonstrated that down regulation of CD19 significantly decreased skin fibrosis, B cell hyper proliferation and IL-6 production.

The purpose of this study was to analyze the effect of rituximab treatment (RTX) in rheumatoid arthritis (RA) and systemic sclerosis (SSc) patients on the CD19-expression on peripheral blood B cells.

Methods: B cells from 21 RA patients and 8 SSC patients were analyzed before and 24 or 48 weeks after initiation of the B cell depleting therapy with RTX. RA patients received 2x 1000mg RTX and the DAS28 was determined before and 24 months thereafter to calculate the EULAR response. SSc patients received 2x 500mg RTX every 3 month and the Rodnan skin score (RSS) and the diffusing capacity of the lung for carbon monoxide (DLCO) were measured before and 48weeks later. CD19 surface expression was determined by mean fluorescence intensity (MFI) and compared with the MFI of CD45 on the cells of interest. B cells were divided into naïve (IgD+/CD27-) and post switch memory cells ((IgD-/CD27+).

Results: Fifteen RA patients had after 6 month a good EULAR response, whereas 6 RA patients were EULAR non responders. In contrast, all SSc patient had a significant improvement in their RSS and DLCO after 1 year. The MFI of CD45 on B cells was not significantly different from the MFI on non B cells and was similar between the patients group. Thus, the MFI±SEM on B cells of RA and SSC patients before RTX was 40,890 ± 2,240 and 32,129 ± 6,718, respectively. The respective CD45 MFI on non-B cells was 41,123 ± 2,896 and 35,710 ± 7,989. Even after RTX no significant alteration was found. In contrast, the MFI of CD19 was significantly reduced on B cells after RTX with the greatest reduction in SSC B cells (9,016 ± 845 and 3,804 ± 281, $p \leq 0.0001$), followed by B cells from RTX-responders (9,156 ± 719 and 5,975 ± 585, $p \leq 0.008$) and RTX-non responders (9,492 ± 603 and 6,712 ± 818, $p \leq 0.031$). Interestingly, analyzing CD19 expression on the B cell subsets demonstrated that naïve B cells in RTX-non responders had no significant reduction in MFI (9,596 ± 677 and 6,890 ± 1,302, $p=0.1663$) compared to RTX responders in RA (9,214 ± 745 and 6,466 ± 635, $p \leq 0.018$) or SSc (8,672 ± 977 and 3,673 ± 607, $p \leq 0.016$). RTX induced the down regulation of CD19 on all post switch B cells irrespective of the treatment response.

Conclusion: These data suggest, that RTX affects disease activity not only by eliminating B cells but also by reduceing the expression of the costimulatory surface molecule CD19. Interestingly, in RTX-non responders newly produced naïve B cells do not significantly down regulate CD19. Thus, they might still be able to activate T cells or produce pro inflammatory cytokines.

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Interstitial lung disease (ILD) associated with RA is a big concern particularly in Japanese patients evidenced by the reports that the cause of death in approximately 10 % of patients with RA is ILD. We have reported that ILD exacerbated in 24 % (14/58) of RA patients associated with ILD when TNF-inhibitors were administrated and 2 of 14 died of ILD, although the degree of exacerbation was minimal

in half of the patients (Nakashita T, et al. BMJ open 2014). We extended this study, namely, we added the number of patients, elongated the observation periods and tried to extract the risk factors for the exacerbation of ILD after administration of bDMARDS.

Methods:

Subjects were 93 patients with RA (male/female = 40/53, mean age 63) associated with ILD who were administrated with various bDMARDS. Chest X-ray film (CXR) was taken at least every 3 months. Chest CT scan was done before and every yearly, and when newly developed shadows were found on CXR or when patients complained of respiratory symptoms for more than 2 weeks, chest CT scan was done. The severity of ILD was graded into 4, grade 0 to grade 3, according to the extent of ILD on chest CT by the method of Gochuico et al. (Arch Intern Med 2008). Chest CT images were graded by 2 independent respirologists. The patterns of ILD were also evaluated by 2 respirologists. Risk factors for the exacerbation of ILD were extracted by discriminant analysis.

Results:

The mean observation period was 23.9 months (range 2 – 90 months). MTX and prednisolone (PSL) were under use at the introduction of bDMARD in 61 % (mean 7.6 mg/week) and in 85 % (mean 7.2 mg/day), respectively. The administrated bDMARDS were as follows; abatacept (ABT) in 23, adalumumab (ADA)in 2, certolizumab (CZP) in 3, etanercept (ETN) in 43, infliximab (IFX) in 10, and tocilizumab (TCZ) in 12, respectively. The ILD grades were 1 in 54 patients, 2 in 29, and 3 in 10, respectively. The ILD patterns evaluated by HRCT were NSIP in 72 patients, UIP in 8, and OP in 13, respectively. Exacerbation of ILD was recognized in 15 patients (16 %), with the mean administration period of 6.5 months (2 – 14 months). The bDMARDS at the time of ILD exacerbation ware ABT in 1, ADA in 1, ETN in 8, and IFX in 5, respectively. Discriminant analysis was done incorporating 19 variables such as kind of bDMARDS, age, gender, duration of bDMADS administration , ILD pattern, ILD grade, dose of MTX and PSL, KL-6 value, DAS28ESR, RF titer, and others, and only 1 significant risk factor (TNF-inhibitors) was extracted. Odds ratio of ILD exacerbation for TNF-inhibitors was 10.

Conclusion: We should be cautious for the exacerbation of ILD when TNF-inhibitors were administrated.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Down-titration of biological therapy (BT) in rheumatoid arthritis (RA) patients with a good clinical response is frequently applied in daily clinical practice. An important factor in order to know if this can be safely applied is the response to retreatment in flaring patients. We have analyzed the risk of relapse and the effectiveness of retreatment in RA patients receiving BT (in daily clinical practice) who had been previously down-titrated.

Methods: Retrospective observational study from a single center. RA patients receiving BT (infliximab, adalimumab, etanercept, certolizumab pegol, abatacept and tocilizumab) previously down-titrated (quarterly dose of BT less than or equal to 83% of the approved dose) were included. Retreatment consisted of increasing the dose to previous or standard (European Medicines Agency approved) dose, at the discretion of the attending physician. Relapse was defined as an increase greater than or equal to 0.6 points from baseline DAS28 or according to the attending physician criteria. Response to retreatment was considered if patients achieved the same level of DAS28 (remission, low or moderate disease activity) as prior to down-titration. Numerical data are expressed as mean and standard deviation for continuous variables and percentages for qualitative variables. Univariate and multivariate analysis was used in order to identify potential predictors of greater risk of relapse after BT down-titration.

Results: Two hundred and fifty-six RA patients were under BT and 91 patients were down-titrated of whom 52% were in remission, 24% with

low disease activity and 24% with moderate disease activity according to DAS28. Most patients (68.1%) were receiving first line BT. Twenty eight patients relapsed and received retreatment at full dose (61%) or previous dose (39%). The average time between down-titration and retreatment was 17.2 ± 13.7 months. Mean DAS28 at the time of retreatment was 4.01 ± 0.99. Most patients (75%) achieved a clinical response before 6 months of retreatment, regardless the use of standard or previous dose. No statistically significant predictors of flare were identified although a trend to greater risk of flaring was observed in patients not in remission at down-titration.

Conclusion: Although down-titration carries a risk of relapse in RA, most patients achieve a good response after retreatment.

The Multi-Biomarker Disease Activity Score in Methotrexate Incomplete Responders Predicts Clinical Responses to Non-Biological Versus Biological Therapy in Early RA

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The Swedish Farmacotherapy (SWEFOT) trial and other trials in rheumatoid arthritis (RA) demonstrated that in MTX incomplete responder patients (MTX-IR) the addition of anti-TNF was only marginally better than stepping up to triple therapy (TT) at the group level. However, it is likely that each treatment choice is better for some subsets of patients. We here evaluate whether the multi-biomarker disease activity (MBDA) score could be used to predict optimal choice of second-line treatment.

Methods: 157 MTX-IR patients from the SWEFOT trial were analyzed. Last observation carried forward was applied in case of incomplete data. Proportions of clinical responders at year 1 among patients with low (<30) moderate (30-44) and high (>44) MBDA scores at randomization (Month 3) were compared by Fisher's exact test. Overall difference of the responses in the two therapy arms was analyzed by Breslow-Day test (for homogeneity of odds ratio).

Results: For patients with a low MBDA (<30) score at randomization, the likelihood of response to TT was significantly greater than to anti-TNF (88% vs. 18%, p=0.006), whereas for patients with high MBDA (>44) the reverse was true (35% vs. 58%, p=0.04, Figure 1A). Comparison of ROC curves with MBDA as a predictor for each treatment identified a threshold of 38 as optimal, corresponding to the lowest quartile of MBDA values in this population. The overall difference of the responses to the treatments based on this cut-off (≤ vs. >38) was highly significant (p=0.001, Figure 1B).

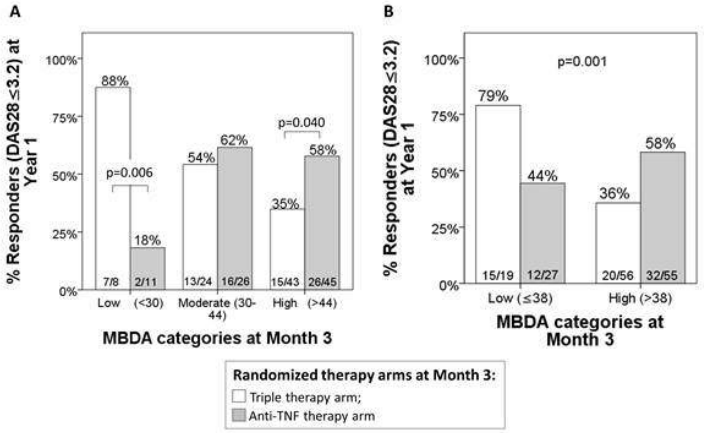

Figure 1. Proportion of responders (DAS28≤3.2) at Year 1 among different categories according to the MBDA score at Month 3. Patients grouped into 3 categories: low (<30), moderate (30-44) and high (>44) **(A)**. Patients grouped into 2 categries: low (≤38) and high (>38) **(B)**.

Conclusion: In patients with early RA and incomplete response to MTX, MBDA score predicts the relative efficacy of subsequent treatment with triple therapy versus anti-TNF. Perhaps most importantly, low MBDA score identifies a subset of patients who are significantly more likely to respond to conventional triple therapy than to anti-TNF. These findings may have major implications for the development of more individualized and cost-effective therapeutic algorithms in RA.

Long-Term Adverse Events after Daily Concomitant Treatment with 10mg Prednisone in the 2-Year Computer Assisted Management in Early Rheumatoid Arthritis Trial-II

Maria de Hair, Nicole IJff, Johannes Jacobs and Jacob van Laar, Rheumatology & Clinical Immunology, University Medical Center Utrecht, Utrecht, Netherlands

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

On behalf of the Society for Rheumatology Research Utrecht (SRU)

Background/Purpose: To investigate the frequency of long-term adverse events (AEs) in early rheumatoid arthritis (RA) patients treated additionally with prednisone 10 mg/day.

Methods: In the Computer Assisted Management in Early Rheumatoid Arthritis (CAMERA) II trial patients initiated treatment with methotrexate (MTX) with 10 mg/d prednisone or placebo for 2 years; the trial was tight-controlled aiming for remission. Thereafter, patients were followed according to a protocol in clinical care. The occurrence of adverse events (AEs) with onset after the 2 year trial period as well as the use of prednisone after the end of the 2 year trial period, when it was the strategy to taper and stop the prednisone, was collected retrospectively from the patient medical charts. For the patients in the former prednisone strategy (pred), the proportion of patients who discontinued prednisone and time until discontinuation of prednisone was described. The frequency of long-term AEs in the pred group versus the former placebo strategy (plac) was analyzed using Fisher's Exact tests.

Results:

Of the 236 patients included in the CAMERA-II trial, follow-up data was available of 118 patients (4 of 7 participating centers; data of the other

patients are being collected): pred N=57, plac N=61; no longer followed according to protocol N=17. The median (IQR) follow-up time after the end of the 2-year trial period was 83 (61-100) and 79 (65-95) months, respectively. 49 (86%) patients treated with prednisone discontinued prednisone after median (IQR) 12 (3-88) months after the trial period. The other patients could not discontinue prednisone due to an increase in RA disease activity when tapering prednisone. The number (%) of AEs are described in Table 1. No statistically significant difference between the two groups was found for any of the AEs, except for cardiovascular diseases; there was a trend toward increased mortality.

Table 1. Frequency of adverse events in the pred vs plac groups

Adverse event (AE)	pred N=57	plac N=61	p-value
≥ 1 AE, n (%)	23 (40.4)	22 (36.1)	0.71
Hypertension, n (%)	2 (3.5)	7 (11.5)	0.17
Diabetes mellitus II, n (%)	1 (1.8)	1 (1.6)	1.00
Gastrointestinal, n (%)	1 (1.8)	0 (0.0)	0.48
Cataract, n (%)	5 (8.8)	7 (11.5)	0.76
Glaucoma, n (%)	0 (0.0)	0 (0.0)	-
Fracture, n (%)	7 (12.3)	8 (13.1)	1.00
Cardiovascular, n (%)	10 (17.5)	3 (4.9)	0.04
Mortality, n (%)	6 (10.5)	1 (1.6)	0.06

Conclusion: Overall, a low occurrence of AEs was found in this preliminary study, but we found an increased cardiovascular risk for the early RA patients treated at least during 2 years with 10mg/d prednisone.

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The RA-MAP consortium is a UK flagship industry-academic partnership investigating clinical and biological predictors of disease outcome in patients with rheumatoid arthritis (RA).

Methods: One RA-MAP workstream investigated clinical predictors of remission by collation of patient-level data from non-biologic arms of academic- and industry-sponsored clinical trials, completed since 2002, evaluating therapies in early inflammatory arthritis and RA. Anonymised data on key baseline and follow-up variables were requested and amalgamated. Logistic regression was used to identify predictors of remission at 6 months, as defined by DAS28-ESR. Initial models considered separate effects of potential predictors after adjusting for age, gender, disease duration, race and treatment arm. Multivariate models were built with variables important at initial screen and with low percentage of missing values. Latent class mixed models were used to characterise disease activity over time, adjust for potential predictors and introduce random effects, and to cluster trajectories that may identify clinically important sub-populations. Both Akaike and Bayesian information criteria were used to decide on number of clusters.

Results: 19 trials were received, comprising 3555 patients with over 30,000 baseline and follow-up records. The non-biologic arms included treatment with placebo, intramuscular steroids, methotrexate or other DMARDs, or methotrexate in combination with other drugs. 78% of patients were female, 86% white and 72% rheumatoid factor positive. Mean age at onset (SD) was 46.7 (13.9) years. Mean age (SD) and median disease duration (IQR) at entry were 52.8 (12.8) years and 3 (1-9) years respectively. Mean baseline DAS28-ESR, 28-swollen and tender joint counts (SDs) were 6.4 (1.1), 12 (6) and 14.7 (7.2). Remission rate, 6 months from entry, was 11% (95%CI 9.8%-12.3%). In the final multivariate

logistic model, remission at 6 months was predicted by being white, male, younger, never smoked, RF negative, methotrexate naïve at entry, randomised to methotrexate singly or in combination, better functional health and lower levels of baseline disease activity (Table 1). Latent class mixed modelling suggested patients could be clustered into sub-populations that included fast improver and non-responder groups and one or two intermediate classes - a slower improver group and a possible sub-population that improved in the first 6 months then showed no further improvement.

Conclusion: Through this novel partnership, the RA-MAP project has confirmed several known factors related to non-biologic induced remission. The remission rate of 11% provides a benchmark for non-biologic arms of future RA trials. The potential to stratify RA patients into distinct disease activity trajectories was demonstrated and may become the basis of personalising treatment choices.

Session Title: Sjögren's Syndrome Poster I: Clinical Insights into Sjögren's Syndrome
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: The diagnosis of Sjögren′s Syndrome (SS) is often difficult and many patients are symptomatic for years with other diagnoses before confirmation of SS. Overlapping clinical and serologic features of SS with other connective tissue disorders, in particular rheumatoid arthritis (RA) and systemic lupus erythematous (SLE), may in part drive the misdiagnoses.

Methods: 1191 subjects with sicca were evaluated in a multi-disciplinary clinic and classified for SS based on the American-European Consensus Criteria. They were interrogated for a past history of suspicion or diagnosis of RA, SLE or SSc and these diseases were confirmed or ruled out by applying the corresponding classification criteria if the patients responded affirmatively.

Results: 531 (44.6%) subjects reported previous diagnosis or suspicion of RA, SLE or SSc; we confirmed the suspected diagnosis in 130, but the remaining 401 (75.5%) did not meet criteria for these diseases. Of those previously diagnosed with another illness, 183 (45.6%) met criteria for primary Sjögren′s syndrome. Rheumatoid factor was present in 31/71 patients with a previous diagnosis of RA compared to 185/830 without a history of RA diagnosis ($p<0.0001$), while 118/147 with a diagnosis of SLE had positive ANA compared to 621 of 926 without the diagnosis ($p=0.012$). Age also influenced prior diagnoses: people with suspected RA were older than those without the diagnosis ($p<0.0001$), while patients with SLE suspicion were younger ($p=0.009$). Presence of anti-Ro/SSA showed a gradient that was progressively less common in subjects who were pure SS, RA and/or SLE overlap with SS, misdiagnosed RA or SLE, and lowest in non-SS sicca. History of a diagnosis of RA or SLE did not distinguish Sjögren′s syndrome from non-Sjögren's sicca.

Conclusion: Among subjects classified as Sjögren′s syndrome, the presence of a positive ANA or rheumatoid factor was associated with a previous, apparently erroneous diagnosis of SLE or RA, respectively.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Sjögren's Syndrome Poster I: Clinical Insights into Sjögren's Syndrome
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Dry eyes can compromise quality of life in Sjogren's Syndrome (SS) and is often one of the most troublesome symptoms. Clinical practice guidelines were developed to provide evidence based consensus recommendations for SS dry eyes management.

Methods: Following the principles of AGREE, a national panel of eye care providers and consultants with representation from rheumatology and oral medicine was convened to evaluate peer-reviewed publications and develop guidelines for the evaluation and management of SS dry eye disease. Definitions from the 2007 Report of the International Workshop on Dry Eye (DEWS) were used to identify patient subsets and clinical issues. Studies on non-SS dry eye disease guided management when considered essential or helpful. Bias was reduced as much as possible by pre-defining parameters for literature searches. Publications were graded for level of evidence according to the American Academy of Ophthalmology Preferred Practice Pattern guidelines and, for strength of the recommendation according to GRADE (Grading of Recommendations, Assessment, Development and Evaluation). Recommendations were formulated and revised using a Delphi consensus process with 75% agreement required for consensus. Revision of guidelines that failed to achieve consensus was permitted up to 3 rounds before the recommendation was discarded.

Results: Key recommendations for all SS dry eye patients included: 1) evaluation of symptoms of discomfort and visual disturbance 2) determination of the relative contribution of aqueous tear deficiency vs. evaporative tear loss to the patient's dry eyes 3) use of objective parameters (tear film stability, tear osmolality, degree of lid margin disease, ocular surface damage) to stage the severity of dry eye disease and 4) a stepwise treatment algorithm based on disease severity that includes patient education as to the nature of the problem, aggravating factors, and goals of treatment; tear supplementation and stabilization, control of inflammation of the lacrimal glands and ocular surface, systemic therapy with secretogogies, and tear preservation measures.

Conclusion: Management of dry eyes in SS necessitates a comprehensive evaluation to identify the cause or causes of dry eyes as well as the gradation of severity based upon symptoms and objective parameters. A stepwise algorithm based on overall dry eye disease severity and response to prior therapy is recommended.

The Sjögren's Syndrome Foundation (SSF) Clinical Practice Guidelines are fully supported by the SSF with no pharmaceutical support. No compensation was paid to any author. All participating authors completed Conflict of Interest forms of the American College of Rheumatology.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Sjögren's Syndrome Poster I: Clinical Insights into Sjögren's Syndrome
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: The American-European Consensus Group (AECG) Criteria (1) for Sjögren's syndrome (SS) require the presence of at least one of the following two conditions: the histopathology (focus score > / = 1) or the presence of anti- SSA and / or SSB antibodies. The study aims to compare patients who, while satisfying the AECG criteria, do not present the positivity for anti-SSA/SSB antibodies, with patients that meet the AECG criteria and are positive for anti-SSA/SSB antibodies.

Methods: 598 patients were selected from the database of the Italian study group on SS (2) based on the following criteria: 1. Fulfillment of the AECG criteria for SS, 2. Execution of the biopsy of the minor salivary glands, 3. Search for anti-SSA/SSB antibodies, 4. Absence of hepatitis C virus infection. Univariate and multivariate analyses were performed. Differences were considered significant for P value <0.05. Variables with P <0.1, were then selected for the multivariate analysis.

Results: 206 patients were positive for histopathology, but negative for autoantibodies (group 1), 342 were positive for both the histopathology and for anti-SSA/SSB antibodies (group 2), and finally 50 patients were negative for the histopathology and positive for anti-SSA/SSB antibodies (group 3). This group has been excluded from the comparisons for the small size.

We found the following statistically significant differences between the two groups of patients (group 1 vs. group 2): age at diagnosis [mean ± standard error (SE)] (55 ± 0.8 vs. 48 ± 0.8, p <0.0001), glandular swelling (52/206 vs. 121/342, p = 0.013), skin involvement (14/206 vs. 47/342, p = 0.01), hematologic involvement (47/206 vs. 124/342, p = 0.001), leukopenia (36/170 vs. 110/230, p = 0.0001), lymphoma (22/342 vs. 2/206, p = 0.002), low C3 (24/187 vs. 63/316, p = 0.04), low C4 (12/187 vs. 43/316, p = 0.013), hypergammaglobulinemia (37/200 vs. 214/336, p <0.0001), ANA (323 vs. 133/202 / 337, p <0.0001), rheumatoid factor (59/198 vs. 224/331, p <0.0001), serum cryoglobulins (24/278 vs. 5/149, p = 0.039). The duration of follow-up (mean ± SE) was higher in the group 2 (4.0 ± 0.4 vs. 5.6 ± 0.3, p = 0.001).

By contrast, there were no statistically significant differences for the following variables: sex, dry eye, dry mouth, joint involvement, Raynaud's phenomenon, purpura, kidney, lung, central and peripheral nervous system involvements, stomach, heart or muscle involvements, fibromyalgia, and the presence of serum monoclonal component, or prevalence of thyroiditis.

By multivariate analysis the following variables were selected as associated with the group 2: antinuclear antibodies (OR 6.9 95% CI 3.2 to 15.1), hypergammaglobulinemia (OR 5.1 95% CI 2.9 to 9.0), rheumatoid factor (OR 2.3 95% CI 1.4 to 3.9), age at diagnosis (OR 0.9 95% CI from 0.96 to 0.99).

Conclusion: B-cell related clinical manifestations and biologic activity appears less relevant in seronegative SS. Personalized treatment in SS as well as trial design of new therapies for SS should take into account these differences for patients' recruitment beyond the fulfillment of the classification criteria.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Sjögren's Syndrome Poster I: Clinical Insights into Sjögren's Syndrome
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Salivary dysfunction in Sjögren's (SS) can lead to serious and costly oral complications including accelerated caries and, in some cases, loss of dentition. Clinical Practice Guidelines for oral disease management were developed to improve the quality and consistency of care.

Methods: Following the principles of AGREE as well as ACR and ADA recommendations for guidelines development, a national panel of oral medicine experts with representation from other specialties convened to define clinically significant oral care issues for guidelines recommendations. Clinical questions were developed in a PICO (Population, Intervention, Comparison and Outcomes) format for the first overarching topic in oral management of Caries Prevention and included use of fluoride, antimicrobials, salivary stimulants, and non-fluoride remineralizing agents. A systematic literature search was conducted on articles from January 1991 to April, 2015 selected according to pre-established parameters. Data were extracted by at least two members and evidence rated by the full group. Evidence grading and strength of the recommendations were based on a variation of GRADE (Grading of Recommendations, Assessment, Development and Evaluation). Recommendations were finalized following a Delphi consensus panel process involving at least 40 dentists and dental hygienists from academia and community-based practice and other healthcare professionals with a minimum of 75% agreement required for consensus. Revision of guidelines that failed to achieve consensus was permitted up to 3 rounds before the recommendation was discarded.

Results: Final recommendations include: 1) Topical fluoride SHOULD BE USED in all Sjögren's patients with dry mouth (Strong); 2) Chlorhexidine administered by varnish, gel or rinse MAY BE CONSIDERED in SS patients with dry mouth and high root caries rate (Weak); 3) While no studies link improved salivary flow to caries prevention, it is generally accepted by the oral health community that increasing saliva may contribute to decreased caries incidence. Therefore, in SS patients with dry mouth, increasing saliva through gustatory, masticatory or pharmaceutical stimulation (*e.g.* sugar-free lozenges or chewing gum, pilocarpine or cevimeline) MAY BE CONSIDERED (Weak); and 4) Non-fluoride remineralizing agents MAY BE CONSIDERED as an adjunct therapy in Sjögren's patients with dry mouth and a high root caries rate. (Moderate).

Conclusion: The incidence of caries in SS patients can be lessened with the use of topical fluoride and other preventative strategies. Development of guidelines for caries management, restoration and oral mucosal management are currently in progress.

The Sjögren's Syndrome Foundation (SSF) Clinical Practice Guidelines are fully supported by the SSF with no pharmaceutical support. No compensation was paid to any author. All participating authors completed Conflict of Interest forms of the American College of Rheumatology.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Sjögren's Syndrome Poster I: Clinical Insights into Sjögren's Syndrome

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: There are currently no FDA approved immunomodulating agents available for treatment of the extraglandular manifestations of Sjogren's (SS). Clinical practice guidelines were developed for the rheumatologic/systemic manifestations of SS in order to improve quality and consistency of care.

Methods: Following the principles of AGREE and ACR recommendations for guidelines development, key stakeholders were surveyed to define clinically important management issues. Of 97 initial questions, 16 were selected for rheumatology guidelines development, redefined using the PICO (Patient, Intervention, Comparison, Outcome) format and prioritized. Guidelines development was completed for the first 3 topics: use of DMARDS for treatment of inflammatory musculoskeletal pain (MSK), management of fatigue and use of biological therapy. Each PICO question was assigned to a 3 member topic review group (TRG) for systematic literature review, data extraction and drafting of one or more guidelines. All articles were reviewed by at least 2 TRG members. Quality of evidence and strength of recommendation were rated using a modification of GRADE. Guidelines were drafted based on the available medical evidence and/or expert opinion. The clinical rationale, evidence summaries, data extraction tables, and drafted recommendations were submitted to a consensus expert panel for consideration and approval. Each panel was comprised of 30-40 participants including clinicians (rheumatologists, other specialists), nurses and patients. A modified Delphi process was used with 75% agreement required for consensus. Revision of guidelines that failed to achieve consensus was permitted up to 3 rounds before the recommendation was discarded.

Results: Consensus was achieved for 20 guideline recommendations. Eighteen recommendations required 1 Delphi round, 1 required 2 and 1 required 3. Key recommendations included: 1) a decision tree for the use of oral DMARDs for MSK with hydroxychloroquine (HCQ) as first line therapy; 2) use of self-care measures and exercise to reduce fatigue and the use of HCQ in selected patients with fatigue. The committee also recommended that 3) the use of rituximab may be considered in certain clinical situations including, vasculitis with or without cryoglobulinemia, severe parotid swelling, inflammatory arthritis, pulmonary disease and mononeuritis multiplex; The committee 4) strongly discouraged the use of TNFα inhibitors for sicca symptoms and for the majority of clinical contexts in primary SS.

Conclusion: Development of clinical practice guidelines for systemic manifestations should improve the standard and uniformity of care for SS and help define areas for future study. The guidelines committee updates its systematic reviews regularly and will revise recommendations as needed.

The Sjögren's Syndrome Foundation (SSF) Clinical Practice Guidelines are fully supported by the SSF with no pharmaceutical support. No compensation was paid to any author. All participating authors completed Conflict of Interest forms of the American College of Rheumatology.

Efficacy of Belimumab and Targeting of Rheumatoid Factor Positive B-Cells in Sjögren's Syndrome: Follow-up of the Open-Label Phase II Study

Luca Quartuccio[1], Sara Salvin[2], Laura Corazza[1], Saviana Gandolfo[2], Martina Fabris[3] and Salvatore De Vita[4], [1]S. Maria della Misericordia,

University of Udine, Italy, Udine, Italy, [2]Rheumatology Clinic, University of Udine, Udine, Italy, [3]Clinic of Rheumatology, University of Udine, Udine, Italy, [4]Santa Maria della Misericordia Hospital, University of Udine, Udine, Italy
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Sjögren's Syndrome Poster I: Clinical Insights into Sjögren's Syndrome
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Belimumab, a monoclonal anti-B lymphocyte Stimulator (BLyS) antibody is preliminary found to be effective in Sjögren's syndrome (SS) patients with moderate to high systemic activity in the phase II open-label BELISS study (1). Belimumab was administered for 12 months in 30 SS patients coming from two Centres (Udine, Italy and Paris, France) (1, 2). The ESSDAI score and the serum levels of rheumatoid factor (RF) and IgM immunoglobulins were significantly affected by this treatment in the long term (2). The aim of this study is to report the one year follow-up after the end of the BELISS study in the Italian cohort of patients in order to further support the clinical and biological benefits of belimumab in SS.

Methods: Clinical and laboratory data of 13 SS patients were collected at one year after the end of the belimumab treatment in the BELISS study. No other immunosuppressors were employed in these patients after the end of the trial. Clinical evaluation was also available up to three years for all the patients. Patients (all female, age 54±15) were all anti-SSA and/or anti-SSB positive. Statistical comparisons by t-test were performed between baseline data and month +12 after the end of the trial, and between the last evaluation in the trial (i.e., week 52) and month +12 after the end of the trial. **Results** are reported as mean±standard deviation (SD).

Results: The ESSDAI score was 8,8±6,9 at baseline, 3,5±3,7 at week 52 (end of the trial) and 7,0±5,7 at month 12 after the end of the trial (baseline vs. month +12, p=0,2; week 52 vs. month +12, p=0,003). Thus, a significant increase in the ESSDAI score was observed between week 52 (end of the trial) and month +12 after the end of the trial, with the mean score coming back in the range of moderate disease activity from the low level. Clinical worsening started between month +6 and month +12. Interestingly, after the end of the trial, the development of B-cell lymphoma from non neoplastic parotid sialadenitis was observed in two patients, and in a third patient a stage progression of local MALT lymphoma was recorded. In an additional patient new onset of hypergammaglobulinemic purpura was documented. RF level was 79,2±86,1 IU/ml at baseline, 59,0±65,7 IU/ml at week 52 (end of the trial), 174,1±220,3 IU/ml at month 12 after the end of the trial (baseline vs. month +12, p=0,5; week 52 vs. month +12, p=0,008). IgM level was 177,6±92,8 mg/dl at baseline, 131,9±73,6 mg/dl at week 52 (end of the trial), 165±84,6 mg/dl at month 12 after the end of the trial (baseline vs. month +12, p=0,3; week 52 vs. month +12, p=0,04).

Conclusion: targeting BLyS by belimumab seems to be effective in SS. A possible control of RF-positive B cell clones in SS by belimumab may be suggested. However, this effect may require a continuous and prolonged suppression of BLyS.

Clinical Subsets and Presenting Features in Primary Sjögren's Syndrome: Results from a Single Center Inception Cohort Study

Chiara Baldini[1], Francesco Ferro[1], Nicoletta Luciano[1], Rosaria Talarico[1], Leonardo Lorenzini[1], Daniela Martini[1], Marta Mosca[2] and Stefano Bombardieri[1], [1]Rheumatology Unit, University of Pisa, Italy, Pisa, Italy, [2]University of Pisa, Pisa, Italy
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Sjögren's Syndrome Poster I: Clinical Insights into Sjögren's Syndrome
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Aim of the study was to characterize the spectrum of presenting clinical features in a single-centre inception cohort of patients with primary Sjögren's syndrome (SS) focusing in particular on the leading symptoms for the diagnosis, on the mean latency between the onset and the diagnosis and, on how the clinical presentation may impact on the long term follow-up of the disease.

Methods: Data were obtained from an inception cohort of patients with SS (AECG 2002) recruited from 2000. The following data were recorded: demographics, presenting symptoms leading to the diagnosis, mean latency from the onset of the disease to the diagnosis, patients' laboratory assessment, histological data at the diagnosis and clinical features at last follow-up. Descriptive statistics were used to assess clinic-serological correlations.

Results: Among 378 patients enrolled (368 F) 99.2% were Caucasians. Mean age (SD) of patients at diagnosis was 51(15) years, and mean latency between the onset of the disease and the diagnosis was 78 (71) months. At disease onset, four clinical subsets were recognizable. The vast majority of the patients presented either isolated sicca symptoms (127/378, 33.7%) or sicca symptoms associated with Raynaud's phenomenon, artralgias/arthritis, and mild cytopenias (188/378, 49.7%). A third subset (23/378, 6%) was characterized by the presence of more severe systemic manifestations, including: interstitial lung disease (8/23), serositis (5/23), polineuropathy (3/23), central nervous system involvement (3/23), myositis (1/23) skin rashes (1/23) and renal involvement (2/23). Finally, a fourth subset (40/378, 10.6%) was represented by patients presenting recurrent salivary gland enlargement, purpura , peripheral nervous involvement and/or other features traditionally associated with a higher risk for non-Hodking's lymphoma (NHL) occurrence. Patients with isolated sicca symptoms were significantly older, presented less likely a positivity for anti-Ro/SSA, anti-La/SSB autoantibodies and Rheumatoid Factor and showed a lower mean focus score (FS) in the minor salivary gland biopsies. Patients presenting risk factors for lymphoma had a higher mean FS, and were more likely to present low C4 levels, cryoglobulins and monoclonal gammopathy. At last follow-up severe systemic manifestations requiring immunosuppressants were observed in additional 35 patients who had presented at the onset only mild signs of autoimmunity and in 9 patients who had also developed a NHL over the time. Overall, 24 patients developed a NHL; out of them, 21/24 had presented either salivary gland enlargement, purpura and/or peripheral nervous involvement since the diagnosis.

Conclusion: In this study we described different clinical subsets in patients with SS at the diagnosis. The impact of the disease clinical presentation on the subsequent disease course seems to be not negligible thus highlighting the importance of a comprehensive disease assessment since the early phases of the disease.

Session Title: Sjögren's Syndrome Poster I: Clinical Insights into Sjögren's Syndrome
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

To evaluate the fulfilment of classification criteria for cryoglobulinemic vasculitis (CV) at diagnosis in a large cohort of patients with primary Sjögren syndrome (SS) and their correlation with poor outcomes.

Methods:

We included 515 consecutive patients tested for serum cryoglobulins who fulfilled the 2002 classification criteria for primary SS. CV classification criteria and serum cryoglobulins at diagnosis were assessed as predictors of death and lymphoma using Cox proportional-hazards regression analysis adjusted for age and gender.

Results:

Positive serum cryoglobulins were detected in 65 (12%) patients, of whom 21 (32%) fulfilled CV classification criteria. Patients with CV had a higher frequency of type II cryoglobulinemia (86% vs. 43%, p=0.04), a higher mean cryocrit level (6.58% vs. 1.25%, p<0.001), and a higher cumulated mean ESSDAI score (35.3 vs. 16.2, p<0.001) in comparison with patients carrying serum cryoglobulins who did not fulfill CV criteria. After a mean follow-up of 110 months, 45 (9%) patients developed B-cell lymphoma and 33 (6%) died. In comparison with patients without cryoglobulinemia, patients with cryoglobulins showed a high risk of development of B-cell lymphoma; the risk was higher for those who fulfilled the CV criteria (HR 7.47, CI95% 3.38-16.53) than for those who did not fulfill the CV criteria (HR 2.56, CI95% 1.03-6.35); statistical differences were found in the univariate analysis, but were not confirmed by the multivariate models. With respect to mortality, patients with CV had a higher risk of death in both the univariate (HR 11.68, CI95% 4.44-30.74) and multivariate (HR 4.36, CI95% 1.32-14.47) adjusted models in comparison with those without cryoglobulins.

Conclusion:

Patients with primary SS who fulfilled the classification criteria for cryoglobulinemic vasculitis at diagnosis are at higher risk of death.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Sjögren's Syndrome Poster I: Clinical Insights into Sjögren's Syndrome

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Salivary gland ultrasonography has been proposed as a promising novel tool for the diagnosis of primary Sjögren's syndrome (SS). An increasing number of studies have shown strong correlations between parenchymal inhomogeneity and disease histological and serological features. However, the correlation between abnormal findings at the salivary gland ultrasonography and traditional risk factors for lymphoma development has not been explored, yet. Aim of this study was to evaluate whether potential abnormalities at the salivary gland ultrasonography might be correlated to any of the traditional histological and serological risk factors for lymphoma development in order to assess the role of salivary gland ultrasonography in the prognostic stratification of primary SS patients.

Methods: Patients with SS (AECG 2002) and different disease duration were consecutively enrolled in this study and systematically evaluated for traditional risk factors for lymphoma (current or past history). Salivary gland ultrasonography was performed by using a Logic 9 system. A simplified scoring system based on parenchymal inhomogeneity (ranging from grade 0 to grade 4) was adopted to assess major salivary gland involvement on the ultrasound. A grade ≥2 was considered as pathological.

Results: We included in the study 127 patients with SS (mean age = 57±5 yrs; disease duration= 14±7 yrs). The mean ultrasonographic score of the overall population was 2.5±2.3 (range 0-8). Seventy-nine patients (62.2%) presented a moderate to severe parenchymal inhomogeneity (i.e ultrasonographic score ≥2). A significantly higher mean ultrasonographic score was detected in patients with history of purpura (4.5±2.7 vs 2.4±2.3, p=0.01), salivary gland enlargement (4.3±1.9 vs 1.8±2.0, p<0.001), positivity for cryoglobulins (5.52±1.8 vs 2.4±2.3, p=0.008), and presence of germinal center in the minor salivary gland biopsy (3.9±2.3 vs 1.6±2.1, p<0.001).The overall ultrasonographic score directly correlated with the IgG levels (r=0.384, p=0.000) and inversely with both C4 levels (r= -0.207, p=0.000) and lymphocytes count (r=-232, p=0.01).

Conclusion: This study suggested that salivary gland ultrasonography may represent a non invasive additional tool to be used in clinical practice for the prognostic stratification of patients with SS and, specifically to distinguish those patients at higher risk for lymphoma development.

Can Extraglandular Manifestations Differentiate Primary Sjögren's Syndrome from Sjögren's-Systemic Lupus Erythematosus Overlap Syndrome?

Steven E. Carsons[1], Suneel Movva[2], Sabatino Ienopoli[3], Steven Aziz[4], Maryam Gul[5], Rose Calixte[6] and Tracy Brodsky[7], [1]Rheumatology, Allergy and Immunology, Winthrop University Hospital, Mineola, NY, [2]Rheumatology, Winthrop University Hospital, Mineola, NY, [3]Medicine, Winthrop University Hospital, Mineola, NY, [4]Winthrop, Mineola, NY, [5]Internal Medicine, Winthrop University Hospital, Mineola, NY, [6]Winthrop University Hospital, Mineola, NY, [7]NYIT, Old Westbuyr, NY

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Sjögren's Syndrome Poster I: Clinical Insights into Sjögren's Syndrome
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Differentiating between primary Sjögren's syndrome (PSS) with systemic manifestations (SM), and Sjögren's -SLE overlap syndrome (OL) can be a clinical challenge. Approximately 30 % of PSS patients have systemic manifestations, while 30 % of SLE patients display sicca symptoms and are SS-A/B positive. This study was undertaken to determine if the prevalence and pattern of SM can differentiate PSS with SM from OL.

Methods:

Charts of 118 patients were retrospectively evaluated to compare the prevalence of SM, and association of diagnosis with twelve categories of SM. Of 118 patients, 91 were classified as PSS and 27 were classified as OL. All PSS patients met AECG criteria for PSS, and had two or fewer ACR SLE criteria. OL patients were defined as having greater than two AECG criteria, and greater than two SLE criteria. The cohorts were also compared with respect to serological features. Two-sample test and Wilcoxon rank sum test were used to test for association between SM and diagnostic category. All associations with $p<0.3$ were further tested using an adjusted logistic regression model.

Results:

There were no significant differences in demographics between PSS and OL patients. However, in the adjusted model white race was more common 4.09 times more common in PSS. There were no significant differences in frequency of xerostomia and xeropthalmia between PSS and OL. Neurologic disease was the most prevalent SM in PSS (43 %), whereas arthritis was most common in OL (52%). There were significant differences in association between PSS and OL with regards to arthritis ($p<0.001$), leukopenia ($p=0.009$), thrombocytopenia ($p=0.001$), and serositis ($p=0.037$) . There was no significant difference in prevalence of renal manifestations. There also were similar rates of Raynaud's. Positivity for SS-A, and SS-B was similar. Overall, patients with OL had a higher median number of EGM than patients with PSS ($p=0.009$).

Conclusion:

Conclusion

PSS and OL patients are similar with regards to age of presentation and gender, but the two groups differ significantly in ethnicity with non-Caucasian race more likely to develop overlap features with SLE. Xerostomia and xeropthalmia cannot differentiate between these groups. Inflammatory arthritis, leukopenia, thrombocytopenia, and serositis may assist in differentiating between PSS and OL. Lower than expected rates of renal disease in the OL group suggest a possible modifying effect of the Sjögren's phenotype. SS-A, and SS-B as well as Raynaud's do not appear to discriminate between these two disease states.

Session Date: Sunday, November 8, 2015
Session Title: Sjögren's Syndrome Poster I: Clinical Insights into Sjögren's Syndrome
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Sicca syndrome is a clinical presentation that is common for several systemic diseases that may infiltrate the exocrine glands. The most frequent disease is Sjögren's syndrome (SS), but other systemic diseases such as sarcoidosis, amyloidosis of IgG4-related disease may also infiltrate salivary glands. We analyzed the safety and usefulness of a new diagnostic tool for investigating minor salivary glands (minimally-invasive biopsy technique) in patients presenting with sicca syndrome.

Methods:

We present a prospective analysis of 200 patients presenting with sicca syndrome (defined by the presence of xerostomia and xerophthalmia, with positive results for ocular tests and/or parotid scintigraphy) in whom a minimally-invasive biopsy of minor salivary glands was carried out at a single center. For all biopsy samples, a cumulative focus score of lymphoplasmacytic infiltration was evaluated (Chisholm Mason score, CMs), together with investigation of other infiltrative processes caused by granuloma, amyloid, lipids or IgG4-positive cells.

Results:

All biopsies but two disclosed salivary gland tissue. Only 28 patients (14%) reported transient adverse events recovered completely during the first 24h. Histopathological diagnosis was available in 189 cases (158 women, 31 men, mean age 59 years): 44% of patients showed a non-specific chronic sialoadenitis (NSCS) (CMs=1-2), 21% focal lymphocytic sialoadenitis (FLS) suggestive of primary Sjögren syndrome (CMs=3-4), 12% chronic atrophic sialadenitis (CAS) (CMs unclassifiable), 18% normal glandular tissue (CMs=0) and other diagnosis in the remaining 4% (1 case of amyloidosis, 1 of sarcoidosis, 6 of lipoid infiltration and 1 salivary oncocytic cystadenoma); no patient had IgG4-related disease. The higher mean age was found in patients with CAS (69 years), followed by those with NSCS (59 years), those with FLS (57 years) and those with a normal result (54 years) ($p<0.001$). A higher frequency of FLS was found in patients with positive immunological markers including RF, anti-Ro, anti-La, hypocomplementemia and cryoglobulins ($p<0.05$). The percentage of patients diagnosed with Sjögren syndrome varied according to the concomitant systemic features: 13% of patients presenting with an isolated sicca syndrome had FLS in comparison with 32% of those who present with extraglandular involvement ($p<0.05$).

Conclusion:

We found sialoadenitis in nearly 80% of patients presenting with sicca syndrome. One quarter of these patients were diagnosed with Sjögren syndrome (focal lymphocytic sialadenitis). An older age was associated with a higher frequency of atrophic and chronic histopathological findings, while the presence of systemic features was associated with a higher frequency of focal lymphocytic sialadenitis. Only 1% of patients showed other systemic infiltrative diseases (one case of sarcoidosis, one of amyloidosis); no patient showed infiltration by IgG4+ cells.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Sjögren's Syndrome Poster I: Clinical Insights into Sjögren's Syndrome
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Circulating anti-Ro/SSA antibodies may rarely affect the adult conduction-system. A direct autoantibody-mediated electrophysiological inhibition of cardiomyocyte calcium-channels (*acquired form*) or an ante-natal subclinical injury induced by maternally-acquired anti-Ro/SSA with an autoantibody-independent worsening with age until a late diagnosis in the adulthood (*late progressive congenital form)* are the putative mechanisms involved.

Methods: We collected three clinical cases that provide further evidences of this view.

Results:

Case 1. A 29-years-old woman presented with chest pain and faintness. The ECG demonstrated the presence of III° atrioventricular block (AVB). The clinical history was negative except for autoimmune thyroiditis and subclinical positivity for anti-Ro/SSA A pacemaker was implanted but after methylprednisolone 40 mg/daily normal AV conduction was restored.

Case 2. A I°AVB with episodes of II°AVB and high-grade AVB was discovered in an asymptomatic 23-year-old woman who underwent routine screening. Her clinical history was negative. A previous ECG demonstrated that I°AVB was already present at 9 years of age. Anti-Ro/SSA were negative, but these antibodies were positive in the mother. A backup permanent pacemaker was implanted.

Case 3. A 21-year-old woman with autoimmune thyroiditis presented with III°AVB. The laboratory evaluation demonstrated a positive test for anti-Ro/SSA-52kD (immuno-Western blot), although FEIA testing was negative. Her mother was totally asymptomatic for connective tissue diseases (CTDs), but was found to be positive for anti-Ro/SSA-52kD (immuno-Western blot). Methylprednisolone 1 mg/Kg/day was initiated resulting in a rapid disappearance of III°AVB. At the interruption of the therapy 3 months after there was the reoccurrence of complete AVB, and again methylprednisolone rapidly restored normal AV conduction. The opportunity of implanting a pace-maker is under consideration.

Conclusion: these 3 cases provide an exemplification of the different forms of anti-Ro/SSA-associated AVB in adults. The patient 1 and patient 2 represent respectively a case of *acquired form* and a case as a *late progressive congenital form*. Finally, the patient 3 may represent a *mixed form*, in which both the above mechanisms have been involved. In conclusion a specific anti-Ro/SSA testing (ELISA + immuno-Western blot) in the patient and patient's mother may be diagnostic in rare adults with unexplained AVB, also in the absence of signs of CTDs; if anti-Ro/SSA are present, a prompt immunomodulating therapy may induce a rapid reversion of this life-threatening rhythm disturbance, thus avoiding or delaying pacemaker implantation.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Sjögren's Syndrome Poster I: Clinical Insights into Sjögren's Syndrome
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-centromere antibodies (ACA) define a subgroup of Sjögren's syndrome (SS) patients who are often older, have more frequent Raynaud's phenomenon, and a lower frequency of anti-SSA and anti-SSB antibodies, hyperglobulinemia, rheumatoid factor, and leucopenia. We sought to determine whether the presence of ACA is associated with more severe impairment of exocrine glandular function in SS.

Methods: We obtained data on 3297 participants of the Sjögren's International Collaborative Clinical Alliance (SICCA) registry with suspected or established SS for whom there were complete data on the three objective criteria for SS (as defined by the ACR classification criteria). We identified 1361 who could be classified with SS by these criteria and who did not have a definite diagnosis of an underlying connective tissue disease by criteria extant at the time of SICCA registration. The presence of anti-centromere antibodies was determined by immunofluorescence on HEp-2 cells and was performed as part of the routine serologic evaluation of SICCA participants (Quest Diagnostics, Madison, NJ).

Results: ACA were present in 82 (6%) of the 1361 primary SS participants and were associated with an older median age (59 vs 52; p<0.0001), female gender (99 vs 93%; p=0.0379), and lower frequencies of anti-SSA and/or anti-SSB antibodies (29 vs 82%, p<0.0001), rheumatoid factor (39 vs 60%, p=0.0003), and IgG>1445 mg/dl (30 vs 58%). Median focus score was higher in the ACA (+) patients: 2.8 vs 2.5, p=0.0433). There was an increased frequency of Raynaud's phenomenon (62 vs 28%, p<0.0001), sclerodactyly (16 vs 1%, p<0.0001) and dilated nailfold capillary loops (20 vs 5%, p<0.0001) in the ACA (+) vs ACA (-) subjects. The 2013 Systemic Sclerosis classification criteria were fulfilled by 14/82 (17%) of the ACA (+) subjects. Exocrine gland function was worse in the ACA (+) compared to the ACA (-) subjects: Schirmer's test value (mean of both eyes): median 4.5 vs 6.5 mm/5 min, p=0.0002; unstimulated whole saliva flow rate: median 0.077 vs 0.367 ml/5 min, p<0.0001. In univariate analyses, duration of dry eye and dry mouth symptoms was not associated with ACA status. Individuals with ACA had an increased risk of UWSF<0.1 ml/min [OR=12.1 (95% CI, 4.9-40.7)] and Schirmer value <5 mm/5 min [OR=2.5 (95% CI, 1.5-4.4) after correcting for age, gender, presence of anti-SSA/SSB, and focus score.

Conclusion: ACA are uncommon in primary SS but define a subset characterized by more severe impairment of exocrine glandular function, in addition to older age and a lower frequency of anti-SSA/SSB antibodies, rheumatoid factor and hyperglobulinemia. This impairment of glandular function is independent of age, gender, focus score, and SSA/SSB serology. Although the majority have Raynaud's phenomenon, only a minority have sufficient other clinical features to satisfy the 2013 classification criteria for systemic sclerosis.

Session Date: Sunday, November 8, 2015
Session Title: Sjögren's Syndrome Poster I: Clinical Insights into Sjögren's Syndrome
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

To analyse the epidemiological, clinical and immunological characteristics at diagnosis of the largest international cohort of patients diagnosed with primary Sjögren syndrome (SS) according to the 2002 AE classification criteria.

Methods:

The Big Data Sjögren Project is an international, multicentre registry formed in 2014 to take a “high-definition” picture of the main features of primary SS at diagnosis by merging international SS databases. International experts participating in the EULAR-SS Task Force were invited to participate. By June 2015, the database included 6120 consecutive patients recruited from 14 countries (Europe, America and Japan), of whom 6047 fulfilled the 2002 classification criteria for primary SS (some diagnostic tests are pending in the remaining patients). The main features at diagnosis (time of criteria fulfilment) or at recruitment were collected and analysed.

Results:

Of the 6047 patients, 5648 (93.4%) were women and 399 (6.6%) were men (female:male ratio, 14:1), with a mean age at diagnosis of primary SS of 49.96 years (range, 5-97), of which 79% were Caucasian and 81% from European countries. The frequency of fulfilment of the 2002 criteria was: 94.1% for dry eye, 93.6% for dry mouth, 88.3% for positive salivary gland biopsy, 86% for positive ocular tests, 79.1% for positive oral tests and 72.2% for positive Ro/La autoantibodies. With respect to the criteria fulfilled, 10.6% fulfilled 3 criteria, 30.6% 4 criteria, 40.7% 5 criteria and 18% all 6 criteria. The percentage of diagnostic tests performed varied from 70% to nearly 100%: Ro/La autoantibodies were tested in 99.5% of patients, ocular diagnostic tests (Schirmer’s test and/or corneal stainings) in 89.7%, oral tests in 81.3% and salivary gland biopsy in 71.8% of patients. The four diagnostic tests included in the 2002 AE criteria were made (complete diagnostic approach) in 3459 (57%) patients, while in the remaining 2588 (43%), only two or three tests were made (incomplete diagnostic approach). A complete diagnostic approach was more frequent in patients from non-European countries (73% vs 55%, $p<0.001$), Ro/La negative patients (79% vs 50%, $p<0.001$), ANA-negative patients (75% vs 57%, $p<0.001$), RF-negative patients (66% vs 55%, $p<0.001$) and patients with normal C3/C4 values (74% vs 59%, $p<0.001$).

Conclusion:

In the largest cohort of primary SS patients diagnosed homogeneously according to the 2002 AE criteria, a full diagnostic evaluation was made in less than 60% of patients. In addition, the diagnostic approach was heterogeneous and varied according to the geographical area and the baseline immunological profile; in contrast, gender and age did not influence the number of diagnostic tests made to achieve fulfilment of the criteria.

Seronegative Sjögren's Syndrome Is Associated with a Higher Frequency of Patient-Reported Neuropathic Pain: An Analysis of the Sjögren's International Collaborative Clinical Alliance Cohort

Alan N. Baer[1] and Julius Birnbaum[2], [1]Division of Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD, [2]Medicine (Rheumatology), Johns Hopkins University School of Medicine, Baltimore, MD

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Sjögren's Syndrome Poster I: Clinical Insights into Sjögren's Syndrome

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with Sjögren's syndrome (SS) and negative SSA/SSB serology (ie. seronegative SS) have phenotypic characteristics different than seropositive ones, and thus may constitute a disease subset with a unique pathogenesis. Since these patients are older and have a lower frequency of hypergammaglobulinemia, rheumatoid factor, hypocomplementemia, they might be expected to have a more benign phenotype. However, recent reports highlight that these patients have more severe pain and a higher frequency of small fiber sensory neuropathy. We sought to determine if self-reported neuropathic pain was more prevalent among primary SS participants of the Sjögren's International Collaborative Clinical Alliance (SICCA).

Methods: We obtained data on 3297 participants (pts) of the SICCA registry with suspected or established SS for whom there were complete data on the three objective criteria for SS (as defined by the ACR classification criteria). We identified 1361 who could be classified with SS by these criteria and who did not have a definite diagnosis of an underlying connective tissue disease. Responses of each pt to written questions regarding the presence and frequency of neuropathic pain symptoms were analyzed; these questions were adapted from validated tools for this purpose.

Results: SSA/SSB serology was positive in 1071 and negative in 290 of the primary SS participants. Reports of painful dysesthesia were higher in the seronegative SS pts: "persistent or frequent burning discomfort" (27 vs 18%, p=0.0006; χ^2); "sharp 'jabbing' needle-like pain" (37 vs 28%, p=0.0038), and "more or less continuous 'prickling' or 'tingling' feeling" (40 vs 35%, p=0.0846). In contrast, there were no differences in reports of decreased ability to feel surface features, pain/cuts/injuries, and hot from cold. Depression, assessed by responses to the PHQ-9 questionnaire, was more frequent in the seronegative SS pts (scores≥10, 32 vs 22%, p=0.0004). In a multivariate analysis, we found that pts who reported dysesthetic neuropathic pain were 1.6 times more likely to have negative SSA/SSB serology (95% CI 1.1-2.2; p=0.013) than those with positive serology, after controlling for age, gender, ethnicity, duration of dry eye and dry mouth, and depression.

Conclusion: Self-report of neuropathic pain is more prevalent in seronegative primary SS, a finding which is independent of age, gender, ethnicity, duration of sicca symptoms, and concomitant depression. Although our findings need to be verified with validated neuropathic pain scales, they suggest that seronegative SS has a pathogenesis unique from that of seropositive SS.

Session Title: Sjögren's Syndrome Poster I: Clinical Insights into Sjögren's Syndrome

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-SSA/SSB antibodies represent the most specific serologic marker of Sjögren's syndrome; however, in up to 30% of SS patients the test is negative. Anti-alpha-fodrin (AFA) antibodies have been associated with SS; thus, we aimed to evaluate the utility of AFA antibodies in combination with RF and/or ANA as alternative immunological criterion in SS.

Methods: 350 patients (100 each diagnosed with RA, SLE, and scleroderma, each, according to current classification criteria, and 50 with clinical diagnosis of primary SS) were selected from our patient registry and assessed for SS using a structured approach. All patients were tested for ANA, RF, anti-SSA/SSB, and AFA antibodies. *Diagnosis of SS* was made on clinical basis by two rheumatologists with expertise in SS who independently evaluated every patient considering the results of the 6-item screening questionnaire, history of parotid enlargement, Schirmer-I test, Wafer test, NSWSF rate, fluorescein staining test, autoantibodies, lip biopsy, medical notes from Ophthalmology and Oral Medicine, and medical chart review. *Non-SS diagnosis* was defined as lack of clinical diagnosis and not fulfilling either AECG and/or ACR criteria. *Statistical analysis.* We focused on patients testing negative for anti-SSA and/or anti-SSB antibodies. The 2012 ACR SS criteria were applied to each study participant substituting the immunological criterion as follows: 1) RF plus ANA >1:320, 2) RF plus AFA, 3) ANA plus AFA, 4) RF alone, and 5) Two positive tests out of RF, ANA >1:320, or AFA. We estimated the sensitivity (SN), specificity (SP), positive predictive value (PPV), negative predictive value (NPV), and positive likelihood-ratio with 95% CI, for each criterion item.

Results: 236 (67%) patients tested negative for anti-SSA/SSB antibodies, of whom 65 (27.5%) were clinically diagnosed as SS, and 149 (63%) with non-SS. The performance of ACR criteria using diverse substitute immunological criterion is shown in the table. RF + AFA, and ANA + AFA performed similarly as RF + ANA >1:320 as substitute immunological criterion. Although RF + ANA >1:320 performed well, incorporating AFA improved the number of SS patients classified by the ACR criteria. Particularly, the model 2 out of RF, ANA, or AFA, improved the sensitivity of 2012 ACR SS Criteria to capture SS patients with negative anti-SSA and/or anti-SSB serology from 37 to 46 out of 65 patients studied.

Conclusion: RF plus AFA, and ANA plus AFA antibodies performed similarly as RF plus ANA >1:320, as a substitute immunological criterion in patients with SS with negative anti-SSA/SSB serology. However incorporating AFA to RF and ANA >1:320 in a 2 out of 3 model improves the sensitivity to capture SS patients with negative anti-SSA/SSB serology. This improvement will benefit clinical studies and clinical trials in SS.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Sjögren's Syndrome Poster I: Clinical Insights into Sjögren's Syndrome

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Recent insights from open studies and randomized clinical trials have shown the effectiveness of Rituximab (RTX) in controlling disease activity, patients' subjective symptoms and patient-reported outcomes in primary Sjögren's syndrome (SS). To date, only few cases of patients with SS undergoing repeated B lymphocyte depletion courses with RTX have been described. Aim of this study was to assess safety and efficacy of repeated B-cell depletion with RTX in patients with primary SS.

Methods: Out of an inception cohort of 378 patients (AECG 2002) we selected those subjects who had been treated with multiple courses of RTX on the basis of disease activity and/or lymphoproliferative complications. In addition to patients' demographics, clinical and serological features, we retrieved the following information: indication for RTX therapy, previous and concomitant treatments, number of RTX courses, regimens, time to re-treatment, changes in the ESSDAI, in lab and serology tests and adverse events.

Results: Out of 17 SS patients who had been treated with RTX, we identified 5 female who had received repeated B lymphocyte depletion therapy. Patients had median age of 60 years (range31-65) and median disease duration of 36 months (range 12-120). All the patients were positive for antinuclear antibodies, anti-Ro/SSA and Rheumatoid Factor (RF); 2/5 (40%) had also a positivity for anti-La/SSB and cryoglobulins. HCV antibody test resulted negative in all patients. Initial indications for RTX included: MALT non-Hodgkin's lymphoma (NHL) (3/5), central and peripheral nervous involvement (pns)(1/5) and diffuse skin vasculitis (1/5). Three patients received 2 cycles of RTX, 1 received 3 cycles and 1 received 4 cycles. Indications for re-treatment included: MALT lymphoma recurrence (1/5) and/or increased disease activity in the other cases. Median ESSDAI before RTX re-treatment was 11 (range 6-13) with patients presenting mainly enlargement of major salivary glands, reactive lymphoadenopathy, skin vasculitis, neuropathy and glomerulonephritis. Moreover, all patients presented low C3/C4 levels, and/or hypergammaglobulinemia and/or cryoglobulins. Three patients presented a high titer of RF and 2/5 had a moderate lymphopenia. Each course consisted of 1 g RTX intravenous (IV) on days 1 and 15 or 375 mg/m2 IV once weekly for 4 doses. Median interval between courses was 9 months (range 8-48). Multiple courses of RTX resulted in significant improvement of the ESSDAI and IgG levels compared with baseline ($p<0.05$). Despite not statistically significant, we also observed beneficial effects on C3, C4, RF and ESR. Retreatment with RTX was well-tolerated. None of the patients developed mild serum-sickness-like disease. Infectious events included: recurrent urinary tract infection (2/5), skin infection (1/5) and Herpes Zoster reactivation (1/5). Falls in total Ig levels occurred in one patient requiring Ig replacement therapy.

Conclusion: Repeated B-lymphocyte depletion over a median 36-months period appears to be an acceptable and relatively well-tolerated therapy in SS. Further studies are needed to investigate optimal indications and timing of retreatment of RTX in SS patients.

Session Title: Sjögren's Syndrome Poster I: Clinical Insights into Sjögren's Syndrome

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Primary Sjögren syndrome (pSS) shares many clinical, inflammatory, and immunological features with rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE). SLE and RA are characterized by a high risk of cardiac involvement. However, there are limited data on the risk of overt cardiac involvement in pSS. We sought to use a cardiac magnetic resonance imaging (CMR) approach to assess cardiac involvement and determine its association with disease characteristics in pSS patients without cardiac symptoms.

Methods: Consecutive pSS patients, according to ACR classification criteria (2012), without a history or clinical findings of hypertension, cardiovascular disease, diabetes, or dyslipidemia underwent contrast CMR. Late gadolinium enhancement (LGE) was obtained for the assessment of myocardial fibrosis. Using a black-blood T2-weighted image (T2-WI), myocardial inflammation could be assessed. Sjögren syndrome disease activity index (ESSDAI) was determined. Eighty percent patients had documentation of a minor salivary gland biopsy. Salivary gland biopsy data were classified by focus score (FS). We investigated the patients in terms of prevalence of CMR abnormalities and explored possible associations between CMR abnormalities and pSS disease characteristics.

Results: Thirty-six female pSS patients were enrolled (mean age: 55.9 ± 7.1 years). On average, cardiovascular risk was low for the group, with patients demonstrating no ECG abnormalities, and the patients had generally low traditional cardiovascular risk factors, with a mean Framingham 10-year hard cardiovascular risk score of 4% ± 2%. The mean ESSDAI was 3.5 ± 2.1. Twelve pSS patients (33%) demonstrated myocardial abnormalities. T2-WI was seen in 4 pSS patients (11%). LGE was found in 11 pSS patients (30%), 3 of whom also demonstrated T2-WI. The main finding observed in 7 of these 11 patients (63%) was a linear pattern without coronary distribution. A patchy nodular enhancement pattern was observed in 4 patients (36%). Compared with LGE- and T2-WI-negative patients, LGE- and T2-WI-positive patients showed no significant difference related to ESSDAI. Anti-SSB antibodies were significantly higher in LGE-positive than LGE-negative patients ($p = 0.002$). Raynaud phenomenon was significantly associated with LGE- and T2-WI-positive patients ($p = 0.006$ and $p = 0.04$, respectively). Other pSS characteristics such as disease duration, commodities, and cardiovascular risk factors were not significantly associated with myocardial abnormalities. The greatest relative difference between LGE-positive and -negative patients was observed in focus score ≥ 3, with an adjusted odds ratio of 3.0. After adjusting for confounding by age, pSS duration, and anti-SSB antibodies, the association of LGE with Raynaud phenomenon remained significant ($p = 0.023$).

Conclusion: Subclinical myocardial involvement, as detected by cardiac MRI, was frequent in pSS patients without cardiac symptoms. Our results suggest that Raynaud phenomenon has a role in promoting cardiac involvements in patients with pSS.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Sjögren's Syndrome Poster I: Clinical Insights into Sjögren's Syndrome

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: EULAR Sjögren's syndrome Patient-Reported Index (ESSPRI) is an index to evaluate symptom severity and recommended

as an efficacy measure for clinical trials in primary Sjögren's syndrome (pSS) patients. The prevalence of sleep disturbance has reportedly increased in pSS and sleep disturbance could affect pSS symptom severity. However, the association between insomnia and ESSPRI in pSS has not been reported.

Methods: Forty-three pSS patients, who fulfilled the American-European Consensus Group (AECG) criteria, consecutively were enrolled. The patients completed questionnaires on quality of life (EQ5D), ESSPRI, insomnia (Insomnia Severity Index, ISI), sleep quality (Pittsburgh Sleep Quality index, PSQI), fatigue (Fatigue Severity Score, FSS), and depression (Korean Beck Depression Inventory, KBDI). Additionally, they were evaluated by 100 mm-VAS scale for patient global assessment (PGA), oral or eye dryness, eyeball pain, and anxiety. Data were also collected on demographic, clinical, and laboratory variables.

Results: Among 43 pSS patients, 10 (23.3%) had clinical insomnia (ISI>14) and 24 (55.8%) had no sleep disturbance (ISI<8). Patients with clinical insomnia had significantly higher ESSPRI (p=0.005), scores for FSS and KBDI (both p<0.01), and VAS levels for dry eye, eyeball pain, anxiety, and PGA (all p<0.05) than those without clinical insomnia. Furthermore, they had significantly lower EQ5D score (p=0.005). ISI was significantly correlated with ESSPRI, scores of EQ5D, FSS, and KBDI, and VAS levels of oral or eye dryness, nocturnal xerostomia, eyeball pain, anxiety, and PGA (all p<0.05). The distribution of ISI was significantly different according to tertiles of ESSPRI (p<0.05, Figure 1). When high levels were defined by the upper tertile of each continuous variables or according to the cuff off points for ISI, KBDI, and FSS, a logistic regression analysis showed that high ESSPRI was significantly associated with high PGA (p<0.01, OR 10.3) and clinical insomnia (p<0.05, OR 12.5, Table 1).

Conclusion: Our results suggest that clinical insomnia is able to independently affect ESSPRI levels and insomnia symptom might be a target to improve ESSPRI levels in pSS patients.

Table 1. Logistic regression analysis of the association of between high ESSPRI (defined as the highest tertile) and clinical insomnia

	Beta	Odds ratio	95% CI	P value
High PGA* for pSS	2.330	10.28	1.88 – 56.16	0.007
Clinical insomnia	2.522	12.45	1.72 – 89.94	0.012

*, high PGA was defined as the highest tertile.

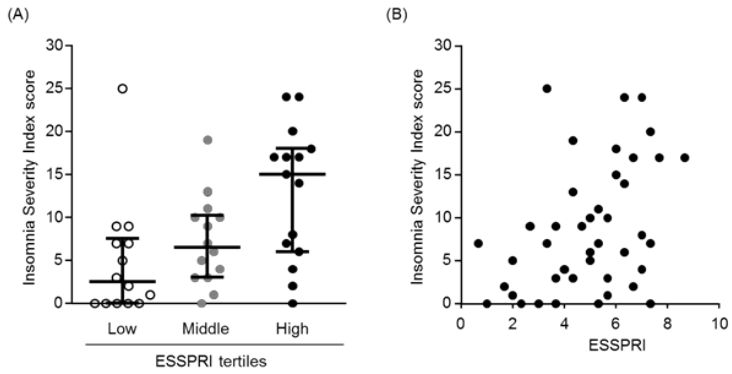

Figure 1. The association between Insomnia Severity Index (ISI) and ESSPRI. (A) ISI scores increased according to tertiles of ESSPRI in pSS patients. P value was calculated by Kruskal-Wallis test. (B) Scatter plot showed a positive correlation between ESSPRI and ISI in pSS patients. P value was calculated by Spearman's correlation.

Sjögren's Syndrome in Male Patients Presents with Higher Autoantibody Levels and More Extraglandular Manifestations

Jorge Ramírez[1,2], Marika Kvarnstrom[2,3] and Marie Wahren-Herlenius[1,2], [1]Department of Medicine, Karolinska Institutet, Solna, Sweden, [2]Department of Medicine, Experimental Rheumatology Unit, Solna, Sweden, [3]Department of Medicine, Unit of Rheumatology, Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden

Session Title: Sjögren's Syndrome Poster I: Clinical Insights into Sjögren's Syndrome

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Primary Sjögren's syndrome (pSS) and SLE are chronic autoimmune diseases that predominantly affect women, with a female:male ratio of approximately 9:1. SLE in men is more severe than in women, but studies of sex-related clinical features in pSS have given ambiguous results. In this study, we therefore investigated the clinical presentation of pSS in men and women in a cohort of pSS at time of diagnosis, all treatment naïve cases collected in a population-based manner during a 5-year period.

Methods:

Patients represent incident cases of pSS in Stockholm County from January 1, 2007 to December 31, 2011, and were diagnosed at the Department of Rheumatology at the Karolinska University Hospital, Stockholm, Sweden (women n=136, men n=10). Patients were examined according to an established protocol including clinical and laboratory investigations and all fulfilled the 2002 revised American–European Consensus Criteria (AECC). Extraglandular manifestations (EGM) were defined as those included in the EULAR Sjögren's Syndrome Disease Activity Index (ESSDAI). Serum was sampled at the time of diagnosis, anti-Ro52 levels were measured by ELISA and a cut off at 80 AU was used for categorization into high and low levels. The Chi-square test was used for analyzing frequencies of patient subgroups and prevalence of EGM, and the Mann-Whitney U-test was used when comparing autoantibody levels and age at diagnosis between female and male patients with pSS.

Results:

Male patients were younger at the time of pSS diagnosis than female patients (48.0 ±12.2 versus 57.0 ±14.1, p=0.04). No difference was observed for frequencies of Ro and La autoantibodies, but male patients with pSS displayed a tendency towards higher Ro52-autoantibody levels (p=0.06), and more male patients had high levels (p=0.03). Notably, cutaneous vasculitis was more common in male patients with pSS (p<0.001), and pulmonary disease in terms of interstitial lung disease and alveolitis occurred more often in male patients with pSS (p<0.001 and p<0.001). No EGM was more common in female pSS patients. Further, concomitant presentation of EGM was more common in male than in female patients (p=0.02).

Conclusion:

There are differences in the clinical presentation of pSS between the sexes. Our study, based on a cohort of incident, treatment naïve cases collected in a population-based manner during a 5-year period, indicates that disease onset is earlier in men, and that the immune-activity is higher. Importantly, half of the male patients presented one or more EGM at diagnosis, supporting the conclusion that pSS in men represents a more severe form of disease, regardless of the lower risk for males to develop the disease.

Session Title: Sjögren's Syndrome Poster I: Clinical Insights into Sjögren's Syndrome

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Fatigue is a common clinical manifestation in patients with primary Sjögren¡¯s syndrome (PSS). The aims of this study were to investigate the association between fatigue severity and other clinical characteristics in PSS patients and to determine the factors contributing to fatigue.

Methods: We analyzed 219 participants from the Korean Initiative of PSS (KISS) prospectively. The KISS was formed in 2013 with the aim of establishing a nationwide prospective cohort to obtain overall clinical data and samples from PSS patients and to develop diagnostic and treatment tools for PSS. All participants fulfilled the 2002 American-European Consensus group and/or the 2012 American College of Rheumatology classification criteria. Fatigue was assessed according to the fatigue domain of the European League Against Rheumatism Sjögren¡¯s Syndrome Patient-Reported Index (ESSPRI). Health related quality of life (HRQOL) was evaluated using the EuroQol-5 dimension (EQ-5D). Multiple linear regression analysis was used to estimate the effect of each variable on fatigue severity.

Results: The median age of all participants was 54 (IQR, 46–60) years and a median PSS duration was 2.3 (IQR, 0.5–5.4) years were included in the study. The median total ESSPRI score was 5 (interquartile range, 4–6). Thirty-four percent of patients reported a fatigue score >= 7. Younger and premenopausal patients presented with more fatigue (P = 0.028 and < 0.001, respectively). A higher xerostomia inventory score (*P* < 0.001) and Ocular Surface Dryness Index (*P* < 0.001) were observed in patients with a fatigue score >= 7. Pain, xerostomia inventory and age were determined to be significantly associated with fatigue severity after adjusting for depression/anxiety by multivariate linear regression analysis (Table 1). The median EQ-5D TTO value was 0.85 (IQR, 0.78–0.91), and the median EQ-5D VAS score was 70 (IQR, 50–80). PSS patients with a fatigue score >= 7 were associated with worse mobility, daily activity, pain/discomfort, and depression/anxiety EQ-5D scores (*P* < 0.001) (Figure 1). Moderate correlations were detected between fatigue and EQ-5D TTO values (*rho* = -0.397, *P* < 0.001) and the EQ-5D VAS score (*rho*= -0.311, *P* < 0.001).

Conclusion: In Korean patients with PSS, younger age, xerostomia, and pain were all found to increase the risk of fatigue, and fatigue was significantly associated with HRQOL.

Table 1. Stepwise multiple regression models of ESSPRI fatigue score and its predictors

Variables	Estimate (SE)	Standardized estimate (¥â)	p-value	R^2
ESSPRI pain	0.377 (0.053)	0.435	<0.001	0.205
Xerostomia Inventory	0.045 (0.018)	0.164	0.003	0.238
Age	-0.039 (0.013)	-0.177	0.002	0.272
Ocular Surface Dryness Index	0.013 (0.007)	0.123	0.053	0.305
Intercept	6.730 (1.412)	0	<0.001

Session Title: Sjögren's Syndrome Poster I: Clinical Insights into Sjögren's Syndrome

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Fatigue is frequently reported as an important symptom in need of management by patients with Primary Sjögren's Syndrome (SS) [1-3]. It can be severe, having a major effect on quality of life, but many patients report that their fatigue is not always well managed [3, 4]. Furthermore, PSS patients often present with complex multiple co-morbidities, but, until now no analysis of assignable causes of fatigue has been attempted in this patient group. This study attempts to identify the aetiology of fatigue in a large cohort of PSS patients.

Methods:

We studied fatigue in 795 PSS patients from the UK Primary Sjögren's Syndrome Registry. All patients met the American-European Consensus Group criteria [5] for PSS. The objective of the study was to identify assignable causes of fatigue in PSS patients. The following conditions were considered potentially treatable conditions that can cause fatigue independent of PSS: thyroid disease, diabetes mellitus, celiac disease, significant anaemia (Hb<10), and depression. Medications that can cause drowsiness (e.g. antipsychotics) were also included in the analysis.

Results:

43% (n=340) of patients had assignable cause(s) other than PSS for their fatigue. Of these, 50% (n=172) had hypothyroidism or abnormal TSH, 8% (n=28) had depression, 6% (n=20) had celiac disease, 6% (n=20) had non-insulin-dependent-diabetes, 2% (n=7) had insulin-dependent-diabetes, and 2% (n=7) had significant anaemia. Concurrent medications ranged from 0-26 with 50% (n=169) of the cohort with an assignable cause for their fatigue taking medications that can cause drowsiness. 78% (n=266) of these patients had 1 assignable cause for their fatigue apart from SS, 19% (n=64) had 2 assignable causes and 3% (n=10) had 3.

Having said this, the fatigue in the majority of patients in this study cohort was unassignable (57%, n=455). There were few other tangible differences between those with an assignable cause for their fatigue to those without. The number of pSS medications prescribed ranged from 0-8, with 56% (n=444) of the total cohort taking at least 1 medication. 601 patients from the entire cohort (n=795) were classed as having "abnormal fatigue" (score of >2 on the profile of fatigue score), of those with an assignable cause for their fatigue 82% (n=279) had "abnormal fatigue" compared to 71% (n=322) patients whose cause of fatigue is unknown. Physical fatigue was ranked as the first or second most important symptom in need of improvement by 71% (n=243) patients with an assignable cause for their fatigue and 69% (n=316) in those without an assignable cause for their fatigue.

Conclusion:

Overall, 70% of PSS patients rate their fatigue as one of the most important symptoms needing improvement demonstrating the need for fatigue management. A significant proportion (43%) of PSS patients have assignable causes for fatigue other than PSS. Fatigue management is critical to patients with PSS, therefore, screening for and appropriate management of any other assignable causes of patients' fatigue is important. However, the majority of PSS patients with fatigue have no obvious assignable causes, further investigation into the biological basis of fatigue in PSS is necessary.

Session Title: Sjögren's Syndrome Poster I: Clinical Insights into Sjögren's Syndrome
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

We undertook this study to describe the racial and ethnic diversity of SS compared to that found among patients with SLE. SLE is known to be more common and severe in Black Americans than White Americans, and related to SS in regard to clinical manifestations and serological findings.

Methods:

Individuals with sicca were evaluated by a rheumatologist, ophthalmologist and a dentist in our Sjögren's syndrome research clinic. Detailed history and physical examination with stimulated and timed whole unstimulated salivary flow (WUSF) and a lip biopsy along with collection and storage of saliva, ocular surface staining with Lissamine green and fluorescein, an unanaesthetised Schirmer's test, collection and storage of tears as well as general laboratory tests were performed. Subjects were classified using ACEG and ACR criteria for primary SS (pSS). We compared the non-Hispanic Black pSS subjects to the non-Hispanic White pSS subjects with one to four age and sex match in terms of clinical manifestations, focus score, WUSF, Schirmer's, Lissamine green, anti-Ro (or SSA) and anti-La (or SSB) antibody positivity. We also compared the study group with subjects with non-Sjogren's Sicca (nSS) and those in a SLE cohort followed in the same facility. P values were corrected for multiple comparisons. Due to low representation of other ethnic groups in our study population we only considered non-Hispanic Blacks and non-Hispanic Whites in the study.

Results:

We classified 327 subjects in the clinic as pSS of which 201 were considered for the study. Among these 187 (92.1%) were self-identified as White, while only 14 (6.9%) were self-identified as Black. There were 7 (3.05%) Blacks and 223 (96.95%) whites in nSS group. Among the SLE subjects, there were 106 (29.5%) Black and 253(61.5%) as White. Thus, we found that black Americans were 5 times more likely to have SLE compared to pSS (χ^2=36.17, p <0.00001, OR=5.45), while there was no such difference when compared to subjects with nSS (control group)(χ^2=2.76,p=0.0966,OR=0.41). We next compared the clinical manifestations found in Black and White subjects with pSS. Concerning the classification criteria, we found no statistical difference for positive versus negative results. We also evaluated pSS subjects for systemic manifestations. Black subjects with pSS were found to have higher incidence of hypergamaglobulinemia-IgG type ($p=4.98\times10^{-7}$ by Fisher's Exact test) than corresponding Whites. There were no statistically significant differences in other extra-glandular clinical or laboratory findings.

Conclusion: In contrast to SLE, where the disease risk and severity are known to be greater in Black Americans as compared to Whites, pSS shows no such predilection.

Session Title: Sjögren's Syndrome Poster I: Clinical Insights into Sjögren's Syndrome

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Studies from our and other laboratories have shown that clinical, laboratory and serological features at the first evaluation of a patient with primary Sjogren's syndrome (pSS), can predict non-Hodgkin lymphoma (NHL) development in the future. In this study, we aimed to create a predictive model for NHL development, based on risk factors found at a routine clinical, serological and histopathological evaluation.

Methods: In the present retrospective case control study, clinical, serological and histopathological variables at the time of SS diagnosis (based on revised European/American classification criteria) were recorded in 381 pSS patients and 92 pSS patients complicated by NHL, after thorough chart review. For the identification of predictors for NHL development multivariate logistic regression models were constructed. The probability for NHL development was estimated, by adding the observed risk factors consecutively, one to the other.

Results: Clinical, serological and histopathological manifestations at the time of SS diagnosis, including salivary gland enlargement (SGE), palpable purpura, peripheral neuropathy, Raynaud's phenomenon, lymphadenopathy, the presence of autoantibodies against Ro/SSA and/or La/SSB antigens, rheumatoid factor (RF) positivity, low C4 complement levels, cryoglobulinemia, monoclonal gammopathy and Tarpley score ≥ 3 in minor salivary gland biopsy, were shown as independent predictors for lymphoma development (Table 1). The probability for NHL development in pSS patients, depending on the presence of the above mentioned risk factors, was 25.5% [OR (95%CI): 4.44 (2.07-7.50), p<0.0001] for patients carrying anti-Ro/anti-La antibodies, 39.4% [OR (95%CI): 3.61 (2.10-6.25), p<0.0001] for those having in addition to autoantibodies a Tarpley score ≥ 3, 54.7% [OR (95%CI): 5.93 (3.15-11.16), p<0.0001], for those having in addition to the above risk factors SGE, 72.7% [OR (95%CI): 9.16 (2.36-35.58), p=0.001] for those having also a monoclonal gammopathy and 80% [OR (95%CI): 13.03 (1.43-118.61), p=0.01] for those having additionally lymphadenopathy. This probability reached 100%, if in the latter subset of risk factors any of the remaining found risk factors was added. When ROC curves for the predictive model were fitted, the area under the curve (AUC) was 0.86, 95%CI: 0.81-0.90, p<0.0001.

Conclusion: This work showed that if more than five (anti-Ro/La antibodies positivity, Tarpley score ≥ 3, SGE, monoclonal gammopathy and lymphadenopathy) of the observed adverse predictors are present at the first evaluation of a pSS patient, the probability for lymphoma development is 100%.

Table 1. Independent adverse predictors for SS related NHL development, identified by multivariate analysis.

	Independent risk factors	OR [95%CI]	p-value
Clinical	SGE	5.27 [3.07-9.04]	<0.0001
	Lymphadenopathy	4.45 [2.45-8.11]	<0.0001
	Raynaud's phenomenon	1.64 [0.92-2.92]	0.09
	Palpable purpura	3.31 [1.79-6.08]	<0.0001
	PNS involvement	3.02 [0.87-10.49]	0.08
Serological	Monoclonal gammopathy	4.76 [1.63-13.92]	0.004
	RF positivity (>20IU/ml)	3.36 [1.54-7.34]	0.002
	Anti-Ro/SSA or/and anti-La/SSB positivity	7.50 [2.21-25.52]	0.001
	Low C4 levels (< 20 mg/dl)	2.94 [1.46-5.91]	0.002
	Cryoglobulinemia	2.71 [1.16-6.32]	0.02
Histopathological	Tarpley score ≥ 3 in MSG biopsy	5.84 [2.73-12.47]	<0.0001

SS: Sjogren's syndrome, SGE: salivary gland enlargement, NHL: non-Hodgkin's lymphoma, PNS: peripheral nervous system, RF: rheumatoid factor, MSG: minor salivary gland

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Sjögren's Syndrome Poster I: Clinical Insights into Sjögren's Syndrome
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Different studies showed that systemic inflammation, elevated levels of inflammatory cytokines and immune dysregulation, typical of the inflammatory autoimmune disease, play a role in accelerated atherosclerosis. However, only few studies focused on sub-clinical cardiovascular (CV) involvement in patients with primary Sjögren's syndrome (pSS) are available (1). Aim of our study was to investigate sub-clinical CV involvement in pSS patients by means of carotid stiffness, asymmetric dimethyl arginine (ADMA) plasma levels, intima-media thickness (cIMT) and coronary flow reserve (CFR).

Methods:

Fifty-three consecutive outpatients with pSS (7 M, 46 F; mean age 59.8 yrs, range 43-80 yrs; mean disease duration of 59.5 months, range 6-156 months) without classical CV risk factors and/or known CV diseases, and 22 matched healthy controls were enrolled. MyLab 60 machine (Esaote,Italy) with radio frequency technology for evaluating quality intima media thickness (RF-QIMT) and quality arterial stiffness (RF-QAS) was used to assess cIMT and pulse wave velocity (PWV), respectively. Dipyridamole transthoracic stress echocardiography was performed by IE33 (Philips Medical Systems, USA) in order to obtain CFR values. Plasma ADMA levels, inflammatory markers and autoantibodies were also evaluated.

Results:

pSS group was matched with control in terms of age (59.8±8.5 vs 59.25±2.08 yrs, p=0.14), sex (46F, 7M vs 16F, 6M, p=0.8), BMI (25.5±3.3 vs 23.69±1.12. p=0.17) and blood pressure values (126.66±13.4 vs 125.61±12.48, p=0.59 and 79.4±4.6 vs 80.45±8.25. p=0.32). Serum levels of CRP (3.72±2.89 Vs 0.41±0.09 mg/L, p<0.0001), ESR (30.25±20.2 Vs 4.8±0.24, p<0.0001) and, although within the normal range, total cholesterol (182.77±7.12 Vs 163.33±5.59, p<0.001) were significantly lower in the control group. PWV and ADMA plasma levels, as markers of subclinical atherosclerosis and endothelial dysfunction respectively, were significantly higher (9.2±1.8m/s vs 6.8±0.9m/s. p<0.0001 and 0.76±0.07 vs 0.54±0.05 μM, p<0.0001) in pSS group. QIMT values were similar in the two groups; however, the percentage of pSS patients with abnormal value was higher compared with controls (47/53 vs 12/22, p=0.001). Although within the normal range, CFR values in pSS patients were lower than in controls (2.6±0.23 vs 3.2±0.32 p<0.0001).

Conclusion:

Higher ADMA levels, higher PWV values, higher percentage of patients with pathological Q-IMT and normal CFR values, suggested that pSS patients compared to healthy controls suffer from early endothelial dysfunction and sub-clinical atherosclerosis.

Session Title: Sjögren's Syndrome Poster I: Clinical Insights into Sjögren's Syndrome

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The histopathological hallmark and a major diagnostic criterion of Sjögren's syndrome (SS) is the presence of periductal lymphocytic infiltrates in the labial minor salivary glands (LMSG). SS can occur either as an entity alone (primary SS-pSS) or with rheumatoid arthritis (RA) and other autoimmune diseases. Sicca symptoms (primarily ocular) are observed in around 20-25% of RA patients. The present study examines the LMSG infiltrates in sicca-RA patients and compares their composition with this described in pSS.

Methods: 100 consecutive RA patients (2010 ACR criteria) answer a validated sicca symptoms questionnaire. Positive responders were evaluated for ocular and oral dryness including a LMSG biopsy. All samples in addition to haematoxylin and eosin were stained for the immunocyte populations in serial sections [CD3: total T cells, CD4 and CD8: T cell subpopulations, CD20: B cells, CD68: macrophages (MΦ), S100 and fascin: interdigitating and follicular dendritic cells (DC)]. Stained cells and total mononuclear cells (MNC) were counted in the entire section. Counts were expressed as cell incidence (percentage of cell type number/total infiltrating MNC number).

Results:

44/100 RA patients responded positively for sicca symptoms. Their anthropometric and clinicoserologic characteristics are shown in Table 1. In total, 30 out of 100 RA patients had LMSG with a focus score ≥ 1. The immune cell composition in LMSG was found to differ from that of pSS [1] (Table 2): The incidence of DC and MΦ was higher, T cells were increased in severe lesions (ANOVA test, $p=0.03$) and DCs were inverse correlated with lesion severity (S100: $p= 0.0004$, $r=-0.56$; fascin: $p=0.08$, $r=-0.29$). In sicca-RA patients, MΦ and DC incidence correlated positively with the patients' RA score (ACR criteria) (CD68: $p<0.0001$, $r=0.65$; S100: $p=0.01$, $r=0.41$; fascin: $p=0.07$, $r=0.31$) and was higher in those who had biopsy focus score<1 and were anti-Ro negative [MΦ ($p=0.02$) and DC (S100: $p=0.002$; fascin: $p=0.001$)].

Conclusion:

The cell composition of the LMSG infiltrates of sicca-RA patients is different compared to that seen in biopsies of pSS patients. These differences, coupled with the known genetic and serologic dissimilarities may further attest for diverse pathophysiologic process operating in the genesis of these two entities.

Session Title: Sjögren's Syndrome Poster I: Clinical Insights into Sjögren's Syndrome

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Primary Sjögren's syndrome (pSS) is an autoimmune disease characterized by dysfunction of the exocrine glands. The frequency of neurological manifestations in pSS ranges from 0-70% depending on the inclusion criteria and diagnostic methods. Peripheral neuropathy (PN) is usually is a late onset event in primary Sjögren Syndrome associated with purpura, cryoglobulinemia, hypocomplementemia and increased risk of lymphoma. Objectives: To describe the frequency of PN in patients with pSS and identify related factors.

Methods: Adult patients in the GESSAR (Sjogren study group Argentina Society of Rheumatology) database who met 2002 criteria for pSS. Demographic, clinical, laboratory and electromyogram (EMG) findings were recorded. PN was defined with clinic manifestations and EMG. Other causes of PN were excluded. To compare groups, all patients with PN were included (cases) and a random sample of patients without PN (controls) with a 1:4 ratio was used. Mann-Whitney was used for numeric variables and X2 or Fisher's for categorical. An α of 0.05 was considered significant.

Results:

Of 368 patients, 95% were female. Mean age at analysis was 55 y/o (21-87) and 50 y/o (20-89) at diagnosis. The frequency of PN was 11.68% (43/368). Sensory PN was found in 63% (28/43), predominantly small fibers involvement in 41.8% (18/43), axonal PN in 20.9% (9/43) and ataxic in 2.3% (1 / 43). Somatosensory manifestations were found in 37% (16/43) with axonal involvement in 30.2% (13/43) and mononeuritis multiplex in 6.9% (3/43), none had autonomic PN. When comparing groups (43 vs 172 controls) patients with PN had a higher frequency of vasculitis (11.7% vs 1.7%;p=0.002), purpura (23.8% vs 4.7%,p=0.0001), renal tubular acidosis (7.6% vs 1.2%,p=0.020), leucopenia (30.7% vs. 12.1%,p=0.005), low C3 (48.5% vs. 10.3%, p=0.0001) and C4 (66.6% vs. 18.2%,p=0.0001), (+) Anti-Ro/SSA (85.3% vs. 66.6%,p=0.019), (+) RF (72.5% vs. 52.1%,p=0.022), cryoglobulinemia (42.1% vs. 10.9%,p=0.0001) and higher frequency of hypergammaglobulinemia (60.5% vs 44.6%,p=0.09), Raynaud's (27.5% vs 11.6%,p=0.051) and glomerulonephritis (4.6% vs 0.5%,p=0.018), although without statistical significance.

Conclusion:

The frequency of PN was 12%, similar to other cohorts. Small fibers and axonal somatosensory PN were the most common. PN was significantly associated with vasculitis, purpura, renal tubular acidosis, cryoglobulinemia, leucopenia, hypocomplementemia and anti-Ro and RF positivity.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Sjögren's Syndrome Poster I: Clinical Insights into Sjögren's Syndrome
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Primary Sjögren's syndrome (pSS) has a strong female bias of greater than 10 to 1. This difference in risk of disease between the sexes has not been explained. We hypothesize that the number of X chromosomes is important for this bias, and that examination of patients for rare X chromosome aneuploides will inform the sex bias for those with a normal chromosome complement.

Methods:

We evaluated the hypothesis of an X chromosome dose effect by analyzing the presence of 47,XXY (Klinefelter's syndrome, 1 in 500 live male births) among a large cohort of subjects with pSS. All subjects with pSS met the American-European Consensus Classification Criteria for Sjögren's syndrome. The presence of extranumerary X chromosomes was determined by examination of fluorescence intensity of single nucleotide polymorphisms from the X and Y chromosomes from either Illumina genome-wide association study platform or the ImmunoChip. Karyotype or fluorescent *in situ* hybridization confirmed some of these results.

Results: Among 126 pSS men, there were 4 with 47,XXY. This was significantly different from healthy controls (1 of 1254 had 47,XXY, p=0.0012 by Fisher's exact test) as well as when compared to men with rheumatoid arthritis and the expected population frequency, but not different from published results in men with systemic lupus erythematosus (SLE). Using Bayes' theorem along with the population prevalence of Sjögren's and Klinefelter's syndromes as well as the finding of ~1 in 30 Sjögren's men with 47,XXY, we calculate that men with Klinefelter's syndrome have a risk of pSS about equal to that of women.

Conclusion: Combined with our previous data that 3 of 1,033 SS women, but only in two of the 7,074 female controls, have 47,XXX, which is found in 1 in 1000 live female births (p=0.02, OR=10.29, 95% CI: 1.18-123.47), these results are consistent with the hypothesis that the number of X chromosomes is important for the sex bias of pSS.

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Psoriatic Arthritis Quality of Life (PsAQol), Ankylosing Spondylitis Quality of Life (ASQoL), and Dermatology Life Quality Index (DLQI) are tools that assess different aspects of health-related quality of life (HRQoL) in psoriatic arthritis (PsA). We aimed to determine if each of the three tools capture HRQL domains relevant to both skin and joints.

Methods:

Patients with PsA (physician diagnosed) completed PsAQoL, ASQoL, and DLQI in a 15-country longitudinal study [1] designed to develop new composite measure for PsA. We used Rasch analysis to determine the reliability and validity, including how well the tools targeted the skin and joint aspects of HRQoL.

We assessed the following: (i) fit to the Rasch model to determine different aspects of validity in PsA, (ii) person- separation index to determine internal consistency, (iii) differential item functioning (DIF) across five regions (Asia, Europe, N. America, S. America and the UK) to determine cross-cultural validity, and (iv) person-item threshold location maps to determine targeting of the tools to skin and joint aspects of HRQoL.

Results:

The sample comprised 503 patients (male/female = 286/217) with mean (SD) age, 50.8 (13.1), and PSA duration, 9.8 (9.9) years.

Expectations of the Rasch model were satisfied only in N America PsAQoL, UK ASQoL and both UK & N America DLQI datasets. Reliability was adequate and the measures were invariant to age and gender. There were not enough data in each country to reliably determine cross-cultural invariance, therefore targeting and discrimination properties of the tools were based on N. American dataset (Figure 1).

DLQI targeted better (than PsAQoL) articular and skin aspects of HRQoL. DLQI discriminated better HRQoL related to skin involvement (fig 1B and 1F) but not spinal involvement (fig 1D), where ASQoL was better at discriminating this aspect ($F(1,66) = 13.76$, $p<0.001$).

Figure 1. Targeting and discriminating properties of the tools

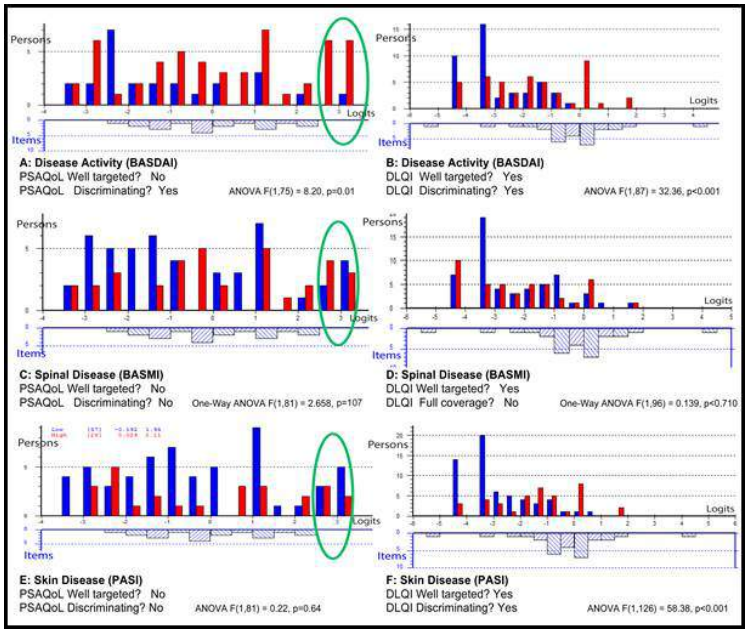

Figure legends: The left side of the plots represents low PSAQoL or QLQI scores (good HRQoL). The right side represents high scores (impaired HRQoL). The blue plots represent people with low/mild disease while the red plots those with severe disease. Significant ANOVA p-values suggest ability of the tool to discriminate between persons with low/high disease. Green circles mark persons with severe HRQoL not targeted by PsAQoL items.

Conclusion:

The data suggest that PsAQoL does not cover the full spectrum of HRQoL in psoriasis. Conversely, DLQI does not cover the full spectrum of HRQoL of articular disease in PsA. PsAQoL, (or ASQoL) and DLQI complement each other in capturing both joint and skin aspects of HRQoL. Confirmation of these findings is needed using larger datasets.

ASDAS-Based Remission Was Less Frequent Than Basdai-Based Remission, and Both Were Related to CRP and Smoking in Early Axial Spondyloarthritis

Daniel Wendling[1], Xavier Guillot[2], Laure Gossec[3], Clément Prati[4], Alain Saraux[5] and Maxime Dougados[6], [1]Université de Franche-Comté, Besançon, France, [2]Service de Rhumatologie, CHRU J Minjoz, Besançon, France, [3]Rheumatology, Pitié Salpetriere Hospital, Paris, France, [4]Service de Rhumatologie, CHU J Minjoz, Besancon, France, [5]Rheumatology Department, CHU de la Cavale Blanche, Brest Cedex, France, [6]Cochin University Hospital, Paris, France

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Remission is the final goal for treat to target strategy in axial spondyloarthritis (axSpA). No clear definition is currently recognized, but ASDAS-CRP inactive state or BASDAI threshold (1) have been proposed. The frequency of remission using these definitions and factors associated with remission are unknown in early axSpA.

Aim.

To evaluate the percentage of patients in remission in early AxSpA, comparing different definitions of remission, and to evaluate factors associated with remission at inclusion in the DESIR cohort and after 24 months.

Methods:

DESIR is a prospective observational cohort of patients with recent onset (less than 3 years) inflammatory back pain, beginning before 45 years, suggestive of axial SpA. For each of three definitionsof remission (ASAS partial remission (PR), ASDAS-CRP less than 1.3(ASDAS-R), BASDAI less than 3.6 (1)(BASDAI-R)), the ability to detect patients in remission according to the two other definitions was assessed using ROC curves and Areas Under the Curve (AUC). Data at baseline (M0) and M24 were analyzed, to look for factors (clinical, biological and imaging) associated with remission in uni and multivariate analysis by logistic regression.

Results:

706 patients were evaluated at M0 and 577 at M24. At M0, the percentage of patients in remission was 4% (PR), 8% (ASDAS) 34 % (BASDAI), and at M24 : 15%, 24% and 54% respectively, in the whole population and in Amor, ESSG and ASAS classified patients, but lower in mNY patients (data not shown). BASDAI less than 3.6 detected best patients in PR and ASDAS-R, with AUC of 0.84 and 0.86 respectively. In univariate analysis at M0, lower ESR and CRP, DKK-1, low BMI, male gender, absence of psoriasis, less smoking, HLA-B27 positivity, ASAS criteria fulfillment, positive sacro iliac imaging, less analgesics use and less subsequent use of anti TNF at M24 were associated with remission (ASDAS-R, BASDAI-R). No association was found with age, disease duration, enthesitis, uveitis, IBD, NSAID use, mSASSS. In multivariate analysis, remission was associated with lower ESR, less smoking, use of analgesics. At M24, low ESR and CRP, female gender, less smoking, less NSAID use , lower NSAID score, ASAS criteria fulfillment, lower biologics use and lower systemic steroid use were associated with

remission in univariate analysis. In multivariate analysis, remission was associated with less smoking, less analgesics, ASAS clinical arm fulfillment, less NSAIDs (ASDAS-R), low CRP(ASDAS-R), low BMI(BASDAI-R).

Remission	ASDAS-R ASDAS < 1.3	r,p	BASDAI-R BASDAI<3.6	r,p
M0 N=706	CRP Smoking Analgesics	-0.59 *** -1.5 ** 1.55 ***	ESR Smoking Analgesics	-0.04 * -0.93 * 1.39 **
M24 N=577	CRP Smoking ASDAS clinical NSAIDs Analgesics	-0.6 *** -1.08 * 1.76 * -1.4 ** -2.02 ***	BMI Smoking ASAS clinical Analgesics	-0.14 ** -1.16 ** 1.28 * -1.74 ***

Results of multivariate analysis; r : regression coefficient , *p<0.05 ; **p<0.001; ***p<0.0001

Conclusion:

In this population suggestive of early SpA, BASDAI less than 3.6 seems a fair assessment of remission. As expected, acute phase reactants and analgesics were associated with remission at baseline and M24, but smoking appears as a major marker of disease activity and remission in early AxSpA.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Minimal disease activity (MDA)[1] is a clinically meaningful and comprehensive treatment target for psoriatic arthritis (PsA). The purpose was to determine if baseline (BL) disease activity and/or patient (pt) demographics predict the ability to achieve MDA at weeks (wks) 12 through 144 in pts with PsA, and to evaluate patient-reported outcomes (PROs) at wk 24 and 144 associated with achieving MDA.

Methods: Data was from the ADEPT trial, where PsA pts were randomized to adalimumab or placebo for 24 wks, followed by an open-label (OL) period out to 144 wks. In this post-hoc analysis, BL characteristics which predicted achievement of MDA at wk 12, 24, 48, 96 and 144

were identified by univariate (UV) and multivariate (MV) analyses (LASSO). A more stringent assessment was made for correlation with sustained MDA (defined as MDA achievement at 2 time points, 12 wks apart). Continuous variables were age, weight, modified total Sharp score (mTSS), tender/swollen joint count (T/SJC), Pt Global Assessment of disease activity (PtGA) or pain (PtGA-pain), Physician's Global assessment of disease activity (PhGA), HAQ, enthesitis (2 sites), Psoriasis Area Severity Index (PASI) and Physician's Global Assessment of Psoriasis (PhGA-Psoriasis). Categorical variables were gender, smoking, alcohol use, methotrexate use, investigator-reported spondylitis, CRP (<2.87 vs ≥2.87), duration of psoriasis/ PsA (< 5 or ≥5 years). Pts achieving MDA were termed achievers and those who did not, non-achievers (NA). Quality of life (QoL) - related PROs assessed at wks 24 (and for completers at wk144), were Dermatology Life Quality Index (DLQI), SF-36, and Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F) score.

Results:

The numbers of MDA achievers vs NA were as follows: 18.9% vs 81.1% (wk 12, N=127); 21.6% vs 78.4 (wk 24, N=125); 40.5% vs 59.5% (wk 48, N=116); 38.5% vs 61.5% (wk 96, N=104); 43.2% vs 56.8% (wk 144, N=88). In the UV analysis, lower PtGA-pain, TJC, SJC, enthesitis and HAQ at BL were associated with MDA at later time points. Sustained MDA at all/most time points was associated with lower TJC, SJC, HAQ and enthesitis at BL. MV analysis confirmed BL HAQ as a significant limiting factor for achieving MDA at later time points. A one unit increase in BL HAQ reduced the odds of achieving MDA at later time points by 64-77%. Lower age, TJC and HAQ at BL were associated with sustained MDA at wk 48; lower BL enthesitis with sustained MDA at wk 144. At week 24, MDA achievers demonstrated significantly better scores for QoL-related PROs compared to NA[2]; for pts completing 144 weeks, no significant differences in PRO scores were observed.

Conclusion: Lower scores at BL for HAQ increased the likelihood of MDA at later time points. Lower age and impairment at BL, as measured by TJC, HAQ and enthesitis increased the likelihood of reaching sustained MDA, suggesting the importance of early intervention. MDA achievers had significantly improved QoL compared to NA at wk 24; however, among pts completing 144 weeks, these differences were not evident.

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

The performance of different classification criteria sets for spondyloarthritis in the ASAS-COMOSPA study

Background/Purpose: Spondyloarthritis (SpA) includes patients with (predominantly) axial spondyloarthritis (axSpA) and patients with (predominantly) peripheral spondyloarthritis (pSpA) including psoriatic arthritis (PsA). Over time, several classification criteria sets have been developed to cover the whole spectrum of SpA. However, the performance of the different classification criteria sets has been insufficiently

evaluated. By this study we aim to compare the performance of different SpA classification criteria sets in the worldwide ASAS-COMOSPA study.

Methods: The ASAS-COMOSPA study is an international, cross-sectional study. Patients clinically diagnosed with SpA by the rheumatologist were included consecutively via routine care. For this analysis, patients were classified according to the ESSG, AMOR, mESSG (addition of MRI), mAMOR (addition of MRI), CASPAR and ASAS criteria for axSpA and pSpA.

Results: From 5 continents, 22 participating countries included 3984 patients: age 44 ± 14 years, 65% male gender, 56.2% HLA-B27+, psoriasis: 21.4%, uveitis: 19.6%, peripheral arthritis: 61.5%, mNY+ 64.4%, sacroiliitis on MRI (ASAS definition): 33.6%, negative rheumatoid factor (RF): 80.6%. Patients with up to 6 missing values were included (missing values set as absent); patients with ≥7 variables missing were left out of the analysis. Most common missing variables: MRI of the sacroiliac joints (ASAS definition; MRI-SI) (n=1951), juxta-articular bone formation (n=999), HLA-B27 (n=907), good response to NSAIDs (n=803), RF (n=613), radiographic sacroiliitis (n=341). Patients were classified according to the different classification criteria sets (table): data shown for all patients (left) and for patients with complete data regarding presence/absence of (radiographic/MRI) sacroiliitis and HLA-B27 (right). In addition, the overlap between the different classification criteria sets was assessed for patients with back pain and patients without back pain. The majority (of the patients) was classified by AMOR & ESSG & ASAS axSpA-criteria (n=1068). Most of the patients that were picked up by 1 criteria set only were classified by the ASAS axSpA-criteria (n=141; n=27 by AMOR and n=25 by ESSG). Similar trends were seen with regard to the mESSG and mAMOR-criteria. Regarding the patients with no back pain (peripheral complaints): again substantial overlap between the criteria was seen (ASAS pSpA, AMOR, ESSG, CASPAR).

Conclusion: In this worldwide ASAS-COMOSPA study including established patients with SpA according to the rheumatologist, most patients fulfil several classification criteria sets; the biggest overlap between AMOR, ESSG and ASAS SpA. If patients fulfil only 1 criteria set this is most frequently the ASAS axSpA-criteria.

Classification criteria	**Number of patients fulfilling the criteria n (%)** All patients Total n = 3942	**Number of patients fulfilling** **the criteria n (%)** Patients with complete data regarding imaging and HLA-B27 Total n = 1693
AMOR	3282 (83.3%)	1338 (79.0%)

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Axial spondyloarthritis (axSpA) includes ankylosing spondylitis (AS) and non-radiographic axSpA (nr-axSpA).[1] AS significantly affects patient (pt) workplace productivity in both performance and disease-related absenteeism.[2] The impact of nr-axSpA on productivity is less well characterized. Few studies investigate associations between improvements in workplace and household productivity and symptom relief with available therapies in axSpA. Here we evaluate the association between improvements in clinical and pt-reported outcomes (PROs) and improvements in productivity in the workplace and at home in axSpA pts treated with certolizumab pegol (CZP), including AS and nr-axSpA pts.

Methods:

Associations between clinical outcomes or PROs and work and household productivity were made using Week (Wk) 24 data from the double-blind and placebo-controlled period of RAPID-axSpA (NCT01087762),[3] for pts originally randomized to CZP. Clinical outcomes included achievement of ASAS40 and ASDAS Major Improvement (MI). PROs included achievement of MCID for BASFI (≥1 decrease from baseline [BL]), total back pain (≥1 decrease from BL) and ASQoL (≥2 decrease from BL). Responders and non-responders at Wk24 were compared in terms of change from BL (CFB) in workplace and household productivity, as assessed using the validated arthritis-specific Work Productivity Survey.[4] Groups were compared using a non-parametric bootstrap-t method. Missing data were imputed using LOCF for WPS outcomes and NRI for clinical outcomes and PROs.

Results:

218 CZP pts entering RAPID-axSpA were included in Wk24 analyses (121 AS; 97 nr-axSpA). Pts employed at Wk24: 73.9% axSpA; 73.6% AS; 74.2% nr-axSpA. Overall, pts achieving a clinical or PRO response at Wk24 reported greater improvements in workplace and household productivity than non-responders (Table). Improvements in ASQoL and clinically meaningful reductions in functional limitation and pain were associated with improved workplace absenteeism and presenteeism. Similar results were seen in both AS and nr-axSpA pts. Numerically greater CFB was seen in nr-axSpA pts, potentially due to a slightly higher BL productivity burden in nr-axSpA vs AS.[5] Responders also reported greater improvements in participation in family, social and leisure activities (not shown). Results should be interpreted with caution, due to differences in pt number between groups and because analyses were not adjusted for differences in BL productivity.

Conclusion:

Clinical responses and clinically meaningful improvements in PROs are associated with improved workplace and household productivity in axSpA pts treated with CZP, including both AS and nr-axSpA pts.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Patients (pts) with psoriatic arthritis (PsA) report poorer health-related quality of life (HRQoL) compared to the general population. As with psoriasis (PSO), it is expected that HRQoL may be worse in PsA pts with skin manifestations affecting visible body areas. Previous reports of RAPID-PsA (NCT01087788) demonstrated improvements in clinical outcomes and HRQoL in PsA pts treated with certolizumab pegol (CZP) over 96 weeks (wks).[1] Here we report improvements in skin outcomes by body area affected and investigate associations with HRQoL.

Methods:

RAPID-PsA was double-blind and placebo (PBO)-controlled to Wk24, dose-blind to Wk48 and open-label to Wk216. Pts had active PsA and failed ≥1 DMARD. Pts were randomized at baseline (BL) to PBO or CZP. Primary clinical endpoint (Wk12 ACR20 response) was reported previously.[2] Skin outcomes are presented for Wk0 CZP-randomized pts with ≥3% PSO body surface area (BSA) at BL. PASI scores are presented by body region. Spearman correlations are calculated to assess BL associations between Dermatology Life Quality Index (DLQI) and PASI in all pts with ≥3% PSO BSA at BL. Absence of PSO was defined as PASI=0 by body region and summarized separately by PsA subgroups with/without respective body region PSO at BL. Observed data are shown.

Results:

Of 409 pts randomized, 273 received CZP from Wk0 (166 [60.8%] had ≥3% BSA at BL; mean BL PASI 12.0). RAPID-PsA primary endpoint was met (ACR20 [NRI]: 58.0%, 51.9% vs 24.3%; for CZP 200 mg Q2W, 400 mg Q4W vs PBO). HRQoL improvements to Wk24, assessed by HAQ-DI, were maintained to Wk96 (mean change from BL HAQ-DI [SD]: -0.5 [0.6] at Wk24; -0.6 [0.6] at Wk96).

Improvements in mean PASI body region scores were observed to Wk96 of CZP treatment (mean PASI body region scores at BL vs Wk96 were: Head: 12.0 vs 1.7; Upper extremities: 12.2 vs 1.9; Trunk: 10.8 vs 1.4; Lower extremities: 12.9 vs 2.4).

A moderate, positive correlation was observed at BL between DLQI and total PASI score (r=0.50) and in the PASI body regions of upper extremities, trunk and lower extremities (range, r=0.43–0.50), and a weak, positive correlation was shown between DLQI and PASI head (r=0.28). Correlations between changes in PASI and DLQI to Wk24 were similar to BL correlations.

Over 40% of pts with body region PSO at BL achieved absence of PSO at Wk24; by Wk96, this increased in all regions and was as high as 79% (Table). Overall, only 9 pts without body region PSO at BL developed PSO in that region.

Conclusion:

Improvements in all PASI body region scores were observed in PsA pts following 96 wks of CZP treatment. DLQI had moderate positive correlations with all PASI body regions apart from the head (weakly correlated). At Wk96, absence of body region PSO was attained in at least half of pts with PSO of the respective body region at BL.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

The Hospital Anxiety and Depression Scale (HADs) is a generic measure of psychological status comprising anxiety and depression subscales. The aim of this study was to assess the psychometric properties of HADs in psoriatic arthritis (PsA), to calibrate the scale, and to provide interval-level scale for use in parametric analyses when required.

Methods:

We used HADS data from patients with PsA recruited in PRESTA trial. [1] The data was subjected to Rasch analysis to determine fit to the Rasch model (implying construct validity and unidimensionality), reliability and targeting in subjects with PsA.

Results:

The number of evaluable subjects was 740 at baseline, 701 at week 12, and 653 at week 24. Both the anxiety subscale and the depression subscale satisfied the expectation of the Rasch model (table 1). The overall scale was shown to fit the Rasch model (item-by-severity interaction Chi-Square = 15.878, p = 0.601) and had excellent reliability (person separation index = 0.888). Validity and reliability of HADS were confirmed at baseline and both follow-up visits.

Figure 1 presents person location relative to all items (logarithmically transformed scores) along the same scale (logits). The top plot representing 'persons severity'; those with higher scores (impaired psychological status) on the right of the scale and those with lower scores (better psychological status) on the left. The bottom plot presents relative 'difficulty' of the items. HADS appears to be well targeted across all 'severity' levels, providing for calibration of the scale by transforming raw scores into interval-level (Rasch-transformed) scores.

Conclusion:

The validity and reliability of the HADS are confirmed in PsA and continues to be a useful psychological status instrument to use in PsA clinical studies. Raw scores can be Rasch-transformed into interval scores for use alongside other outcomes in parametric analyses.

Table 1. Fit Statistics for the Anxiety and Depression Subscales in PsA (Baseline).

Subscale	Location	SE	Item Fit Residuals	Chi-Square	DF	p-value
Anxiety	-0.120	0.021	-0.074	6.494	9	0.690
Depression	0.120	0.022	0.356	9.384	9	0.403

SE, Standard error; DF, Degrees of freedom, Non-significant p-value for Chi-Square suggests fit to Rasch model

Figure 1. Person-item Threshold Distribution Showing Targeting of the HADS (Baseline Data)

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The Psoriatic Arthritis Impact of Disease (PsAID) PRO measure was developed for clinical trials (9 item) and routine care (12 item) in Psoriatic arthritis (PsA) in multiple languages including Turkish. PsAID12 items (pain, fatigue, skin, work/leisure, function, discomfort, sleep, coping, anxiety, embarrassment, social life, depression) are 11 point numerical rating scales from 0 none/very well to 10 extreme/very poorly. PSAID12≤4 is considered patient acceptable symptom state. The performance of PsAID12 has not been reported to date in an independent PsA cohort.

Methods: Hacettepe University Rheumatology Biological database is a single center registry of 2700 patients with inflammatory arthritis (including PsA) on biologicals followed longitudinally. We collect demographics, clinical characteristics, 28 tender/swollen joint counts, CRP, health assessment questionnaire (HAQ), dermatology life quality index (DLQI), Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankylosing Spondylitis Functional Index (BASFI), 100mm visual analog scales (VAS) for patient global assessment (PtGA), fatigue and pain. At the baseline visit we calculated: Spearman correlation coefficient of PSAID12 with measures of disease activity, function, quality of life and symptoms; and kappa statistic for agreement of PSAID12>4 with DAS28>2.6 and BASDAI>4.

Results: There were 163 PsA patients 66.3% female, 27.6% axial disease, mean(SD) (yrs) age 44.8(11.8), duration of PsA 10.3(7.3) and psoriasis 16.8(8.7). Mean(SD) scores were PsAID12 4.1(2.5), DAS28 3.04(1.41) and BASDAI 3.9(2.2). A PsAID12 score >4 (52.8% patients) was associated with female (59% vs 40%, p=0.020), BMI>30 (66.6% vs 43.5%, p=0.005), diabetes (80.0% vs 50.0%, p=0.027), hypertension (70.0% vs 48.8%, p=0.036), no axial disease (57.6% vs 40.0%, p=0.044). Correlations between measures are presented in Table. PsAID12>4 agreement with DAS28>2.6 was kappa=0.53 (95%CI 0.38-0.67) and with BASDAI>4 was kappa=0.60 (95%CI 0.48-0.73).

Conclusion: In this group of PsA patients, PSAID12 had moderate-high correlation with PROs reflecting PsA symptoms, functional impairment and quality of life, but not with CRP. PSAID12had moderate-high agreement with PsA disease activity as measured by DAS28 and BASDAI. Our data support convergent construct validity of PsAID12 in an independent PsA cohort. Additional evaluations of longitudinal construct validity and responsiveness are needed.

Table : Correlation coefficients of PsAID12 with disease activity and PsA outcome measures

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

PQoL-12 is a validated composite tool (range: 0–120) assessing patients' quality of life in PsO and PsA. RAPID3 is another validated composite index (range: 0–10) measuring physical function, pain and patient global assessment in rheumatoid arthritis and ankylosing spondylitis, but not in PsO/PsA. If RAPID3 could be used to assess PsO/PsA patients' quality of life, it may save time in busy practices. This study investigates the correlation between PQoL-12 and RAPID3 in PsO and PsA patients, and also the cut-off values for RAPID3 that correlate best with PQoL-12 of 48 (mild) and 96 (moderate QoL impairment).

Methods:

Data from PsO and PsA patients seen from 2008 onwards in the Center of Excellence in Psoriasis and Psoriatic Arthritis clinic at Oregon Health & Science University were used (N= 555, 390 with PsO, 165 with PsA). Nonlinear least squares regressions modeled PQoL-12 with functions of RAPID3 while controlling for time since first visit. Nonparametric ROC analysis determined RAPID3 scores best correlating with PQoL-12 cut-

offs.

Results:

Baseline mean age was 46.7(12.8) and 45.9(12.8) years for PsO and PsA. The M:F ratio was 3:2 and 1:1 for PsO and PsA. Mean disease duration was 0.93(1.08) and 1.11(1.20) years for PsO and PsA. Baseline mean PQoL-12 was 65.8 (29.5) and 75.2 (29.2), and RAPID3 was 2.4 (2.01) and 3.7 (2.4) for PsO and PsA. For PsO, PQoL-12 was explained by RAPID3 (b = 16.6; s.e.= 1.63), RAPID3^2(b = -1.22 ; s.e. = 0.0701), time since first visit (b = -0.00211 ; s.e.= 0.00467), and a saturation (q = 281; s.e. = 116) of time since first visit^2 (b = 0.000211; s.e.= 0.000174) with adjusted R^2=0.414 (figure 1). For PsA, PQoL-12 was explained by RAPID3 (b =12.9; s.e.= 2.99), change (q = 2.28; s.e. = 81.5) in slope of RAPID3 (b =-7.39 ; s.e.=3.38), time since first visit (b = -0.00172 ; s.e.= 0.00685), and a saturation (q = 223; s.e. = 116) of time since first visit^2 (b =0.000417; s.e.= 0.000388=4) with adjusted R^2=0.340 (figure2). RAPID3 cut-offs for PQoL–12 scores of 48 and 96 in PsO were 1.38 and 7.22 (71.2% and 88.4% correctly classified) and in PsA were 2.06 and 6.61 (70.4% and 89.0% correctly classified).

Conclusion:

RAPID3 correlates poorly with PQoL-12. These indices assess different aspects of PsO and PsA, and provide distinct and important information regarding the patients' diseases.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is a complex inflammatory disease with variable phenotype affecting skin, joints, ligaments/tendons, nails, and the spine. Heterogeneity of clinical manifestations complicates PsA assessment and broadens its impact (1). PsA activity is a difficult concept to measure since outcome measures in use do not systematically cover health areas prioritized by patients (2). The experience of PsA from the perspective of patients, while essential for choosing outcome measures, is not known.

Methods: Patients with PsA meeting CASPAR criteria followed longitudinally in an academic clinic were recruited after informed consent. Focus groups (FG) and individual interviews were conducted using a semi-structured guide on the following topics: 1) presence of PsA in daily life; 2) life changes since diagnosis; 3) PsA activity. Qualitative data were analyzed by 3 researchers (1 physician, 1 medical anthropologist, 1 sociologist) using inductive thematic analysis and discussions to achieve consensus.

Results: Data were analyzed from 8 participants in 2FGs and 25 participants in individual interviews. Demographics and clinical characteristics are described in Table and represent the range of PsA manifestations.

Several overarching themes and corresponding codes were identified: 1) Psoriatic disease state/symptoms; 2) Life impact; 3) Strategies to minimize life impact. A draft conceptual framework based upon the coding structure for the PsA experience is illustrated in Figure 1.

Conclusion: Participants described the PsA experience not only through symptoms but also through life impact and individual strategies to prevent/minimize impact on their life. Comprehensive PsA assessment may need to include measures for life impact and also for effectiveness of individual compensating strategies.

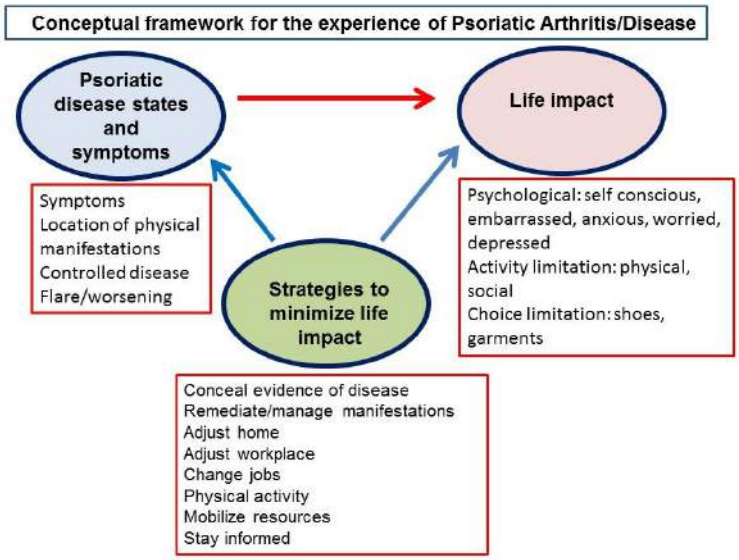

Figure 1. Conceptual framework for PsA experience elicited from qualitative research with participants with PsA.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The self-administered comorbidity questionnaire (SCQ) was developed to understand the impact of 13 common comorbidities on functioning and resource utilisation. In patients with ankylosing spondylitis, we recently showed that criterion- and construct validity of the SCQ was good, and improved after removing rheumatic items from the questionnaire (SpA-SCQ) (1). However, this modification (SpA-SCQ) does not address uveitis, psoriasis and inflammatory bowel disease, which are frequently occurring extra-articular manifestations (EAMs) in spondyloarthritis (SpA), and might have a relevant impact on disease specific and generic outcomes. The aim of the present study was to assess and compare criterion and construct validity of the SpA-SCQ and the SpA-SCQ with 3 items representing the EAMs ("SpA-SCQ-EAM").

Methods: Data from the CO-MOrbidities in SPA (COMOSPA) study, conducted in 22 countries, were used. We hypothesised that the criterion validity of the added EAM, assessed by agreement (kappa) between patients' self-reported and physicians' confirmed diagnoses of each of the three EAM, was good. For construct validity, we hypothesised that the SpA-SCQ-EAM would correlate moderate (r>0.30) and somewhat better (r-difference >0.05) than SpA-SCQ with demographics, physical function (BASFI), work-ability (WPAI) and health utility (EQ-5D),and that both would have low correlation with disease activity (ASDAS-CRP). We further hypothesized that the SpA-SCQ(-EAM) correlated better with these outcomes (but not disease activity) than the rheumatic disease comorbidity index (RDCI).

Results: 3,984 patients (age 43.6 (SD 13.9) years, 2,588 (65.0%) male, disease duration 8.2 (SD 9.3) years, of which 2,217/3,067 (72.4%) HLA-B27 positive) contributed to the analyses. The mean SpA-SCQ was 2.0 (SD 2.8) and the SpA-SCQ-EAM 2.8 (SD 3.3). The agreement between patient and physician diagnosed EAMs was substantial to almost perfect (uveitis κ=0.81, IBD κ=0.74, psoriasis κ=0.78), and was not systematically different across countries. Table 1 shows the correlations between the SpA-SCQ-(EAM) and outcomes, and makes clear that the hypothesis of a better correlation of the SpA-SCQ-EAM than SpA-SCQ with outcomes could not be confirmed. On the other hand, both the SpA-SCQ and the SpA-SCQ-EAM performed better with respect to the correlations with outcomes than the RDCI (Table 1). Similar results were found for patients with axial and 'pure' peripheral SpA.

Conclusion: EAMs can be reliably assessed through self-report by patients with SpA. Notwithstanding, adding the EAMs to the SpA-SCQ can improve the face validity of this questionnaire. Both the SpA-SCQ and SpA-SCQ-EAM correlated better with health outcomes than the RDCI in patients with (axial and peripheral) SpA.

Table 1: Construct Validity of the SpA-SCQ and the SpA-SCQ-EAM

	SpA-SCQ	SpA-SCQ-EAM	RDCI
SpA-SCQ	-	**0.95**	**0.59**

EQ-5D (French tariff)	**-0.33**	**-0.34**	**-0.20**

Bold: correlation coefficient significant

The SpA-SCQ was based on the following items: heart disease, hypertension, lung disease, diabetes, ulcer or other stomach disease, kidney disease, anaemia or other haematological disease, cancer, depression and fractures. For the SpA-SCQ-EAM we also included uveitis, inflammatory bowel disease and psoriasis. The RDCI was based on the information collected by the physician, only depression was based on the information from the patients.

SpA-SCQ, spondyloarthritis self-administered comorbidity questionnaire; EAM: extra-articular manifestations; RDCI, Rheumatic Disease Comorbidity Questionnaire; BMI, body mass index; ASDAS, Ankylosing Spondylitis Disease Activity Score; CRP, C-reactive protein; BASFI, Bath Ankylosing Spondylitis Functional Index; EQ-5D, EuroQoL index

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Although there are various Psoriatic arthritis (PsA) screening questionnaires, the most optimal screening instrument is not known. The objective of the present study was to evaluate the sensitivity and specificity the four psoriatic arthritis screening tools (TOPAS II, PASE, PEST and EARP) in diagnosing Psoriatic Arthritis in patients with Psoriasis with CASPAR as gold standard.

Methods:

This was a non-interventional, cross sectional study in which 302 patients diagnosed with PsO completed the Toronto Psoriatic Arthritis Screening Questionnaire (TOPAS II), Psoriatic Arthritis Screening And Evaluation (PASE), Psoriasis Epidemiology Screening Project (PEST) and Early Arthritis For Psoriasis Patients (EARP) prior to rheumatologic evaluation. The cutoff scores used in the original validation studies of these questionnaires were used to designate positive and negative cases. Sensitivities and specificities of these questionnaires were determined by comparing the score with the diagnosis made by the CASPAR criteria.

Results:

Out of 302 patients with PsO, 45 had PsA according to CASPAR criteria (14.9%). 27 patients had a TOPAS II score of ≥8 suggestive of PsA. The mean TOPAS II score of the PsO patients was 2.93±2.6 and that of PsA patients was 6.84±1.9. 36 patients had a PEST questionnaire score of ≥3 suggestive of PsA. The mean PEST score of the PsO patients was 0.86±1.24, that of PsA patients was 2.73±1.45. For calculation of PASE score, 2 cutoffs were used separately. 50 patients had a PASE questionnaire score of ≥44 (recommended in a validation study of PASE) suggestive of PsA. 47 patients a PASE score 47(used in development of PASE questionnaire). 72 patients had EARP questionnaire score of ≥3 suggestive of PsA. The mean EARP score of the PsO patients was 1.44±2.33 and that of PsA patients was 5.47±2.25.The sensitivities and specificities of EARP, $PASE_{44}$, $PASE_{47}$ PEST, and ToPAS II were 91.1%, 80%, 75.6%, 53.3%, 44.4% and 87.9%, 94.6%, 94.9%, 95.3% 97.3% respectively.

Conclusion: Out of the four screening questionnaires, EARP was most sensitivity while TOPAS II had least sensitivity. TOPASII had highest specificity while EARP had least specificity.

ASDAS Can be Reliably Calculated When Only the Patient's Overall Basdai Score Is Available, but Not the Score(S) of Its Individual Component(S)

Pinar Cetin[1], **Gokce Kenar**[1], Sedat Capar[2], Handan Yarkan[1], Berrin Zengin[1], Ismail Sari[1], Merih Birlik[1], Fatos Onen[1] and Nurullah Akkoc[3], [1]Rheumatology, Dokuz Eylul University Faculty of Medicine, Izmir, Turkey, [2]Dokuz Eylül University Faculty of Statistics, Izmir, Turkey, [3]Department of Rheumatology, Dokuz Eylul University, Faculty of Medicine, Izmir, Turkey

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: ASDAS is a composite measure of disease activity for ankylosing spondylitis (AS). Its calculation includes three BASDAI questions, BASDAI Q2 (back pain), Q3 (peripheral pain/swelling), and Q6 (morning stiffness), plus ESR or CRP, depending on the version. In many patients' clinical records, BASDAI total score is included but the scores of its individual components are missing. Our aim was to assess the validity of imputing missing BASDAI items from the overall BASDAI score in order to calculate the patient's ASDAS in such a clinical situation.

Methods: Patients with complete baseline data for ASDAS and BASDAI components were identified from our local AS database. Original ASDAS calculations were repeated by replacing each or all of the BASDAI items included in the formula with the overall BASDAI score. Kappa statistics was used to assess the agreement between the original and the imputed ASDAS scores, in classifying patients into different disease activity states (inactive, moderate, high and very high). The mean difference between scores was calculated. The analysis was completed with the *Bland–Altman* method.

Results: 403 patients with AS (age 44.4±11.8 years; 73.7% males) with a mean disease duration of 9.7±8.1 years were included in this analysis. Their mean (SD) BASDAI, ASDAS-CRP and ASDAS-ESR scores were 3.6 (2.3), 3.1 (1.1), and 3.1 (1.1), respectively. Kappa values ranged from 0.80 to 0.89 (weighted kappa values from 0.84 to 0.96), with lower limits of the 95%CI all over 0.75 in the different imputation schemes (Table 1). The largest mean difference between the original and the imputed scores was 0.17.

Conclusion: The close agreement between the original and the imputed ASDAS scores observed in this analysis support the validity of imputing missing BASDAI items from the overall BASDAI, when the score(s) of its individual component(s) are lacking.

Table 1. Agreement between the original ASDAS and imputed scores after replacing individual BASDAI item values with overall BASDAI scores

	Agreement level between the methods		**Limits of agreement between the methods***		
	Kappa value	**95% CI**	**Mean difference**	**Lower limit**	**Upper limit**
ASDAS CRP vs ASDAS CRP imputed for three BASDAI items	0.8	0.74 to 0.85	0.07	−0.4	0.53
ASDAS CRP vs ASDAS CRP imputed for BASDAI item 2	0.8	0.75 to 0.85	0.17	−0.25	0.59
ASDAS CRP vs ASDAS CRP imputed for BASDAI item 3	0.88	0.84 to 0.92	−0.09	−0.38	0.2
ASDAS CRP vs ASDAS CRP imputed for BASDAI item 6	0.83	0.78 to 0.88	−0.02	−0.02	0.26
ASDAS ESR vs ASDAS ESR imputed for three BASDAI items	0.88	0.84 to 0.92	−0.02	−0.47	0.43
ASDAS ESR vs ASDAS ESR imputed for BASDAI item 2	0.89	0.85 to 0.93	0.12	−0.16	0.4
ASDAS ESR vs ASDAS ESR imputed for BASDAI item 3	0.82	0.78 to 0.88	−0.12	−0.49	0.26
ASDAS ESR vs ASDAS ESR imputed for BASDAI item 6	0.88	0.84 to 0.93	−0.02	−0.34	0.31

Abstract Number: 662

Can the New Contest Questionnaire Identify Psoriatic Arthritis in a Primary Care Population?

Laura C Coates, Laura J Savage, Anna R. Moverley and Philip S. Helliwell, Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: There is a need for screening questionnaires to identify patients with psoriasis who have undiagnosed psoriatic arthritis but the optimal method is unknown. We developed the CONTEST questionnaires using the most discriminative items from 3 existing tools:

CONTEST consists of 8 yes/no items and CONTESTji the same items with the addition of a joint manikin. Our aim was to test the new proposed CONTEST questionnaires alongside the validated PEST questionnaire in a primary care setting.

Methods: Patients with psoriasis were identified from 5 GP surgeries in Yorkshire and a random sample were invited to participate in the study. Patients had to be over 18 years old, have a diagnosis of psoriasis and no diagnosis of PsA, RA or AS. Consenting patients were asked to complete the PEST and CONTEST questions and were then assessed by a dermatologist and rheumatologist. Diagnosis of PsA was made by the assessing rheumatologist as lab and radiographic data were unavailable to assess the CASPAR criteria. Receiver operator characteristic (ROC) curve analysis was used to assess the PEST and CONTEST questionnaires using physician diagnosis as the gold standard. Sensitivity and specificity of potential cut points were examined.

Results: A total of 932 packs were sent out to recruit 191 (20.5%) participants attending for assessment. Of these, 169 (88.5%) had current or previous psoriasis. Using physician diagnosis 17 (10.1%) were found to have previously undiagnosed PsA, 90 (53.3%) were found to have another musculoskeletal complaint and 62 (36.7%) had no musculoskeletal problems.

Using ROC curve analysis, all of the questionnaires showed a significant ability to identify PsA. The area under the curve (AUC) for the CONTEST and CONTESTjt questionnaires was slightly higher than that of PEST (see table 1) but there was no significant difference between any of the questionnaires. Examining the sensitivities and specifities for the different cut points, suggested that a PEST score of ≥2 would perform better in this dataset, and optimal scores for CONTEST and CONTESTjt seemed to be 3 and 4 respectively.

Conclusion: The accuracy of the PEST and CONTEST questionnaires to identify PsA appeared similar with slightly higher AUC for the CONTEST questionnaires. Optimal cut points in this study appeared lower than in previous studies (PEST≥2, CONTEST≥3, CONTESTjt≥4).

Test	Score	AUC	Sensitivity	Specificity
PEST	2	0.652	0.824	0.449
	3	0.652	0.529	0.660
	4	0.652	0.235	0.816
CONTEST	2	0.694	0.882	0.388
	3	0.694	0.765	0.565
	4	0.694	0.529	0.680
	5	0.694	0.353	0.816
CONTESTjt	2	0.704	0.941	0.337
	3	0.704	0.765	0.531
	4	0.704	0.706	0.633
	5	0.704	0.412	0.735
	6	0.704	0.353	0.844

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Enthesitis is one of the potential extra-axial manifestations found in patients with spondyloarthritis (SpA). Enthesitis can be quantified using the MASES (Maastrich Ankylosing Spondylitis Enthesitis *Score*), consisting 13 pre-defined entheses assessed for tenderness. There are few data on the MASES outside of RCTs. To better understand enthesitis real live data could be helpful.

Objective:

To analyse cross-sectionally the correlation of enthesitis with clinical and personal outcome parameters in patients with axial spondyloarthritis.

Methods:

We included all patients from the Swiss national registry SCQM with axial spondyloarthritis and valid MASES at baseline. Patients were analysed for demographics at baseline, medical history, physical assessments (BASMI, BASFI, BASDAI) and patient centred outcomes (SF36). Data was analysed using descriptive statistics and linear regression.

Results:

3241 patients were included into the study with MASES data available at baseline. 45.9% of the patient had no documented entheseal affection at baseline (MASES = 0). Patients had an average age of 41.6 years, symptom duration of 11.8 years and disease duration of 6.3 years since diagnosis on average. There was a predominance (57.5%) for the male gender. 59.7% of the patients were HLA B27 pos. and 60.5% of the patients were suffering from radiographic axial disease as defined by positivity for the New York criteria.

The percentage of patients with a higher MASES (0-13) decreased linearly (slope -63.5, $R^2 = 0.48$). In parallel, average clinical scores BASDAI, BASFI, BASMI, ASDAS, patient´s global assessment of disease activity increased linearly with increasing MASES (BASDAI: slope 0.23, $R^2 = 0.89$; BASFI: slope 0.27, $R^2 = 0.87$; BASMI: slope 0.09, $R^2 = 0.82$; ASDAS: slope 0.09, $R^2 = 0.90$, patient´s global: slope 0.23; $R^2 = 0.85$) whereas the SF 36 decreased (physical component score: slope -0.73, $R^2 = 0.76$; mental component score: slope -0.72, $R^2 = 0.67$).

Conclusion:

Entheseal involvement is a frequently occurring contributor to disease activity and function in patients with axial SpA. MASE scores correlate well with disease activity and patient centred outcomes.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Enteropathic spondyloarthritis (ES) are included in the group of the spondyloarthritis (SpA). Because articular involvement is the most frequent extra-intestinal manifestation in patients with inflammatory bowel diseases (IBD), the coexistence of gut and articular inflammation advocates an integrated approach for the clinical management of these patients in clinical practice (Olivieri I. et al. *Autoimmun Rev* 2014, 8:822-30).

We carried out a clinical study, henceforth defined **SPIB** (**SP**ondyloarthritis in **I**nflammatory **B**owel disease), in the outpatient clinics and in the clinical ward of the gastroenterology and internal medicine departments, having the following end-points; a) the early diagnosis of ES; b) the evaluation of the quality of life before and after therapeutic integrated approach.

Methods:

From January, 2014 to January 2015, 198 consecutive IBD pts were screened; 48 refused to participate to the study and 154 were evaluated at baseline and after 6 and 12 months for gastrointestinal symptoms and activity, patient-reported outcomes of the quality of life and rheumatologic symptoms (Fig.1, table I). Upon a gastroenterologist and rheumatologist evaluation, the therapeutic strategy was chosen in concert based on gastrointestinal and joint disease activity, and the presence of peripheral and/or axial involvement of the joints.

Results:

65 (33,6%) of the 154 pts complained of articular symptoms and in 51 of 65 (25,8% of all IBD pts) an active enteropathic SpA (ES) was diagnosed. Peripheral arthritis was present in 23 pts (45%) and axial involvement in 28 pts (55%). Articular symptoms had been present for 5±4,9 yrs in 51% of the ES pts. The quality of life in the cohort of ES pts, compared to that of IBD pts, was significantly worsened by articular symptoms (Fig.1A). At baseline, 20 ES pts were treated with methotrexate, 2 with salazopyrine, 5 with infliximab, and 23 with adalimumab.

After 12 months of treatment, 90% of the ES pts reported a significant improvement in their quality of life (Fig.1B). A significant improvement of both gastrointestinal (Fig.1B) and articular disease (Fig.1C) was achieved in 88% of the patients, mostly in pts receiving anti-TNF-alfa drugs.

Conclusion:

The early diagnosis of enteropathic spondyloarthritis and the choice of the optimal therapeutic strategy constitute a novel major topic in clinical practice (Olivieri I. et al. *Autoimmun Rev* 2014, 8:822-30).

Our study reinforces the importance of an integrated clinical evaluation of ES pts carried out by the gastroenterologist and rheumatologist, for a correct diagnosis and the choice of the optimal therapeutic strategy.

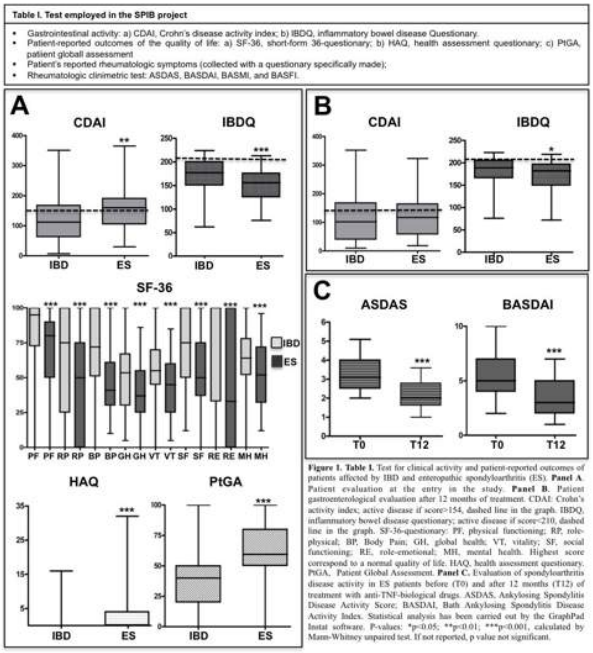

Figure 1. Table I. Test for clinical activity and patient-reported outcomes of patients affected by IBD and enteropathic spondyloarthritis (ES). **Panel A**. Patient evaluation at the entry in the study. **Panel B**. Patient gastroenterological evaluation after 12 months of treatment. CDAI: Crohn's activity index; active disease if score>154, dashed line in the graph. IBDQ, inflammatory bowel disease questionary; active disease if score<210, dashed line in the graph. SF-36-questionary: PF, physical functioning; RP, role-physical; BP, Body Pain; GH, global health; VT, vitality; SF, social functioning; RE, role-emotional; MH, mental health. Highest score correspond to a normal quality of life. HAQ, health assessment questionary. PtGA, Patient Global Assessment. **Panel C**. Evaluation of spondyloarthritis disease activity in ES patients before (T0) and after 12 months (T12) of treatment with anti-TNF-biological drugs. ASDAS, Ankylosing Spondylitis Disease Activity Score; BASDAI, Bath Ankylosing Spondylitis Disease Activity Index. Statistical analysis has been carried out by the GraphPad Instat software. P-values: *p<0.05; **p<0.01; ***p<0.001, calculated by Mann-Whitney unpaired test. If not reported, p value not significant.

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Disease Activity for Psoriatic Arthritis (DAPSA) is a composite index that assesses disease activity in patients with Psoriatic Arthritis (PsA) taking into account peripheral arthritis. The aim of our study was to validate DAPSA and to evaluate its performance using minimal disease activity (MDA) and different cut-off points.

Methods: Patients ≥18 years with PsA according to CASPAR criteria, belonging to RAPSODIA cohort were included. We recorded demographic data, clinical presentation, comorbidities and treatment. Morning stiffness, pain and global activity by patient and physician were assessed using visual analogue scale (VAS). We evaluated tender (68) and swollen joints (66), dactylitis and enthesitis by MASES (Maastricht Ankylosing Spondylitis Enthesitis Score). CRP and ESR were measured. ASQoL (Ankylosing Spondylitis Quality of Life), PsAQoL (Psoriatic Arthritis Quality of Life), HAQ (Health Assessment Questionnaire,) BASFI and BASDI were completed. DAS28 (Disease Activity Score), DAPSA, SDAI (Simplified Disease Activity Index), CDAI (Clinical Disease Activity Index), and CPDAI (Composite Psoriatic Disease Activity Index) were calculated. Hypothetical cases of patients with PsA with data necessary to calculate DAPSA were assessed by 10 rheumatologists trained in the evaluation of patients with PsA. They had to consign if the patient was in remission, low, moderate or high disease activity. *Statistical analysis*: Student T test and ANOVA for continuous variables and Chi2 test and Fisher's exact test for categorical variables.

Spearman Rho, and ROC curves for cut-off points.

Results: We included 112 patients, 57 males (50.9%), with a median age of 54 years (IQR 42-63) and median disease duration of 9 years (IQR 5-15). DAPSA had excellent correlation with DAS28 (Rho:0.85), CDAI (Rho:0.95), SDAI (Rho:0.94) and tender joint count (Rho:0.84), and good with BASDI (Rho:0.68), CPDAI (Rho:0.58), ASQoL (Rho:0.63), PsAQoL (Rho:0.51), BASFI (Rho:0.58), HAQ (Rho:0.59), swollen joint count (Rho:0.69), pain (Rho:0.79) and patient´s global activity (Rho:0.72). Patients who achieved MDA were significantly discriminated by DAPSA (mean 4.9±4.21 vs 20.6±12.5) as well as by the other composite indexes. Using established cut-off values of SDAI for Rheumatoid Arthritis (RA) and experts opinion we performed ROC curves for different cut-off values for DAPSA. Based on these values, a DAPSA score ≤ 5.3 was considered remission, 5.4 to 14.8 low disease activity, 14.9 to 37.7 moderate disease activity and ≥ 37.8 high disease activity. These cut-off values had a sensitivity and specificity ≥ 90%, with an area under the curve of 98%.

Conclusion: DAPSA is a valid and easy to calculate index for peripheral joint activity in PsA patients. It can perfectly discriminate patients in MDA and we proposed possible cut-off values for different disease activity states.

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Well known comorbidities of Psoriatic arthritis (PsA) such as cardiovascular disease, metabolic syndrome and diabetes mellitus are closely related with body mass index (BMI). Obesity is a risk factor for development of arthritis in patients with psoriasis but at the same time can be a marker of disease severity. Our objective was to assess association of disease activity indicies with obesity in a multicenter large PsA cohort.

Methods: PsART (**Ps**oriatic **A**rthritis **R**egistry of **T**urkey) is a prospective, multicentre, web-based, nationwide study in Turkey on patients with PsA. Patients are consecutively recruited to this registry, if they are diagnosed as PsA. Until May 2015, 1060 PsA patients from 37 centers enrolled to PsART. BMI≥30 was defined as obesity. The demographics were recorded including tender/swollen joint counts, body surface area (BSA), ESR, health assessment questionnaire (HAQ), Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankylosing Spondylitis Functional Index (BASFI), 100mm visual analog scale (VAS) for patient global assessment (PtGA), physician global assessment (PGA), fatigue, pain. Minimal disease activity (MDA) items (SJC≤1, TJC≤1, HAQ≤0.5, PtGA≤20, BSA≤3, pain≤15) and PGA, BASDAI, BASFI, fatigue, ESR used the following cut-offs to dichotomize groups: PGA≤20, BASDAI<20, BASFI<20, fatigue<20, ESR < ULN.

Results: Within PsA patients whose BMI data were available (n=1054), 64.5% was female. Mean (SD) age was 46.8 (12.9) years with a disease duration of 188 (135) months for psoriasis and 77 (89) months for psoriatic arthritis. Mean (SD) BMI was 27.9 (5.2) and 30.9% of patients had a BMI>30. Obese patients were older (50.5 (11.8) vs 45.1 (12.9), p<0.001), had a lower education level (7.0 (4.2) vs 9.2 (4.5) years, p<0.001) and more frequent comorbidities such as DM (25.2% vs 11,4%, p<0.001) and HT (36.2% vs 19.6%, p<0.001). These patients had more fatigue, higher BASDAI and BASFI scores, and moderate PGA, pain and ESR (Table). Minimal disease activity items (except PtGA) were similar according to BMI. Disease activity groups by BMI categories are shown in Table.

Conclusion: Obesity was foud to be associated with a lower probability of achieving sustained MDA state in a longitudinal PsA cohort (1). On the other hand, our results did not support to association of obesity and achieving low disease activity. . Interstingly, other than MDA items

especially fatigue was significantly higher at obese patients. Fatigue has multidimensional affect on impact of patients' health, and may be linked to body weight in inflammatory diseases.

Table. Disease activity and patient reported measures by BMI categories

	BMI > 30	**BMI<30**	**p-value**
SJC ≤ 1 n (%)	204/304 (67.1)	466/693 (67.3)	0.96
TJC ≤ 1 n (%)	134/311 (43.1)	318/688 (46.2)	0.36
BSA ≤ 3 n (%)	67/123 (54.5)	150/243 (61.7)	0.18

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Little is known about how psoriatic arthritis patients and their providers perceive response to therapy. Discrepancies in perceptions of therapy response may indicate that providers are not adequately measuring the aspects of disease that are meaningful to patients. Insufficient assessments of disease states may lead to non-ideal therapies and may contribute to patient non-compliance.

Methods:

Comparisons of patient and provider assessments of response to therapy formulate possible discrepancies. Of the 109 patients enrolled in the Psoriatic Arthritis Research Consortium (PARC) during August 2014 to June 2015, 64 patients rated their response(s) to therapy. Participants and their providers rated response to therapy on a 4-point scale (Very well, Moderately well, A little, Not at All). Participant response ratings were categorized as concordant if their rating was the same as the provider. Discordant participant responses were categorized as either less favorable or more favorable than the provider's rating. Participant and disease characteristics were compared between participants with discordant and concordant ratings. These characteristics included age, gender, alcohol use, current smoker(s), Body Mass Index, education, disability, IBP, radiographic changes, and psoriatic fingernails.

Table 1. Baseline demographics, PsA characteristics, and therapies

n=64	No. (%) or Mean (SD)
Age	53.0 (14.1)
Female gender	35 (54.7%)
White race	60 (93.8%)
Ethnicity (hispanic/latino)	2 (3.1%)
Body Mass Index	29.3 (7.5)
Psoriatic arthritis duration from onset (years)	13.7 (13.5)
Psoriatic arthritis duration from diagnosis (years)	6.6 (8.8)
Synovitis documented by physician	57 (89.1%)
Dactylitis documented by physician	12 (18.8%)
Enthesitis documented by physician	35 (54.7%)
Inflammatory back pain	20 (31.3%)
Tender joint count (0-68)	4.7 (8.2)
Swollen joint count (0-66)	1.6 (3.1)
Classification Criteria for PsA diagnosis	49 (76.6%)
PGAxBSA	1.8 (4.7)
Peripheral radiographic changes consistent with PsA	28 (43.8%)
Axial radiographic changes consistent with PsA	10 (15.6%)
Biologic and non-biologic DMARDs, current	52 (81.3%)
Biologic and non-biologic DMARDs, past	10 (15.6%)

PGAxBSA = psoriasis Physician Global Assessment x Body Surface Area

Results: Forty percent of response ratings were concordant between participants and providers, while 29. 3% of participant ratings were less favorable than the provider ratings and 30.5% were more favorable.

Table 2. Comparisons of patient and provider ratings

	Concordant ratings (reference)	Discordant ratings Less Favorable ratings		More Favorable ratings	
	n=18	n=13	p value or % change	n=17	p value or % change
Education (yrs)	16.2 (2.9)	14.8 (2.9)	0.19	14.4 (2.5)	0.06
Age	55.9 (15.5)	49.1 (15.6)	0.24	49.7 (11.0)	0.19
Body Mass Index	30 (6.8)	29.7 (8.2)	0.93	28.5 (7.2)	0.53
Psoriatic fingernails	4 (22.2%)	7 (53.9%)	31.7%	10 (58.8%)	36.6%
Inflammatory Back Pain	6 (33.3%)	3 (23.1%)	10.2%	4 (23.5%)	9.8%
Peripheral radiographic changes	7 (38.9%)	6 (46.2%)	7.3%	8 (47.1)%	8.2%
Axial radiographic changes	1 (5.6%)	2 (15.4%)	9.8%	4 (23.5%)	17.9%
Female	9 (50.0%)	9 (69.2%)	19.2%	9 (53%)	3.0%
Alcohol Use	9 (50.0%)	4 (30.8%)	19.2%	4 (23.5%)	26.5%
Current Smokers	0 (0.0%)	1 (7.7%)	7.7%	1 (5.9%)	5.9%
Disabled	1 (5.6%)	2 (15.4%)	9.8%	2 (11.8%)	6.2%
Not working because of PsA	0 (0.0%)	0 (0.0%)	0%	3 (17.7%)	17.7%

n=number of patients evaluated with rating

Conclusion:

Participants and providers rated response to therapy identically 40.2% of the time. Discordant response ratings were similarly distributed in the less favorable and more favorable categories. No differences in participant or disease characteristic were identified when discordant ratings were compared to concordant ratings.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Several disease activity measures were developed for use in psoriatic arthritis (PsA) . Little data is available on their performance in usual care. This study aims to describe longitudinal evolution of the PASDAS, CPDAI and MDA in the first 6 months after treatment start and in addition treatment initiation and disease characteristics at baseline.

Methods:

Data was used from PsA patients participating in the ongoing DEPAR cohort in 11 Dutch hospitals in the period August 2013 to May 2015. Data was analyzed using a linear mixed model to evaluate PASDAS (0-10) and CPDAI (0-15) over time and descriptives were used to summarize patient characteristics and treatment and % of patients achieving MDA (5 out of 7 domains).

Results:

Untill May 2015 213 patients had had a baseline assessment, 177 had a 3 months and 139 a 6 months assessment. 52% were male; the mean age was 50.3 years (sd 21.7). Mono-, oligo-, and polyarthritis were present in 21% (48.9 sd 12.9; 51% male), 38% (48.8 sd 13.6; 61% male) and 33% (53.7 sd 14.3; 48% male), respectively. 6.5% was diagnosed with enthesitis and 1.5% with axial disease only. Methotrexate was started in 110 patients (51.6%), while 11 patients (6.1%) received prednisone monotherapy (IA or IM), Sulfasalazine was given to 5 patients (2.3%) and 9 patients used other DMARDS (4.6%; 4 used a biological at baseline due to skin disease). Further baseline details are presented in table 1. At baseline PASDAS scored 2.6 (sd 0.70; n=115), CPDAI 5.9 (sd2.9; n=113) and MDA was present in 13 patients (9%; n=145). Over time all measures decreased, see figure 1. At 3 months low PASDAS(<=3.2) was achieved by 95% of the patients, low CPDAI(<=4) by 51% and MDA by 23% and at 6 months this was 97%, 54% and 24%, respectively.

Conclusion:

Methotrexate was the most common DMARD initiated after diagnosis of Psoriatic Arthritis. MDA evolution over time seems the most stringent criterion to guide treatment on compared to the PASDAS and CPDAI in a real world early Psoriatic Arthritis Cohort. Further evaluation of these measures is needed to assess the impact on patient's quality of life and radiological progression.

Assessment of Spinal Mobility in Axial Spondyloarthritis: First Validation Steps of a New Electronic Quantification Tool

Xenofon Baraliakos, David Kiefer, Susanne Herbold and Jürgen Braun, Rheumazentrum Ruhrgebiet, Herne, Germany
First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Spinal mobility is a major health issue of patients with axial spondyloarthritis (axSpA), especially in ankylosing spondylitis (AS) while non-radiographic axSpA (nr-axSpA) has been less well studied in this regard. The available tools such as the BASMI and, indirectly, also the BASFI have limitations in exactly quantifying spinal mobility. In this study, we evaluate the performance of a newly developed electronic tool to measure spinal mobility.

Methods: Consecutive patients with axSpA, mechanical back pain and healthy controls were examined by the Epionics spine device (ESp), a novel electronic system, which measures the range of motion (ROM) for spinal mobility using non-invasive angle sensor strips in 12 evenly spaced locations along the spine. ESp has been shown to reliably measure the ROM for all domains of spinal mobility (flexion, extension, rotation and combinations). Physical examinations (BASMI), questionnaires (BASFI) and a recently proposed tool to assess function (ASPI, 1) were performed in parallel. The assessors were unaware of the results of the other tests. The time to use the device was measured. Statistical comparisons between groups were performed with the Mann-Whitney-U-test.

Results: A total of 65 patients with axSpA (38 (58%) with AS and 27 (42%) with nr-axSpa), 48 patients with mechanical back pain (mBP) and 20 healthy controls (HC) were included in this prospective study. The BASFI and BASMI values were generally higher in patients with AS (4.1±2.3 and 2.7±2.3) vs. nr-axSpA (3.8±1.9 and 1.2±1.0), mBP (4.0±2.4 and 1.3±1.1) and HC (0.5±0.7 and 0.6±0.8). Using ESp, the measured range of ROM AS patients performed worse in all aspects (Table). The mean duration of performance of ESp was 12±3 minutes.

		Spinal flexion	Spinal extension	Rotation to left	Rotation to right	Lateral flexion to left	Lateral flexion to right	Flexion and rotation from left to right	Extension and rotation from left to right	Flexion and rotation from right to left	Extension and rotation from right to left

	SD	14,2	9,6	9,2	8,7	7,1	7,1	14,6	4,6	13,0	5,9
p-value nr-axSpA vs. AS		***0,124***	***0,018***	***0,011***	***0,159***	***0,006***	***0,008***	***0,043***	***0,134***	***0,122***	***0,410***
mBP	Mean	48,4	23,9	22,7	24,6	23,6	25,5	43,8	9,8	44,2	8,7
	SD	13,0	12,0	10,0	9,7	7,9	7,1	13,2	7,7	12,5	7,6
p-value mBP vs. AS		***0,033***	***0,001***	***0,266***	***0,214***	***0,001***	***0,001***	***0,001***	***0,010***	***0,315***	***0,784***
HC	Mean	51,6	28,2	26,8	27,9	30,4	30,9	45,9	10,1	47,7	10,4
	SD	11,4	11,5	10,6	9,1	7,6	8,8	12,3	10,7	10,9	9,3
p-value HC vs. AS		***0,007***	***0,001***	***0,033***	***0,022***	***0,001***	***0,000***	***0,004***	***0,245***	***0,318***	***0,722***

Table: ROM (in angles) for the different patient subgroups

Conclusion: The Epionics spine device had good construct, content and face validity in this first study, which prospectively compared patients with axSpA, mechanical back pain and healthy volunteers. It will be interesting to study its correlation to single BASMI and BASFI items and to learn whether it provides higher sensitivity to change as compared to conventional assessments of spinal mobility and function.

Session Date: Sunday, November 8, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Limited information exists about the characteristics of pre-clinical phases of psoriatic arthritis (PsA). We aimed to assess whether the presence and trends in non-specific musculoskeletal symptoms predict the development of PsA in a prospective cohort of patients with psoriasis.

Methods: This prospective cohort study involved patients with psoriasis who were assessed at baseline by a rheumatologist to exclude the presence of clinical inflammatory arthritis. The study participants were assessed annually according to a standard protocol. The presence of musculoskeletal symptoms and patients' scores of pain (visual analogue scale (VAS) 0-10), fatigue (Fatigue Severity Scale), stiffness (VAS 0-10) and physical functioning (SF-36 physical component score) were recorded at each visit. These variables served as predictors for the development of PsA. Patients who developed inflammatory arthritis or spondylitis were classified as PsA if they fulfilled the CASPAR criteria. Cox proportional hazard models, involving fixed and time-dependent explanatory variables were fitted to obtain estimates of relative risk (RR) for the onset of PsA in multivariate models controlling for age, sex, body mass index, nail pitting and psoriasis area and severity index (PASI).

Results: The results of 410 patients with psoriasis who were followed for an average duration of 45.1±25.3 months were analyzed. A total of 57 patients developed PsA since enrollment (mean duration to diagnosis of PsA 46±27.8 months). At baseline, the presence of arthralgia in women (RR 2.6, 95% Confidence Interval (CI) 1.2, 5.9), heel pain (RR 4.2, 95% CI 1.3, 13.8), fatigue score (RR 1.2, 95% CI 1.04, 1.3) and stiffness score (RR 1.2, 95% CI 1.1, 1.3) predicted subsequent development of PsA. In addition, an increase from baseline in fatigue score (RR 1.3, 95% CI 1.1, 1.5), pain score (RR 1.3, 95% CI 1.1, 1.6) and stiffness score (RR 1.2, 95% CI 1.0, 1.4) and a worsening in physical function score (RR

0.96, 95% CI 0.92, 0.99) predicted the development of PsA. The changes in fatigue and stiffness scores over time are shown in Figures 1-3.

Conclusion: A preclinical phase exists in patients with PsA prior to the diagnosis of the disease. This phase is characterized by non-specific musculoskeletal symptoms including joint pain, fatigue and stiffness.

Discrepancy Between Patients and Physicians Acceptable Symptomatic States in Axial Spondyloarthritis: Findings from the RAPID-AxSpA Study

Maxime Dougados[1], **Owen Davies**[2], Tommi Nurminen[3], Geoffroy Coteur[4] and Laure Gossec[5], [1]Medicine Faculty, Paris-Descartes University, Paris, UPRES-EA 4058, Cochin Hospital, Rheumatology B, Paris, France, [2]UCB Pharma, Slough, United Kingdom, [3]UCB Pharma, Monheim, Germany, [4]UCB Pharma, Brussels, Belgium, [5]Sorbonne Universités, UPMC Univ Paris 06 GRC-UPMC 08 (EEMOIS); AP-HP, Hôpital Pitié Salpêtrière Rheumatology Department, Paris, France

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Discordance between patient (pt) and physician (phy) assessment of disease activity (DA) in spondyloarthritis (SpA) is recognized, with phys tending to score DA less severely than pts.[1]Perceptual differences need to be understood to improve pt-phy dialogue, set shared treatment goals and ultimately improve outcomes. The objectives were to: 1. Investigate the proportion of axial SpA (axSpA) pts with acceptable symptomatic states as scored by the pt or their phy before and after initiation of anti-TNF treatment and 2. Explore discrepancies between pt and phy assessments.

Methods:

RAPID-axSpA (NCT01087762) was double-blind and placebo (PBO) controlled to Week (Wk) 24.[2]Pts fulfilled ASAS criteria and had active axSpA. At baseline (BL) 325 pts were randomized 1:1:1 to PBO, or certolizumab pegol (CZP) 200 mg Q2W / 400 mg Q4W. In addition to conventional axSpA outcomes (eg ASDAS / BASDAI) information on pt acceptable symptomatic state was collected from the pt (Pt Acceptable Symptomatic State [PASS]) and their phy (Phy Acceptable Symptomatic State [PhSS]) (see Box for questions).

Analyses also investigated underlying DA thresholds considered ‘acceptable’ by pts or phys. Based on pt’s global assessment of DA (PtGADA) and PASS, interval-censored observations estimated each pt’s ‘acceptability threshold’. Assuming normal distribution, the mean was estimated using LIFEREG in SAS (v 9.3). Similar procedure was used for phys.

Results:

Of 324 pts assessed, 218 received CZP from Wk0 and 106 PBO. At BL 29 (9%) pts were in PASS and 120 (37%) in PhSS, despite high DA in pts with PhSS (mean ASDAS 3.8; BASDAI 6.4). Similar proportions of pts and phys agreed regarding pt symptomatic state at BL (62%) and Wk24 (68%; Fig A); this was similar for CZP and PBO (BL CZP 62%, PBO 63%; Wk24 CZP 67%, PBO 70%).

Improvements following CZP treatment (dose combined) were seen from Wk1 (Fig B). Differences in proportions of pts in PASS vs PhSS at BL were maintained to Wk24, with 104 (48%) CZP treated pts in PASS and 158 (73%) in PhSS (Fig B). At Wk24 mean underlying DA level considered ‘acceptable’ was similar for pts and phys and was not dependent on treatment (PtGADA CZP 3.9 vs PBO 3.7; PhGADA CZP 3.9 vs PBO 4.0).

Preliminary analyses investigating BL characteristics indicate that pts with Wk24 PASS had lower BL DA scores than pts without; no differences were seen for pts in / not-in PhSS at BL or Wk24.

Conclusion:

CZP treatment was associated with improvements in PASS and PhSS to Wk24. Despite high DA at BL over a third of phy scored pts as having acceptable symptomatic states, which represented a notable discrepancy compared to pt scoring. This discrepancy was maintained to Wk24 and was independent of treatment. These findings confirm previous reports of discordance in phy and pt assessment of DA and highlight a need for closer partnership between phys and pts to set shared treatment goals.

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Because ankylosing spondylitis (AS) is relatively uncommon, large electronic medical record (EMR) databases with longitudinal follow up offer an important opportunity for epidemiologic research in AS. However, the validity of AS diagnoses recorded by a general practitioner in such databases is unknown. We sought to assess the validity of several algorithms for identifying AS patients in The Health Improvement Network (THIN).

Methods: THIN is an EMR database of over 10 million persons in the UK, with data entered by general practitioners (GPs). In 2014, we administered a questionnaire to the GPs of 100 patients aged 18-59 years for whom at least one AS diagnostic code was recorded during years 2000-2013. As high positive predictive value (PPV) is of critical importance in epidemiologic studies of AS (i.e.- accurate identification of subjects who truly have AS), our questionnaire was designed to determine the PPV of an AS diagnostic code, using the GP's clinical impression as the "gold standard". We also determined characteristics for other AS case identification algorithms including: more than one AS diagnostic code, absence of osteoarthritis (OA) or rheumatoid arthritis (RA) codes, prescription of a nonsteroidal anti-inflammatory drug (NSAID), or presence of a disease modifying anti-rheumatic drug (DMARD) or biologic.

Results: Questionnaires were returned for 85 out of 100 patients with an AS code, and in 61 of those patients the GP's clinical impression confirmed the AS diagnosis, resulting in an overall positive predictive value (PPV) of 72% (**Table**). The highest PPV (89%) was with an algorithm requiring two AS codes at least 7 days apart, however PPV was also high for an algorithm requiring at least one AS diagnostic code plus a DMARD or biologic drug prescription (86%). Sensitivity was reduced with algorithms requiring 2 AS codes (64%) and a DMARD/biologic prescription (30%). Algorithms also requiring prescription of an NSAID, or the absence of an OA or RA code had lower PPV (71-75%) and higher sensitivity (95-98%).

Conclusion: AS case identification algorithms of: (A) two AS diagnostic codes separated by at least 7 days or (B) one AS diagnosis plus a DMARD or biologic prescription provided the highest PPV in THIN. One or both of these algorithms should be used for AS case identification in epidemiologic studies in THIN.

Table. Ankylosing spondylitis case identification algorithms and characteristics in The Health Improvement Network

Algorithm	Total (N)	Confirmed AS (N)	PPV (95% CI)	Sensitivity* (95% CI)
One or more AS codes	85	61	71.8 % (60.5-83.1)	N/A
Two AS codes, > 7 days apart	44	39	88.6 % (78.7-98.6)	63.9 % (48.9-79.0)
AS + absence of OA code	77	58	75.3 % (76.0-97.3)	95.1 % (89.5-100)
AS + absence of RA code	80	58	72.5 % (61.0-84.0)	95.1 % (89.5-100)
AS + DMARD or Biologic	21	18	85.7 % (69.5-100)	29.5 % (8.4-50.6)
AS + NSAID	84	60	71.4 % (60.0-82.9)	98.4 % (95.1-100)

AS = ankylosing spondylitis, DMARD = disease modifying anti-rheumatic drug, NSAID =nonsteroidal anti-inflammatory drug, OA = osteoarthritis, RA = rheumatoid arthritis, N/A= not assessable.

*Sensitivity with the additional feature (e.g. absence of an OA code) for a verified diagnosis of AS by GP report among patients with at least one code for AS, not the overall sensitivity and specificity of the algorithm as false negatives were unavailable.

Session Date: Sunday, November 8, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Despite guidelines and evidence indicating that early diagnosis and treatment of PsA is critical, few studies have described referral and care-management patterns in a real-world setting. This study estimated the prevalence and incidence of PsA in the Sutter Health system, a large integrated U.S. health delivery network, and explored referral patterns and associated care-management practices within this population.

Methods: This was a retrospective review of electronic medical records and medical claims data of patients (age ≥18yrs) diagnosed with PsA

(ICD-9-code 696.x) from 2011-2013. Medical chart review by a rheumatologist and/or registered nurse of a sample of prevalent and incident PsA patients was utilized to confirm the diagnosis. Prevalence and incidence rates (defined as no PsA report 2 years before the index PsA record) were estimated annually/100,000 patients. Care management included ascertainment of the physician type recording the first PsA diagnosis and/or treating the patient (specialist vs. non-specialist). Referral patterns ascertained the physician type making the first referral to a specialist.

Results:

Among 1,362,288 adults (≥18 yrs, 59% female) in the health plan, 2,029 were identified as diagnosed with PsA. The average 1-year period prevalence was 161/100,000; incidence: 43/100,000. Mean age at incident diagnosis was 53 years (s=14.3) for women and 51 years (s=13.6) for men. Chart review revealed low rates for misclassification (5%) of PsA diagnosis. Approximately 54% of all PsA-related encounters were with rheumatologists. The majority of care was provided by rheumatology, primary care, and dermatology, accounting for 54%, 21%, and 19% encounters, respectively. Rheumatologists were first to diagnose PsA in 61% patients followed by primary care physicians (PCP): 24%, dermatologists: 10%, and others: 5%. Of those referred to a rheumatologist, 65% were referred by a PCP, followed by dermatologists: 6%, other rheumatologists: 4%, orthopedists: 3%, podiatrists: 2%, others: 3% and self/ no record: 18%. Overall, in sampled patients, non-rheumatologist providers were less likely to perform a joint exam or document joint abnormalities, and no providers documented a disease activity score. Of 1665 prevalent cases with a documented encounter with a rheumatologist within the system, 557 (33%) were prescribed biologic agents, 851 (51%) DMARDs, and 359 (22%) steroids. Among 2029 prevalent cases, 346 (17%) had no documented encounter with a Sutter Health rheumatologist; 30% were prescribed biologics and 26% DMARDs. Chart review revealed that most of these patients had had contact with specialists outside the network.

Conclusion:

Estimated prevalence of PsA in the Sutter Health System was similar to U.S. estimates: between 0.02 and 0.25%. Although rheumatologists provided the majority of care, many patients did not have a record of a rheumatology encounter. Further research is needed to better understand gaps in PsA health care in real world settings.

Session Date: Sunday, November 8, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Intravesical instillation of BCG is used as an effective immunotherapy of bladder cancer. However it may have, as adverse event, a reactive arthritis (ReA) and the incidence are known as about 0.5 to 1 %. To evaluate clinical characteristics and incidence of Japanese patients with ReA induced by intravesical BCG therapy (iBCG) for bladder cancer.

Methods: The clinical symptoms, laboratory, and imaging findings of Japanese patients who received iBCG (n=453 (182 and 271 in Kochi University Hospital (KUH) and Kurashiki Medical Center (KMC), respectively)) for bladder cancer from March 1997 to April 2015 (for 19 years) were retrospectively assessed. Especially, the patients with ReA and conjunctivitis/uveitis were examined. All data are presented as mean ± SD.

Results: Of the patients received iBCG (age 71±10 and 69±11; male/female 134/48 and 215/56 in KUH and KMC, respectively), 50/182 (27%) and 35/271 (13%), 51/182 (28%) and 48/271 (18%), and 78/182 (43%) and 73/271 (27%) in KUH and KMC presented fever, hematuria and painful urination, respectively. ReA was revealed in 4/182 (2.2%) and 3/271 (1.1%), uveitis in 3/182 (1.6%) and 1/271 (0.4%), and conjunctivitis in 15/182 (8.2%) and 14/271 (5.2%) in KUH and KMC, respectively. As the total evaluation, ReA was revealed in 7/453 (1.5%). Moreover, most patients with ReA also had hepatic dysfuntion. All ReA were developed after 3-times of iBCG. Clinical, ultrasound and FDG-PET/CT findings of ReA induced by iBCG showed asymmetric polyarthritis/polyenthesitis pattern in shoulder, sternoclavicular joints, spinous process, sacroiliac joints, ischial tuberosity, hip, knee and ankle. Laboratory examinations showed high CRP (>10mg/dl), 25% HLA-B27 positivity (in 1 of 4 cases), 50% HLA-B51 positivity (in 2 of 4 cases). All ReA patients were improved by treatments with prednisolone and isoniazid.

Conclusion: The incidence of ReA induced by iBCG in Japanese population was 1.5 % and it might be almost equal or more than the incidence, 0.5 to 1 %, in the Western countries from previous reports. Positive HLA-B27 was revealed in 25% of ReA patients as background in our study, suggesting lower frequency than 51 to 55% in the Western countries. Therefore, besides HLA phenotype, a cross reaction between a mycobacterium epitope and an antigen of joint cartilage might be suggested in the pathogenesis of ReA induced by iBCG in Japan.

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

To study the association between 25-hydroxyvitamin D (25(OH)D) levels and the clinical characteristics of patients with chronic inflammatory rheumatic diseases (CIRD).

Methods:

Cross section from the baseline visit of the CARMA project (CARdiovascular in rheuMAtology), a 10-year prospective study evaluating the risk of cardiovascular events in rheumatoid arthritis (RA), ankylosing spondylitis (AS) and psoriatic arthritis (PsA) patients, and non-CIRD patients who attended rheumatology outpatient clinics from 67 hospitals in Spain. Non-CIRD group was frequency matched by age with the joint distribution of the three CIRD groups included in the study. 25(OH)D deficiency was defined if 25(OH)D vitamin levels were < 20 ng/ml.

Results:

2.234 patients (775 RA, 738 AS and 721 PsA) and 677 non-CIRD subjects were assessed. The median [p25-p75] 25(OH)D levels were: 20.4 [14.4-29.2] ng/ml in RA, 20.9 [13.1-29.0] in AS, 20.0 [14.0-28.8] in PsA, and 24.8 [18.4-32.6] ng/ml in non-CIRD patients. 25(OH)D deficiency was detected in 40.5% RA, 39.7% AS, 40.9% PsA and 26.7% non-CIRD controls ($p<0.001$). A statistically significant positive association between RA and 25(OH)D deficiency was found (adjusted (adj.) OR=1.46; 95% CI=1.09-1.96); p= 0.012. This positive association did not reach statistical significance for AS (adj. OR 1.23; 95%CI=0.85-1.80) and PsA (adj. OR 1.32; 95%CI=0.94-1.84). When the parameters of disease activity, severity or functional impairment were assessed, a marginally significant association between 25(OH)D deficiency and ACPA positive in RA patients (adj. OR=1.45; 95%CI=0.99-2.12; p=0.056), and between 25(OH)D deficiency and BASFI in AS patients (adj. OR=1.08; 95%CI=0.99-1.17); p=0.07) was also found.

Conclusion:

Patients with CIRD, in particular those with RA, show an increased risk of having 25(OH)D deficiency compared to non-CIRD controls.

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Recent treat-to-target guidelines in PsA recommend that minimal disease activity (MDA) is achieved as early as possible. Patient reported outcomes (PROs) have been criticized for not accurately assessing PsA disease activity as they may reflect aspects not directly related to PsA such as fibromyalgia, depression or other comorbidities. The aim of this analysis was to assess the proportion of patients failing to achieve MDA based on PROs in a real-world, routine clinical care setting in Canada.

Methods: BioTRAC is an ongoing, prospective registry of patients initiating treatment for rheumatoid arthritis, ankylosing spondylitis, or PsA with infliximab (IFX) or golimumab (GLM). Eligible participants for this analysis included those with PsA treated with IFX who were enrolled since 2005 or with GLM enrolled since 2010 and with available MDA information at baseline, 6 months, and/or 12 months. MDA was defined as the fulfillment of ≥5 of the following criteria: TJC28≤1, SJC28≤1, PASI≤1 or BSA≤3, pain (VAS)≤15 mm, PtGA (VAS)≤20 mm, HAQ≤0.5, tender entheseal points ≤1. Near MDA was defined as fulfillment of 4/7 criteria.

Results: A total of 196 PsA patients (51.4% male) were included with a mean (SD) age of 49.8 (11.1) years and disease duration since diagnosis of 5.4 (6.3) years. The majority (62.2%) received concomitant DMARD therapy. The proportion of patients with MDA at baseline, 6 months and 12 months was 11.7%, 43.5%, and 44.8%, respectively. Overall, achievement of each individual MDA criterion was: TJC28: 43.0% of cases; SJC28: 51.3%; PASI 68.7%; pain: 27.7%; PtGA: 34.9%; HAQ: 36.8%; entheseal points: 79.4%. Among the 309 instances of non-MDA, 51 (16.5%) were near MDA cases. The most common reason for non-MDA in near MDA cases was patient-reported pain (82.4%) followed by PtGA (68.6%), and HAQ-DI (60.8%). Assuming that these criteria were met (i.e., not included in the MDA formula), the total number of MDA instances would increase from 29.6% to 36.7% (HAQ), 37.6% (PtGA), and to 39.2% (pain).

Conclusion:

The results of the current analysis have shown that, similar to prior analyses in RA, the most common limiting factors in achieving MDA in PsA are PROs, including PtGA, pain, and HAQ-DI, accounting for as many as 82.4% of near MDA cases. Further analyses are required to identify the determinants of the differences in PROs and clinical outcomes.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Psoriatic Arthritis (PsA) is a chronic immune-mediated condition with multiple manifestations; joint inflammation with subsequent joint damage is a key component. Across a number of immunological conditions a high level of patient satisfaction is reported, despite patients having ongoing disease activity.

The objective is to describe and compare the characteristics of PsA patients with active joint disease who are satisfied with their current PsA treatment against those who are unsatisfied.

Methods:

Data were extracted from the Adelphi 2011 / 2014 Rheumatology Disease Specific Programmes, two 'Real World' surveys of US rheumatologists and their PsA patients. Selected rheumatologists who make treatment decisions for PsA patients were recruited. Rheumatologists provided patient demographics, PsA disease characteristics and comorbidities. Patients reported their satisfaction with current control of their PsA, and impairment via the Work Productivity Activity Impairment (WPAI) and alternative HAQ-DI (excluding aids and devices) questionnaires.

Descriptive statistics including means and frequencies were derived for the population with active joint disease (defined as more than 3 tender joints) and stratified by patient satisfaction with PsA treatment (satisfied or dissatisfied).

Results:

From the database, 78 patients were identified with active joint disease and patient satisfaction reported. 54 (69.2%) patients were satisfied with the treatment of their PsA and the remaining 24 (30.8%) dissatisfied. Compared with dissatisfied patients with active joint disease, satisfied patients tended to be older (53.5 vs. 44.3 years), of male gender (59.3% vs. 50.0%), had a longer duration since PsA diagnosis (6.5 years vs. 3.6) and more likely receiving a biologic DMARD (bDMARD) therapy (64.8% vs. 56.5%). The level of disease activity in the joints was similar in satisfied and dissatisfied patients (mean tender joints: 7.9 vs 7.8; swollen joints: 5.1 vs. 5.0) but the extent of skin involvement was lower in satisfied patients (BSA >3%: 71.4% vs. 82.6%). Overall among patients with active joint disease the most common concomitant conditions were hypertension (30.8%), obesity (25.6%), depression (23.1%), elevated cholesterol (21.8%), diabetes (20.5%), and anxiety (19.2%). Dissatisfied patients had more comorbidities overall (2.2 vs. 1.6) and in particular a greater proportion of dissatisfied patients had depression (33.3% vs. 18.5%) and anxiety (33.3% vs. 13.0%) and were less impaired by their PsA (mean % WPAI activity impairment: 38.5% vs. 47.9%; mean alternative HAQ-DI: 0.657 vs. 0.761).

Conclusion:

These findings add further evidence that even when patients have active joint disease they may still report being satisfied, and suggests that with longer disease duration or prescription of bDMARD therapy, physicians and patients may settle for sub-optimal control of the joint aspects of PsA particularly in relation to joint involvement. These findings serve as a signal that there are challenges to managing PsA appropriately as patients progress in their disease, although further investigation and validation in a larger sample is needed.

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriatic arthritis (PsA) exhibits considerable heterogeneity in its presentation and course, which contributes to the complexity of diagnosis and assessment. Enthesitis, inflammation at the insertion sites of tendons and ligaments, and dactylitis, the diffuse swelling of digits, are important extra-articular manifestations of PsA and are present in many patients. The objective of this analyses was to characterize the demographic and clinical characteristics of PsA patients with dactylitis or enthesitis and evaluate the association with outcomes such as minimal disease activity (MDA) and functional status, measured by health assessment questionnaire (HAQ) in a large national observational cohort of PsA and spondyloarthritis patients (Corrona).

Methods: All PsA patients ≥18 years enrolled in the Corrona registry were included in the study. Descriptive analyses of patient characteristics, disease activity, and functionality measures at registry enrollment were assessed for patients with and without enthesitis and dactylitis. Regression models were used to evaluate the associations of enthesitis and dactylitis status, separately, with the clinical outcome measures MDA and HAQ (0-3); adjusted for age, gender, race, BMI, disease duration, history of biologic use, history of conventional synthetic DMARD use, and history of prednisone use.

Results: Of the 1567 PsA patients included in the analysis, 228 (14.6%) had dactylitis and 420 (26.8%) had enthesitis at enrollment. Patients with enthesitis or dactylitis had greater disease activity, as reflected in swollen and tender joint count, DAS28-CRP,and CDAI; a lower percentage were in minimal disease activity (MDA) and higher pain and fatigue compared to those who did not have dactylitis or enthesitis (Table). Multivariable analysis showed patients with dactylitis were almost 3 times (OR=2.53, 95% CI=1.55, 4.15) more likely to not be in MDA compared to patients with no dactylitis and patients with enthesitis were over 4 times (OR=4.38, 95% CI=2.77, 6.95) more likely to not be in MDA compared to patients with no enthesitis. Sensitivity analysis evaluating the associations between enthesitis and a modified MDA (5/6 criteria excluding enthesitis) showed consistent results (OR=1.88, 95% CI=1.23, 2.86). Adjusted models showed a mean difference of 0.08 (95% CI= -0.02, 0.17) in HAQ in patients with dactylitis compared to patients with no dactylitis, although not statistically significant. A significant difference of 0.16 (95% CI=0.09, 0.24) in HAQ was seen in patients with enthesitis compared to those who did not have enthesitis.

Conclusion: PsA patients with enthesitis or dactylitis are more likely to have elevated disease activity than patients without these manifestations and have less likelihood of being in MDA and to have worse functional status as assessed by the HAQ.

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriatic arthritis (PsA) divides into different subtypes, of which polyarthritis and spondylitis would be expected with the highest disease severity. We compared disease burden in PsA patients with oligo- and polyarthritic subtype in the national database of the German Collaborative Arthritis Centres.

Methods: We added a specific PsA module to the standard documentation of the national database of the German arthritis centres, containing data on the predominant PsA subtype (according to physicians' decision), associated skin, joint and other musculoskeletal manifestations. In addition to the Dermatology Life Quality Index (DLQI 0-30), patients reported specific questions concerning PsA-related disease burden. Between 2007 and 2013, in total 707 patients were documented.

Results: PsA patterns comprised 41% oligoarthritis (OA), 46% polyarthritis (PA), 6.4% arthritis of the distal interphalangeal joints (ADIP) or exclusively axial PsA (aPsA) each, and 0.8% patients with dominant arthritis mutilans. Age was comparable between all groups; female proportion was highest in OA. Disease severity was assessed by the physician as highest in aPsA, disease activity as highest in PA and ADIP. Focussing on OA and PA, joint and axial involvement, dactylitis, osteoproliferations and comorbid conditions were more frequent in OA, while psoriasis severity was higher in PA. OA was less often treated with biologics, while use of NSAIDs and opioids was higher than in PA. Patient reported outcomes (PRO) were worse in OA with regard to joint and skin conditions, pain and fatigue. When matching OA and PA by disease duration and gender (n=222 pairs with similar age, data not shown), disparities in physician's disease assessment and PROs as well as treatment differences persisted. In addition to the higher comorbid burden, current regular smoking was more frequently seen in OA patients (23% vs. 16%).

Table 1: Patient characteristics of different PsA subtypes

	predominant oligoarthritis	predominant polyarthritis	predominant arthritis of the DIP joints	exclusively axial PsA
n	287	324	45	45
Age (mean)	56.3	55.1	57.4	54.4
female sex	63.4%	58.6%	53.3%	53.3%
disease duration (median)	11.1	7.2	7.6	11.2
high disease severity	7.4%	10.1%	2.3%	20.9%
disease activity*, 4-10	12.1%	15.5%	16.7%	11.9%
any tender joints (76 joint count)	64.9%	48.4%	54.5%	52.5%
any swollen joints (74 joint count)	42.9%	32.4%	45.5%	10.0%
axial involvement	35.3%	22.0%	-	100.0%
dactylitis	14.1%	9.0%	20.5%	7.0%
enthesitis	16.2%	14.7%	18.2%	18.2%
psoriasis, moderate to severe	12.1%	20.2%	22.7%	18.6%
body surface area (0-100%)	4.1%	5.4%	5.1%	6.8%
nail involvement	34.3%	38.6%	60.0%	37.5%
radiologic alterations	51.7%	48.8%	73.5%	32.3%
osteoproliferations	63.6%	43.2%	77.3%	43.8%
comorbid conditions	82.8%	68.3%	69.8%	81.0%
synthetic DMARDs	80.4%	78.7%	66.7%	74.4%
biologic DMARDs	11.1%	16.8%	9.5%	4.7%
systemic glucocorticoids	23.4%	25.2%	16.7%	18.6%
NSAIDs	57.9%	46.2%	42.9%	65.1%
opiods	14.2%	7.0%	9.5%	37.2%
PRO: joint condition*, 7-10	26.3%	15.5%	32.4%	38.9%
PRO: skin condition*, 7-10	15.3%	9.5%	12.1%	29.4%
PRO: pain*, 7-10	29.5%	17.6%	26.8%	47.5%
PRO: fatigue*, 7-10	28.0%	19.4%	29.3%	48.8%
DLQI, very to extremely large (11-30)	10.9%	6.5%	12.1%	16.1%

* Numerical rating scale with range 0-10, 10 indicating worst status; PRO = patient reported outcome

Conclusion: Despite comparable disease activity and severity measured by clinical examination PsA patients with oligoarthritic compared to polyarthritic subtype show a higher patient reported disease burden, which has to be further examined. Optimising therapy, incorporating comorbidities and councelling the patient against smoking may bear potential to further improve quality of life in PsA-OA.

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The BASDAI, BAS-G, and a VAS for spinal pain (VAS-pain) are used to assess disease outcomes in AS. The intervals with which these patient-reported outcome measures (PROMs) are assessed vary widely, depending on the purpose of the assessment, and as such variability in outcome may occur. However, it is currently unknown what the extent and relevance of this variability is, and what the consequences of applying increasing intervals are on follow-up of individual patients. The aim of the study was to evaluate in AS 1) the variability of self-reported disease activity, patient global and spinal pain during 2 years of follow up, 2) the clinical relevance of this variability on a patient level, and 3) the effect of increasing intervals between two measurements on this variability on a measurement level.

Methods: Dutch patients from the Outcome in AS International Study (OASIS) completed the BASDAI, BAS-G, and VAS-pain every 2 months during 2 years. Mixed linear models were used to analyze time trends in the average scores over time. The minimal clinically important difference (MCID) was used to detect relevant changes (worsening or improvement) between two measurements. On a patient level, the frequency of exceeding the MCID, using intervals of 2 months, was calculated. Next, the intervals between two measurements (from 2- to 24-months) were increased to investigate the variability using all available measurements from individual patients.

Results: 90 patients (mean age 47.3 (SD 11.4) years, 68% male, mean symptom duration 25.2 (SD 11.3) years) completed the PROMs. The mean of each measure was stable over time. On the patient level, however, large variability was found. Using 2-months intervals, the average frequency of exceeding the MCID (in either direction) was 4.7 (SD 2.5) times for the BASDAI, 3.3 (SD 2.3) for the BAS-G, and 2.8 (SD 2.0) for the VAS-pain in the 2-year period (from a maximum of 12). On an observational level, exceeding of the MCID was frequently seen in all intervals. This markedly increased with prolongation of the interval in observations showing worsening over time (Table 1).

Conclusion: Substantial variability in the BASDAI, BAS-G, and VAS-pain was found in individuals over time. Clinically relevant changes were frequently observed, especially in observations with worsening more frequently relevant changes occurred with prolongation of the intervals. This intermediate information between two measurements, which may be clinically important, might be missed when intervals are prolonged.

Table 1. Observations exceeding the MCID with different time intervals in a 2-year follow up period

Measurement instrument	Interval (months)	Number of measurements	Number (%) of measurements exceeding MCID			
			Improvement	p-value	Worsening	p-value
BASDAI	2	1044	213 (20.4%)	0.91	199 (19.1%)	**<0.01**
	4	957	205 (21.4%)		186 (19.4%)	
	6	870	169 (19.4%)		181 (20.8%)	
	12	609	131 (21.5%)		146 (24.0%)	
	18	348	72 (20.7%)		85 (24.4%)	
	24	87	17 (19.5%)		31 (35.6%)	
BAS-G	2	1008	136 (13.5%)	0.12	145 (14.4%)	**<0.01**
	4	924	150 (16.2%)		162 (17.5%)	
	6	840	136 (16.2%)		138 (16.4%)	
	12	588	96 (16.3%)		124 (21.1%)	
	18	336	66 (19.6%)		82 (24.4%)	
	24	84	17 (20.2%)		23 (27.4%)	
VAS-pain	2	984	109 (11.1%)	0.23	122 (12.4%)	**<0.01**
	4	902	106 (11.8%)		138 (15.3%)	
	6	820	97 (11.8%)		124 (15.1%)	
	12	574	84 (14.6%)		111 (19.3%)	
	18	328	37 (11.3%)		66 (20.1%)	
	24	82	9 (11.0%)		25 (30.5%)	

BASDAI, MCID=1.0; BAS-G, MCID=1.5: VAS-pain; MCID=2.0.

These analyses were performed by using all available measurements per patient with intervals of 2-, 4-, 6-, 12- and 24-months. A Chi Square test was performed to evaluate if the number of observations exceeding the MCID was different between the intervals.

MCID; minimal clinically important difference. BASDAI; Bath Ankylosing Spondylitis Disease Activity Index. BAS-G; Bath Ankylosing Spondylitis Patient Global Score. VAS-pain; Visual Analogue Pain spinal pain.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Previous studies have shown that treatment outcomes are affected by disease-related aspects (e.g., disease severity and chronicity, treatment type and intensity) and patient-related factors (e.g., stress and mood). The aim of this analysis was to compare ankylosing spondylitis (AS) patient profiles in terms of patient characteristics and disease parameters based on disease duration and to investigate the impact of disease duration on patient reported and clinical outcomes in patients treated with anti-TNF in a Canadian routine clinical practice setting.

Methods:

Biologic Treatment Registry Across Canada (BioTRAC) is an ongoing, prospective registry of patients initiating treatment for rheumatoid arthritis, ankylosing spondylitis, or psoriatic arthritis with infliximab (IFX) or golimumab (GLM). Eligible people for this analysis included AS pts treated with IFX and enrolled since 2005 or with GLM and enrolled since 2010. Pts were classified in three subgroups (≤1 yr, 2-10 yrs, >10 yrs) based on the tertile distribution of the time elapsed since their diagnosis. The impact of disease duration on outcomes upon adjusting for potential confounders was assessed with generalized linear models and logistic regression.

Results: A total of 580 AS pts were included in this analysis with a mean (SD) age of 45.8 (12.2) yrs and disease duration since diagnosis of 8.3 (10.2) yrs. The majority were male (61.8%) and 92.6% were biologic naïve. At baseline, mean (SD) BASFI was 5.6 (2.6), BASDAI was 6.2 (2.2), and ASDAS was 3.6 (1.0). With the exception of age which was significantly higher among pts with longer disease duration (43.7 vs. 43.5 vs. 50.0, respectively; P<0.001) no significant between-group differences were observed in baseline demographics and disease parameters.

Upon 6 months of treatment, clinically meaningful and statistically significant improvements were observed in BASFI, BASDAI and ASDAS which were further enhanced at 12 months. Upon adjusting for baseline age and respective parameter levels, pts diagnosed within ≤1 yr experienced significantly lower improvements in BASFI (-1.5 vs. -2.3; P=0.030), BASDAI (-1.6 vs. -2.9; P<0.001), and ASDAS (-1.5 vs. -2.3; P=0.030) at 12 months as compared to pts with disease duration >10 ys. For ASDAS, concomitant DMARD use was also identified as a significant predictor of improved outcome (P=0.042). Gender and prior biologic experience did not have a significant impact on outcomes. Inactive disease or moderate disease activity, based on ASDAS, was achieved by 47.2% of pts while clinically important and major improvements were observed for 54.9% and 32.7% of pts, respectively. Similarly to the absolute improvements, pts diagnosed within ≤1 yr were significantly less likely to achieve these endpoints.

Conclusion: The results of this real-world analysis have identified prior disease duration at anti-TNF initiation as a significant independent predictor of treatment outcome. In addition, concomitant use of a DMARD was associated with significantly higher improvement in ASDAS. These results suggest that pts with early disease may be harder to treat and highlight the need for more aggressive treat-to-target approaches in this patient subgroup.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Psoriatic Arthritis (PsA) is a chronic immune related condition affecting the joints and commonly occurs alongside psoriasis. Well-established

physician patient relationships are instrumental to obtaining the best patient outcomes.

The objective of this analysis was to assess the extent of misalignment between physicians and their PsA patients in terms of satisfaction with current control of their PsA. We then compared aligned and misaligned patients in terms of demographic factors, drug treatments, symptoms, comorbid conditions and patient reported outcomes.

Methods:

Data were drawn from the Adelphi 2011 and 2014 Rheumatology Disease Specific Programmes surveys of rheumatologists and their PsA patients in the USA. Rheumatologists with responsibility for managing PsA patients were recruited and provided patient demographics, clinical details, comorbidities and satisfaction with PsA treatment. Patients reported their satisfaction, and completed the Work Productivity Activity Impairment (WPAI) questionnaire, and alternative HAQ-DI (excluding aids and devices) questionnaire.

Levels of satisfaction agreement between physician and patient responses were constructed and compared: aligned (physician and patient both satisfied, or physician and patient both dissatisfied with PsA treatment) and misaligned (physician and patient reported satisfaction with PsA treatment was different). Descriptive statistics including means and frequencies were derived.

Results:

From 305 paired rheumatologists and PsA patient records, 233 (76.4%) were ‘aligned’, consisting of 65.3% with both physician and patient satisfied, and 11.1% with both dissatisfied.72 (23.6%) cases were ‘misaligned’. The aligned and misaligned groups were similar in terms of age (mean 50.0, 49.8) and sex (% female: 44.6, 45.8). However, the aligned group had longer time since diagnosis compared with misaligned (mean years: 6.4, 5.2) and were more likely to receive biologic DMARD (bDMARD) therapy (% receiving bDMARD: 62.9, 49.3).

The misaligned group tended to be more symptomatic, having higher TJC (mean 5.6 vs. 2.9), SJC (mean: 3.7, 1.9), higher BSA (>3% BSA affected: 64.2% vs. 55.1%), higher number of PsA symptoms (mean: 6.8, 4.9). The most common concomitant conditions were hypertension (28.9%), elevated cholesterol (20.0%), depression (14.1%), obesity (13.8%) and anxiety (10.8%). A greater proportion of misaligned patients had depression (20.8% vs. 12.0%) and anxiety (15.3% vs. 9.4%). As reported in the WPAI, the misaligned were also more impaired in their overall work (mean 38.7% vs. 21.4%), while at work i.e. presenteeism (mean 36.2% vs. 16.5%) and in their daily activities (mean 38.7% vs. 22.3%). Additionally they had higher disability (mean alternative HAQ-DI score: 0.563 vs. 0.369).

Conclusion:

Misalignment between rheumatologists and their PsA patients in satisfaction with PsA treatment exists in almost a quarter of cases. In cases of misalignment, disease severity and patient reported outcomes were worse. The findings suggest that a greater degree of alignment might result in improved outcomes, although further research would be required to verify this hypothesis.

Referral Strategies for the Early Diagnosis of Axial Spondyloarthritis- a Systematic Review

Abhijeet Danve[1] and Atul A. Deodhar[2], [1]Internal Medicine - Rheumatology, University of Nebraska Medical Center, Omaha, NE, [2]Division of Arthritis & Rheumatic Diseases, Oregon Health & Science University, Portland, OR

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Axial Spondyloarthritis (axSpA) is often misdiagnosed or diagnosed late (average delay 8 to 11 years) since low back pain (LBP) is very

common in general population and only 5% of those have axSpA. Effective screening and selective referral of high-risk patients (Pt) can help avoid this delay. There are no recommendations for a referral strategy for axSpA in the United States (US). We performed a systematic review to assess the effectiveness of various referral strategies on the final diagnosis of axSpA, and feasibility of their use in US health system.

Methods:

Pubmed and EMBASE search was performed to identify relevant articles using MeSH terms. After screening abstracts and titles of 135 retrieved articles, 9 full length articles were included for initial review. Three articles were excluded; 2 had different outcome and one was poor quality study. We included a single abstract since it describes the only available study in the US assessing a referral strategy. Final review included 6 full articles and 1 abstract. Data about referral source, referral strategy, Pt characteristics and outcomes were collected. Feasibility was determined by ease of the application of a strategy.

Results:

Most studies used "age at symptom onset <45 years and duration >3 months" as entry criterion (EC) for referral. Pt fulfilling EC only or EC plus combinations of spondyloarthritis (SpA) features (inflammatory back pain (IBP), HLA-B27 (B27), imaging sacroiliitis (iSI), good response to NSAIDS, family history of SpA, uveitis) were referred to rheumatologists. Commonest sources of referral were primary physicians, physical therapists and orthopedists. (See table) Application of simple (EC + 1 of 3 features) and complex strategies (EC + 2 of 5 or 2 of 6 features) produced similar results with 35-45% Pt finally diagnosed as axSpA. Even among studies that used only EC, 33 % to 41% of Pt were diagnosed to have axSpA. Simple strategy of fulfilling EC + 1 of 3 of IBP, B27 and iSI was found to be convenient, feasible and widely acceptable in multicenter studies. Presence of >1 SpA features was associated with higher likelihood of axSpA (24.6%, 44.9%, and 75.5 % for 1, 2 and 3 features respectively). As a single SpA feature in addition to EC, iSI, B27 and IBP were associated with final diagnosis of axSpA in 50%, 55% and 24% respectively, thus confirming low specificity of IBP.

Conclusion:

Referral strategies are effective tools for screening Pt with chronic back pain for presence of axSpA. Simple strategies work equally well compared to complex strategies. With appropriate application of any strategy, rheumatologist will need to see 2-3 Pt with chronic LBP to identify one Pt with axSpA. We believe that in the US, referring Pt with chronic LBP for >3 months, age of onset <45 years AND one of IBP, B27, iSI to rheumatologist for assessment of possible axSpA would be practical, with an acceptable efficacy.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The Patient Acceptable Symptom State (PASS), a single-question outcome, has been defined as an absolute level of patient well-being. A few studies have assessed PASS in patients with ankylosing spondylitis (AS), but it is not known whether the results of those studies apply also to the group of non-radiographic (nr) axial spondylarthritis (axSpA). The objective of this study is to estimate the PASS values for disease activity and several patient reported outcomes both in the whole group of axSpA and in the two subgroups of AxSpA.

Methods: This single-center cross-sectional analysis included patients fulfilling the ASAS criteria for axSpA, who have been registered in our local database. All patients responded to the global yes/no question for PASS. A variety of other outcome measures in regard with global scales, disease activity, functional status, health status and quality of life were collected at the same time. The thresholds at which patients rated themselves in PASS for disease activity (BASDAI and ASDAS) and for each of the assessed patient self-reported outcome measures were estimated using the 75th centile (25th centile for SF 36)estimation and receiver operating characteristic (ROC) analyses in the whole group, as well as in each subgroup of axSpA. Contributors which can affect PASS were evaluated with logistic regression analysis.

Results: The analysis was based on 356 axSpA patients (261 AS, 95 nr-axSpA) with a mean age of 42.2±12.0 years and mean disease duration of 14.7±10.8 years. Of the patients with axSpA, 271 (%76.1) considered themselves in PASS (76.6% in AS, 74.7% in nr-axSpA). PASS thresholds for disease activity and all other assessed outcome measures were shown in table and there were not significant difference between AS and nr-axSpA group. PASS cut-off points for BASDAI, BASFI and HAQ identified by the 75th percentile method were slightly higher than those determined by the ROC analysis, but similar for the rest of the outcome measures. The patients with an acceptable status had significantly lower mean disease activity scores and good results with the all outcome measures. PASS had no relationship with age, sex, disease duration and education (years) in logistic regression analysis. Of the axSpA patients with BASDAI (≥4), 61.4% and those with ASDAS (>3.5), 50% rated themselves in PASS, whereas 5.5% of the patients with a BASDAI score <2, and 4.5% of those with ASDAS <1.2 were not in PASS.

Conclusion: PASS thresholds for disease activity and outcome measures were similar to the figures previously reported in some studies with no apparent difference between patients with AS and nr-axSpA. However, more than half the Turkish axSpA patients considered themselves in PASS, which needs to be evaluated in further studies.

Table. Patient Acceptable Symptom State (PASS) cut-off points for disease activity and health status measures in all patients.

Parameter	PASS + 75th Percentile threshold*	ROC cut off	Area under the curve	Sensitivity/ Specificity
Disease activity BASDAI (0-100mm)	46.0	39.5	0.74	68/65
ASDAS	3.1	3.0	0.74	72/68
Functional measures BASFI (0-100mm)	40.0	35.5	0.72	69/64
HAQ-S	0.9	0.79	0.72	67/64
Global scales Pain VAS (0-100mm)	51.0	49.5	0.75	69/69
Global VAS (0-100mm)	56.8	47.5	0.77	65/73
SF 36 PCS	36.0	38.5	0.73	67/69
MCS	41.0	43.5	0.71	67/63
Quality of life ASqol	8.0	6.5	0.71	68/63
EQ 5D	0.84	0.71	0.72	66/64

Sacroiliitis Misdiagnosed As Spondyloarthritis: Clinical Analysis of 581 Cases

Feng Huang, **Yanyan Wang**, Zheng Zhao and Jianglin Zhang, Rheumatology, Chinese PLA General Hospital, Beijing, China
First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: To study other disease conditions which can present with bone marrow edema of the sacroiliac joints mimicking spondyloarthritis(SpA).

Methods: In a retrospective study of 581 patients from January 2007 to January 2014 for inflammatory back pain datas, including clinical manifestations, laboratory examinations, imaging manifestations and sacroiliac joint biopsy pathological features of these patients were reviewed. All of these patients from Chinese PLA General Hospital. The Images were read independently by at least 2 experienced rheumatologists.

Results: Of the 581 patients, 455 (78.3%) were male, and 436 (75%) cases were diagnosed Ankylosing Spondylititis(AS)/SpA. HLA-B27 positivity rate was 87% among those diagnosed with AS/SpA, Among the 145 patients whose diagnosis was not AS/SpA, HLA-B27 positivity rate was only 8% in 145 patients. 46, 40 and 30 patients had an infectious etiology (pyogenic sacroiliitis/tuberculous infectious sacroiliitis/Brucellar infectious sacroiliitis), sclerosing osteitis or hypophosphatemia osteomalacia (HO) respectively. Other less common diagnoses included diffuse idiopathic bone hypertrophy, palmoplantar pustulosis arthritis and sacroiliac joint gout. The causes of HO included 15 cases of tumor-induced osteomalacia, 4 cases of long-term oral adefovir dipivoxil, 3 cases of Fanconi syndrome, 2 cases of hyperparathyroidism, 2 cases of Sjogren's syndrome complicated with renal tubular acidosis. Patients with infectious sacroiliitis presented with MRI abnormalities

which included bone marrow edema, erosion of bone and joint, 44 of the 46 patients who had an infectious sacroiliitis show adjacent muscle involvement in MRI.

Conclusion: Sacroiliitis not due to AS is quite common in daily practice. Rheumatologists should suspect a different diagnosis when patients respond poorly to NSAIDs, have unexplained low grade fever or other clinical manifestations which cannot be fully explained by AS/SpA. This is even more important when making the decision of using anti-TNF therapy or other immunosuppressive agents.

Disclosure: F. Huang, None; **Y. Wang**, None; **Z. Zhao**, None; **J. Zhang**, None.

Does an Educational Leaflet Improve Attendance for Screening for Psoriatic Arthritis?

Laura C Coates, Laura J Savage, Anna R. Moverley and Philip S. Helliwell, Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: There is a need for screening to identify patients with psoriasis who have PsA. We developed an educational leaflet about the risk of PsA to improve screening attendance. Our aim was to investigate the prevalence of PsA in primary care and whether an educational leaflet can improve attendance.

Methods: Patients with psoriasis were identified from 5 GP surgeries in Yorkshire and a random sample were invited to participate. Patients had to be ≥18 years old, have a coded diagnosis of psoriasis and no diagnosis of PsA, RA or AS. At each site, patients were randomised 1:1 to receive study information alone or with the educational leaflet. Consenting patients were then assessed by a dermatologist and rheumatologist. Diagnosis of PsA was made by the assessing rheumatologist. To compare the response rate, we assumed a difference of 20% (50% without leaflet, 70% with leaflet). With an alpha=0.05 and beta 0.9, using a two sided test a minimum sample size of 248 was required. 191 attendees were required for assessment of screening questionnaires.

Results: A total of 932 packs were sent out to recruit 191 (20.5%) participants attending. Of these, 169 (88.5%) had current or previous psoriasis. Using physician diagnosis 17 (10.1%) were found to have previously undiagnosed PsA, 90 (53.3%) were found to have another musculoskeletal complaint and 62 (36.7%) had no musculoskeletal problems. Using data from the practices and correcting for misdiagnosis of psoriasis, the estimated prevalence of PsA was 18.1%.

Overall the response rate was lower than predicted and was not significantly higher when patients received the educational leaflet (22.8% vs 18.3%, p=0.08). Response rates varied by practice (14.7 to 30.6%). Socioeconomic data of the registered patients at each practice provided national statistics on deprivation with each practice given a decile score. In our study, one practice had a deprivation score of 3 (third most deprived), one had a score of 7 and the rest had a score of 10 (least deprived decile). Analysing the impact of the leaflet on response rates by deprivation showed that there was a significant increase in response with the leaflet for deprivation decile of 3 (see table, p<0.001) but no significant differences in the other practices.

Conclusion: The total prevalence of PsA within patients with psoriasis in primary care is estimated at 18.1%, and from a sample of 191, 10.1% are diagnosed with new PsA at screening. An educational leaflet about PsA did not improve attendance for screening overall, but did significantly improve attendance in practices with higher levels of socioeconomic deprivation.

Deprivation Index	Information given	No of packs sent	Response rate (%)	Pearson Chi Squared	P value
3	Leaflet	46	30.4	13.21	<0.001
	No leaflet	54	3.7		
7	Leaflet	75	18.7	1.92	0.166
	No leaflet	75	10.7		
10	Leaflet	340	22.6	0.18	0.894

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

It has been observed that ankylosing spondylitis (AS) patients have a high frequency of asymptomatic chronic gut inflammation, with as many as 60% of AS patients with evidence of microscopic gut inflammation without gastrointestinal symptoms. While much is known about the clinical relationship between AS and IBD, little is understood about the directionality of these relationships or the role of the gut in the pathogenesis of AS. This study aimed to investigate if healthy asymptomatic first-degree relatives (FDRs) of ankylosing spondylitis patients have evidence of subclinical gut inflammation that precedes development of musculoskeletal signs and symptoms of AS.

Methods:

30 healthy FDRs of AS patients between the ages of 18 and 50 years old were recruited for the purpose of this study, of which 18 are included in the current cross-sectional analysis. We collected serum biomarkers of gut inflammation including anti-*Saccharomyces cerevesiae* antibodies (ASCA), antineutrophil cytoplasmic antibodies (ANCA), anti-I2 (associated with anti-*Pseudomonas* activity), anti-*Eschericia coli*outer membrane porin C (anti-OmpC) and anti-flagellin antibodies (anti-CBir1), as well as stool samples to measure fecal calprotectin. Clinical data about symptoms and signs of ankylosing spondylitis was obtained using the Toronto Axial Spondyloarthritis Questionnaire in Inflammatory Bowel Disease (IBD.) Finally, we obtained a pelvic MRI on all subjects using STIR (Short TI Inversion Recovery) sequences to rule in or out the presence of asymptomatic axial spondyloarthritis. FDRs with no MRI evidence of disease will be followed and assessed yearly for the development of AS.

Results:

Of 18 FDRs included in the current analysis, six were found to be HLA B27 positive. Six FDRs (33%) reported back pain, and four FDRs (22%) reported heel pain. No participants reported other extra-articular manifestations and no participants reported gastrointestinal symptoms. On MRI, two FDRs (11%) were found to have evidence of definite sacroiliitis. Four FDRs (11%) were found to have a fecal calprotectin level which was in the upper range of normal. Six FDRs (33%) were found to have at least one positive IBD antibody, five of which have CBir positivity (27%). Two FDRs (11%) had a positive ASCA antibody. Of the six FDRs with a positive IBD antibody, 50% were HLA B27 positive and none reported back pain, gastrointestinal symptoms, or had MRI evidence of sacroiliitis.

Conclusion:

A substantial proportion of healthy FDRs of AS patients have an elevated serum IBD antibody profile, specifically with respect to anti-CBir1, without evidence of clinical IBD, suggestive of mucosal dysregulation. This study will contribute to our understanding of the directionality of the AS-gut inflammation relationship as well as the role of the gut in the etiology of AS. With increasing understanding of whether gut inflammation precedes AS, we can develop a prediction tool for determining who is at risk of developing the disease and begin to intervene at the earliest possible stage in order to delay the onset of debilitating symptoms.

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Obesity is more prevalent among patients with psoriasis and psoriatic arthritis (PsA). This correlation appears to be related to fat tissue-driven systemic inflammation. Although bariatric surgery has been shown to improve several obesity-related comorbidities, the effects of surgical weight loss on psoriasis and PsA are unknown. Our objective was to investigate the effects of weight loss from bariatric surgery on psoriasis and PsA.

Methods: A retrospective database of 9,073 bariatric surgeries performed at a single center between 2002-2013 was queried. Patients with a diagnosis of psoriasis prior to surgery were identified. Patients were contacted about their history of psoriasis, PsA, change in symptoms, and treatment modalities pre- and postoperatively. The primary outcome was the percentage of patients who reported improvement (reduction of >5 on rating scale 0-10) in psoriasis and PsA after surgery. Secondary analyses were performed to define factors associated with improvement in psoriasis and PsA.

Results: We identified 128 patients with a preoperative diagnosis of psoriasis. Eighty-six (67%) patients completed the study. Baseline patient characteristics are listed in Table 1. The mean time from surgery was 6.1 years, with a mean excess weight loss (EWL) of 46.2%. Twenty-one (24%) patients with psoriasis also had a preoperative diagnosis of PsA

At the time of contact, 55% of psoriasis and 62% of PsA patients reported subjective improvement of their disease. Disease severity rating (0-10 scale) significantly decreased from prior to surgery compared to 1 year post surgery for psoriasis (5.6 vs 4.4, $p<0.01$) and PsA (6.4 vs 4.5, $p=0.01$), and was more pronounced among severe (rating >5) psoriasis (7.7 vs 5.7, $p<0.01$) and PsA (8.2 vs 4.8, $p<0.01$).

In secondary analyses of patients with severe psoriasis and PsA, higher EWL at recent follow-up was significantly associated with improvement in psoriasis (59.5 vs 43.5%, $p=0.046$) and higher EWL at 1 year was associated with a trend in PsA improvement (55.4 vs 43.8%, $p=0.47$). Improvement in disease among severe psoriasis patients was associated with higher rating of disease at the time of surgery (8.9 vs 7.4, $p<0.01$) and older age at diagnosis (37 vs 26yr, $p=0.02$).

Conclusion: Although the natural history of psoriasis and PsA is typically chronic, a majority of patients experience improvement after bariatric

surgery. Our results indicate an association between EWL and symptomatic improvement in severe cases of psoriasis. Factors such as older age at diagnosis of psoriasis and severity of psoriasis may be used to identify patients with a greater likelihood of improvement. Despite study limitations, we show for the first time an improvement in PsA after bariatric surgery and a possible association with surgical EWL. Larger prospective studies are needed to further define the true effect of surgical weight loss on psoriasis and PsA.

Table 1: Baseline Characteristics of Study Population (n=86)	
Male Gender, n (%)	33 (38%)
Age (years), mean (SD)	46.5 (12.6)
Preoperative Weight (lb), mean (SD)	288 (55)
Preoperative Body Mass Index (kg/m^2), mean (SD)	45.8 (6.8)

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

In RA, previous studies observed inequalities across countries as well as individual level socio-economic factors, and unequal uptake of biologic DMARDs (bDMARDs) played an important role in these inequalities. It is not known whether the same pattern is present for patients with spondyloarthritis (SpA). Our objectives were to assess (1) independent associations of country level and individual socio-economic determinants of health in patients with SpA and (2) if confirmed, whether this relation is mediated by uptake of bDMARDs.

Methods:

Data from the cross-sectional multinational (22 countries) study Comorbidities in Spondyloarthritis (COMOSPA) was used. ASDAS-CRP and BASFI were the outcomes. First, the contribution of individual socio-economic factors (age, gender, and education) was explored, adjusting for BMI, comorbidities, presence of extra-articular manifestations and axial SpA. Next, country of residence (separate variable for each country) or country's welfare was added to the model. Country's welfare was defined as Gross Domestic product (GDP) per capita (low, medium or high). Multivariable linear regression models were used. Interactions between (1)education (2)age and (3)gender with GDP were tested. The mediating role of uptake of bDMARDs in the relationship between education and ASDAS or GDP and ASDAS was explored by testing indirect effects.

Results:

3984 patients from 22 countries worldwide (41 to 337 subjects/country) were included. Mean age was 44 yrs. (SD14), 65% males, 13% had primary and 45% secondary education, 83% axial SpA. Mean ASDAS and BASFI were 2.4 (SD1.1) and 3.0 (SD2.7), respectively. Five to 68% of patients were currently treated with bDMARDs. Females (vs. males) had higher BASFI (β=0.70 [95%CI 0.54;0.86]) while gender was not relevant for ASDAS and effect of age was negligible for both outcomes. Lower educated individuals had higher ASDAS and BASFI (β=0.21 [0.09;0.33] and β=0.60 [0.37;0.85], respectively) (Table). Large country differences were observed after adjusting for individual confounders. Low GDP (vs. high GDP) was associated with higher ASDAS (β=0.70 [0.60;0.79]) but lower BASFI (β=-0.21 [-0.42;-0.01] (Table). No interactions were detected. Current uptake of bDMARDs did not mediate relationship between education or GDP with ASDAS.

Table. Association between individual and country level (GDP) factors with ASDAS and BASFI. Results of multivariable linear regression model (β [95%CI]).

GDP – Gross Domestic Product in int.$ ASDAS - Ankylosing Spondylitis Disease Activity Score; BASFI - Bath Ankylosing Spondylitis Function Indices

Conclusion:

Lower education was associated with worse disease activity and function in SpA. In addition, even after adjusting for individual factors, substantial differences in these outcomes remained between countries. Interestingly, low GDP societies had higher objectively measured disease activity (ASDAS), but appeared to score slightly better on the more subjective assessment of physical function (BASFI). Relationship between low socio-economic status (individual or country level) and higher disease activity could not be attributed to lower uptake of biologic DMARDs.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Ankylosing Spondylitis (AS) is associated with a high disease burden. The greatest contributor to the burden is loss of productivity. The data on productivity loss in Turkish patients with AS is scarce. Work Productivity Survey (WPS) is a validated tool in AS to assess productivity during the preceding month, both at work and at home. The aim of this study is to assess work productivity in Turkish AS patients using the WPS.

Methods: A total of 397 patients with AS (males:71.4%, mean age: 40.5, mean disease duration 6.8 years) from 19 rheumatology centers across Turkey were included in the study. Patients, with the help of a health professional, completed questionnaires for BASDAI, BASFI, HAQ-S, ASQoL and EQ-5D, total and nocturnal pain and WPS. Student's t test was used to compare continuous variables and chi square analysis was used to compare categorical variables. The association between the responses to WPS questions and scores of disease activity, functional and quality of life scores was assessed using Kendall correlation coefficients.

Results: Of all the patients, 62.4% of were employed, 16.1% were homemakers, 9.6% were retired, 3.0% were student and 5.3% were unable to work due to AS. Non-working patients, as compared to the working patients, were older (44 vs 38, p: <0.001), more likely to be female (54% vs 14%, p: <0.001) and had less favorable scores for BASDAI (3.8 vs 3.0, p: <0.015), BASFI (2.9 vs 2.3, p: 0.001), HAQ (0.8 vs 0.5, p: <0.001), EQ-5D (0.6 vs 0.7, p: 0.005) and productivity. Working AS patients reported missing 1.2 days of work and had 2.8 days productivity reduced by at least half. As compared to the working patients, the non-working patients missed more days of housework (5.4 vs 2.9), more days of family, social or leisure activities, more and had more days with outside help, more days with reduced productivity in house work in the past month (for all comparisons, p: <0.001). However, no difference was observed between the working and not working female patients. WPS questions were shown to have moderate correlation with other clinical and health related quality scores either at workplace or at home (range from r: 0.268 to r: 0.481) (Figure).

Conclusion: AS has a considerable impact on productivity for working and non-working patients, particularly in females. WPS is a useful tool to appreciate the burden of disease in patients with AS not only at workplace, but at also at home, which may be even more important in populations with a low women's workforce participation rates.

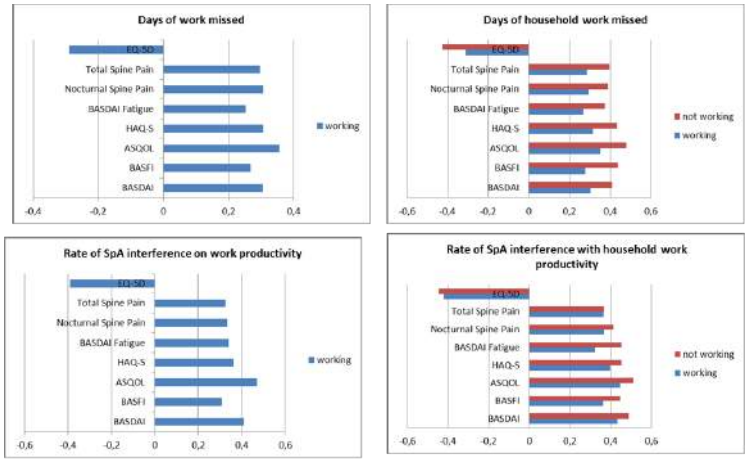

Figure: Kendall correlation coefficient between WPS and clinical and health related quality of life assessments

Standards for the Classification of Non-Radiographic Axial Spondyloarthritis: A European Real World Study

Tim Holbrook[1], Robert Wood[1], **Christopher Black**[2], Xiaohan Hu[2] and Sumesh Kachroo[2], [1]Adelphi Real World, Macclesfield, United Kingdom, [2]CORE, Merck & Co., Inc., Rahway, NJ

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Classification of non-radiographic axial spondyloarthritis (nr-axSpA) requires the presence of Assessment of Spondyloarthritis international Society (ASAS) criteria for AxSpA, without radiologic evidence of sacroiliitis according to the modified New York Criteria. Existing evidence is limited relating to diagnostics in a real-world setting. The aim of this analysis was to investigate how patients are being classified as nr-axSpA in a real-world consulting sample.

Methods: Data were taken from the 2014 nr-axSpA Disease Specific Programme a cross-sectional, multi-national survey of nr-axSpA patients and their rheumatologists conducted in France, Germany, Italy, Spain and the UK. Physicians were asked to recruit their next 2 consecutive, consulting nr-axSpA patients. Inclusion in the survey was based on diagnosis of nr-axSpA by the rheumatologist, regardless of how the patient was actually diagnosed. No specific classification criteria were required. Physicians completed patient record forms containing patient demographics, clinical measurements and symptomology at diagnosis and criteria used to classify the patient with nr-axSpA. Observations were weighted to ensure findings were more representative of the patient population. The weight was applied when calculating all percentages, means and SDs.

Results: A total of 631 patients were included in the analysis (mean age 41.8±12.0 [SD], 70.4% male). Physicians reported that in over half (52.5%) of their patients, the nr-axSpA diagnosis was made using the ASAS criteria, however, 29.5% were diagnosed without any form of classification criteria. The majority (93.7%) of patients had inflammatory back pain (IBP) at diagnosis, while 21.7% had enthesitis, 3.4% had uveitis, 9.4% had dactylitis and 2.9% had psoriatic skin lesions. A family history of Ankylosing Spondylitis (AS) was reported in 18.5% of patients. Mean time since diagnosis was 51.6±59.9 months, while 17.4% of patients were 45 or older at onset of disease. Evidence of sacroiliitis was identified at diagnosis via X-ray or magnetic resonance imaging in 69.1% of patients. Only 149 patients had further information reported regarding sacroiliitis at diagnosis; 56.7% had IBP at diagnosis and sacroiliitis either grade ≥2 bilaterally or grade ≥3 unilaterally, fulfilling the classification for an AS diagnosis.

Conclusion: While there are guidelines in place to aid the classification of nr-axSpA, in real-world practice it appears that there remains some inconsistency in how physicians classify the condition. Under-use of the recommended guidelines suggests an unmet need in accurate classification of nr-axSpA and therefore optimal treatment decisions for patients.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To assess the relationship between improvement or worsening in enthesopathy and changes in functioning and quality of life (QOL) in patients with psoriatic arthritis (PsA).

Methods: Adult PsA patients (n=615) with active disease (≥5 SJC and ≥5 TJC;CRP≥0.3mg/dL) despite DMARD and/or NSAIDs were randomized to UST45mg, 90mg, or PBO at weeks 0, 4, and q12weeks. Patients treated with prior anti-TNF agents were excluded. Stable concomitant MTX was permitted but not mandated. At week16, pts with <5% improvement in TJC & SJC entered blinded early escape (PBO→UST45mg; UST45mg→90mg; 90mg→90mg). Presence or absence of enthesopathy, HAQ and SF-36 were assessed at baseline and week 24. In this post-hoc analysis, the enthesopathy was focused on the Achilles tendon and plantar fascia and was assessed as present or absent. Patients were categorized for enthesopathy into three categories: improved (enthesopathy present at baseline, but not at week 24), worsened (enthesopathy present at week 24, but not at baseline), and unchanged. Patients with an enthesopathy assessment missing at either time point were included in the unchanged category. Improvements in quality of life (assessed by the Short Form-36 mental and physical component scores [SF-36 PCS and SF-36 MCS] and physical function (assessed by the Health Assessment Questionnaire-Disability Index [HAQ-DI]) were assessed by enthesopathy status.

Results: 80% of patients (n=491) reported enthesitis at baseline, and the proportion of patients with enthesopathy was similar in the combined ustekinumab (47.2%) and placebo (52.1%) groups. At week 24, the proportions of patients with enthesopathy were 23.2% and 38.2% for the combined ustekinumab and placebo groups, respectively. Across all patients, those who had an improvement in enthesopathy had a greater improvement in functioning and QOL, compared with those who did not (Table). The results were consistent when the analysis was done separately for each treatment group. Even when the analysis was restricted to those who achieved an ACR 20 response, patients with an improvement in enthesopathy still showed a greater improvement in functioning and QOL compared to those who did not (Table).

Table Enthesopathy status and mean (SD) changes from baseline at week 24

	Enthesopathy Status		
	Worsened	Unchanged	Improved
Overall			
% improvement in HAQ-DI	n=21 17.7(35.9)	n=339 22.6(66.0)	n=113 37.5(47.0)
Change in SF-36 PCS	n=22 4.1(7.1)	n=333 4.9(8.7)	n=116 6.7(9.1)
Change in SF-36 MCS	n=22 -1.5(8.8)	n=333 3.5(10.1)	n=116 6.7(9.6)
ACR 20 responders			
% improvement in HAQ-DI	n=8 33.7(32.8)	n=145 52.8(37.0)	n=72 53.4(39.1)
Change in SF-36 PCS	n=8 8.7(7.4)	n=150 8.7 (8.8)	n=72 9.5(8.8)
Change in SF-36 MCS	n=8 3.5(8.0)	n=150 5.2(10.2)	n=72 7.7(9.4)

Conclusion: Ustekinumab treatment can significantly improve enthesopathy associated with psoriatic arthritis.There is an association between improvement in enthesopathy of the Achilles tendon and plantar fascia and improvement in physical function and quality of life in patients with PsA.

Clinical and Imaging Features of Reactive Arthritis in Guatemala City

Helga Raquel Garcia Ferrer[1], A Garcia Kutzbach[2], Isa Iraheta[3], Jose U. Scher[4], Joan Von Feldt[5,6] and Alexis Ogdie-Beatty[7], [1]Society for Worldwide Med Exchange, North Bay Village, FL, [2]Internal Medicine, Rheumatology Unit (AGAR), Francisco Marroquin University, School of Medicine, Guatemala City, Guatemala, [3]Rheumatology, Guatemalan Association against Rheumatic Diseases (AGAR), Guatemala City, Guatemala, [4]Department of Medicine, Division of Rheumatology, New York University School of Medicine, New York, NY, [5]Philadelphia VA Medical Center, Philadelphia, PA, [6]University of Pennsylvania, Philadelphia, PA, [7]Medicine/Rheumatology, University of Pennsylvania, Philadelphia, PA

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Reactive arthritis (ReA) is an inflammatory arthritis that typically follows infection. The objectives of this study were to describe the joint and enthesial involvement among patients with ReA in Guatemala City and to examine the prevalence of SI joint disease on Xrays and Achilles enthesopathy on ultrasound in patients with ReA and controls.

Methods: We performed a prospective cross-sectional study between January and October 2014 in Guatemala City. ReA was defined as inflammatory arthritis following a gastrointestinal (GI) or genitourinary infection (GU) and meeting the ASAS peripheral spondyloarthropathy criteria. Cases were identified in AGAR Rheumatology clinic and controls with a GI or GU infection in the preceding 3-6 months were recruited from primary care clinics in the same institution. A standardized questionnaire ascertained infection details, family history, medication and herbal

supplement use, medical comorbidities, employment, place of residence (urban vs rural), smoking status, and literacy. Subjects completed the mini-nutritional assessment, a pain assessment, a standardized joint and enthesis examination by same observer, radiographs of the sacroiliac (SI) joints interpreted by a trained radiologist and 2 blinded rheumatologists, and ultrasound of the bilateral Achilles Tendons.

Results: 33 patients with ReA and 31 controls were enrolled. Mean age was 39 (SD 11.3) and 36 (SD 10.1) respectively. None of the controls had swollen or tender joints or entheses. We found that 32 cases (97%) had a recent history of peripheral arthritis. History of uveitis was present in 20 cases (60%). The most frequently tender joint was the right sacroiliac joint (N=27, 81%) followed by left sacroiliac joint (N=25, 75%). The most frequently swollen joint was the left ankle (N=4, 12%) followed by right ankle (N=3, 9%). The most frequently tender enthesis was the Achilles tendon, right and left (N=22 each, 67%) followed by right medial femoral condyle (N=17, 52%). The most common finding on sacroiliac joint Xray was bilateral sacroiliitis (N=15, 45%). Bilateral SI joint abnormalities were also found in 10 controls (32%). Inflammation was noted on Achilles tendon ultrasound in 13 (39%) cases and in one (3 %) of the controls.

Conclusion: Reactive Arthritis is the most common form of the Spondyloarthropathies in Guatemala City. To our knowledge, this is the first study in the Central American region to examine clinical and imaging features of ReA. A strength of the study was inclusion of a control group exposed to infection. We found a high prevalence of peripheral arthritis, tender SI joints, and uveitis. Additionally, Achilles tendon ultrasound was positive in nearly 40% of patients (compared to 3% of controls). Interestingly, SI joint xrays were frequently abnormal in both cases and controls (45% vs 32%).

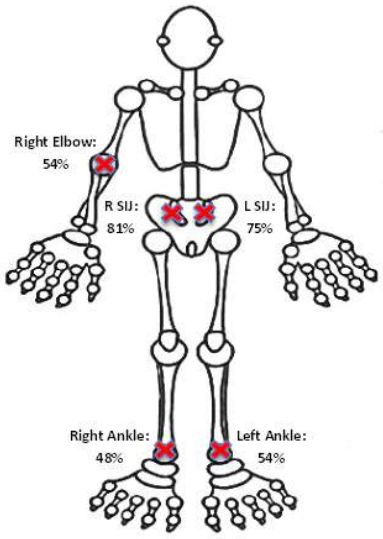

Figure. Tender joints among patients with reactive arthritis in Guatemala City. Abbreviation: SIJ = Sacroiliac joint.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: There is a lack of data on the quality of life (QoL) in patients (pts) with active peripheral spondyloarthritis (pSpA). The purpose of this study was to assess the QoL in pts with pSpA, and compare it to the QoL across other rheumatic diseases.

Methods: Data for this analysis originated from the following five trials of adalimumab versus placebo for various rheumatic diseases: ABILITY-2 for pSpA; ABILITY-1 for non-radiographic axial SpA (nr-axSpA); ATLAS for ankylosing spondylitis (AS); DE019 for rheumatoid arthritis (RA), and ADEPT for psoriatic arthritis (PsA). In each dataset, the QoL at baseline was measured by the Short Form 36 (SF-36) mental component summary (MCS) and physical component summary (PCS). Differences from the norms for an age-and gender- matched healthy control population at baseline were calculated for each rheumatic disease. In order to assess the influence of disease activity and disease duration on MCS and PCS, patients were stratified into tertiles by disease activity or disease duration. The difference in MCS and PCS and the 95% CI for the extreme tertiles (lower vs higher) was compared to that for an age- and gender-matched normal population. Lower vs. higher disease activity was defined as: Bath Ankylosing Spondylitis Disease Activity Score (BASDAI) ≤4.8 or >6.5 for pSpA; ≤6.0 and >7.1 for nr-axSpA; ≤5.6 and >7.1 for AS; 28-joint count disease activity score based on C-reactive protein [DAS28(CRP)] ≤5.3 and >6.1, for RA; Patient's global assessment (PtGA) ≤39 and >60 for PsA. Shorter vs. longer disease duration was defined as: ≤2.6 or >3.4 years (yrs) for pSpA; ≤0.5 or >2.3 yrs for nr-axSpA; ≤5.2 or >13.4 yrs for AS; ≤5 or >12.9 yrs for RA; ≤4.2 or >11.2 yrs for PsA.

Results: Across the five rheumatic diseases, the differences in SF-36 MCS and PCS compared to the norms for an age- and gender-matched population were similar (table). However, the observed difference from the norm was greater for the PCS than for the MCS indicating a greater impact on physical function. For each disease, higher disease activity, but not longer disease duration was associated with a significantly greater difference in PCS and MCS compared to the norms.

Conclusion: Patients with pSpA suffer from a poor quality of life, to a similar extent compared with the other rheumatic diseases included here. Results indicate that current disease activity and not disease duration contributes to this impairment of physical and mental health.

Table: Mean Difference compared to age- and gender matched population norms for SF-36 PCS and MCS at baseline, mean (95% CI)

Is a Geriatric Rheumatology Sub-Group Worth Distinguishing? Disease Characteristics of a Geriatric Psoriatic Arthritis (Gero PsA) Subgroup Compared with Those of below 45 Years of Age

Euthalia Roussou, Rheumatology, Dr, London, United Kingdom
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Adult rheumatologist assess conditions in patients aged 18 and above. There is no distinction to those of the frail age of 65 and above who could belong to a geriatric rheumatology group. **Aims:**To assess whether there are differences between psoriatic arthritis (PsA) patients aged above 65 years (y). To compare demographic, (gender ratio, ethnicity, social habits) disease characteristics, activity and function(disease duration, delay in diagnosis, ESR, CRP, Night pain, sleep disturbance, BASDAI, BASFI) and treatment (Tx)options as wells as treatment effect, and well being over past week (wbpw) and over past 6 months (wb6m) of those above 65y with those aged below 45y.

Methods: From total 719 patients (pts) with Spondyloarthritis (SpA) registered in the London Registry of SpA (LoRoS) which has been developed aiming to assess differences in SpAs between ethnic groups over time, (ethics approval REC 07/H0701/74) 247 pts had confirmed PsA by CASPAR. From the total of 247 pts, 45 pts had their baseline characteristics recorded at age 65y (or above) and formed the Gero PsA group (gPsA) which has been analysed and compared with those patients who entered in the registry at age below45y (b45) (n=73). The remaining patients belonging in the intermediate age group of between 45 to 64 (intag)(n=124) has been analysed where there were discrepancies.

Results: Table shows the disease characteristics of the geroPsA group compared with those of below 45, ssd and CI. The statistically significant difference(ssd) between the ethnic groups studied in our cohort compatible with national ethnic migration reports. Smoking reported by more b45 but did not reach ssd. There was no difference in the Tx between the gPsA and the b45 except a borderline difference in the Tx with Sulphasalazine (SSZ)in that more pts b45 were on SSZ [P=0.08 (CI= -0.21 to 0.18)] while more gPsA patients had joint surgery (p=0.01; CI=0.065 to 0.45).

Conclusion: PsA patients above the age of 65y have differences compared with the younger age group and can form a distinct geriatric PsA group. Differences identified in our cohort were related to ethnicity, social habits, inflammatory markers, function and treatment options and effect.

Items	Gero PsA(n=45) mean (sd)	Below45y (n=73) mean (sd)	Pvalues	CI (lower to upper
Gender	16:29(1:2)	24:49(1:2)	n/a

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The influence of smoking on the development of rheumatoid arthritis, the severity of the disease and the response to treatment is well established. The impact of tobacco use in patients with axial spondyloarthritis (axSpA) is only beginning to emerge. The aim of our study was to review the literature to evaluate the impact of tobacco on the development of axSpA, the activity and the severity of the disease and the therapeutic response.

Methods: Using PUBMED database, COCHRANE and a manual search, we review the literature with the keywords: "Spondylarthropathies"[Mesh] OR "spondylitis"[Mesh] OR "spondylitis, ankylosing "[Mesh] OR "spondylarthropathy" OR spondylitis OR spondylarthropathies) AND (tobacco OR "tobacco"[Mesh] OR smoking OR "smoking"[Mesh] OR "cigarette" OR "environmental" OR "environmental factors". The articles on psoriatic arthritis were excluded. Smoking status was divided into current smoker (CS), past smoker (PS), never smokers (NS), ever smoker (ES) with ES=CS + PS, and non-smokers= PS + NS.

Results: Among 511 articles (493 from PUBMED, 17 from COCHRANE and one from the manual search), we include 15 articles (2 abstracts from congress). No significant difference was found between ES and NS in terms of age at symptoms onset (-0.67 [-3.18 to 1.83]; I^2 = 47%; p=0,60, n=2), on erythrocyte sedimentation rate (ESR) (+2,87 [-7.73 to13.46]; I^2 = 85%; p=0.60; n=2), on C-reactive protein (CRP) (+3.12 [-2.3 to 8.55]; I^2 = 89%; p=0.26; n=3), on BASDAI (+0.16 [-0.05 to 0.37]; I^2 = 12%; p=0.14; n=3), and on HAQ (0.0 [-0.2- 0.2]; I^2 = 83%; p=1.0; n=2). Conversely, BASFI (+0.69 [0.44 to 0.93]; I^2 = 0%; p<0.001; n=3) and ASDAS-CRP was higher in ES versus NS (+0.14 [0.03to 0.25]; I^2 = 0%; p=0.01; n=2). Comparing CS to non-smokers, we found a trend to increased CRP (+2.74 [-0. 44 to 5.93]; I^2 = 0%; p=0.09; n=3) and BASDAI (+ 0.48 [-0.07to1.03]; I^2 = 84%; p=0.08; n=5) and a significant increase of BASFI in (+1 [0.35 to 1,66]; I^2 = 74%; p=0.003; n=5).The systematic review of literature showed that ES had higher inflammation on MRI and axial structural damage on MRI and radiographs than NS. Response to tumour necrosis factor-alpha inhibitor treatment evaluated by BASDAI 50% at 6 and 12 months was decreased in ES compared to NS.

Conclusion: Current and past smocking is associated with an increased disease activity (BASDAI and ASDAS-CRP respectively) and functional impairment. Pathogenesis remains to be determined. Smoking cessation should be encouraged in axSpA although these results suggest that it may not impact disease prognosis.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Current methods for identifying people with axial spondyloarthritis (AxSpA) in large datasets are inadequate because billing codes for most types of spondyloarthrtis (SpA) do not indicate the presence or absence of axial involvement and nomenclature for AxSpA is varied and evolving. This has substantially limited observational research of AxSpA and AxSpA subtypes. The objective of this study was to develop methods for identifying AxSpA in national Veteran Health Administration (VHA) datasets

Methods: Algorithms for identifying veterans with AxSpA were designed to include combinations of SpA features and billing codes (Figure 1). Terms that represent SpA features were identified in clinical documents with natural language processing (NLP). Methods were developed to test and refine the algorithms. Data and computing resources included the Corporate Data Warehouse, Decision Support System, and the Veteran Affairs Informatics and Computing Infrastructure (VINCI).

Results: Terms representing SpA features were explored, identified, selected, extracted, and annotated for the development of NLP modules, using methods and technologies shown in Table 1, Step 1. Methods and software were also designed to build reference populations, identify veterans fulfilling the algorithms, and test the algorithms (Table 1, Steps 2-4). The accuracy of NLP modules exceeded the target accuracy of 90% (Table 2).

Conclusion: The methods for identifying terms representing SpA features in clinical documents are feasible, and SpA feature terms have been identified with high accuracy. Further work is required to apply, test, and refine the algorithms in reference populations with and without AxSpA.

Figure 1. Algorithms for identifying axial spondyloarthritis

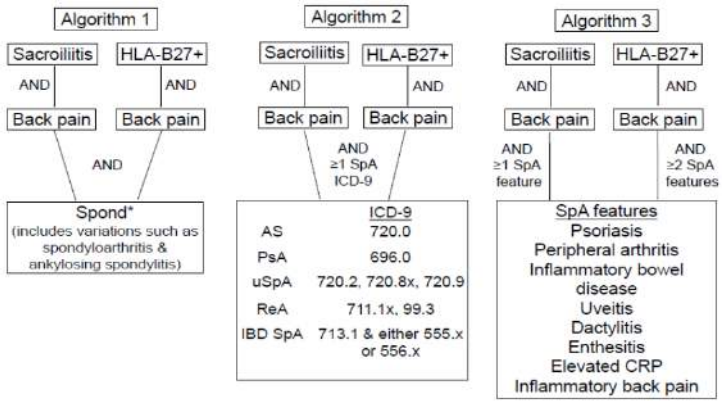

Table 1. Methods for identifying axial spondyloarthritis		
Steps		Software
1	**Identify terms in clinical documents that represent SpA features. For each term:**	
1a	Explore term variations (alternative wording, misspellings, descriptions, etc.) in randomly sampled clinical documents - Identify root words for each variation (includes word fragments with wild cards[*]) - Select root words that represent the intended term in ≥40% of reviewed documents	Voogo
1b	Identify term variations in VA documents - Query root words in VA datasets to identify all term variations mentioned in all documents - Determine the number of times each variation was mentioned in all documents in the database	SQL
1c	Select common and meaningful term variations - Exclude rarely used variations - Exclude variations that don't represent the intended term (not meaningful)	Excel
1d	Extract sections of text containing the selected term variation (snippets) from all documents	Snapshot
1e	Annotate randomly selected snippets - Identify the parts of text necessary to determine if the extracted term represents the intended SpA term - Classify the snippet text according to whether or not it represents the intended term (yes/no/possible) - Develop & revise annotations guidelines - Train annotators until inter-rater agreement is >90% - Annotate 1500 snippets for NLP	Visual Tagging Tool (VTT), eHOST
1f	Develop NLP module - Develop sets of rules (machine learning) that train NLP software how to classify terms in the context of the surrounding text - Test and revise NLP modules with additional annotated snippets until accuracy is >90% for each term	Support Vector Machines (SVM), RED
1g	Classify patients with discordant snippet classifications - Develop and apply rules for classifying patients with snippets assigned to different categories (yes & no)	SQL
2	Develop reference population of veterans with and without AxSpA	
2a	Develop cohort of 2500 randomly selected veterans - Enrich cohort by selecting veterans with at least 2 rheumatology clinic encounters - Create tables with data relevant for determining AxSpA status for each veteran (rheumatology clinic notes, reports from articular radiographs, DMARD exposure, anti-CCP, RF, HLA-B27, etc.) - Import tables into Chart Reviewer software and set software parameters	SQL ChartReview eHOST
2b	Classify veteran in rheumatology reference population - Develop classification guidelines - Determine inter-rater agreement between classifiers - Classify veterans in reference population as AxSpA or no AxSpA	SQL ChartReview eHOST
3	Identify veterans fulfilling algorithms	
	Sequentially apply NLP modules and coded ICD-9 data to: - Rheumatology reference population - General veteran population	SQL
4	Test & refine algorithm(s)	
4a	Test & refine algorithm(s) in the rheumatology reference population - Calculate sensitivity, specificity, and accuracy of each algorithm - If algorithm accuracy is <85%, revise processes ± algorithms	SQL
	Test and refine algorithm(s) in the general veteran population	

4b	- Review charts of randomly selected veterans fulfilling algorithms & manually classify as AxSpA or no AxSpA - Calculate specificity of each algorithm using manual classification as reference - If algorithm specificity is <85%, revise processes ± algorithms	SQL
5	Alternative plan (if necessary)	
	If performance of all algorithms is suboptimal, develop a model that will statistically identify the most predictive combination(s) of terms	SQL

Table 2. Identification of terms in clinical documents that represent SpA features

Term	# Root words with true positive rate >40%	# Term variations found in VA documents	# Meaningful variations in ≥100 documents	# Extracted snippets	Annotator IRR [Kappa (%)]	NLP Accuracy (%)
	(Step 1a)	(Step 1b)	(Step 1c)	(Step 1d)	(Step 1e)	(Step 1f)
Sacroiliitis	16	905	506	326,436	98.1	91.1
Spond*	6	9593	134	802,757	94.8	93.5
HLA-B27+	1	299	3	774,140	93.3	97.2
Back pain	34	4359	416	1,547,520	100	NA*
*NLP unnecessary since extraction methods yielded 97% true positive classification of randomly sampled snippet

[1]PsART study group, Ankara, Turkey

Background/Purpose: Psoriatic arthritis (PsA) is a complex disease with various patterns of joint involvement. PsART (**Ps**oriatic **A**rthritis **R**egistry of **T**urkey) is a prospective, multicentre, nationwide study in Turkey which was built with the objective of understanding the nature of the

disease, clarify differences among different presentation types of PsA and identifying poor prognostic factors. Here we present the cross sectional characteristics of a large group of PsA patients from the registry, with an emphasis on factors associated with axial disease.

Methods: PsART was built in May 2014. Patients are consecutively recruited to this registry, if they are diagnosed as PsA, regardless of any disease characteristics. Data collection was performed through a website. Disease characteristics, treatments and comorbidities were collected in addition to disease activity and function assessment.

Results: Until June 2015, 1060 patients were recruited. Within these 64.5 % (684/1060) were female.. The mean (SD) duration of PsA was 77.7 (89) months. Arthritis was the initial finding in 4.4% and psoriasis preceded in 85.8% (Table). Patients with axial involvement were significantly younger than the other forms of arthritis ($p<0.0001$). Other factors that were associated with axial disease were type of psoriasis (pustular type 31.4% in axial disease vs 21.4 in non-axial forms; $p=0.008$), smoking (43.7% vs 33.3%; $p=0.008$) and having nail disease (53.3% vs 44.6%; 0.013).

Patients who had pustular type of psoriasis, nail disease and smoked had a 1.86 relative risk for having axial disease compared to patients who doesn't have at least one them.

Conclusion: The patient characteristics of the PsART are comparable to the previously reported registries, supporting its external validity. The pattern of arthritis may be foreseen in patients with pustular type of psoriasis and nail disease especially if they have a history of smoking.

Age (mean(SD))	47 (12.9)
BMI (mean (SD))	28 (5.2)
Polyarthritis n (%)	373 (35.2%)
Axial involvement n (%)	270 (25.9%)
Oligoarthritis n (%)	296 (28.4%)
Monoarthritis (%)	30 (2.8%)
DIP joint involvement n (%)	67 (6.3%)
Arthritis mutilans n (%)	6 (0.6%)
Nail disease	504 (47.5%)

Table: Characteristics of PsA patients from PsART. *: data given as mean (SD).

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose : Disease specific self-management interventions are rare. After a needs assessment, focus group discussions, and *Plan, Do, Study, Act* (PDSA) model we developed and tested the *Self Management for Ankylosing Spondylitis* (SMAS) program, for people with Ankylosing Spondylitis (AS). We examined the benefits of an SMSA program for people with AS regarding change in health status, quality of life, and disease activity.

Methods: 134 people were recruited in this case cohort intervention. Exclusion criteria: <18yo; non-English speaking; co-morbid inflammatory musculoskeletal disease; and/or visual, auditory, or cognitive impairment. Participants attended a weekly 2.5 hour self-management education session facilitated by same two health professionals over 6 weeks. The scripted content included multidimensional strategies including stretches; and optional 7th week supervised exercise class.

Demographic, AS disease management characteristics, medication patterns, and outcomes were measured at baseline, 6 weeks, 3 and 6 months using repeated measures ANOVA for: back pain (VAS), fatigue (MAF), anxiety and depression (HAD), health distress (HDq), fatigue severity scale (FSS), pain self-efficacy (PSEQ), quality of life (SF-36) and Evaluating Ankylosing Spondylitis Qol (EASIQol), global perceived health (GPH), patients disease global assessment (PDGA). AS outcomes were analysed using repeated measures ANOVA for: Bath Ankylosing Spondylitis – Global, Disease Activity Index, and Functional Index (BAS-G, BASDAI, & BASFI), and Ankylosing Spondylitis QoL (ASQol).

Results: At baseline, 43.3% were male, and the mean age was 47.2 ± 15.1 years. The median time to AS diagnosis from the index symptom experience was 3 years with an IQR (1-6). The BAS-G improved between baseline and 3 months (p=0.011) and were sustained at 6 months (p=0.039). The BASDAI improved between baseline and 3 months (p=0.01) and were sustained at 6 months (p=0.009). The ASQol improved between baseline and 6 months (p=0.051). A positive trend were seen for the MAFs GFI, back pain (i.e. nocturnal and total), and the PDGA over the 6 months although these trends were not statistically significant. The composite SF-36 (physical and mental), HADs, HDq, FSS, composite Easiqol (physical, disease activity, wellbeing, and social), PSEQ demonstrated no improvement over the study. There was no significant change in medication usage over the 6 months.

Conclusion: SMAS for AS is independently effective in improving AS specific Disease activity, but global QOL scores did not change.

Table 1: Repeated Measures ANOVA for Quality of Life and Disease Activity tools over time.

Problems of Untranslatability: Example of Turkish Version of Basdai

Pamir Atagunduz[1], Elmar Mammadov[2], Ina Dervishi[2], Metin Beyatlı[2], Kubra Nur Salcı[3], Nafisa Auwal Abdulhamid[4], Gulsen Ozen[5], Ali Ugur Unal[1], Zeynep Erturk[1], Nevsun Inanc[5] and Haner Direskeneli[5], [1]Rheumatology, Marmara University School of Medicine, Istanbul, Turkey, [2]None, Marmara University School of Medicine, Istanbul, Turkey, [3]Marmara University School of Medicine, istanbul, Turkey, [4]Marmara University School of Medicine, Istanbul, Turkey, [5]Department of Rheumatology, Marmara University Faculty of Medicine, Istanbul, Turkey

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Translators of self-report forms commonly encounter problems related to untranslatability, a term used to describe words that cannot be meaningfully translated from one language to another.We give an example of Turkish translation of Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), a self-report questionnaire, to illustrate the problems mentioned above.

Methods:

It was noted by the physicians in outpatient rheumathology clinic that the translation of "tender points" in the Turkish version of BASDAI was not correctly understood by the patients. For this purpose, we designed a study that would assess patients' subjective understanding of the item comprising this term to detect enthesitis (4^{th} question, Q4). Initially, BASDAI self-report form was administered to 106 patients, followed by a semistructured interview lead by trained investigators.

Immediately after the interview, participants were asked to rate (on a scale from 0 to 10 on a visual analogue scale) the 4^{th} item one more time (after receiving explanation of what was intended to be asked, BASDAI-E). Afterwards, an entheses examination was performed by a blinded investigator using both "Leeds Enthesitis Index" and "Maastricht Ankylosing Spondylitis Enthesitis Score", and the patients were asked to evaluate the degree of pain they felt during the exam on a scale from 0 to 10. The physical examination was used as the objective measure for detecting the presence and severity of enthesitis, and the level of patients' understanding of the 4^{th}item was elicited by the difference between the scores given in standart BASDAI and those given with the Q4 replaced with the entheses examination scoring of enthesis (BASDAI-Q4).

Results:

Of the 106 patients who participated in this study, 41 (38.7%) were male, and 65 (61.3%) were female. Mean age of the participants was 43.8 (SD=10.91). On average, patients have been diagnosed with Ankylosing Spondylitis for 9.25 years (SD=7.03) and recall having symptoms for 13.57 (SD=9.13) years. Thirteen patients reported the Q4 as "not understood". Twenty eight patients reported not to have an enthesitis area in BASDAI where as 39 patiens were found to have no enthesitis on physical examination. Twenty patients reported enthesitis in BASDAI had no enthesitis on physical examination. And 15 reported no enthesitis in BASDAI had on physical examination. Mean BASDAI score (3.94±2.39) was significantly higher when compared to the BASDAI-Q4 (2.95±2.56) ($p<0.0001$, 95% CI 0.54 to 1.44). Explanation of the domains (BASDAI-E) did not affect the mean BASDAI (3.60±2.62 vs. 3.94± 2.39, $p=0.079$, 95% CI 0.04 to 0.07).

Conclusion: Discrepancies arising between the real and the comprehended meaning of untranslatable terms in self reports, lead to statistically meaningful changes in the total BASDAI score, therefore affecting the whole treatment approach of these patients. We argue that this type of terms should not be tried to be translated into single-sentence questions in self reports. Instead, other methods, including visual or verbal explanations should be attempted for a better understanding by the patients.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Patient global assessment of disease activity (PtGA) is a standard outcome measure used both in randomized controlled trials and in clinical practice to ascertain patient subjective perception of disease activity in psoriatic arthritis (PsA). Given that previous studies have shown gender-specific differences with respect to disease parameters and patient reported outcomes, the aim of this analysis was to compare the patient profile at initiation of the first anti-TNF agent and to assess whether skin disease has a bigger impact on PtGA in women vs. men with PsA treated with infliximab (IFX) or golimumab (GLM) in a Canadian real-world, routine clinical practice setting.

Methods:

BioTRAC is an ongoing, prospective registry of patients initiating treatment for rheumatoid arthritis, ankylosing spondylitis, or PsA with IFX or GLM. Eligible people for this analysis included PsA patients treated with IFX who were enrolled since 2005 or with GLM enrolled since 2010. The correlation between disease parameters was assessed with the Pearson's correlation coefficient (r), while generalized linear models were used to assess the independent predictors of PtGA.

Results:

A total of 238 patients (51.7% male) were included. At baseline, no significant differences in age (49.9 vs. 50.1; P=0.907), disease duration (4.8 vs. 6.2; P=0.214), or concomitant DMARD use (60.2% vs. 58.3%; P=0.765) were observed between genders. Mean (SD) disease parameters (men vs. women) were: PASI: 2.7 vs. 2.7, P=0.985; swollen joint count (SJC28): 4.3 vs. 5.2, P=0.121; tender joint count (TJC28): 5.6 vs. 7.7, P=0.016; HAQ: 1.18 vs. 1.51, P<0.001; pain (VAS mm): 44.2 vs. 50.0, P=0.101; PtGA: 45.4 vs. 51.2, P=0.114; MDGA (0-10 NRS) = 4.9 vs. 5.4, P=0.111.

Overall, a weak linear correlation was observed between PASI and PtGA in both men (r=0.272; P<0.001) and women (r=0.203; P<0.001). A moderate to strong correlation was observed between SJC28 and PtGA (mean: r=0.421, P<0.001; women: r=0.398; P<0.001). Univariate analysis independent of time of assessment showed that female gender (ΔPtGA=3.6; P=0.050), higher PASI [ΔPtGA (for each increase in PASI by 1)=2.2; P<0.001], and higher SJC28 (ΔPtGA=3.2; P<0.001), but not baseline age or disease duration, were associated with increased PtGA. However, upon adjusting for PASI (ΔPtGA=1.6; P<0.001) and SJC28 (ΔPtGA=2.7; P<0.001), no significant differences in PtGA were observed between genders.

Conclusion:

The results of this analysis show that, upon adjusting for PASI and SJC28, no significant differences exist in PtGA between genders. Furthermore, the association of PtGA was stronger with SJC28 than with PASI in both men and women, suggesting that both genders place more emphasis on articular disease severity than on skin symptoms when evaluating the global status of PsA.

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Patient (PtGA) and physician (MDGA) global assessment of disease activity are standard outcome measures used in clinical practice and research to ascertain patient and physician subjective perception of disease activity in psoriatic arthritis (PsA). Given that the PtGA and MDGA measure the same construct from two different perspectives, assessing their concordance may provide valuable insight on patient and physician differences with respect to the relative importance placed on specific disease parameters. The aim of this analysis was to assess the agreement between PtGA and MDGA, and to compare the correlation of PtGA or MDGA with the Psoriasis Area and Severity Index (PASI) in PsA patients treated with infliximab (IFX) in a Canadian real-world, routine clinical practice setting.

Methods:

BioTRAC is an ongoing, prospective registry of patients initiating treatment for rheumatoid arthritis, ankylosing spondylitis, or PsA with IFX or golimumab as first biologics or after having been treated with a biologic for <6 months. Eligible people for this analysis included PsA patients treated with IFX who were enrolled between 2005 and 2012. The correlation between disease parameters was assessed with the Spearman's rho coefficient (r), while the intraclass correlation coefficient (ICC) and Cronbach's alpha (CA) was used to assess internal consistency.

Results:

A total of 92 patients (52.2% male) were included with a mean (SD) age of 48.7 (9.9) years and disease duration of 6.8 (9.1) years. At baseline, mean (SD) disease parameters were: PASI = 3.3 (5.6); swollen joint count (SJC28) = 4.0 (3.8); tender joint count (TJC28) = 5.9 (5.3); PtGA = 5.0 (2.8); MDGA = 5.8 (2.2) cm. Prior to IFX initiation, 78 (84.8%) patients had been treated with a traditional DMARD (71.7% with methotrexate).Overall, a strong agreement was observed between PtGA and MDGA (r=0.632). The correlation of PASI with PtGA was low (r=0.213), whereas it was moderate with MDGA (r=0.343) (Figure 1). Overall, internal consistency was poor between PASI and both PtGA (CA = 0.373, ICC = 0.229) and MDGA (CA = 0.445, ICC = 0.286) although it was higher with the latter. Multivariate linear regression resulted in the exclusion of PtGA from the model, also supporting the stronger association of MDGA with PASI. When considering other disease parameters, PtGA showed a very strong correlation with pain (r=0.885) and strong with HAQ-DI (r=0.596),whereas a strong correlation was observed between MDGA and both pain and HAQ-DI (r=0.652 and r=0.520, respectively).

Conclusion:

The results of this analysis show that the association of PASI is stronger with MDGA when compared to PtGA. However, patient-reported pain and HAQ-DI were better correlated with PtGA and MDGA when compared to PASI, suggesting that both patients and rheumatologists place more emphasis on pain and functional activity than on skin symptoms when evaluating the global status of PsA.

Background/Purpose: Acne vulgaris is a chronic inflammatory disease of accumulation of the pilosebaceous unit in the skin and has a multifactorial aetiology. Isotretinoin is a one of the systemic retinoids and is an effective treatment option for severe and treatment-resistant acne. However, isotretinoin can cause rheumatologic. We aimed to present follow-up results in terms of rheumatologic symptoms of the patients who received systemic therapy for the treatment of acne (isotretinoin and tetracycline) in this prospective, observational study.

Methods: Forty-five patients were started on isotretinoin and 32 patients were started on tetracycline for acne treatment in 2011. Patients were evaluated by rheumatologic symptoms, rheumatological examination, erythrocyte sedimentation rate, C-reactive protein and the Bath Ankylosing Spondylitis Disease Activity (BASDAI) scoring before the treatment, at the time of acute symptoms and after the treatment on 3rd and 6thmonths.

Results: Unilateral Achilles enthesopathy had developed in 3 patients, both Achilles enthesopathy and unilateral sacroiliitis had developed in 1 patient, and inflammatory low back pain had developed in 6 patients in the isotretinoin group; on the other hand, no rheumatologic symptoms were observed in the tetracycline group.

Conclusion: As a result, spondialartropathy (SPA) findings were determined in up to 23.1% of the patients who received isotretinoin treatment.

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Psoriatic arthritis (PsA) is a common form of chronic arthritis strongly associated with the skin disease psoriasis. Although PsA has been included in the spondyloarthritis concept, PsA is often considered to be predominantly peripheral and may be characterized by arthritis, dactylitis and enthesitis. Consequently randomized controlled trials, screening procedures for early detection and treatment strategies largely focus on peripheral disease. Axial involvement is considered less common and is often treated as a variant of ankylosing spondylitis. The BEPAScohort (Belgian Epidemiological Psoriatic Arthritis Study) is a large prospective multicenter real life cohort set up in 17 Belgian large academic and non academic rheumatology practices that offers a unique opportunity to study the axial involvement in this patient group. Purpose:(1) To estimate the prevalence of axial involvement in patients with PsA in general and in the different subtypes; (2) to estimate the prevalence of inflammatory back pain in patients with PsA; (3) to estimate gender differences in spinal involvement in patients with PsA; (4) to estimate the influence of disease duration on spinal manifestations.

Methods:

Patients included in the BEPAS cohort were evaluated for the presence of a clinical phenotype indicating axial involvement, the specific presence of spinal complaints(reported by patients) and the presence of inflammatory back pain according the Rudwaleit criteria. Demographics and clinical features were recorded. BASDAI and BASMI were calculated. Spinal radiographs are collected at entry and after 2 years.

Results:

461 patients (mean age: 52.79 years (+/-12.29), male 57%) were recruited in the 17 centers from December 2012 to July 2014. A spinal phenotype was identified in 342 patients: 0.7% has pure axial disease whereas 73.7% of the the total patient population has combined peripheral and axial involvement. At entry, 159 patients reported spinal pain with no gender difference. Inflammatory back pain (fulfilling at least 2 out of 4 criteria) was present in 243 patients. BASMI in the overall population cohort (n=440) was 3.76 and BASDAI overall population (n=456) was 1.86 with slightly higher values in female than in male patients. 90% of the patients reported a BASDAI lower than 3.5. A family history of ankylosing spondylitis is reported in 3.3% of the patients. Clinical characteristics and demographics are listed in table 1.

Conclusion:

This large cohort reports a higher frequency of spinal complaints than that reported in other cohorts. A considerable number of patients have inflammatory back pain suggesting that inflammatory axial involvement in PsA should not be underestimated. Surprisingly BASDAI are rather low. This may indicate a lower severity as compared to other forms of spondyloarthritis.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: The influence of sex in psoriatic arthritis (PsA) features and treatment outcomes has not been fully elucidated. We investigated the differences between sexes in biologic initiation and methotrexate (MTX) retention rate in a large real-life cohort of patients with PsA .

Methods: This is a retrospective cohort study based on administrative health databases of the Northern Italian Lombardia region (with a 10 million population). Data were extracted from the RECORD database of the Italian Society for Rheumatology. Patients with PsA were defined by the presence of disease specific copayment exemptions, and MTX treatment included as its first prescription. Demographic data, comorbidities (measured using the Charlson Index) and concomitant treatments were recorded. Baseline demographic and disease variables were compared using the chi squared test, two-sample *t* test or Mann-Whitney U test, as appropriate. Cox regression analysis was used for comparing initiation of biologic treatment and MTX retention rate. All statistical tests were two-sided with a level of significance set at 0.05.

Results: A total of 2,118 PsA cases treated with MTX were included and their demographic, clinical and therapeutic features are reported in **Table 1**. We observed significant differences between sexes in the age at the first MTX prescription (55.1±12 in women vs. 51.9±12.5 in men) and concomitant treatment with antidepressants (7.2% in women vs. 2.2% in men). Men and women with PsA were comparable for disease duration, Charlson Index and concomitant arthritis medications (NSAIDs and glucocorticoids). MTX was discontinued in 984 subjects (person-year 8,807.53, incidence rate 0.11, 95% CI 0.10-0.12). The Cox regression analysis for MTX retention rate reported a crude HR of 1.00 (95% CI 0.88-1.14), while the adjusted HR was 1.09 (95% CI 0.96-1.24). A total of 616 subjects (person-year 10,823.3, incidence rate 0.05, 95%CI 0.047-0.055) started a biologic treatment (283 etanercept, 45.9%; 185 adalimumab, 30%; 121 infliximab, 20%, 27 golimumab, 4.4%). No differences were observed between sexes (etanercept 56% vs. 43.8%, adalimumab 50% vs. 49.7%, infliximab 54.5% vs. 45.4%, golimumab 59% vs 40%). The Cox regression analysis for biologic initiation reported a crude HR for sex of 0.81 (95%CI 0.69-0.96, *p*=0.018) and an adjusted HR of 0.80 (95%CI 0.68-0.95; *p*=0.012).

Conclusion: Our data from a real-life cohort of patients with PsA treated with MTX suggest that women are younger at first MTX prescription and are more frequently precribed antidepressants despite similar use of NSAIDs and glucocorticoids or comorbidities. MTX retention rate does not differ between sexes. Female sex is negatively associated with biologic initiation, possibly reflecting different prescription patterns between sexes.

Table 1.

	Total (n = 2,118)	Women (n=1,077)	Men (n=1,041)	*p value*

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Because of low frequency of HLA-B27 (lower than 1%), the prevalence of the spondarthritis (SpA) is thought to be much lower than rheumatoid arthritis (RA) in Japanese. Therefore an evaluation of the inflammatory back pain and enthesitis is not routinely performed, and early diagnosis of the spondarthritis (SpA) is not substantially performed. We examined the presence of clinical findings to suggest SpA in each of the positive cases of the anti-cyclic citrullinated peptide antibody(ACPA) and the negative cases of ACPA in Japanese.

Methods: We randomly selected 300 cases from the patients who had musculoskeletal symptoms as chief complaint in outpatient clinic of Rheumatology, Osaka City University Hospital.We retrospectively examined frequency of clinical findings of SpA including enthesitis, dactylitis, the arthritis of axis joints and the inflammatory back pain according to clinical records in cases of ACPA positive, and ACPA negative.

Results: Among 300 cases, 95 cases showed positive of ACPA and 205 cases showed negative. In the ACPA positive cases, only two cases showed more than one enthesitis, but 88 cases showed either enthesitis (80 cases) or ductilitis (10 cases), the arthritis of axis joints (62 cases), inflammatory lumbago (2 cases) in the ACPA negative cases. The cases with findings to suggest potential of SpA are more frequently in ACPA-negative cases in Japanese. However, the patients themselves actually rarely reported these symptoms, therefore findings suggesting SpA were possibly missed unless we took physical examination adequately.

Conclusion: The Japanese SpA patients may have relatively mild symptoms and may be diagnosed seronegative RA rather than undifferentiated SpA. It is necessary to take physical examination appropriately in ACPA-negative Japanese patients even if they meet classification criteria of RA to prevent passing over SpA, moreover it is necessary to find genetic marker in Japanese such as HLA-B27 in Caucasian.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Enthesitis is one of the potential extra-axial manifestations found in patients with spondyloarthritis (SpA). Enthesitis can be quantified using the MASES (Maastrich Ankylosing Spondylitis Enthesitis *Score*), consisting 13 pre-defined entheses assessed for tenderness. Evidence regarding treatment of enthesitis is limited. There are no specific recommendations for treatment of enthesitis in SpA. To better understand the impact of enthesitis real live data are needed.

Objective:

To analyse the development of enthesitis under treatment.

Methods:

We included all patients from the Swiss national registry SCQM with axial spondyloarthritis and valid MASES at baseline. Patients were analysed for changes in MASES subsequent to treatment in separate for: (A) MASES 0-13; (B) grouped MASES = 0 vs. MASES 1-5 vs. MASES 6-13; (C) time point in treatment strategy (1^{st}, 2^{nd} vs 3^{rd} therapeutic strategy for treatment of axial SpA); (D) response to synthetical DMARDs vs. biologic agents; (E) response to Etanercept vs. antibody-based TNF antagonists (Adalimumab, Infliximab, Golimumab, and Certolizumab). The results of the correlation analyses were calculated using linear regression. Differences between two groups were compared with the Mann-Whitney *U* test and between more than two groups with the Kruskal-Wallis test.

Results:

3241 patients were included into the study. 45.9% of the patient had no enthesial affection at baseline (MASES = 0). The average response of MASES after 1 year increase linearly with increasing average MASES scores (slope -0.41, $R^2 = 0.78$). For detailed responses per group please refer to the table.

	Response at 12 (±3) months, number of patients assessed (n)*	**p-value**
MASES 0	+0.48 (n=667)	p<0.001
MASES 1-5	-1.02 (n=628)	
MASES 6-13	-3.59 (n=176)	
1^{st} therapeutic decision	-1.22 (n=360)	p=0.163
2^{nd} therapeutic decision	-0.62 (n=93)	
3^{rd} and later therapeutic decision	-1.35 (n=74)	
Treatment with TNF antagonists	-1.15 (n=454)	p=0.967
Treatment with synthetical DMARDs	-1.03 (n=59)	
Treatment with Etanercept	-0.97 (n=132)	p=0.540
Treatment with antibody-based TNF antagonists	-1.23 (n=323)	

* Calculated on Patients with available data

Summary:

Patients with a higher MASES developed a significantly better reduction in MASES as compared to patients with lower MASES. Almost one out of two patients with a MASES of 0 at baseline developed an entheseal affection during follow up under treatment. Changes of MASES under TNF antagonist or DMARD treatment did not differ in our cohort. No differences in the therapeutic response to different TNF antagonists were detected.

Conclusion:

Entheseal involvement is a neglected problem in axial SpA patients affecting minimum half of the patients. A focussed therapeutic strategy for entheseal involvement is needed.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Uveitis is commonly defined as inflammation of the uvea, the vascular middle layer of the eye. Standardized and validated outcome measures are lacking in uveitis management, which makes it difficult to compare the efficacy and responses to treatment.

To develop a disease activity score for patients with uveitis and determine its discriminating ability to classify patients based on the level of activity.

Methods: Multicenter cross-sectional observational study. The construct "uveal inflammation activity" was defined as intraocular inflammation. 7 dimensions and 14 items were identified and were agreed among experts through a two-round Delphi technique. The dimensions were: visual acuity, anterior chamber, vitreous cavity and posterior segment inflammation, uveitic macular edema, patient and physician global assessment. 8 Spanish hospitals with uveitis units participated in the study. Patients diagnosed with uveitis, older than 5 years and inflammatory activity at the time of the visit, were selected. Primary endpoint: uveitis inflammatory activity, defined as any intraocular inflammation and categorized as mild, moderate and severe. An ordinal logistic regression model was built whose dependent variable was the inflammatory activity (mild, moderate, severe). The modelling accuracy to classify the patient in the right category was assessed with the Area Under the Curve (AUC). Two AUC measures were calculated: one for the discrimination of mild versus moderate and severe activity level of uveitis and another for the discrimination of mild and moderate versus severe activity.

Results: 195 patients were included, 54% were women and the mean age was 45.8±16.1 years. The results of the regression model revealed that the uveitis was more severe in patients with an elevated number of anterior chamber cells ($OR_{4\ cells\ vs\ 0cells}$=27.85;95%CI=3.42;226.75), high degree of vitreous haze ($OR_{severe\ vs\ null}$=3.95;95%CI=1.40;11.16), macular edema over 315 micras ($OR_{>315\ vs\ \leq 315}$=3.58;95%CI=1.56;8.21), presence of vessel sheathing ($OR_{yes\ vs\ no}$=4.43;95%CI=1.71;11.53), higher patient's evaluation ($OR_{1\text{-}unit\ increase}$=1.23;95%CI=1.09;1.39), presence of papilitis ($OR_{yes\ vs\ no}$=4.05;95%CI=1.18;13.92) and elevated number of choridal or retinal lesions ($OR_{\geq 6\ vs\ 0}$=4.99;95%CI=1.08;23.01). The discriminant capacity of disease activity index is 87% (95%CI:82%-92%) for discriminating patients with mild uveitis from patients with moderate or severe uveitis and 88%(95%CI:84%-95%) for discriminating patients with mild or moderate uveitis from patients with severe uveitis.

Conclusion: This composite disease activity index in uveitis integrates all ocular inflammatory activity and takes into account the assessment of the patient and the doctor. The index has a high capacity to classify the inflammatory activity of the patients with uveitis.

Progression of Patients with Non-Radiographic Axial Spondyloarthritis to Ankylosing Spondylitis: A Population-Based Cohort Study

Runsheng Wang[1], Sherine Gabriel[2] and Michael M. Ward[1], [1]NIH/NIAMS, Bethesda, MD, [2]Division of Rheumatology; Department of Health Sciences Research, Mayo Clinic, Rochester, MN
First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The long-term outcome of patients with non-radiographic axial spondyloarthritis (nr-axSpA) is unclear, particularly whether few or most progress to ankylosing spondylitis (AS). Our objective was to examine the progression to AS in a population-based inception cohort of patients with nr-axSpA.

Methods: The Rochester Epidemiology Project (REP) is a longstanding population-based study of health in residents of Olmsted County, Minnesota. Using a combination of diagnostic and procedural codes for back pain, HLA-B27 and pelvis MRI, we searched the REP from 1985 to 2010 for subjects who potentially fulfilled ASAS criteria for nr-axSpA. We performed detailed review of medical records to identify subjects who satisfied either the ASAS clinical arm or imaging arm criteria, and followed them until March 15th, 2015. We collected demographic, clinical, laboratory and radiology information. We used survival analysis to measure time to progression to AS.

Results: After screening 2151 potential candidates, we identified 83 subjects who met ASAS criteria for nr-axSpA (18 in the imaging arm and 65 in the clinical arm). Fifty-three percent of the subjects were men. The average age at inclusion was 33.3 ± 8.3 years. The age of back pain onset was 30.3 ± 7.9 years. The mean follow up was 10.6 ± 5.6 years.

Sixteen (19%) subjects developed radiographic sacroiliitis that met modified New York criteria for AS. The probabilities of remaining as nr-axSpA at 5, 10, and 15 years were 93.6% (95% confidence interval (CI) 88.3% to 99.2%), 82.7% (74.1% to 92.3%), and 73.6% (62.7% to 86.3%), respectively (fig 1). In a sensitivity analysis using the date of last negative pelvis film as the time for censoring, the probabilities were 89.6% (81.4% to 98.7%), 70.4% (57.0% to 86.8%), and 53.9% (38.3% to 75.8%) at 5, 10, and 15 years, respectively. Subjects in imaging arm progressed more frequently (28%) and rapidly than those in clinical arm (17%), with a hazard ratio of 3.50 (95% CI 1.15 to 10.6), p=0.02 (fig 2). Men tended to progress more often than women, but the difference was not statistically significant.

Conclusion: In this population-based study, a minority of patients with nr-axSpA progressed to AS after 15 years of follow up. This suggests that the classification criteria of nr-axSpA identifies many patients unlikely to progress to AS, or that nr-axSpA is a prolonged prodromal state, requiring longer follow up to evolve to AS.

Figure 1. Kaplan Meier curve of progression from nr-axSpA to AS, with 95% CI (dashed line). X axis: year of follow up; Y axis: proportion remained to be nr-axSpA.

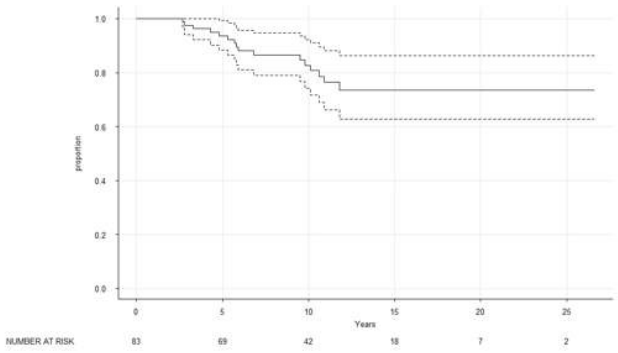

Figure 2. KM curve of progression to AS stratified by inclusion criteria.

Baseline Characteristics of Early, Delayed, and Non-Responders in a Non-Radiographic Axial Spondyloarthritis Study

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Most clinical trials evaluating anti-TNF agents for treating non-radiographic axial SpA (nr-axSpA) place the primary endpoint at 12 wks, and most formularies require assessment of response 12-16 wks after starting anti-TNF therapy. However, data from the EMBARK study (ClinicalTrials.gov identifier: NCT01258738) suggest the 24-wk time point may be more appropriate for evaluating response to etanercept (ETN). This analysis aimed to compare the baseline (BL) characteristics of patients with early, delayed, and no treatment response.

Methods: Patients had axial SpA per Assessment of SpondyloArthritis international Society (ASAS) criteria without meeting modified NY radiographic criteria; Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) score ≥4, disease symptoms for >3 months and <5 yrs, and had failed ≥2 NSAIDs. Patients were randomized to double-blind ETN 50 mg/wk or placebo for 12 wks, then received open-label ETN 50 mg/wk. This analysis includes the open-label modified intent-to-treat (mITT) population that was randomized to ETN. For ASAS20 and ASAS40 response, patients were split into 3 groups: early (12-wk) responders, delayed (24-wk) responders, and non-responders. Observed case (OC) and non-responder imputation (NRI) analyses were performed. Patients with missing data were excluded (OC analysis) or considered non-responders (NRI analysis). Comparison of BL characteristics used one-way analysis of variance with treatment as a factor for continuous variables and Fisher's exact test or chi-square test for yes/no variables.

Results: 99 patients were in the mITT population, OC analysis. Mean (SD) age was 31.8 (7.8) yrs, 64.7% were male, and duration of disease symptoms was 2.4 (2.0) yrs; 66.7% of patients were human leukocyte antigen B27 (HLA-B27)+ and 83.8% had sacroiliitis on MRI (*P*=non-significant across response groups for all). For ASAS20 and ASAS40 responses, the OC analysis demonstrated significant BL differences among response groups for the following: CRP, BASDAI, ankylosing spondylitis disease activity score, patient global assessment, total back pain, inflammation, and Spondyloarthritis Research Consortium of Canada (SPARCC) SI joint score (table). Overall, values for BL disease characteristics were higher (more severe) for responders than non-responders, and highest for early responders. No significant BL differences existed in tender/swollen joint count, enthesitis, Maastricht Ankylosing Spondylitis Enthesitis Score, physician global assessment, or prior response to NSAIDs, per ASAS20 or ASAS40 response. NRI analysis results were similar.

Conclusion: Evaluating ASAS20 and ASAS40 results according to early, delayed, and no response demonstrated significant differences in several BL clinical characteristics and SPARCC MRI scores. These results may aid clinicians in treating patients with nr-axSpA.

Table: Baseline Disease Characteristics of Early and Late Responders and Non-responders								
Baseline Characteristic	Week 12 Responders		Week 24 Responders		Non-Responders		*P*-value*	
	ASAS20 N=55	ASAS40 N=35	ASAS20 N=16	ASAS40 N=15	ASAS20 N=28	ASAS40 N=49	ASAS20	ASAS40

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

The prevalence of ankylosing spondylitis (AS) is 2-3 times higher in men compared to women. Recent studies have suggested that clinical differences exist between both genders with women experiencing a higher burden of disease. This analysis examined gender-specific differences with respect to patient and disease parameters at initiation of infliximab (IFX) or golimumab (GLM) for the treatment of AS in a Canadian routine clinical practice setting.

Methods: Biologic Treatment Registry Across Canada (BioTRAC) is an ongoing, prospective registry of patients (pts) initiating treatment for rheumatoid arthritis, ankylosing spondylitis, or psoriatic arthritis with IFX or GLM. Pts with AS treated with IFX who were enrolled since 2002 or with GLM enrolled since 2010 were included in this analysis. Between group differences were assessed with the Fisher's Exact test or the independent samples t-test, while linear regression was used to assess the independent association of gender with HAQ-DI, ASDAS, BASDAI, and BASFI improvements at 12 months.

Results:

A total of 539 AS pts were included in this analysis; 188 (34.9%) pts were treated with GLM and 351 (65.1%) with IFX. The majority of pts were male (61.8%). Mean age and disease duration were comparable between genders for both GLM and IFX (Table 1). Overall, disease parameters were similar for GLM with the exception of BASDAI where higher disease severity was observed among females. Among pts treated with IFX, between gender differences were observed for CRP with significantly lower levels in female pts; however BASDAI and HAQ-DI where significantly higher in females compared to males.

Table 1: Patient Characteristics at Baseline by Gender			
Parameter **Mean (SD) / %**	**Male**	**Female**	**P-Value**
AS-GLM	**n=115**	**n=73**	
Age: years	46.3 (15.2)	44.4 (11.8)	0.498
Disease duration: years	5.2 (10.0)	6.0 (10.6)	0.704
C-Reactive Protein (CRP): mg/L	12.6 (15.2)	17.5 (50.5)	0.389
ESR: mm/hr	18.0 (16.6)	22.0 (16.2)	0.152
Patient Global (PtGA): VAS mm	52.7 (28.5)	60.7 (21.2)	0.058
Physician Global (MDGA): NRS 0-10	5.2 (2.4)	5.6 (1.9)	0.172
Morning stiffness: min	56.4 (45.2)	60.1 (47.1)	0.603
HAQ-DI	1.02 (0.62)	1.08 (0.58)	0.489
ASDAS	3.3 (1.0)	3.5 (0.8)	0.126
BASDAI	5.6 (2.3)	6.5 (1.7)	***0.007***
BASFI	5.2 (2.6)	5.3 (2.2)	0.587
Prior biologic (<6 months)	6.1%	2.7%	0.486
Concomitant DMARD	7.0%	5.5%	0.769
Concomitant NSAID	23.5%	31.5%	0.240
AS-IFX	**n=218**	**n=133**	
Age: years	45.1 (12.0)	47.0 (10.8)	0.163
Disease duration: years	9.6 (10.3)	8.8 (9.6)	0.505
C-Reactive Protein (CRP): mg/L	19.2 (26.9)	12.5 (17.6)	***0.012***
ESR: mm/hr	23.5 (21.3)	24.5 (20.6)	0.672
Patient Global (PtGA): VAS mm	58.1 (27.0)	59.2 (28.3)	0.864
Physician Global (MDGA): NRS 0-10	6.3 (2.1)	6.3 (2.1)	0.881
Morning stiffness: min	84.5 (115.9)	87.5 (131.8)	0.824
HAQ-DI	1.11 (0.58)	1.27 (0.63)	***0.019***
ASDAS	3.7 (1.0)	3.6 (1.0)	0.482
BASDAI	6.0 (2.1)	6.6 (2.1)	***0.013***
BASFI	5.9 (2.5)	6.1 (2.5)	0.458
Prior biologic (<6 months)	6.4%	8.3%	0.527
Concomitant DMARD	26.1%	24.8%	0.802
Concomitant NSAID	56.4%	51.9%	0.440

Regression analysis showed that, upon adjusting for baseline levels, female gender (ΔBASDAI=0.603; P=0.035) was associated with increased BASDAI at 12 months of treatment as compare to males. HAQ-DI, ASDAS, and BASFI, on the other hand, at 12 months were comparable between genders.

Conclusion:

Overall, at anti-TNF initiation, female AS pts experience greater disease activity relative to men at initiation of biologic therapy. Whether this represents a gender bias in prescribing, concomitant fibromyalgia, a gender based difference in the acceptance of biologic treatment or disease assessment, requires additional research.

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: TNF-α inhibitor therapy is recommended by ASAS/EULAR guidelines for ankylosing spondylitis (AS) patients with moderate-to-high disease activity despite inadequate response to NSAIDs in addition to education and exercise. The purpose of this study is to evaluate factors associated with anti-TNF-α use over a 13 year period in a longitudinal cohort of AS patients enrolled between 2003 and 2013.

Methods: A prospective cohort study of 607 AS patients meeting modified New York criteria were followed for at least 2 years from 5 sites. Patients underwent a comprehensive standardize clinical evaluation and completed questionnaires assessing their disease activity and functional impairment by the BASDAI and BASFI respectively. Demographic, social, and psychological variables were collected. Current medication lists as well as ESR and CRP levels were determined at each visit. Multivariable longitudinal analyses using mixed effect logistic regression models were conducted to assess the clinical, demographic, and lab features associated with anti TNF-α usage accounting for correlation of repeated measures over time.

Results: The patients were 73% male and 82% of white race, with a mean age of 42.7 years (SD = 13.8), mean disease duration of 18 years (SD = 13.2) and average length of follow up of 4.96 years. TNF-α inhibitor therapy was used in 45% of patients at baseline visit, with increased rate of usage over the 13 year study period (p=0.0001). Multivariable longitudinal associations between independent variables and anti TNF-α usage for the 607 AS patients (Table 1) demonstrated significant associations with greater disease activity in the previous week (by patient global assessment) and higher baseline BASRI scores. On the other hand, patients with disease duration of more than 20 years, those with elevated CRP, or those using NSAIDs or prednisone were less likely to be using anti-TNFα therapy. Male gender, BASFI score, BASDAI score, Center for Epidemiologic Studies Depression (CES-D) scale score, greater pain severity (on a visual analog scale), acetaminophen and tramadol use were not significantly associated with usage of TNF-α inhibitors.

Conclusion: This large, prospective, longitudinal cohort study shows multiple subjective and objective factors associated with anti TNF-α therapy. Patients with longstanding disease, laboratory evidence of inflammation and using anti-inflammatory medications were less likely to be using anti-TNF therapy. Those with more severe radiographic changes at baseline and higher patient global assessment of disease activity were more likely to be using TNF-α inhibitors.

Table 1 Multivariable Associations of Selected Variables on Longitudinal anti TNF-α use (N = 607)

Variable	Odds Ratio (95% CI)	p value
Male	1.22 (0.65, 2.3)	0.54
Disease Duration at baseline ≥ 20yrs	0.44 (0.25, 0.8)	0.007
BASFI ≥ 40	1.11 (0.69, 1.79)	0.67
BASDAI ≥ 40	0.85 (0.55, 1.31)	0.46
CES-D >16	0.93 (0.61, 1.42)	0.75
Elevated CRP	0.3 (0.22, 0.42)	<0.0001
Pain severity score ≥ 50	0.68 (0.43, 1.05)	0.085
Patient Global Assessment ≥ 23	2.22 (1.26, 3.93)	0.006
BASRI baseline≥ 6	2.08 (1.12, 3.85)	0.02
NSAID use	0.32 (0.23, 0.44)	<0.0001
Prednisone use	0.53 (0.27, 1.03)	0.059
Tramadol use	1.5 (0.6, 3.74)	0.38
Acetaminophen use	1.17 (0.79, 1.75)	0.43
Diabetic medication use	0.68 (0.24, 1.94)	0.47
Osteoporosis medication use	1.34 (0.59, 3.03)	0.49

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: In the multiphase, randomized, placebo (PBO)-controlled EMBARK study (ClinicalTrials.gov identifier: NCT01258738), clinical signs/symptoms and MRI-measured inflammation were evaluated in patients with early, active non-radiographic axial spondyloarthritis (nr-axSpA) after 12 wks of double-blind (DB) treatment with etanercept (ETN)[1]and 92 wks of open-label (OL) ETN.

Methods: Patients who satisfied Assessment of SpondyloArthritis international Society (ASAS) classification criteria for axSpA, but not modified New York radiographic criteria, and who were unresponsive to ≥2 NSAIDs received DB ETN 50 mg/wk or PBO for 12 wks, followed by OL ETN 50 mg/wk (ETN/ETN or PBO/ETN) to wk 104. All patients continued background NSAIDs. Pre-specified analyses of conventional clinical assessments included ASAS, ASDAS (high sensitivity CRP [hs CRP]), BASDAI, and BASFI; the Spondyloarthritis Research Consortium of Canada (SPARCC) scoring method was used for MRI assessment of SI joint and spine inflammation. Post hoc analysis of sustained ASDAS remission (ASDAS <1.3 for ≥24 continuous wks over 104 wks; no missing data) was also conducted. Binary and continuous endpoints were analyzed in all patients with wk-12 efficacy data who continued into the OL period, received ≥1 ETN dose in OL period, and were included in the modified intent-to-treat (mITT) population in the DB period using non-responder imputation (NRI) and last observation carried forward (LOCF) approaches, respectively. A Cochran-Mantel-Haenszel chi-square test and ANCOVA were used for between-group comparisons of binary and continuous endpoints, respectively, at wk 12.

Results: Of 215 randomized patients (DB-phase mITT population), 205 entered and 169 completed the OL phase (ETN/ETN, n=100/n=83; PBO/ETN, n=105/n=86). At the end of the DB phase (wk 12), 33% and 15% of patients in the ETN and PBO groups achieved ASAS40 (P<0.01, between groups); at the end of the OL phase (wk 104), 49% and 51% of patients in the ETN/ETN and PBO/ETN groups achieved this endpoint (table). By wk 104, 51% (51/100) and 58% (61/105) of ETN/ETN- and PBO/ETN-treated patients achieved sustained ASDAS remission. Significantly greater mean reductions from wk 0 to wk 12 in SPARCC SI joint and spinal scores were seen in patients receiving ETN vs PBO (-3.8 vs -0.8, P<0.001; -2.1 vs -1.2, P<0.05); between wk 0 and wk 104, these scores decreased by -5.4 and -3.5 (SI joint) and -1.9 and -0.8(spinal) in patients receiving ETN/ETN and PBO/ETN. From wk 0 to wk 104, 8% and 7% of patients in the ETN/ETN and PBO/ETN groups had serious adverse events; no new safety signals were seen.

Table. Effects of ETN in patients with nr-axSpA in the EMBARK study*				
	DB phase (wk 12)		OL phase (wk 104)	
	ETN	PBO	ETN/ETN	PBO/ETN
Endpoint	% Patients Achieving Endpoints (n/N)

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment Poster I: Clinical Aspects and Assessments

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Treatment with tumor necrosis factor α (TNFα) inhibitors has been shown to be effective in improving disease activity and functional capacity in patients with non-radiographic axial spondyloarthritis (nr-axSpA). Evidence suggests that clinical response to anti-TNFα agents tends to be enhanced in nr-axSpA patients with magnetic resonance imaging (MRI)-documented sacroiliac (SI) joint inflammation and elevated C-reactive protein (CRP). The objective of this study was to determine if MRI sacroiliitis positivity and/or elevated CRP at baseline are predictive of changes in measures of disease activity following etanercept (ETN) treatment in patients with nr-axSpA.

Methods: Patients with symptom duration >3 mths–<5 yrs, meeting ASAS axSpA classification criteria but not radiographic criteria for AS, having BASDAI ≥4, and failure of ≥2 NSAIDs were randomized to 12 weeks of double-blind treatment with ETN 50 mg QW or PBO. Both groups continued stable NSAID therapy. Standard clinical outcomes were assessed in 4 patient subgroups based on MRI sacroiliitis (positive/negative [+/-]) and hsCRP (elevated/normal [+/-]) status at baseline. MRI sacroiliitis positivity was defined according to the ASAS definition of a positive MRI result; elevated hsCRP was based on the ULN and defined as >3 mg/L.

Results: A total of 215 subjects (ETN, n=106; PBO, n=109) were included in these analyses. At baseline, breakdown according to MRI sacroiliitis and CRP status was: MRI-/CRP-, n=26; MRI+/CRP-, n=97; MRI-/CRP+, n=15; MRI+/CRP+, n=77. At Week 12, the primary endpoint of ASAS40 was achieved by more patients receiving ETN than those receiving PBO irrespective of MRI/CRP status at baseline (Table). The greatest ASAS40 response was observed in those patients with MRI+/CRP+ at baseline and the lowest response was seen in the MRI-/CRP- subgroup. Similar observations were made for other clinical endpoints with a markedly higher proportion of MRI+/CRP+ patients achieving BASDAI 50 and clinically important improvement (Δ≥1.1) in ASDAS-CRP/ESR than those in the other MRI/CRP subgroups.

Endpoint		MRI-/CRP-	MRI+/CRP-	MRI-/CRP+	MRI+/CRP+
ASAS40	**ETN**	2/11 (18.2)	10/46 (21.7)	4/7 (57.1)	19/41 (46.3)*
	PBO	0/14 (0)	8/50 (16.0)	0/7 (0)	8/36 (22.2)
ASAS20	**ETN**	6/11 (54.5)	17/46 (37.0)	5/7 (71.4)	27/41 (65.9)
	PBO	2/14 (14.3)	20/50 (40.0)	1/7 (14.3)	16/36 (44.4)
ASDAS-CRP	**ETN**	2/11 (18.2)	17/45 (37.8)*	3/7 (42.9)	32/41 (78.0)†
	PBO	0/14 (0)	9/50 (18.0)	3/8 (37.5)	14/36 (38.9)
ASDAS-ESR	**ETN**	4/11 (36.4)	16/42 (38.1)	3/6 (50.0)	28/40 (70.0)‡
	PBO	1/14 (7.1)	11/50 (22.0)	1/6 (16.7)	10/35 (28.6)
BASDAI50	**ETN**	2/11 (18.2)	14/46 (30.4)	4/7 (57.1)*	26/41 (63.4)†
	PBO	2/14 (14.3)	13/50 (26.0)	0/8 (0)	11/36 (30.6)

*p<0.05, †p<0.01, ‡p<0.001 vs PBO

Values are patients achieving endpoint n/N (%). Values for ASDAS-CRP/ESR are patients achieving clinically important improvement Δ≥1.1

Conclusion: Our analyses suggest that in patients with early, active nr-axSpA and an inadequate response to ≥2 NSAIDs, a combination of MRI positivity and elevated hsCRP at baseline had a positive predictive value on joint inflammation score and clinical response of ETN subjects. A larger sample size is required to definitively test these findings. Further exploratory analyses are being undertaken to determine the predictive value of HLA-B27 status, gender and age on treatment response in each group.

Session Date: Sunday, November 8, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Vitamin D is a steroid hormone that not only functions in maintaining calcium and bone metabolism, but also displays immunoregulatory and anti-inflammatory properties. Recent studies demonstrate a correlation between vitamin D insufficiency / deficiency and increased disease activity in SLE, but less is known about the role of vitamin D in specific complications of SLE. In the current case-control study, we aimed to evaluate the relationship between low levels of vitamin D and disease activity in SLE compared to controls.

Methods:

We compared serum 25-hydroxyvitamin D (25(OH)D) levels between diagnosed SLE cases with controls, and examined disease characteristics in relationship to 25(OH)D status among cases. The majority of SLE patients and all controls are Gullah African Americans recruited prospectively into the SLE in Gullah Health (SLEIGH) study, currently ongoing since 2003. SLE disease characteristics were assessed by the SLEDAI scores to measure disease activity and damage, respectively. Patients met at least 4 of the 11 ACR Classification Criteria for SLE and active disease was defined as SLEDAI ≥ 6. Data was utilized from a RedCap database of baseline and follow-up visits and included the following: demographics, medical history, SLEDAI, and 25(OH)D serum levels. Our longitudinal population cohort consisted of 392 diagnosed SLE patients (90.7% women, 74% African American; mean age (visit age) 40.9 +/- 15.4 years, mean age at diagnosis 30.9 +/- 14.5 years) and 127 healthy controls (91.7% women; 100% African American, mean age 43.1 +/- 12.8 years) were used.

Results: Out of the 352 patients, 65.2 patients had vitamin D insufficiency [25(OH)D < 30 ng/ml], 40.3 patients had vitamin D deficiency [25(OH)D < 20 ng/ml], and 10.8 patients had severe vitamin D deficiency [25(OH)D < 10 ng/ml]. In the control group, 92.1 subjects had vitamin D insufficiency, 74.8 subjects had vitamin D deficiency, and 40.9 subjects had severe vitamin D deficiency. 25(OH)D deficiency was significantly associated with African Americans (OR 3.74, 95% CI 1.06-2.83), obese SLE patients (OR 1.56, 95% CI 0.95-2.58), current smokers (OR 9.50, 95% CI 1.96-46.15), age at visit (OR 0.97, 95% CI 0.95-0.99), active disease SLE patients (OR 2.2, 95% CI 18.4-22.2), and SLEDAI score (p=0.03, OR 1.09).

		SLE patients (N = 392)	**Controls (N = 127)**
Mean 25(OH) D		26.0 +/- 14.7	15.9 +/- 13.0
25(OH)D < 30 ng/mL	**P-value**	65.2%	92.1%
African American	<0.01	86.2%	100%
Obese	0.01	39.8%	85.7%
Active SLE	<0.01	25.4%	N/a
25(OH)D < 20 ng/mL	**P-value**	40.3%	74.8%
African American	<0.01	92.3%	100%
Obese	0.004	45.5%	75.0%
Active SLE	<0.01	28.8%	N/a
25(OH)D < 10 ng/mL	**P-value**	10.8%	40.9%
African American	<0.01	94.9%	100%
Obese	0.78	**N/s**	**N/s**
Active SLE	<0.01	36.7%	N/a

Conclusion:

Vitamin D deficiency was prevalent in SLE patients (65.2%) and controls (92.1%). African Americans were significantly more likely to be 25(OH)D deficient (86.2%, $p<0.01$), adjusting for visit age, BMI, gender, smoking status, and disease duration. 25(OH)D concentration is significantly associated with obese SLE patients, current smokers, visit age, and having high disease activity by SLEDAI. Our study suggests that vitamin D deficiency, especially in African American patients, is significantly associated with disease activity in SLE.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Urinary biomarkers have a potential for identification, follow-up and assessment of response to treatment in patients with lupus nephritis. Urinary proteomics can help in identification of new biomarkers. Thus we have used urinary proteomics in order to identify proteins that are seen uniquely in patients with active lupus nephritis.

Methods: Urine samples from patients with active and inactive lupus (SLEDAI<4) were collected, spun and immediately frozen at -80°C. After protein extraction, 2D gels were run followed by MALDI-TOF-TOF of the differentially expressed spots in urine from patients with active nephritis to identify the proteins. Biomarkers identified were measured by ELISA in a large group of patients as well as in urine samples from healthy control, RA and diabetes with proteinuria. In addition patients with active nephritis were followed up and samples collected at 6 and 12 months. Disease assessment was done using SLEDAI. All urinary values were normalized to creatinine excretion. Non-parametric tests were used for analysis

Results: There were 88 patients with SLE (Table) and 20 each of healthy controls, RA and diabetes. In addition samples from 33 patients with active nephritis at 0 and 6 months from 2 different centers were also used for validation.

Among the many spots that were differentially expressed in active lupus nephritis as compared to inactive lupus and healthy control, three were selected and identified as retinol binding protein (RBP), alpha-1-antichymotrypsin (AAC) and haptoglobin (HAP).

Table. Clinical and laboratory parameters of SLE patients (cross sectional analysis)

	Active Nephritis	Active Non-Renal	Inactive Disease
Number	45	24	19
F:M	56:2	19:5	38:1
Median age in years	27 (12 - 50)	28.5 (15 - 50)	28 (14 - 48)
rSLEDAI	8 (4-16)	0(0)	0 (0)
SLEDAI	18 (6-28)	10 (5-20)	0 (0-4)
C3 (mg/dl)	48.5 (16.9 - 125)	66.7 (17.3 - 163)	117 (34.2 - 194)
C4 (mg/dl)	7.8 (5.3 – 55.7)	11.05 (5.3 – 32.2)	24.15 (5.6 – 44.7)
Anti-ds DNA (IU)	200 (13 - >300)	185(<6.25 - >300)	44 (<6.25 - 200)
Urinary protein/creatinine ratio	3.22 (0.12 – 8)	0 (0 – 1.45)	0 (0 – 0.87)
Serum Creatinine (mg/dl)	0.9 (0.4 – 3.87)	0.82 (0.4 – 1.4)	0.8 (0.4 – 1.3)
Normalized RBP	0 (0 – 0.75)	0 (0 – 0.21)**	0 (0 – 0.29)*
Normalized AAC	8.67 (1.4-33.7)	1.65 (.06 – 13.2)**	0.4 (0.08 – 52.7)**
Normalized HAP	2.79 (0.02 – 3.8)	0 (0 – 5.4)**	0 (0 – 2.06)**

p-value *= <0.05 ,**= <0.001 as compared to active nephritis group.

On validation, RBP levels were higher in patients with active lupus nephritis as compared to other groups (Table 1; p<0.05) except patient with diabetes. The urinary levels had good correlation with renal SLEDAI (r=0.284; p<0.008) and SLEDAI(r=0.316; p<0.003).On longitudinal study the levels normalized in majority at 6 and 12 months (p<0.01).

AAC levels were much higher in patients with active nephritis as compared to all other groups (Table ; p<0.001) including diabetics. The urinary levels had moderate correlation with renal SLEDAI(r=0.577; p<0.001) and SLEDAI (r=0.461; p<0.001). On follow up the levels reduced at 6 and 12 months (p<0.01).

Haptoglobin levels were more than 10 fold higher than other groups (Table 1; p<0.001). HAP levels also correlated well with renal SLEDAI (r=0.594; p<0.001) and SLEDAI (r=0.371; p<0.001). In majority the levels fell at 6 and 12 months (p<0.001).

A patient who developed ESRD at 6 months had persistently high levels of all three biomarkers. In the second set of samples of active nephritis all the three biomarkers had a significant fall at 6 months (n=33) (p<0.001) as compared to baseline.

Conclusion: Haptoglobin, retinol binding protein and alpha-1 anti-chymotrypsin are potential biomarkers for lupus nephritis activity.

Systemic Lupus Erythematosus and the Evaluation of Poor Sleep: The Sleeps Pilot Study

Alicia Hinze[1], Philip Chu[1], Dany Thekkemuriyil[1], Yo-El Ju[2], Deepali Sen[3], Seth Eisen[1] and Alfred Kim[1], [1]Rheumatology, Washington University School of Medicine, Saint Louis, MO, [2]Neurology, Washington University School of Medicine, Saint Louis, MO, [3]Division of Rheumatology, Washington University School of Medicine, Saint Louis, MO

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Sleep disturbances occur in many autoimmune diseases and are ranked highly as an unmet need in patients with SLE. We hypothesized that poor sleep increased SLE disease activity and decreased quality of life (QoL). The aims of this pilot study was to describe in

SLE patients: 1) the prevalence of sleep problems, 2) evaluate the impact of sleep problems on quality of life (QoL), and 3) compare sleep problems with disease activity.

Methods: 27 patients with a confirmed diagnosis of SLE according to the 1997 ACR classification criteria for SLE or the SLICC classification criteria for SLE were enrolled in this cross-sectional study. Comorbid conditions were identified by patient's clinic intake assessment and review of electronic medical records. Patients completed three sleep surveys at the enrollment visit: Pittsburgh Sleep Quality Index (PSQI), Patient Reported Outcomes Measurement Instrument System (PROMIS) short form for Sleep Disturbance, and PROMIS short form for Sleep Related Impairment. Disease activity assessed using SLEDAI2K Responder Index-50 (S2K RI-50). Lupus Impact Tracker (LIT) evaluated patient reported QoL. Student's t-test compared means from independent samples, ANOVA compared categorical variables with normally distributed continuous variables, and Kruskal Wallis compared categorical variables with non-normally distributed continuous variables.

Results: 1) Prevalence of sleep problems in patients with SLE was 85% as defined by PQSI score > 5 (Table 1). SLE patients experience greater sleep disturbance and sleep impairment as measured by the PROMIS surveys when compared to the general population. 2) SLE QoL was significantly higher in patients with good sleep. 3) Increased S2K RI-50 scores were observed in patients with poor sleep, though results did not reach statistical significance.

Conclusion: There is a higher prevalence of poor sleep quality among patients with SLE and this was shown to strongly associated with patient reported QoL. Higher SLE disease activity was seen in patients with poor sleep, though directionality of this association is unable to be determined in this small, cross-sectional study. Longitudinal studies with actigraphy are currently underway to further examine this relationship.

	SLE cohort	Non-SLE controls	p value	
PQSI score (average)	9.96	N/A	N/A	
PROMIS Sleep Disturbance Score (average)	56	50	0.007	
PROMIS Sleep Related Impairment Score (average)	59	50	0.001	
	% SLE pts	S2K RI-50 score (mean)	χ^2	p value
PQSI ≤ 5	15	1.2	1.36	0.24
PQSI > 5	85	3.0		
PROMIS Sleep Disturbance score < 40 (group 1)	7.4	2.0		
PROMIS Sleep Disturbance score ≥ 40 to 60 (group 2)	55.6	2.9	Group 3 vs group 1=1.74	Group 3 vs group 1=0.19
PROMIS Sleep Disturbance score ≥ 60 (group 3)	37.0	5.0	Group 3 vs group 2=2.58	Group 3 vs group 2=0.11

Urinary MBL : A Promising Biomarker for Predicting Flare in Lupus Nephritis

Sarit sekhar Pattanaik[1], Madhukara HM[1], Aditya kumar Panda[2], Rashmi ranjan Sahoo[1], Rina Tripathy[3] and Bidyut kumar Das[1], [1]Medicine, SCB Medical College, Cuttack, India, [2]Centre for Life science, Central University of Jharkand, Ranchi, India, [3]Biochemistry, SCB Medical College, Cuttack, India

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I

Session Type: ACR Poster Session A

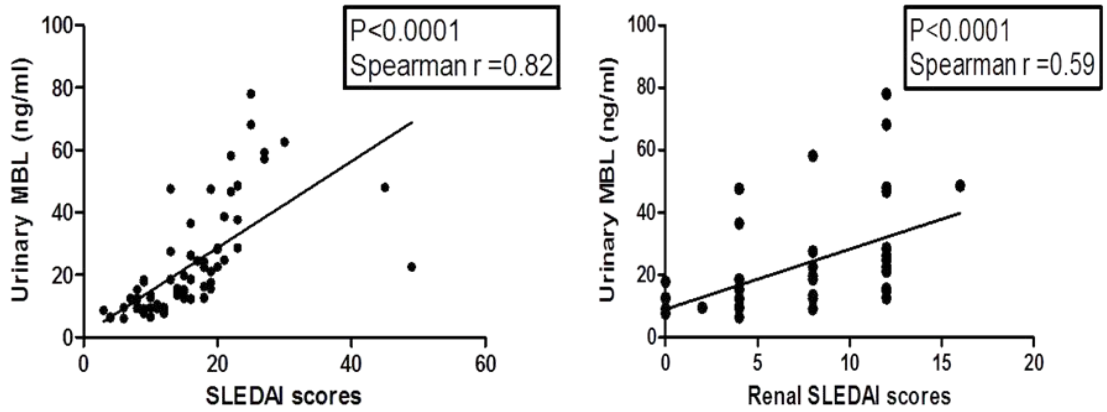
Session Time: 9:00AM-11:00AM

Background/Purpose: Nephritis is the most common cause of mortality and morbidity in SLE, develops in 40 to 70% of cases in 5-10 years with 60% mortality. It is important to detect early involvement and flare for proper management. Renal biopsy, though gold standard for diagnosis, is invasive and cannot be serially repeated for monitoring. Mannose binding lectin (MBL) , member of the collectin type of proteins of PRR family activates complement cascade or acts as opsonin. Studies have shown that plasma MBL levels are elevated in SLE patients and significantly correlate with disease activity of SLE. We hypothesized that urinary MBL would correlate with disease activity in SLE Nephritis.

Methods: In a cross sectional hospital based observational study 65 consecutive cases of SLE nephritis fulfilling the ACR criteria were enrolled. Plasma & urinary MBL levels are measured by ELISA, according to the manufacturer's instructions (R&D systems, Minneapolis, MN, USA). Clinical, serological and other markers of disease activity (C3, C4 and anti-dsDNA) were measured by standard laboratory procedures. Disease activity scores like SLEDAI 2K and renal SLEDAI were calculated. Renal biopsy was done to correlate urinary MBL levels with histopathological staging. Statistical analysis was done using Graphpad prism v5.01.

Results: Urinary MBL was high in patients of SLE Nephritis compared to healthy controls(p=0.01), furthermore patients with nephritis flare (renal SLEDAI >4) had significantly higher levels of plasma & urinary MBL compared to non flare patients(p=0.0008,p=0.004).Urinary MBL showed a strong positive correlation with proteinuria (p<0.0001,r=0.47), SLEDAI (p<0.0001,r=0.82) and renal SLEDAI (p<0.0001,r=0.59), and an inverse correlation was observed between urinary MBL and C3(p=0.03,r=-0.21),C4(p=0.04,r=-0.19). Urinary MBL levels progressively increased with higher histological staging(ISN/RPS)

Conclusion: This is the first study demonstrating a role for urinary MBL in predicting SLE nephritis flare.



Significant positive correlation of Urinary MBL with SLEDAI and renal SLEDAI scores

Session Date: Sunday, November 8, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

SLE has been consistently associated with an increased incidence of malignant lymphoma, especially the DLBCL subtype. Since the last WHO classification of 2008 DLBCL are now further divided, based on the cell-of-origin (COO) subtypes. The two major subtypes were defined by gene expression profiling of fresh frozen (FF) samples as germinal centre B-cell-like (GCB) and activated B-cell-like (ABC). Using tissue

microarray (TMA) and immunohistochemistry (IHC) in diagnostic formalin fixed paraffin embedded (FFPE) in biopsies, COO is routinely defined as GCB or non-GCB. The ABC/non-GCB subtype presents the worse prognosis and has previously been associated with rheumatoid arthritis. Our objective was to compare the frequency of non-GCB and GCB subtypes in DLBCL within a cohort of patients diagnosed with lupus.

Methods:

From a multi-centre cohort, 13 cases of DLBCL in lupus patient were identified, for which tissue and pathologic diagnosis were available. Tissue microarrays (TMA) were then built and submitted to Vancouver where IHC and scoring was performed. Immunostains were performed including lineage markers (CD20, CD3) and COO markers CD10, BCL6, MUM1, GCET1 and FOXP1. The COO was determined using both the Hans and Choi algorithms.

Results:

Eleven cases of DLBCL in patients with established SLE could be included for analysis. The diagnosis of DLBCL was confirmed by a reference hematopathologist. In the SLE DLBCL cases, BCL6 was positive in 5/11 (45%), CD10 in 2/11 (18%), FOXP1 7/11 (64%), in GCET1 0/11 (0%) and MUM1 4/11 (36%). Of the SLE DLBCL cases, 7/11 (64%) were classified as non-GCB and 4/11 (36%) were classified as GCB. This contrasts with a recent analysis of COO based on a population-based registry study of DLBCL in British Columbia (n = 348) using the Hans algorithm, with 59% GCB and 41% non-GCB.

Conclusion:

In conclusion, DLBCL arising in patients with a prior history of SLE show an enrichment of non-GCB cell-of-origin subtype, mimicking data seen in rheumatoid arthritis. Although a small sample size, these findings suggest that like lymphoma development in the face of chronic inflammation, DLBCL arising in SLE patients and related autoimmune disorders tends to be enriched in the ABC/non-GCB subtype. These findings have implications as we enter an era of COO-specific treatments based on improved biological understanding. Further studies are planned to increase the size of the cohort.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Lupus nephritis (LN) may severely affect SLE prognosis and an effective treatment of LN requires correct diagnosis, timely intervention and early treatment of any disease relapse. Biomarkers able to early identify disease relapse are still lacking. The aim of the study was to evaluate if some serum (cystatin C, β2-microglobulin) and urinary (α1-microglobulin and ACR- albumin/creatinine ratio) parameters can be more useful than the conventional parameters in monitoring lupus nephritis and in predicting exacerbations of renal involvement in SLE.

Methods: 73 consecutive SLE patients with renal involvement (active or inactive at baseline) were enrolled. Serum cystatin C and β2-microglobulin, and urinary α1-microglobulin and ACR values were evaluated at baseline (T0) and after 3 (T3) and 6 (T6) months of follow-up, along with routine clinical and laboratory examination. Renal relapse was defined as an arising of 24 hours proteinuria up to 500 mg and/or appearance of active urinary sediment and/or microematuria (>5 red blood cells/hpf).

Results:

Of the 73 LN patients (86.3% female, mean age 38.5±12.0 years, disease duration 13.0±8.8 years), 49 had inactive and 24 active renal disease at baseline. Patients with active nephritis had higher SLEDAI ($p<0.01$) and 24 hours proteinuria ($p<0.01$) values, as expected, as well as higher

levels of cystatin (1.3±0.8 vs 1.0±0.6 mg/l, p=0.01), α1-microglobulin (22.3±82.2 vs 1.2±4.3 mg/l, p=0.005) and ACR (299.5±432.2 vs 76.7±241.2 mg/g, p<0.01) with respect to patients with inactive LN.

During the follow-up, 11 out of the 49 patients with inactive LN at T0 presented some renal relapse. The 11 patients relapsed during the six-month of follow-up showed at baseline higher values of cystatin C (1.6±0.9 vs 0.9±0.2 mg/l, p=0.001), serum β2-microglobulin (4.0±2.6 vs 2.0±0.8 mg/dl, p=0.001), urinary α1-microglobulin (5.2±8.2 vs 0.0±0.2 mg/l, p<0.01) and ACR (279.9±440.1 vs 6.9±12.0 mg/g, p<0.01), than patients with stable inactive nephritis, while no differences were found in traditional parameters (C3 levels, anti-DNA title and/or positivity, 24 hours proteinuria, SLEDAI, serum creatinine).

Conclusion: This study seems to show that these biomarkers can be integrated to the conventional parameters for predicting lupus nephritis exacerbations.

Geographic Differences in Demographics, Clinical Characteristics, and Standard of Care in Multinational Studies of Patients with Moderate to Severe Systemic Lupus Erythematosus

Richard Furie[1], M Khamashta[2], L Wang[3], J Drappa[3], W Greth[3] and G Illei[3], [1]Division of Rheumatology, North Shore - LIJ Health System, New York, NY, [2]Graham Hughes Lupus Research Laboratory, The Rayne Institute, St Thomas' Hospital, London, United Kingdom, [3]MedImmune, Gaithersburg, MD

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Most randomized controlled trials (RCTs) in systemic lupus erythematosus (SLE) include stratification factors to ensure a balanced allocation of subgroups that might respond differently to therapeutic interventions. Strata could include baseline disease activity, baseline corticosteroid dosage, or race. Despite such stratification, geographic differences have influenced responses in some studies. Sifalimumab and anifrolumab, fully human, IgG1 κ monoclonal antibodies, have each been investigated in Phase II studies in SLE (NCT01283139 and NCT01438489). Sifalimumab binds to and neutralizes the majority of IFN-α subtypes, while anifrolumab binds to the type I IFN receptor and thus prevents signaling by any of the type I IFNs. This study analyzed potentially impactful differences in baseline characteristics between geographic regions.

Methods: This *post-hoc* analysis first combined data from the two studies and then compared the baseline characteristics of the region with an expected high placebo plus standard of care response rate (Region 1 [R1]: Central America, South America, Eastern Europe, Asia) to those of the region with an expected low placebo plus standard of care response rate (Region 2 [R2]: North America, Western Europe, South Africa). Eligibility criteria, similar for the two studies, resulted in the enrollment of patients with moderate to severe SLE with inadequate responses to standard of care. Patients with severely active lupus nephritis or severe neuropsychiatric SLE were excluded.

Results: Of the 736 randomized and dosed patients, 68.9% were from R1, and 31.1% were from R2. There were no significant baseline differences between regions in mean SLEDAI-2K, BILAG 2004 composite, or Physician's Global Assessment scores. However, differences were seen in other clinical characteristics as well as demographic and background medication use (table).

Conclusion: SLE patients enrolled in RCTs from different geographic regions had notable differences in some demographic and baseline clinical characteristics as well as in standard of care medications. These differences may impact the analysis of the treatment response to standard of care and/or investigational drug. Therefore, the possibility of an imbalance in patients recruited from regions with expected high or low standard of care response should be considered in the design of SLE RCTs.

Demographics, Clinical Characteristics, and Standard of Care Medications

	Region 1 (N=507)	Region 2 (N=229)	*P*-value

Session Date: Sunday, November 8, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: We have previously validated several urine proteomic biomarkers for Lupus Nephritis (osteoprotegerin, MCP-1, VCAM-1 and urine TWEAK). In this discovery effort we looked for urine biomarkers for Class IV and V Lupus Nephritis.

Methods: This analysis is based on specimens from six different SLE patients, three with Class IV Lupus Nephritis, two with Class V and one SLE control. Protein differences in urine samples were determined by quantitative proteomics using TMT 6-plex isobaric mass tags after immunoaffinity depletion of albumin on an Agilent MAR6 column. Raw spectrum-level values were extracted and filtered to less than 1% FDR and 30% isolation interference using Thermo Scientific Proteome Discoverer software. These data were imported into the Partek Genomics Suite for normalization and further analyses.

Results: Some urine biomarkers such as **afamin and orosomucoid 1(alpha-1-acid glycoprotein)** were consistently higher in Class IV/V,

compared to control**.** Some other biomarkers such as **apolipoprotein A-I and transthyretin** were only higher in Class V, which might allow them to serve as a biomarker to distinguish Class V from IV. Some of the biomarkers discovered might not be surprising. For example, several hemoglobin urine biomarkers (**HBG2, HBB, etc.**) were found to be higher in Class V, but are common in any patient with poor renal function.

Based on these lower/higher levels of urine proteins, possible pathways potentially important in Lupus Nephritis were identified using Ingenuity Pathway Analysis software. Table 2 presents the most likely pathways. The second column shows the protein modules associated in the pathway. The third column shows the comparisons from which the pathway was identified.

Table 1 Biomarkers identified in different comparisons

	Gene Name (NCBI)	*IV vs. Cont*	*V vs. Cont*	*IV vs. V*	*IV and V vs. Cont*
	Fc fragment of IgG, low affinity IIIa, receptor (CD16a)	Lower in IV			
CADM2	**cell adhesion molecule 2**	Lower in IV			
APOC1	**apolipoprotein C-I**		Higher in V		
LCP1	**lymphocyte cytosolic protein 1 (L-plastin)**	Higher in IV		IV higher than V	
ADIPOQ	**adiponectin, C1Q and collagen domain containing**			IV higher than V	
CFHR1	**complement factor H-related 1**	Higher in IV	Higher in V		Higher in Cases
AZGP1	**alpha-2-glycoprotein 1, zinc-binding**	Higher in IV	Higher in V		Higher in Cases
HMGN2	**high mobility group nucleosomal binding domain 2**			IV higher than V	
PGLYRP2	**peptidoglycan recognition protein 2**			IV higher than V	
HYAL1	**hyaluronoglucosaminidase 1**		Lower in V		Lower in Cases
PZP	**pregnancy-zone protein**	Higher in IV	Higher in V		Higher in Cases
AFM	**afamin**	Higher in IV	Higher in V		Higher in Cases
TTC26	**tetratricopeptide repeat domain 26**			IV higher than V	
ORM1	**orosomucoid 1**	Higher in IV	Higher in V		Higher in Cases
FCGRT	**Fc fragment of IgG, receptor, transporter, alpha**	Lower in IV			Lower in Cases
MPO	**myeloperoxidase**	Higher in IV			
SERPINA6	**serpin peptidase inhibitor, clade A (alpha-1 antiproteinase, antitrypsin), member 6**		Higher in V		Higher in Cases
CARD18	**caspase recruitment domain family, member 18**		Lower in V		
BCHE	**butyrylcholinesterase**	Higher in IV			Higher in Cases
ORM2	**orosomucoid 2**	Higher in IV	Higher in V		Higher in Cases
APOA1	**apolipoprotein A-I**		Higher in V	IV lower than V	
MB	**myoglobin**		Higher in V		
KRT85	**keratin 85, type II**			IV lower than V	
SELL	**selectin L**	Higher in IV			Higher in Cases
S100A12	**S100 calcium binding protein A12**			IV higher than IV	
MUC5B	**mucin 5B, oligomeric mucus/gel-forming**		Higher in V	IV lower than V	
APOA2	**apolipoprotein A-II**			IV lower than V	
FUCA2	**fucosidase, alpha-L- 2, plasma**		Higher in V		

TTR	**transthyretin**		Higher in V		Higher in Cases
CA1	**carbonic anhydrase I**		Higher in V	IV lower than V	Higher in Cases
UBE2V2	**ubiquitin-conjugating enzyme E2 variant 2**			IV lower than V	
CD300LF	**CD300 molecule-like family member f**		Higher in V		
AHSP	**alpha hemoglobin stabilizing protein**		Higher in V		
HBG2	**hemoglobin, gamma G**		Higher in V	IV lower than V	
ZNF648	**zinc finger protein 648**		Higher in V	IV lower than V	
HBB	**hemoglobin, beta**		Higher in V	IV lower than V	
KRT33B	**keratin 33B, type I**		Higher in V	IV lower than V	
SERPINA1	**serpin peptidase inhibitor, clade A (alpha-1 antiproteinase, antitrypsin), member 1**			IV higher than IV	
HBD	**hemoglobin, delta**		Higher in V		
RBP2	**retinol binding protein 2, cellular**	Higher in IV			
KRT86	**keratin 86, type II**			IV lower than V	
HBA1	**hemoglobin, alpha 1**			IV lower than V	
KRT36	**keratin 36, type I**			IV lower than V	
POMC	**proopiomelanocortin**		Lower in V		
FABP4	**fatty acid binding protein 4, adipocyte**			IV higher than IV	

Table 2 Pathways identified by comparing Class IV and V with control

Name	*Modules*	*Associated Comparisons*
Acute Phase Response Signaling	CP,ORM2,ITIH3,CRP,A2M, C4A/C4B, ORM1,RBP2, SERPINA1,IL1RAP,FTL,TTR,ALB	IV, V
Production of Nitric Oxide and Reactive Oxygen Species in Macrophages	LYZ,APOB,ORM1,MPO,ORM2, SERPINA1,APOC1,ALB	IV,V
LXR/RXR Activation	LYZ,C4A/C4B,APOB,ORM1,ORM2, SERPINA1,IL1RAP,APOC1,A1BG,ALB,TTR	IV, V
IL-12 Signaling and Production in Macrophages	LYZ,APOB,ORM1,ORM2,SERPINA1, APOC1,ALB	IV,V
FXR/RXR Activation	C4A/C4B,APOB,ORM1,ORM2, SERPINA1,APOC1,A1BG,ALB,TTR	IV,V
Atherosclerosis Signaling	LYZ,APOB,ORM1,ORM2,SERPINA1, APOC1,VCAM1,ALB	IV,V
LPS/IL-1 Mediated Inhibition of RXR Function	GSTM1,FABP4,IL1RAP,GSTA2, APOC1,ALDH1A3,FABP2	IV,V
Clathrin-mediated Endocytosis Signaling	LYZ,APOB,ORM1,ORM2, SERPINA1,APOC1,TFRC,ALB	IV,V
Melatonin Degradation III	MPO	IV,V
Glutathione-mediated Detoxification	GSTM1,GSTA2	IV,V
Retinoate Biosynthesis I	RBP2,ALDH1A3	IV
Pyrimidine Ribonucleotides De Novo Biosynthesis	NUDT5,CMPK1	IV
Pyrimidine Ribonucleotides Interconversion	NUDT5,CMPK1	IV
RAR Activation	RBP2,RPL7A,ALDH1A3	IV
PXR/RXR Activation	GSTM1,GSTA2	IV
Xenobiotic Metabolism Signaling	GSTM1,GSTA2,FTL,ALDH1A3	IV
Extrinsic Prothrombin Activation Pathway	FGB,SERPINC1,FGG	V
Lymphotoxin β Receptor Signaling	VCAM1,DIABLO	V
Coagulation System	A2M,FGB,SERPINC1,FGG	V
IL-17 Signaling	CRP,MUC5B	V

Conclusion: In this discovery effort several interesting pathways were identified that might be important in Lupus Nephritis overall or differentially in Class IV versus Class V. In particular, reactive oxygen species, IL-12, LPS/IL-1, IL-17, atherosclerosis and coagulation pathways might be novel targets. Validation of this discovery effort is underway.

Oral Ulcers in Systemic Lupus Erythematosus: Characterization and Clarification of an Important Clinical Manifestation

Robert Durcan[1], Wei Fu[2] and Michelle Petri[3], [1]Beaumont Hospital, Dublin, Ireland, [2]Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD, [3]Johns Hopkins University School of Medicine, Baltimore, MD

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Oral ulcers (OU) are a common manifestation of systemic lupus erythematosus (SLE). They are included in both classification criteria and disease activity indices. Despite this, there has been little done to further characterize them. This work was undertaken to evaluate the disease specific features associated with OU in SLE. We then sought to specifically evaluate a subgroup of individuals regarding the patient reported features of OU in SLE.

Methods: The prevalence of OU in a large SLE cohort was examined and their relationship to the other SLICC criteria explored using logistic regression. Phase 2 involved the administration of a questionnaire outlining the characteristics, location, duration and number of OU.

Results: There were 2417 SLE patients in the initial analysis. The frequency of OU in the cohort was 51.6%. Male gender (OR=0.48, 95% CI =0.35, 0.66) and African-American race (OR=0.52, 95% CI = 0.33, 0.80) were negatively associated with oral ulcers. The relationship between OU and the other SLICC clinical and laboratory criteria, after adjusting for ethnicity, are as outlined in Table1.

Oral ulcers were positively associated with cutaneous lupus, alopecia and arthritis. They were associated with pleurisy but not pericarditis. Oral ulcers were negatively associated with “seropositivity” (low complement, high anti-dsDNA) and renal lupus. 123 patients were surveyed (3 could give no details). 68 (56.6%) had as history of OU. Mean duration of OU was 7.43 days (range: 1 to 90). Regarding location, 22 (32.4%) described them on their tongue, 23 (33.8%) on the palate and 50 (73.5%) on their buccal mucosa. 34 (50%) described crops of OU. Addressing pain, 54 of the 68 patients provided information. 34 (63%) said that they only had painful episodes, 12 (22%) had only painless episodes, and 8 (15%) have both.

Table 1 Relationship between OU and the other SLE manifestations.

SLICC Criteria		History of OU (%)	No OU (%)	Odds ratio	95% CI	P value (unadjusted)	P value (adjusted for ethnicity)
Acute cutaneous lupus	Malar Rash	55.6	42.4	1.58	(1.34,1.86)	<.0001	<.0001
	Bullous Lupus	1.1	0.4	2.61	(0.91,7.43)	0.0883	0.0731
	Photosensitivity	60.7	43.3	1.84	(1.56,2.17)	<.0001	<.0001
Chronic cutaneous lupus	Discoid Lupus	20.4	18.4	1.38	(1.12,1.71)	0.2124	0.0027
Alopecia		60.9	49.2	2.11	(1.77,2.52)	<.0001	<.0001
Arthritis		74.2	69.3	1.32	(1.1,1.59)	0.0078	0.0024

	Acute Confusional State	5.0	3.2	1.60	(1.05,2.43)	0.0259	0.0297
Hemolytic Anemia		8.5	11.7	0.75	(0.57,0.99)	0.0120	0.0393
Leukopenia		46.5	45.4	1.16	(0.99,1.37)	0.6081	0.0718
Thrombocytopenia		19.2	21.6	0.89	(0.73,1.09)	0.1493	0.2493
ANA		96.2	96.9	0.88	(0.56,1.38)	0.3328	0.5775
Anti-dsDNA		58.2	65.2	0.77	(0.65,0.91)	0.0004	0.0022
Anti-Sm		19.0	22.0	1.01	(0.82,1.25)	0.0753	0.9244
Anti-phospholipid	LAC	25.7	27.1	0.88	(0.73,1.07)	0.4738	0.1977
	Anticardiolipin	48.6	48.5	0.99	(0.84,1.16)	0.9683	0.8645
	Anti-beta 2 gly	27.8	30.3	0.85	(0.67,1.07)	0.2859	0.1682
Low complement	C3	51.1	58.7	0.78	(0.66,0.92)	0.0002	0.0034
	C4	45.7	49.4	0.88	(0.75,1.04)	0.0683	0.1274
Coombs		17.3	23.4	0.75	(0.60,0.94)	0.0008	0.0133

Conclusion: Mouth ulcers occur in 51% of SLE patients. They are negatively associated with “seropositivity” (meaning anti-dsDNA and low complement) and with renal lupus. Surprisingly, they are associated with pleurisy but not pericarditis. The majority occur on the buccal mucosa. In contradistinction to the ACR criteria, 63% of patients have painful episodes.

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Mycophenolate mofetil (MMF), along with corticosteroids, is considered as the standard of care in lupus nephritis (LN); however, its efficacy in extra-renal manifestations of systemic lupus erythematosus (SLE) is less well known. This study aimed to determine its effectiveness in non-renal lupus.

Methods: One hundred seventy seven SLE patients (diagnosis according to the 1997 ACR criteria or 3 criteria and a compatible renal biopsy) were enrolled; 105 for whom MMF was introduced for active LN (age 35.6±10.7 years, disease duration 8.9±7.8 years) and 72 for extra-renal manifestations (age 38.6±11.7 years, disease duration 11.7±9.2 years). The main indication for MMF initiation was based on the respective SLE Disease Activity Index (SLEDAI-2K) element that was present at that time. Patients were subdivided according to the major non-renal manifestation (central nervous system involvement, vasculitis, musculoskeletal features, skin disease, serositis, immunological and hematological abnormalities). Improvement was defined as the absence of the initial clinical or laboratory manifestation after 6 and 12 months. The statistical software SAS 9.3 was used for analysis; $p<0.05$ was considered significant.

Results: Cumulatively, the initial clinical manifestation or hematological abnormality was resolved in 42/72 non-renal patients (58.3%) after 6 months and in 45/72 (62.5%) after 12 months. Corticosteroid dose was reduced in 44/72 (61.1%, $p<0.001$) patients (mean dose 18.4±12.6mg/day at baseline to 12.1±9.0mg/day after 12 months, $p<0.05$). In renal patients, 40 (38.1%) had complete resolution of the extra-renal manifestation after 6 months, while 53 (50.5%) achieved complete response after 12 months. Prednisone dose was reduced in 73/105 patients (69.5%) after 12 months (mean dose 29.2±16.6mg/day at baseline to 15.3±9.7mg/day, $p<0.001$). Details on the improvement rates of the different clinical features are shown in the table.

		CNS	VASC	MSK	Renal	Skin	SERO	IMMUNO	HEMA
Non-renal patients (n=72)	Baseline	11	2	19	0	27	8	45	10
	6 months	8 (72.7%)	2 (100%)	11 (57.9%)	0 (0%)	7 (25.9%)	6 (75%)	11 (24.4%)	8 (80%)
	12 months	8 (72.7%)	1 (50%)	14 (73.7%)	0 (0%)	11 (40.7%)	5 (62.5%)	12 (26.7%)	6 (60%)
Renal patients (n=105)	Baseline	7	6	11	105	30	7	85	3
	6 months	3 (42.9%)	6 (100%)	10 (90.9%)	20 (19%)	10 (33.3%)	4 (57.1%)	15 (17.6%)	2 (66.7%)
	12 months	6 (85.7%)	6 (100%)	11 (100%)	29 (27.6%)	16 (53.3%)	7 (100%)	15 (17.6%)	2 (66.7%)

CNS: central nervous system, VASC: vasculitis, MSK: musculoskeletal (arthritis, myositis), SERO: serositis, IMMUNO: immunological abnormalities (low C3/C4 and/or increased anti-DNA titers, HEMA: hematological abnormalities.

Conclusion: MMF is an efficacious therapeutic approach for the management of refractory non-renal manifestations of SLE in 6 and 12 months, leading to complete resolution of the initial clinical manifestation in more than half of the patients and significant reduction in corticosteroid dose.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Serositis is one of the classification criteria for systemic lupus erythematosus and a common type of extra renal flare. Comparison of associates of pleurisy and pericarditis separately has not been previously done in Caucasians and African Americans.

Methods: 2,390 SLE patients in the Hopkins Lupus Cohort were analyzed for demographic, clinical and serologic associates of pleurisy or pericarditis, defined using the SELENA revision of the SLE Disease Activity Index (SLEDAI). We reported associates with a p-value of less than 0.05 for both and for pleurisy or pericarditis separately.

Results: 43% had pleurisy and 22% had pericarditis. African-American ethnicity was associated with pericarditis. Renal lupus and seizure were associated only with pericarditis, whereas arthritis was associated only with pleurisy. Only pericarditis was associated with anti-RNP and anti-Sm. Both pleurisy and pericarditis are associated with anti-dsDNA and low complement.

Table 1. Demographic Characteristics Associated with Serositis in SLE (p<0.0001)

Characteristics	Subgroup	Negative	Positive	OR	95% CI	P-value
Factors significantly associated with only Pericarditis						
African-American ethnicity	Pericarditis	38.54%	53.64%	1.85	1.51-2.26	<0.0001
Factors significantly associated with only Pleurisy						
Age at SLE Diagnosis	Pleurisy	33.44±13.54	31.03±12.01			<0.0001
Factors significantly associated with both Pericarditis and Pleurisy						
None						

Table 2. Clinical and Laboratory Features Associated with Serositis in SLE (p<0.0001)

Characteristics	Subgroup	Negative	Positive	OR	95% CI	P-value
Factors significantly associated with only Pericarditis						
Proteinuria	Pericarditis	40.37%	57.36%	1.99	1.63-2.42	<0.0001
Nephrotic Syndrome	Pericarditis	15.33%	26.78%	2.02	1.60-2.55	<0.0001
Seizure	Pericarditis	8.23%	14.31%	1.86	1.39-2.50	<0.0001
Factors significantly associated with only Pleurisy						
Arthritis	Pleurisy	66.32%	79.48%	1.97	1.63-2.37	<0.0001
Arthralgia	Pleurisy	87.66%	95.85%	3.25	2.30-4.60	<0.0001
Malar Rash	Pleurisy	45.75%	54.26%	1.41	1.20-1.65	<0.0001
Factors significantly associated with both Pericarditis and Pleurisy						
Fever	Pericarditis	32.60%	50.76%	2.13	1.75-2.60	<0.0001
	Pleurisy	29.39%	45.95%	2.04	1.72-2.42	<0.0001
Lymphadenopathy	Pericarditis	28.35%	41.79%	1.81	1.48-2.22	<0.0001
	Pleurisy	26.34%	37.78%	1.7	1.43-2.02	<0.0001
Raynaud's Syndrome	Pericarditis	48.90%	63.34%	1.81	1.48-2.21	<0.0001
	Pleurisy	47.08%	58.37%	1.58	1.34-1.86	<0.0001
Hemolytic Anemia	Pericarditis	8.34%	16.37%	2.15	1.61-2.87	<0.0001
	Pleurisy	7.91%	12.87%	1.72	1.31-2.26	<0.0001

Table 3. Serologic Features Associated with Serositis in SLE (p<0.0001)

Characteristics	Subgroup	Negative	Positive	OR	95% CI	P-value
Factors significantly associated with only Pericarditis						
Anti-RNP	Pericarditis	25.89%	37.82%	1.74	1.41-2.14	<0.0001
Anti-Sm	Pericarditis	17.97%	28.80%	1.85	1.47-2.32	<0.0001
Factors significantly associated with only Pleurisy						
None						
Factors significantly associated with both Pericarditis and Pleurisy						
Anti-DNA	Pericarditis	58.74%	73.09%	1.91	1.54-2.36	<0.0001
	Pleurisy	58.01%	66.99%	1.47	1.24-1.74	<0.0001
Low C3	Pericarditis	51.86%	65.46%	1.76	1.44-2.15	<0.0001
	Pleurisy	50.81%	60.10%	1.46	1.24-1.72	<0.0001
Low C4	Pericarditis	44.85%	57.63%	1.67	1.38-2.04	<0.0001
	Pleurisy	43.77%	52.75%	1.43	1.22-1.69	<0.0001
ESR	Pericarditis	71.71%	83.85%	2.05	1.59-2.64	<0.0001
	Pleurisy	70.40%	79.51%	1.63	1.35-1.98	<0.0001

Conclusion: Pleurisy is more common than pericarditis. There are specific associates of pericarditis (African-American ethnicity, renal lupus, seizure, anti-RNP and anti-Sm) and pleurisy (arthritis). This challenges the dogma that serositis has one mechanism in SLE.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Melanocortins such as corticotropin and alpha-MSH may modulate steroid-independent immune responses relevant to SLE pathophysiology. We previously reported that repository corticotropin injection (RCI), an FDA approved melanocortin therapeutic, attenuated B cell development, circulating autoantibody titers, and disease activity in a murine SLE model, supporting the efficacy of RCI as a treatment alternative for patients with SLE.

Methods:

This 8 wk double-blind randomized placebo-controlled study assessed clinical efficacy of RCI in patients with persistently active SLE despite moderate dose corticosteroids. The primary objective was to explore the effects of RCI on the Hybrid SLE Disease Activity Index (hSLEDAI), with key secondary objectives to evaluate effects on British Isles Lupus Assessment Group-2004 (BILAG), Cutaneous Lupus Erythematosus Disease Area and Severity Index (CLASI), and 28-joint count score. Patients were eligible if they had persistently active SLE (hSLEDAI >2) with arthritis and/or skin involvement and BILAG A or B in mucocutaneous and/ or musculoskeletal systems despite 7.5-30 mg prednisone daily for ≥ 4 wk prior to screening. 38 subjects were randomized to receive SC RCI 80 U every other day (RCI80; n=13) or 40 U daily (RCI40; n=13), or SC Placebo gel (n=12). Study medication was maintained at the assigned regimen for 4 wk, then tapered over 4 wk to 2x/wk administration of the assigned dose. Clinical response was assessed by change from baseline for hSLEDAI (wk 2, 4, 6 & 8), BILAG, CLASI, and Tender & Swollen Joint Count (wk 4 & 8).

Results:

Mean hSLEDAI scores at baseline were 9.8±2.1, 8.7±2.9, 11.3±3.3, and 10.0±3.3 in the Placebo, RCI40, RCI80, and combined RCI groups, respectively (mean ±SD). Baseline BILAG and CLASI scores were similar between groups, though tender swollen joint count was higher in subjects randomized to RCI80 vs RCI40 or Placebo (p≤ 0.05). RCI led to significant improvement in key efficacy endpoints compared with Placebo, including total hSLEDAI and BILAG scores, CLASI Activity, and Tender & Swollen Joint Count. There were no significant differences in the incidence of treatment-emergent adverse events between groups.

Activity index *change from baseline*	**Time**	**Placebo** *LS mean (SE)*	**RCI 40U QD** *LS mean (SE)*	**RCI 80U QOD** *LS mean (SE)*	**RCI (combined)** *LS mean (SE)*
hSLEDAI	**4 wk**	-1.2 (0.6)	-1.2 (0.6)	-2.1 (0.6)	-1.6 (0.4)
	6 wk	-1.4 (0.7)	-2.9 (0.7)	-3.5 (0.7)* **p=0.045*	-3.2 (0.5)* **p=0.040*
	8 wk	-0.8 (0.9)	-3.7 (0.9)* **p=0.026*	-3.9 (0.9)* **p=0.020*	-3.8 (0.6)* **p= 0.008*
BILAG	**4 wk**	-4.7 (1.6)	-5.2 (1.5)	-7.2 (1.6)	-6.1 (1.1)
	8 wk	-1.8 (1.5)	-8.1 (1.4)* **p=0.005*	-9.3 (1.6)* **p=0.002*	-8.6 (1.0)* **p=0.001*
CLASI Activity	**4 wk**	-0.2 (0.7)	-2.2 (0.7)* **p=0.051*	-1.7 (0.7)	-2.0 (0.5)* **p=0.050*
	8 wk	-0.6 (1.0)	-3.7 (1.0)* **p=0.030*	-2.3 (1.1)	-3.1 (0.7)* **p=0.047*
Tender & Swollen Joint Ct	**4 wk**	-2.5 (0.8)	-2.3 (0.7)	-3.5 (0.8)	-2.8 (0.5)
	8 wk	-2.5 (0.5)	-2.8 (0.5)	-4.4 (0.6)* **p=0.019*	-3.5 (0.4)

Conclusion:

These data demonstrate that RCI reduces disease activity in patients requiring corticosteroids for persistently active SLE, and that improvements occur within 8 wk of treatment initiation. The tolerability, steroid-sparing effects, and impact of RCI on long-term disease control are being further evaluated in an ongoing open-label extension of this study.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Hematologic involvement is common in patients with SLE. Thrombocytopenia and autoimmune hemolytic anemia (AIHA), prevalences of which have been reported as 10-40 % and 5-10 % respectively, have considerable impact on prognosis. Herein, we aimed to investigate the frequencies of these hemocytopenias, their clinical and serological associations and effect on disease outcome in a large single centre cohort of patients.

Methods:

We analysed our cohort of 852 patients who fulfilled at least 4 of the ACR criteria for SLE. The data presented was the cumulative clinical and serological manifestations throughout the follow-up period. Hemolytic anemia was defined as a drop in hemoglobin accompanied by increased reticulocyte count, high serum lactate dehydrogenase and reduced haptoglobin levels in the presence of a positive Coombs' test. Thrombocytopenia was defined as a platelet count of $<100x10^9/mm^3$. Demographic characteristics, clinical features, autoantibody profiles, damage and mortality data retrieved from the database were compared between patients with and without each hematological abnormality. The X^2 test, logistic regression and Kaplan-Meier survival analyses were used.

Results:

There were 93 (10.9%) patients with AIHA and 215 (25.3%) with thrombocytopenia. Patients with AIHA was significantly younger at diagnosis (27±13 vs 31±12, $p<0.05$) and significantly had a shorter disease duration (95±84 vs 118±85 mo, $p<0.05$). AIHA and thrombocytopenia were both associated with neuropsychiatric (NP) involvement ($p<0.05$) and associated with each other ($p<0.05$) and leukopenia ($p<0.05$). Comparison of patients with AIHA or thrombocytopenia to the rest of the cohort displayed significant associations with antiphospholipid syndrome (APS), anticardiolipin (aCL) antibodies and lupus anticoagulant (LA). In patients with thrombocytopenia the relationship with APS features, namely both thrombosis and pregnancy morbidity, was stronger ($p<0.001$). Compared to the rest of the cohort, more patients in both groups had organ damage and their mean SLICC damage score was significantly higher. Association to NP damage was discernible in both groups ($p<0.05$). In addition, damage in renal and cardiovascular domains and diabetes were more pronounced in patients with thrombocytopenia ($p<0.001$). Kaplan Meier survival analysis showed that patients with AIHA had significantly reduced survival rates at 10 (94 vs 77%) and 20 (88 vs 77%) years ($p<0.001$). In the thrombocytopenia group, despite the lack of significant differences, there was a tendency for lower survival rates.

Conclusion:

We demonstrated that both AIHA and thrombocytopenia were associated with aCL antibodies, coexisting APS and NP involvement and damage in our cohort. There was a strong link between AIHA and thrombocytopenia. Patients with AIHA had a younger age at disease onset with reduced survival. No significant reduction in survival rates was observed in patients with thrombocytopenia. However, besides NP involvement, thrombocytopenia delineated a subgroup of patients with a higher renal and cardiovascular damage which perceivably can affect prognosis. Overall, AIHA and thrombocytopenia may predict a poorer outcome in patients with SLE.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: The anti-BAFF antibody belimumab is the first biologic drug approved for treatment of mild-moderate SLE. While the efficacy of belimumab for this indication is not questioned, the mechanism for drug efficacy in humans remains to be established. Mouse studies have shown that BAFF regulates the selection of naïve autoreactive B cells, particularly between the transitional T1 and transitional T2 stage, but that not all autoreactive specificities are subject to regulation by BAFF. Whether belimumab regulates the autoreactive B cell repertoire in humans is not yet known. In addition, an acute increase in CD27+ memory B cells has been noted in patients treated with belimumab. Whether this reflects memory B cell expansion or mobilization, or expansion of the CD27+ B1 subset is not known.

Methods: Peripheral cells from 15 SLE patients treated with Belimumab for >3 years were compared to cells from 17 matched SLE patients and 12 healthy donors. Blood was also collected from 7 patients before and 4-8 weeks after initiation of belimumab treatment. Dendritic cell, monocyte, T cell and B cell subsets were analyzed by multi-parameter flow cytometry. Immunoglobulin heavy chain gene libraries were generated from sorted naive B cells using primers from iRepertoire.

Results: As expected, B cell numbers were 85% lower in chronically treated belimumab subjects than in SLE or healthy controls. Although all B cell subsets were depleted by belimumab, there was relative sparing of the class switched memory subset. In 60% of the patients B cell deletion occurred before the transitional stage, presumably in the bone marrow and in the other 40% it occurred between the T1 and T3 stage. Naïve B cell populations were sorted for immunoglobulin repertoire analyses and good quality libraries were obtained from 14/15 subjects; deep sequencing and analysis are in progress. A modest increase in CD27+ B cells that occurred in patients newly starting belimumab was accounted for by an increase in class switched memory cells but not non-class switched memory or B1 cells. There were no significant differences in dendritic cell, monocyte or T cell subsets between the three groups.

Conclusion: The effects of belimumab on human B cells are more variable than those in mice and deletion often occurs at an earlier stage of B cell development than the peripheral T1 stage. The increase in CD27+ B cells previously observed early after belimumab therapy is due to an increase in class switched memory cells. Pending repertoire analyses will inform us as to whether there is preferential depletion of autoreactive B cells in belimumab treated patients.

Early Symptoms of Systemic Lupus Erythematosus As Reported By Members of the German Lupus Erythematosus Patient Association

Nicolai Leuchten[1], Barbara Milke[1], Borgi Winker-Rohlfing[2], David I. Daikh[3], Thomas Dorner[4], Sindhu R. Johnson[5], Martin Aringer[1] and on behalf of the SLE Classification Criteria Steering Committee, [1]Medicine III, University Medical Center and Faculty of Medicine at the TU Dresden, Dresden, Germany, [2]Lupus Erythematodes Selbsthilfegemeinschaft e.V., Wuppertal, Germany, [3]Rheumatology, UCSF/VA Medical Center, San Francisco, CA, [4]Charité University Medicine Berlin, Berlin, Germany, [5]Dept of Rheumatology, Toronto Western and Mt. Sinai Hospitals, University of Toronto, Toronto, ON, Canada
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: EULAR and ACR have jointly funded a project to develop systemic lupus erythematosus (SLE) classification criteria, aiming at earlier and more accurate classification of the disease. This abstract reports on an early phase of that project, aimed at collecting potential candidate criteria. The objective of this study was to identify early symptoms of SLE from the patient perspective. Since SLE patients usually experience the onset and diagnosis as a critical life event, memories of this time appear remarkably accurate.

Methods: As approved by the local ethics committee, we conducted a cross-sectional survey of German SLE patients. An anonymous self-report questionnaire was published in the "Schmetterling" the quarterly journal of the "Lupus erythematodes Selbsthilfegemeinschaft", the German SLE patient association. Patients were asked for year of and age at their initial diagnosis. The questionnaire included typical organ manifestations, symptoms and autoantibodies. In addition, patients were asked to add additional symptoms in free text. For each symptom, boxes were provided to indicate the presence of the symptom before diagnosis, in the first year of diagnosis and at the time of completion of the questionnaire.

Results: 300 patient questionnaires were completed and mailed. Of the respondents, 93% were female, their mean age at diagnosis was 36 years, their mean disease duration was 17 years, 82% reported to definitely be ANA-positive. Joint, skin and kidney involvement were reported at 82%, 65% and 34%, respectively. 22% of patients reported fibromyalgia. For the time before and shortly after diagnosis, more than 50% of the patients reported fatigue (90%), joint pain (87%), hypersensitivity to sunlight (79%), myalgias (77%), skin rashes (71%), fever (53%), hair loss (51%) and Raynaud's (50%). Approximately one third (35%) affirmed shortness of breath. Free text symptoms reported frequently before or early in diagnosis are listed in Table 1.

Table 1: Symptoms added in free text by at least 10 patients for the time before or shortly after the SLE diagnosis

	n (%)
Diarrheas/abdominal pain	32 (11%)
Headache/migraine	31 (10%)
Sicca symptoms	30 (10%)
Depression/mood disorder	25 (8%)
Cognitive impairment	23 (8%)
Dizziness/vertigo	18 (6%)
Polyneuropathy/paresthesias	15 (5%)
Sleep disturbance	12 (4%)

Conclusion: For a Caucasian European SLE patient population, the overall characteristics suggested meaningful representation. While many symptoms were reported as expected, a significant number of patients volunteered gastrointestinal complaints and symptoms of the central and peripheral nervous system. These data add to the information on early SLE symptoms that may be relevant for distinguishing early SLE from other diseases.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Damage in SLE is associated with mortality. Not every damage manifestation is associated in the same way. Some studies were made assessing this relation but in small and heterogeneous samples making difficult to obtain meaningful conclusions. Purpose:To evaluate patterns of damage accrual and mortality in a large sample of SLE patients.

Methods:

SLE patients from RELESSER were studied. After K-means cluster analysis, different clusters of patients with similar characteristics in terms of damage accrual were identified. Kaplan-Meier log-rank test and Cox regression were used to analyse mortality in each group.

Results:

3,656 SLE patients from 45 Rheumatology Units across Spain were studied. 90.33% were women. 93.15% were Caucasian, 5.21% Latinamerican and 1.64% other races. Mean age (±SD) at SLE diagnosis was 35.16±14.67 years. Mean follow-up time (±SD) was 120.19±87.67 months. Mean SLICC/ACR damage index (SDI) score was 1.15±1.67. Average number of organ systems affected in terms of damage was 0.65±1.06. 207 (5.66%) patients died.

The SDI organ systems most frequently damaged were: musculoskeletal(MS) (13.78%), ocular (8.51%), cardiovascular(CV)(7.99%) and renal (6.15%). The least frequently present were: gastrointestinal (1.96%), diabetes mellitus (2.41%) and premature gonadal failure (2.52%).

Three clusters (C) were formed. C1 had mild or no damage. All patients in C2 had MS damage but no CV. In C3 all patients had CV damage.

Among the 3 clusters, there were statistically significant differences ($p<0.001$) in the prevalence of damage in each organ system assessed by the SDI, in the average SDI score, in the number of SDI organ systems damaged and mortality rate. Comparative detailed data are shown in the table below.

In C3 patients were older at SLE diagnosis and had higher % of males, differences statistically significant between the 3 clusters for both variables ($p<0.001$).

Comparing survival curves of the 3 clusters, the log-rank test showed significant differences ($p <0.001$ for the triple and double comparisons). Analysing the survival rate at 10, 20 and 30 years from diagnosis of SLE, it was found lower survival in patients of C2 and C3 compared to C1 ($p =0.068$ when C2 is compared to C1 at 10 years, $p<0.01$ for all the other cases). Between C2 and C3, there were no significant differences in survival at 10 years and it was significantly lower in C3 at 20 and 30 years ($p=0.025$ for both).

Cox regression analysis showed that, compared with C1, the mortality hazard ratio of C2 and C3 was 1.9 and 3.5 higher respectively, being statistically significant, $p<0.001$ in both.

Conclusion:

SLE patients can be divided into different homogeneous groups (clusters) based on damage accrual. These clusters have different mortality rates.

Factors:	CLUSTER 1 n=2949 (80.66%)	CLUSTER 2 n=415 (11.35 %)	CLUSTER 3 N=292 (7.99%)	p-value

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Belimumab is the first biologic drug approved to treat Systemic Lupus Erythematosus (SLE). The efficacy of belimumab has been demonstrated through 2 phase III clinical trials. Real-life experiences are anticipated in order to form an opinion of how belimumab is used in clinical praxis and provide guidance for improvements in its future use. We investigated the clinical effects of belimumab in patients with active SLE despite standard of care therapy.

Methods: Fifty-two patients from Karolinska (n=25), Skåne (n=19), and Linköping (n=8) University Hospitals treated with belimumab were enrolled in this study and followed longitudinally. Global disease activity was assessed using the SLE Disease Activity Index 2000 (SLEDAI-2K), Systemic Lupus Activity Measure-Revised (SLAM-R), and a 100 mm Visual Analogue Scale (VAS) for Physician's Global Assessment (PGA). Organ damage was evaluated according to the Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index (SDI). Quality of Life (QoL) was evaluated by patients' reports for pain, fatigue and well-being levels using 100 mm Visual Analogue Scales. Global health outcome was determined by the EuroQol Research Foundation 5 Dimension (EQ-5D) health questionnaire, scored according to the UK tariff. Functional status was assessed using the Stanford Health Assessment Questionnaire (HAQ) functional disability index.

Results: Belimumab was mainly given for musculoskeletal (n=24), mucocutaneous (n=24), hematological (n=10), renal (n=5), respiratory (n=4), and neurological (n=3) manifestations.

Significant decreases over time were observed for SLEDAI-2K (median baseline score: 7; range: 2–24; $p<0.001$), corresponding to a decrease of 3.42 over a year, SLAM-R (median baseline score: 13; range: 5–26; $p<0.001$) and PGA ($p<0.001$). We also observed decreases of prednisone equivalent dosages (mean baseline dose: 12.3 mg/day; range: 0–60 mg/day; $p<0.001$), corresponding to a decrease of 4.93 mg/day over a year. C4 levels increased significantly ($p=0.006$), but C3 levels remained unchanged. We observed significant improvements in well-being ($p<0.001$), pain ($p<0.001$) and fatigue ($p=0.018$), but no significant changes in HAQ and no significant improvements in EQ-5D. SDI scores remained stable.

Reasons for discontinuation included inadequate or uncertain effect (n=7), flare (n=5: increased proteinuria; arthritis, headache; rash, alopecia; biopsy-proven lupus nephritis WHO class III; CNS-lupus), adverse events (n=3: acute myeloid leukemia; ground glass opacity in computed tomography scan of the lungs, pulmonary arterial hypertension; insomnia, arrhythmia), allergic reactions (n=2) and pregnancy plans (n=2).

Conclusion: In this real-life observational study, belimumab treatment decreased disease activity, reduced corticosteroid usage and improved the patients' quality of life in terms of pain, fatigue and well-being over time, but had no significant effects on their functional status. There was no progression of organ damage during the follow-up. The tolerability and safety profiles of belimumab in this study were comparable with those in previous reports from the phase III trials.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: To describe the demographic, clinical and immunological manifestations in patients with late onset systemic lupus erythematosus (SLE)

Methods: Patients diagnosed of SLE in the RELESSER data base (National Registry of Patients with Systemic Lupus Erythematosus of the Spanish Society of Rheumatology) were included**.** Late-onset was defined as >50 years of age at time of first SLE-related symptom. Design: multicenter retrospective cross-sectional study. Socio-demographic variables, comorbidities, classification, clinical and immunological manifestations were evaluated. Pearson´s chi-square test, t-Student

Results: Of the 3628 patients included: 566 (15.6%) patients had late-onset SLE, 3062 (84.4%) patients were younger than 50 years. The mean age at diagnosis was 60.7(Sd 8.5) years in the late-onset SLE and 30.5 (Sd 9.96) years in the younger onset group. In the late onset group: 91 (16.1%) were male and 475 (83.9%) women. The male/female ratio was 5/1. Diagnosis in the younger onset group was sooner than in late-onset group (28.2 Sd 48.9 days compared with 45.3 Sd 70.3 days with P <0.0001).

Comparing comorbidities by age group, it was found that SLE patients over 50 years of age had more comorbidities with p<0.0001. Secondary Sjogren's syndrome was more frequent in the older age group (p<0.001). Table 1: Clinical manifestations. During follow-up 205 patients died: 74 (14.3%) with late-onset SLE and 131 (4.7%) younger than 50 years (P <0.0001). Evaluating the cause of death, the group of younger patients had higher mortality due to SLE with statistical significance. The cause of death from severe infections and cancer was higher in patients over 50 years, but without statistical significance

Clinical manifestation		Older than 50 years. N (%)	Younger than 50 years. N (%)	Missing N (%)	VALUE OF P
Systemic Manifestations	Lymphadenopathy	36(6,5%)	332(11%)	95 (2,6%)	0,002
Cutáneous Manifestations	Inflamatory rash	286(51,9%)	2076(87,9%)	84 (2,3%)	<0,0001
	Alopecia	115(21%)	1161(38,7%)	108 (3,0%)	<0,0001
Osteoarticular Manifestations	Avascular bone necrosis	9(1,6%)	140(4,7%)	89 (2,4%)	0,001
	Arthritis	74(13,2%)	285(9,4%)	81 (2,2%)	0,007
	Osteoporosis	94(17,3%)	164(5,5%)	141 (3,9%)	<0,0001
Pulmonary Manifestations	Pleural fibrosis	19(3,4%)	52(1,7%)	64 (1,7%)	0,009
	Pulmonary thromboembolism	24(4,3%)	79(2,6%)	55 (1,5%)	0,030
Cardiovascular Manifestations	Valvular disease	68(12,3%)	150(5%)	113 (3,1%)	<0,0001
	Valvular dysfunction	31(5,9%)	90(3,1%)	245 (6,7%)	0,001
	Angina	31(5,5%)	37(1,2%)	75 (2,1%)	<0,0001
	Acute myocardial infarction	26(4,7%)	45(1,5%)	83 (2,3%)	<0,0001
	Cardiomyopathy	41(7,4%)	63(2,1%)	100 (2,7%)	<0,0001
Peripheral vascular Manifestations	Raynaud	131(24,1%)	1055(35,7%)	160 (4,4%)	<0,0001
Renal Manifestations	Lupus nephritis	78(14,3%)	1003(33,4%)	110 (3,0%)	<0,0001
	HTA in the first outbreak	39(7,1%)	360(12,4%)	201 (5,5%)	<0,0001
	Hematuria	94(17,7%)	940(32,8%)	264 (7,2%)	<0,0001
	Pyuria	47(9%)	687(24,6%)	337 (9,2%)	<0,0001
	Creatinine clearance = 50 irreversible	41 (7,4%)	150 (5%)	131 (3,6%)	0,025
	Proteinuria = 3,5g/24hs	6(1,1%)	127(4,3%)	145 (4,0%)	<0,0001
	End stage renal disease	8(1,5%)	89(3%)	164 (4,5%)	0,039
Neuro psychiatric Manifestations	Lupus headache	13(2,4%)	199(6,6%)	110 (3,0%)	<0,0001
	Depression	122(22,2%)	481(16%)	111 (3,0%)	<0,0001
Ocular Manifestations	Cataract	111(20,3%)	201(6,7%)	123 (3,4%)	<0,0001
Immunology	Complement	327(59,2%)	2433(81,2%)	108 (3,0%)	<0,0001
	Ac anti RNP positive	84(15,2%)	792(26,9%)	162 (4,4%)	<0,0001

Conclusion: Patients with late-onset SLE have a higher risk of mortality than the younger-onset SLE. The diagnostic delay is higher in patients over 50 years. This group of patients have more comorbidities and higher risk of joint, pulmonary and cardiovascular involvement, on the contrary renal involvement is less common

Session Date: Sunday, November 8, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: This study describes the disease patterns, flare incidence, hospitalizations and causes of mortality in a cohort of Filipino patients with systemic lupus erythematosus (SLE), observed over a period of 1 year at a single tertiary care center.

Methods: Included were SLE patients consecutively seen at the Rheumatology Lupus Clinics of the University of Santo Tomas Hospital in Manila, Philippines from 2012 to 2014 who were assessed over a period of at least 1 year up to May 2015. Data were obtained at minimum 3 time-points: baseline, 12 + 1 month from baseline, and at least 1 clinic visit or hospitalization within the 12-month period. Demographics, SLE disease characteristics, SLICC/ACR Damage Index (SDI), and medications history were obtained at baseline. SLE Disease Activity Index (SLEDAI), SLE flare index (SFI) and flare characteristics, reasons for hospitalizations and causes of mortality when applicable, were obtained at each clinic or hospital visit.

Results: 162 SLE patients (148, 91% females) participated in this study, with mean 27.96 years + 10.09 SD (range 5-59) age at diagnosis and mean 8.51 + 6.24 SD (range 1-32) years disease duration. Mucocutaneous (151, 93%), musculoskeletal (142, 88%) and renal (107, 66%) were the most common organ system involvement. Cataracts were the most common SDI involvement (23, 19%), followed by cerebrovascular accident (CVA) (18, 15%) and avascular necrosis (15, 13%). Mean cumulative prednisone / equivalent dose was 29.07 g+ 24.58 SD. Other medications included hydroxychloroquine (86%), mycophenolate mofetil (57%), cyclophosphamide (44%), azathioprine (22.6%), tacrolimus (4.8%), belimumab (3.6%) and rituximab (2.4%). Over the 1 year observation period, there were total 89 flares in 74 (46%) patients, 27 of which were characterized as severe; 35 (44%) of flares involved the kidneys. Sixty-five (40%) were identified to have relapsing/remitting course, 57 (35%) had chronic active disease and 16 (10%) had long quiescent disease; 24 (15%) were in remission ie without corticosteroids and immunosuppressants. Of 11 patients who were hospitalized, 5 were due to infection, 4 for disease flare, and 2 for infection with concommitant disease activity. In addition, 6 patients died during the 1 year study period, 5 of whom had active disease and/ or systemic infection at the time of death.

Conclusion: This prospective observational study describes disease patterns, morbidity and mortality in a cohort of Filipino SLE patients, reflecting the high costs of health resource utilization and burden of illness among these patients.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: To investigate the efficacy and safety of belimumab in patients affected with active systemic lupus erythematosus (SLE) refractory to standard therapy.

Methods: Fifty-eight patients, 54 female and 4 male, mean age 39.9±10.7 years, mean disease duration 13.1±8.3 years, affected with SLE (ACR criteria), with active disease manifestations and active serology (low C3/C4 and high dsDNA) unresponsive to standard therapy were treated with belimumab (10 mg/kg at day 0, 14 and 28 and then every 28 days). SLEDAI-2K, SLICC/ACR damage index (SDI), anti-dsDNA, C3 and C4 serum levels, and prednisone daily dose were recorded at baseline, at month 3, 6, 9, 12, and every 6 months thereafter. SDI calculated 5 years before the initiation of belimumab was also considered. DAS-28, 24-hour proteinuria, CLASI (Cutaneus LE Disease Area and Severity Index), blood cell count were recorded to evaluate organ response to belimumab. SLE flares were defined by SLEDAI flare index and flare rate was reported as number of flare/100 patients/year. SLE flare rate was evaluated in the 12 months before and after belimumab initiation.

Adverse events (AEs) were recorded at every clinical evaluation and were defined as follow: infectious AEs, non-infectious AEs, infusion or hypersensitivity reactions. AE were considered severe (SAEs) in case of hospitalization and/or death and/or life-threatening manifestations.

Results: Mean follow-up period was 14.1±7.7 months. Refractory manifestations requiring the use of belimumab as add on therapy were musculoskeletal (35.9%), mucocutaneous (27.2%), renal (22.1%), hematologic (11.7%), and constitutional (3.1%). At 3, 6, 9, 12, and 18 months of follow-up SLEDAI-2K, prednisone daily dose and DAS-28 significantly declined compared with baseline (Table 1). Moreover, a reduction of 24-hour proteinuria and CLASI (Table 1) and an increase in C3 and C4 values, although not significant, was also found. We observed 82 flares/100 patients/year before and 37 flares/100 patients/year (p=0.0001) after belimumab initiation. SDI was 0.62±0.65 five years before belimumab initiation, 0.86±1.03 at baseline and 0.86±1.03 after 18 months of follow-up.

One hundred fifty-one AEs were observed. Thirty five patients (60.3%) experienced ≥1AEs. Infectious AEs, non-infectious AEs, infusion and hypersensitivity reactions were 50.4%, 17.2%, 1.3% and 31.1% of total AEs, respectively. Two SAEs were observed, one non-infectious (deep vein thrombosis) and one infectious AEs (pneumonia). No severe infusion reactions and no discontinuation due to AEs were observed.

Conclusion: Belimumab was effective and safe in a clinical practice setting. Notably, belimumab reduced the number of flares and prevented the progression of damage in our patients with active SLE.

Complement Activation As a Marker for Increased Thrombosis Risk in SLE Patients with Antiphospholipid Antibodies

H. Michael Belmont[1], Janet Nwaukoni[2] and Jill P. Buyon[2], [1]Hosp for Joint Disease, New York, NY, [2]Medicine, Division of Rheumatology, New York University School of Medicine, New York, NY

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: We and others have suggested that complement activation can serve as an initiating signal that increases the thrombosis risk in SLE patients with antiphospholipid antibodies. Generation of complement activation products can result in proinflammatory and/or prothrombotic responses providing a permissive environment for the pathological effects of antibodies to negatively charged phospholipid protein complexes.

Methods: We analyzed the NYU SLE SAMPLE Biorepository initiated in September 2013 which consists of 539 patients fulfilling ACR and/or SLICC criteria for systemic lupus erythematosus. We identified 91 patients whose criteria included the presence of one or more for the following APLS antibodies: lupus anticoagulant, IgG or IgM anti-β_2-glycoprotein-I, or IgG or IgM anticardiolipin antibodies and determined if these patients received SLEDAI points for hypocomplementemia during any encounter. We then reviewed each patient's medical record to identify the prevalence of thrombosis defined as DVT, PE, CVA, arterial occlusion with gangrene or amputation, and obstetric events as well as noncriteria manifestation of thrombocytopenia or valvulitis. We then compared the prevalence of these APLS manifestations in the SLE patients with and without evidence of complement activation.

Results: The NYU SLE SAMPLE biorepository includes 539 patients (90% female, mean age 43.0 ± .9, and 10 % men, mean age 41.0 ± .3). 54% Caucasian, 31% African American, 15% Asian, 30% Hispanic White, and 5% Hispanic Black. 91 of the 539 SLE patients had APLS antibodies, 79 female and 12 male (mean age 43.0 ± .2, 56% Caucasian, 33% African American, and 11% Asian). 24 % Hispanic white and 4% Hispanic Black. The total number of patients with adverse events is 48 of 91 (53%) with 29/48 (60%) in the SLE patients with APLS and evidence of hypocomplementemia and 19/43 (44%) in the patients without evidence of hypocomplementemia. The most common thrombotic event was DVT followed by CVA.

Conclusion: The prevalence of APLS as a criteria in the NYU SLE registry is 91 of 539 and adverse events were more common in the patients with evidence of hypocomplementemia (29/48, 60%) as compared to the patients without complement activation (19/43, 44%).These findings can inform decisions regarding which patient subsets may benefit from the prophylactic use of low-dose aspirin for primary prevention in asymptomatic lupus patients. Moreover, future clinical trials should be stratified on the basis of complement consumption to be sure that equal numbers of these patients appear in both the experimental and comparator treatment arms. Finally, future prospective studies should explore the interaction between complement activation products, platelets, neutrophils, mononuclear cells, endothelial cells, coagulation cascade, etc. in the adverse events that constitute antiphospholipid syndrome.

ACR Abstract – A Paper Patient-Based Flare Study in Systemic Lupus Erythematosus (SLE)

Isenberg D, Sturgess J, Allan E, Aranow C, Aringer M, Askanase A, Sang-Cheol B, Bernatsky S, Bruce I, Buyon J, Cervera R, Chambers S, Cortedoat-Chalumeau N, Croca S, Clarke A, Dooley Mary Anne, Fortin P, Giles I, Ginzler E, Gladman D, Gordon C, Griffiths B, Hanly J, Inanc M, Jacobsen S, Kamen D, Khamashta M, Lanyon P, Lim, Manzi S, Moreland E, Mosca M, Nived O, Peschken C, Petri M, Kalunian K, Rahman A, Ramsey-Goldman R, Ruiz-Irastorza G, Sanchez-Guerrero J, Schneider M, Steinsson K, Sturfet G, Urowitz M, van Vollenhoven R, Vasconcelos C, Wallace D, Zoma A, Merrill J

Background/Purpose:

Data are restricted with regard to the usefulness of activity indices when assessing flares in patients with SLE. One study of 16 flaring SLE patients provided modest encouragement (1) but a recent cohort review (2) indicated that medication changes may not be appropriate in defining the degrees of flare. We now report assessments of flares from 989 SLE case histories provided by rheumatologists from over 30 centres in 10 different countries.

Methods:

Each case history was abstracted from medical records of real patients and provided together with an opinion as to whether each patient was experiencing a severe, moderate or mild flare or 'ongoing/grumbling' disease. Two further opinions were sought on each case history from the panel of rheumatologists and ultimately 451 patient histories, for which there was complete agreement about their flare status were selected for further study. Six different pairs of rheumatologists, were each asked to agree the assessments of approximately 30 cases using BILAG 2004 or SELENA-SLEDAI flare indices or the revised SELENA flare index.

Results:

For all three tools, the Flare classification generated by each, matched the consensus view of the cases in a similar proportion of times [BILAG-2004 – 66%; SELENA Flare – 65%; SELENA-SLEDAI – 75%; the slightly higher rate in the SELENA-SLEDAI being due to the single mild/moderate category].The corresponding weighted kappas for each tool were BILAG 0:82; SELENA flare 0.64; SELENA-SLEDAI 0.59).

Of particular note was a consistent pattern across all three tools of over-scoring moderate flares as severe. Closer examination of the data suggests that this over-scoring is driven by treatment. Removal of treatment decisions from the assessment of flare using the SELENA-Flare and SELENA-SLEDAI tools led to an increase in the proportion of correctly assessed cases to 72% and 80% respectively (weighted kappa; 0.68 and 0.74).

Conclusion:

Distinguishing different types of flare in patients with SLE remains a challenge. Given the difficulty caused by the inadequate provision of data in some of the case histories (making accurate BILAG assessment in particular problematic on occasion) the results are nevertheless very encouraging.

The overall performance characteristics of these flare instruments suggest that they can be useful in clinical trials where results are studied at the group level, whereas in clinical flare assessment must still be based on clinical judgement.

Session Date: Sunday, November 8, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Apoptosis is needed to eliminate auto-reactive T and B cells during immune responses; failure of elimination is important in development of systemic lupus erythematosus (SLE). The BCL-2 family helps regulate immune cell homeostasis; elevated Bcl-2 expression may contribute to cell death abnormalities for auto-reactive cells. Venetoclax (ABT-199), a selective, small-molecule BCL-2 inhibitor, was examined in a phase 1 study of safety, tolerability, pharmacokinetics, and pharmacodynamics (PD) in female patients (pts) with SLE.

Methods: This was a single and multiple ascending dose, double-blind, randomized, placebo-controlled study (NCT01686555) in women aged 18–65 y with SLE for >6 mo, receiving stable SLE therapy. Twelve cohorts were planned (N=96); in each cohort, 6 pts received venetoclax and 2 received placebo. Pts in cohorts 1–6 received single doses of venetoclax 10, 30, 90, 180, 300, and 500 mg, respectively. Pts in the multiple ascending dose arms (cohorts 7–12) received 2 cycles (once daily for 1 wk, then 3 wk off in each cycle) of venetoclax 30, 60, 120, 240, 400, and 600 mg, beginning after safety evaluation of the single-dose venetoclax 90-mg cohort.

Results: In 98 enrolled pts, common adverse events (AEs) were headache and gastrointestinal disorders (diarrhea, nausea, vomiting; **Table**). Most drug-related AEs were mild to moderate; no serious AE was reported with venetoclax. There were no deaths and no clinically relevant abnormalities of vital signs or electrocardiograms. Exposure to venetoclax was dose proportional, with a half-life of ~7–17 h after single doses. PD effects of Bcl-2 inhibition included dose-dependent reductions of total lymphocytes and subsets **(Figure)** after single and multiple venetoclax doses up to 600 mg. B cells were most sensitive to Bcl-2 inhibition, with >80% reduction from baseline in high-dose groups. For lymphocytes and T cells, changes were less marked with multiple dosing, and recovery of total lymphocytes occurred during the dosing interval of cyclic

multiple dose regimens **(Figure)**. Compared with lymphocytes and subsets, levels of neutrophils, platelets, reticulocytes, hemoglobin, and safety laboratory values showed no consistent patterns or marked changes across single- and multiple-dosing groups.

Conclusion: In female SLE pts, venetoclax was well tolerated in single (10–500 mg) and multiple (30–600 mg) doses; exposure appeared consistent with findings in cancer pts. PD assessments demonstrated specific reductions of lymphocytes and subsets by inhibition of BCL-2, as expected from preclinical and ex vivo findings.

Session Date: Sunday, November 8, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I

Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: An increasing number of studies have investigated factors that are associated with thrombosis in SLE. However, few have examined risk factors specific for venous thrombosis in patients with SLE and no study to date has compared the relative influence of risk factors on venous versus arterial thrombosis prospectively. We examined the effect of traditional and disease specific risk factors on both venous and arterial thrombosis.

Methods: The analysis is based on 1951 patients who were enrolled in a prospective cohort from April 1987 through September 2014. In 12,638 person years of follow up, 189 thrombotic events were observed. We fit separate multivariable models for venous and arterial thrombosis that included variables that were most important based on the age-adjusted and preliminary regression models.

Results: Table 1 includes variables that were independently associated with thrombosis. Even after controlling for all the other variables in the model, there was a strong association between recent systolic blood pressure, diabetes and current prednisone dose on both venous and arterial thrombosis. Recent cholesterol was an independent risk factor only for venous thrombosis but not arterial thrombosis. Current Plaquenil use was protective only against venous thrombosis. A history of lupus anticoagulant was associated with an increased risk of venous thrombosis, but was not significant for arterial thrombosis (p=0.17.) A history of low C3 was associated with an increased risk of venous thrombosis whilst recent low C3 was more important than a history of low C3 when considering arterial thrombosis.

Table 1: Independent Risk Factors for Venous and Arterial Thrombosis Based on a Multivariable Model

	Venous Thrombosis		Arterial Thrombosis	
Variable	Risk Ratio (95% CI)	P – value	Risk Ratio (95% CI)	P- Value
Recent SBP 140 mmHg +	1.9 (1.2, 3.1)	0.010	1.6 (1.1, 2.4)	0.028
Recent Cholesterol 200-249 (vs. < 200) 250+ (vs. < 200)	1.2 (0.7, 2.0) 1.8 (1.0, 3.3)	0.54 0.071	Not a significant independent risk factor	
Diabetes	2.5 (1.5, 4.0)	0.002	1.9 (1.2, 2.9)	0.0034
History of low C3	2.0 (1.1, 3.4)	0.020		
Recent low C3	Not a significant independent risk factor		1.7 (1.1, 2.5)	0.021
History of Lupus Anticoagulant	1.6 (1.0, 2.6)	0.036	1.3 (0.9, 2.0)	0.17
Current Prednisone Treatment (mg/day) 1-9 10-19 20+	1.3 (0.7, 2.4) 1.9 (1.0, 3.6) 3.3 (1.6, 6.5)	0.35 0.04 0.0008	1.8 (1.1, 3.0) 3.1 (1.9, 5.2) 6.4 (3.7, 11.3)	0.019 <0.0001 <0.0001
Current Plaquenil Treatment	0.7 (0.4, 1.0)	0.070	0.8 (0.5, 1.1)	0.21

Conclusion: Venous or arterial thromboses are equally associated with modifiable risk factors such as blood pressure and diabetes (however only venous thrombosis was associated with cholesterol in the multivariate model). Current use of prednisone at a dose greater than 20mg increased the risk of both arterial and venous thrombosis more than any other risk factor.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Autoantibodies to the nuclear autoantigen dense fine speckles 70 (DFS70) are associated with a new paradigm whereby when they are found in isolation (monospecific – no other detectable autoantibodies), they are purported to rule out the diagnosis of systemic lupus erythematosus (SLE) and other anti-nuclear antibody (ANA)-related conditions. Anti-DFS70 can be screened by indirect immunofluorescence (IIF) and quantified and confirmed by chemiluminescence immunoassay (CIA). The reported frequency of anti-DFS70 by CIA in SLE is low compared to healthy individuals (0-6% vs. 7-20%). Furthermore, anti-DFS70 monospecificity is reported to be low in SLE patients (<1%). To date, there have been no studies examining the frequency of anti-DFS70 in early inception SLE cohorts. The purpose of this study was to determine the prevalence of anti-DFS70 in newly diagnosed SLE patients and to identify any univariate associations with demographic and clinical features.

Methods: Patients fulfilling the American College of Rheumatology (ACR) Classification Criteria for SLE were enrolled in the Systemic Lupus Erythematosus International Collaborating Clinics (SLICC) inception cohort within 15 months of diagnosis. Demographic and clinical data, including disease activity (SLEDAI-2K), were collected at enrollment. ANAs were detected by IIF on HEp-2 cells (ImmunoConcepts, Sacramento, CA), and extractable nuclear antigens (ENAs) and double-stranded DNA (ds-DNA) by an addressable laser bead immunoassay (FIDIS Connective 13, TheraDiag, Paris). Anti-DFS70 antibodies were measured by CIA using cutoffs suggested by the manufacturer (Inova Diagnostics Inc., San Diego, CA).

Results: 1137 patients were included; 89.4% were female and 94.4% were ANA IIF positive (Table 1). The frequency of anti-DFS70 by CIA

was 7.1% [95%CI: 5.7-8.8%] (81/1137 patients). 11/1137 (0.97%) [95%CI: 0.5-1.7%] of the entire cohort were positive for anti-DFS70 only with no detectable ENA or anti-dsDNA and were therefore considered ÔmonospecificÕ for anti-DFS70. Patients with a negative anti-DFS70 by CIA were more likely than those with a positive anti-DFS70 to have other SLE-related autoantibodies including anti-U1-RNP (31.5% vs. 21.0%), anti-Ro60 (46.3% vs. 34.6%), and anti-SSB (16.0% vs. 4.9%). Age, gender, ethnicity, disease features included in the ACR classification criteria, SLEDAI-2K score, or concomitant therapies did not differ between the anti-DFS70 negative and positive patients.

Conclusion: The prevalence of anti-DFS70 measured by CIA in newly diagnosed SLE patients was at the high end of the range as compared to that in previously published SLE cohorts (7.1% vs. 0-6%). However, "monospecific" anti-DFS70 was rare (0.97%) in this SLE inception cohort and, therefore, the presence of monospecific anti-DFS70 is a potentially useful test to discriminate between ANA positive healthy individuals and those newly diagnosed with definite SLE.

Table 1. Baseline demographic, clinical, and autoantibody profile anti-DFS negative and positive patients newly diagnosed with SLE

	DFS-negative N = 1056	DFS-positive N = 81	Difference (95%CI)

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Patient and physician treatment satisfaction influences long-term adherence with a treatment regimen. The primary objective was to identify factors linked to satisfaction with the use of belimumab in clinical practice, in the United States (US). Understanding the impact of belimumab on clinical and patient outcomes was a secondary objective.

Methods: The Adelphi Lupus Plus Project (GSK study 202146) involved US rheumatologists (n=70) who completed paper-based data collection forms for five consecutive, eligible patients. Patients were ≥18 years old, diagnosed with SLE for ≥6 months, and receiving intravenous belimumab plus standard SLE care for ≥3months. Each rheumatologist only included one patient who had received belimumab for 3-6 months. The Western Institutional Review Board granted an IRB exemption for this study.

Results: The belimumab cohort (n=376) was 95% female, mean age 42, and Caucasian (56.1%) or African American (27.1%). Mean time since SLE diagnosis was 7 years and mean time treated with belimumab was 13 months, 65% were employed or were students. The majority of patients had disease involving both skin and joints (64%); 19.8% had only joint involvement. Prior to adding belimumab, most had 'moderate' (60%) or 'severe' (24%) disease and disease that was "deteriorating" (85%).

The patient self-completion form was completed by 72% of patients (n=270). The majority of patients (86%) reported a level of satisfaction with belimumab; 28% were 'very satisfied', 32% 'satisfied' and 26% were 'somewhat satisfied'. Most physicians were satisfied with belimumab (83%). Concordance between physician and patient satisfaction was moderate (Kappa Score = 0.4541). Predefined, multivariate analysis identified factors strongly associated with satisfaction (Table 1).

Table SEQ Table * ARABIC 1. Multivariate analyses identified factors associated with patient and physician satisfaction with beliumumab. Factors reported by the patient are denoted by (Pt) and by the Rheumatologist (Rh)	
	OR (95% CI)
PATIENT SATISFACTION	
Patient satisfaction is associated with:	
Improved ability to engage in leisure activities (Pt)	4.66 (2.12 - 10.25)
Reduction in fatigue severity (Rh)	3.72 (1.77 - 7.79)
General symptom improvement (Pt)	3.02 (1.15 - 7.94)
Improvement in pain/achiness (Pt)	2.71 (1.12 - 6.52)
Satisfaction with time taken to receive belimumab (Pt)	2.69 (1.40 - 5.15)
Satisfaction with frequency of belimumab (Pt)	1.94 (1.04 - 3.62)
Patient dissatisfaction is associated with:	
More severe disease prior to belimumab (Rh)	0.36 (0.14 - 0.92)
Current use of immunosuppressants (Rh)	0.40 (0.19 - 0.84)
RHEUMATOLOGIST SATISFACTION	
Physician satisfaction is associated with:	
Improvement in pain/achiness (Pt)	6.16 (2.20 - 17.24)
Satisfaction with frequency of belimumab (Pt)	3.91 (2.02 - 7.56)
Reduction in fatigue severity (Rh)	3.76 (1.93 - 7.35)
Physician dissatisfaction is associated with:	
Disease classed as currently ‘deteriorating or unstable ' (Rh)	0.13 (0.06 - 0.26)
Disease not classed as currently ‘mild' (Rh)	0.29 (0.13 - 0.63)
Improved ability to remember things (Pt)	0.43 (0.22 - 0.87)
Current use of immunosuppressants (Rh)	0.46 (0.26 - 0.83)
Higher numbers of flares in last 12 months (Rh)	0.75 (0.63 - 0.91)

Patient satisfaction was higher for those treated with belimumab for > 6 months, versus 3-6 months. For the majority of patients, physicians reported an improvement in overall symptoms (89%), reduction in flare severity (75%) and flare frequency (75%) since starting belimumab. Patients themselves stated an improvement in overall symptoms (89%), fatigue (83%), and pain (83%). Patients also reported improvements in feeling rested upon waking (91%), improved concentration (59%), and work (52%), as well as an improved ability to engage in leisure activities, daily activities and caring for children.

Conclusion: Adding belimumab improved symptoms of fatigue and pain and both factors were positively associated with patient and physician satisfaction. Improvement in the ability to engage in leisure activities and general symptom improvement were strongly associated with higher patient satisfaction. This insight into satisfaction should enhance the dialog between physicians and their patients about the outcomes expected during belimumab initiation; in turn, this may improve adherence.

IgM Antibodies Against Malondialdehyde and Phosphorylcholine Are T Cell Dependent and Strong Protection Markers for Atherosclerosis in SLE

Md Mizanur Rahman[1], Ingiäld Hafström[2], Anquan Liu[1] and Johan Frostegård[1], [1]Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden, [2]Department of Medicine, Rheumatology unit, Karolinska Institutet, Stockholm, Sweden

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Atherosclerosis is characterized by activated immune competent cells and lipid oxidation, where two major epitopes forming adducts are phosphorylcholine (PC) and malondialdehyde (MDA). We here study the regulation and properties of IgM antibodies against these (anti-PC and anti-MDA) and their role in SLE where atherosclerosis and CVD are much increased.

Methods:

Peripheral blood mononuclear cells (PBMC), B, CD3 T, CD4 T and CD8 T cell were isolated from buffy coat. PBMC derived monocyte were differentiated into dendritic cells (DCs) and treated with or without PC-KLH or MDA-HSA. For activation naïve autologous T cells were co-cultured with pre-treated DCs. B cell alone, or with CD3 T, CD4 T or with CD8 T cells were cultured to examine anti-PC IgM production. In addition to mixed B cell with CD3 T cell culture, B cells with CD3 T cells were also cultured in transwell co-culture plate. Further, B cells alone and mixed B cell with CD3 T cell cultures with or without anti HLA II or CD40 blocking antibody were cultured 6 days. Also, CD40 was silenced and cultured similar days.

Antibody level in serum of SLE patients from the SLEVIC cohort (n=114) were compared with age- and sex-matched population-based controls (n=108). Common carotid intima-media thickness (IMT) and plaque occurrence were determined by B-mode ultrasound. Plaques were graded according to echogenicity (a measure of vulnerability).

Results:

Flow cytometry analysis showed PC-KLH and MDA-HSA stimulated DC mediated T cell activation. In addition, pro-inflammatory effects of inflammatory lipids were inhibited by anti-PC and anti-MDA.

More than 8 fold higher levels of anti-PC IgM were detected by ELISA in mixed B cell with CD3 T cell cultures in comparison to B cells alone. After the co-culture of B and CD3 T cells in transwell plate there were no increased antibody levels indicating that B and T cells need to interact to augment anti-PC IgM production. Furthermore, anti-PC IgM was abolished by anti HLA II blocking antibody in mixed B and CD3 T cells culture, also inhibited by CD40 blocking antibody. In addition, CD40 role was ensured by CD40 gene silencing. Further, the lack of increased anti-PC IgM in mixed B with CD8 T cells culture and the increased levels of anti-PC in mixed B with CD4 T cells culture support the role of helper T cell for the anti-PC IgM production.

In serum having high levels, above 66rdpercentile, of both anti-PC and anti-MDA was a striking protection marker for plaque prevalence and vulnerability (OR 0.08, CI (0.01-0.46) and OR 0.10 and CI (0.01-0.82) respectively)

Conclusion:

Anti-MDA and anti-PC are T-cell dependent, anti-inflammatory and strong protection markers for atherosclerosis and plaque vulnerability in SLE and in general. This finding could indicate an underlying mechanism in autoimmune disease, namely low levels of natural antibodies and opens up therapeutic possibilities with these antibodies in autoimmune diseases.

Behavior of Complement Levels and Risk of Organ Involvement in SLE Patients

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: the complement system plays a major role in autoimmune diseases, and in particular in systemic lupus erythematosus (SLE). Complement deficiencies are a genetic risk factor for SLE. Also a reduction in complement levels has been associated with an increase in SLE activity, with certain organ involvement (ie glomerulonephritis) and as a predictor of a SLE flare. Our objective was to analyze clinical course of SLE patients with permanent low complement levels, and compare them with those with fluctuant levels or persistently normal levels.

Methods: complement determinations (C3 and C4 levels) were analyzed in patients with SLE (fulfilling ACR or SLICC criteria) seen at a University hospital between 2000 and 2013. Patients were grouped in those with permanent C3 and/or C4 low values (low complement group) those with C3 and C4 constant normal values (normal complement group), and those with fluctuant values (periods of normal and periods of low values, during follow up: fluctuant group). Mortality, clinical characteristics, organ involvement and antibodies were analyzed and compared between groups.

Results: Two hundred and seventy SLE patients were included (242 females, 89.6%), mean age at diagnosis was 34.2 years (SD 15.8). Patients were divided according to complement levels during follow up in 3 groups: persistent low complement levels (n=79), normal complement levels (n=116), and fluctuant levels (n=75). Demographics, clinical and serological characteristics are shown in table 1. Mortality was similar between the three groups (5%, 4% and 7%, respectively). Lupus glomerulonephritis was more frequent in patients with fluctuant levels of complement (both proliferative and membranous glomerulonephritis). Patients with normal complement had less frequency of hematological involvement and antiDNA antibodies. On multivariable analysis persistent low complement levels were neither associated with mortality nor with organ damage as measured by SLICC (SLICC>0). Only increased age was associated with mortality, and increased age and neurologic involvement with SLICC >0.

Conclusion: Different behavior of complement levels in SLE patients was not associated with differences in outcomes (mortality and organ damage). Although there were some differences in organ involvement (higher prevalence of glomerulonephritis in fluctuant levels group, and hematological involvement and anti DNA antibodies in low and fluctuant levels groups), do not appear to represent clear different sub-groups of patients.

Table 1. SLE patients grouped by behavior of complement levels during follow up.

	Normal complement (n=116)	Persistent Low complement (n=79)	Fluctuant complement (n=75)	P value
Females, n (%)	107 (92.2)	70 (88.6)	65 (86.7)	0.439

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

The clinical presentation may be different between adult-onset SLE (aSLE) and childhood-onset SLE (cSLE). The profile of cytokine may the clarify of SLE pathophysiology. The aim of this study was to determine the serum levels of Th1 (IL-12), Th2 (IL-6 e IL-10) longitudinally as well as its possible associations in aSLE and cSLE.

Methods:

The included SLE patients were recruited from outpatient Rheumatology and Pediatric Rheumatology –State University of Campinas, matched for disease duration. Sera samples were obtained quarterly from all participants, in each routine visit we made a blood collection, totaling four different periods in all patients, in the absence of infections. We further assessed disease activity through of the SLE Disease Activity Index (SLEDAI) and damage through Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index (SDI), mood and anxiety through Becks Depression (BDI) and Anxiety Inventory (BAI) and current drug exposures. Th1 (IL-12), Th2 (IL-6 and IL-10) cytokines levels were measured by ELISA using commercial kits. Data were compared by non-parametric tests.

Results:

We included 63 cSLE patients (mean age 19.7±4.3 and disease duration 7.35±4.22), 67 aSLE patients (mean age 39.9±11.8 and disease duration 7.73±3.18) and 40 healthy controls (mean age 29.6±10). In aSLE patients compared with healthy controls during the four periods evaluated, IL-6 levels were significantly increased in patients (p=0.03, p=0.003, p=0.002, p=0.002), IL-12 fluctuated during the period evaluated (p=0.75, p=0.50, p=0.01, p=0.001) and IL-10 It had no significant difference (p=0.32, p=0.13, p=0.99, p=0.08). In cSLE patients compared with healthy controls, we observed a significantly increase of IL-12 (p=0.04, p=0.001, p=0.01, p=0.02), we did not observe significant difference in IL-10 (p=0.94, p=0.85, p=0.81, p=0.95) and IL-6 (p=0.66, p=0.14, p=0.25, p=0.21). Comparing the levels of cytokines between aSLE and cSLE, we observed that IL-12 fluctuated during the period evaluated (p=0.07, p=0.001, p=0.99, p=0.14) and had no significant difference in IL-6 (p=0.97, p=0.11, p=0.15, p=0.53) and IL-10 (p=0.09, p=0.29, p=0.59, p=0.25). We did not observe an association between disease activity and cytokines in any period (p>0.05). The aSLE patients had a significant decrease of disease activity indices during periods evaluated (p=0.021), There was no significant difference in disease activity among cSLE and aSLE patients (p>0.05). No significant difference in SDI scores between aSLE and cSLE (p=0.10). Regarding medication, we observed that aSLE (p=0.001) and cSLE (p=0.001) patients had a significant decrease of use of prednisone during the four periods. In disorders of mood and anxiety, during the four evaluated periods, no significant variation in BAI, cSLE (p=0.52) and aSLE (p=0.13), and BDI, cSLE (p=0.29) and aSLE (p=0.65) was observed. When comparing the patients we observed that aSLE have significantly higher scores of BDI (p≤0.002) and BAI (p≤0.006) than cSLE.

Conclusion:

Cytokines behave differently in aSLE and cSLE patients. The analyzed cytokines fluctuated throughout the study period, however were not associated with disease activity markers.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

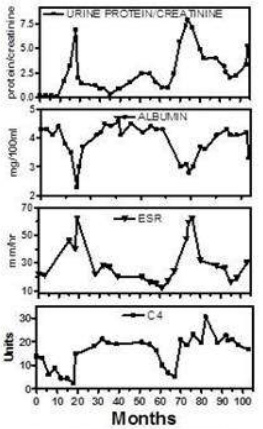

Fig. 1 Relationship between changes in the urine protein/creatinine ratio with serum albumin, ESR and C4. In this patient the relationship with C3 and HCT was similar.

Background/Purpose: When a complex patient with long term lupus is seen for the first time, there is a need for a readily and commonly available serum marker to graphically indicate the severity and course of their disease. Serum albumin levels are known to reflect SLE activity, especially lupus nephritis, but the utility of this marker to assess longitudinal activity has not been studied. Here we have compared serum albumin levels with other measures of lupus activity

Methods: We selected 10 patients with lupus nephritis followed at the USC+LAC Medical Center for 1 to 10 years. Other patients without nephritis were also studied. Using the urine protein/creatinine (UPC) ratio as a reference standard for nephritis, we looked for the correlation with serum albumin levels, ESR, CRP, hematocrit, anti-dsDNA levels, serum C3, and C4. Both Pearson and Spearman r values were calculated and p values determined. The UPC of patients studied was >2.

Results: The Table shows that changes in serum albumin levels correlated highly with UPC in all patients studied ($p < 0.01$). C3 levels were the only other marker to correlate significantly with UPC in more than one half of the half the subjects. However, as an example of how lab markers can relate to UPC, Fig.1 shows a significant correlation of all markers examined in a patient we treated for more than 8 years. In cases without lupus nephritis, similar decreases in serum albumin levels were observed in patients with severe organ system disease, but not in lupus patients with only moderate skin involvement or serositis. There was no relationship with serum albumin levels disease activity in most cases of rheumatoid arthritis.

Conclusion: With the increased use of the computerized medical record, we believe that in the first encounter of a lupus patient with longstanding disease, graphing serum albumin levels will reveal useful information regarding the severity of systemic activity, and the dates of this involvement. Inspection of the medical record on these dates will reveal the response or lack of response to the agents used, and the rheumatologist can then rapidly formulate the appropriate treatment regimen for that patient in a timely manner.

Table Correlation of lab tests with Urine Protein Creatinine Ratio

	Albumin	α-DNA	CRP	ESR	C3	C4	HCT
Mean correlation coefficient (r value)	-0.87	0.54	0.44	0.49	-0.64	-0.47	-0.46

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

EULAR and ACR have jointly funded a project to improve existing classification criteria for SLE; this abstract reports on the early phase of this project. Classification criteria are being developed using multicriteria decision analysis methods. The goal of the initial phase of this project was to generate a broad set of items potentially useful for the classification of SLE and select a list of candidate items for use in forced-choice decision analysis. The aims were to include items that encompass a broad spectrum of SLE, including patients whose disease is in the early stage as well as those in the late stage, and that are in accordance with criteria used for diagnosis of SLE in clinical practice.

Methods:

135 expert lupus clinicians were asked to independently rate items derived from the ACR and SLICC classification criteria for their importance in diagnosing early and established SLE, respectively, in an online survey. Answers were retrieved from 120 experts (N= 54 from EULAR centres, n=66 from North American). In addition, open commentary fields were provided for the suggestion of novel items.

Results:

Interestingly, while 58% of those would not diagnose SLE without a positive ANA by immunofluorescence on at least one occasion, 23% said they would make a diagnosis and 19% were unsure. The experts were in agreement that characteristic autoantibodies as well as specific renal features and skin manifestations are key for diagnosing SLE, regardless of whether early or established SLE. When asked about organ system involvement, 51,1% stated that one organ system would been sufficient for making the diagnosis of SLE, but that additional typical laboratory features (ANA, dsDNA) would be required.

Notably, 85% of the expert group would make the diagnosis of SLE if renal pathology shows lupus nephritis, but skin histology was not rated nearly as specific.

Conclusion:

A survey of international SLE experts indicates that they consider a broad range of items for the diagnosis of SLE. Nevertheless, it is interesting that a majority would diagnose SLE based only on renal pathology, as suggested by the SLICC group, as well as upon single organ system involvement in the presence of additional laboratory findings such as ANA and dsDNA. These ideas will be explored in more detail in the next phases of the project.

Table 1:

Would you make the diagnosis of SLE in absence of ANA (immunofluorescence)?	Yes 23%	No 58%	Unsure 19%
How many organ systems would be enough for you to make the diagnosis of SLE?	52% one organ system	38% two organ systems	6% three organ systems
Would one pathological finding be enough to make the diagnosis?	Yes 85%	No 15%

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with systemic lupus erythematosus (SLE) have a higher incidence of thrombotic thrombocytopenic purpura (TTP). Differentiating TTP from SLE activity may represent a challenge to clinicians, and there is no adequate biomarker to help distinguish between both entities. The aim of this study was to correlate different molecules associated with vascular and platelet regulation in patients with SLE-associated TTP at diagnosis (dx), after plasmapheresis (ap) and at remission (rem).

Methods: We included 73 subjects (13 SLE/TTP patients, 14 SLE-remission, 13 active hematological SLE, 14 non-hematological active SLE and 19 healthy controls). Patients were diagnosed with TTP in the presence of the following parameters: microangiopathic hemolytic anemia, thrombocytopenia ≤100,000 cel/µl, high LDH levels and negative Coombs test. Patients with SLE were diagnosed with at least ≥ 4 ACR classification criteria. We obtained serum samples for each subject, including serial samples for SLE/TTP patients (dx, ap and rem). Serum sCD40L and VEGF were measured by ELISA, and different cytokine levels were measured by luminometry.

Results: The main characteristics of each group are depicted in table 1. We found increased sCD40L levels in active hematological and non-hematological SLE in comparison to SLE/TTP^{dx} (p=0.039 and 0.001 respectively), but there were no differences between SLE/TTP^{rem} and active hematological SLE (3044±403 vs 3397±708 pg/ml, p=0.77). Interestingly, mean sCD40L levels progressively increased in treated SLE/TTP patients (see table) an also a positive correlation between sCD40L and VEGF levels was found (r=0.62, p=0.004), regardless of the improvement in platelet count. There were no significant differences in SLEDAI score among TTP and active SLE groups (p=0.54). Furthermore, CXCL1 levels were lower in SLE/TTP^{dx} *vs* active hematological SLE (22.5±5.7 vs 136.7±33.5 pg/ml, p=0.040). Other analyzed cytokines (IL2, 6, 8, 10, TNFα e IFNγ) were not different among groups.

Conclusion: Our findings suggest that SLE/TTP patients have sCD40L depletion at baseline, which represents a differential serologic profile from active SLE. After the proper treatment is initiated, sCD40L levels increase progressively. It is possible that the depletion of this costimulatory molecule could be associated with recruitment at the vascular wall, denoting its potential pathogenic role in microangiopathy-associated endothelial dysfunction. Prospective studies, which ideally should include TTP patients without any autoimmune disease, are needed to confirm those findings.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Ethnic variations in systemic lupus erythematosus (SLE) are well described, with more prevalent and severe disease in

non-Caucasians including North American Asians. However, Asian ethnicity includes broad cultural, geographic and genetic diversity, and there is limited data examining SLE among Asian ethnicity subsets. We describe SLE in 3 Asian subgroups from a large SLE cohort.

Methods: The 1000 Faces of Lupus is a multicentre Canadian cohort of over 2000 SLE patients. Sociodemographics, ACR classification criteria (ACRc), autoantibodies, disease activity scores (SLEDAI), Systemic Lupus International Collaborating Clinics damage index (SDI) scores, and treatments are collected using standardized tools. Ethnicity was self-reported and Asian subgroups were divided by geographic country of origin into East Asian (EA), Southeast Asian (SEA), South Asian (SA) and Central Asian (CA). Data at cohort entry for Asians and Caucasians were abstracted and cross-sectional univariate analyses including T tests, one-way ANOVA, and chi-square tests were performed.

Results: There were 334 Asians (176 EA, 78 SEA, and 78 SA, and 2 CA), and 1275 Caucasians. CA were excluded. Onset age for Asians was similarly young (EA=23±13 years; SEA=21±10 years; SA=20±11 years) compared to Caucasians (33±15 years, p<0.001). Childhood onset was frequent in Asians (EA=49%; SEA=51%; SA=61%) compared to Caucasians (17%, p<0.001). Over 40% of all Asians were immigrants. The proportion of males was higher in Asians (EA=15%; SEA=16%; SA=19%) compared to Caucasians (10%, p=0.008). ACRc or SLEDAI scores were not different, while all Asians had a higher frequency of nephritis (EA=57%; SEA=63%; SA=51%), compared to Caucasians (33%, p<0.001). More Asians were dsDNA+ (ever) (EA=62%; SEA=63%; SA=78%) compared to Caucasians (52%, p<0.001). SEA were most frequently antiSm+ and antiRNP+ (ever) (EA=31%; SEA=50%; SA=30%; p=0.01, and EA=20%; SEA=32%; SA=22%; p=0.03), but all Asians were higher than Caucasians (19%, p<0.001; 16%, p<0.001). More SA were antiphospholipid antibody positive (ever) (EA=26%; SEA=18%; SA=37%, p=0.04) but overall not different from Caucasians (24%). Over 90% of Asians graduated high school compared to Caucasians (83%, p=0.007). Most Asians were in the highest income tier (EA=55%; SEA=42%; SA=58%), similar to Caucasians (51%). Treatment with prednisone (EA=55%; SEA=67%; SA=65%), cyclophosphamide (EA=13%; SEA=21%; SA=20%), and mycophenolate (EA=15%; SEA=19%; SA=9%) was relatively frequent in Asians, likely reflecting the high frequency of nephritis. The mean disease duration in Asians was 8 years but most had not accumulated damage (SDI=0 in 66% EA; 64% SEA; 79% SA) compared to Caucasians (47%, p<0.001).

Conclusion: This is the first study to compare SLE in North American Asian subgroups. Childhood onset SLE is more common in Asians than Caucasians. Disease appears severe but not different between the Asian groups. People of Asian subcontinental ethnic origin are the fastest growing ethnic group in North America. Young onset age and a high proportion of 1st generation immigrants suggest the potential for a growing burden of SLE in this population. Future studies of outcomes and optimal treatments are indicated.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Systemic lupus erythematosus (SLE) is a prototypic autoimmune disease characterized by immune complexes of antinuclear antibodies. As a source of these antigens, increased levels of apoptosis and defective clearance of dead cells have been proposed. As now recognized, during apoptosis and cell activation, microvesicles (MVs) are released extra-cellularly. MVs are small membrane bound vesicles that enclose intracellular contents. To determine whether MVs contain nuclear molecules and can form immune complexes, we quantified by flow cytometry the content of nucleic acids; High Mobility Group Box-1 (HMGB1), a non-histone protein with alarmin activity; and bound immunoglobulin on MVs from SLE patients and controls.

Methods:

Fasting plasma samples from 294 patients with SLE (4≥ of 1982 ACR criteria) and 309 age- and sex-matched population controls were investigated. MVs were analyzed by flow cytometry as vesicles less than 1.0 μm in size and positive for SYTO 13, a cell permeable dye binding to DNA or RNA. We also measured expression of HMGB1, IgG and IgM on MVs.

To determine whether factors in SLE blood can bind MVs, MVs from healthy volunteers were incubated for 60 min at room temperature with plasma from SLE patients (n=5). After incubation, the MVs were isolated and the amounts of IgG and IgM were measured.

Results:

Blood of SLE patients had significantly higher numbers of MVs containing nucleic acids and these MVs expressed more HMGB1, IgG and IgM as compared to controls (Figure 1A-D).

In-vitro experiments revealed that incubation of MVs obtained from healthy volunteers with MV-free plasma obtained from SLE patients, significantly increased the levels of IgG and IgM on MVs (IgG: 0.3±0.03 vs 0.64±0.07 mean fluorescence intensity (MFI); IgM: 0.29±0.02 vs 0.41±0.08 MFI; $p<0.0001$ and $p<0.05$ respectively).

Conclusion:

MVs containing nucleic acids are significantly more abundant in the blood of SLE patients than in controls. Many of these MVs expose the alarmin HMGB1, IgG and in particular, IgM on their surface. Furthermore, plasma from SLE patients increased immunoglobulin binding on MVs from controls. Together, these studies indicate that release of MVs into the blood is a feature of SLE and that immunoglobulins can bind to antigenic sites on MVs. Since MVs are plentiful, form immune complexes, and display an alarmin, these vesicles could drive SLE pathogenesis as a source of immune complexes and immunostimulatory molecules such as HMGB1.

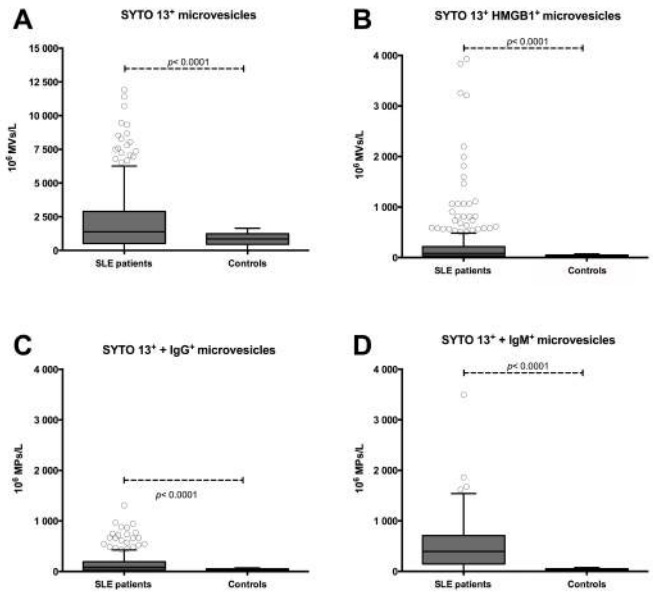

Figure 1. Microvesicles were analyzed by flow cytometry and defined as vesicles less then 1.0 μm in size and positive for SYTO 13 (A) and co-expression of HMGB1 (B), IgG (C) and IgM (D), in SLE patients and matching controls.

Belimumab for Systemic Lupus Erythematosus: A Cochrane Systematic Review and Meta-Analysis

Jasvinder A. Singh[1] and Nipam Shah[2], [1]University of Alabama at Birmingham, Birmingham, AL, [2]University fo Alabama at Birmingham, Birmingham, AL

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Belimumab is a new approved treatment option for patients with lupus. Our objective was to perform a systematic review of benefits and harms of belimumab for systemic lupus erythematosus (SLE).

Methods:

We searched multiple databases for eligible studies using a search strategy developed by a Cochrane librarian. We included randomized controlled trials (RCTs) or controlled clinical trials (CCTs) of belimumab (alone or in combination) compared to placebo/control treatment, in adults with lupus. Two authors independently assessed search results, trial quality and risk of bias, and extracted data. Review manager was used for data analyses.

Results:

Four studies (N=2205) qualified for qualitative and/or quantitative analyses. 5 studies pooled data from up to three of these original studies. Compared to placebo, belimumab 10mg/kg (approved dose) was associated with significantly higher likelihood of achieving improvement/reduction in SELENA-SLEDAI score (a validated SLE disease activity score) by >=4-points and SLE responder index (SRI) at 52-weeks (level of evidence, high for both outcomes; I^2 =0% for both) with risk ratios of 1.29 (95% CI 1.10 to 1.51, I^2= 0%) and 1.31 (95% CI 1.11 to 1.55, I^2= 0%) , respectively. Change in HRQOL, assessed by SF-36 PCS score improvements, with belimumab 10mg/kg was a mean 1.35 units (95% CI 0.68 to 3.38) greater change than placebo, which did not meet statistical or clinical significance of 2.5-5 unit greater improvement (level of evidence, moderate; I^2 =0%). The proportion of patients with >=1 serious AE, >=1 serious infection and withdrawals due to adverse events did not differ significantly between belimumab 10mg/kg and placebo;1.09 (95% CI 0.76 to 1.56), 0.97(95% CI 0.53 to 1.78); 1.40 (95% CI 0.32 to 6.22) (level of evidence, moderate; I^2 =0% for all three). Mortality was rare, and didn't differ significantly between belimumab 10 mg/kg and placebo (level of evidence, low; I^2=0%). Belimumab-treated patients were also more likely than placebo-treated patients to experience improvement (decrease of >=0.3) in patient global assessment (PGA) and were able to reduce corticosteroid dose by >=50% and less likely to have any SLE flare and severe SLE flare. Similar findings were noted for efficacy of belimumab 1 mg/kg compared to placebo.

The number needed to treat (NNT) for SRI at 52 weeks was 8 (95% CI: 5 to 23) and the number needed to treat (NNT) for SELENA-SLEDAI at 52 weeks was 8 (95% CI: 5 to 25). We found overall quality of evidence to be high. Belimumab at 10mg/kg dose was found to be associated with higher improvements in disease signs and symptoms and disease activity (greater effects on SRI, SELENA-SLEDAI, BILAG, PGA) than belimumab at 1mg/kg dose.

Conclusion:

At the FDA-approved dose of 10mg/kg, belimumab was associated with significantly more benefits compared to placebo in patients with lupus based on well-designed high-quality RCTs that used validated outcomes. Evidence related to harms is inconclusive and of low quality.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I
Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Rituximab (anti-CD20 monoclonal antibody) has been frequently used to treat various autoimmune diseases in which B-cells are participants, and for hematological malignancies in which CD20-bearing cells are increased. Infusion reactions including fever, chills and rigors, as well as allergic (Type IV) anaphylactoidspectrum reactions and less commonly serum sickness (or Type III) hypersensitivity reaction have been reported with its administration. It is important to recognize this as re-exposure can result in recurrent and more severe manifestations. We perform a systematic review and meta-analysis to characterize RISS in autoimmune diseases and hematological malignancies.

Methods: A comprehensive search of MEDLINE, EMBASE, ACR and EULAR databases was performed for relevant articles of patients with RISS from inception to September 2014 (Figure 1). Statistical analysis of demographic and clinical features was performed using Microsoft EXCEL 2007 and SPSS version 20.0.

Results: In the 33 patients (from 25 reports) with RISS, the mean age of presentation was 39.1±17.5 years with a female preponderance (n=23, 76.67%). The majority of cases were associated with an underlying autoimmune condition (n=28, 84.85%), most commonly immune thrombocytopenic purpura (n=10) and Sjögren'ssyndrome (n=7 and lymphomas in 5/33 cases (15.15%) (Table 1). Symptoms of RISS began 6.63±3.83 days following infusion with most episodes occurring during the first cycle. Classic triad of serum sickness (fever, rash and arthralgia) was reported in 16 (48.5%) cases. Time from drug exposure to symptom onset was significantly greater with the first doses of rituximab compared to the second dose (mean time 10.00 vs. 4.05 days, P=0.002), and time to resolution was significantly greater for rheumatologic vs. hematological indications (mean time 2.50 vs 1.00 days, P=0.035). Corticosteroids were the most commonly used treatment (n=21), with all cases reporting a complete resolution of symptoms in 2.15±1.34 days.

Conclusion: It is important to recognize and diagnose RISS clinically as it may mimic exacerbation of various rheumatologic conditions such as RA. Although elevated RF, immunoglobulins and HACA levels may play a role in the pathogenesis, these are not predictable markers, as the serologic and Ig levels are features of the underlying disease. RISS is often a benign condition with prompt and complete resolution with corticosteroids. That some patients have experienced recurrent RISS with re-exposure indicates that providers should carefully weigh risks and benefits of continuing or reintroducing rituximab.

Session Date: Sunday, November 8, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Although gout has historically been thought to be a rare in patients with SLE, recent case series suggest that the incidence of gout in SLE may be greater than previously thought. Here we report a retrospective analysis of a large lupus cohort to determine the prevalence and risk factors for gout in an outpatient population.

Methods: Patients from the University of Michigan lupus cohort who met criteria for acute gout were identified by either the 1977 ACR or the 1968 New York gout criteria. All patients met 4 ACR criteria for a diagnosis of lupus and were seen in the outpatient rheumatology clinic between 1997 and 2014. Characteristics of the patients identified as having gout, including age, race sex, uric acid levels, medication use, and lupus activity were recorded and compared to the 827 remaining patients in the cohort without a diagnosis of gout..

Results: 27 of 856 lupus cohort patients were identified as having gout, including six with crystal-proven gout. Of these 27, 8 were male, 10 were black, 15 white and 2 were of Asian ancestry and the average age at the time of presentation with gout symptoms was 55 years. The average BMI was 33.5 +/- 6.8. All patients were hyperuicemic with an average uric acid level of10.8 +/- 2.3. Compared to the cohort as a whole, a significant number (12/27 patients) were treated with a loop diuretic (p=0.001) and a significant number (6/27) were treated with a thiazide diuretic (p=0.01). Reduced renal function, defined as CKD stage IIIa or worse was found in 17/27 (p=0.0001) patients. 25/27 were taking some dose of prednisone with an average of 6 mg, a minimum of 1 mg and a maximum of 13 mg. A total of 6/27 patients had a history of kidney transplant and were being treated with cyclosporine. C3 and C4 Complement levels were within the normal range for all 27 patients.

Conclusion: Gout was documented according to standard criteria in 27/854 (3.2%) of patients in the lupus cohort. Most risk factors including age, male sex, and kidney transplant history were non modifiable. However there was a striking association between gout and the administration of a diuretic, either for edema (12/27 patients) or for other indications (6/27 patients), especially in the setting of impaired renal function. Lupus patients with a history of compromised renal function who are being treated with diuretics should be monitored closely for hyperuricemia and symptoms of gout.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The aim of this study was to examine whether circulating levels of the pro-inflammatory glycoprotein tenascin-C (TSC) are useful as an activity-specific or predictive biomarker in SLE.

Methods: Serum TSC levels were determined by ELISA at inception visit in a prospective cohort of 59 SLE patients, and in 65 healthy controls (HC). SLE patients were followed for a median of one year, and disease activity (assessed by SLEDAI-2K), and changes in glucocorticoids (GC) and immunosuppressants (IS) were serially recorded every 3-6 months. We examined cross-sectional relationship between serum concentrations of TSC and SLE status, SLEDAI-2K scores, strata of disease activity, and levels of anti-dsDNA, anti-nucleosomal antibodies and

C3, C4. We also explored the utility of TSC levels to predict disease flare defined as (i) increase in SLEDAI ≥3, (ii) new/increased GC, and (iii) new/increased GC or IS.

Results: Baseline characteristics are shown in table 1. There was no statistical difference in the mean levels of TSC between all SLE patients and HC. However, in SLE patients with active disease (SLEDAI≥ 6) the levels of TSC were significantly higher than in HC (p=0.004) or patients with no/low disease activity (p=0.004). In SLE patients, TSC levels were significantly associated with the positivity of anti-dsDNA (p=0.03) and anti-nucleosomal antibodies (p=0.008), and there was a trend to a positive correlation with SLEDAI (R=0.25, p=0.06) and clinical SLEDAI scores (R=0.25, p=0.06) – see table 2. Higher baseline levels of serum TSC showed significantly greater risk of disease flare defined as the need to escalate glucocorticoids (HR 1.39; 95% CI: 1.11- 1.73, p = 0.004) or any immunosuppressive therapy (HR 1.25, 95% CI: 1.02-1.52, p=0.028). We also conducted a separate analysis in which serum TSC level was treated as a categorical variable. In accordance with the result above, the risk of reaching the flare (ii) or (iii) was significantly higher in the group of patients wither higher TSC levels (see table 3).

Conclusion: TSC is not disease-specific, but it seems to indicate the activity of SLE and may predict the need to escalate immunosuppressive therapy. TSC levels may thus serve as a useful activity-specific and predictive biomarker in SLE. **Acknowledgements:** This study was supported by grant IgA NT 13707.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Cyclophosphamide (CYC) is effective in inducing remission of lupus nephritis (LN). CYC, as a pro-drug, requires bioactivation through multiple hepatic cytochrome P450s and glutathione S transferases (GST). Methods: We conducted a retrospective study that included 70 patients with proliferative LN treated with CYC. Patients were genotyped for polymorphisms of the *CYP2B6, CYP2C19, GSTP1, GSTM1* and *GSTT1* genes. We examined the association between these genotypes and achievement of renal response and occurrence of side effects. **Results:** In univariate analysis, patients expressing the *GSTP1* null genotype showed a trend toward a lower probability of achieving renal response (73.3% versus 91.2%, p=0.059). Expression of the *GSTM1* null genotype was associated with a higher occurrence of side effects (43.9% versus 21.4%, p<0.05). In multivariate analysis, the *GSTP1* null genotype was an independent factor of treatment lower response (p<0.05). The only factor that influenced the occurrence of side effects was the polymorphism of *GSTM1* (p<0.05). No association between polymorphisms of the cytochrome P450 gene and efficacy or side effects was observed. **Conclusion:** Despite small sample size, this study suggests that determination of *GST* genotypes may be valuable for predicting the renal response and occurrence of side effects in lupus nephritis patients treated with CYC.

Session Date: Sunday, November 8, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Lupus Nephritis (LN) significantly contributes to morbidity and mortality among Systemic Lupus Erythematosus (SLE) patients. We have established the Renal Activity Index for Lupus (RAIL) in pediatric LN with an accuracy of > 92% in predicting activity. The goal of this study was to validate the RAIL algorithm for adults with LN.

Methods:

Adult SLE patients who required a kidney biopsy as part of their standard care were enrolled. A urine sample was collected at the time of biopsy. Demographic information, SLE status (diagnostic criteria, laboratory and clinical data, renal disease activity (R-SLEDAI) and chronicity (SDI-R)), medications were collected. Kidney biopsies were read in a blinded fashion and the National Institute of Health Activity and Chronicity indices (NIH-AI, NIH-CI) were reported. Patients were dichotomized as high activity or not based on their NIH-AI scores. Fifteen urinary biomarkers (UBMs) were collected and the **SIX UBMs**used in pediatric RAIL data were used for the analysis (neutrophil gelatinase associated lipocalin, monocyte chemotactic protein 1, ceruloplasmin, adiponectin, hemopexin, kidney injury molecule 1). Urinary microalbumin and creatinine concentrations were measured to normalize for proteinuria in the analysis. Adult RAIL predictors were firstly assessed of associations to AI using univariate analyses, followed by prediction analyses to develop the RAIL algorithms using stepwise multiple logistical regression

models. Predictive accuracy of the RAIL algorithm was calculated using the area under the Receiver Operating Characteristic (ROC) curve (AUC).

Results:

We studied 75 adults (mean age 32.4±10.1 years) and the majority were females (78.7%) with equal representation for Caucasian and African American ethnicities (46.7%). Their mean NIH-AI and NIH-CI scores were 4.57± 4.11 and 3.23 ± 2.59, respectively. 11 (15%) patients had high activity with NIH AI scores >10. Age, gender, ethnicity and LN stage were not significantly different between the two activity groups. Using the 6 UBMs used in the pediatric RAIL algorithm, an excellent prediction was obtained (AUC 0.87 (0.77, 0.97)). Using adult population based UBMs with total 10 UBMs there was notable improvement in diagnostic accuracy of the model (AUC 0.92 (0.84, 1.00)). The RAIL algorithms showed little noticeable improvement with adjustment for creatinine and microalbumin [Table 1].

Conclusion:

We have successfully validated the pediatric RAIL algorithm among adults to accurately and reliably measure LN disease activity. Further, in adults we found that adjustment for microalbumin or creatinine levels dose not cause a great change in diagnostic accuracy of RAIL. Using an adult model based RAIL with 10 UBMs does increase the accuracy of the algorithm. Further studies to independently validate and further study the relationship of these UBMs with specific biopsy findings are needed.

TABLE 1: Diagnostic Accuracy of RAILs using Pediatric Model and Adult Model

		CREATININE adjusted		CREATININE adjusted	MICROALBUMIN
	Raw Score	Score	Raw Score	Score	adjusted Score

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

To evaluate the performance of 4 novel serum protein markers for detecting concurrent disease activity in systemic lupus erythematosus (SLE).

Methods:

Consecutive patients who fulfilled >=4 ACR criteria for SLE and healthy controls were recruited for serological testing of 4 serum protein markers identified by a proteomic screening study using a commercially available antibody-coated microarray, namely Axl, Ferritin, insulin growth factor binding protein-2 (IGFBP2) and tumor necrosis factor receptor-2 (TNFR2) (assayed by ELISA kits from the R&D Systems [Minneapolis, Minnesota, USA] - Axl (Cat#: DY154), TNFR2 (Cat#: DY726), IGFBP2 (Cat#: DY674); Ferritin was assayed using an ELISA kit from Raybiotech, Inc [Norcross, Georgia, USA]). Elevated levels of these markers were defined as values ≥ mean + 2SD of the controls. SLE disease activity was assessed by the SELENA-SLEDAI, physician's global assessment (PGA) and the SELENA flare instrument. Levels of these markers were correlated with disease activity scores and conventional markers of SLE activity. The specificity and sensitivity of these markers in detecting clinical SLE activity was determined.

Results:

94 SLE patients (98% women; age 28.7±9.4 years, disease duration 5.4±5.0 years) and 49 healthy controls were studied. Fifty-two (55%) patients had clinically active SLE (SLEDAI score ³6 or having a flare by the SELENA flare instrument). The SLEDAI and PGA score of the patients was 8.3±1.1 and 1.11±0.92, respectively. Organ damage, defined as a SDI damage score of ≥1, was present in 37 (39%) of patients. Among the 52 patients with clinically active SLE, the involved organ systems were as follows: renal (60%), mucocutaneous (50%), musculoskeletal (40%) and hematological (25%). Elevated anti-dsDNA titer (>25% of the upper normal range) was present in 44 (85%) patients and depressed complement C3 level was present in 45 (87%) patients. The serum concentrations of Axl, ferritin, IGFBP2 and TNFR2 were significantly higher in patients with active SLE than inactive SLE or controls. The levels of these markers correlated strongly and significantly with the levels of anti-dsDNA, C3, clinical SLEDAI (total SLEDAI minus points contributed by low C3 and elevated anti-dsDNA) (Axl ρ=0.39; TNFR2 ρ=0.59; Ferritin ρ=0.52; IGFBP2 ρ=0.61; P <0.001 in all) and PGA scores (P<0.001 in all). The sensitivity of these markers in detecting SLE activity (Axl 0.67; TNFR2 0.77; Ferritin 0.71; IGFBP2 0.69) was lower than that of elevated anti-dsDNA (0.85) or depressed C3 (0.87), but their specificity for ascertaining clinical SLE activity were generally higher (Axl 0.79; TNFR2 0.71; Ferritin 0.76; IGFBP2 0.76; anti-dsDNA 0.45; C3 0.33). Levels of Axl, TNFR2 and IGFBP2, but not ferritin, could differentiate active renal from active non-renal or inactive SLE. The specificity of Axl (0.68) and IGFBP2 (0.71) for active lupus renal disease was higher than that of elevated anti-dsDNA (0.40) or depressed C3 (0.32).

Conclusion:

Serum proteomic markers are potentially useful for diagnosing SLE and monitoring disease activity. The performance of Axl and IGFBP2 in monitoring lupus nephritis should be further studied in a larger longitudinal cohort of SLE patients.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

There is presently no consensus on how to best measure disease activity in systemic lupus erythematosus (SLE). Available validated measures, such as SLE Disease Activity Index (SLEDAI) and SLE Activity Measure (SLAM), are composite scores that in addition to laboratory tests require investigation by a physician. These scores are insensitive to change and have failed to differentiate treatment responses in clinical trials. It would be an important step forward, for clinical practice and for clinical trials, if one or several biomarkers could be used as proxies for disease activity in SLE.

Methods:

In a cross-sectional setting we examined 433 patients with SLE (fulfilling four or more of the 1982 revised ACR criteria) and 322 age and gender matched population controls. Disease activity was assessed according to both SLEDAI and SLAM by a rheumatologist. Basic laboratory tests and analyses on MSD 30-plex cytokine assay (Mesoscale Discovery, K15054D) were performed on fasting blood samples (total >50 biomarkers). The discriminatory power for investigated biomarkers was tested between patients and controls. Correlations with SLAM/SLEDAI scores were calculated among patients.

Results:

Many biomarkers discriminated between patients and controls. Best discriminatory power ($p<1x10^{-35}$) was observed for: TNF-α, IL-6, orosomucoid, plasma (P)-albumin and sedimentation rate (SR), see table.

Variables with the strongest correlation with SLAM/SLEDAI (Spearman correlation $\rho>0.20$ or $\rho<-0.20$) are presented in the table. Strong positive correlations were observed for TNF-α, and negative for P-albumin. The ratio between TNF- α and P-albumin improved the correlations, see figure. As SR is part of SLAM, and Complement factor 4 (C4) an item in SLEDAI, expected positive correlations were observed, see table.

Conclusion:

Of more than 50 investigated biomarkers TNF-α was the best discriminator between SLE patients and controls. Furthermore TNF-α was the biomarker, which correlated best with disease activity. These correlations were further improved by the ratio between TNF-α and P-albumin. We propose that the TNF-α/P-albumin ratio merits further investigations as a clinically useful biomarker for diagnostic and surveillance purposes in SLE.

Biomarkers with the best Discriminatory Power between SLE patients and controls and/or strongest Correlations with SLE Disease Activity, as measured by SLEDAI and SLAM

Biomarker	Patients (95 % CI)	Controls (95 % CI)	p-value Patients vs. Controls	SLEDAI Spearman's ρ	SLAM Spearman's ρ
TNF-α pg/ml	5.6 (5.2 - 6.0)	2.6 (2.2 - 3.0)	7.0×10^{-63}	0.32 $p= 6.0 \times 10^{-12}$	0.34 $p=5.0 \times 10^{-13}$

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Higher accrual of damage has been reported in Hispanics with systemic lupus erythematosus (SLE) in the United States. This study was initiated to evaluate the clinical characteristics including the accumulated damage of Dominican patients with SLE residing in

New York City (NYC) compared to Dominicans with SLE living in the Dominican Republic (DR).

Methods: One-hundred and fifty-one Dominican SLE patients fulfilling ACR SLE criteria were cross-sectionally studied: 76 from NYC and 75 from the Dominican Republic. Socio-demographic and clinical characteristics, disease activity (SLEDAI-2K), SLICC/ACR- damage index (SDI), and comorbidities were compared between the two patient groups and linear regression models were constructed to test the association with the SDI, adjusting for pertinent covariates.

Results: The mean age was 40 (±14), and 36 (±11) years for the NYC and DR patients, respectively. Both groups had a median disease duration of 8 years and mild disease activity based on their last SLEDAI-2K. The NYC patients were more likely to have discoid lesions (20% vs. 3%), positive anti-ds-DNA (79% vs. 64%), and anti-SSB antibodies (41% vs. 7%). Prevalence of hypertension, diabetes, antiphospholipid antibody syndrome, and use of medications other than corticosteroids did not differ among the groups. Those in the DR had more lupus nephritis (LN) (64% vs. 47%), were more likely to be on corticosteroids (83% vs. 38%), and less likely to have medical insurance (25% vs. 100%) (Table 1). However, a higher SDI was seen in NYC patients (0.96 vs. 0.24, p=<0.0001), driven by a higher prevalence of damage in the neuropsychiatric (16% vs. 3%, p=0.009)), renal (22% vs. 4%, p=0.0009), pulmonary (22% vs. 1%, p=<0.0001), and musculoskeletal (32% v s. 16%, p=0.02) domains. This association remained statistically significant after adjusting for pertinent covariates (1.26 vs. 0.57, p=<0.0001) (Figure 1).

Conclusion: SLE Dominican patients residing in NYC have a higher SDI than those in the DR. Longitudinal studies are needed to ascertain whether this difference is due to biological, environmental factors, or immigration patterns, or may reflect a survival bias.

Table 1. Patient characteristics.

	DR (n=76)	NYC (n=75)	P value
Socio-Demographics			
Age (years)	36 ± 11	40 ± 14	0.09

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Peripheral CD4+CD28null T-cells are a subset of long-lived cytotoxic CD4+ T-cells with pro-inflammatory functions, and they are increased in autoimmune and cardiovascular diseases. Prolactin has several pro-inflammatory functions, and in patients with SLE has been associated with disease activity, pro-inflammatory body mass distribution and disease damage. The aim of this study was to determine whether prolactin levels are independently associated with this T-cell subset in SLE patients.

Methods: This cross-sectional study was conducted in consecutive SLE patients seen in our Rheumatology Department from September 2013 to April 2014. An interview, medical records review, physical examination and laboratory tests were performed. SLE was defined using the 1997 revised and updated ACR criteria. Prolactin levels were recorded in ng/ml. Disease activity was ascertained using the SLEDAI, disease damage with the SLICC/ACR damage index (SDI) and comorbidities with the Charlson Comorbidity Index (CCI). Use of prednisone was recorded as current dose and total time of exposure. Use of antimalarials and immunosuppressives was recorded as current, past or never. CD4+CD28null frequency was analyzed by flow-cytometry. The association of prolactin levels and CD4+CD28null T-cells was examined by univariable and multivariable linear regression models, adjusting for age at diagnosis, gender, disease duration, CCI, SLEDAI, SDI and use of prednisone, antimalarials and immunosuppressive drugs. All analyses were performed using SPSS 21.0.

Results: One hundred and four patients were evaluated; they were representative of the entire cohort (n=268); their mean (SD) age at diagnosis was 36.5 (13.6) years, 96 (92.3%) were female; all patients were mestizo (mixed Caucasian and Amerindian ancestry). Disease duration was 7.2 (6.5) years. The SLEDAI was 5.3 (3.9), the SDI 0.9 (1.3) and the CCI 1.4 (0.8). The current dose of prednisone was 7.0 (5.2) mg/d and the total time of exposure to prednisone was 6.8 (7.0) years; 82 (78.8%) and 12 (11.5%) were current and former users of antimalarials. Forty-seven (45.2%) and 26 (25.0%) were current and former users of immunosuppressive drugs. Prolactin levels were 20.6 (19.7) ng/ml. The percentage of CD4+CD28null was 17.7 (15.1) In the univariable analysis, prolactin levels were positively associated with a higher percentage of CD4+CD28null (B= 0.26, 95% IC= 0.12-0.40; p<0.001) and remained associated in the multivariable analysis (B=0.20, 95%CI= 0.04-0.37, p=0.018).

Conclusion: In SLE patients, prolactin levels are independently associated with a higher percentage of CD4+CD28null. These data support the role of prolactin as a proinflammatory hormone among autoimmune diseases and could explain its association with damage accrual.

Session Date: Sunday, November 8, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Belimumab is licensed as add-on therapy to standard lupus care (SoC) in patients with active SLE. Physicians have inquired about the efficacy and safety of belimumab 10 mg/kg used in combination with various concomitant SLE medications.

Methods: We conducted a post hoc analysis (Study 201224) of the efficacy and safety of intravenous belimumab 10 mg/kg plus SoC versus placebo (SoC) in four baseline concomitant medication groups, from the BLISS-52 and BLISS-76 combined database: steroids only, anti-malarials (AM) only, steroids + anti-malarials (steroids + AM), and steroids + anti-malarials + immunosuppressants (steroids + AM + IS). The primary endpoint was the SLE Responder Index (SRI) at Week 52. Safety was examined using adverse events (AEs).

Results: The size of the baseline concomitant medication groups varied (below). Steroid + AM was the largest concomitant medication group and had the shortest disease duration. Patients receiving multiple concomitant medications were younger; disease activity appeared similar across groups. Steroid doses over 7.5 mg/day were common.

	Steroids only	AM only	Steroids + AM	Steroids + AM + IS
Baseline	n=139	n=77	n=346	n=272
Mean age, years	39.4	43.1	36.5	34.9
Disease duration, years	7.1	7.1	5.7	6.4
Mean (SD) steroid dose	15.3 (8.41)	NA	11.5 (7.58)	12.7 (8.95)
% steroid use >7.5 mg	86%	NA	62%	64%
SELENA-SLEDAI	10.4	9.5	9.5	9.9
Mean PGA score	1.5	1.4	1.4	1.4
Primary endpoint, Week 52				
SRI (PBO, BEL)	49%, 59%	38%, 40%	44%, 59%	32%, 42%

AM, anti-malarials; BEL, belimumab; IS, immunosuppressants; PBO, placebo; PGA; Physician Global Assessment; SD, standard deviation; SELENA-SLEDAI, Safety of Estrogens in Lupus Erythematosus: National Assessment-Systemic Lupus Erythematosus Disease Activity Index; SRI, SLE Responder Index

At Week 52, SRI improvement was highest for belimumab 10 mg/kg (59%) compared with placebo in the steroids only (49%) and steroids + AM (44%) groups. Overall, the incidence of AEs was comparable between concomitant medication groups; the steroids + AM group had a numerically higher percentage of serious AEs reported for belimumab (8% placebo, 16% belimumab) compared with SoC.

Patients were not randomized by concomitant medications group at baseline, therefore, subgroup size differed; the study was not powered to examine differences in these concomitant medication subgroups.

Conclusion: These data may be helpful in understanding practice trends and the associated effects when belimumab is added to a treatment regimen. Data interpretation is limited by the use of baseline concomitant medication use, as over 52 weeks, treatment regimens may have changed.

Neurometabolic Alterations in Korean Lupus Patients with Chronic Daily Headache

Ji-Min Kim[1], Tae-Han Lee[1], Chang-Nam Son[1], Sung Soo Kim[2], Hyuk Won Chang[3] and Sang-Hyon Kim[1], [1]Division of Rheumatology, Department of Internal Medicine, Dongsan Medical Center, Keimyung University School of Medicine, Daegu, South Korea, [2]Division of Rheumatology, Department of Internal Medicine, Ulsan University School of Medicine, GangNeung Asan Hospital, Gangneung, South Korea, [3]Department of Radiology, Keimyung University School of Medicine, Daegu, South Korea

Session Date: Sunday, November 8, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Neuropsychiatric systemic lupus erythematosus (SLE) includes a broad spectrum of neurologic and psychiatric manifestations. One of the most commonly observed neuopsychiatric symptoms is headache. However, the lack of specific clinical distinctions for headache in SLE has made it difficult to elucidate its pathophysiology. Proton magnetic resonance spectroscopy (^{1}H-MRS) permits the detection of neuronal metabolic alterations noninvasively. Most studies used ^{1}H-MRS to compare patients with minor NPSLE vs patients with major NPSLE or they compared the SLE patients according to the existence of NPSLE. However, no study has been conducted using ^{1}H-MRS with a focus on specific symptoms, such as headache. The aim of this study is to evaluate the neurometabolic changes in patients with SLE who suffer from chronic daily headache (CDH).

Methods:

SLE patients with CDH (primary headache occurring at least 15 days per month for longer than 3 months), fibromyalgia patients with CDH, and healthy controls were recruited. Subjects were all Korean. ^{1}H-MRS metabolite ratios were evaluated in bilateral basal ganglia (BG) and bilateral peritrigonal white matter (PWM).

Results:

^{1}H-MRS showed a significantly decreased *N*-acetylaspartate (NAA)/creatine (Cr) ratios in right BG in SLE patients with CDH compared to fibromyalgia patients with CDH and healthy controls (p=0.029 and p=0.020, respectively). Left PWM NAA/Cr and Choline (Cho)/Cr ratios of SLE patients with CDH were lower than those of fibromyalgia patients with CDH (p=0.019 and p=0.029, respectively). NAA/Cr and Cho/Cr ratios were similar between fibromyalgia patients with CDH and healthy controls.

Conclusion:

This study suggests the clues that CDH in patients with SLE might be associated with neuronal dysfunction and neurometabolic changes. The distinctive neurometabolic features found in patients with SLE suggest the possible existence of different mechanisms in the development of CDH.

The Interferon Signature Correlates with Longitudinal Disease Severity in Systemic Lupus Erythematosus, but Adds Little to Conventional Prognostic Indicators

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Type I interferon (IFN) is thought to play an important part in the pathophysiology of systemic lupus erythematosus (SLE), and cross-sectional data suggests an association between IFN-induced gene expression and SLE disease activity. However, interest in the IFN signature as a clinical biomarker has been tempered by a lack of fluctuation with disease activity over relatively brief durations (1-2 years) of follow up. In previous work we observed a significant reduction in the IFN signature in patients who had achieved prolonged clinical remissions off prednisone and immunosuppressives, as compared to relapsing and remitting SLE patients. This led us to question whether the IFN signature could act as a prognostic marker of disease severity.

Methods:

IFN induced gene expression was measured in the whole peripheral blood at baseline in 73 SLE patients, using nCounter (NanoString) multiplexed profiling. The expression levels of five representative interferon responsive genes were summed to yield a composite IFN-5 score. Adjusted mean SLEDAI-2K, number of flares, mean steroid dose, immunosuppressive use, and change in SLICC/ACR damage index (SDI) were obtained for all patients over the subsequent five year period. Clinical outcomes were compared to the baseline IFN-5 score by linear regression.

Results:

Of the 73 patients, 65 patients completed five years of follow-up, with 3 patients dying over the study period. As observed in previous studies, the IFN-5 score was positively associated with baseline disease activity ($p=0.0007$) and negatively associated with baseline age ($p=0.004$) and disease duration ($p=0.003$). Upon analysis of clinical outcomes over the subsequent 5 years, the baseline IFN-5 score demonstrated a significant positive association with the adjusted mean SLEDAI at the end of the study period ($p=0.003$), number of flares ($p=0.03$), and number of immunosuppressives used ($p=0.03$). There was also a positive trend between the IFN-5 score and mean steroid dose ($p=0.23$) and progression of damage ($p=0.46$). However, in a multivariate analysis incorporating conventional prognostic indicators including age, baseline disease activity, disease duration, immunosuppressive use, and the IFN-5 score, only age and baseline disease activity were independently associated with the outcome as measured by the adjusted mean SLEDAI-2K.

Conclusion:

Although higher interferon scores correlate with several clinical markers of increased disease severity over the subsequent 5 years, they do not appear to be independently associated with disease severity. This suggests that measurement of the interferon signature may be of limited utility as a prognostic biomarker.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The determinants behind the increased risk of non-Hodgkin Lymphoma (NHL) in systemic lupus (SLE) are unclear. The most common type of NHL in SLE (as in the general population) is the Diffuse Large B-Cell lymphoma (DLBCL) subtype. Using data from a recent NHL genome-wide association study (GWAS), our objective was to determine if certain lupus-related single nucleotide polymorphisms (SNPs) were also associated with the risk of DLBCL.

Methods: We focused on 28 SNPs associated with SLE in European Caucasians; all of these SNPs of which have been strongly associated with lupus risk, with a p value of 10-7 or stronger. Our hypothesis was that these SNPs would also be associated with DLBCL. GWAS data on European Caucasians from International Lymphoma Epidemiology Consortium (InterLymph) studies and participating cohort studies were based on a total of 3,857 DLBCL cases and 7,666 controls. For each SLE-related SNP, the odds ratios and 95% confidence intervals (CIs) were computed using a log-additive logistic regression model. **Results** from three previously conducted DLBCL GWAS studies were pooled in a fixed-effect meta-analysis. With 28 multiple comparisons, an alpha of 0.05 would correspond to a Bonferroni-corrected p value of 0.0018.

Results: Among the 28 SLE-related SNPs investigated, two were clearly associated with risk of DLBCL when correcting for multiple comparisons. These two included the rs3024505 SNP on chromosome 1, a variant allele of IL10 (OR per risk allele =1.14, 95% CI 1.05-1.23, p value 0.0013), and the HLA SLE risk allele rs1270942 on chromosome 6 (OR per risk allele 1.20, 95% CI 1.08-1.33, p value 0.0007). Of additional possible interest were the rs4810485 and rs2205960 SNPs. The OR for the rs4810485 (CD40 gene) risk allele was 1.09 (5% CI 1.02, 1.16, p value 0.013). The rs2205960 SNP, encoding a cytokine of the tumor necrosis factor superfamily, TNFSF4 was associated with an OR per risk allele of 1.08, 95% CI 1.02-1.15, p value 0.044.

Discussion: In terms of a link between the SLE-related rs3024505 SNP and DLBCL, serum IL-10 levels have previously been suggested as a prognostic factor in NHL and IL-10 prevents spontaneous death of germinal center B cells by induction of the bcl-2 protein. Existing data also suggest that some HLA polymorphisms influence risk of DLBCL, CD40 is a member of the tumour necrosis superfamily and it has a central role in regulating B-cell proliferation; CD40 is expressed on several B-cell neoplasms including DLBCL. Finally, tumor necrosis factor ligand superfamily involvement has been suggested in the pathology of malignant lymphomas.

Conclusion: These data suggest several plausible pathways linking DLBCL and SLE.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Azathioprine (AZA) is a commonly used immunosuppressive agent for a number of systemic rheumatic diseases. Although it is regarded to be relatively safe to prescribe in daily clinical practice, untoward rare side effects, especially gastrointestinal adverse events (GIAE) are sporadic, severe and troublesome. There is currently no test or guideline to help predict or prevent this event.

Methods: We reviewed medical records of patients followed at a rheumatology outpatient clinic in a single center (2012.3.1-2015.2.28, SMG-SNU BRMH). Clinical parameters including demographic data, underlying conditions, AZA dose and duration of use, concomitant medications,

and laboratory exams were analyzed. Patients with AZA GIAE were defined as those having severe nausea, vomiting or diarrhea, and malaise during AZA ingestion unexplained otherwise. In total, 12 patients with GIAE and 37 control patients (with no side effects after 6 months of AZA) were identified, and among those, whole blood was drawn from 10 GIAE patients and 23 age/gender-matched controls for thiopurine methyltransferase (TPMT) testing (Green Cross Labs).

Results: The baseline data of AZA GIAE patients showed mean age of 58.4 years, and 58% were females. Mean disease duration of the underlying condition was 29.9 months. The initial dose of AZA was 56.3 mg/d, and GIAE was detected after 57.9 days, when on 85.4 mg/d (all mean values). Around that same period, the control group was on 66.7 mg/d of AZA (p= 0.057). Other clinical parameters between the two groups were comparable. TPMT genotype all GIAE patients were that of wild type, and mean TPMT enzymatic activity of GIAE patients and controls were 34.42 U, 34.23 U, respectively (p= 0.97). Notable laboratory results are described below (table).

Conclusion: These results suggest that early prediction of AZA GIAE is still challenging; physician's awareness, gradual AZA dose increment, early follow-up of liver function tests are conventional, yet important principles to follow.

Table. Selected notable laboratory findings at the period of the adverse event of azathioprine

Laboratory test	GIAE (n=12)	Controls* (n=35)	*p*-value
White blood cells, mm^3	8055 ± 856.0	7120 ± 523.7	*p*= 0.367
Aspartate aminotransferase, IU/L	115.2 ± 28.7	24.9 ± 2.3	*p*< 0.001
Alanine aminotransferase, IU/L	171.7 ± 46.3	20.5 ± 2.3	*p* < 0.001
Alkaline phosphatase, IU/L	260.3 ± 83.5	83.7 ± 11.5	*p*= 0.0014
Erythrocyte sedimentation rate, mm/hr	32.2 ± 7.3	19.4 ± 3.5	*p*= 0.0854
C-reactive protein, mg/dL	1.0 ± 0.3	0.4 ± 0.1	*p*= 0.0505

*Laboratory value at 57.9 ± 14 days after starting azathioprine

GIAE, gastrointestinal adverse event

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose : There is a need to identify biomarkers that track disease response in systemic lupus erythematosus (SLE). The value of various biomarkers in monitoring of SLE subjects with active disease was assessed. This consisted of cell bound complement activation products (CB-CAPS, erythrocytes EC4d, EC3d), complement (C3 and C4) levels anti-dsDNA, anti-chromatin, anti-C1q and Complement Receptor 1 (ECR1).

Methods : SLE patients enrolled in this prospective biomarker study all presented with active disease. At baseline, all subjects were screened

for abnormal CBCAPS (e.g. erythrocytes C4d [EC4d]> 14 MFI). Those with disease activity accompanied by elevated CBCAPS were followed monthly for 12 consecutive visits at 4 week intervals. At each visit, the non-serological (ns) SELENA-SLEDAI (without anti-dsDNA and low complement components) and the BILAG score index were determined as was a random protein to creatinine (P/C) ratio. Short form 36 questionnaires (SF-36) were also collected. All soluble markers were determined using immunoassays, while cellular markers (EC4d, EC3d and ECR1) were determined using flow cytometry. Statistical analysis consisted of generalized linear mixed models with random intercept and fixed slopes. All investigators were blinded to CBCAPS, anti-C1q and anti-chromatin throughout the study. Anti-dsDNA titers and serum C3/C4 levels were available to investigators throughout the study.

Results : A total of 36 CB-CAPS positive SLE patients (mean age 34 years; 94% female) were enrolled and evaluated monthly for a total of 385 consecutive study visits (average 11 visits per patient). The majority of these subjects presented with anti-dsDNA positivity (64%) and low complement (72%). Clinical improvements were observed during the study, with significant decrease in ns-SELENA SLEDAI scores, BILAG index score, P/C ratio, and increase in all domains of the SF-36 ($p<0.01$). By univariate analysis, the longitudinal changes in the ns-SELENA-SLEDAI were significantly associated with all biomarkers measured ($p<0.05$). The change in BILAG index score correlated with 6/8 biomarkers ($p>0.05$ for anti-dsDNA and anti-chromatin) while the changes in proteinuria correlated with EC4d, ECR1, C3, C4 and anti-C1q. EC4d and EC3d levels were each associated with improving quality of life in 6/8 domains of the SF-36. In contrast, the other markers were each associated with 2 or fewer SF-36 domains. By multivariate analysis both complement C4 and EC3d were associated with the ns-SELENA-SLEDAI and BILAG index scores ($p<0.06$)(Table). Similarly, both complement C4 and EC4d were associated with proteinuria ($p<0.01$).

Conclusion : CBCAPS are helpful in monitoring SLE disease in combination with complement C3 and C4.

Table: Multivariate analysis of the clinical improvements

Outcome variables	Predictor 1 Complement C4 (mg/dl)	Predictor 2: EC3d or EC4d (log net MFI)
ns-SELENA-SLEDAI*	-0.11±0.004; p<0.01	0.65±0.35 p=0.06
BILAG Index	-0.25±0.07; p<0.01	2.03±0.61; p<0.01
Proteinuria (g/g)	-0.04±0.02; p=0.04	0.86±0.22; p<0.01

*For 10 mg/dl increase in C4 (predictor 1) and one log Net MFI decrease in CBCAPS (predictor 2), the ns-SELENA-SLEDAI change was -0.11x[10] + 0.65x[-1]=-1.75

Session Date: Sunday, November 8, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Epidemiological studies in systemic lupus erythematosus (SLE) have been reported in the literature in many countries and ethnic groups. Although SLE in Jamaica has been described in the past, there has not been a detailed evaluation of SLE patients in urban Jamaica a largely Afro-Caribbean population. The goal of this study was to describe the clinical features particularly disease activity, damage index and immunological features of 150 SLE subjects.

Methods:

150 adult patients (≥ 18 years) followed in rheumatology clinic at a tertiary rheumatology hospital center (1 of 2 of the major public referral centers in Jamaica) and the private rheumatology offices in urban Jamaica who fulfilled four or more SLICC criteria were included. Data was collected by retrospective chart review, detailed clinical interview and examination and laboratory investigations. Hence demographics, SLICC criteria, immunological profile, SLEDAI-2K and SLICC/American College of Rheumatology (ACR) damage index (SDI) were documented.

Results:

: Of the 150 patients 145 were female and 5 were male (F: M=29:1); the mean age at SLE onset was 33.2 ± 10.9. Mean disease duration was 11.3 ±8.6 years. The most prevalent clinical SLICC criteria was musculoskeletal with 94% of subjects experiencing arthralgia/arthritis followed by mucocutaneous manifestations of alopecia (68.7%) and malar rash (46%). The most common laboratory SLICC criteria were positive ANA (90.6%) followed by anti-dsDNA (63.3%) and low complement (C3) levels (25.3%). 27% of patients met SLICC diagnostic criteria with only a positive ANA/ds-DNA and lupus nephritis on renal biopsy. The lowest SLICC score of 3 occurred in 2 patients in whom there was a positive ANA and biopsy proven lupus nephritis. 42 patients (28%) presented with lupus nephritis and 37 patients (24.7%) had neuropsychiatric manifestations. Mean SLEDAI score was 6.9 ± 5.1 with a range of 0-32. The most frequent manifestations of active SLE was found in the immunological laboratory variables of the disease namely increased ds-DNA binding (81.3%) and low complement levels (26.7%) and the clinical variable of arthritis in 27.3%. Organ damage occurred in 129 patients (86%); Mean SDI was 2.4 ± 1.8, range of 0-9. Every single organ system was affected by damage. The most frequent organ system involved in damage was the peripheral vascular system (75 patients, 50%), neurological (47 patients, 31.3%), skin (38 patients, 25.3%), ocular (29 patients, 19.3%), diabetes (28 patients, 18.67%), cardiovascular (18 patients, 12%) and renal (15 patients, 10%).

Conclusion: These results are similar to the clinical manifestations reported in other Afro-Caribbean populations; however distinct differences exist with respect to organ involvement and damage particularly with respect to renal involvement which appears to be reduced in this cohort. These differences support the need that further studies are required among similar groups of African descent to determine the spectrum of SLE that exists within this group.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose : Clinicians are aware that the interpretation of any clinical diagnostic test and post-test probability of disease is highly influenced by pre-test probability or prevalence of the condition in which the test result is used. We have recently established that a group of primary fibromyalgia and systemic lupus erythematosus (SLE) patients can be distinguished by anti-dsDNA and cell bound complement activation products (CB-CAPS) in multi-analyte assay (MAAA) panel. The purpose of this study was to translate these findings in the context of patients evaluated for SLE or another mimicking disease by community based rheumatologists in the United States.

Methods : From February 2014 to May 2015, a total of 35,792 CB-CAPS in MAAA panels were requested by 902 physicians during the course of clinical diagnostic care of 35,792 patients (mean ± SD 51±15 years, 84% females). Venous blood was collected from all patients and shipped to our NY/CAP accredited centralized laboratory conducting routine testing for CB-CAPS (erythrocyte and B-lymphocyte C4d) plus a panel of diagnostic immunology markers including anti-nuclear antibodies (ANA) and anti-double stranded DNA antibodies. Abnormal CB-CAPs are defined by EC4d or BC4d levels above the upper 95th percentile of a group of normal healthy individuals. CB-CAPS are combined with anti-dsDNA and other anti-cellular antibodies in two consecutive tiers of analysis that produces a positive or negative assessment reported to ordering clinicians. For the purpose of this study, de-identified laboratory result assessments were extracted from our clinical laboratory information

system and analyzed in our population health data warehouse system. Pre-test probability of SLE was estimated using the method developed by Rogan and Gladen (*Am J Epidemiol. 1978 107:71)* that uses sensitivity (Se), specificity (Sp), and positivity rate (R) for the diagnostic: prevalence= [R – (1-Sp)]/(Se – (1-Sp)]. Predictive values of positive test assessments (PPV) were derived from pre-test probability using standard statistics.

Results : In this cohort of 35,792 patients, positivity rate of ANA was 49%, anti-dsDNA 5.0%, CB-CAPS 10% and CB-CAPS in MAAA panel 14% (Table). Applying the formula for estimation of SLE prevalence (pre-test probability) yielded very similar rates from 16-20%. The predictive value of a positive test (PPV) ranged from 59% to 86%. Furthermore CB-CAPS in MAAA positive test results identified of a higher number of SLE patients (n=4259) than anti-dsDNA alone (n=1047), with fewer false positive results.

Conclusion : These tests are being used by rheumatologists appropriately in patient populations where the possibility of SLE is being considered. In this context high CB-CAPs in MAA identified more true SLE patients with fewer false positive results.

Table: Derivation of pre-test and post probability of SLE in US rheumatology based practice

	Positivity Rate	Sens.	Spec.	Pre-test probability	PPV	True positive	False positive
Anti-dsDNA	5.0%	17.3%	>97.5%	16.9%	58.5%	1047	743
High CB-CAPS	10.1%	44.4%	96%	15.6%	66.6%	2408	1207
CB-CAPS in MAAA	13.9%	60.0%	>97.5%	19.8%	85.6%	4259	716

Session Date: Sunday, November 8, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Current SLE disease activity measures, such as SLEDAI and BILAG, can be challenging to score and interpret, making them impractical for use in a busy clinic and difficult to evaluate when used as outcomes in clinical trials. The LFA- REAL is composed of individual visual analog scales (0-100mm each) representing different manifestations of SLE. A clinician can quickly rate only the active features in a given patient, immediately generating organ-specific as well as total disease activity scores. The objective of this study was to compare LFA-REAL scores between clinical investigators (investigators) trained in scoring SLE disease activity instruments and clinicians without specialized SLE instrument training (clinicians), and to correlate REAL scores with other disease activity measures.

Methods: 99 SLE patients in four rheumatology clinics were evaluated, of whom 70 returned for an additional follow-up assessment. At each visit, an investigator scored SLEDAI, BILAG, PGA, and LFA-REAL and a clinician scored only the LFA-REAL. Level of agreement was determined by Spearman rank correlations.

Results : The study included 93% women, 31% Caucasian, mean age 43.4 years, mean disease duration 10 years. Mean (SD) of the disease activity scores for the first and second visits are shown below. There was excellent correlation between the clinician and investigator REAL scores at both visits (ρ=0.80 for visit 1; 0.86 for visit 2).

		SLEDAI	BILAG	PGA	REAL
Visit 1	Investigator	5.5 (4.5)	6.7 (7.8)	33.6 (24.5)	46.2 (42.9)
	Clinician	---	---	---	56.1 (53.6)
Visit 2	Investigator	5.2 (5.2)	6.0 (9.1)	31.9 (21.2)	41. 3 (36.7)
	Clinician	---	---	---	48.3 (42.6)

Global REAL scores also correlated well with the PGA, SLEDAI, and BILAG.

	SLEDAI (ρ)	BILAG (ρ)	PGA (ρ)
Visit 1 Investigator REAL Clinician REAL	0.70 0.58	0.86 0.70	0.79 0.63
Visit 2 Investigator REAL Clinician REAL	0.72 0.58	0.88 0.81	0.81 0.63
Change (V2-V1) Investigator REAL Clinician REAL	0.63 0.56	0.61 0.42	0.80 0.50

Organ specific correlations between the REAL and individual BILAG organs were > 0.7 for musculoskeletal, mucocutaneous and renal domains, for both investigators and clinicians.

Conclusion: The LFA-REAL shows promise as an efficient tool for clinical trials and for accurate monitoring of patient progress by busy clinicians without special instrument training. Community input, refinement and formal validation is planned to optimize the format, consistency and applicability of the instrument.

Evaluation of Soluble alpha-Klotho in Neuropsychiatric Systemic Lupus Erythematosus

ABSTRACT

Background/Purpose: Neuropsychiatric systemic lupus erythematosus (NPSLE) is a serious complication in SLE that presents a variety of symptoms. No reliable diagnostic markers for NPSLE have been identified, because of the variability of NPSLE manifestations and the absence of appropriate diagnostic criteria. Alpha-Klotho is a single-pass transmembrane protein expressed in multiple tissues, especially brain and kidneys. A reduction of Klotho protein is known to be associated with endothelial dysfunction and neuronal damage.

Methods: We sought to determine whether soluble alpha-Klotho (s-Klotho) in cerebrospinal fluid (CSF) could be a candidate marker for the diagnosis of NPSLE. We retrospectively analyzed the laboratory data, symptoms and radiological image findings of patients with NPSLE (n=34) admitted to our hospital during a 10-year period from 2006 through 2015. Patients with SLE (n=17), viral meningitis (VM) (n=19), multiple sclerosis (MS) (n=15) or neuromyelitis optica (NMO) (n=16) were included as controls. The s-Klotho level in the CSF of each subject was measured by enzyme-linked immunosorbent assay. We conducted univariate and multivariable competing-risks regression analyses to determine the predictive factors for diagnosing NPSLE. We also evaluated a cutoff value of s-Klotho for the diagnosis of NPSLE by determining the receiver operating characteristic (ROC) curve.

Results: There was no significant difference in the clinical background between the NPSLE and SLE patients. The median CSF s-Klotho level in the NPSLE, SLE, VM, MS and NMO groups (in pg/mL) were 136.7, 380.2, 302.1, 186.4 and 203.1, respectively. We found that the CSF s-Klotho levels of the NPSLE patients were significantly lower than those of the other groups. The multivariable analyses revealed that lower CSF s-Klotho level (odds ratio [OR], 0.98; 95% confidential interval [CI], 0.96–0.99), lower anti-Smith antibodies (U/mL) (OR, 0.93; 95%CI, 0.82–0.99) and higher C3 (mg/dL) (OR, 1.08; 95%CI, 1.02–1.18) were significant factors for predicting NPSLE. The sensitivity and specificity of the CSF s-Klotho level for the diagnosis of NPSLE were 94.1% and 76.5%, respectively at the cut-off value of 294.8 pg/mL.

Conclusion: Our data suggested that lower CSF s-Klotho levels may be associated with the endothelial dysfunction and neuronal damage in NPSLE patients. The determination of CSF s-Klotho levels may contribute to the diagnosis of NPSLE and may help elucidate the mechanisms underlying this disease.

Figure:CSF α-Klotho in NPSLE was significantly lower than SLE

	CSF α-Klotho(pg/mL)	vs. NPSLE
NPSLE, median (IQR)	136.7 (113.3 - 205.4)	-
SLE, median (IQR)	380.2 (306.8 - 527.6)	<0.0001*
VM, median (IQR)	302.1 (282.8 - 479.2)	<0.0001*
MS, median (IQR)	186.4 (158.7 - 288.5)	0.0186*
NMO, median (IQR)	203.1 (148.3 - 257.6)	0.0447*

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: A major unmet need in SLE is the identification of a biomarker that consistently tracks with disease activity. One current approach is measuring complement activation by evaluating consumption of serum C3 and C4. However, since they are acute phase reactants (Gabay & Kushner, *NEJM*, **340**:448, 1999), interpretation of these levels is challenging as serum levels may not decrease until late in a disease flare (Sturfelt & Sjoholm, *Int Arch Allergy Appl Immunol*, **75**:75, 1984). iC3b is a proteolytically derived molecule of C3b, and increases with complement activation. iC3b/C3 ratio measures complement consumption relative to production, which may provide for a more accurate assessment of complement activation. We hypothesize that blood iC3b and iC3b/C3 levels will provide as a more specific and reliable marker of complement activation and disease activity in SLE.

Methods: 90 adult SLE patients were enrolled in this observational study, encompassing 188 longitudinal visits. C3 and C4 were measured by nephelometry; iC3b using the Kypha lateral flow assay test. Linear models analysis was used to generate predictive models of S2K RI-50 scores using iC3b, C3, iC3b/C3 ratio, C4, anti-dsDNA Abs, ESR, and CRP from single visit data. Mixed model repeated measures analysis was used to evaluate longitudinal data.

Results: Using single visit data, blood levels of iC3b, C3, iC3b/C3 ratio, C4, and ESR each correlated with SLE disease activity (Table 1). Linear models analysis yielded a predictive model using iC3b/C3 ratio, C4, and ESR. In the longitudinal dataset, after modeling for variance structure, S2K RI-50 scores increased by 0.52 for every 1 unit increase in iC3b/C3 ratios (Table 2). C4 was also found to mildly influence S2K RI-50 scores.

Conclusion: iC3b/C3 ratios correlated with S2K RI-50 scores and linear model analysis confirmed the predictive value of iC3b to S2K RI-50 scores. After adjusting for both correlation and other covariates, the longitudinal data further established a significant relationship between iC3b/C3 ratios and SLE disease activity. These data warrant further investigation of iC3b as a potential biomarker for disease activity in SLE.

Table 1. Univariate and linear model analysis from single visit data

	R^2	p value
iC3b	0.138	0.0004
C3	0.172	<0.0001
C4	0.173	<0.0001

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Current validated disease assessment instruments (DAIs) in systemic lupus erythematosus (SLE) such as SLEDAI-2K and BILAG, require disease expertise and/or involve complex scoring systems, and are often impractical for use in daily clinical practice and hence are seldom used routinely in clinical practice. In an attempt to address this issue, several new simplified DAIs in SLE are in different stages of development, including SLE Activity Tracking Evaluation Tool (LAST; 14 items; includes medications, Physician Global Assessment (PhGA) 0-10 scale, Patient Global Assessment (0-10 scale), C3, C4 & anti-dsDNA lab measures), Clinical LAST (C-LAST; 11 items; similar to LAST, without lab measures), Total Lupus Activity Score (TLAS; 30 items; includes 15 physician clinical assessments and 15 patient self-assessment of lupus symptoms), and Simple Disease Assessment for People with Lupus Erythematosus (SIMPLE; 17 items; includes patient self-assessment of lupus symptoms, Lupus Impact Tracker, steroid medication, C3, C4 & proteinuria). The primary objective of this analysis is to assess the convergent validity of these various tools as well as PhGA indices in relation to SLEDAI-2K at baseline in a diverse sample of SLE patients in the US.

Methods: This is a prospective real-world observational cohort study of SLE patients receiving standard care at two academic and two private practice settings in the US. Consecutive patients meeting study criteria were screened within the study recruitment window. Physicians and patients are asked to complete their respective portions of the studied instruments at four different time points: baseline, 3 months, 6 months, and 12 months; PhGA:0-3 scale and SLEDAI-2K was completed for all patients; BILAG was assessed for patients at the academic sites; TLAS and SIMPLE for approx. 152 patients each; LAST & C-LAST algorithm for 169 patients each. Baseline data (presented here) was analyzed and Pearson correlation coefficients were calculated comparing mean SLEDAI-2K score to the individual DAI scores. Correlations with BILAG will be assessed in the longitudinal analysis in the future.

Results: A total of 201 SLE patients consented and enrolled in the study (mean age: 45 yrs; female: 91%; Black/African American (AA): 56%; Hispanic: 10%). At study entry (baseline), mean SLEDAI-2K score was 3.4 (range: 0-16); each of the DAIs (PhGA:0-10 scale, PhGA:0-3 scale, LAST, C-LAST, SIMPLE & TLAS) had a statistically significant positive correlation with the SLEDAI-2K, as shown in table-1. Analysis stratified by AA and non-AA status revealed similarly significant correlations between SLEDAI-2K and the other DAIs.

Conclusion: In the baseline cross-sectional analysis, each of the studied DAIs appeared to have convergent validity with the SLEDAI-2K. Further analyses with longitudinal data will assess additional metric properties of these instruments.

Table 1. DAI Scores and Correlations with SLEDAI-2K

Assessments	n	Median Score (IQR)	Mean Score (SD; range)	Pearson correlation with SLEDAI-2K r; p-value
LAST (0=No activity - 100=High activity)	169	23.0 (15.0-32.0)	23.9 (13.0; 0-70.0)	0.566; <0.0001
PhGA:0-10 scale (0=No activity - 10=High activity)	168	2 (1-3)	2.3 (1.9; 0–8)	0.563; <0.0001
SIMPLE (0=No activity - 100=High activity)	152	21.5 (15.1-27.8)	23.2 (11.2; 6.2-68.5)	0.560; <0.0001
PhGA:0-3 scale (0=No activity - 3=High activity)	201	1 (N/A)	0.9 (0.7; 0-3)	0.553; <0.0001
C-LAST (0=No activity - 70=High activity)	169	20.0 (12.5-27.5)	20.3 (11.1; 0-50.0)	0.450; <0.0001
TLAS (0=No activity - 120=High activity)	153	56 (50-64)	56.9 (10.8; 31.0-86.0)	0.348; <0.0001
SLEDAI-2K (0=No activity - 105=High activity)	199	2 (0-6)	3.4 (3.2; 0-16)	N/A

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Deregulation and activation of the classical complement system is known to be associated with systemic lupus erythematosus (SLE). As such, several investigators have proposed that the determination of C4d fragment, the activation product of C4 in its soluble or cell-bound form to erythrocytes (EC4d), or B-lymphocytes (BC4d) could help diagnose SLE. However, one of the challenges in

determining complement activation is the stability of these products post-phlebotomy. Our objective was to quantify the effects of time and temperature on soluble and cell bound C4d.

Methods: Venous blood was collected in EDTA-containing tubes from 12 subjects with SLE (67% females, mean age 39 years) and 15 normal healthy volunteers (NHV) (48% females, mean age 38 years). All subjects enrolled provided informed consent. Following venipuncture, the blood was equally distributed into polypropylene tubes and stored at either 4°C or ambient room temperature (22°C) for up to two days post phlebotomy. These conditions mimic the transportation condition of a typical specimen. Starting on the day of collection (day 0), and the following two days, plasma was isolated from the stored whole blood. Soluble plasma C4d concentration was determined using immunoassays (MicroVue C4d EIA, Quidel). EC4d and BC4d were determined from stored whole blood using flow cytometry and reported as net mean fluorescence intensity (MFI). The relationship between the change in the markers from baseline as a function of time and temperature was estimated with linear mixed-effect models.

Results: Soluble C4d (baseline levels 0.8±0.3 µg/ml) was significantly affected by both time (increase of 1.1 ± 0.1 µg/ml per day) and storage conditions (increase of 0.7 ± 0.1 µg/ml at ambient temperature versus 4°C) (Table 1). After two days storage at ambient temperature, soluble C4d levels increased by more than 2 fold compared to baseline plasma concentrations. By comparison, EC4d and BC4d levels were not significantly impacted by time and storage at ambient temperature. EC4d and BC4d levels were 15.9 and 62.5 net MFI after two days storage at room temperature, respectively, by comparison to 15.8 and 65.5 net MFI at day 0. In this small population of subjects, elevated CBCAPS (EC4d>14 net MFI or BC4d>60 net MFI) were 73% sensitive for SLE and 100% specific (vs. NHV).

Conclusion: Our data suggest soluble C4d is unstable during transportation and delivery of specimen to the clinical laboratory. However, cell-bound C4d is a stable measure of complement activation and could be used as complement activation biomarker in multi-centered studies.

Table 1: Estimates for biomarker change as a function of storage days and temperature. Days represent the per-day change of each marker at 4°C. Ambient temperature represents the overall increase for each marker at that temperature.

*The predicted soluble C4d concentration at 2 days storage at ambient temperature is 0.8 + 1.1×[2] + 0.7×[1] = 3.1 µg/mL

Marker (Units)	Day0 Levels (CI95%)	Days	Ambient Temperature (22°C)
Soluble C4d (µg/mL)	0.8 ± 0.3	1.1 ± 0.1	0.7 ± 0.1
EC4d (Net MFI)	15.8 ± 2.8	-0.2 ± 0.2	0.1 ± 0.3
BC4d (Net MFI)	65.5 ± 12.8	-2.0 ± 1.3	1.1 ± 2.1

Session Date: Sunday, November 8, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: In the setting of a negative ANA, antibodies to extractable nuclear antigens (ENA) should be correspondingly negative, but alternative clinical scenarios occasionally arise. This study evaluated the frequency of ANA negative/ENA positive results and associated clinical information, including diagnoses.

Methods: All patients from a single institution who underwent ANA and ENA testing on a single blood draw in 2014 were evaluated for occurrence of a negative ANA with positive ENA. ANA testing was performed via enzyme-linked immunosorbent assay, and ENA via multiplex flow immunoassay, including SS-A, SS-B, Smith, RNP, Scl70, and Jo-1. This testing was part of routine clinical practice and performed at the

discretion of the clinical provider. The first 100 individuals in chronologic order of testing were further evaluated for clinical diagnoses by review of the complete medical record.

Results: A total of 4123 patients had ANA and ENA testing performed on the same draw. The majority were ANA negative (3267, 79%). Two hundred-eighty (6.8%) had at least one positive ENA result paired with a negative ANA. Of these, the vast majority (270, 96%) had only a single positive ENA result. The most common positive result was RNP (54%) followed by SS-A (19%), SS-B (16%), and Scl70 (14%). Smith (1%) and Jo-1 (0%) were exceedingly rare. Ten patients had double positive results, with the most common combination of RNP/Scl70 in 4.

Among the first 100 patients, 61 were female. The mean (standard deviation) age at testing was 56.5 (16.0) years. Ninety-nine had a single positive result; 1 patient had a double positive of RNP and Scl70. The most common positive antibody was RNP (56%) followed by SS-A (18%), Scl70 (15%), and SS-B (12%). No patients had positive Smith or Jo-1 antibodies. Neurology was the most common specialty to order the test (28%) followed by Rheumatology (27%), Pulmonary (15%), and Primary Care (13%) with Dermatology and Internal Medicine subspecialities accounting for the remaining.

Only 1 patient had a history of lupus with diagnosis occurring 20 years earlier and no current evidence of active disease. One patient was diagnosed with drug induced lupus in the setting of TNF inhibitor use for inflammatory bowel disease. One additional patient had lupus panniculitis. Six patients were felt to have Sjögren's syndrome while another 7 were diagnosed with undifferentiated connective tissue disease. An additional 6 patients had what was felt to represent "possible" connective tissue disease. Five patients had a diagnosis of rheumatoid arthritis or seronegative inflammatory arthritis. Another patient was diagnosed with large/medium vessel vasculitis. Ten patients had thyroid disease. Four patients had diagnosis of new malignancy or recurrence. Twenty individuals had peripheral neuropathy or dysesthesias. An additional 11 patients had interstitial lung disease as a part of their presentation.

Conclusion: ANA negative/ENA positive results, while rare, do occur. It is quite uncommon to have a diagnosis of lupus but does not exclude the possibility of connective tissue disease. This emphasizes the importance of a corresponding clinical history and exam to interpret serologies.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: EULAR and ACR have jointly funded a project to improve existing SLE classification criteria, aiming at earlier and more accurate classification of the disease. This abstract reports on an early phase of that project.

ANA constitute the immunological hallmark of SLE, and ANA testing is widely used for SLE diagnosis based on its reportedly high sensitivity. Although indirect immunofluorescence on Hep-2 cells (IIF-Hep2) is considered the gold standard of ANA testing (1), the performance of different ANA titers and the possibility of including positive ANA as an entry criterion for the classification of SLE have not been systematically evaluated. We therefore reviewed the literature on the performance of IIF-Hep2 ANA testing for the classification/diagnosis of SLE.

Methods: A systematic literature search was conducted in MEDLINE, EMBASE and Cochrane trial database for articles published between January 1990 and March 2014. The research question was structured according to PICO (Population, Intervention, Comparator, Outcome) format rules, and PRISMA recommendations were followed where appropriate. Meta-regression analysis for diagnostic tests was performed using the ANA titer as independent variable and sensitivity and specificity as dependent variables.

Results: A total of 3919 publications were screened in abstract and title and 623 articles were evaluated in full-text. Of these, 61 matched the eligibility criteria and were included in the analysis. The included studies comprised 10,309 SLE patients in total, of whom 9,797 (95.0%) were reported to be ANA positive at various titers. For ANA at titers of 1:40, 1:80 and 1:160, meta-regression gave sensitivity values of 98.6% (95% confidence interval [CI] 97.7-99.1%), 97.9% (CI 96.9-98.6%) and 95.9% (CI 93.9–97.3%), respectively. The corresponding specificities were 72.5% (CI 63.8-79.7%), 79.6% (CI 72.4-85.3%) and 89.6% (CI 84.8-93.0%), respectively.

Conclusion: The results of this systematic literature search and meta-regression confirm the high sensitivity of a positive ANA test for SLE. However, a small subgroup of true ANA negative SLE patients suggests that positive ANA should not be an absolute entry criterion for classifying SLE, but that it might function well in a combined entry criterion, such as positive ANA and/or low complements.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

EULAR and ACR have jointly funded a project to improve existing classification criteria for SLE; this abstract reports on the early phase of this project. Classification criteria are being developed using multicriteria decision analysis methods. The goal of the initial phase of this project was to generate a broad set of items potentially useful for the classification of SLE and select a list of candidate items for use in forced-choice decision analysis. The aims were to include items that encompass a broad spectrum of SLE, including patients whose disease is in the early stage as well as those in the late stage, and that are in accordance with criteria used for diagnosis of SLE in clinical practice.

Methods:

Items of potential utility for SLE classification criteria were identified by a large international group of lupus clinicians in independent exercises via response to online surveys. In the first survey, respondents were asked to evaluate existing ACR and SLICC classification items and invited to propose additional, nontraditional clinical items. Submitted novel candidate items were summarized, de-duplicated, and the number of total items reduced via a Delphi process.

Results:

135 individuals were invited to participate in each survey. In the first survey, 120 (89% response rate) proposed a total of 196 unique novel items for consideration. Combining items with significant overlap resulted in 159 items, including six that each contained one or more closely related modifiers. Nine items that are difficult to routinely assess in current clinical practice (eg, “elevated MCP1”) were removed from consideration. The resulting 150 items were evaluated in a second online survey. Items achieving a threshold significance score were retained for inclusion in SLE case scenarios to be evaluated by lupus clinicians in the next phase of the project.

Conclusion:

This approach to the development of SLE classification criteria represents application of state-of-the-art methods for criteria development. The

resulting core item list will be assessed for discriminative characteristics in specific clinical scenarios to create a weighted item list. The performance (sensitivity, specificity) of the weighted item list will then be compared to existing classification criteria using data collected from SLE patients and controls.

Table. Sample submitted, novel items for evaluation in new SLE classification criteria

General manifestations	Laboratory findings	Other organ manifestations
Constitutional symptoms (fevers, fatigue, weight loss)	Anti C1q antibody	Chillblain lupus
Family history of Autoimmune disease (first and second degree relatives)	Anti chromatin antibody	Cytoid bodies (retinal)
History of miscarriages	Anti thyroid antibodies	Diffuse alveolar hemorrhage
Persistent adenopathy	Complement fragments	Early cardiovascular disease
	von Willebrand factor antigen	Interstitial lung disease
		Libman-Sacks endocarditis
		Lupus band test
		Acute confusional state
		Nasal ulcers
		Pre-eclampsia
		Persistent proteinuria (>0.5g/day)
		Pulmonary arterial hypertension

Session Date: Sunday, November 8, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

A positive ANA test is a diagnostic criterion for several rheumatic diseases, although it may appear in other autoimmune disorders and healthy individuals. An ideal diagnostic test should be both specific and sensitive. Current recommendations from ACR suggest ANA done by IIF in Hep-2 cells as an initial test to investigate autoimmunity and anti-ENA are only recommended for patients who test positive for ANA. However, there is scarce evidence of the advantages of this practice versus focalized auto-antibody evaluation according to clinical suspicion. ANA negative lupus has been reported at 5%, these patients test positive for anti-Ro/SSA and/or anti-La/SSB.

We aimed to establish the sensitivity of ANA to detect anti-Ro/SSA antibodies since we consider this stepwise approach might lead to sub diagnosing patients.

Methods: We reviewed immunological studies sent to Quest Diagnostics between January 2010 up to December 2014. Inclusion criteria were patients who had both ANA and anti-Ro/SSA done simultaneously; we excluded patients in which any one of those were missing. We obtained the sensitivity of ANA for detection of anti-Ro/SSA.

Results:

In total 900 tests were reviewed. Both ANA by IIF and anti-Ro/SSA by ELISA were done in 499 patients of whom 71 patients (14.22%) had positive anti-SSA. Of these, 33 patients (46.47%) had positive ANA and 38 patients (53.53%) had negative ANA. Considering presence of ANA at any titer as positive, sensitivity of the test was 77.5%; considering ANA positive with a titer of at least 1:320 sensitivity decreased to 46.5%.

Conclusion: The ACR recommendations of evaluating for rheumatic disease with ANA exclusively are based on cost-efectiveness more than evidence. We found a sensitivity of 77.5% at best considering any titer as positive. According to our findings 22.5% to 53.5% of individuals with positive anti-Ro/SSA could go undetected. We find the ANA test to be a poor initial test to investigate for the presence of anti-Ro/SSA antibodies. Our most important limitation is our sample size, another one is that actual autoimmune disease could not be confirmed since we did not have access to clinical data; however our findings warrant further investigation. The ANA test done by Hep-2 has a lower sensitivity in detecting anti-Ro/SSA than that reported in the literature, making it a poor screening test in patients suspected to have rheumatic disease associated with anti-Ro/SSA antibodies. Changes in the proposed diagnostic algorithm may be at hand.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

SLE is associated with a broad spectrum of autoantibodies, but currently there is no single serologic test to diagnose SLE definitively. Diagnosis is thus based on multiple ACR or SLICC criteria, including autoantibodies taken together in routine clinical settings. Anti-nuclear antibody (ANA) testing is a standard procedure in evaluating suspected lupus patients. While the test is highly sensitive [97 percent of patients with lupus will have a positive ANA test(1) (ANA+)], the test has poor specificity since approximately 13.8 % of healthy individuals test positive at a 1:80 dilution(2). As a result, ANA+ results can be misleading, leading to patient concern, unnecessary testing and even inappropriate therapy (3). A test to rule out the diagnosis of lupus in ANA+ patients without disease would be a valuable adjunct to current serological testing and important application of the SLE-*Key*TM Rule Out technology.

Methods:

We previously developed the SLE-*key*TM Rule Out test to exclude the diagnosis of SLE based on the iCHIP®(4) by profiling 250 SLE patients compared to 250 healthy controls and developing classifier algorithms. In the current study, serum samples from 136 self-declared healthy

controls were available for comparative ANA testing and were sent to an external lab for fluorescence ANA (fANA) analysis.

Results:

Four different classification methods (support vector machine, Logistic regression, linear discriminant analysis and Quadratic discriminant analysis) were used to develop and validate classifier algorithms to differentiate SLE patients from the ANA positive and negative healthy subjects. Of the 136 healthy samples, 24 samples (17.6%) were found to be ANA+ at the dilution of 1:80 by fANA testing. The SLE-Key™ classification models excluded SLE in up to 80% of these ANA+ subjects, depending on the particular statistical model.

Conclusion:

SLE-*Key*™ classifiers can successfully rule out the diagnosis of SLE in up to 80% of ANA+ subjects depending on the analytic approach. These initial findings suggest that the iCHIP™ technology can be applied to develop more refined classifications to rule out SLE in the ANA+ population.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Analyses of the association between autoantibodies and SLE clinical manifestations using cluster analyses assume that centroid and within-cluster residuals are similar inside the cluster and different between clusters. However, these antibodies and their combinations within a cluster may have different clinical impact; moreover, the residuals of two clusters may not be different enough leading to incorrect conclusions. We have therefore evaluated these associations individually and in combinations overcoming the problems noted above.

Methods: Patients with available data for anti-dsDNA, anti-histone, anti-Sm, anti-RNP, anti-Ro and anti-La from a multinational SLE cohort were included. Autoantibodies were evaluated individually and in pre-specified combinations (anti-dsDNA + anti-histone; anti-Sm + anti-RNP; anti-Ro + anti-La). About 100 clinical manifestations were systematically recorded using a common protocol. Logistic regressions were used to examine the association between autoantibodies and clinical manifestations and components of the last SLICC/ACR Damage Index (SDI) and a Poisson regression with the last total SDI.

Results: Three hundred and thirty-eight patients representative of the entire cohort (n=1480) other than for their ethnic distribution (50.6% vs. 38.1%, Caucasians; 37.9% vs. 45.3%, Mestizo and 11.5% vs. 16.6%, others p=0.001) were studied. Of them, 329 (97.3%) fulfilled ≥4ACR criteria. Mean age at diagnosis was 28.5 (SD: 11.5) years, 308 (91.1%) were female; follow-up was 4.6 (1.7) years. Baseline SLEDAI was 10.5 (7.6) and baseline SDI was 1.0 (1.3). The associations between clinical manifestations and autoantibodies are depicted in Tables 1 and 2. The associations between autoantibodies and the last SDI and its components are depicted in Table 3.

p-value for the interaction		0.017	0.027		
Individual autoantibodies					
Anti-Sm				**0.43 (0.19-0.96); 0.040**	
Anti-La		**1.52 (1.23-1.88); <0.001**			**3.18 (1.01-9.97); 0.047**

SDI: SLICC/ACR damage index. RoM: Rate of Means. OR: Odds ratio. 95%CI: 95% confidence interval.

Conclusion: Autoantibodies profiles are associated with different manifestations and damage among SLE patients. Anti-histone positivity, among anti-dsDNA positive patients and anti-La positivity were associated with damage accrual, but anti-Sm positivity among anti-RNP negative patients was negatively associated with damage accrual. The interaction between autoantibodies should be evaluated in larger populations in order to evaluate less frequent manifestations.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Our objective was to derive a cognitive map of how stakeholders perceive patient-identified facilitators to establish a theoretical framework for the purpose of developing future interventions to improve medication decision-making process for lupus patients.

Methods:

We first conducted 8 Nominal group technique (NGT) meetings and a card-sort task were used to obtain formative data from 52 lupus nephritis patients at two teaching hospitals. Patients prioritized 98 facilitators as having relatively more influence in their own decision-making processes. Next, 24 stakeholders independently grouped those 98 facilitators based on similarities. The data were analyzed using multidimensional scaling and hierarchical cluster analysis. The stakeholders also used a 5-point Likert scale to indicate their level of agreement or disagreement, with the ability of each facilitator that can be used to improve patient decision-making processes.

Results: The stakeholders included 11 physicians, 3 patients, 2 patient representatives, and 8 medical professionals. A 2-dimensional 10-cluster cognitive map provided an organizational

framework for understanding those facilitators: 1) Hope for normal/healthy life, 2) Understanding benefits and effectiveness of taking medications, 3) Minimal side effects, 4) Medication education, 5) Medication effectiveness for me, 6) Family focused, 7) Confidence in physician, 8) Reassurance about medication, 9) Medication economics, and 10) Medication research. We mapped the facilitators along 2 dimensions: the x-axis represented patients' internal needs about lupus treatment with medication education on the left and family focused on the right. The y-axis represented external issues with confidence in physician at the top, and minimal side effects at the bottom. The top 4 facilitators from each cluster are depicted in the Figure 1 and mean ratings are listed in the Table 1. Based on their ratings, stakeholders highly agreed that the hope for normal/healthy life cluster (mean ± SD, 4.67±0.12) is most important. They indicated that the Medication research cluster (3.41 ± 0.56) is least important.

Conclusion: The identified clusters generated by stakeholder agreement using cognitive mapping provide a basis for a theoretical framework, such as the theory of reasoned action, from which to develop future tailored interventions to improve patient decision-making processes.

Table 1. Clusters of Facilitators and Attributes in Each Cluster

Card#	Cards	Mean	SD
	Cluster 1: Hope for normal/healthy life	**4.67**	**.12**
1	Wanting to live as normal life as possible	4.78	.42
18	To be able to live a normal life without so many complications	4.70	.47
65	Wanting to be healthier to work/to live	4.68	.48
21	Desire to stay active/healthy	4.50	.67
	Cluster 2: Understanding benefits and effectiveness of taking medications	**4.46**	**.12**
11	Knowing how effective the medication is	4.57	.51
25	Knowing what the benefits are for me if I take the medication	4.52	.51
71	Understanding how important the medication is for me	4.30	.56
22	Getting an explanation of side effects and the benefits the medicine has for my kidney	4.43	.59
	Cluster 3: Minimal side effects	**4.26**	**.20**
68	If the medicine had the least amount of side effects	4.00	.82
72	If it does not have extreme side effects	4.35	.57
7	Knowing that it won't aggrevate other conditions (e.g., having side effects on lung)	4.22	.67
6	Knowing about the side effects	4.48	.51
	Cluster 4: Medication education	**3.65**	**.37**
87	Hearing about studies that have been done and if they were successful	3.96	.98
97	Seeing how much research is available about the medication	3.87	.97
63	Would like more research on the failure of medication	3.14	.94
37	Having proof of concept (evidence/statistics--that the medication works)	3.65	.83
	Cluster 5: Medication effectiveness *for me*	**3.65**	**.39**
81	You've tried everything else and nothing has worked	4.00	.74
88	Knowing that the drug won't affect my ability to have children	3.43	1.38
53	Having a positive outlook on my diagnosis and treatment	3.96	1.07
84	The fewer the medicine, the better	3.22	1.20
	Cluster 6: Family focused	**3.64**	**.46**
41	To be able to have a healthy pregnancy in the future	3.27	1.35
95	Being able to do the stuff that my spouse expects me to do	3.57	1.34
49	Not having to have as many doctor visits	3.41	1.05
2	My kids are the reason and I want be there for them (if I don't take the medication, I am a mess)	4.30	.70
	Cluster 7: Confidence in physician	**3.59**	**.39**
56	If the doctor tell you what he wants and expects to see happen with you if you take the medication	3.57	.73
86	It would be nice to know if the doctors are not being paid/sponsored for prescribing the medication	3.65	1.23
38	Doctor's knowledge of the drugs prescribed	4.04	.93
5	Because the doctors know more than I do	3.09	1.12
	Cluster 8: Reassurance about medication	**3.48**	**.12**
60	Hearing about people who have been treated with this medication and that it worked	3.65	1.15
83	Getting education about how the medicine would affect my pregnancy	3.43	1.38
62	If I will be able to stop taking medicine after a period of time	3.36	.90
69	Understanding how the medicine will affect my ability to have children in the future	3.45	1.44
	Cluster 9: Medication economics	**3.47**	**.12**
35	Having resources to pay for the drugs	3.57	1.08
43	Being able to afford it	3.50	1.19
4	Low cost	3.52	1.31
9	If it is affordable	3.30	1.33
	Cluster 10: Medication research	**3.41**	**.56**
19	Knowing if it is approved by FDA or is it just an experimental drug	3.04	1.11
28	Having proof that the medication works	4.22	.80
51	Researching on my own	3.39	.58
46	Knowing how long the medicine has to be taken--the shorter the better	3.00	.93
Total		**3.83**	**.56**

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a multisystemic autoimmune disease characterized by fluctuating disease activity over periods of years. The estimated 5-year survival rate of patients with SLE has improved greatly from 50% to over 90% over the last several decades, and the 10-year survival rate has also increased to nearly 90%. In patients who survive longer than 10 years, the major cause of death has become not simply active SLE itself, and recently the management of SLE has been aimed at not only remission induction and control of disease activity, but also long-term prevention of organ damage resulting from treatment and complications. In SLE patients, organ damage has been principally assessed using the Systemic Lupus International Collaborating Clinics (SLICC)/American College of Rheumatology (ACR) Damage Index (SDI), which has been extensively validated. In this study, we examined the long-term outcome, causes of death, and factors associated with damage accrual using the SDI in a single-center cohort of SLE patients.

Methods: We examined a cohort of 557 patients who had been referred to Niigata University Hospital and diagnosed as having SLE between 1961 and 2013. The patients' data at the latest visit were collected from their clinical records on April 2014, and causes of death were also defined on the basis of those data. Survival from the time of diagnosis was calculated by the Kaplan-Meier method. The SDI was calculated, and analyzed using Spearman's correlation coefficient and stepwise multiple regression analysis to reveal the factors associated with any organ damage.

Results: Data from 458 of the patients were successfully obtained. The overall 5-year survival rate was 89.9%, the 10-year survival rate was 86.0%, the 20-year survival rate was 78.6%, and the 30-year survival rate was 76.4%. The patients diagnosed after 2000 had a significantly high 5-year survival rate of 97.1%. Among 115 patients who died during the observation period, the main causes of death were infections (22.6%),

vascular disease (22.6%), and SLE-related complications (21.7%). Of the 343 patients who were alive at the time of this study, common complications were hypertension (40.8%), dyslipidemia (26.8%), diabetes mellitus (15.7%), and osteonecrosis (11.1%). The mean SDI was 0.80±1.07 and was positively correlated with age (r=0.2963, p<0.001), disease duration (r=0.1459, p<0.001), and hypertension (r=0.2299, p<0.001), whereas it was negatively correlated with administration of bisphosphonate (r=-0.115, p=0.049). Stepwise multiple regression analysis selected age (standardized beta=0.2762, p<0.001), hypertension (standardized beta=0.2267, p<0.001), and antiphospholipid antibody syndrome (standardized beta=0.1533, p=0.005) as positive independent variables, whereas administration of bisphosphonate (standardized beta=-0.1295, p=0.016) was selected as a negative independent variable.

Conclusion: These results suggest the significance of disease control as well as management of chronic complications such as hypertension and osteoporosis to prevent organ damage in SLE patients receiving long-term treatment.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Recently, the study of anti-nucleosome antibodies (ANUCs) has been suggested that they may be useful in the diagnosis of systemic lupus erythematosus (SLE) and in the monitoring of disease activity.

Our objective was to compare the diagnostic performance of ANUCs versus anti-nDNA in the diagnosis of SLE and analyze their correlation with markers of disease activity.

Methods:

ANUCs and anti-nDNA were prospectively determined in 122 patients with SLE (SLICC 2012 criteria) and 136 patients without the disease (control population). ANUC determination was determined using a dot-blot + ELISA and anti-nDNA using FEIA + IFI. For each of the antibodies, sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), positive likelihood ratio (LR+), negative likelihood ratio (LR-) and diagnostic accuracy were calculated for the SLE diagnosis. Diagnostic accuracy was calculated according to the following formula: (true positives + true negatives) / (true positives + true negatives + false positives + false negatives).

The correlation of the ANUC titer with different markers of SLE activity (SLEDAI 2K, anti-nDNA antibody titer, lymphocyte count, C3 and C4 complement fractions, ESR and C reactive protein) was analyzed using a Pearson product-moment correlation coefficient.

Results:

In the 122 patients with SLE, 80 (66%) were ANUC positive and 83 (68%) were anti-nDNA positive: 62 (51%) patients were ANUC and anti-nDNA positive, 18 (15%) were ANUC positive/anti-nDNA negative, 21 (17%) were ANUC negative/anti-nDNA positive, and 21 (17%) were ANUC and anti-nDNA negative.

Eleven (8%) patients in the control population were anti-nDNA positive, and 39 (29%) control patients were ANUC positive. Patients from the control population with positive ANUC had psoriasis (many of them were treated with anti-TNF therapy), infections (pneumonia, HCV, or HIV infection), or an autoimmune disease (pemphigus, Crohn's disease, glomerulonephritis associated with ANCA, primary anti-phospholipid syndrome, rheumatoid arthritis, or autoimmune hepatitis).

The following table shows the diagnostic value of both antibodies:

	ANUC	Anti-DNAn
Sensitivity	66%	68%
Specificity	71%	91%
PPV	67%	88%
NPV	70%	76%
LH +	2.30	8.4
LH -	0.47	0.34
Accuracy	0.686	0.806

The ANUC titer was significantly correlated with the SLEDAI-2K score (r = 0.425, p = 0.031), anti-nDNA titer (r = 0.603, p = 0.001), the number of lymphocytes (r = -0.410; p = 0.038), and ESR (r = 0.414, p = 0.036). No statistically significant correlation was observed with levels of complement or CRP.

Conclusion:

ANUCs exhibit similar sensitivity as anti-nDNA for SLE diagnosis but a lower specificity. Therefore, the presence of ANUCs does not appear to increase diagnostic accuracy.

A simultaneous determination of ANUCs and nDNA increases the diagnostic yield, whereas ANUCs are useful in diagnosing disease in anti-nDNA negative patients.

The ANUC titer was positively correlated with disease activity and can therefore be considered a complementary marker in monitoring these patients

Background/Purpose:

Assessment of systemic lupus erythematosus (SLE) is complex due to its heterogeneous manifestations and its fluctuant clinical course. Current instruments stressed one specific aspect of disease activity such as improvement, flares or ongoing activity, but clinicians should evaluate all these aspects with one-single instrument. We designed a new instrument based on classic lupus descriptors but we added parameters such as treatment modifications and changes in physician global assessment (PGA). Here we present our preliminary results.

Methods:

A cross-sectional study was performed. All the patients satisfied the 2012 SLICC classification criteria for SLE. The instrument was based on thirty descriptors grouped in one of the following categories: clinical activity (CA) (visceral, mucocutaneous and articular involvement and constitutional symptoms), physician global assessment (PGA) (0 to 3), biologic activity (BA) (SLE autoantibodies and erythrocyte sedimentation rate (ESR)) and treatment (T) (corticosteroids, DMARDs and biologic treatment). A positive score (+1 to +4) was assigned according to descriptor severity. A negative score (-1 to -3) was assigned whether both a reduction in PGA or in treatment was verified in the last month. A comparison with both SLEDAI score and SELENA-SLEDAI flare index (SFI) was performed by T test and linear regression analyses.

Results:

Fifty-two SLE patients were included, 94.5% were females. Mean age was 45.1 (± 13.9) years. Lupus nephritis was recorded in 13.4% of patients. Mean SLEDAI was 4.85 (± 2.4) and the mean value of the new instrument was 5.12 (± 3.42). A good correlation with SLEDAI was noted (r= 0.8, CI95% 0.63-0.89, p< 0.001). Thirteen patients (25%) experienced at least 1 episode of severe flare according to SFI. In those patients where a severe flare was retained by an increase of SLEDAI of more of 12 points, an increase of 15.4 (± 3.6) points was noted in the new instrument. Remarkably, in the group of patients where a severe flare was retained by steroid / immunossuppresor introduction or hospitalization, SLEDAI increased only by 5.4 (± 2.2). By contrast the new instrument showed a mean increase of 16 (±1.4) points.

Conclusion:

These preliminary data show that this new instrument has a good correlation with SLEDAI score and it is sensitive to recognize flare episodes that are not retained by an increase in SLEDAI. The performance of this instrument must be tested in a longitudinal cohort. Our future goal is to assess SLE recognizing persistent activity, flares and improvements through a one-single instrument.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: We recently reported the frequency of symptomatic osteonecrosis (ON) among systemic lupus erythematosus (SLE) patients of the lupus cohort to be 13.6%

The aim of this study is to identify predictive factors for the development of osteonecrosis in patients with SLE.

Methods:

Patients who developed ON after clinic entry were identified from the Lupus Clinic Database. ON was defined as patients with clinical symptoms and osteonecrosis confirmed by imaging (radiographs, bone scan, CT, MRI). Cases were matched to controls (SLE patients without ON) by gender, year of entry to clinic, year of birth, and disease duration.

Univariate conditional logistic regressions were carried out on each potential predictor, and variables meeting the p-value < 0.2 or clinically regarded as important risk factors were selected for multivariate regression analysis.

Results: 1781 patients with SLE were in the Lupus Clinic Database. Of these, 171 cases of symptomatic ON were identified and 162 cases were successfully matched to controls (Table 1).

Age at ON, black race, steroid-related SLICC damage, mean total cholesterol 3 years prior to ON or last visit, mean steroid dose, cumulative steroid dose, and mean duration of immunosuppressant and bisphosphonate use were included in the multivariate analysis. Mean steroid and cumulative months on bisphosphonate were independent predictors for ON adjusting for other covariates in the model, with odds ratio and 95% confidence intervals of 1.036 (1.012, 1.061) and 1.018 (1.000, 1.035) correspondingly. However, only small numbers of patients were on bisphosphonate therapy (cases = 28, controls = 16).

Table 1

	Cases (n=162)	Controls (n-162)
Female gender	148 (91.4%)	148 (91.4%)
Age at ON or last visit (years)*	36.98 ± 12.45	37.48 ± 12.34
Age at SLE diagnosis (years)*	27.77 ± 10.56	27.94 ± 9.74
Black Race	30 (18.5%)	16 (9.9%)
Disease duration at ON/last visit (years)*	9.35 ± 8.75	9.54 ± 9.05
AMS 3 years before ON/last visit*	6.17 ± 4.73	6.10 ± 5.94
AMS without dsDNA or complement 3 years before ON/last visit*	5.43 ± 4.47	5.36 ± 5.77
SLICC at ON/last visit*	1.29 ± 1.56	1.04 ± 1.63
SLICC steroid-related damage at ON/last visit*	1.07 ± 1.36	0.79 ± 1.31
Raynaud's ever before ON/last visit	83 (51.2%)	94 (58.0%)
Smoking ever at ON/last visit	49 (30.2%)	54 (33.3%)
CNS ever at ON/last visit	69 (42.6%)	61 (37.7%)
Vasculitis ever at ON/last visit	51 (31.5%)	45 (27.8%)
Arthritis ever at ON/last visit	46 (28.4%)	51 (31.5%)
Renal ever at ON/last visit	94 (58.0%)	100 (61.7%)
Total cholesterol 3 yrs before ON or last visit*	5.39 ± 1.22	5.08 ± 1.49
APLA positivity ever at ON/last visit	37 (22.8%)	41 (25.3%)
Cumulative steroids dose to ON/last visit (g)*	31.00 ± 30.11	23.74 ± 40.98
Average steroids dose to ON/last visit (mg)*	17.14 ± 11.15	11.81 ± 12.87
Antimalarial treatment before ON/last visit	103 (63.6%)	106 (65.4%)
Duration of immunosuppressive treatment before ON/last visit (months)*	22.88 ± 35.05	16.98 ± 39.06
Duration of bisphosphonate treatment before ON/ last visit (months)*	5.23 ± 20.98	2.85 ± 13.01

*Mean ± standard deviation

Conclusion: Osteonecrosis remains an important comorbidity among patients with SLE, and corticosteroid use remains a significant risk factor. Continued judicious use of corticosteroid therapy is needed in mitigating this event, and ongoing studies are needed to identify additional predictive factors.

Electronic Health Record (EHR) As a Powerful Tool to Establish Clinical Research Lupus Cohorts

Srilatha Kothandaraman[1], Frederick Ramsey[2], David Fleece[3], Aaron Sorenson[2], Lai Ping[4], Srikanth Mukkera[1], King Goh[1] and Roberto Caricchio[5], [1]Rheumatology, Temple University, Philadelphia, PA, [2]Clinical Sciences, Temple University, Philadelphia, PA, [3]Pediatrics, Temple University, Philadelphia, PA, [4]Temple University, Philadelphia, PA, [5]Medicine, Rheumatology, Temple University, Philadelphia, PA

Session Date: Sunday, November 8, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Enhancing a typical EHR through implementation and utilization of research-validated instruments is termed Electronic Data Capture (EDC). EDC is found to be more efficient than standard paper-based data collection systems for accuracy, timeliness, speed and quality. We report our experience in establishing a validated lupus cohort via EDC for clinical, quality improvement and translational research and to determine predictors of damage index as the initial validation step

Methods:

Since January 2014 customized, lupus-specific documentation flow sheets such as the Systemic Lupus Erythematosus (SLE) disease activity index (SLEDAI) and Systemic Lupus International Collaborating Clinics (SLICC) damage index (SDI) were built and deployed within our Epic Care EHR for all patients with a 710.0, ICD-9 diagnosis of SLE when seen in the rheumatology clinic. Diagnosis was retrospectively validated by the SLICC classification criteria and patients met at least four. A retrospective-prospective cohort study design was implemented in which the SLE indices were linked to longitudinal EHR data collected every visit. The EHR data include demographics, vitals, comprehensive past history, medications, and labs. An example of data linking included the aligning of lab results, which shortly preceded or immediately followed clinic visits during which SLE indices scores were recorded. All statistical analyses were performed using SAS 9.4.

Results:

180 patients were enrolled in the cohort. 61.1% were African American and a significant number were hypertensive (60%). Mean SLEDAI was 3.6. Mean SDI (n=137) was 1.4. 62% had an SDI score of ³ 1. The frequency of SLEDAI and SDI components is shown in figure 1. Factors associated with worse SDI were older age (p=0.001), female gender (p=0.09), presence of hypertension (p=0.002), positive Smith/RNP (p=0.10) antibody, elevated ESR (p=0.006) and CRP (p=0.07), use of antiplatelet/anticoagulant agents (p=0.01). Hydroxychloroquine use (79.4%) (p=0.0005), positive SS-A/B (p=0.03/0.07) and pleuritis (p=0.03) were associated with lower damage. The association of worse damage with age, hypertension and protective effect of hydroxychloroquine were analogous to the SLICC and Hopkins lupus cohort.

Conclusion:

EHR-EDC is a powerful tool for clinical and translational research. The careful design, validation and integration within the EHR along with lupus indices allow regular automatic data extraction. Therefore with the increasing availability of EHR, the generation of cohorts for lupus and other diseases should also be achievable by centers with limited clinical research resources. Finally EHR-EDC also enables routine performance assessment for continuous improvement of care for lupus patients. Our lupus cohort had significant cardiovascular burden and was associated with worse damage, therefore requiring aggressive preventive measures.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

An easy, quick tool, requiring minimal training or physician input for disease activity (DA) assessment in SLE, would have potentially greater uptake for routine use among rheumatologists and primary care physicians. Furthermore, integration into busy work flow processes would be easier for the same reason. Most DA tools for SLE are complex, require training and physician time; and are not performed during routine care visits for most SLE patients. SIMPLE (Simple Disease Assessment for People with Lupus Erythematosus) [1] is a numeric composite index based on patient reported questions and two laboratory values, and requires minimal input from health care provider which can be provided by nurse or a physician extender. Here, we prospectively evaluate the correlation of SIMPLE index with physician based DA measure.

Methods:

Fifty consenting patients meeting ACR classification criteria for SLE were recruited from two academic center clinics. Primary outcome of interest was correlation between Simple Index (SI) and SELENA-SLEDAI (SS). Secondary outcome of interest was correlation between SI and Physician Global Assessment (PGA). Patients filled the self-reported components of SI in the waiting room prior to their visit. PGA, SS and total numeric BILAG were assessed at the same visit by the physician. Descriptive and spearman correlational analyses were obtained. Stratified analysis by fibromyalgia status (FMS) was also conducted. P value of ≤ 0.05 was considered significant on two tailed tests. We considered correlation coefficient of <0.30, 0.30 to 0.49 and >0.50 as weak, moderate and strong correlation, respectively.

Results:

Mean (SD) age was 41.4+13 yrs, and 90% participants were women. Ethnic background of the participants was as follows: 56% Blacks, 24% Whites, 10% Asians and 10% others. Median (IQR) SI was 27.8 (18.3). Range for SI was 58.4. Median (IQR) values of PGA, total SS, total numeric BILAG and SDI were 0.5 (0.8), 4.0(6.0), 10.5(9.0) and 1.0(1.0), respectively. Spearman correlation coefficient between SI and PGA and SS were 0.547 (p 0.001), 0.545(p 0.001), respectively. In a sub analysis excluding fibromyalgia patients, these correlations were 0.718(p 0.001, n=34), 0.622(p 0.001, n=36) respectively.

Conclusion:

SIMPLE index is strongly correlated with PGA and SS in SLE, and the correlation is even stronger is SLE patients without FMS. It is quick, easy and requires minimal physician input. Larger and longitudinal studies that include patients with greater DA and test responsiveness are currently ongoing.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Articular manifestations affect a majority of patients with systemic lupus erythematosus (SLE), at least at some time during the disease course. Several investigators have estimated the frequency of erosive arthritis in SLE to about 5%. Detection of antibodies to 'cyclic citrullinated peptide' (anti-CCP) is an important diagnostic and prognostic tool in arthritis, since it is highly specific for rheumatoid arthritis (RA) and predictive of erosive disease. While anti-CCP reactivity in RA is citrulline-dependent, it has been suggested that anti-CCP in SLE is generally not, and thus also reacts with the corresponding 'cyclic arginine peptide' (CAP). Recently, it has been shown that antibodies targeting carbamylated proteins (anti-CarP) may occur in anti-CCP/rheumatoid factor negative cases even before the onset of RA. We analyzed anti-CCP, anti-CAP and anti-CarP in sera from patients in our well-characterized regional SLE register and related the findings to X-ray data, physical function and smoking habits.

Methods:

We included 236 patients (88% women) in the 'Clinical Lupus Register in Northeastern Gothia'. 212 had established disease, whereas the remaining 24 had recent-onset SLE at the timepoint of blood sampling. 75% met the ACR criterion for arthritis. Cases were classified as SLE according to any of the following criteria sets: the 1982 American College of Rheumatology criteria (84%) or the 2012 Systemic Lupus International Collaborating Clinics (SLICC-12) criteria (99%). IgG anti-CCP and anti-CAP ELISA kits (Euro-Diagnostica) were used. IgG anti-CarP was quantified with ELISA as previously described. X-ray data (hands, wrists and/or feet) were available in medical records of 91 cases (39%).

Results:

16 patients (6.8%), all meeting SLICC-12, were anti-CCP positive, 9 of whom were also anti-CAP positive. 4 of the 7 patients with citrulline-dependent anti-CCP had a history of biopsy-proven nephritis. 23 patients (9.7%), all meeting SLICC-12, were anti-CarP positive. Only 6 of the anti-CarP positive cases were identified as anti-CCP positive. Neither anti-CCP nor anti-CarP were associated with arthritis judged by physical examination, nor to any other SLE phenotype. The presence of anti-CarP was associated with a positive lupus anticoagulant test (Fisher's exact test, p=0.019). Smoking habits and HAQ did not associate with any of the antibodies. X-ray-proven erosions were found in 10 patients (4.2%) and were significantly associated with anti-CarP (Fisher's exact test, p=0.025), whereas the association with anti-CCP did not reach statistical significance (Fisher's exact test, p=0.07).

Conclusion:

Erosive arthritis is uncommon in SLE and our findings are in line with previous observations reporting a prevalence of 4-5%. Anti-CarP antibodies have previously not been studied in SLE. Herein, we demonstrate that anti-CarP in SLE: (1) is more frequently found than anti-CCP; (2) mainly identifies a different subgroup of cases compared with anti-CCP; and (3) associates significantly with erosive disease.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Disease Specific Patient reported outcome measure tools capture unique domains relevant to patients with a specific disease. LupusPRO is targeted towards measuring health (HRQOL) and non-health related quality of life (Non HRQOL) among patients with systemic lupus erythematosus (SLE). LupusPRO V 1.7 and its translated versions in various languages have measurement equivalence and are responsive to changes in changes in patient reported changes in health and physician based disease activity assessments. However, items pertaining to sleep, or impact of vitality and pain on quality of life were placed together in the same domain (Vitality-Pain) based on factor loadings in initial studies and in interest of parsimony. For purposes of charting changes in individual components of this combined domain (Pain-Vitality), we separated the sleep, pain and vitality items into separate domains, keeping intact the concepts, content and language of the items, in version 1.8. We present

the psychometric properties of LupusPRO v1.8, with special attention to LupusPRO domains of sleep, vitality and pain.

Methods:

Fifty consenting SLE patients fulfilling ACR classification criteria were given self-administered surveys (MOS SF36 FACIT-Fatigue, Pain, Insomnia Severity Index for sleep, Perceived Stress Scale (PSS)-4, Patient Health Questionnaire-9 (PHQ-9) for depression, LupusPRO V 1.8) to complete at routine care visit. Disease activity and damage were assessed at visit using SELENA-SLEDAI (SS), numeric BILAG and SLICC-SDI/ACR (SDI). Internal consistency reliability (ICR) for each domain was obtained using cronbach alpha. Convergent construct validity (CV) with corresponding domains of SF36 was tested using spearman correlation coefficient.

Results:

Mean (SD) age was 41.4±13 yrs., 90% participants were women. Ethnic background was as follows: 56% Blacks, 24% Whites, 10% Asians and 10% others. Median (IQR) values of PGA, total SS, and SDI were 0.5 (0.8), 4.0(6.0) and 1.0(1.0), respectively. Results for LupusPRO V1.8 domains descriptives, ICR and CV are shown in Table 1. ICR for LupusPRO sleep, vitality and pain domains exceeded 0.80. LupusPRO Sleep domain scores inversely and strongly correlated with the Insomnia severity index scores, while LupusPRO Vitality (4 items) correlated strongly with FACIT-Fatigue (13 items) and SF36 Vitality scores. LupusPRO Pain domain correlated strongly with the Pain score and SF36 Bodily pain domain. Lupus symptom domain (3 items) showed significant correlation with PGA, SS and BILAG. LupusPRO domains of Physical and Emotional Health had good ICR and significant correlation with corresponding SF36 domains (Table 1).

Conclusion:

LupusPRO V1.8 (including its sleep, vitality and pain domains) has acceptable reliability and validity. It offers significant advantages over LupusPRO V1.7 and its 36 items comprehensively cover HRQOL in SLE.

Table 1: Validity and Reliability of LupusPRO V1.8

HRQOL	Items	Median (IQR)	ICR	Conv. Validity rho (p value)
Lupus Syptoms	1-3	66.7 (41.7)	0.80	PGA -0.40 (0.02), SELENA-SLEDAI -0.36 (0.03), Numeric BILAG -0.31 (0.05)

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Sub-classification of Lupus Erythematosus (LE) patients is largely based on defined clinical criteria while biological factors associating with or contributing to these clinical features are less defined. Further elucidation of molecular events present in distinct clinical subsets of LE patients may aid in the identification of subjects more responsive to existing therapeutics, disease-classifying biomarkers and new therapeutic targets. To that end, cross-sectional studies were undertaken with SLE subjects having active skin involvement and subjects with Discoid Lupus Erythematosus (DLE) or Subacute Cutaneous LE (SCLE) to determine if LE patient subsets with skin manifestations can be molecularly distinguished.

Methods:

A prospective multicenter cross-sectional biomarker study (NOCOMPOUNDLUN0001) was undertaken with LE patients having SLE, SCLE or DLE, all with active cutaneous involvement at time of sample collection. A second single center independent study also occurred to procure SLE, SCLE, DLE and healthy volunteer (HV) samples. In total, samples from 6 SLE, 21 SCLE, 19 DLE and 10 HV were collected under informed consent. Serum collected from these donors was extensively profiled for autoantibody specificities and cytokines using ProtoArray® and DiscoveryMAP® v 3.3 systems, respectively. In addition, RNA was extracted from skin biopsy collections at lesional and/or non-lesional sites from individual subjects or from HV donors and gene expression quantified using Affymetrix arrays. All data was further analyzed using "R" software. Topological networks were created using Ayasdi.

Results:

Serum samples from DLE, SCLE, SLE and HV subjects were extensively profiled for autoantibody specificities and soluble cytokines. Protein array chips containing more than 9,000 protein features were utilized to determine if unique autoantibody specificity profiles associate with LE patient sub classifications. Antibodies against 84 distinct proteins were significantly elevated in the sera of LE versus HV subjects. 55, 10, and 16 of these were uniquely enriched in DLE, SCLE and SLE subsets, respectively. Cytokine profiling was also performed using a bead-based panel containing over 300 analytes. 75 cytokines were significantly elevated in the sera of LE versus HV subjects. Of these, 5, 33, and 5 were uniquely enriched in DLE, SCLE and SLE patient subsets, respectively. 15 cytokines were elevated across DLE, SCLE and SLE subjects versus HV. Gene expression data from skin also demonstrated unique gene signatures for each LE subset. Topological networks from this data set corroborated these findings and indicate that unique proteomic and gene expression profiles associate with specific LE patient subsets.

Conclusion:

In the LE cohorts examined, serum autoantibody and cytokine profiles were identified that distinguished subsets of cutaneous patients or were commonly elevated across SLE, DLE and SCLE subjects. These findings correlated with the identification of SLE, DLE and SCLE specific molecular pathways in skin found by gene expression array. Further studies with more subjects are required to further validate these findings.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The Coombs test is now one of the SLICC classification criteria for SLE classification. We investigated the association of the Coombs test with other clinical manifestations, in particular with autoimmune hemolytic anemia.

Methods: 2417 patients with SLE (age 50.8 +/- 14.3, 92.4% females) in a longitudinal cohort were included. The direct Coombs test was determined at cohort entry. Patients were then followed quarterly.

Results: 20% had a positive coombs test. The association of the direct Coombs test with other clinical and laboratory manifestations is shown in Table 1.

Table 1:

	Odds Ratio (95% CI)	**p-value**
Fever	1.45 (1.16,1.82)	0.0011
Lymphadenophathy	1.68 (1.34,2.11)	<.0001
Mouth Ulcers	0.69 (0.55,0.85)	<.0001
Vasculitis	2.01 (1.51,2.67)	<.0001
Leg Ulcers	2.44 (1.34,4.42)	0.0034
Panniculitis	0.97 (0.48,1.94)	0.9217
Pleuritis	1.46 (1.17,1.82)	<.0001
Pericarditis	1.46 (1.13,1.87)	0.0032
Proteinuria	2.59 (2.06,3.25)	<.0001
Nephrotic Syndrome	1.91 (1.48,2.48)	<.0001
Hematuria	2.08 (1.65,2.62)	<.0001
Renal Insufficiency	1.97 (1.53,2.53)	<.0001
Seizure	1.57 (1.11,2.21)	0.0099
Psychosis	1.94 (1.14,3.3)	0.0149
Hemolytic Anemia	12.76 (9.34,17.44)	<.0001
Leukopenia <4	1.78 (1.42,2.22)	<.0001
Platelet<100	2.19 (1.72,2.8)	<.0001
LAC (RVVT)	2.14 (1.7,2.71)	<.0001
Anticardiolipin	1.63 (1.3,2.04)	<.0001
Anti B2 glycoprotein	1.9 (1.43,2.52)	<.0001
Sjogren's Syndrome	0.52 (0.38,0.72)	<.0001
Hepatomegaly	2.86 (1.7,4.82)	<.0001
Splenomegaly	2.75 (1.75,4.33)	<.0001
Anti-dsDNA	3.19 (2.43,4.18)	<.0001
Anti-Sm	1.81 (1.41,2.32)	<.0001
Anti-Ro	1.66 (1.32,2.09)	<.0001
Anti-La	1.63 (1.21,2.19)	0.0013
Anti-RNP	1.71 (1.35,2.16)	<.0001
Low CH50	2.34 (1.73,3.15)	<.0001
Low C3	3.17 (2.47,4.08)	<.0001
Low C4	3.32 (2.61,4.22)	<.0001
ESR	4.68 (3.23,6.8)	<.0001

Only 38% of those with the direct Coombs test ever developed an autoimmune hemolytic anemia. Those who did develop hemolytic anemia were significantly more likely to have renal and CNS-SLE (Table 2).

Table 2:

	OR (95% CI)	P-value
High School Education	0.26 (0.13,0.53)	0.0001
Fever	1.94 (1.28,2.93)	0.0017
Pericarditis	1.75 (1.12,2.74)	0.0137
Nephrotic Syndrome	1.72 (1.09,2.71)	0.0192
Renal Insufficiency	1.94 (1.25,3.02)	0.0031
Renal Failure	3.02 (1.61,5.66)	0.0006
Seizure	2.41 (1.33,4.37)	0.0039
Meningitis	3.92 (1,15.38)	0.0505
Stroke	3.28 (1.35,7.93)	0.0085
Thrombocytopenia	1.95 (1.27,3)	0.0023
Anticardiolipin	0.59 (0.39,0.89)	0.0132
Heart Murmur	2.14 (1.41,3.23)	0.0003
Hepatomegaly	5.75 (2.24,14.76)	0.0003
Splenomegaly	2.73 (1.32,5.68)	0.0070

Conclusion: The direct Coombs test is strongly associated with hemolytic anemia but only 38% develop hemolytic anemia. Those who do develop hemolytic anemia are more likely to have had renal or CNS-SLE. Direct Coombs positivity that leads to hemolytic anemia portends a particularly poor prognosis.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The Intervention to **I**mprove **Q**uality of life for **A**frican-America**N** lupus patients (IQAN) Project is designed to examine whether a uniquely tailored intervention program can improve quality of life, decrease indicators of depression, and reduce perceived and biological indicators of stress in African American lupus patients. This study builds on three decades of work conducted in the field of arthritis self-management but differs in that the intervention mode, the disease (lupus), and the study population (African-Americans) are unstudied or understudied.

Methods: A unique 'a-la-carte' self-management program was offered to 50 African-American lupus patients participating in a longitudinal observational web-based SLE Database at the Medical University of South Carolina (MUSC). Each individualized intervention plan (IIP) included 1-4 options, including a mail-delivered arthritis kit, addition and access to a message board, participation in a support group, and enrollment in a local self-management program. A 'set menu' control group of 50 lupus patients was offered a standardized chronic disease self-management program only, and a control group of 50 lupus patients received usual care (UC), void of intervention components. Validated measures of stress, depression, and quality of life were collected in all patients in each condition before and after intervention activities. All participants met at least four components of the 1997 ACR revised criteria for SLE. In order to evaluate changes between baseline and 6 months post-intervention and 12 months post-intervention, compact scores were calculated after merging similar variables within the same topic area. Compact scores were then compared for each group, using two-sample t-tests.

Results: Between baseline and 6 months post-intervention, marginally significant improvements were observed in areas of stress management and pain management. The mean number of times participants applied stress management techniques increased from 0.69 to 1.68 in the intervention group ($p=0.05$). Improvements in the other two groups were not significant. The mean score of the intervention group increased from 8.83 to 11.29 ($p=0.08$) in the frequency of managing pain by applying positive techniques, but the other two groups did not display such improvements. Between baseline and 12 months post-intervention, an increasing trend persisted in the intervention group in the frequency of applying stress management techniques ($p=0.02$). Additionally, decreasing trends in activity limitation were observed in both the intervention and set-menu control groups.

Conclusion: Self-selection of program components has not been explored as an approach to improve disparate trends in quality of life, disease activity and depression, and stress among African-American lupus patients, but better self-management outcomes have been documented when participants are able to choose/dictate the content and/or pace of the respective treatment/intervention program. As there is currently no "gold standard" self-management program specifically for SLE, the IQAN project may have a considerable impact on future research and policy decisions.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Self-management (SM) skills are vital to the physical and emotional health adolescents with systemic lupus erythematosus (SLE). These self-management skills may also affect successful transition to independent self-care. We developed an online educational course for young adults with SLE as well as a social media site where participants could discuss the content of the educational site, or other spontaneous issues, during the 8 week intervention.

Methods: SLE patients were recruited to participate in an 8-week, 8 module online SLE educational course. Participants were randomized to answer questions at the end of each week either in a written journal (control) or on a social media site (SM). Outcome measures were examined in the entire group and between the two groups before and after the intervention. These measures included medication adherence (as measured by the Medication Adherence Self-report Inventory (MASRI) and the Mediation Possession Ratio (MPR)), empowerment processes and outcomes, sense of agency (SOC) and sense of community (SOC), quality of life (as measured by the Simple Measure of Impact of Lupus Erythematosus in Youngsters (SMILEY), and self-efficacy (using the Children's Arthritis Self-Efficacy Scale (CASE) questionnaire.

Results: 33 SLE patients, ages 13-24, participated in the study. The control (N=15) and SM (N=18) groups were similar in age, race, gender, and disease duration. The overall mean MPR and MASRI were quite high for this group of subjects. The mean MPR and MASRI for all subjects improved throughout the study. All of the secondary measures described, including SOC, SOA, empowerment outcomes, and quality of life, improved over the course of the study as well. Some measures showed a more robust improvement in the SM group, including SOA, SOC, and CASE. In particular, those participants who participated in the SM group had significantly better empowerment outcomes as compared to the control subjects.

Conclusion: We have developed an online education intervention for young adults with SLE, which improves self-management skills. Additional involvement in social media with other young adults with SLE appears to improve empowerment. This intervention would be ideal for a multi-site trial.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment Poster Session I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

The risk of high-grade squamous intraepithelial lesions is significantly increased in SLE patients compared with healthy female controls. High-risk human papillomavirus infection (HR-HPV) is associated with the risk of cervical dysplasia and carcinoma. However, longitudinal studies analyzing HPV persistence in SLE women are limited. Our objective was to study the incidence, persistence, cumulative prevalence, and clearance of HPV infection in patients with SLE and to assess risk factors for the acquisition and persistence of HPV infection.

Methods:

Prospective, observational cohort study of 127 SLE women. Patients were evaluated at baseline and at 3 years. Traditional and SLE-related disease risk factors were collected. A gynaecological evaluation and cervical cytology screening were made. HPV detection and genotyping were made by PCR and linear array.

Results:

The cumulative prevalence of HPV infection increased significantly (22.8% at baseline vs. 33.8% at 3 years; p = < 0.001). With respect to type-specific HPV infection, 20.1% of patients experienced 42 incident infections. The risk of acquiring any HPV infection was 10.1 per 1000 patient-months. The cumulative prevalence of HR-HPV infection (19.6% at baseline vs. 29.1% at 3 years; p = 0.007) and multiple HPV infection (11.0% at baseline vs. 15.7% at 3 years; p = 0.03) also increased significantly. The most frequent newly-acquired HR types were HPV-16 (2.4 per 1000 patient-months) and 53 (1.4 per 1000 patient-months). Detection of the same type of HPV at two examinations occurred in only 6 (12.8%) of incident infections. At 3 years, 41 (87.2%) prevalent infections were cleared. Independent risk factors associated with incident HPV infection included higher number of lifetime sexual partners (OR= 1.8, 95% CI= 1.11-3.0) and cumulative cyclophosphamide dose (OR= 3.9, 95% CI= 1.2-12.8). Potential risk factors associated with persistent HPV infection included lupus activity at baseline (p = 0.03) pre-existing HVP infection (p = 0.008), and multiple HVP infection at baseline (p < 0.001). However, those possible associations were not confirmed when logistic multivariate analysis was performed.

Conclusion: In women with SLE, the cumulative prevalence of HPV infection, including HR-HPV and multiple HPV infections, increased significantly over time. Most persistent infections were LR-HPV. Number of lifetime sexual partners and cumulative cyclophosphamide dose were independently associated with incident HPV infection.

Session Date: Sunday, November 8, 2015

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Umbilical cord (UC)-derived mesenchymal stem cells (MSCs) have been confirmed to exert therapeutic effects on systemic lupus erythematosus (SLE). Deficiency in SLE macrophages exhibits excessive activation and inefficient clearance of self nuclear antigens. However, whether the benefit effect of UCMSCs on SLE was mediated by regulatory effects on macrophages remains to be elucidated. We aim to explore whether UCMSCs could educate SLE macrophage to become a kind of alternatively activated macrophage and increase its phagocytic activity.

Methods: UCMSCs were injected into B6.MRL-*Fas*^{lpr} mice. The therapeutic effects of MSCs transplantation were evaluated by the renal pathology, proteinuria, spleen index, T lymphocyte subpopulation and plasma cells. Murine peritoneal/renal macrophages were isolated to detect the proportion of alternatively activated macrophage (F4/80^{+}CD206^{+}). To determine the phagocytic activity of murine peritoneal/renal macrophages, FITC-labeled flurospheres were added into the cultures. The uptake of FITC-labeled flurospheres was determined by flow cytometry. CD14^{+} monocytes were isolated from peripheral blood of healthy donors (HC) and SLE patients. We cultured human monocytes for 7 days with macrophage colony-stimulating factor (M-CSF) to generate macrophages, and then cocultured them for 2 more days with UCMSCs in a transwell culture system. The levels of CD206 and phagocytic activity of macrophages were detected by flow cytometry.

Results: Compared with C57BL/6 mice, B6.MRL-*Fas*^{lpr} mice macrophages exhibited lower level of CD206, the marker of alternatively activated macrophages. In addition, the phagocytic activity of B6.MRL-*Fas*^{lpr} mice macrophages was also decreased. UCMSCs transplantation could rescue both the proportion of CD206^{+} macrophages and the phagocytic activity. Interestingly, the proportion of CD206^{+} macrophages was positively correlated with the phagocytic activity. Similar to the lupus mice, macrophages from SLE patients showed lower expression of CD206 and phagocytic activity. SLE macrophages cocultured with UCMSCs consistently increased the expression of CD206 and phagocytic activity. In addition, the up-regulation of phagocytic activity by UCMSCs was only appeared in CD206^{+} macrophages. This phenomenon was also observed in UCMSCs transplanted SLE patients. Furthermore, the addition of specific neutralizing antibodies/inhibitor/siRNA of HGF, TGFβ1, PGE2 and HO-1 could not reverse the effects of UCMSCs on SLE macrophages.

Conclusion: UCMSCs could alleviate SLE through promoting the generation of CD206^{+} macrophage and increasing its phagocytic activity, and these effects was independent of HGF, TGFβ1, PGE2 and HO-1.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Discoid lupus erythematosus (DLE) is the most common form of chronic cutaneous lupus. Lesional skin of DLE patients contains macrophages that may transition from a pro-inflammatory M1 subtype to an anti-inflammatory M2 subtype, and vice versa. To test our hypothesis that M1 macrophages would be increased in DLE skin, we examined macrophage features in DLE and normal skin using histochemical and gene expression approaches.

Methods: DLE lesional and normal control skin samples were analyzed for CD163 expression by immunohistochemistry. Gene expression of RNA from both skin groups was compared by microarrays and quantitative RT-PCR. Double immunofluorescence studies were performed to characterize protein expression of CD163^{+} macrophages.

Results: CD163^{+} macrophages were increased near the epidermal-dermal junction and perivascular areas in DLE lesional skin compared with normal skin. Gene set enrichment analysis comparing differentially expressed genes in DLE and normal skin with previously published gene sets associated with M1 and M2 macrophages [1] showed strong overlap between up-regulated genes in DLE skin and M1 macrophages ($p=0.02$) (Table 1). Quantitative RT-PCR showed that several M1 macrophage-associated genes (e.g. CXCL10 (47.2 fold change (FC), CCL5 (25.9 FC), STAT1 (11.96 FC), TNF-α (1.92 FC), CD127 (8.01 FC), $p<0.05$) had amplified mRNA levels in DLE skin (Figure 1a-e). However, double immunofluorescence studies of CD163^{+} macrophages revealed co-expression of M1 (CXCL10, TNF-α, CD127), and M2 (CD209, TGF-β) macrophage-related proteins in DLE skin.

Conclusion: The variation of macrophage subtypes in DLE skin may reflect their propensity to switch polarization and possible transition from a M1-dominant acute phase to an M2-dominant chronic phase, though this requires verification. Macrophage plasticity makes these cells ideal targets for future therapies.

High mobility group box-1 (HMGB1) affects macrophage polarization and phagocytosis in systemic lupus erythematosus patients.

F Schaper, G Horst, K de Leeuw, H Bootsma, PC Limburg, P Heeringa, M Bijl, J Westra

Background/Purpose: Decreased phagocytosis of apoptotic cells, leading to necrosis and exposure of nuclear autoantigens, plays an important role in the pathogenesis of Systemic Lupus Erythematosus (SLE). One of these nuclear autoantigens is High Mobility Group Box 1 (HMGB1), which acts as an alarmin when secreted. Increased serum levels have been found in SLE patients. We hypothesized that increased HMGB1 levels might lead to skewing in the differentiation of monocytes into M1 macrophages, instead of M2 macrophages. As M1 macrophages are less efficient phagocytes this might fuel SLE. We studied expression of M1 and M2 markers of peripheral blood monocytes and *in vitro* differentiated macrophages of SLE patients were compared to healthy controls (HC). Phagocytic capacity of macrophages and the effect of HMGB1 on differentiation of macrophages and phagocytosis was also investigated.

Methods: For this study SLE patients with quiescent or mild disease (SLEDAI 0-5) and age- and sex-matched HC were included. Monocytes and differentiated M1 and M2 macrophages were phenotyped by flow cytometry for expression of CD86 (M1 marker) and CD163 (M2 marker). Monocytes of 19 patients and HC were isolated by negative sorting and analyzed by RT-qPCR to determine mRNA levels of CD86, TLR2, TLR4, TNF-α, IL-6 (M1) and CD163, Mannose Receptor, and IL-10 (M2). HMGB1 was added (4 or 24 hours) during M2 differentiation to investigate the effect on macrophage phenotype and effect on phagocytosis of apoptotic Jurkat cells.

Results: Expression of CD86 on monocytes was similar between patients and HC, but expression of CD163 was significantly lower on monocytes from SLE patients ($p=0.022$). Moreover, IL-6 mRNA levels were significantly increased in monocytes of patients ($P<0.0001$). After cytokine induced differentiation no differences were observed between M1 and M2 macrophages from SLE patients and HC regarding surface receptor expression and phagocytic capacity. Addition of HMGB1 during differentiation of M2 macrophages resulted in high IL-6 and TNF-α mRNA expression in macrophages. Preincubation of HMGB1 with apoptotic Jurkat cells resulted in reduced phagocytosis by M2 macrophages.

Conclusion: Monocytes from SLE patients display an M1-like phenotype, shown by decreased expression of CD163 and increased IL-6 mRNA expression. *In vitro* differentiation abolishes these differences between SLE and HC. HMGB1 induces differentiation into M1-like phenotype and reduces phagocytosis of apoptotic cells. So, this study shows that the phenotype of monocytes or macrophages is determined by their environment, such as presence of cytokines and HMGB1, and thereby contributes to the pathogenesis of SLE.

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Our previous gene expression studies in sorted immune cell populations in SLE has shown that different cell types from the same blood sample demonstrate diverse gene expression parameters. These studies also suggested that heterogeneity in gene expression runs deeper than major immune cell subsets. In this study, we examine IFN signatures in single monocytes isolated from SLE patients.

Methods:

$CD14^{++}CD16^{-}$ classical monocytes (CLs) and $CD14^{dim}CD16^{+}$ non-classical monocytes (NCLs) from 14 SLE patients were purified by magnetic separation. The Fluidigm single cell capture and pre-amplification System was used for single cell capture and target gene pre-amplification. Fluidigm Biomark system (Rt-PCR system) was used to quantify expression of 87 monocyte-related genes. IFN-induced genes in monocytes were identified by culturing monocytes isolated from whole blood of healthy controls with or without IFN-α. Genes significant up-regulated by IFN were identified as IFN-induced genes in current study. Limit of Detection (LOD) of Rt-PCR was set at 28 cycles. An individual cell IFN score was given based upon the sum of expression of IFN-induced genes. Hierarchical clustering was generated by using Cluster 3.0 and Java Treeview.

Results: Both CLs and NCLs demonstrated a wide range of expression of IFN-induced genes, and NCL monocytes had higher IFN scores than CL monocytes. Hierarchical clustering of all cells displayed clustering of cells in subsets within the CL and NCL lineages, as well as expression patterns that were shared by both lineages. We found four gene sets that clustered monocytes functionally. These included an IFN-induced gene set, two inflammatory gene sets, and one immunosuppressive gene set. Interestingly, we could define a large subset of NCL monocytes with upregulation of suppressive transcripts (including TGF-β and PDL1) and IFN-induced transcripts were also upregulated, while the two inflammatory gene sets were down-regulated. These cells were highly over-represented in a patient with inactive disease who was on immunosuppressants at the time of blood draw. The proportion of anti-inflammatory gene set expressing NCLs was inversely correlated with anti-dsDNA titers (rho = -0.77, p=0.0051) and positively correlated with C3 complement (rho = 0.68, p=0.030) in the SLE patient group, suggesting that these cells are also associated with serological quiescence.

Conclusion: Using single cell gene expression, we have identified a unique population of NCL monocytes in SLE patients with upregulation of a combination of anti-inflammatory and IFN-induced transcripts. These cells correspond with clinical and serological quiescence.

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis Poster I
Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disorder that arises from genetic and environmental factors. Thus, patients with different ancestral backgrounds display differences in clinical presentation and severity that are likely a result of variation in cell physiology. Prior to SLE diagnosis, most SLE patients transition from anti-nuclear antibody negative (ANA-) to anti-nuclear antibody positive (ANA+), however, ANA positivity does not obligate autoimmune disease. Understanding differences in immune cell physiology between ANA+ healthy individuals and individuals that go on to clinical SLE remains a critical goal in the understanding of SLE etiology and is likely to vary by ethnicity.

Methods: Blood specimens and information on disease activity were collected from 56 European American (EA) and 38 African American (AA) individuals classified as either ANA- healthy controls, ANA+ healthy individuals or SLE patients. SLE patients were matched by age (±5 years), race, and gender to an ANA+ and ANA- healthy control. Single-cell analysis of cell surface markers was completed by mass cytometry on PBMCs and cellular heterogeneity was visualized using viSNE. Further, phospho-specific flow cytometry was used to measure basal levels of pERK, pPLCγ2 and p38 and expression following CD3/CD28 (TCR) and anti-IgG and IgM (BCR) stimulation.

Results: Compared to ANA- controls, EA ANA+ individuals had a higher frequency of myeloid cells ($p=0.048$), specifically myeloid derived suppressor-like cells ($CD33^{+}CD11b^{+}HLA\text{-}DR^{-}CD14^{\pm}$) were higher in ANA+ individuals ($p=0.037$) compared to SLE patients. Further, EA SLE patients had an increased frequency of $CD14^{+}CD33^{-}$ activated monocytes compared to healthy controls ($p<.05$), which positively correlated with SLEDAI disease activity ($p=0.040$). EA effector T cells had elevated basal levels of p38 and pERK ($p<0.005$) in ANA+ individuals compared to ANA- controls. However, following TCR stimulation, the fold change of pERK and p38 in effector CD4+ T cells was significantly decreased in ANA+ individuals and remained the same in SLE patients compared to ANA- controls ($p<0.05$). Interestingly, AA SLE patients and ANA+ individuals had no myeloid cell differences, but did have variations in B cell and CD4+ T cell subsets. Decreased frequencies of transitional B cells ($CD27^{-}CD38^{+}CD24^{+}$) were observed in AA SLE patients compared to both healthy controls ($p=.007$). In addition, $CD4^{+}CD27^{+}$ T cells were elevated in AA SLE patients compared to controls ($p<0.05$). AA SLE patients had higher basal expression of p38 and pERK in myeloid cell subsets. Following BCR stimulation, ANA+ AA individuals had increased fold change in myeloid cell pERK compared to ANA- controls ($p=0.026$), however, B cell pERK expression following BCR stimulation was decreased in SLE patients compared to ANA+ individuals ($p=.0225$).

Conclusion: Our results indicate that early differences in myeloid cell subsets of European Americans and lymphocyte subsets of African Americans may contribute to loss of tolerance and systemic inflammation in autoimmunity. Further, differences in cell signaling in SLE patients and ANA+ individuals may enhance these defects.

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a devastating autoimmune disease with severe complications such as immune-complex mediated nephritis and scarring skin lesions. Treatment modalities for cutaneous lesions are often ineffective and pathogenic mechanisms driving rash development remain poorly understood. Interleukin-6 (IL-6) is a pro-inflammatory cytokine which has gotten recent attention in SLE as IL-6 is increased in the serum of active patients and blockade of IL-6 is therapeutic in several murine lupus models. Further, several phase I human trials have suggested IL-6 blockade may be promising for treatment of SLE. However, the role that IL-6 plays in cutaneous lupus erythematosus (CLE) rashes remains unclear.

Methods: All studies were approved by the University of Michigan Internal Review Board (IRB# 72843 and 66116). RNA was isolated from formalin fixed, paraffin-embedded biopsies of CLE rashes, which were obtained from the University of Michigan Pathology database. Real-time PCR was used to determine the expression level of the myxovirus (influenza virus) resistance 1 (MX-1) and interleukin-6 (IL6) genes. Biopsies were stained for IL-6 using immunohistochemistry. Skin biopsies were obtained from uninvolved skin of SLE patients with a history of cutaneous involvement or healthy controls followed by isolation and culture of keratinocytes. At confluence, cultures were treated with various concentrations of TLR ligands or UVB and IL-6 release was measured via ELISA.

Results: Real-time PCR analysis of subacute cutaneous lupus erythematosus (sCLE) (n=21) and discoid (DLE) (n=22) rashes demonstrated a significant upregulation of both the IFN-regulated gene, MX1, and the pro-inflammatory cytokine IL-6 when compared with control samples (n=9). Immunohistochemical analysis of skin biopsies confirmed upregulation of IL-6 in the epidermis when compared to control. Keratinocytes from healthy skin of lupus patients produced significantly more IL-6 when stimulated by TLR2, 3 or 4 agonists or exposed to UVB radiation when compared to identical passage keratinocytes from healthy controls.

Conclusion: IL-6 is increased at the RNA and protein level within cutaneous lupus biopsies when compared to healthy control skin. Keratinocytes are a major producer of IL-6 in the skin and lupus keratinocytes have enhanced production of IL-6 in response to TLR ligands and UV radiation. These data suggest that the epidermis, which is an important barrier for environmental insults, is primed for IL-6 production and that this may be one mechanism by which factors such as UV exposure may trigger rash development. Further investigations should focus on the pathogenic significance of IL-6 upregulation in the skin and whether targeting this pathway will have an impact on cutaneous disease activity.

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Cutaneous lupus rashes can be substantial, disfiguring, and often refractory to usual lupus therapies. Phenotypic presentation and risk of systemic lupus manifestations differs by rash subtype and pathogenic factors contributing to rash remain poorly understood. For this study, we evaluated the transcriptional profiles of discoid lupus (DLE) and subacute cutaneous lupus (sCLE) rashes and characterized them in the context of contributing cellular populations and the unique profiles which may contribute to individual rash phenotype.

Methods: Formalin-fixed paraffin-embedded (FFPE) tissue blocks of 26 DLE and 27 sCLE rash biopsies were acquired from the University of Michigan Anatomic Pathology repository. RNA was isolated from five 10 micron sections and analyzed via Affymetrix ST 2.1 array. Gene expression changes were compared to 7 similarly treated and isolated healthy control biopsies. Genomatix, Ingenuity and *in silico* immunophenotyping were used for data analysis.

Results: Using q-value of <0.01 and|log Fold Change|>1 as filters, we identified 394 genes commonly upregulated and 175 genes commonly downregulated in sCLE and DLE compared to control. Genomatix analysis confirmed enhancement of known lupus-associated pathways (especially type I interferon (IFN) regulated genes), and transcription factor analysis revealed important gene regulation by STAT1, STAT4 and IRF1. Upregulation of TLR2 and inflammasome-associated genes were also noted. Immunophenotypic analysis demonstrated a significant proportion of upregulated genes were likely to be derived from myeloid cells within the skin. Alternatively, many of the downregulated genes were associated with keratinocytes. 173 genes were uniquely regulated in DLE and 116 genes were uniquely regulated in sCLE. Unique to DLE, a strong upregulation of IFN gamma associated pathways was noted and Ingenuity pathway analysis identified IL-4 as a likely prominent regulator of DLE-specific gene expression. In sCLE, type I IFN signaling predominated and unique expression of CD14 and the chemokines CCL20 and CCL2 were seen.

Conclusion: These data suggest that DLE and sCLE have overlapping and unique changes which may guide pathologic phenotype. Importantly, the role of myeloid populations in cutaneous lupus pathogenesis should be considered. Confirmation and further study of these identified dysregulated genes may identify targets for novel therapy of cutaneous lupus lesions.

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Neutrophil extracellular traps (NETs) consist of decondensed chromatin and antimicrobial peptides and are able to trap and kill pathogens. Several studies suggest a pathogenic role for NETosis in autoimmune disease (AID), such as systemic lupus erythematosus (SLE), ANCA-associated vasculitis (AAV) and rheumatoid arthritis (RA). For investigation of NET triggers in relation to AID, NET release should be quantified with a standard and reliable method. Thus far, methods for NET quantification are heterogeneous, e.g. based on fluorescence microscopy, measuring DNA release or measuring other NET components. The aim was to develop an assay for inducing and quantifying NETs, preferably applicable to use in a high-throughput system.

Methods:

Neutrophils were isolated from healthy volunteers and were labelled with a membrane staining, PKH26, for visualization in immunocytochemistry (ICC). Neutrophils were seeded in a 96-well plate and incubated with different stimuli. IgG aggregates were used as a positive control. Extracellular DNA was stained with Sytox green. Further stainings used were Hoechst, anti-myeloperoxidase (MPO), anti-neutrophil elastase (NE) and anti-citrullinated histon3 (acitH3). Images were obtained with a BD Pathway 855 that was programmed to automatically and randomly obtain pictures from different locations within the well. Titration experiments with IgG aggregates were performed to induce NET release and image NETs with a 10x, 20x and 40x magnification lens. Subsequently NETs were quantified and the results obtained with different lenses were compared to find the optimal magnification for NET visualization and quantification.

Results:

We found that IgG aggregates were able to induce NET release in a dose-dependent manner. NET release in this assay was confirmed with acitH3, NE and MPO stainings. We quantified the amount of NETs with ImageJ software, by determining the ratio between positive Sytox green area and the positive PKH26 area, of which we found that it accurately represents the amount of cells present. NET quantification using different magnification lenses showed that the 20x magnification was able to capture the same amount of information compared to the 40x magnification and was able to increase the area for analysis up to 11% of the total area compared to the standard 2%.

Conclusion:

We developed a semi-automatic and reproducible system that reliably quantifies the NET-inducing capacity of many samples simultaneously and that is applicable as a high throughput system.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: While type I interferon (IFN) has been linked to atherosclerosis progression in systemic lupus erythematosus (SLE), little is known about its regulation and intervention. In this study, we assessed the effect of IFN-alpha on several classic atherosclerosis related factors, including macrophage migration inhibitory factor (MIF), vascular endothelial growth factor (VEGF) and numbers of peripheral endothelial progenitor cells (EPC), and explored the role of artesunate (ART), an anti-malarial agent extracted from Chinese herbs, on this process.

Methods: Levels of MIF and VEGF in serum or cultured supernatants were measured by ELISA, and numbers of peripheral EPC were detected by flow cytometry. Their relationships with IFN scores that calculated by 5 type I IFN gene (LY6E, OAS1, OASL, ISG15 and MX1) expression levels were assessed by Spearman correlation analysis. ART at different concentrations was added to human umbilical vein endothelial cells (HUVEC) cultures with or without prior IFN- alpha 1b stimulation and to SLE peripheral blood mononuclear cells (PBMC) cultures. To find out how ART regulated IFN signaling, the levels of total and phosphorylated (p) STAT1, 3, 5 in cultured HUVECs were tested by Western blot.

Results: Compared to age- and gender- matched normal controls, SLE patients had lower EPC numbers, lower VEGF levels, but higher MIF levels (all $p < 0.0001$). The reduction of EPC numbers and the increase of MIF levels were tightly correlated with the elevation of IFN score in SLE patients (both $p < 0.001$). *In vitro* cultures showed that HUVEC produced significantly higher amount of MIF after IFN-alpha stimulation, while VEGF levels varied at different time periods by showing a decline after 12 hours stimulation but an increase at 24 hours. ART at 20 μmol/L significantly suppressed IFN-alpha promoted VEGF and MIF production at 24 hours, along with the dramatic decline of IFN inducible gene expressions. Similar to that in HUVEC, ART treatment also inhibited VEGF and MIF production in SLE PBMC cultures. As shown in Figure 1, over-expression of p-STAT1, but not p-STAT3 or 5, was detected after IFN-alpha stimulation, which was completely reversed at the presence of ART.

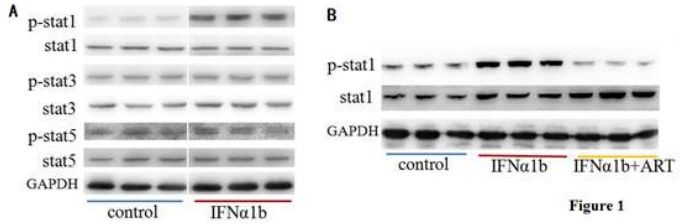

Figure 1

Conclusion: Our data supports a potential role for type I IFN signaling in atherosclerosis. ART may down-regulate IFN-alpha modulated pro-atherosclerotic factors through the inhibition of STAT1 phosphorylation, thus could have therapeutic effect on SLE-associated atherosclerosis.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Type I interferon (IFN) signaling has been a central pathogenic pathway in systemic lupus erythematosus (SLE). The application of specific inhibitors of IFN pathway has emerged as a promising treatment for SLE and it would be interesting to pharmacologically modulate the sensitivity to IFNa receptor stimulation .In this study, we screened 463 genes to identify novel regulators and tried to find a novel therapeutic target for the over-activated IFN signaling in SLE.

Methods:

High throughput ISRE-luciferase assay was used to screen candidate genes regulating IFN signaling pathway. Western blot was used to investigate IFN signal transduction. qRT-PCR was used to detect the expression of individual ISGs. Differential expression of CDK1 and ISGs between SLE patients and healthy controls was analyzed using data from RNA-seq and microarray experiments.

Results:

We developed a high-throughput ISRE-luciferase assay by co-transfection of ISRE-luciferase plasmids with a siRNA library of 463 genes in HELA cells. 60 genes which significantly enhanced ISRE activity (greater than 2 folds) and 14 genes which inhibited ISRE activity (approximately 50% reduction) were identified. And then we analysed expression of candidate genes in whole blood from SLE patients and healthy donors by using microarray data. As CDK1 could effected ISRE activity obviously and had a differiential expression between SLE patients and healthy control.What's more , CDK inhibitors also functioned in many clinnical trials for malignancy disease,we wonder whether CDK1 inhibitor could be a repositioning drug for SLE. Since we have seen that CDK1 enhanced IFN induced ISRE mediated reporter gene expression, we further tested the expression of ISGs and IFN induced phosphorylation of STAT1 could also be altered by knocking down CDK1 . After identifying the vital effect of CDK1 on IFN signaling, we wondered whether CDK1 was responsible for the amplified IFN signaling in SLE patients. We found CDK1 was over-expressed in peripheral blood mononuclear cells (PBMCs) and renal biopsies of SLE patients and was positively correlated with the "IFN scores". Meanwhile, CDK1 expressed higher in the patients with severe disease than those with mild or moderate disease. Since we have proposed that CDK1 might be the reason for excessive IFN signaling in SLE, we further tested if CDK1 inhibitor, RO-3306, could alleviate the over-activated IFN signaling in SLE patients. PBMCs obtained from 5 SLE patients who had high IFN scores were treated with RO-3306 and the expression of ISGs were significantly reduced.Meanwhile, RO-3306 could also function in kidney cells from lupus mice expressed high level of ISGs . These indicated a potential role of RO-3306 as a candidate for modulating IFN signaling sensitivity in SLE patients.

Conclusion:

Our data suggest that CDK1 is a positive regulator of IFN signaling pathway. Over-expression of CDK1 in SLE might contribute to the abnormally amplified type I IFN signaling and inhibition of CDK1 could be used to interfere with the type I IFN signaling in SLE. Our data extend the knowledge of specific mechanism of abnormal IFN signaling pathway in SLE, and indicate a novel therapeutic target for SLE treatment.

Session Date: Sunday, November 8, 2015
Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

The type I interferon (IFN) system is important in the pathogenesis of systemic lupus erythematosus (SLE). We have previously shown an inhibitory effect of IFN-α on interleukin (IL)-6/IL-1 mediated hepatocyte production of C-reactive protein (CRP) *in vitro* as well as *in vivo*, partly explaining the poor correlation between disease activity and circulating CRP in SLE. The non-hepatic long pentraxin 3 (PTX3) belongs to the same protein family, and shares some key properties with CRP regarding the handling of cellular debris. This study aimed to evaluate PTX3 as a potential biomarker in SLE, as well as to assess its possible interference with IFN-α by targeting levels in patients and in mechanistic studies on isolated leukocytes.

Methods:

Sera from 243 SLE patients meeting the 1982 ACR and/or the 2012 SLICC classification criteria, and 100 healthy controls were analysed for PTX3 (ELISA) and IFN-α (dissociation-enhanced lanthanide fluoroimmunassay). Disease activity (SLEDAI-2K) varied considerably among the SLE patients at the time point of blood sampling. The majority had established SLE, whereas 9% had recent onset disease.

Neutrophils and peripheral blood mononuclear cells (PBMC) were isolated by density gradient centrifugation of heparinised blood from healthy donors. Leukocyte PTX3 production was stimulated by IL-1β, tumour necrosis factor (TNF), lipopolysaccharide (LPS), and IFN-α. Cell supernatants were analysed for PTX3 by ELISA.

Results:

PTX3 levels were significantly lower in SLE patients (median 2.5 ng/ml) compared to healthy controls (median 4.5 ng/ml); ($p < 0.0001$). PTX3 levels were not correlated with SLEDAI-2K, but with leukocyte-associated variables. Cross-sectional analysis revealed a slight negative correlation between PTX3 and IFN-α ($r=-0.154$, $p=0.017$). Patients with no detectable IFN-α (<1 U/ml) had however significantly higher levels of PTX3 (median 2.7 ng/ml) compared to patients with IFN-α >1 U/ml (median 2.1 ng/ml; $p=0.01$).

In vitro experiments showed IFN-α dependent inhibition of stimulated PTX3 production in healthy blood donor PMBC. No such effect was observed in neutrophils.

Conclusion:

Average PTX3 levels are lower in SLE patients compared to controls. IFN-α partly inhibits leukocyte PTX3 production *in vitro*, and its inverse correlation with PTX3 in SLE implies that IFN-α mediated suppression of PTX3 synthesis also occurs *in vivo*. Since pentraxins have a suggested protective role in SLE, these findings are of interest regarding the handling of apoptotic material and the pathogenesis of SLE.

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

: Epigenetic changes have been described in systemic lupus erythematosus (SLE) and offer a potential explanation for the chronicity of disease. We previously found a global increase in histone H4 acetylation (H4ac) in SLE monocytes and transcription factor motif analysis found 63% of genes with increased H4ac had potential interferon regulatory factor (IRF) 1 binding sites within the 5kb upstream region. We identified specific H4 lysine acetyl groups with significant hyperacetylation in SLE monocytes, as well as an imbalance in specific histone acetyltransferases (HATs) and histone deacetylases (HDACs) in favor of hyperacetylation. We then demonstrated that IRF1-overexpression can drive H4 hyperacetylation and showed IRF1 recruitment of HAT p300 to target genes with increased IRF1 binding and pathological expression in SLE monocytes.

IRF1 is highly inducible by prolactin, a hormone implicated in the pathogenesis of SLE: hyperprolactinemia has been reported in 15-33% of SLE patients as compared to 0.4-3% of controls. Prolactin upregulation of IRF1 can lead to H4ac in Nb2 T cells, representing a potential pathological pathway in SLE. Prolactin-induced IRF1 activation in primary monocytes and THP1 cells was examined, with the aim to identify IRF1 interactions with histone acetyltransferases (HATs) and histone deacetylases (HDAC) leading to pathological H4ac in SLE.

Methods:

Flow cytometry for acetylated H4 lysines: K5, K8, K12, K16 were run on the Accuri C6 with isotype controls. H4ac was defined in primary monocytes from 12 normal males under both unstimulated and prolactin-stimulated conditions. Real-time quantitative reverse transcription polymerase chain reaction (qRT-PCR) evaluated HAT/HDAC expression in monocytes. IRF1 activation by prolactin in primary monocytes was studied by immunofluorescence confocal microscopy. Further interactions of IRF1 and HATs/HDACs were studied in THP1 cells by ChIP analysis.

Results:

Flow cytometry found significantly increased total H4ac, H4K5, H4K8, H4K12, and H4K16 acetylation (p = 0.01, 0.01, 0.01, 0.002, 0.04) in monocytes stimulated at prolactinoma levels (2000 ng/mL); acetylation at total H4ac, H4K5, H4K8, H4K12, and H4K16 was also increased at pregnancy levels (200 ng/mL).

Immunofluorescence showed translocation of IRF1 from the cytoplasm to the nucleus in prolactin-stimulated primary monocytes at both 200 ng/mL and 2000 ng/mL cells by 1 hr, demonstrating IRF1 activation.

qRT-PCR studies of HAT/HDAC expression patterns found increases in PCAF and ATF2 expression monocytes stimulated by prolactin that was dose dependent (p = 0.12 and 0.05). This is comparable to the increase in PCAF expression that was seen in SLE. Additionally, ChIP assays in THP1 cells suggested that prolactin-stimulation can recruit p300 to IRF1 and prolactin target genes.

Conclusion:

These data demonstrate that prolactin stimulation of monocytes induces IRF1 activation and a pattern of acetylated H4 that corresponds to the changes seen in SLE. This helps to explain the known association of prolactinomas with SLE. The identification of candidate HATs that associate with IRF1 in the context of prolactin stimulation may provide for potential therapeutic targets in SLE.

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

SLE patients have increased expression of interferon-stimulated genes (ISG) and multiple autoantibodies. Some patients initially present with early incomplete SLE (E-ILE) with ANA but not full SLE criteria. These patients may or may not progress to established SLE. To understand progression of autoimmunity, we compared autoantibodies and ISG expression between E-ILE and established SLE.

Methods:

We studied patients with SLE (≥4 ACR/SLICC criteria (n=86)), E-ILE (1-3 ACR/SLICC criteria including ANA <1 year (n=23)), RA (n=19), and age and sex matched healthy controls (n=20). 33 Type 1 ISGs were analysed in PBMCs using TaqMan®. Relative expression was ln-transformed and normalised to HC (value - HC mean / HC SD) and summed to give a 33-gene-IFN score. Antibodies to dsDNA, Ro52, Ro60, La, Sm, RNP and Chromatin were analysed using Bioplex-2000. Two-way ANOVA was used to compare IFN score vs. presence of extractable nuclear antigens (ENA) between groups.

Results:

Descriptively there was a strong relationship between interferon score and diagnosis of SLE. Mean (95% CI) IFN score was 3.0 (-12.2, 18.2) in RA, which was not substantively different from the HC mean (0). IFN score was considerably higher than HC in SLE [45.6 (34.8, 56.3)]. In E-ILE, IFN score was intermediate [22.3 (0.9, 43.7)]. Formal statistical comparisons were not attempted due to the variation in sample sizes between the groups.

There was a strong relationship between autoantibody status and interferon score. Interferon score was significantly higher in those with positive ENA antibodies (all $p<0.05$) but did not differ according to anti-dsDNA status (Fig 1).

This relationship between ENA status and interferon score was stronger in E-ILE (mean score ENA negative -25.6 vs. positive 47.8) than in established SLE (negative 22.9 vs positive 59.7; interaction=0.099; Fig 2). Indeed, in ENA-negative E-ILE, mean interferon score was significantly lower than HC ($p=0.027$).

Conclusion:

ISG expression is increased in E-ILE in patients with antibodies to ENA, but is low in their absence. In established SLE, ISG expression is higher, and interferon activity is increased even in the absence of ENA antibodies. This suggests that during progression to established SLE there is increasing dysregulation of interferon activity. This may be due to: diversification of the antibody repertoire during progression (not measured by this assay), or because in established SLE IFN becomes stimulated by other immune mediators or tissue damage. Longitudinal follow up will help resolve this question.

STAT1 Activation Promotes TLR8 Overexpression and Facilitates Mirokine Signaling Via Exosomes Containing a Mir-21 Endogenous Ligand: A Novel Innate Inflammatory Pathway in Systemic Lupus Erythematosus

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

The adaptive arm of the immune system plays a significant role in the pathophysiology of Systemic Lupus Erythematosus (SLE). However, recent studies suggest that innate immunity may also serve an important pathological role. Toll-like Receptor-8 (TLR8) is an innate immunity receptor that binds to single-stranded viral RNA sequences that is regulated by the transcription factor STAT1 and is also upregulated by estrogen. Intriguingly, recent work has uncovered that miR-21 can act as an endogenous TLR8 ligand in cancer cells via an exosomal delivery approach.

Methods:

Microarray data was acquired from a publicly available database. Peripheral Blood Mononuclear Cells (PBMCs) from patients meeting the ACR 1997 criteria for SLE or healthy controls were treated with estrogen, miR-21, and a known TLR8 agonist. To examine the functional significance of STAT1 and Estrogen Receptor-a (ERa), siRNA targeted against these proteins was utilized. Samples were collected at various time points for qPCR or Western blot analysis. Liposomal complexes containing fluorescently-labeled miR-21-Cy3 (red) were incubated with THP-1 cells; cells were imaged in real time using fluorescent microscopy and TLR8 expression was measured by qPCR.

Results:

Microarray data indicated an over 4-fold increase in myeloid cell STAT1 expression in patients with SLE as compared to healthy subjects. Estrogen stimulated STAT1 expression and phosphorylation of STAT1 were enhanced at the protein level in primary human cells and cell lines. Using siRNA to target either STAT1 or ERa, estrogen-mediated TLR8 induction was inhibited. Stimulation with miR-21 not only greatly induced expression of STAT1 but TLR8 expression was also significantly upregulated.

Conclusion:

Analogous to a cytokine or chemokine, exosome-encapsulated miR-21 can function as an inflammatory signaling molecule, or miRokine, by virtue of being an endogenous ligand for TLR8. Collectively, our data elucidates a novel innate inflammatory pathway in SLE by showing that estrogen-mediated expression of STAT1 promotes TLR8 expression, which can subsequently be activated and further stimulated by miR-21. Our data suggest that endogenous TLR ligands functioning through miRokine signaling may significantly influence autoimmune inflammation. Future focus of this work will be to identify additional agonists and to block exosomal miRNA signaling using antagomiR-based silencing.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

IFN-alpha is a pathogenic factor in SLE. High serum interferon activity (IFN-high) marks a subgroup of SLE patients strongly associated with increased disease severity and autoantibody formation. Genetic variations associated with risk for SLE are enriched within this subgroup, however differences in the cellular immune system between IFN-high and IFN-low patients remain largely unknown. In this study, we sought to better characterize the IFN-high and IFN-low subgroups in human SLE by studying relevant immune cell subsets, and stimulated cytokine responses post whole blood stimulation by Toll-like receptor (TLR) agonists.

Methods:

SLE patients (n= 25) meeting ACR criteria for SLE and healthy controls (n=10) were recruited. Serum IFN-activity scores were calculated using the WISH assay, and used to bin patients as IFN-high and IFN-low. Demographic and serologic data were analyzed. Immune cell subsets including plasmacytoid dendritic cells (pDCs) and $CD19^{+}CD24^{hi}CD38^{hi}$ regulatory B cells (Bregs) were quantitated by flow cytometry of whole blood. Microspheres allowed for the quantitation of absolute numbers of CD24 and CD38 receptors on Bregs. Whole blood was dispensed into tubes coated with the TLR agonists LPS, CpG and R848 (Tru-Culture.) The stimulated IFN-alpha production was measured by WISH. Flow and Tru-Culture stimulation were performed within 6 hours of less of phlebotomy.

Results:

Of the 25 patients studied, 9 were IFN-high and 16 were IFN-low. Compared to IFN-low, IFN-high patients were younger (39.0 versus 46.5 years) and had more autoantibodies such as anti-Sm and anti-dsDNA, similar to previous studies. Medication usage was not significantly different between groups. The frequency of circulating pDCs was significantly lower in IFN-high SLE patients as compared to controls ($p=0.0159$). The frequency of Bregs and their surface expression of CD38 was also lower in IFN-high compared IFN low and controls. With respect to TLR signaling, both IFN-high and IFN-low SLE patients responded more robustly to R848 stimulation than controls. Interestingly, IFN-high patients responded more dramatically to LPS than IFN-low SLE patients ($p<0.05$), and controls ($p=0.05$).

Conclusion:

We have observed clinical and novel biologic differences between IFN-high and low SLE subgroups. The fact that pDC counts were only reduced in the high IFN patients would suggest trafficking out of the circulation and into inflamed tissue prior to IFN production. We find decreased Breg numbers and decreased CD38 expression in the IFN-high patients, which could indicate decreased regulatory potential from this cell type in high IFN SLE. Finally, our study demonstrates that IFN-high patients are significantly more responsive to TLR4 stimulation– a novel finding that may shed light on differential responses to SLE therapies. Further studies of Breg function in SLE and the stimulated inflammatory cytokine response are ongoing.

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

With higher prevalence of renal and cardiovascular diseases (CVD), as well as HTN, African American (AA) SLE patients experience accelerated damage accrual and excess morbidity and mortality. Genome wide association studies have identified two Apolipoprotein L1 (APOL1) risk variants (RV) in individuals of African Ancestry which confer an evolutionary advantage in resisting African Trypanosomiasis, but an increased risk of renal failure and CVD in homozygous carriers across many disease states. As an innate immune factor, APOL1 expression is regulated by inflammatory conditions. This study focused on RV dependent clinical correlates in SLE, and the interaction between the SLE inflammatory milieu and APOL1 expression.

Methods:

Genotyping was done by conventional PCR/sequencing in 93 AA SLE subjects. Chart review furnished clinical data including demographics, comorbidities, medications, and laboratory values. Serum sE-selectin (as a marker CVD risk) was measured by ELISA and mean concentrations stratified by carrier status (ancestral, RV heterozygous, RV homozygous). APOL1-genotyped primary human endothelial cells (ECs) isolated from healthy AA fetal cord tissue were used to address inflammation-dependent APOL1 expression. Inflammatory conditions present in SLE were simulated using IFNα and supernatants from TLR stimulated macrophages. PCR products were genotyped to establish concordance with chromosomal DNA.

Results:

The ancestral (WT/WT), RV heterozygous, and RV homozygous groups comprised 37.6%, 49.4%, and 13% of the cohort respectively. Subjects were AA (100%) and predominantly female (90.3%). There were no significant differences in age, SLE duration or disease activity (SLEDAI scores), current proteinuria, or history of nephritis among the groups. However, a significantly increased risk of hypertension in heterozygous (OR: 3.6 p: 0.01) and homozygous (OR: 5.6 p: 0.04) RV subjects vs ancestral controls, supported an incomplete dominance model. In the RV heterozygous and homozygous groups, increased sE-selectin concentration was associated with SLEDAI >8, increased dsDNA, and decreased C4 (p= 0.009, 0.003, 0.03 respectively). In contrast, there were no associations between the above parameters and sE-selectin in the ancestral group (p= 0.93, 0.53, 0.57 respectively). Primary EC cultures from 5 healthy subjects (WT/WT= 1, RV/WT= 2, RV/RV= 2) were plated in serum free media, IFN-α, or supernatant from macrophages previously activated with ssRNA, hY3 (SLE-relevant TLR 7/8 agonist). Cells were > 95% CD31 positive by FACS analysis. At 4 hours IFN-α alone, and macrophage supernatants increased APOL1 expression 9.21 fold (+/-1.8; p= 0.001) and 3.99 fold (+/-0.61; p= 0.0004) vs no treatment, respectively. RV heterozygous cells showed biallelic expression on genotyping of the qPCR product. Fold increase of sE-selectin was 2.24 (+/-0.2) (p=0.009) in response to IFNα.

Conclusion:

Chronic inflammation in SLE may lead to RV over-expression in EC and resultant systemic endothelial dysfunction. In AA SLE patients, tighter inflammatory control may be a step forward in preventing APOL1 RV-related damage in vascular beds.

Session Date: Sunday, November 8, 2015

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Patients with SLE have an increased risk of cardiovascular disease (CVD), which is not fully explained by traditional risk factors and may be mediated by systemic inflammation and autoantibodies. Increasing interest has focussed upon the involvement of pro-coagulant serine proteases (SP), thrombin (Thr) and Factor (F)Xa, in atherosclerotic plaque formation. These SP have extended cellular/inflammatory effects beyond coagulation through their activation of protease activated receptors (PARs). Direct inhibitors of FXa and Thr have been shown to reduce pro-inflammatory effects and stabilise atherosclerotic plaque in ApoE mice. Levels of anti-FXa and anti-Thr IgG are raised in patients with SLE compared with healthy controls, but the effects of these IgG on atherosclerosis are unknown. Here we explore associations between presence and number of sub-clinical atherosclerotic plaques detected by a vascular ultrasound study in 100 patients with SLE and the presence of anti-FXa and/or anti-Thr in the same patients.

Methods:

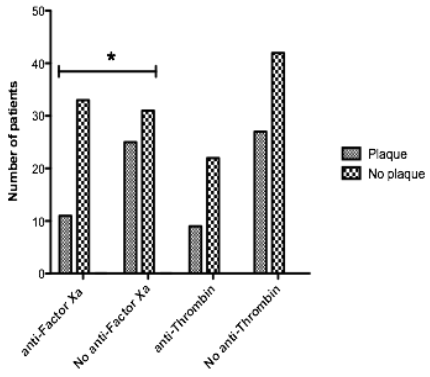
Carotid and femoral arteries of 100 patients fulfilling ACR criteria for SLE but with no history of previous CVD were scanned by ultrasound. We recorded presence of plaque, number of plaque sites, total plaque area and intima media thickness. Serum samples from these patients, taken at or near the time of scanning, were tested for anti-FXa and anti-Thr IgG by ELISA. Statistical analysis of the association of antibody positivity/negativity and presence/absence of plaque was determined by chi^2 test.

Results:

Of the 100 patients, 95% were female with mean age of 45.2 (range 20-66, SD 12.4) years. Overall, 36% had plaque and 64% had no plaque. Anti-FXa IgG were found in 44% and anti-Thr IgG in 31% of all patients. Anti-FXa IgG positivity was seen in 33/64 (52%) of patients without plaque and 11/36 (31%) of patients with plaque ($p<0.04$). Among the 36 patients with plaque, the number of plaque sites per patient was lower in anti-FXa positive than in anti-FXa IgG negative patients ($p<0.02$). Although anti-Thr IgG positivity was also higher in patients without plaque (22/64 = 39%) compared to patients with plaque (9/36 = 25%), this difference did not reach statistical significance ($p=0.3$). There was no association between anti-Thr positivity and number of plaque sites.

Conclusion:

Patients with SLE who were positive for anti-FXa IgG had reduced atherosclerotic plaque burden (presence and total number of sites) compared with patients who were anti-FXa IgG negative. A similar relationship however, was not found between anti-Thr IgG and plaque. Further research is now required to determine whether anti-FXa IgG may be protective against the pro-atherogenic effects of FXa in patients with SLE.



Patients with SLE and atherosclerotic plaque are less likely to have Factor Xa antibodies than patients with SLE without atherosclerotic plaque (* p value<0.0422). There was no association between anti-thrombin positivity and atherosclerotic plaque.

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: B19 virus (B19V) is common, infects all ages, and is associated with various clinical syndromes including SLE-like autoimmunity. We previously demonstrated that B19 NS1, a superfamily 3 (SF3) viral helicase, is expressed in human cells non-permissive for virion production, damages host cell DNA by single strand nicking and bulky adduct formation, induces apoptosis, and produces apoptotic bodies (ApoBods) that are internalized by phagocytic cells. We hypothesized that ApoBods containing B19 NS1-modified DNA could break tolerance to self DNA. We developed an *in vivo* mouse model in which mice were inoculated with B19 NS1-induced ApoBods; we then examined serum dsDNA antibody production and tissue damage.

Methods: A baculovirus expression vector was used to tranduce B19 NS1 in HEp-G2 cells. ApoBods were harvested from culture supernatants at 72 hours post transduction. ApoBods generated by an inducer of apoptosis, staurosporine, were used as a positive control for ApoBods. BALB/c mice were untreated or injected subcutaneously with PBS, or 25 µg, 50 µg or 100 µg, respectively, of B19 NS1-induced ApoBods or staurosporine-induced ApoBods. Pristane, known to induce a lupus-like murine disease, was used as a positive control for autoimmunity induction. Serum dsDNA antibodies were examined with a *Crithidia luciliae* indirect immunofluorescence assay (IFA) using an anti-mouse IgG conjugate and quantitated with an in-house dsDNA ELISA. Paraffin-embedded tissue sections were examined for immune cell infiltration and damage.

Results: The *Crithidia* assay demonstrated positive kinetoplast and nuclear fluorescence staining with sera from mice treated with pristane, staurosporine ApoBods, or B19 NS1 ApoBods. dsDNA antibody by ELISA from 100 µg B19 NS1 ApoBod treated mice was significantly higher than untreated ($p<0.0001$), PBS-treated ($p<0.0001$), 100 µg Staurosporine ApoBod-treated ($p<0.0006$), and pristane-treated mice ($p<0.02$). Tissue histology revealed immune cell infiltration in kidney, brain, liver, and heart in treated groups, but not in untreated or PBS control groups.

Conclusion: B19 NS1 ApoBod inoculation induces dsDNA autoantibodies and tissue damage. While B19 NS1 ApoBod-, staurosporine ApoBod-, and pristane-treated mice all had tissue damage and dsDNA antibody by *Crithidia* testing, the B19 NS1 ApoBod-treated group had significantly elevated dsDNA antibody by ELISA compared to the other groups. This study supports the hypothesis that B19V and possibly other SF3 helicase-expressing viruses, such as Epstein-Barr virus, can induce tissue damage and dsDNA antibody production above that seen with ApoBods alone; dsDNA antibody production may be induced through helicase modification of self DNA.

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Periodontitis is an inflammation of the soft and hard tissues supporting the tooth. *Aggregatibacter actinomycetemcomitans (Aa)*, a gram negative bacterium, is strongly associated with the aggressive form of periodontitis, particularly in young females. *Aa* and its toxins induce apoptotic cell death in immune cells and hence can modulate the mucosal immune responses. In this study, we tested the hypothesis that an infection with *Aa* is associated with increased autoimmunity in lupus patients.

Methods: Circulating antibodies to *Aa* are indicative of an ongoing or prior infection with the organism. Thus, serum antibodies to *Aa* in lupus patients and controls from the Oklahoma cohort of rheumatic disease were measured by ELISA. The lupus patients with anti-*Aa* antibody units higher than mean+2SD of controls were classified as positive for anti-*Aa*. To determine the association between anti-*Aa* and autoantibodies to lupus-associated antigens (dsDNA, Ro/SSA, La/SSB, Sm, RNP, Ribosomal P, and Jo-1), contingency tables were constructed and statistical significance calculated using Fisher's exact test. Neutrophil extracellular traps (NETs) are suspected to be the source of autoantigens in lupus. Thus, the ability of *Aa* to induce NETosis was tested by using bone marrow derived neutrophils from lupus-prone mice. NET formation was evaluated by staining for DNA and citrullinated histones.

Results: A significant number of lupus patients (128/534, 23.97%) were positive for anti-*Aa* antibodies, compared to controls (1/21; 4.76%; p=0.037). Stratification of lupus patients by race showed that African American patients had significantly higher anti-*Aa* antibody titers as compared to patients of Caucasian origin. However, regardless of the race, anti-*Aa* antibody positivity was significantly associated with higher anti-dsDNA (p=0.002). No association was observed with other autoantibody specificities. Incubation of neutrophils with *Aa* readily induced NETosis.

Conclusion: This study shows that an ongoing or prior infection with the periodontogenic bacterium *Aa* is associated with increased anti-dsDNA in lupus patients. Our data suggests the possibility that *Aa* induced NETosis might be involved in the amplification of anti-dsDNA response in lupus patients. Considering that the incidence of periodontitis is higher in African Americans, our study provides a strong rationale to investigate the possible link between periodontal disease and lupus in African American patients

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: SLE is a multisystem autoimmune disease that displays quantitative and qualitative deficiencies of regulatory T cells (Treg), notably because of a compromised IL-2 production. Signaling lymphocyte activator molecule receptor family 3 (SLAMF3) is a type I transmembrane receptor implicated in co-regulatory mechanism of T cell activation. We examined the effects of SLAMF3 mediated co-stimulation on the IL-2 response of peripheral $CD4^+$ T cells from SLE patients.

Methods: T cells or naive CD4+ T cells isolated from SLE patients and matched controls were stimulated with plate bound anti-CD3, anti-SLAMF3 and/or anti-CD28 antibodies. Cells were then stained for surface markers (CD4, CD8, CCR7, CD45RA, CD25, CD122, CD127, SLAMF3), for intracellular cytokines (IL-2) and/or transcription factors (pSTAT5, FoxP3) and analyzed by flow cytometry. CD25 mRNA levels

were evaluated by qPCR, and pSTAT5/STAT5 ratio by western immunoblots. Cells proliferation was determined by CFSE dilution. Treg differentiation was performed on naive $CD4^+$ T cells cultured under Treg polarizing conditions (in the presence of IL-2 and TGFb) for 6 days. Suppression capacity was determined by assessing the proliferation of autologous CFSE-labeled T cells in the presence of induced Treg.

Results: Stimulation of naive $CD4^+$ T cells with anti-CD3/anti-SLAMF3 upregulated surface CD25 (IL-2Ra) and CD122 (IL-2Rb), at higher level compared to anti-CD3/anti-CD28 activation. Anti-CD3/anti-SLAMF3 co-stimulation of naive $CD4^+$ T cells led to increased phospho-STAT5 (pSTAT5) levels compared to anti-CD3/anti-CD28 activation. Although naive $CD4^+$ T cells from SLE patients displayed decreased pSTAT5 levels compared to control subjects upon anti-CD3 or anti-CD3/anti-CD28 stimulation, co-stimulation of SLE T cells with anti-SLAMF3 restored pSTAT5 to a normal level. The effect of SLAMF3 on the IL-2/IL-2R/STAT5 signaling pathway does not occur through increased IL-2 production, as the percentage of IL-2 producing cells remained comparable between anti-CD3 and anti-CD3/anti-SLAMF3 mediated co-stimulation. Exogenous IL-2 increased proliferation of anti-CD3/anti-SLAMF3-activated $CD4^+$ T cells compared to anti-CD3/anti-CD28 stimulation. Naive $CD4^+$ T cells activated with anti-CD3/anti-SLAMF3 under Treg polarizing condition expressed high levels of FoxP3 and CD25, low level of CD127, and, more importantly, exhibit a potent suppressive effect.

Conclusion: SLAMF3-mediated co-stimulation enhances naive $CD4^+$ T cell response to IL-2 in SLE patients and promotes Treg generation. These results suggest that using a monoclonal antibody directed against SLAMF3 may increase the response to IL-2 in conditions where its availability is compromised, like SLE.

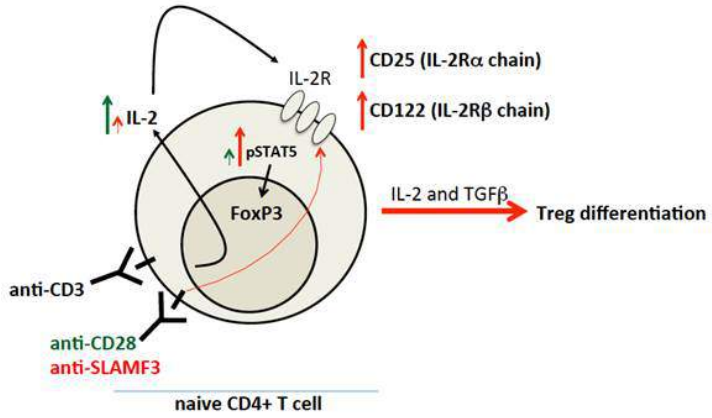

Figure 1. SLAMF3 mediated co-stimulation promotes the IL-2 response of naive CD4+ T cells

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Inducible costimulator (ICOS) is an immunostimulatory receptor that belongs to the CD28/CTLA4 family. ICOSL (ICOS ligand), which belongs to the B7 family, is the ligand for ICOS and is crucial for T helper cell and B cell differentiation. The costimulatory signal of ICOS/ICOSL in T cell/antigen presenting cell interactions might be involved the pathogenesis of systemic lupus erythematosus (SLE). Clinical trial of monoclonal antibody targeting ICOSL in SLE is underway. However, the expression of ICOSL and the role of ICOS/ICOSL signaling in

the interactions between T cells in the pathogenesis of SLE are not well characterized. We investigate the expression and function of the ICOSL on T cells in patients with SLE

Methods: To investigate the expression of the ICOSL on CD 4+ T cells, we evaluated surface ICOSL expression on CD4+ T cells in peripheral blood (PB) from 24 patients with SLE, PB from 15 healthy controls using flow cytometry. We also evaluated soluble ICOSL expression in the plasma of 24 patients with SLE and 14 healthy controls. To explore the role of ICOS/ICOSL signaling in CD4+ T cells in SLE, we examined CD4+ T cell proliferation from seven patients with SLE. After blockade of the ICOS/ICOSL signal using anti-ICOSL antibody or ICOS immunoglobulin, CD4+ T cell proliferation in response to treatment with anti-CD3 antibody was evaluated. During the proliferation assay, cytokine levels (ILF-gamma, TNF-alpha and IL-17) in the CD4+ T cell culture supernatants were assessed.

Results: The proportion of ICOSL+ CD 4+ T cells was significantly increased in the PB of patients with SLE (13.6 ± 7.6%, range 3~29%) as compared with the level observed in the PB of healthy controls (1.3 ± 1.2 %, range 0~4%, $P < 0.01$). The soluble ICOSL protein level in patients with SLE was significantly higher than that of healthy controls (43.0 ± 39.2 pg/mL vs 2.0± 2.9 pg/mL,$P < 0.01$). The level of soluble ICOSL protein correlated with surface ICOSL expression on the CD4+ T cells (γ =0.69, $P<0.01$). After blocking of the ICOS/ICOSL pathway, the suppression of CD4+ T cell proliferation was not significantly different between the two treatment groups (ICOS immunoglobulin and anti-ICOSL antibody) and the control groups. The expression level of TNF-alpha and IL-17 were also significantly depressed in the treatment groups (ICOS immunoglobulin) compared to the control groups.

Conclusion: In this study, we found that ICOSL, a ligand of ICOS, was significantly up-regulated on CD4+ T cells in the PB in patients with SLE. In addition, blockade of ICOS/ICOSL signaling suppressed the expression of TNF–alpha and IL-17 but it did not affect CD4+ T cell proliferation. Our results support a contribution of the ICOS/ ICOSL pathway to the pathogenesis of SLE.

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Accelerated atherosclerosis is the leading cause of death in systemic lupus erythematosus (SLE). How SLE promotes accelerated atherosclerosis remains elusive. The purpose of this study was to show that actors of SLE pathogenesis – such as CD4+ T cells and plasmacytoid dendritic cells (pDCs) - contribute to atherosclerosis.

Methods: Internal carotid wall thickness was prospectively assessed, as a measure of atherosclerosis, in 51 SLE patients asymptomatic for cardiovascular disease and 18 controls. The expression of CXCR3, a chemokine receptor involved in tissue migration of T cells, on peripheral blood mononuclear cells was measured. We analyzed in vitro the effect of pDCs-derived IFN-α production on CD4+ T cells and on CXCR3 ligands production by endothelial cells. Eventually, the impact of TLR-9 stimulated pDCs on atherosclerosis development was studied in a mouse model

Results:

SLE patients displayed an increased frequency of pro-inflammatory CD4+ T cells expressing CXCR3 that correlates with subclinical atherosclerosis. Furthermore, IFN-α produced by pDCs upon TLR-9 stimulation enhances both CD4+CXCR3+ T cells expansion and CXCR3 ligands production by endothelial cells in vitro. Eventually, TLR-9 stimulation of pDCs was shown to accelerate atherosclerosis development in ApoE-/- mice by enhancing the CD4+CXCR3+ T cells recruitment in arterial wall.

Conclusion: In SLE, IFN-α produced by pDCs both expands CD4+T cells expressing CXCR3 and induces endothelial cells to secrete CXCR3 ligands, which drive CD4+T cell migration into the arterial wall and atherosclerosis. Our findings support a multi-step model in which SLE-immune dysfunction is associated with the development of atherosclerosis

Session Date: Sunday, November 8, 2015

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

The interplay between effector and regulatory T cells (Tregs) is a key element among peripheral tolerance mechanisms in Systemic Lupus Erythematosus (SLE). Resistance to suppression has been acknowledged as part of the defects shown by lupus T cells. The E3 ligase Cbl-b has been shown to modulate T cell unresponsiveness in SLE. However its role in peripheral Tregs tolerance has not been addressed. The aim of this study was to assess Cbl-b expression and its relationship to the resistance to suppression phenotype, as well as the ubiquitination profile in SLE.

Methods:

We included 30 SLE patients (20 with active disease and 10 with clinical remission) and 30 age and gender matched healthy controls. Peripheral blood mononuclear cells were isolated by density-gradient sedimentation. Effector ($CD4^+CD25^-$) and Tregs ($CD4^+CD25^+CD127^-$) were purified by magnetic selection. The expression of Cbl-b and the ubiquitination profile were analyzed by western blot. Proliferative responses were assessed in allogeneic and autologous cocultures by CFSE method. Differences were assessed by t Student test. $p<0.05$ was considered as statistically significant.

Results:

We found decreased Cbl-b expression in Tregs from SLE patients in comparison to healthy controls (1.1±0.9 vs 2.5±1.8+6, p=0.003), which was associated with resistance to suppression in proliferation assays (r=0.633, p=0.039). This phenomenon was related to a differential polyubiquitination profile characterized by deficient expression of Lys63 (K63) substrates in regulatory T cells from SLE patients when compared to healthy controls. We analyzed different signaling molecules that are prone to K63 regulation and found increased expression of phosphorylated STAT3 (pSTAT3) in T cells from SLE patients in comparison to healthy controls.

Conclusion: Our data suggest that Cbl-b is able to regulate the interplay between effector and Tregs, particularly, the resistance to suppression by regulating the K63 polyubiquitination profile in T cells from SLE patients. Moreover, deficient K63 polyubiquitination mainly of STAT3 is associated to the enhanced pSTAT3 expression and might play a role in the maintenance of resistance to suppression in SLE, as has been previously reported for other autoimmune diseases.

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: We recently identified a human B cell population, which is naturally autoreactive and tolerized by functional anergy. This population was naïve, fully mature, negative for surface IgM and expressing only IgD BCR (BND cells: naïve, D-only). The BND cells have antibody variable region genes in germline configuration and a significant proportion of anergic cells exhibit natural reactivity to antinuclear antigens and dsDNA. Break of B cell tolerance leading to presence of autoantibodies in systemic autoimmune rheumatic diseases may cause the initiation and perpetuation of autoimmune processes. The aim of this study was therefore to investigate if anergy in BND cells could be overcome by T cell mediated signals, as has been reported in murine systems. Furthermore, investigate the molecular mechanisms underlying this process, and determine whether autoreactive BND cells are tolerized in Systemic Lupus Erythematosus (SLE) patients.

Methods: Untouched naive and BND human B cells from healthy blood donors or SLE patients were purified and cultured in the presence of T cell help (e.g. IL-4 and CD40L) followed by functional assays such as Ca2+-flux, phospho-flow (pSyk, pLyn) and standard flow cytometry measurements of intracellular and surface B cell markers. Finally, CD45 phosphatase activity was measured utilizing a novel fluorescent peptide-based assay.

Results: Here we report that T helper signals reverse the state of anergy allowing BND cells to fully respond to antigenic stimulation by restoring signaling through the B cell receptor. The mechanism was dependent on increased activity of the tyrosine phosphatase CD45, and CD45-dependent activation of Lyn and Syk kinases. CD45 phosphatase activity was upregulated by T cell help both in BND and naïve B cells, suggesting that CD45 is a key regulator of B cell receptor signaling thresholds mediated by T cell help. Furthermore, we found that BND cells obtained from SLE patients exhibited increased CD45 activity and B cell receptor signaling capacity, thus being less tolerized,than BND cells from healthy controls.

Conclusion: We discovered that T helper signals regulate CD45 phosphatase activity in B cells, and that this lead to increased B cell receptor signaling and recovered ability of tolerized BND cells to respond to antigen. Strikingly, we found that BND cells obtained from SLE patients were less tolerized than BND cells from healthy controls. This raises the possibility that BND cells could represent precursors of autoantibody-secreting plasma cells and suggests a role for these autorective B cells in contributing to autoimmunity if not properly controlled. Our data provide new insight in the break of humoral immune tolerance with possible diagnostic and therapeutic implications in patients with SLE and other systemic autoimmune and rheumatic diseases.

Circulating Endothelial Cell (CEC) and CEC-Bound C4d Levels As Biomarkers of Systemic Lupus Erythematosus

Chau-Ching Liu[1], Susan Manzi[2] and Joseph Ahearn[3], [1]Allegheny Singer Research Institute, Pittsburgh, PA, [2]Rheumatology, Allegheny Health Network, Pittsburgh, PA, [3]Allegheny Singer Research Institute, Allegheny Health Network, Pittsburgh, PA

Session Date: Sunday, November 8, 2015

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Accelerated atherosclerotic disease has been widely recognized in patients with SLE. Circulating endothelial cells (CECs) are a rare cell population believed to detach from the vessel wall as a result of vascular injury. Increased numbers of CECs have been reported previously in patients with SLE. However, the interaction between complement and CECs with regard to inflammatory vascular injury in SLE has not been explored. Previous studies have shown that complement activation product C4d is present specifically on platelets of SLE patients and correlates with cerebrovascular disease. These observations led us to hypothesize that increased numbers of CECs bearing C4d may serve as a sensitive and specific biomarker of SLE-associated vascular diseases.

Methods:

To verify this hypothesis, a pilot study investigating CEC numbers and CEC-bound C4d levels was conducted using the blood samples taken from 129 patients with SLE, 125 patients with other immune-inflammatory diseases, and 30 healthy individuals. Peripheral blood mononuclear cells were isolated, and CECs therein were detected and analyzed for surface-bound C4d by flow cytometry.

Results:

Preliminary results showed that CEC numbers per se were not significantly elevated in patients with SLE. Notably, however, the levels of CEC bearing C4d (CEC-C4d) were significantly elevated in patients with SLE (specific median fluorescence intensity (SMFI) = 16.7), compared to patients with other diseases (SMFI = 5.7; p <0.001) and healthy controls (SMFI = 3.5; p <0.001). In a preliminary cross-sectional analysis, CEC-C4d measure was 45% sensitive and 100% specific for SLE versus healthy controls, and 86% specific for SLE versus other diseases. Furthermore, there was a correlation between CEC-C4d and platelet-bound C4d levels (Spearman r = 0.40, p <0.001). Because platelets play important roles in hemostasis and thrombosis and have increasingly been recognized as being important mediators of inflammation, this finding suggests an interactive participation of platelets and CECs in SLE-associated inflammatory vascular disease.

Conclusion:

The results obtained indicate that CEC-C4d is a potential diagnostic marker of SLE and possibly a stratification biomarker for vasculature-specific SLE disease activity.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

The onset of SLE, a prototypical autoimmune disease characterized by immune dysregulation and consequential inflammatory tissue injury, may be insidious with non-specific symptoms. The current standard for diagnosing SLE is based on the ACR classification criteria. A diagnosis of definite SLE is made when a patient has met 4 of the 11 criteria, which may take years to fulfill. Patients who have met less than 4 ACR criteria may have pre-SLE and may go on to develop definite SLE, in whom serious organ damages might have occurred unnecessarily due to the missed opportunity of early treatment. Our recent studies have shown that cell-bound complement activation products (CB-CAP), particularly cell-bound C4d, can serve as unique biomarkers not only for diagnosis but also for disease activity monitoring in patients with SLE. We hypothesize that profiling the CB-CAP patterns in patients at risk for developing SLE may provide a “window” that may allow physicians to identify patients at an early stage of SLE and institute appropriate treatment accordingly.

Methods: To verify this hypothesis, a cross-sectional study investigating C4d levels on various circulating cells was conducted using blood samples taken from 429 patients with definite SLE, 51 patients with pre-SLE, 285 patients with other immune-inflammatory diseases, and 196 healthy individuals. Seven circulating cell types, including erythrocytes, reticulocytes, platelets, T and B lymphocytes, monocytes, and granulocytes, were detected and analyzed for surface-bound C4d by flow cytometry. Cell-bound C4d measure on each cell type was also classified in a binary positive (score = 1) and negative (score = 0) fashion and a cumulative CB-C4d score (ranging from 0 to 7) was derived for each study subject.

Results:

The results showed that C4d levels on all 7 circulating cell types were significantly elevated in patients with definite SLE or pre-SLE, compared to patients with other immune-inflammatory diseases, and healthy controls. However, the CB-C4d levels, with the exception for T cell- and B cell-bound C4d, were statistically indistinguishable between patients with definite SLE and patients with pre-SLE. When the cumulative CB-C4d scores of individual patients were calculated and compared, patients with definite SLE and pre-SLE were inclined to accrue higher CB-CAP scores (with an average score of 2.44 and 2.12, respectively) than did patients with other immune-inflammatory diseases (average score 0.72). Moreover, high CB-C4d scores were more prevalent in patients with definite SLE and pre-SLE than in patients with other immune-inflammatory diseases. The frequency distribution of CB-C4d scores within the patient group of pre-SLE resembled that within the patient group of definite SLE, but was considerably different from that within the patient group of other diseases.

Conclusion:

Collectively, the results suggest that CB-CAP generation may occur early during the pathogenic process of SLE. CB-CAP profiling may help identify patients at risk for developing full-blown SLE and thus provide preventative care to minimize disease progression.

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Various autoantibodies have been identified in cerebrospinal fluids (CSF) of neuropsychiatric systemic lupus erythematosus (NPSLE). They are supposed to form immune complex with complement to induce inflammatory responses. We therefore measured the 3rd component of complement (C3) and other inflammation-related molecules in CSF of NPSLE patients.

Methods: This study included 51 SLE patients. According to the 1999 ACR definition criteria, 43 patients were diagnosed with NPSLE whereas 8 patients were diagnosed with non-NPSLE. We measured levels of C3, alpha-2-Macroglobulin (α2MG) and IL-6, in CSF or serum by sandwich ELISA.

Results: Quantitative ELISA revealed that the IL-6 levels in CSF of NPSLE (441.9 ± 1233 pg/ml) were significantly higher than that of non-NPSLE (3.36 ± 2.58 pg/ml) ($p = 0.0010$), which is consistent with the previous observation reported by Hirohata *et al*. (Clin Rheumatol. 2009). IL-6 is a primary cytokine, which induces various inflammatory responses including complement activation. We examined C3 expression in CSF of NPSLE patients. C3 levels in CSF of NPSLE (4.94 ± 3.79 μg/ml) were significantly higher than that of non-NPSLE (1.92 ± 1.14 μg/ml) ($p = 0.0071$). It is possible that elevation of C3 in CSF is due to upregulation of serum C3. We therefore analyzed serum levels of C3. No significant difference in serum C3 levels was observed between NPSLE (645 ± 311 μg/ml) and non-NPSLE (824 ± 374 μg/ml) ($p = 0.2767$). In addition, correlation of C3 levels between CSF and serum was weak in NPSLE ($r = 0.2885$, $p = 0.0380$), suggesting that upregulation of C3 in CSF is independent of C3 levels in serum. Another inflammatory protein we analyzed was α2MG, which is a protease inhibitor for localizing proteolytic

responses in the inflammatory focus. Quantitative ELISA revealed that levels of α2MG in NPSLE (2.90 ± 3.69 μg/ml) were significantly higher than that of non-NPSLE (0.72 ± 0.26 μg/ml) ($p = 0.0010$). In contrast, serum levels of α2MG were similar in both specimens. Correlation of α2MG levels between CSF and serum was weak ($r = 0.2582$, $p = 0.0674$), suggesting independence of α2MG concentration between CSF and serum. It was notable that CSF levels of C3 and α2MG showed strong correlation ($r = 0.6990$, $p < 0.0001$). In addition, that CSF levels of IL-6 was correlated with that of C3 and α2MG, ($r = 0.5102$, $p = 0.0003$) and ($r = 0.5662$, $p < 0.0001$), respectively, suggesting that IL-6 upregulates C3 and α2MG in CSF.

Conclusion: We demonstrated the increase of IL-6 in CSF of NPSLE patients. IL-6 may upregulate C3 and α2MG in CSF as "local" inflammatory response.

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Decreases in peripheral blood levels of complement components of C3 and C4 are associated with SLE and often indicate a lupus flare. The aim of this study is to identify the biologic events that underline changes in complement levels and their clinical implications by characterizing peripheral blood features that are associated with low C3 or C4 levels in patients with SLE.

Methods: PBMC samples and multiple clinical and laboratory parameters were collected longitudinally for 71 patients that met ACR criteria for SLE. C3 and C4 were measured by nephelometry (the normal ranges for C3 and C4 were 79–152 mg/dl and 16–38 mg/dl, respectively). Longitudinal PBMC gene expression data were generated by microarray (2-8 visits/patient) for 22 SLE patients from the above group. Based on the data obtained, we built separate statistical models (linear mixed model) for C3 and C4. The relationships of C3 and C4 with the studied parameters were obtained, the p value threshold was set at 0.05 and a multiple testing correction was applied.

Results: C3 and C4 fluctuated during the disease course and from patient to patient. C3 and C4 showed a significant relationship ($p<0.05$) with each other. Both C3 and C4 correlate positively with serum albumin, alkaline phosphatase and calcium. C3 is positively correlated with WBC, RBC, serum albumin and C-reactive protein, and is negatively correlated with disease activity, as determined by SELENA-SLEDAI or BILAG2004. C3 was lower in patients with high serum creatinine, chloride, proteinurea (by definition of SLEDAI), DNA binding and lymphopenia. Based on longitudinal microarray data, C3 and C4 showed either positive or negative relationships with 1147 transcripts and 37 transcripts, respectively. There were 29 genes correlating with both C3 and C4. The functional analysis of selected transcripts indicates important categories, such as regulation of innate immune response and RNA preprocessing. Transcripts negatively correlating with C3 and C4 include NFATC1, MAP3K8, EGR1 that mediate T cell activation; or such important molecules as NF1, TNFAIP3, BTG1, DUSP2, CXCR4, NEDD and SHARPIN.

Conclusion: Our data confirmed the usefulness of C3 and C4 for monitoring disease activity in SLE and indicate that C3 might have better prognostic potential than C4. Patients with low C3 tend to have more prominent kidney involvement. Interestingly, C3 showed a better correlation with PBMC gene transcript expression than C4, and low C3 was associated with increased expression of transcripts involved in T cell activation, among other immune activation pathways. The results point to important molecular mechanisms that are associated with SLE disease activity.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: CD146 is a transmembrane glycoprotein belonging to Ig-superfamily. Human endothelial cells, activated fibroblasts and Th17 cells express CD146 that involved in angiogenesis, fibrosis and inflammation. CD146+ T cells secrete IL-17, IFN-g, and TNF-a. CD146 also exists as a soluble form (sCD146) that has biological activity. The aim of this study is to establish an enzyme-linked immunosorbent assay (ELISA) for detecting sCD146 , and to determine the serum levels of sCD146 in patients with systemic sclerosis (SSc), and examine the relationship with the clinical manifestations.

Methods: We used two non-cross-blocking CD146 mAbs to develop a sandwich ELISA for measuring serum sCD146. Recombinant sCD146 was used to obtain the standard curve. IRB approved blood sampling and measuring protocol was established at the Juntendo University School of Medicine and Toyo University and enrolled healthy controls. Blood samples were drawn from patients fulfilling criteria for SSc proposed by the 2013 classification criteria for SSc (ACR/EULAR). Levels of sCD146 were quantified in 40 serum samples from patients with SSc by the ELISA and compared with those of 14 healthy controls. The clinical manifestation and laboratory data of the patients were also examined.

Results: We established a sensitive and specific ELISA system for testing sCD146. Systemic sclerosis was focused from the result of screening various SCTDs for serum sCD146. The levels of sCD146 were significantly higher in 40 patients with SSc (14.12 ng/ml) than those in 14 healthy controls (6.73 ng/ml; $p<0.001$) [Figure]. However, there was no statistical correlation between sCD146 and the clinical manifestations, such as lung fibrosis and area of skin fibrosis. But the level of sCD146 was significantly correlated with the level of E-selectin, a marker of vascular damage. In addition,serum levels of sCD146 were decreased in SSc patients treated with glucocorticoid.

Conclusion: We identified the presence of sCD146 in SSc serum. It is suggested that sCD146 is involved in inflammation through vascular endothelial cells as well as E-selectin. The pathogenic and clinical significance of sCD146 in SSc should be further examined.

Session Date: Sunday, November 8, 2015

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic scleroderma (SSc) is a generalized connective tissue disease characterized by fibrosis of the skin and internal organs, vascular dysfunction and immune disorder. Patients with SSc typically develop Raynaud's phenomenon (RP) and persistent digital ischemia, and often develop digital ulcers (DU). Currently, there is no satisfactory treatments for RP in SSc. Recently, it was reported that botulinum toxin A (BTX-A) injection was effective for the treatment of RP in SSc patients. Objective was to assess the efficacy and safety of BTX-A on RP in Japanese SSc patients.

Methods: In the prospective, open-label trial, 10 Japanese SSc patients with RP received 10U of BTX-A injections into the hand. The change in severity of RP, including the frequency of attacks/pain, color changes, duration time of RP and the severity of pain was assessed by the Raynaud score and pain VAS at each visits during 16 weeks. The recovery of skin temperature 20 minutes after cold-water stimulation was examined by thermography at baseline and 4 weeks after injection. The number of DU and adverse events were assessed at each visits.

Results: BTX-A injection decreased Raynaud's score and pain VAS from 2 weeks after injection, and the suppressive effect was continued until 16 weeks after injection. The symptoms of RP in 10 SSc patients without BTX-A treatment remained unchanged 4 weeks after injection, however, those in 10 patients with BTX-A injection were significantly improved. Skin temperature recovery after cold-water stimulation at 4 weeks after injection was significantly elevated compared to that before injection. All DU in five patients were healed within 12 weeks after injection. Neither systemic nor local adverse events was observed in all patients.

Conclusion: We conclude that BTX-A injection significantly improved the activity of RP in SSc patients without any adverse events, suggesting that BTX-A might have possible long-term preventive and therapeutic potentials for RP and RP-related DU in Japanese SSc patients.

Session Date: Sunday, November 8, 2015

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Our aim was to examine and confirm the association between anti-IFI16 antibodies and clinical features of scleroderma.

Methods: Sera from a discovery sample of 94 scleroderma patients and 47 healthy controls were assayed for anti-IFI16 antibodies by ELISA, and associations were examined using regression analyses. As anti-IFI16 autoantibodies strongly associated with digital gangrene in the discovery sample, a subsequent 1:1 disease-duration matched case-control study was designed to further explore this association. Cases were patients with scleroderma and digital gangrene, while controls were patients with scleroderma and Raynaud's alone (n=52 pairs). Nonparametric

unadjusted matched-pair analyses, univariate and multivariable conditional logistic regression were performed.

Results: Anti-IFI16 antibodies in the discovery sample were more prevalent in scleroderma than in healthy controls (18% vs. 2%; p=0.01). Patients with anti-IFI16 antibodies were more likely to have limited scleroderma (77% vs. 46%; p=0.03), longer disease duration (15.2 [10.6-18.3] vs. 6.0 [3.4-13.8] years; p <0.01), digital gangrene (24% vs. 4%; p=0.02), and a low DLCO (p <0.01). In the matched case-control study, 38/104 (37%) were anti-IFI16 positive. Anti-IFI16 antibody levels were found to be significantly higher in cases than matched controls (p=0.02). Adjusted for age, cutaneous subtype, smoking, and DLCO, high anti-IFI16 antibody levels associated significantly with digital gangrene case status (adjusted OR 2.4; 95% CI 1.0, 5.4).

Conclusion: Anti-IFI16 antibodies are associated with digital gangrene in scleroderma. Longitudinal prospective studies exploring the role of anti-IFI16 antibodies as a scleroderma disease biomarker, and biological studies investigating the pathogenicity of these antibodies, are warranted.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

To investigate familial aggregation of systemic sclerosis and the relative risks (RRs) of other autoimmune disease in relatives of affected patients.

Methods:

We identified 23,658,577 beneficiaries registered with the National Health Insurance in 2010, of whom 1,891 individuals had systemic sclerosis. We identified 21,009,551 parent-child relationships and 17,168,340 full sibling pairs. The familial risks of systemic sclerosis, rheumatoid arthritis and systemic lupus erythematosus, familial transmission and expected proportion of sporadic cases were estimated.

Results:

The prevalence of systemic sclerosis was 7.99 (95% confidence interval [CI], 7.64–8.36) per 100,000 people in the general population of Taiwan in 2010; in comparison, the prevalence was 387.60 (95% CI, 46.97–1393.06) per 100,000 people. The adjusted RR (95% CI) for systemic sclerosis was 81.21 (11.40–579.72) for siblings of systemic sclerosis patients. The familial transmission (heritability plus shared environmental contribution) was 0.72; despite this, 84.1% of patients was expected to be sporadic cases. The RR (95% CI) in first-degree relatives of systemic sclerosis patients was 7.43 (2.42–22.86) for rheumatoid arthritis; 9.82 (3.76–25.70) for systemic lupus erythematosus.

Conclusion:

The risk of systemic sclerosis and other autoimmune diseases is increased in relatives of people with systemic sclerosis and family factors explain over two-thirds the phenotypic variance of the disease. Despite this, the majority of patients were expected to be sporadic cases.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: During the last decade, it has been shown that cardiovascular disease (CVD) in systemic sclerosis (SSc) is increased and accounts for ~30% of the SSc mortality. However, whether this is due to accelerated atherosclerosis and how to detect patients with high risk are still unclear. In this study we aimed to determine the frequency of subclinical atherosclerosis in patients with SSc compared to rheumatoid arthritis (RA) and to determine the ability of CV risk indices in detecting those SSc patients with high CV risk.

Methods: Eighty one SSc patients (F/M=74/7; mean age 49.7±12.1 years) and 80 age- and sex-matched RA patients (F/M=73/7; mean age 50.1±10.5 years) without a history of CVD were assessed. All patients were evaluated with carotid ultrasonography (US). Carotid intima-media thickness (cIMT) > 0.90 mm and/or carotid plaques were used as the gold standard test for subclinical atherosclerosis and high CV risk (US+). Systematic Coronary Risk Evaluation (SCORE), QRisk II and 2013 American College of Cardiology/American Heart Association (ACC/AHA) 10-year atherosclerotic CV disease risk (ASCVD) indices were calculated.

Results: Fifteen patients (18.5%) in SSc group and 19 patients (23.8%) in RA group were US+ and the presence of subclinical atherosclerosis and the mean cIMT were similar in SSc and RA patients (P=0.41, P=0.74, respectively) (Table 1). None of the CV risk factors in SSc patients were worse than RA patients except for lower HDL-chol levels (Table 1). However atherogenic index (Total-chol/HDL-chol) were not different (3.6±0.9 vs 3.5±1.1, P=0.67). When US+ and US- SSc patients were compared, it was observed that US+ SSc patients were older, had significantly more pulmonary arterial hypertension (PAH), elevated ESR, HT and less immunsuppressive usage than US- patients. In multivariable logistic regression analysis, age (OR=1.1, 95% CI [1.02-1.8], P=0.014), elevated ESR (OR=9.3, 95% CI [1.6-55.5], P=0.014) and PAH (OR=4.8, 95% CI [1.12-20.8], P=0.035) were independently associated with subclinical atherosclerosis. Concerning CVD risk indices, all 3 CV risk indices for general population failed to identify patients with subclinical atherosclerosis. Of the 15 US+ patients only 0 (0%), 1 (6.7%) and 3 (20%) patients were classified as high CV risk according to SCORE, QRisk II and ACC/AHA 10-year ASCVD risk, respectively.

Conclusion: Subclinical atherosclerosis in SSc is as frequent as in RA in which accelarated atherosclerosis is clearly defined. Atherosclerosis in SSc is independently associated with age, elevated ESR and PAH. However CV risk indices for general population, SCORE, QRisk II and ACC/AHA 10-year ASCVD risk are considerably insufficient to detect those patients with subclinical atherosclerosis. In future studies, elevated ESR and presence of PAH may be helpful in the SSc-specific CV risk estimation.

Table 1. CV risk factors of SSc and RA patients

	SSc patients (n=81)	RA patients (n=80) (n=80)	*P*

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Despite the advent of potent immunosuppressive and vasoactive therapies it is not clear that longevity of patients with systemic sclerosis (SSc) has improved. Therefore we sought to evaluate the age of death of SSc inpatients (inpts) relative to general inpts, the number of hospital inpt days and comorbidities in SSc patients.

Methods: The Hospital In-Patient Enquiry system was evaluated from 57 Irish hospitals from 1995-2011 for patients admitted with a diagnosis of SSc. Age, length of stay (LOS), gender and admitting indication were recorded. **Results** are shown as totals and mean (Standard deviation). Trends were examined by logistic regression analysis; Mann –Whitney U was used to compare groups. $p<0.05$ was considered statistically significant.

Results: 2667 inpt admissions occurred; 4:1, F:M, mean age 59yrs (15). On average 157 (15) admissions occurred annually for SSc patients, without variation (p=0.7). 146 patients died in hospital at average 65yrs (5) without annual improvement ($r^2=0.03$, p=0.5). SSc age of death was younger than general inpts ($p<0.0001$), whose longevity improved from 72 to 74yrs ($r^2=0.9$, $p<0.0001$). Male SSc inpts were average 6yrs younger than female at death (60yrs (10) v 66 yrs (6); $p<0.01$) in contrast to general inpts when men were average 3yrs younger than women at death (70 yrs v 73 yrs). SSc LOS increased from 11 to 14 days ($r^2=0.3$, p=0.03), as did age of admission ($r^2=0.4$, $p<0.01$). Autoimmune disease (predominantly scleroderma) was the commonest admitting diagnosis (n=945). Lung disease accounted for 383 admissions (170 infection, 62 PAH), CVS disease n=397 (236 limb / cardiac / cerebral ischaemic events, 51 heart failure, 32 arrhythmia), GI n=301, Rehab n= 151, MSK n=120, Haematological n=89 (52 anaemia), Renal n= 85 (51 Failure, 19 infection). 16 pregnancies were recorded with 2 spontaneous abortions, 3 pre-eclampsia incidents, and 9 unspecified complications. Imaging was the commonest principal procedure (n=346), followed by IV therapy (n=297), allied health professional intervention (n=277), gastroscopy (n=208) with 62 patients undergoing limb amputation and 9 having kidney

transplants.

Conclusion: Age of death among SSc inpts is not improving in contrast to unaffected inpts whose age of death is increasing, worse in men. SSc LOS is increasing in contrast to unaffected inpts whose LOS is decreasing. Cardiopulmonary comorbidity predominates among Irish SSc inpts supporting the need for more awareness and therapeutics to address this aspect of SSc.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Laser speckle contrast analysis (LASCA) is an innovative technique to quantify peripheral blood perfusion (PBP) over a given area. Quantification of blood flow might be of interest in diseases with affection of the microcirculation e.g. systemic sclerosis (SSc). In order to be used as an outcome measure, first reliability of LASCA needs to be attested. This study investigates the reliability of the quantitative assessment of PBP by LASCA between two raters in a SSc cohort.

Methods:

Two independent raters evaluated PBP in 40 consecutive patients with SSc (all fulfilling the 2013 ACR/EULAR classification criteria) using LASCA (Pericam PSI, Perimed, Jarfalla). PBP was measured at the level of the fingertips, dorsal and volar bilaterally, for 30 sec each. Measurements were performed under standardized conditions (acclimatization in a temperature controlled darkened room at 25°C for 20 min; seated position; hand at heart level on flat underground; working distance 14.3-14.8 cm; no movement or speaking during measurement; time interval between two raters maximal 30 min). PBP values were reported as perfusion units (PU) by creating regions of interest with fixed 1 cm diameter at central area of 2nd, 3rd, 4th and 5th fingertips. Mean PU per finger, left and right, dorsal and volar, per rater was calculated. Inter-rater agreement was assessed by calculation of intraclass correlation coefficients (ICC). Patients with flexion contractures (n=6) were excluded because they could not meet the standardization requirements.

Results:

The mean PBP values (in PU) are described in Table 1. ICC (95% confidence interval) for PBP values measured by the two raters varied from 0.82 (0.67 to 0.91) to 0.91 (0.83 to 0.96) for the dorsal fingertips, and from 0.74 (0.55 to 0.86) to 0.86 (0.74 to 0.93) for the volar fingertips (Table 2).

Conclusion:

This is the first study to demonstrate reliability of the quantitative assessment of peripheral blood flow by LASCA in a SSc cohort between two raters, performed under standardized patient, instrumental and environmental conditions. Reliability of LASCA is essential for further use of this tool in SSc trials.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: As there is currently no existing index for quantifying organ damage in systemic sclerosis (SSc), we sought to develop a disease damage index in SSc (SSc-DI) for use in interventional and observational studies.

Methods: The SSc-DI working group, together with patient partners and expert advisors from disciplines other than rheumatology, has developed the initial SSc-DI using the following steps: (1) Definition of the concept of damage in SSc using consensus methods in survey form (Figure 1); (2) Item generation and definition through systematic literature review; (3) Item reduction using an online survey distributed to over 300 SSc experts internationally, together with Rasch modelling. (5) Univariable and multivariable regression modelling to (i) determine the relationship between the reduced list of items and death and (ii) to weight the items, using prospectively acquired data from the Australian Scleroderma Cohort Study (ASCS).

Results: A total of 83 items from 7 domains (organ systems) were included in the online survey. A total of 93 responses from SSc experts representing Australasia, North America and Europe were analysed. 58/83 items were retained based on the Delphi survey responses (³60% experts deemed item appropriate). A further 27 items were dropped after Rasch modelling, leaving 31 items to be considered for inclusion in the SSc-DI. Eight of the 31 remaining items were not collected in the ASCS and therefore were unable to be analysed in regression models. The cohort data set consisted of 1,544 patients, with 172 deaths (11.4%). The univariable relationship with death was statistically significant in 16 items. The final SSc DI with weighted scores can be seen in Table 1. Four items, although dropped in the Rasch analysis, were included in the final index by the investigators as they were felt to reflect damage and conferred a mortality risk. The model demonstrated good discrimination and calibration power (area under ROC curve = 0.83 and Hosmer-Lemeshow p = 0.54)

Conclusion: The combined use of consensus and data driven methods has resulted in a weighted 16-item Damage Index that predicts mortality. Further work includes creation of a separate index reflective of morbidity and external validation of these indices using prospective cohort data.

Figure 1: Consensus definition of "damage" in SSc

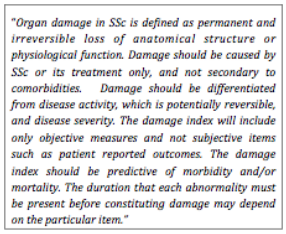

Table 1: Systemic Sclerosis Damage Index (SSc-DI)

Damage Item	Univariable p value	Multivariate p value	Coefficient	Weighted Score
Digital amputation	0.037	0.52	0.20	1
GORD based on symptoms and confirmed on endoscopy*	0.05	0.29	0.24	1
History of SRC	0.18	0.71	0.20	1
Small joint contracture	0.036	0.55	0.34	2
Esophageal stricture confirmed on endoscopy or barium swallow	0.031	0.13	0.46	2
Gastric antral vascular ectasia confirmed on endoscopy	0.10	0.41	0.30	2
Digital ulcerations	<0.001	0.39	0.41	2
Pseudo-obstruction with symptoms and dilatation of the small and/or large bowel on imaging	0.13	0.48	0.35	2
Scleroderma myocardial disease based on clinical features and supported by MRI and/or endomyocardial biopsy	0.031	0.34	0.55	3
ILD based on > 25% extent of lung disease on HRCT chest	0.031	0.31	0.81	4
Need for supplemental oxygen	0.031	0.36	0.78	4
Moderate to severe right ventricular dysfunction on TTE	0.031	<0.001	0.88	4
Pulmonary arterial hypertension defined as mean pAP > 25 mmHg and wedge pressure < 15mmHg	0.031	<0.001	0.97	5
Low BMI of < 18.5 kg/m2 and/or weight loss of > 10% in the last 12 month	0.031	<0.001	0.98	5
ILD with FVC < 70% predicted	0.031	0.33	0.93	5
Six minute walk distance < 250 meters	0.031	<0.001	1.3	7
Total				50

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Gastrointestinal (GI) tract involvement is a common and serious complication of systemic sclerosis (SSc). However, the prevalence of fecal incontinence (FI) and its relationship with other GI symptoms in SSc remain largely unknown. In this study, we aimed to establish the prevalence and severity of FI in an SSc cohort, to study the association between FI and constipation, small intestinal bacterial overgrowth (SIBO) and other potential predictors of FI, and to determine the impact of FI on health-related quality of life (HRQoL) in SSc.

Methods: We performed a multicenter, cross-sectional study of 271 patients with SSc followed in the Canadian Scleroderma Research Group registry (CSRG). In addition to the standardized data collection protocol, participants were asked to complete three validated questionnaires: Bristol stool scale (BSS; measuring consistency of stool from 1, being hardest, to 7, being completely liquid stool), Jorge-Wexner score (JWS; FI severity score ranging from 0-20, with 20 being most severe), and Fecal Incontinence Quality of Life scale (FIQOL; measuring 4 domains: lifestyle, coping/behaviour, depression/self perception, embarrassment). The Rome III criteria were used to define constipation. Descriptive statistics and multivariate regression analyses were generated to determine associations between the JWS and other clinical variables.

Results: Mean age was 59.3±12.1 years, 87.4% were women, median (interquartile range, IQR) disease duration was 10.3 (6.6-17.8) years and 30.0% had diffuse cutaneous SSc. Median BSS was 4.0 (3.0-4.0), 103 (39.6%) subjects met the criteria for constipation and 34 (13.2%) had been treated with antibiotics for SIBO since disease onset. FI, defined as a JWS ≥5, was identified in 74 (27.3%) subjects; among them 33 (12.2%) were mild (score 5-9) and 41 (15.1%) moderate to severe (score ≥10).

In multivariate logistic regression analyses, variables associated with FI were (OR (95% confidence interval)): loose (BSS≥6) vs well-formed (3≤BSS<6) stools (5.93 (1.81-19.42), p=0.003); history of forcep use at time of delivery (2.37 (1.13-4.94), p=0.022); constipation (3.21 (1.46-7.06), p=0.004) and history of antibiotic use for SIBO (4.82 (1.88-12.32), p=0.001). Other variables associated with FI in univariate but not multivariate analyses included advancing age (p=0.031), female gender (p=0.002), urinary incontinence (p<0.001), use of stool softeners

(p=0.022) and domperidone (p=0.034). No difference was found with disease duration (p=0.918), limited or diffuse cutaneous disease subsets (p=0.670) or SSc-specific antibodies (all p >0.4). HRQoL decreased significantly as severity of fecal incontinence increased (correlation coefficients of JWS with all 4 domains of FIQOL between -0.6 and -0.7, all p<0.001).

Conclusion: In this multicenter study, FI was common and often severe in SSc. Loose stools, SIBO, as well as constipation were strongly associated with FI. FI had a strong negative impact on HRQoL. These data can inform the design of future interventional studies aimed at improving the management of FI and HRQoL in SSc.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Calcinosis is a debilitating complication of systemic sclerosis (SSc). We sought to determine the clinical factors associated with calcinosis in an international multi-center collaborative effort with the Scleroderma Clinical Trials Consortium (SCTC).

Methods: This is a retrospective cohort study of 5180 patients with SSc from 9 centers within the US, Australia, Canada, United Kingdom, Italy, and Mexico. Calcinosis was determined by physical examination and/or radiography. Logistic regression was used to obtain odds ratios (OR) relating calcinosis to various clinical features in multivariate analyses adjusted for disease duration, gender, and modified Rodnan skin score (mRSS).

Results: A total of 1290 patients (24.4%) had calcinosis. In univariate analyses (Table), not correcting for multiple comparisons, patients with calcinosis were older than patients without calcinosis, more likely to be female, and had longer disease duration from first non-Raynaud symptom. Patients with calcinosis were more likely to have digital ulcers, telangiectasias, and acro-osteolysis, cardiac disease, pulmonary hypertension, gastrointestinal involvement, and arthritis, but less likely to have myositis. Osteoporosis was much more common in patients who had calcinosis. Scl-70, RNA-polymerase-III, and RNP autoantibodies were significantly less common in patients with calcinosis, while anticentromere (ACA), PM-1, and anticardiolipin were more frequent. In multivariate analysis, the strongest associations with calcinosis were digital ulcers (OR 3.7, 95%CI 2.6-5.3, p<0.0001), and osteoporosis (OR 3.9, 95%CI 2.1-7.4, p<0.0001). After controlling for steroid use and body mass index in the model, the association with osteoporosis persisted in stratified analyses in non-obese patients (OR 6.5, 95%CI 1.8-23.8, p=0.004).

Conclusion: Almost one quarter of patients with SSc have calcinosis. Our data support a strong association of calcinosis with digital ulcers and osteoporosis in non-obese patients. We were successfully able to gather data from many sources, which markedly increased the power of our study in this rare disease. Our study sets a precedent for future studies of calcinosis in SSc and our results may guide the development of future therapies.

Mycophenolate Decreases the Frequency of Endoscopic Therapy for Gastric Antral Vascular Ectasia in Patients with Systemic Sclerosis

Tiffany Lin[1], James Bena[2], Shannon Morrison[2] and Soumya Chatterjee[3], [1]Rheumatology, Cleveland Clinic Foundation, Cleveland, OH, [2]Quantitative Health Sciences, Cleveland Clinic Foundation, Cleveland, OH, [3]Cleveland Clinic Foundation, Cleveland, OH

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Gastric antral vascular ectasia (GAVE) is an increasingly recognized cause of upper gastrointestinal bleeding in patients with systemic sclerosis (SSc). These patients may require frequent interventions, which negatively impact quality of life. There is currently no defined role for immunosuppressive therapy in the treatment of GAVE. The goal of this study was to determine whether immunosuppressive therapy, used for any indication, also has a role in reducing the frequency of interventions for GAVE in patients with SSc.

Methods: A retrospective chart review was performed on patients that were seen within the past 10 years at our institution who had SSc complicated by GAVE. Data on demographic and clinical characteristics were collected. Types of immunosuppressive therapies and the time periods used were recorded. Intervention rates (hospitalizations, blood transfusions, and endoscopic therapies) were compared using repeated measures Poisson regression models to account for the different medication periods for each patient.

Results: Forty-eight patients with SSc complicated by GAVE were identified (Table 1). Twenty-nine received immunosuppressive therapy. Those who received immunosuppressive therapy had anti-centromere antibodies less often than those who did not receive therapy (17.2% versus 52.6%, p=0.010). Other patient characteristics were not significantly different between the two groups. The most commonly used therapy was mycophenolate (n=14), followed by glucocorticoids (n=11), hydroxychloroquine (n=7), cyclophosphamide (n=4), intravenous immunoglobulin (n=3), methotrexate (n=3), and azathioprine (n=1). When receiving immunosuppressive therapy, patients required therapeutic endoscopies less frequently (0.51/year versus 1.37/year, p=0.009) (Table 2). This decrease in frequency was more pronounced with mycophenolate in particular (0.25/year versus 1.37/year, p=0.013). There were no significant differences in hospitalization or blood transfusion frequencies.

Conclusion: Mycophenolate may have the potential to alter the course of disease in patients who have GAVE associated with SSc, and can be considered in those who require frequent therapeutic endoscopies. Further studies are needed to confirm these findings.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Loss to follow-up is a major threat to the conduct of chronic disease cohort research. Tracking the survival status of patients who are lost to follow-up is limited by restricted access to death certificate data and patients moving. One strategy to gather mortality data is to use online obituaries. Although commonly used clinically, it is uncertain if this is appropriate for research. The primary objective of this study was to evaluate the reliability and validity of online obituaries as a source of mortality data in 2 chronic diseases, systemic sclerosis (SSc) and idiopathic pulmonary arterial hypertension (IPAH).

Methods: Patients whose survival status was known were randomly selected from the Toronto Scleroderma Program and the University Health Network Pulmonary Hypertension Program. Five commonly used online obituaries were evaluated. Two investigators, blinded to survival status, independently entered the first and last name of each patient in each website. If the patient was identified as deceased, other matching variables (date of birth, postal code, disease) were used to verify the patient. Pearson's correlation coefficient (r) was used to evaluate the correlation between the website finding and actual survival status. Intra-rater and inter-rater reliability was evaluated using the intra-class correlation coefficient (ICC).

Results: We studied 365 patients (273 females, 92 males) including 219 SSc (171 females, 48 males) and 146 IPAH (102 females, 44 males) patients. There was a significant positive correlation between website 1 and the actual survival status ($r = 0.36$ (95%CI 0.27, 0.45, $p<0.001$)) and was similar across diseases, SSc ($r=0.34$ (95%CI 0.21, 0.45, $p<0.001$) and IPAH ($r=0.41$ (95% CI 0.26, 0.53, $p<0.001$). The ICC for the intra-rater reliability of websites 1 and 3 were 0.95 (95%CI 0.93, 0.96) and 0.96 (95%CI 0.95, 0.97) respectively, which were higher compared website 2, 4, 5 (0.77 (95%CI 0.72, 0.80), 0.75 (95%CI 0.71, 0.80) and 0.21 (95%CI 0.11, 0.31) respectively). The ICC for inter-rater reliability was strong (0.82 (95%CI 0.78, 0.85).

Conclusion: Use of selected online obituaries is a valid and reliable method to gather mortality data. They could be used in clinical research to track patients who are lost to follow up.

Session Date: Sunday, November 8, 2015

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Studies investigating the immunogenicity of pneumococcal vaccine in patients with systemic sclerosis (SSc) are scarce. We aim to investigate the impact of SSs disease and treatment with disease modifying antirheumatic drugs (DMARDs) on antibody response elicited by either 13-valent pneumococcal conjugate vaccine (PCV13) or 23-valent pneumococcal polysaccharide vaccine (PPV23) in patients with SSc compared to healthy controls (HC).

Methods: In total, 44 SSc patients receiving standard of care treatment and 49 HC were vaccinated with a single dose of either PCV13 or PPV23. of 44, 12 SSc patients received DMARDs (mycophenolate mofetil=7; azathioprine=4 and azathioprine+hydroxychloroquine=1). Response to two pneumococcal capsular polysaccharides (6B and 23F) were measured in serum before and 4-6 weeks after vaccination using standard ELISA. Geometric mean levels (GML) were calculated from log transformed pre- and postvaccination antibody levels and then compared using paired T-test. Antibody responses between vaccines were also compared.

Results: Both vaccines were generally well tolerated. Number of patients, percentage female (%), mean age and mean disease duration (years) at vaccination were: 32, 94%, 57.5 and 11.4 years in SSs without DMARDs; 12, 100%, 55.5 and 6.2 years in SSc patients on DMARDs and 49, 63% and 50.6 years in HC. Numbers of patients immunized with PCV13 or PPV23 and GML (95% CI) for both serotypes tested are shown in Table. Prevaccination antibody levels to both serotypes did not differ between three groups (Mann-Whitney U-test). Prevaccination antibody levels for both serotypes increased significantly in SSc without DMARDs and HC ($p<0.001$) but not in SSc patients on DMARDs ($p=0.115$ for 6B and $p= 0.091$ for 23F). Compared to HC and SSc without DMARDs patients with SSc treated with DMARDs had lower postvaccination antibody levels for both serotypes. There were no significant differences in antibody levels between SSc patients without DMARDs and HC. When pre- and postvaccination antibody levels for 6B and 23F were compered between individuals immunised with PCV13 and those immunised with PPV23, no significant difference was seen within the same treatment group or within the whole study population.

Conclusion: Pneumococcal vaccination using either PCV13 or PPV23 yielded satisfactory antibody response in SSc patients not treated with DMARDs but decreased levels in patients treated with synthetic DMARDs suggesting a need of vaccination before start of treatment. Type of pneumococcal vaccine (conjugate vs polysaccharide) did not have a significant impact on the vaccination response.

ClinicalTrials.gov Identifier: NCT02240888

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Between 16 and 20% of patients with systemic sclerosis (SS) have arthritis, which is occasionally erosive. In addition, between 1 and 5% of patients show syndrome overlap with rheumatoid arthritis (RA).

The initial management of this complication is typically similar to RA, with the use of methotrexate as a first-choice DMARD. In refractory cases, anti-TNF therapies could be useful. However, many of these patients develop diffuse interstitial lung disease (DILD), which contraindicates the use of these drugs.

Our objective was to evaluate the efficacy and safety of rituximab (RTX) in the treatment of joint disease in patients with SS.

Methods:

An ambispective study of 13 patients with SS (ACR/EULAR 2013 criteria) and severe polyarticular disease treated with RTX was performed. The primary efficacy outcome was an improvement of joint counts, as evaluated by DAS28-ESR at the end of the follow-up period

Results:

Of the 13 patients included (12 women), seven (54%) had diffuse SS and six had a limited form of the disease. The mean age (± SD) was 54 ± 11 years, and the time of evolution (median) was 7 ± 12 years. Two (15%) patients had positive ACPA and fulfilled the criteria for RA classification. The baseline DAS28-ESR score was 6.4 ± 1.8.

The main clinical characteristics and response to treatment are shown in the following table.

Indication	DAS28 at the beginning	Time tracking (months)	Number of cycles	DAS28 at last visit	Previous treatments
Polyarthritis + DILD	6.55	12	2	2.21	MTX, LEF, Etanercept
Polyarthritis (overlap RA)	6.47	18	3	3.01	MTX, LEF, D-penicilamina
Polyarthritis	6.61	18	3	2.45	MTX, LEF, D-penicilamina
Polyarthritis + DILD	7.92	18	3	2.31	CFM, MMF
Polyarthritis	6.78	12	2	2.41	MTX, SZP, MMF
Polyarthritis	7.88	6	1	6.66	MTX, SZP, LEF, HCQ
Polyarthritis	7.05	18	3	3.43	MTX, CFM, SZP, MMF
Polyarthritis + DILD	4.47	27	4	3.06	MMF
Polyarthritis + DILD	4.38	16	2	1.89	MMF
Polyarthritis + DILD + calcinosis	3.39	16	2	2.52	MMF
Polyarthritis + DILD + severe skin disease	4.85	48	4	2.12	MMF, Imatinib
Polyarthritis + DILD + severe skin disease + calcinosis	4.36	24	4	3.20	CFM
Polyarthritis + DILD	3.49	30	3	1.19	CFM, MMF

RTX treatment was only ineffective in one patient (8%) and was suspended at six months because of ineffectiveness. In the remaining 12 patients (92%), a good control of joint counts was achieved, and at the end of the follow-up period (median ± SD) of 18 ± 10 months (range, 12-48), the mean DAS28-ESR score decreased to 2.8 ± 1.3 (% improvement: mean -46.89%; range, -70.83% to -15.48%). In eight patients (61%), joint

disease remission (DAS28 < 2.6) was achieved. Three patients (23%) had low activity (DAS28 ≤ 3.2), and one (8%) had moderate activity.

The frequency of adverse effects was low, occurring in only two (15%) patients: one patient had two episodes of transient neutropenia (one feverish, prompting hospitalization), and the other had several mild infections (gastroenteritis, a urinary tract infection, and a respiratory infection). In neither of the two cases was it necessary to discontinue RTX treatment. In the patients with concomitant DILD, no worsening was observed in lung function tests.

Conclusion:

In our experience, RTX is a safe and effective drug for the treatment of joint disease in patients with SS

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Systemic sclerosis (scleroderma, SSc) is an autoimmune connective tissue disease with increased mortality from various internal organ involvement. Scleroderma renal crisis (SRC) usually occurs in the diffuse cutaneous systemic sclerosis (dcSSc) subset. It causes acute severe hypertension and acute renal failure. In recent years, it has been treated with angiotensin-converting enzyme (ACE) inhibitors with great success and improved mortality. The prevalence of SRC since its classification in the early 1970s was determined as it is our impression that SRC prevalence is decreasing over time.

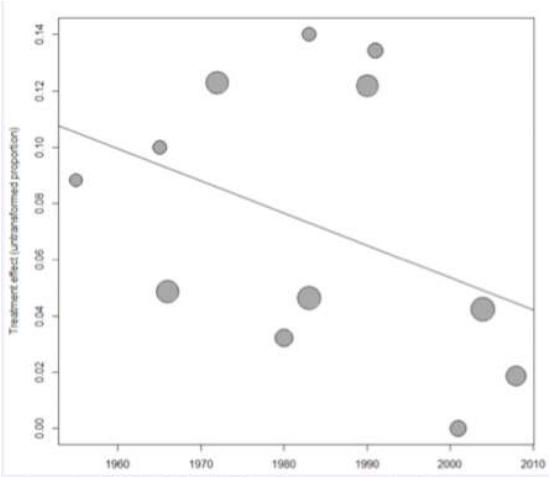
Methods:

A review of published articles and unpublished data was conducted up to May 2015 using MEDLINE, EMBASE, CINAHL, and Cochrane databases. Articles were included if they pertained to the prevalence of SRC in a cohort of patients. Articles were excluded if they were not in English, did not have a cohort of at least 50 dcSSC patients, if they were review articles, or solely abstracts.

Results: Of the 5306 citations identified, only 11 qualified. They were from Europe, USA, Australia, UK, and India. Years of publication were from 1983 to 2011 and cohort size varied from 68 to 3656 patients with SSc totaling 11,139 patients (4,536 [40.7%] with dcSSc). Dividing data by year of publication, before and including 1990, SRC occurred in 13.5% of dcSSc, from 2002 to 2007, SRC was in 7.9% and in 2010 and 2011, SRC had was infrequent at 2.4% (Figure). In lcSSc the range was from 0 to 4% with no obvious decreasing over time.

Conclusion:

It appears that SRC remains very uncommon in lcSSc and the rate in this group may be stable over time. However, the frequency of SRC has dropped dramatically in the dcSSc subset. The reasons for this are not known, especially as there is longer survival in SSc. Prophylactic use of ACE inhibitors does not seem to decrease the risk of SRC (observed in other studies) so it may be the changing etiology of SSc over time.



Graph of SRC in dcSSc by year of cohort

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a severe, systemic auto-immune disease with limited treatment options. Previous observational studies showed possible efficacy of Rituximab (RTX), a monoclonal antibody against CD20. Our objective was to evaluate safety and efficacy of RTX in patients with SSc.

Methods: In this randomized, double-blind, placebo-controlled, single centre trial, patients with SSc (ACR 1980 criteria), diagnosed less than 2 years ago, were assigned to receive either 1000mg RTX or placebo on day 1, 15 and at 6 months. Patients were followed for 2 years with 3 monthly evaluation of modified Rodnan Skin Score (mRSS) , pulmonary function, laboratory tests and 6 monthly evaluation of high resolution CT thorax and cardiac ultrasound. Primary endpoints of the study were treatment related mortality, treatment related toxicity and clinical efficacy reflected by progression-free survival. Adverse events (AE) and serious adverse events (SAE) were recorded every visit. Progression was defined as ³ 10% drop in Forced Vital Capacity (FVC)of predicted, and/or ³ 15% drop in Diffuse Capacity of the Lung for Carbon Monoxide (DLCO) of predicted, and/or ³ 15% drop in left Ventricle Ejection fraction (LVEF), and/or ³ 15% drop in body weight, and/or ³ 30% drop in creatinine clearance, and/or ³ 30% increase in mRSS on 2 consecutive visits.

Results: Seventeen patients, including 14 females (82%), 11 Caucasians (65%), mean aged 39 (SD 14) years and a mean mRSS of 13 (SD 10), were included. One patient did not start treatment due to disease progression within 2 weeks after screening. Of the remaining patients, 8 received RTX and 8 received placebo. At baseline, patients characteristics were comparable between the groups. Two patients dropped out after 6 months, n = 1 (RTX) at own request, and n = 1 (placebo) due to active disease. This patient eventually died of a renal crisis after autologous stem cell transplantation.

After a median follow-up of 22 months (19-26 IQR), in total 90 AE (n=54 AE in n=8 for RTX; n=36 AE in n =8 for placebo; p=0,442) were reported of which 11 SAE (n=6 SAE in n= 5 for RTX; n=5 SAE in n=2 patients for placebo; p=0.335; none could be related to RTX). With placebo, disease progression according to prespecified criteria was observed in 1 patient (T= 18 months; based on ³ 30% increase in mRSS) ,

while progression free survival was 100% with RTX (p=0.13). Over time, no significant differences in mean mRSS, FVC, DLCO, LVEF and creatinine clearance were observed between the groups (Table 1: mean mRSS).

Conclusion: These preliminary results show that treatment with RTX is well tolerated by SSc patients. Although no differences in clinical parameters were observed between the groups, progression free survival was 100% with RTX and 75% with placebo. More detailed analyses on clinical and serological parameters, and functional ability scores, are currently being performed to evaluate efficacy of RTX.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster I

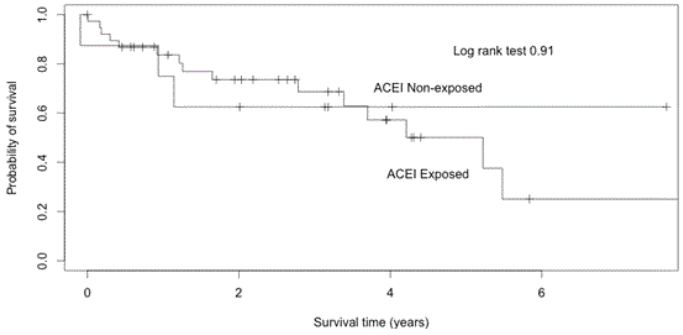
Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Scleroderma renal crisis (SRC) is a life-threatening complication of systemic sclerosis (SSc). Since the advent of angiotensin converting enzyme inhibitors (ACEI), the outcome of SRC has improved. There has also been more liberal use of ACEI to treat Raynaud's phenomenon and systemic hypertension in SSc. There is some evidence suggesting that exposure to ACEI prior to the onset of SRC may be associated with worse outcomes. The objective of this study is to evaluate the risk of death in SSc patients with SRC who were and were not exposed to ACEI prior to the onset of SRC.

Methods: We conducted an international multicenter retrospective cohort study of incident SSc patients with SRC. The exposure was treatment with ACEI prior to SRC. The primary outcome was time to death. Cox proportional hazards models were used to estimate risk in those exposed and not exposed to ACEI prior to SRC expressed as hazard ratios (HR).

Results: More than 3000 SSc patients were screened to identify 48 incident SSc patients with SRC, with a mean age of 59.4 years. Forty-one (85.4%) were female, 41 (85.4%) had diffuse SSc and 19/27 (70.3%) had RNA polymerase III antibodies. Prior to SRC, 18 (39.1%) subjects had systemic hypertension, and mean creatinine was 78.5 umol/L. Eight (17.4%) patients were on an ACEI. Post SRC, 30 (63.8%) subjects had new hypertension, mean creatinine was 262.5 umol/L, and 41 (85.4%) were on an ACE inhibitor. Post SRC, there were 19 (39.6%) deaths, 3 (37.5%) in the ACEI exposed group and 16 (40%) in the ACEI non-exposed group. The probability of 1-year survival was 75.0% (95% CI 50.3%, 100%) in the ACEI exposed compared to 83.6% (95% CI 72.4%, 96.6%) in the ACEI non-exposed. Kaplan Meier analysis found no difference in survival curves (log rank test p=0.91). In the unadjusted model for survival, ACEI prior to SRC had a HR 0.93 (95% CI 0.27, 3.23). Adjusting for baseline hypertension, the HR for ACEI exposure was 0.73 (95% CI 0.19, 2.88). Interestingly, in the unadjusted model for survival, calcium channel blocker (CCB), exposure prior to SRC had a HR 1.12 (95% CI 0.43, 2.87). Adjusting for baseline hypertension, the HR for CCB exposure was 1.06 (95% CI 0.40, 2.78).



Conclusion: Exposure to ACE inhibitors prior to onset of scleroderma renal crisis was not associated with increased mortality. Some limitations of this study include the design, which may be associated with left truncation, and low power, as evidenced by the wide confidence intervals. Further international efforts will be required to definitely resolve this important clinical question.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) is recognized as one of the most fatal rheumatic diseases, but it also promotes many detrimental effects on health-related quality of life (HRQOL). However, previous studies on HRQOL in SSc have lacked power, due to the difficulties involved in recruiting large samples for such a rare condition. Indeed, most previous studies focused on the outcome of patients in the early stages of disease or with DcSSc. The purpose of this study was to assess HRQOL and disease perception in a large, international group of SSc patients using validated questionnaires.

Methods: We conducted an international cross-sectional survey supported by EUSTAR, FESCA and Scleroderma US Foundation, from December 2013 to April 2014. We designed a standardized questionnaire translated and available on a website, including: Socio-demographic information, disease characteristics and self-assessment questionnaires namely Short Form 36 (SF-36) and Revised Illness Perception Questionnaire (IPQ-R).

Results: 1902 SSc patients from 60 countries were included with a mean±standard deviation (SD) age of 54±16 years and a mean±SD disease duration of 13±12 years. 712 (34.4 %) patients had DcSSc, 853 (44.8 %) had limited cutaneous SSc (LcSSc) and 122 (6.4 %) had SSc sine scleroderma.

HRQOL was found to be strongly impaired in SSc; in physical health (PCS, mean±SD 43.4±23.4; 100=best health) but also in mental health (MCS, mean±SD 52.3±23.1; 100=best health). SSc patients also had strongly perceptions about the chronic nature and negative consequence of the disease, and experienced negative emotions due to SSc.

Patients with DcSSc had a poorer HRQOL than those with LcSSc, for both physical (PCS, mean±SD 46.6±23.7 vs. 39.8±22.3; $p<0.0001$) and mental components (MCS, mean ± SD 53.8±23.0 vs. 50.3±23.2; $p=0.003$). They also had a more negative perception of their disease. Late-stage SSc patients were more likely to perceive their disease chronic ($p<0.0001$), less controllable ($p=0.03$) and with more consequences ($p=0.008$), but they also had a better understanding of their disease and experienced fewer negative emotions due to SSc.

Raynaud's phenomenon was the organ involvement with the most severe impact on daily life, associated with the most negative perception of illness severity followed by gastrointestinal complications, musculoskeletal and skin lesions.

Non-European SSc patients reported greater impacts on QOL, particularly for the physical component (PCS, mean±SD 39.9±22.6 vs. 46.0±23.7; $p<0.0001$), and they had a more negative perception of their illness than European SSc patients, but they had a better understanding of their disease and experienced fewer negative emotions.

Conclusion: This study provides unique information about the patients' perception of the disease and its impact on QOL, according to disease subset, disease duration and various geographical origins. The key message overall is the major impact on QOL and the negative perceptions of their disease expressed by SSc patients. Nevertheless, perceptions of the illness tended to improve with disease duration, suggesting the development of effective coping strategies. These results should be taken into account in patient management and future trials.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic sclerosis (SSc) has been linked with environmental and occupational exposures. Silica and solvent exposure have the strongest known correlation with SSc. Other agents, notably aerosolized particles, may have a potential role in pathogenesis. To date, there has been limited information on how these exposures relate to disease phenotype. The objective of this study was to evaluate associations between occupational exposures and SSc phenotypes.

Methods: We used a large, prospectively enrolled, single-center SSc cohort for analysis. At the first visit, self-reported occupational exposure data is routinely collected. We reviewed this occupational exposure data on all patients seen between January 1, 2000 and December 31, 2014. Exposure was categorized as: none, solvent, silica/dust, other exposure (examples include fumes, aerosols), or ≥ 2 categories. We evaluated associations with disease phenotypes including cutaneous subtype (diffuse vs. limited), serum autoantibody (anti-Scl70, anti-RNA polymerase 3, anti-centromere and other) profile, and pulmonary involvement. Pulmonary arterial hypertension (PAH) was defined as a mean pulmonary artery pressure (PAP) > 25 mmHg on right heart catheterization or transthoracic echocardiogram with PAP > 45mmHg and PAH diagnosed by a cardiologist. Interstitial lung disease (ILD) required the presence of radiographic fibrosis. Chi-square analysis was used to compare groups by exposure status.

Results: The total cohort (n=746) was 78% female, 99% Caucasian and average age was 54 years. Of the 746 patients, 135 reported an occupational exposure. There were no differences between the exposed and unexposed groups in age or race, although there were more males compared to females in the exposed group (57% vs 14%, p <0.001). There was no difference in exposure between cutaneous subtype or serum autoantibodies. ILD was more frequent in the exposed (51%) vs. unexposed (37%) group (p=0.004). Subanalysis of the exposed groups found individuals with dust/silica exposure have a significantly higher rate of ILD than unexposed individuals (p=0.007). There was no difference between the exposed and unexposed group in PAH prevalence (p=0.29). However among the exposed group, those with "other" had a markedly higher rate of PAH at 32% (p=0.01).

Table 1: Prevalence of PAH and ILD by Occupational Exposure Group

	No Exposure n=611	Solvent n=47	Silica/Dust n=46	Other Exposure n=31	≥ 2 Exposures n=11
Pulmonary arterial hypertension	64 (10.5%)	4(8.5%)	4 (8.7%)	10 (32.3%)	1 (9.1%)
Interstitial lung disease	228 (37.3%)	22 (46.8%)	27 (58.7%)	13 (41.9%)	7 (63.6%)

Conclusion: Males had higher rates of occupational exposure. There was no relationship between exposure and cutaneous or autoantibody subtype. Silica/dust exposure was significantly associated with an increased frequency of ILD, whereas an increased frequency of PAH was seen in those who reported an occupational exposure that was not solvent or silica. These descriptive findings suggest that further investigation into occupational exposures and relationship to SSc-ILD and SSc-PAH is warranted.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Cutaneous Telangiectasia (CT) are common in systemic sclerosis (SSc) patients but their input to risk stratify the patients is poorly known. The aims of our study were to determine whether the number and size of CT i) were related to the pattern of microvascular lesions assessed by nailfold videocapillaroscopy (NVC) and ii) were associated with other disease characteristics, and more particularly with markers reflecting the severity of SSc-related vasculopathy.

Methods: We performed a cross-sectional study including consecutive SSc patients over a 6-month period. We considered three subsets of patients according to the number of hand or face CT: absence of CT, ≤10 hand or face CT (minor to moderate CT) or >10 CT (profuse CT). Pseudotumoral CT were also taken into account and were defined as CT with > 5mm diameter. NVC was performed and classified as early, active and late patterns.

Results: 87 patients were included (69 females), with median age of 57 years (range 19-89 years), and median disease duration of 11 years (range 0-53 years). 52 patients (60%) had the limited cutaneous subset. 75 patients (86%) had CT: 27 (36%) had profuse CT, and 19 (25%) pseudotumoral CT.

In univariate analysis, patients with profuse and pseudotumoral CT were more likely to have the late NVC pattern (p=0.003 and p=0.001 respectively). Profuse and pseudotumoral CT were also associated with capillary loss (5.09±1.25 vs. 7.73±2.1 capillaries/digit, p<0.001, and 5.34±1.11 vs. 7.34±2.03 capillaries/digit, p=0.002, respectively) and neoangiogenesis (p=0.009 and p=0.003 respectively).

Regarding disease characteristics, patients with profuse or pseudotumoral CT were significantly older than patients without these lesions (p=0.018 and p=0.037, respectively); patients with profuse or pseudotumoral CT were also more likely to have increased sPAP on echocardiography (>40mmHg, p=0.007 and p=0.004, respectively) and increased plasma HS-cTnT levels (>14 ng/L, p<0.001 and p=0.025, respectively). The likelihood of pseudotumoral CT was significantly higher in patients with precapillary pulmonary arterial hypertension (PAH) (p=0.008). A trend was observed for an association between profuse CT and past or current digital ulcers (DU) (p=0.055).

Then, a logistic regression analysis was performed including profuse or pseudotumoral CT as outcomes together with covariates reflecting the severity of vascular involvement. This analysis revealed that profuse CT were independently associated with past or current DU (odds ratio, OR: 2.95, 95% confidence interval, CI: 1.09-16.93, p=0.034), and above the cut-off value of HS-cTnT (OR: 7.66. 95% CI: 1.07-54.85, p=0.043). Pseudotumoral CT were independently associated with late NVC pattern (OR: 4.84, 95% CI 1.32-26.19, p=0.018) and precapillary PAH (OR: 12.60, 95% CI 1.68-94.53, p=0.014).

Conclusion: We demonstrate that the number and size of CT are associated with the most severe NVC pattern. In addition, profuse and pseudotumoral CT identify a subset of patients with a more severe vascular phenotype. Thus, the number and size of CT may reflect the vasculopathy of SSc and could represent a clinical biomarker for vascular disease.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Systemic sclerosis (SSc) is a well established disease associated with primary biliary cirrhosis (PBC), however original 1980 American College of Rheumatology (ACR) criteria have poor sensitivity, especially for detection of earlier SSc in previous studies. The objective is to evaluate the prevalence of SSc in PBC patients using more sensitive 2001 LeRoy criteria and the recent 2013 ACR/European League Against Rheumatism (EULAR) classification criteria, and secondarily the frequency of individual clinical features.

Methods:

100 PBC patients without previously diagnosed SSc were recruited over 18 months from a tertiary care gastroenterology clinic. All patients underwent a clinical, biological, and capillaroscopic evaluation. Fulfillment of the three different criteria sets were analyzed.

Results:

1% of the PBC patients met the ACR 1980 criteria. 22% met the 2001 LeRoy's criteria for early SSc and 16% the 2013 ACR/EULAR criteria. Raynaud phenomenon, SSc related antibodies and SSc nailfold capillaroscopy changes were the most prevalent findings with the highest

sensitivities to help guide future screening.

Conclusion:

Our data show a high prevalence of SSc and possible underestimation of previous studies using the original ACR 1980 criteria. SSc based on newly described criteria may lead to improved detection and increased benefits of earlier treatment in ameliorating SSc related morbidity and mortality.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Interstitial lung disease (ILD) is the leading cause of mortality in patients with systemic sclerosis (SSc). KL-6, a mucin-like glycoprotein highly expressed on type II pneumocytes, is known as a circulating biomarker for lung injury and various forms of ILD. Previous cross-sectional studies have shown that circulating KL-6 level is elevated in patients with SSc-ILD and is inversely correlated with percent predicted forced vital capacity (%FVC). We have recently found that elevated KL-6 level at baseline is an independent predictor of %FVC decline and mortality, although information on serial changes of KL-6 during the course of SSc is scarce. In **this study, we investigated clinical utility of serial KL-6 measurement in patients with SSc-ILD using a prospective cohort.**

Methods: We enrolled 58 consecutive patients who were diagnosed as having SSc between 2006 and 2012. These patients were selected from our SSc database, based on fulfillment of 1980 American College of Rheumatology preliminary criteria, disease duration ≤8 years at diagnosis, follow-up period >2 years, availability of pulmonary function test (PFT) and chest high-resolution CT (HRCT) at diagnosis, and availability of serial PFT results in an interval of <2 years. Serum KL-6 was measured using a monoclonal antibody-based kit (Eidia, Japan) at every visit. Clinically meaningful change of KL-6 levels was defined as 20% increase or decrease from the baseline. All clinical information had been prospectively recorded on the database.

Results: Twenty-three patients (40%) were classified as having diffuse cutaneous SSc, and 39 (67%) had ILD detected by HRCT at diagnosis. Baseline serum KL-6 level was significantly elevated in SSc patients with ILD than in those without ($P = 0.001$), and was higher in extensive than in limited disease in patients with ILD ($P < 0.001$). In 19 patients without ILD at diagnosis, KL-6 was below 500 U/ml at baseline, and was pretty stable during disease course. In contrast, baseline KL-6 level was highly variable in patients with ILD: 51% <500 U/ml, 18% 500-1000 U/ml, and 31% >1000 U/ml. KL-6 levels changed with variation in patients with ILD: 7 increase, 19 unchanged, and 13 decrease during 4.5 ± 1.1 years (range 2.0 - 6.3 years), regardless of the treatment. Yearly change of %FVC was inversely correlated with both the final KL-6 level and the final to initial KL-6 ratio ($p = 0.047$ and <0.001, respectively). Moreover, 20 patients who showed sustained increase of KL-6 (>500 U/ml) experienced significantly higher %FVC deterioration than those who did not ($p = 0.03$). Eleven patients with ILD received treatment with oral or intravenous cyclophosphamide during disease course. In these patients, KL-6 level significantly reduced at 12 months after initiation of the treatment ($p = 0.045$).

Conclusion: Serial measurement of KL-6 may be useful in predicting progression of pulmonary function and in evaluating treatment response of cyclophosphamide in patients with SSc-ILD.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Heart involvement both of primary origin or secondary to lung disease is a key contributor to morbidity and mortality in systemic sclerosis (SSc). While Echocardiography is a primary tool of assessment in this setting, we have already reported that N-terminal Pro-brain natriuretic peptide (NT-proBNP) allows the reliable detection of reduced left and/or right ventricular ejection fraction (LVEF and RVEF) and of pulmonary arterial hypertension (PAH). Whereas NT-proBNP could predict mortality is SSc patients remains unknown.

Methods: This is a longitudinal, multicenter study that included 523 patients with SSc: mean age = 54±13 years, 323 women (61.8%), 8±9 years disease duration, diffuse cutaneous form in 168. Plasma NT-proBNP was measured at baseline and patients were followed up annually to 5 years. **Results:** At baseline, 37 patients had manifestations of cardiac involvement, including 17 with proven (PAH) and 20 with reduced LVEF<55%. 32 patients (7%) died within 3 years of follow-up and 59 (16%) within 5 years. NT-proBNP concentration was increased in SSc who died within 3 years versus those who survived (203 [129-514] versus 88 [47-167] ng/l respectively, p<0.001). Similar results were observed for a 5-years follow-up period (p<0.001), or after the exclusion of patients having PAH or reduced LVEF at baseline (p=0.001). Using a 125 ng/l cutoff value, NT-proBNP reliably predicts 3-y and 5-y mortality (respective sensitivities of 78.1% and 59.3%) (Figure 1). Negative predictive values for 3-y and 5-y mortality of a NT-proBNP concentration <125 ng/l were 97.6% and 90.0% respectively). Receiver-operating-characteristics analysis confirmed that NT-proBNP reliably predicted mortality (area under the curve 0.76). Of the most interest, in multivariate analyses, elevated NT-proBNP was an independent predictor of mortality at 3 years (p=0.03) such as pulmonary functional tests (FVC, p=0.008 and DLCO/VA, p= 0.01).

Conclusion: NT-proBNP reliably and independently predicted 3- and 5-years mortality in patients with SSc. Remarkably, our data show that NT-proBNP levels provide additional prognostic information that is independent of the one offered by common characteristics of the disease. Therefore, NT-proBNP may be considered as a first-line tool for prognostic assessment in SSc patients. This adverse prognostic marker might be considered as a potential eligibility criterion for risk stratifying SSc patients and for investigational or high-risk interventions.

Figure 1 : Kaplan Meier representation of 3y mortality according to NT-proBNP concentration (cox model for analysis)

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Skin involvement may be evaluated in systemic sclerosis (SSc) by modified Rodnan skin score (mRSS), the validated method to distinguish between patients with limited (lcSSc) or diffuse (dcSSc) cutaneous skin involvement (1). In lcSSc the skin involvement is confined to the extremities (hands, forearms, feet, legs and face), whilst it is present also on arms, chest, abdomen and thighs in dcSSc patients (2). However, mRSS is unable to identify slight alterations in dermal thickness (DT) (3), and several studies report the utility of high frequency skin ultrasound (US) for early identification of skin involvement in SSc patients (4,5). DT was found progressively higher in SSc patients with worsening pattern of nailfold microangiopathy (5).

The aim of this study was to measure DT by US in both SSc patients and healthy subjects, looking for differences between the groups and correlations between US and mRSS.

Methods: Forty-eight SSc patients (ACR/EULAR criteria) (mean age 64±11SD years, mean disease duration 6±5 years) and 20 healthy subjects (mean age 66±14 years) were enrolled, after informed consent (1). Dermal thickness (DT) was evaluated by both mRSS and US transducer with 22 MHz frequency (Esaote, Genoa, Italy) at the level of the usual seventeen skin areas (cheeks, fingers, dorsum of hands, forearms, arms, chest, abdomen, thighs, legs, feet) in both SSc patients and healthy subjects. Nailfold videocapillaroscopy (NVC) was also performed to detect and classify SSc patients into the proper pattern of nailfold microangiopathy (“early”, “active” or “late”) (6).

Results: By US, DT was found significantly higher in both dcSSc and lcSSc patients than in healthy subjects in all the seventeen skin areas (median total DT 21.5 vs 19.1 vs 14.9 millimetres, respectively; $p<0.01$). Of great importance, lcSSc patients showed a statistically significant higher DT than healthy subjects in all the skin areas even with normal mRSS (mRSS=0), in contrast with the classificative diagnosis of lcSSc (median DT 1.20 vs 0.86 for right arm, 1.10 vs 0.86 for left arm, 1.30 vs 1.13 for chest, 1.40 vs 1.13 for abdomen, 1.40 vs 1.10 for right thigh, 1.40 vs 1.10 for left thigh, respectively; $p<0.01$). A significant progressive increase of DT was observed by US in SSc patients with different NVC pattern of microangiopathy at the level of all areas (median total DT 17.53 vs 21.20 vs 21.43 millimetres respectively for "early", "active", or "late" pattern, $p<0.05$). Finally, a statistically significant positive correlation was found between mRss and US in DT evaluation ($r=0.67$, $p<0.0001$).

Conclusion: This study demonstrates the utility of high frequency skin US to detect the subclinical diffuse dermal involvement even where the mRSS is normal in patients with lcSSc. This observation could make a contribution for future classification of the disease.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

The majority of published models for prediction of PH use cross-sectional data, while studies exploring the use of repeated measurements of lung function tests (PFTs) are lacking. Gas transfer factor (DLCO) and forced vital capacity (FVC) are among the most powerful predictors of development of pulmonary hypertension (PH) in patients with systemic sclerosis (SSc).

We examine the changes in FVC and DLCO over time in a large unselected cohort of SSc patients and to explore their association with development of PH.

Methods:

We identified subjects with SSc with follow-up data for over 10 years and PFTs performed on at least two occasions. Linear mixed models were used to look for associations between repeated measurements of FVC and DLCO and development of PH over the follow-up period.

Results:

In this study we included 371 SSc subjects – 13% of those were male, 36% had diffuse cutaneous (dc)SSc. The cohort demonstrated antibody frequencies similar to other previously published studies - 27% had anti-centromere antibody (ACA), 20% had anti-topoisomerase I antibody, 8% had anti-RNA polymerase antibodies (ARA) and 6% had anti-U3RNP antibodies. Of the whole cohort, 15% had developed PH at the end of follow-up and its cumulative incidence was 4% at 5 years and 13% at 10 years. PFTs were performed on average every 15 months, between 2 and 20 times (median 6 times).

The extrapolated average FVC and DLCO of the cohort at the time of disease onset (baseline) were 86% and 68% respectively. Overall, FVC tended to increase over time by an average of 0.5% per year (SD 1.29) while DLCO decreased by an average of 1% per year (SD 1.3).

Without adjusting for other factors, patients who developed PH had 8.5% lower baseline FVC, compared to those who did not develop PH ($p=0.008$). Over time, FVC decreased by 0.4 % per year in PH while in non-PH subjects it increased by 0.6% on average ($p<0.001$). As expected, the rate of change in FVC was influenced by a number of other clinical characteristics (Table 1.). Even after adjustment, baseline FVC was on average 7.1% lower in PH subjects compared to non-PH ($p=0.014$). While in non-PH patients FVC increased by about 1% per year, in those who developed PH, the increase was <0.1% ($p=0.003$).

Similarly, unadjusted analysis demonstrated that PH subjects had on average 12.6% lower baseline DLCO, compared to non-PH ($p<0.001$). In PH patients, DLCO decreased by 2.6% per year, while in non-PH, the yearly decrease was 0.8% ($p<0.001$). When adjusting for other covariates, PH was still associated with a substantially lower baseline DLCO (11.2% difference, $p<0.001$) and this decreased by 1.9% per year compared to 0.2% ($p<0.001$) in non-PH patients, when keeping all other covariates constant (Table 1).

Conclusion:

Our findings confirm the particular value of serial measurements of lung function in the identification of patients at risk of PH. Subjects who develop PH have lower baseline FVC and DLCO levels with increased rates of DLCO reduction over time.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Patients with systemic sclerosis (SSc) experience high rates of morbidity and mortality, but few studies have evaluated health care utilization such as hospitalization rates and in-hospital mortality associated with SSc. Moreover, it is unclear if and how these domains have changed over time and how they compare to other systemic rheumatic conditions. To address this knowledge gap, we evaluated in-hospital mortality and overall hospitalization trends in patients with SSc between 1999 and 2011 using a US nationwide inpatient database.

Methods:

The US National Inpatient Sample (NIS) contains all discharge data from a sample of hospitals from 44 states, making it the largest publicly

available all-payer inpatient health care database in the US. We studied all hospitalizations between 1999 and 2011 of adults (≥18 years) with a primary discharge diagnosis of SSc, identified by ICD-9 CM code 710.1. We evaluated in-hospital mortality and hospitalization rates over time and compared these rates to those of the overall hospitalized population and other systemic rheumatic conditions. All analyses were performed using hospital-level sampling weights provided by the NIS to obtain US national estimates.

Results:

Between 1999 and 2011, the rate of in-hospital mortality for patients admitted with SSc decreased from 9.6% to 5.8% (p for trend, <0.001), representing a yearly relative decrease of 4.0% (95% CI -7.2% to -0.8%) (**Figure 1**). Despite this decline, the in-hospital mortality rate in 2011 for patients with SSc (5.8%) remained substantially higher than for other systemic rheumatic conditions, including systemic lupus erythematosus (SLE) (0.93%) and granulomatosis with polyangiitis (2.6%), as well as than for the overall hospitalized population (2.1%). Among patients with a primary diagnosis of SSc who died during their hospitalization, the five most common secondary diagnoses were lower respiratory disease, fluid and electrolyte disorders, respiratory failure, pulmonary vascular disease and renal failure. These diagnoses did not change substantially during the study period, with the exception of congestive heart failure, which was replaced by renal failure. From 1999 to 2011, the rate of overall hospitalizations for SSc decreased slightly from 1.06 to 0.81 per 100,000 persons.

Conclusion:

Based on nationally representative inpatient data, our findings indicate a decrease in SSc in-hospital mortality between 1999 and 2011, suggesting that clinical care of SSc patients may be improving. Despite this encouraging trend, the in-hospital mortality rate remains approximately 6%, which is considerably higher than that of both the overall hospitalized population and any other systemic rheumatic condition. This highlights the need for continued improvement in the care of patients with SSc, including the development and implementation of effective therapeutic modalities.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster I

Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Heart involvement is common in Systemic Sclerosis (SSc), even if often clinically silent, and represents one of the leading cause of death in these patients. Recently it has been reported the role of NT-proBNP and high sensitivity Troponin T (cTnT) in patients with SSc-related pulmonary arterial hypertension (PAH), but their prognostic role is lacking in primary cardiac involvement. The aim of our study was to define the role of cardiac troponin T (cTnT) and NT-proBNP to identify cardiac involvement in SSc.

Methods: High sensitivity cTnT and NT-proBNP were measured in 200 consecutive SSc patients and in matched healthy controls. Patients with renal failure and with PAH on right heart catheterization were excluded. Data regarding disease subtype and organ involvement were available and all SSc-related deaths were registered. Classical cardiovascular risk factors were also considered. A mean follow-up of 48.6±20.6 months was reached.

Results:

cTnT levels and NT-proBNP values were higher in scleroderma patients (cTnT: 0.03±0.06 ng/ml and NTproBNP: 507.3±1718.9 pg/ml) than in healthy controls (cTnT: 0.006±0.0004 ng/ml and NT-proBNP: 90.6 ± 70.9, pg/ml,$p<0.00001$ for both comparisons).

cTnT levels were upper the normal limit in 65 SSc patients (32.5%), 72.6% complained cardiac symptoms, while 27.4% was completely asymptomatics. At multivariate analysis diffuse skin involvement (RR: 2.1 [1.2-4.4] and the presence of right bundle branch block (RBBB) on ECG (RR: 8.1 [1.4-45.5]) emerged as indipendent predictors of elevation of cTNT. NT-proBNP levels were above the cut-off limit of 125 ng/ml, recommended by the manufacturer, in 66 patients (33.3%), 72% of whom complained cardiac symptoms, while 28% was asymptomatic. Thirty-eight patients (19.0%) presented either an increase of cTnT either of NT-proBNP. At multivariate analysis diffuse skin involvement (RR: 2.3 [1.1-4.9]) and age (RR: 1.2 [1.03-1.09]) were indipendent predictors of elevation of NT-proBNP.

During the follow-up, 12 SSc-related death occurred; 8 of these were directly related to cardiac involvement (sudden cardiac death or heart failure). Cumulative survival estimated by Kaplan-Mayer curve was worse in patients with increased baseline levels of cTnT (X^2=10.2, p=0.001) and NT-proBNP (X^2=11.1, p=0.001), but patients with increase of cTnT and NT-proBNP had the worst outcome (X^2=13.5, p=0.003).

Conclusion:

cTnT and NT-proBNP are useful markers to identify symptomatic and asymptomatic SSc patients with a subclinical heart disease and a bad cardiac outcome.

Nitroglycerin Patch Application in Systemic Sclerosis: Evaluation By Laser Doppler Imaging

Georgiana Bentea, Aurelien Wauters, Jean-Claude Wautrecht and Elie Cogan, Erasme Hospital, Brussels, Belgium
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Systemic sclerosis (SSc) is a complex autoimmune disease, commonly associated with Raynaud phenomenon (RP). The aim of this study was to characterize the microvascular reactivity to nitroglycerin (NTG) patch application in SSc patients by Laser Doppler imaging (LDI), and investigate predictive markers of the NTG response.

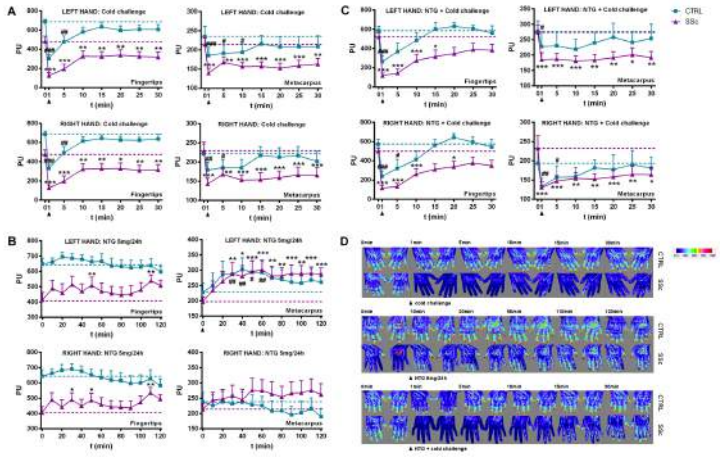
Methods:

The study included 21 SSc patients and 13 age-matched healthy volunteers. The SSc patients recruited from Erasme Hospital, Brussels, Belgium, met the American College of Rheumatology criteria for SSc, and presented with secondary RP. Blood flow was evaluated by LDI, and expressed in perfusion units (PU), as well as the area under the perfusion-time curve normalized for baseline flux (AUC). Microvascular morphology was evaluated by nailfold capillaroscopy (NC). Baseline measurements were complemented by dynamic studies analyzing microvascular function following application of a NTG 5mg/24h patch (left hand metacarpus, during 120 min). Subjects also underwent a cold challenge (both hands, 1 min at 15^{o}C) in the absence of, and following NTG application.

Results:

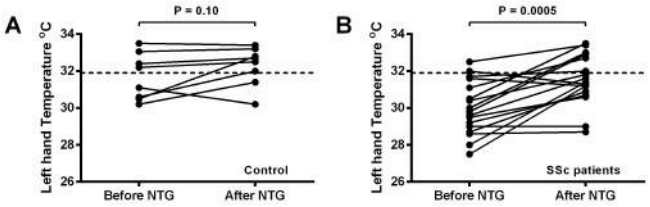
LDI measurements revealed decreased fingertip baseline perfusion in SSc patients compared to control. Moreover, SSc patients demonstrated a stronger vasoconstrictor response to a cold challenge, at both hands (Fig 1A).

Figure 1.



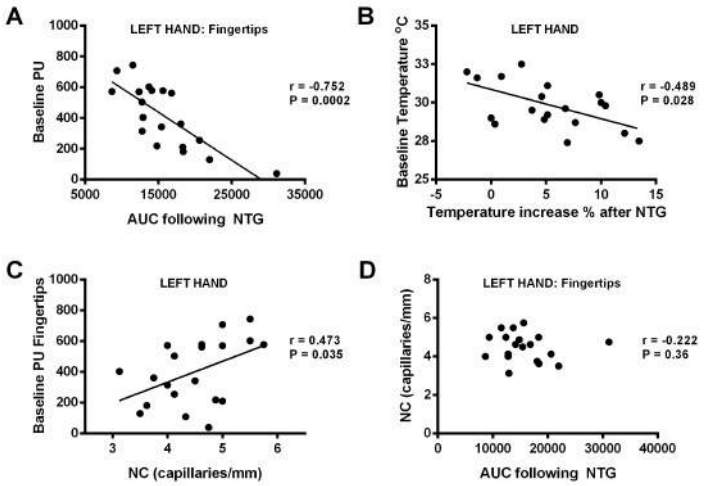
Metacarpal application of NTG patch led to an increase in blood flow and hand temperature in SSc patients but not in controls (Fig 1B, Fig 2). Furthermore, NTG administration led to a faster reperfusion after cold challenge (Fig 1C).

Figure 2.



Correlations analyses revealed that the magnitude of the vasodilatory response following NTG was inversely related with baseline fingertip perfusion and hand temperature (Fig 3A, B), but unrelated with structural microvascular features assessed using NC (Fig 3D).

Figure 3.



Conclusion:

We provide evidence of a vasodilatory reaction following application of a NTG patch in SSc patients using LDI. Furthermore, the magnitude of the response to NTG was related with functional, but not structural, features. In particular, SSc patients that showed decreased baseline condition (lower fingertip perfusion and hand temperature) benefited the most after NTG application. Our results support a further evaluation of the NTG patch as a possible effective treatment for SSc-associated RP.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Interstitial lung disease (ILD) is a common cause of mortality in systemic sclerosis (Ssc). Decreased forced vital capacity (FVC) in Ssc-ILD is associated with increased dyspnea, is predictive of more rapid development of clinically significant pulmonary fibrosis, and is associated with increased mortality. **Methods** are needed to prospectively identify patients at risk for progressive ILD to guide clinical trial enrollment and early treatment.

Methods: Continuous curves indicating the most likely future FVC values of a given individual are predicted using clinical data (see Fig. 1). Our model uses individual characteristics including demographic (gender and race) and serologic measurements (ACA and Scl-70 antibody positivity). In addition, it uses the FVC history of the individual to dynamically update predictions. Key to our approach is the idea of disease subtypes: subgroups of individuals with similar lung disease trajectories [1]. These trajectories are derived with a statistical learning algorithm (see for example [2]) using prospectively collected data. Individual-specific model parameters further personalize predictions. Our algorithm is being adapted to a web-based interface, allowing practitioners to obtain personalized estimates of a patient's future disease course.

Results: Figure 1 shows two individuals who test positive for Scl-70 antibodies and diffuse skin disease—both typically associated with development of progressive ILD. The two most probable subtypes are shown. Baseline FVC levels are comparable across both patients. After one year of followup, indicated by points (A) and (B), our model is able to correctly predict that the FVC in the individual in the first row will remain stable, while the other will experience FVC decline. After a transient decrease in FVC in the top patient resulting from an episode of cholecystitis, the predicted FVC trajectory appropriately continued to predict a largely stable course of ILD. After 4 years of data the confidence in each prediction is strengthened in spite of the sharp consecutive drop that both individuals exhibit—indicated by points (C) and (D). Using 10-fold cross validation on 672 patients, our model achieves mean absolute errors of 10.37, 8.95, and 6.98 when predicting pFVC values between 8-12 years of followup using 1, 2, and 4 years of data respectively.

Conclusion: Our prognostic model allows dynamic prediction of an individual's FVC trajectory from limited initial demographic and serologic data, and could inform recruitment of patients with similar expected ILD course into clinical trials. Incorporation of the model into a web-based decision-support tool could provide real-time prognostic data for widespread clinical practice.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Heart disease occurs in most patients with systemic sclerosis (SSc), as emerged by autopsy and imaging studies. It can cause cardiac blocks (CBs), ventricular arrhythmias (VA), Q waves, and congestive heart failure (CHF), referred to as "severe heart disease" (SHD), as they may require a pacemaker/defibrillator implant (PM/DF) or ensue in death/sudden death (SD) in about 20% of cases. In a retrospective study, SHD has been recently found in 211/1119 SSc patients from the European Scleroderma Trial and Research (EUSTAR) database at first visits. We aimed to look for SHD incidence in a large SSc cohort and to identify SHD-related predictors.

Methods: SSc patients prospectively enrolled by 14 centers into the EUSTAR database from April 16 2013 to April 30 2015 with at least 1 follow-up (FU) visit were analyzed. At baseline, the prevalence of SHD manifestations was calculated. Incidence rates of SHD manifestations and their associations with demographics, disease features, and vasodilatory treatment were also calculated (study protocol at *www.clinicaltrials.gov;* NCT01836263).

Results:

Out of 449 patients meeting the new ACR/EULAR criteria for SSc with complete data on SHD, 284 (63%) had at least 1 FU visit (median FU 1.01 years, range 0.18-1.99) and were analyzed. Eighty-seven % were females; median age was 57 years (range 13-86); median disease duration 8 (range 0-61); 26% had diffuse cutaneous SSc; 74% limited cutaneous SSc. ANA were positive in 98% of patients (42% ACA; 34% anti-Scl-70; 5% anti-RNA polymeraseIII; 3% anti-PmScl; 3% anti-U1RNP). At baseline, 65/284 (23%) patients had at least 1 SHD manifestation: 52/280 (19%) had CBs, 2/267(1%) VA, 9/269 (3%) CHF, 6/262 (2%) Q waves, and PM/DF had been applied in 3/269 (1%). There was no statistical difference in any demographic and disease feature nor in the prevalence of SHD manifestations between the whole cohort and the patients investigated. During FU, 32 patients had a new SHD manifestation (20 CBs, 7 VA, 4 CHF, 2 Q waves, 1 PM/DF), with incidence rates of 11/100 patient*year for any SHD, 7/100 patient*year for CBs, 2.5/100 patient*year for VA, 1.43/100 patient*year for CHF, 0.7/100 patient*year for Q waves, and 0.4/100 patient*year for PM/DF. In univariate analysis, newly developed SHD manifestations were associated with baseline SHD, dyspnea, chest X-ray fibrosis, FVC and DLCO<80% of predicted, echo-assessed pulmonary hypertension (PH), modified Rodnan Skin Score (mRSS) and active disease (European Scleroderma Study Group Activity Index). At multivariate Cox-regression analysis, mRSS (HR 1.1, 95%CI 1.03-1.21) and echo-assessed PH (HR 17, 95%CI 4.4-66) were independent predictors of new SHD manifestations. New cases of CHF were only observed in patients with preexisting SHD.

Conclusion: To our knowledge, this is the first study investigating the incidence of all SHD manifestations in SSc. Our results suggest that mRss and echocardiographic PH mark an increased risk of new SHD manifestations over time and that CHF only develops in patients with preexisting SHD.

Does the Clinical Context Improve the Reliability of Rheumatologists Grading Digital Ulcers in Systemic Sclerosis?

Michael Hughes[1], Chris Roberts[2], Andrew Tracey[1], Graham Dinsdale[1], Andrea Murray[1] and Ariane L. Herrick[1], [1]Centre for Musculoskeletal Research, University of Manchester, Manchester Academic Health Science Centre, Manchester, United Kingdom, [2]Centre for Biostatistics, Institute of Population Health, University of Manchester, Manchester, United Kingdom

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Digital ulcers (DUs) are often a primary end point in SSc clinical trials, although the reliability of rheumatologists grading DUs is poor to moderate at best. This is of concern as DUs are often a primary outcome measure in SSc clinical trials. DU assessment in recent trials has been based upon visual inspection alone, which potentially misses ‘real-world' clinical contextual information (e.g. pain and discharge). Our aim was to investigate whether this clinical information improves the reliability of rheumatologists grading DUs.

Methods:

80 photographs of a range of digital lesions were collected from patients with SSc-spectrum disorders (mainly SSc). The following clinical information was collected for each image: duration of the lesion (patient reported), pain associated with the lesion on a visual analogue score (100 being most severe) and its temporal relationship (whether the pain was less, the same or worse than a week ago), and the presence of discharge (both patient reported and clinician observed). A custom web-based interface was constructed to display the images and record the grading. Rheumatologists were invited to participate through SSc-specialist networks and were randomised to receive all images either with or without context. Lesions were graded on an ordinal scale of severity: ‘no ulcer', ‘inactive ulcer' or ‘active ulcer'. Reliability was assessed using a weighted kappa coefficient, with bootstrapping to generate estimates of confidence intervals. Ordinal logistic regression was used to investigate the relationship between the clinical context and grading.

Results:

51 rheumatologists completed the study (25 with and 26 without context), from 15 countries (mainly the US, UK, Canada and Italy). A total of 4590 (4080 unique and 510 repeated) image gradings were obtained. The intra and inter-rater reliability both without and with the context is presented in Table 1. There was no significant increase in the overall intra- or inter-rater reliability with the clinical context. There was a trend towards an increase in intra-rater reliability for ‘no ulcers' vs. ‘inactive ulcers' and ‘no ulcers' vs. ‘inactive'/'active ulcers', and a decrease for ‘inactive ulcers' vs. ‘active ulcers'. Patient reported discharge (OR= 2.67, 95% c.i. 2.02 to 3.53, P = <0.001) and pain VAS (OR= 1.02, 95% c.i. 1.01 to 1.03, P = <0.001) were associated with increased lesion severity, and lesion duration with reduced severity (OR= 0.81, 95% c.i. 0.76 to 0.86, P = <0.001).

Conclusion:

1. The overall intra and inter-rater reliability did not significantly improve with added clinical context.

2. There was a trend that clinicians may use the clinical context to help classify lesions as ‘no ulcer'.

3. Patient reported discharge and pain were associated with increased lesion severity and duration with reduced severity.

Table 1: Intra- and inter-rater reliability without and with context.

		INTRA-RATER RELIABILITY (95% CI)		INTER-RATER RELIABILITY (95% CI)	
		Without context	With context	Without context	With context
Overall		0.64 (0.53, 0.75)	0.71 (0.64, 0.78)	0.32 (0.25, 0.39)	0.36 (0.28, 0.44)
Pairwise	No ulcers vs. inactive ulcers	0.36 (0.08,0.60)	0.67 (0.50,0.84)	-0.07 (-0.17,0.02)	-0.03 (-0.12,0.05)
	No ulcers vs. active ulcers	0.95 (0.90,1.0)	0.90 (0.84,0.95)	0.42 (0.34,0.51)	0.44 (0.35,0.53)
	Inactive vs. active ulcers	0.53 (0.38,0.67)	0.41 (0.22,0.60)	0.22 (0.14,0.30)	0.21 (0.12,0.30)
Dichotomised	No ulcers vs. inactive/active ulcers	0.71 (0.60, 0.81)	0.82 (0.75, 0.89)	0.22 (0.16, 0.27)	0.26 (0.21, 0.31)
	No ulcers/inactive ulcers vs. active ulcers	0.74 (0.66, 0.82)	0.72 (0.65, 0.79)	0.32 (0.25, 0.39)	0.35 (0.27, 0.43)

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Clinical Aspects and Therapeutics Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Health-related quality of life (HRQoL) research is a priority in systemic sclerosis (SSc). Yet, much of the data comes from prevalent cohorts with established disease. There is a paucity of HRQoLdata in early SSc. The objective of this study was to estimate the magnitude of impairment in HRQoL, measured using the Medical Outcomes Trust Short Form-36 (SF-36), and the clinical correlates of physical and mental HRQoLin an inception SSc cohort.

Methods:

Cross-sectional study of incident SScsubjects (defined as < 2 years since onset of first non-Raynaud's disease symptom) enrolled in the International Systemic Sclerosis Inception Cohort (INSYNC) cohort. Subjects were assessed at entry with standardized clinical histories, medical examinations, and self-administered questionnaires and data were entered and harmonized in a central Redcap database. Multiple linear

regression was used to assess the relationship between selected demographic and clinical variables and the SF-36 Physical Component Summary (PCS) and Mental Component Summary (MCS) scores, adjusting for age, gender and race/ethnicity. Norm based scoring, where the mean score for the general population is 50 with a standard deviation (SD) of 10, was used to score SF-36 domain and summary scores. Values below 50 therefore indicate worse and above 50 better HRQoL, and each point is one tenth of a SD, compared to the general population.

Results:

The study included 483 incident SSc subjects (81% woman, mean (+SD) age 54.1+13.1 years, 89% White). Almost half (48.7%) of the cohort had diffuse cutaneous SSc (dcSSc), 27% interstitial lung disease (ILD), 6.0% pulmonary arterial hypertension (PAH) and 5.1% scleroderma renal crisis (SRC).

There were considerable impairments in all 8 SF-36 domains, with the worst scores for physical functioning (mean 36.5±12.7), role physical (36.4±13.9) and general health (38.6+10.8). Impairment was almost 1.5 SD below that of the general population in the SF-36 PCS (37.2± 12.0) and almost half of a SD below in the SF-36 MCS (45.7+12.7).

In multiple linear regression analysis, dcSSc (β -7.3, 95% confidence interval (CI) -10.0; -4.5, p<0.001), PAH (β -10.8, 95% CI -17.0; -4.6, p=0.001) and SRC (β -5.8, 95% CI -11.5; -0.15, p=0.04), but not ILD, were significant independent correlates of the SF-36 PCS score. The model explained 15% of the variance in the SF-36 PCS. On the contrary, ILD (β-4.1, 95% CI -7.6; -0.7, p=0.019), but not dcSSc, PAH or SRC, was a significant independent correlate of the SF-36 MCS. This model explained 4.7% of the variance in the SF-36 MCS.

Conclusion:

This study provides robust evidence of the magnitude and correlates of impairment in HRQOL in early SSc. Effective therapies are urgently needed to improve HRQoL in SSc.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Vasculitis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To facilitate clinical care and research, validated algorithms are needed to accurately identify patients with granulomatosis with polyangiitis (GPA; Wegener's). This study, sought to evaluate and validate case-finding algorithms for GPA in 2 large health administrative databases.

Methods: 250 patients were randomly selected from 2 large healthcare systems (125 patients per system) using the International Classification of Diseases version 9 (ICD9) code for GPA: 446.4. Because eosinophilic granulomatosis with polyangiitis (Churg-Strauss) shares the same ICD9 code with GPA, patients who have ever had ICD9 codes 288.3 (eosinophilia) or 493.* (asthma) were excluded. 30 case-finding algorithms were constructed using a combination of ICD9 code, encounter type (1 inpatient ICD9 code on 3 consecutive days or 2 outpatient ICD9 codes 3 months apart), physician specialty (Rheumatology, Nephrology, Pulmonology, or Otorhinolaryngology), use of immunosuppressive medications, and whether an ANCA test was ordered. 2 time periods for ICD9 code submission were examined: 1 year and 2 years. The diagnosis was confirmed by chart review using the modified ACR classification criteria or the Chapel Hill Consensus Conference definitions for GPA. Patients who did not have a clear diagnosis were excluded from the analysis.

Results: 97 patients from the first healthcare system (site 1) and 98 patients from the second system (site 2) were included in the analysis after

excluding patients with unclear diagnosis. 38/97 (39%) patients had a confirmed diagnosis of GPA at site 1 and 66/98 (67%) patients at site 2. Table 1 shows the positive and negative predictive values of the studied algorithms in each healthcare system. An algorithm excluding patients with eosinophilia or asthma and including the encounter type and the physician specialty had the highest average positive predictive value (PPV: 87.1%). An algorithm excluding patients with eosinophilia or asthma and including the physician specialty had the highest average negative predictive value (NPV: 83.1%). There were no differences between the 2 time periods with regards to the algorithms' PPV or NPV.

Conclusion: Case-finding algorithms can accurately identify patients with GPA using large administrative databases. A simple algorithm excluding patients with eosinophilia or asthma and including the encounter type and the physician specialty has the highest positive predictive value. Similarly, an algorithm excluding patients with eosinophilia or asthma and including the physician specialty has the highest negative predictive value. These algorithms can be used to assemble population-based cohorts of patients with GPA and facilitate future research in healthcare use, outcomes, and comparative effectiveness.

Table 1. Test characteristics of the GPA algorithms in both healthcare systems

GPA Algorithms	Site 1 (n=97)		Site 2 (n=98)

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Vasculitis Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: The Icelandic population is geographically isolated, genetically homogenous and with distinct environmental exposures. Deviations in disease occurrence compared to other Western countries might provide clues with respect to etiology of disease. ANCA-associated vasculitis (AAV) is a collective term for three rare small vessel vasculitides: Granulomatosis with Polyangiits (GPA), microscopic polyangiitis (MPA) and eosinophilic granulomtosis with polyangiitis (EGPA). The objective was to assess the incidence of AAV in the Icelandic Population.

Methods: Data from the Landspitali University Hospital and Akureyri Regional Hospital were used. Together, these hospitals provide care within the specialities of rheumatology, nephrology and immunology for the entire Icelandic population. The electronic medical records at those hospitals were search for ICD-9 and ICD-10 diagnoses corresponding to AAV from 1996-2006. Individual patient records were pulled for review. Final determination of AAV status was made if information in the patient record guided fulfilled the ACR classification criteria or the Chapel Hill nomenclature for systemic vasculitis. Information age, sex, ANCA measurements and organ involvement were obtained from the medical record. Numerical information on the size of the Icelandic population were obtained from the National Statistics Office. Incidence rate of AAV is expressed as number of new cases of AAV per million person-years of the Icelandic population during the study period.

Results: During the study period, 32 individual were diagnosed with AAV, an IR=10.30 (95% CI 6.7-13.9). Most subjects had GPA (N=20, IR=6.44(95%CI 2.9-10.0)) and 6 subjects had MPA and EGPA respectively. Mean age of patients was 54.7 years (range 20-87) and 20 (62.5%) of patients were women. Among patients with GPA, 65% had PR3-ANCA and 15% had MPO-ANCA. Among patients with MPA, 83% had MPO-ANCA and among patients with EGPA, 50% had MPO-ANCA.

Conclusion: The incidence of AAV is lower in Iceland that in most other Northern-European countries with an uneven female:male ratio. Prevalence and specificity of ANCA is similar as in other cohorts.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Vasculitis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: pathogenesis of ANCA-associated vasculitis (AAV) is multifactorial and most likely involves the interaction of environmental and genetic factors. Environmental seasonal exposures may play a role in the manifestation of the disease and incidence of relapses. Our objective was to investigate whether there are different clinical manifestations according to the seasonal period of the beginning of symptoms and if frequency of relapses differs in seasons in patients with ANCA vasculitis.

Methods: Patients with diagnosis of ANCA vasculitis (Chapel Hill 2012) (Granulomatosis with polyangiitis [GPA], Eosinophilic granulomatosis with polyangiitis [EGPA], Microscopic polyangiitis [MPA], and renal limited ANCA vasculitis [RLV]) seen between years 2000 and 2014 were included. Medical records we reviewed and dates of beginning of symptoms (symptoms included in the Birmingham vasculitis activity score attributed to the disease) and dates of relapses (recurrence of symptoms or new symptom attributed to vasculitis) were identified. Clinical and serological manifestations of ANCA vasculitis in patients beginning their disease in autumn-winter were compared with those beginning in spring-summer. Rate of relapses in the different seasonal periods was also compared.

Results: one hundred patients with AAV were included (females 70%, CI 60.9-79.1; mean age at diagnosis 58.4, SD 18.8, GPA=38, MPA=19 EGPA=15, RLV, =28). Forty seven patients began their vasculitis symptoms in autumn-winter, and another 47 in spring-summer. Dates of initial symptoms could not be established in 6 patients. Patients' characteristics at disease onset are compared in table 1. Clinical manifestations were similar in patients beginning their disease in different seasons except for sinus involvement that was more frequent in those starting symptoms in autumn-winter. A total of 26 patients (26%, GPA= 11, EGPA=7, MPA=4 and RLV=4) had relapses of AAV during follow-up, with a total of 30 relapses. Relapses were more frequent in autumn-winter (n=21) than in spring-summer (n=9) (p=0.004) for all patients, and in particular in GPA (p=0.03) and EGPA (p=0.03) (table 2).

Conclusion: no disease characteristic pattern at disease onset was observed according to seasonal period of the beginning of AAV. Relapses were more frequent in autumn-winter in GPA and EGPA, suggesting that environmental seasonal exposures may trigger them.

Table 1. ANCA vasculitis patients grouped by season of beginning of symptoms

	Beginning of symptoms in autumn-winter (n=47)	Beginning of symptoms in spring-summer (n=47)	P
Females, % (CI95)	74.5 (61.7-87.2)	63.8 (49.8-77.9)	0.264
Age at diagnosis, media (SD)	58.9 (SD 19.2)	59.1 (18.2)	0.98
Follow up, years, median (IQR)	6.9 (2.5-9.7)	6 (1.7-9.4)	0.54
GPA, n (%)	18 (38.3)	16 (34)	0.67

Session Title: Vasculitis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Clinical characteristics of elderly patients with ANCA- associated vasculitis (AAV) have not been fully elucidated. Advancing age is a risk factor for treatment-related side effects and mortality in AAV patients. Also comorbidities at time of AAV diagnosis have been associated with reduced patients and renal survival. Our objective was to analyze clinical features and outcomes in older patients with AAV compared with younger ones.

Methods: All patients seen at our hospital between years 2000 and 2014 with diagnosis of Granulomatosis with polyangiitis (GPA), Eosinophilic granulomatosis with polyangiitis (EGPA), Microscopic polyangiitis (MPA) and renal-limited ANCA vasculitis (RLV) were included. Patients were divided in an elderly group (age >=65 years) and a younger group (age <65 years). Clinical features, comorbidities, treatments, renal outcome and mortality were analyzed.

Results: one hundred patients were included (females 70%, mean age at diagnosis 58.4, SD 18.8). Younger patients (n=55) were compared with older ones (n=45) (table 1). Vasculitis renal involvement was significantly more frequent in older patients (p=0.045). No other clinical differences were found between both groups. Hypertension and dyslipidemia were more frequent in patients over 65 years. While relapses were more frequent in the younger group (p=0.02), mortality was increased in the older group (p=0.03). In a logistic regression analysis, chronic renal insufficiency was the only variable associated with mortality (OR 7, CI 1.18-41.7, p=0.032).

Conclusion: elderly patients with AAV had more renal involvement, hypertension and dyslipidemia and increased mortality. Relapses were more frequent in younger patients. Chronic renal insufficiency was independently associated with mortality in the whole group.

Table 1. Comparison between young and elderly patients with ANCA associated vasculitis

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Vasculitis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: 1/to assess the prognostic value of comorbidities, frailty and dependency as measures by dedicated geriatric scales, in older adults with ANCA-associated vasculitis (AAV). 2/ to identify factors that predict functional decline in Instrumental Activities of Daily Living.

Methods: Retrospective single center study of patients diagnosed with AAV after 65 y between 2000 and 2013. Comorbidities, frailty and dependency were measured using the Charlson Index, the CSHA Clinical Frailty Scale (CFS) and the Instrumental Activities of Daily Living 4 items (IADL4). These score were evaluated at 3 time points: 1 year prior to AAV diagnosis (baseline), at AAV diagnosis and 1 year after AAV diagnosis. Multivariate analysis was performed using Cox model.

Results: Fourty four patients were analysed, including 33 with MPA and 11 with GPA. Mean age was 76 years. Mean eGFR was

49ml/min/1.73m^2. As first line, 29 patients (66%) were treated with corticosteroids plus cyclophosphamide. Overall, a significant improvement of CFS and IADL were seen between disease onset and year 1 after the diagnosis. In multivariate analysis mortality was higher in patient with PR3 ANCA (HR=4.2), palliative care (HR:3.5) and worse baseline IADL4 (HR:1.84). Relapse-free survival was longer in patients with worse baseline CFS score (HR=0.41) and those with MPA (HR=0.25). IALD4 was the only factor that predicted infection-free survival (HR=1.95). Predictive factor of functional decline at 1 year were PR3 ANCA (HR=85), Charlson comorbidity index (3.2) and IADL4 at time of diagnosis (HR=3.9).

Conclusion: Geriatric assessment scales appear to have high prognostic value in older adults with AAV. These simple tools can be better predictors of outcome than age or some usual biological parameters such as eGFR. Multicenter prospective studies are needed to confirm our results. These tools may help identify at risk patients who may require more intensive supportive care.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Vasculitis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

NETosis, a unique form of cell death of neutrophils, is characterized by the active release of chromatin fibers called NETs, that trap and kill invading microbes extracellularly. Although NETosis plays a crucial role in host defense, excessive NETs formation becomes self-defeating by promoting tissue injury and organ damage.

It has been known that NETs are implicated also in the pathogenesis of autoimmune diseases such as SLE, RA and ANCA –associated vasculitis (AAV). We observed NETs formation of neutrophils from MPO-AAV patients which is a majority type of AAV in Asia, and examined the effects of immunosuppressive therapy on the release of NETs in order to investigate the role of NETs in MPO-AAV. We also observed the damage of human renal glomerular endothelial cells (HRGECs) by neutrophils in order to investigate the role of NETs in AAV.

Methods:

Isolated peripheral blood neutrophils from healthy donors, pre/post-treatment MPO-AAV patients were incubated with phorbol myristate acetate (PMA), which is known as a strong inducer of NETs, PMA plus anti-MPO antibody or PMA plus anti-PR3 antibody. Neutrophils were stained with Hoechst 33342,SYTOX Green and the percentage of NETs producing cells were calculated. Brd-U labeled HRGECs stimulated by PMA were co-cultured with neutrophils. A cellular DNA fragmentation ELISA was used to quantitatively determine HRGECs damage.

Results:

Neutrophils from pre-treatment MPO-AAV patients produced much more fiber-like NETs than neutrophils from controls and the shape of fiber-like NETs were different from controls. Anti-MPO antibody increased the release of fiber-like NETs both in controls and MPO-AAV patients. The release of fiber-like NETs decreased in tandem with the decrease of ANCA titer after initial treatment and increased with the rise of ANCA titer in some MPO-AAV patients.

Although PMA-stimulated HRGEC were damaged in the presence of neutrophils, HRGEC without PMA stimulation were not damaged. When HRGEC and neutrophils were separated by transwell chamber, damage of HRGEC by neutrophils were substantially suppressed.

Conclusion:

Neutrophils from pre-treatment MPO-AAV patients released different type of fiber-like NETs and the amount of fiber-like NETs correlated with

the activity of AAV. HRGECs stimulated with PMA were damaged in the presence of neutrophils. It is suggested that both some soluble factors and fiber-NETs released from neutrophils are involved in the damage of HRGECs. These data suggest the release of fiber-like NETs by neutrophils at vascular endothelium is important for the pathogenesis of AAV.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Vasculitis Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Prompt, aggressive therapy is vital for anti-neutrophil cytoplasmic antibody (ANCA)-associated glomerulonephritis (GN). In this regard, we aimed to identify predictors of distinct renal histopathological classes at the time of clinical diagnosis.

Methods: An inception cohort of patients with biopsy proven ANCA-associated GN was studied retrospectively. Demographics, clinical, laboratory, serological and radiological parameters were analyzed. Patients were classified on the basis of renal histopathology, according to the report by Berden (1) et al into: focal class (≥50% normal glomeruli that were not affected by the disease process), crescentic class (≥50% of glomeruli with cellular crescents), sclerotic class (≥50% of glomeruli with global sclerosis), while all remaining biopsies were by definition not characterized by any of the predominant glomerular phenotypes and were classified as mixed class. Clinical phenotypes were assigned according to the second Chapel Hill vasculitides nomenclature Consensus Conference (2). A risk score was developed for each histopathological class using univariate and logistic regression analyses.

Results:

Of 147 eligible patients (136 from the University of Athens and 11 from the University of Ioannina), 105 had biopsy proven renal involvement. None of these patients had received any kind of immunosuppressive treatment at the time of kidney biopsy. Twenty out of the 105 pateints with renal involvement were excluded as they were younger than 16 years and had inadequate biopsy specimens (<10 glomeruli). Thus, the final study population consisted of 85 ANCA positive patients with biopsy proven GN.

Variables independently associated with focal class included disease duration up to diagnosis < 8 weeks, absence of red blood cell (RBC) casts by urine microscopy and eGFR > 49ml/min/1.73m^2; with crescentic class > 40 erythrocytes/hpf, identification of RBC casts in urine, ear nose and throat (ENT) involvement and eGFR < 49ml/min/1.73m^2; with mixed class age > 54 years, male gender, and absence of ENT involvement. In the presence of 2 or 3 risk factors a predictive risk score of each histopathological class was calculated: odds ratio (OR), 95% confidence intervals (CI), for focal class (≥2 risk factors) 17.5 (95% CI) [4.9-62.9], 38.0 [6.8-213.7] for crescentic class (≥3 risk factors), and 8.3 [1.0-67.5] (≥2 risk factors) for mixed class.

Conclusion: We propose a predictive algorithm of specific histolopathological classes of ANCA-associated GN, which might provide a crude estimation of the disease activity in the glomeruli at presentation. This tool might assist the clinician in making decisions regarding the level of intensity of inductive immunosuppressive therapy at clinical diagnosis.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Vasculitis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Neutrophil/lymphocyte ratio (NLR) has recently been extensively studied as a prognostic indicator in various malignancies, as well as an indicator of severity in cardiovascular disorders, including coronary arterial disease and hypertention. Its prognostic value in vasculitic disorders remains to be investigated. Aim of the study was to investigate NLR and its association with renal outcome in patients with granulomatosis with polyangiitis.

Methods: We studied 41 patients (mean±SD age 50±14 and M/F 23/17) with granulomatosis with polyangiitis. Data were obtained retrospectively from medical records. 17 patients had renal involvement of the vasculitis. Baseline C-reactive protein (CRP) levels, erythrocyte sedimentation rate (ESR), neutrophil and lympocyte counts were recorded. NLRs were calculated using the formula (neutrophil count/lymphocyte count). Serum creatinine levels at baseline and at 6-month follow-up were also recorded. Non-parametric tests were used for analyses.

Results: Median NLR of the entire group at baseline was high (4,5 [IQ range 5,8]). NLR at baseline correlated significantly with ESR and CRP levels (r=0,402, p<0,001 and r=0,481, p<0,001, respectively). Patients with NLR greater than 8.3 (the highest quartile) had significantly higher creatinine at baseline, as well as at 6 month follow-up (Mann-Whitney test p=0.002 and p=0.05, respectively). Patients with vasculitic renal involvement had higher NLR at baseline compared to those with non-renal vasculitis (5,0 [IQ range 10,9] vs 2,9 [IQ range 7,7], p=0,05). In the subgroup with renal involvement, baseline NLR correlated significantly with baseline creatinine levels (r=0,52, p=0,026). Moreover, in this subgroup, those with NLR at the highest quartile had significantly higher baseline, as well as 6-month follow-up creatinine (p=0,011 and 0,037, respectively) compared to those with renal involvment but lower NLR.

Conclusion: Results suggest that NLR at baseline correlates with renal function and those with a higher NLR at baseline have worse kidney outcome at 6 month follow-up. Further studies are needed to elucidate the function of neutrophils in the pathogenesis of tissue damage in a lymphocyte-mediated disease, such as granulomatosis with polyangiitis.

Session Title: Vasculitis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Anti-neutrophil cytoplasmic antibody (ANCA)-associated glomerulonephritis (GN) is considered a “pauci-immune” disease, characterized by absent or mild glomerular tuft staining for immunoglobulin and/or complement. However, it is not unusual for renal biopsies in such cases to exhibit some immune complex (IC) deposition within glomeruli on immunofluorescence (IF) and/or electron microscopic study. Their potential pathologic and clinical significance is not clear, although a possible synergistic effect between immune complexes and ANCA in producing more severe glomerulonephritis is suggested by some authors. The aim of this study was to evaluate the prevalence and clinical significance of immune deposits in ANCA-associated pauci-immune GN.

Methods:

We included retrospectively all patients with biopsy-proven ANCA GN: granulomatosis with polyangiitis (GPA), granulomatosis with polyangiitis and eosinophilia (GPAE), microscopic polyangiitis (PAM) and renal limited vasculitis (RLV) between January 2002 and May 2013. Patients were divided into 2 groups: Group A: biopsy without IC deposits (less than 2+ intensity of immunostaining) and Group B: biopsy with IC deposits (more than 2+ intensity of immunostaining). IF included Ig (IgG, IgA and IgM) and complement components (C3 and C1q). Serum creatinine, estimated glomerular filtration rate (eGFR) at time of the biopsy, amount of proteinuria and hematuria, requirement of dialysis and extra renal involvement were recorded.

Results:

Fifty-three patients (75.4% females) were included. The mean age at the time of the biopsy was 66.3 (SD: 14.3). Typical pauci-immune GN was found in 39 patients (73.5%, group A). In 14 patients (26.4%, group B) histopathological examination revealed substantial deposition of Ig or complement in the mesangium and/or along the glomerular capillary wall. IC deposition was more frequent in GPA and GPAE compared with PAM and RLV. C3 deposition on the capillary wall was the most frequent finding (64.2%), followed by C3 + IgG (21.4%) and IgG alone (14.2%). No patient presented positive staining for C1q. IgM and IgA were found only in two patients but along with C3. Compared with patients in group A, those in group B demonstrated significantly more 24 h proteinuria (mean 0.8 (SD: 7.6) vs 1.6 (SD: 10.7), p= 0.0036). No differences between groups were found related to age, gender, renal function, extra renal organ involvement at the time of biopsy, and in response to induction therapy (table 1).

Conclusion:

Our results confirm that in ANCA GN a substantial percentage of patients have evidence of Ig or C3 deposition in renal biopsies (26.4%). In this subgroup, IC deposition was associated with a significantly greater degree of proteinuria. Further clinical and basic research is needed to elucidate the significance of IC deposition in ANCA GN.

TABLE 1. DIFFERENCES BETWEEN THE GROUPS

	GROUP A, N=39 (less than 2+ intensity of immunostaining)	GROUP B, N=14 (more than 2+ intensity of immunostaining)	p

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Vasculitis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Granulomatosis with polyangiitis (Wegener's granulomatosis, GPA) is a systemic vasculitis of unknown etiology. It is characterized by necrotizing granulomatous inflammation and affects predominantly small vessels. Upper respiratory tract is involved in some phase of the disease in about 90% of the patients and most frequently at the beginning of the disease. Median diagnostic delay was reported as 4-17 months and it was most remarkable in patients with head and neck symptoms. Up to now clinical manifestations of GPA were described retrospectively and discriminative ability of nasal history and examination findings was never systematically evaluated before. Therefore we aimed to determine the predictive value of history items and nasal endoscopic examination findings in the diagnosis of GPA.

Methods: Seventeen GPA patients (12 [67%] male; mean age 49,3 ± 13,9), 29 patients with rheumatologic disease other than GPA (8 [28%] male; mean age 46.8 ± 16.3) and 67 healthy subjects (28 [42%] male; mean age 47,3 ± 15,2) were included in the study. Patients' history was taken by a physician blinded to diagnosis and each patient was examined with flexible nasal endoscope and nasal endoscopic images are recorded and evaluated blindly. The following history items were noted and graded as present or absent; sneezing, rhinorrhea, nasal obstruction, cough, postnasal drip, facial pain, taste disturbance, decreased smell, epiphora, epistaxis, saddle-nose. Nasal endoscopic findings noted were edema of middle meatus, nasal secretion, polypoid changes of middle meatus mucosa, nasal polyposis, hypertrophy of inferior turbinate, septal

perforation, nasal crusting, adhesions, granuloma, hemorrhagic fragile nasal mucosa.

Results: Regarding the history items univariate analysis revealed that rhinorrhea (p=0,003), postnasal drip (p=0,022), epistaxis (p<0,001), and saddle nose deformity (p=0,046) were statistically significantly different between groups. However in binary logistic regression analysis none of these history items have a statistically significant predictive role in selecting patients with GPA. A univariate analysis demonstrates that the following endoscopic findings demonstrates statistically significant difference; nasal secretion (p=0,003), nasal septal perforation (p < 0,001), nasal crusting (p< 0,001), nasal adhesion (p < 0,001), nasal granuloma (p=0,046), polypoid changes of middle meatus mucosa (p=0,42), and hemorrhagic fragile nasal mucosa (p < 0,001). In regression analysis hemorrhagic fragile nasal mucosa (p< 0,001, OR=41) was the only significant predictor for GPA.

Conclusion: The results of the present study suggest that patients with hemorrhagic fragile nasal mucosa should alert the physician about the possibility of GPA. The role of the other nasal mucosal findings in the differential diagnosis of GPA needs to be verified by larger studies.

Abstract Number: 863

Contribution of MPO-/PR3-ANCA Tests to the Diagnosis of ANCA-Associated Vasculitis in a Community Hospital: Evaluation of 2,782 Samples

Eishi Uechi, Chiai Nakata, Tomoo Murayama and Yoshiki Shiohira, Rheumatology, Tomishiro Central Hospital, Okinawa, Japan
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Vasculitis Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

The purpose of this study was to evaluate the contribution of MPO-/PR3-ANCA tests to the diagnosis of ANCA-associated vasculitis (AAV).

Methods:

We extracted patients who underwent MPO-/PR3-ANCA tests during the 5-year period from June 2009 to July 2014 using an electronic medical record system of a general hospital that has Departments of Rheumatology, Nephrology, Respiratory Diseases, Neurology, Cardiology, General Internal Medicine, and Dermatology in Okinawa, Japan. In the extracted patients, the clinical diagnosis and patients' background were confirmed using this system.

Results:

From June 2009 to July 2014, 2,782 samples obtained from 2,019 subjects were presented to the MPO-ANCA and PR3-ANCA tests (CLEIA method). MPO-ANCA and PR3-ANCA were positive in 107 (5%) and 36 (2%) subjects, respectively, of whom 50 (48.0%) and 3 (8.3%), respectively, had AAV, and 12 (11.2%) and 12 (33.3%), respectively, had infection. In the MPO-ANCA-positive patients, those with AAV showed a significantly higher MPO-ANCA level than the non-AAV patients (p = 0.001). In the PR3-ANCA-positive patients, the PR3-ANCA level did not differ between AAV and non-AAV patients. In this study, the sensitivity, specificity, positive predictive value, and negative predictive value of the MPO-ANCA test in AAV diagnosis were 0.85, 0.69, 0.47, and 0.93, respectively, and those of the PR3-ANCA test were 0.25, 0.79, 0.08, and 0.93, respectively.

Conclusion:

In daily practice in the Department of Rheumatology and the other departments, many samples had been presented for MPO-/PR3-ANCA tests. However, the percentage of patients positive for each test was low (< 10%). In this study, the positive predictive values of both MPO-ANCA and PR3-ANCA tests were low. Most ANCA-positive patients had diseases other than AAV, including many with infection. These results suggest that the results of the ANCA tests in daily practice should be carefully interpreted, and differential diagnosis between AAV and other diseases such as infection is important. The MPO-ANCA level was higher in the AAV group than in the non-AAV group. However, both the MPO-ANCA and PR3-ANCA values markedly varied in each group, and AAV diagnosis based on the ANCA level was difficult. In a previous large-scale study, the sensitivity and specificity of the MPO-ANCA test for MPA were 58 and 91%, respectively, and those of the PR3-ANCA test for GPA were 65-67 and 86-89%, respectively. The low specificity of the MPO-ANCA test based on data in this hospital suggests the presence of many patients with ANCA-negative MPA. In addition, compared with the previous study, the sensitivity and positive predictive value of PR3-

ANCA were extremely low. These results may reflect the low prevalence of GPA in Japan.When samples are presented for ANCA tests, patients in whom the pre-test probability of AAV is high should be selected, and the results of the test should be carefully interpreted even when samples are positive.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Vasculitis Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Anticytokine autoantibodies (ACAs) are pathogenic in many hematologic, pulmonary and infectious diseases. Evaluation in autoimmune diseases, including systemic lupus erythematosus (SLE), shows that ACAs are biologically active and may contribute to disease pathogenesis. The prevalence of ACAs and their correlation to circulating cytokine levels in vasculitis has not been characterized and was the focus of this study.

Methods:

Patients with various forms of vasculitis were selected from a multicentered, observational cohort and fulfilled modified ACR classification criteria for the respective diseases. All patients had active disease at the time of sample collection and had not received cyclophosphamide or rituximab within 6 months prior to sample collection. Plasma samples from patients with 5 types of vasculitis (n=149) and healthy controls (n=25) were tested for autoantibodies against 34 cytokines using a multiplex bead-based assay. For each ACA concentrations above two standard deviations of the mean of healthy controls and more than 1000 fluorescence intensity were classified as positive. Cytokine measurements were done using Human 25-Plex Panel (Invitrogen, Inc). Data were acquired on a Bio-Plex 100 instrument. Spearman's correlation coefficients were calculated to detect potential associations between levels of cytokines and the relevant ACA.

Results:

The majority of patients (57%) had at least one ACA; however, the prevalence of individual ACA ranged from 0 to 33% (Table 1). Autoantibodies against TNF and LT**a** were seen in the setting of anti-TNF monoclonal therapy. Compared to other types of vasculitis, an increased prevalence of autoantibodies against Th2 cytokines (IL-4, 5, 10, 13, up to 17%) were seen in Takayasu's arteritis and autoantibodies against G-CSF (15%) and IL-2 (23%) were detected in granulomatosis with polyangiitis (GPA). No autoantibodies against IL-6 were seen. Significant correlations were identified in 2 of 18 relevant pairings between ACAs and corresponding cytokine levels. IL-12 levels correlated weakly with anti-IL-12 autoantibodies ($r=0.21$, $p<0.01$), and soluble IL-2R levels, but not IL-2, negatively correlated with anti-IL-2 autoantibodies ($r=0.23$, $p<0.01$). Plasma IL-2R levels were significantly higher in patients with GPA compared to the other types of vasculitis

(668.3 vs 288.8 ng/ml, p<0.01); among patients with GPA IL-2R levels were 2-fold lower in patients with anti-IL-2 autoantibodies.

Conclusion:

ACAs occur at differing frequencies across the spectrum of vasculitis. Interestingly, autoantibodies directed against IL-2 were observed in a subset of patients with GPA and were negatively correlated with plasma IL-2R levels, suggesting that these autoantibodies may play a functional role in disease pathogenesis. Functional studies of candidate ACAs in vasculitis are warranted.

Table 1: Distribution of Anticytokine Autoantibodies in Patients with Vasculitis

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Vasculitis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Studies have shown a strong prevalence of cardiovascular events among patients with systemic necrotizing vasculitides (SNV). Recent studies indicate that visceral adipose tissue (VAT) is highly associated with cardiovascular events. The aim of this study was to assess the relevance of abdominal adipose tissue measurement by Dual energy X-ray Absorptiometry (DXA) as a potential surrogate marker for cardiovascular risk in patients with SNV.

Methods: Patients with SNV seen in our department were prospectively included in a cross-sectional study assessing cardio-vascular complications and risk factors, and other sequelae. DXA was performed to evaluate body composition and abdominal adipose tissue (both subcutaneous (SAT) and visceral (VAT)).

Results: One hundred and twenty consecutive patients with SNV were analyzed (66 female and 54 male, mean age 53±18 years, median disease duration of 54 months). Diagnoses were granulomatosis with polyangiitis in 61 patients, eosinophilic granulomatosis with polyangiitis in 30, polyarteritis nodosa in 14, microscopic polyangiitis in 13, and cryoglobulinemia vasculitis in 2. The median daily dose of glucocorticoids was 8.5 mg/day (0-80), with an estimated total cumulative dose of 15000±10000 mg of glucocorticoids.

High cardiovascular risk, as defined by the NCEP-ATPIII, was present in 28 (23.3%) patients, including 15 (12.5%) with previous cardiovascular disease. Variables significantly associated with high cardiovascular risk after multivariate analysis were an increased age [OR 1.04 (1.00-1.08); P=0.048] and an increased VAT/SAT ratio [OR 1.06 (1.03-1.09); P<0.0001]. The VAT/SAT ratio was significantly higher in patients with high cardiovascular risk (66.3±21.2 vs. 39.4±18.2%, P<0.0001), particularly those with previous cardiovascular history (75.2±13.4 vs. 41.1±19.5%, P<0.0001). A higher VAT/SAT ratio was independently associated with increased age (P<0.0001), male gender (P<0.0001), and elevated levels of triglycerides (P=0.01), glycated hemoglobin (P=0.007) and troponin (P=0.05).

The Framingham cardiovascular risk score, predicting a subject's risk of developing an ischemic cardiac disease in the next 10 years, was strongly correlated with the VAT/SAT ratio in our patients (r=+0.60, P<0.0001), but also with the 10-year probability of major osteoporotic (r=+0.35, P=0.0009) and hip (r=+0.51, P<0.0001) fractures using the FRAX.

Conclusion: This is the first study showing a significant association between a high VAT/SAT ratio assessed by DXA and cardiovascular risk in patients with SNV. The measurement of the abdominal adipose tissue seems to be an accurate and independent surrogate marker of cardiovascular risk in these patients. Finally, cardiovascular and osteoporotic fracture risks were strongly associated suggesting that optimal management of both risks is crucial in these patients.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Vasculitis Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose : Increased rate of severe infection (SI) in patients who exposed to immunosuppressive drugs has been a well-known complication in inflammatory rheumatic diseases. However, there are few reports on SI complicating AAV course.

Methods: We retrospectively investigated the characteristics of "SI requiring hospitalization" in AAV patients with lung involvement who were previously included into a study evaluating lung damage. Data were collected from hospital records between 2000-2014. Demographics, data on infection investigation including blood, sputum and urine cultures, viral serology, PPD/QTB tests, procalcitonin, imaging and biopsy findings,

comorbidites, vasculitis activity and damage scores, cumulative dose of glucocorticoid (GC), cyclophosphamide (CYC) and rituximab (RTX) were noted into a predefined protocol. Infections that could not be revealed by cultures but succesfully treated with antibiotics were categorized as unidentified (UI). We compared the demographic and clinical data, presence of comorbidities, initial BVAS and cumulative VDI scores and GC/CYC doses according to the presence of SI by Mann-Whitney U test.

Results: Fifty-one AAV patients with lung involvement (25 female) (40 GPA, 8 MPA, 3 e-GPA) who were diagnosed according to ACR and CHCC criteria were included into the study. Age at diagnosis and total duration of follow-up were as follows: 49 ± 13 years (med 51), 67 ± 52 mo (med 47). Lung (100%), kidney (78 %), ENT (72 %), nervous system (25 %) were the involved organs. ANCA positivity was 94% (66% cANCA/anti-PR3, 34% p-ANCA/anti-MPO). Initial BVAS and cumulative VDI scores were 22±7 (4-38) (med 23), 3,4±2,2 (0-9) (med 3), respectively. Twenty-nine relapses occurred in 15 (29%) patients. Cumulative dose of GC and CYC were 16±9 g (med 14), 17± 25 (med 6), respectively. RTX was used in 17 patients. Diabetes (18%), chronic kidney failure (25%) were the major comorbidities and 7% had ESRD. Influenza and pneumococcal vaccination and TMP-SMX prophylaxis were applied in one forth and two-thirds of AAV cohort, respectively. Five patients (10%) had neutropenia (4 severe, 1 moderate) and suffered from SI. Eightyseven SI noted in 25 (52%) patients. Identified and unidentified SI in AAV cohort were shown in Table-1. Recurrent SI occurred in 27% of pulmonary and 33% of non-pulmonary groups. SI was associated with relapse in 16%. Serum

procalcitonin level increased in 93% (3.5±16.5, med 0.26, (0.5-95)) of 33 AAV patients. SI proportion was found to be increased during the first six months (%35) and after the 60th month of follow-up (30%). There were no significant difference between the patients with or without SI according to the risk factors.

Bacterial (35%) n=30	Pulmonary	M.tuberculosis (1), Klebsiella (3), Pseudomonas (6), S.pneumoniae (1), E.coli (3), S.marcescens (1)

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Vasculitis Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Vitamin D acts as innate and adaptive immune response immunomodulator. 25-hydroxyvitamin D (25OHD) deficiency was reported to be associated with autoimmune diseases flares and also with increased frequency of viral and bacterial infections. Procalcitonin (PCT) is a marker of bacterial and fungal infection and high levels may be related to disease activity in autoimmune diseases. There is no study evaluating simultaneously 25OHD and PCT serum levels in GPA patients and the association with disease activity and infections. The objective of this study is to determine the possible association of 25OHD and PCT serum concentrations with disease activity and respiratory infections in patients with GPA.

Methods: Thirty-two GPA patients were evaluated in winter/spring (n=32) and summer/autumn (n=27). 25OHD and PCT were measured by electrochemiluminescence. Disease activity was assessed using the Birmingham Vasculitis Activity Score (BVAS≥1) and ANCA. Airways respiratory infection was defined according to the CDC (Centers For Disease Control and Prevention) criteria. T-student, Mann Whitney and Fischer exact tests were performed for statistical analyses, with $p < 0.05$ considered significant.

Results: Fifty three percent (17/32) of patients were women, 65.6% (21/32) were caucasian, with a mean age of 46.2 ± 13yrs, disease duration of 8.9 ± 4.2yrs and 71.8% (23/32) presented generalized form of GPA. Of the 59 samples, 39 (66%) were in vitamin D replacement (800-7,000 U/day). There was no difference between 25OHD concentrations of those with (34.87 ± 12.51 ng/mL) or without (36.31 ± 12.81 ng/mL) vitamin D supplementation. In winter/spring season concentrations of 25OHD were lower compared to summer/autumn (32.31 ± 13.10 vs. 38.98 ± 10.97 ng/mL, p=0.04). Seven patients were diagnosed with airway infections, 5 of them in autumn/winter, with a predominance of tracheobrochitis (71.4%). Patients with airway infection had lower 25OHD concentrations compared with those without infection (24.51 ± 11.81 vs. 36.82 ± 11.98 ng/mL, p=0.01) whereas no difference was observed for PCT serum levels (0.07 ± 0.06 vs. 0.04 ± 0.03 ng/mL, p=0.26). With regard to activity, higher PCT serum levels was observed in patients with concomitant BVAS≥1 and positive ANCA compared with patients BVAS=0 and ANCA negative (0.07 ± 0.06 vs. 0.03 ± 0.01 ng/mL, p=0.02). Further analysis regarding the follow-up of ten patients that presented PCT ≥ 0.05 ng/mL and BVAS ≥ 1, five of them evolved for remission (BVAS = 0) and a decline of PCT was observed; 2 patients remained with active disease and PCT levels remained high (PCT > 0.10). Of note, 25OHD levels were comparable in patients with and without disease activity (BVAS≥1 and positive ANCA), (33.60 ± 11.84 vs. 36.19 ±12.89 ng/mL, p=0.46).

Conclusion: The observed association of low 25OHD levels with airway infection and high PCT levels with activity in patients with GPA suggests that simultaneous measurements of these markers may be helpful to distinguish disease activity from infection in GPA patients.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Vasculitis Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) is a disease entity characterized by inflammatory cell infiltration and necrosis of blood vessel walls. AAV usually needs intensive immunosuppressive treatment for remission induction, that sometimes brings about serious infection. Cytomegalovirus (CMV) reactivation is one of the opportunistic infections for immunosuppressed patients, therefore, identifying patients at risk for CMV reactivation is of importance. This study was to investigate risk factors relevant with CMV in patients with AAV during remission induction therapy.

Methods: All patients with AAV including microscopic polyangiitis (MPA), granuromatosis with polyangiitis (GPA), and eosinophilic granulomatosis with polyangiitis (EGPA) in Keio University from April 2008 until May 2015 were retrospectively reviewed. Clinical information during remission induction therapy were collected from their medical charts. CMV reactivation was defined by the detection of detecting pp65 antigen in polymorphonuclear leukocytes from peripheral blood. Mean values and proportions were compared by Student's t-test and chi-square test, respectively, and multivariate logistic analysis was performed.

Results: Seventy AAV patients (MPA 33, GPA 19, and EGPA 18) were enrolled in this study. In total of 102 cases were treated with glucocorticoid and/or immunosuppressive agents as a remission induction therapy irrelevant of new onset or recurrence. We analyzed 67 cases (MPA 34, GPA 21, and EGPA 12) in whom CMV pp65 antigen was regularly measured during the treatment course. Patient characteristics were as following; mean age 65.5 ± 13.7 years old, female 35 (52%), disease duration 70.1 ± 142.9 weeks, and recurrence case 20 (31%). The mean initial dose of prednisolone (PSL) was 44.7±14.7 mg. Steroid pulse therapy was conducted in 11 patients (30%) and intravenous cyclophosphamide (IVCY) therapy in 30 patients (42%).

CMV was reactivated in 28 cases (42%). Six cases were treated with antiviral agents including 2 cases with organ involvement (CMV retinitis, and CMV colitis). While mean age and baseline performance status were not significantly different between the CMV-positive group (n = 28) and the CMV-negative group (n = 38), the initial prednisolone dose was higher (50.4 ± 11.4 mg vs. 40.6 ± 15.5 mg, $p = 0.007$), methylprednisolone pulse therapy (43% vs. 21%, $p = 0.049$) and IVCY (68% vs. 23%, $p < 0.001$) were more frequently conducted, and baseline serum creatinine level was higher (1.3 ± 0.8 mg/dl vs. 0.9 ± 0.3 mg/dl, $p = 0.004$) in CMV-positive group. Multivariate logistic analysis identified initial PSL dose ≥ 40 mg/day ($p = 0.031$), IVCY therapy ($p = 0.005$), recurrence case ($p = 0.018$), and higher Brinkmann index ($p = 0.033$) as independent risk factors for CMV reactivation. Correspondingly, all six cases treated with anti-CMV agents were treated with IVCY.

Conclusion: Initial PSL dose, IVCY, recurrence case, and high Brinkmann index are risk factors for CMV reactivation during induction therapy for AAV. Patients with those risks require a particular attention.

Abstract Number: 869

Lymphoma in Patients with Granulomatosis with Polyangiitis

Karin Hjorton[1], Erik Hellbacher[1], Christer Sundstrom[2], Eva Baeckstrom[1] and Ann Knight[1], [1]Department of Medical Sciences, Section of Rheumatology, Uppsala University, Uppsala, Sweden, [2]Department of Genetics and Pathology, Uppsala University, Uppsala, Sweden
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Vasculitis Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

The risk of malignancy in patients with Granulomatosis with Polyangiitis (GPA) is increased, as shown in several previous studies. The risk of lymphoma has been described as high as 4-5-fold increased. In addition, lymphoma in the sinonasal region, especially NK/T-cell lymphoma, has been reported to mimic GPA localized to the ear-throat-nose (ENT) region. Several previous publications report cases where a sinonasal lymphoma initially was misdiagnosed as GPA. We therefore had a particular interest in investigating the presence of lymphoma localized in the

ENT-region. Our aim in this study was to assess the clinical characteristics and treatment of patients with GPA complicated by lymphoma and to describe the lymphoma types, sites and prognosis in a population-based setting.

Methods:

From the Swedish population based patient register all individuals with a diagnosis of GPA between 1964 and 2012 were identified (n=3,224). Through linkage with the Swedish cancer register all lymphoproliferative malignancies (ICD7:200-202) registered after the first discharge listing GPA were identified. The medical records of all patients with GPA and lymphoma were collected and the GPA diagnosis was evaluated using the EMEA Consensus Algorithm for Classification of Vasculitis (1). To confirm the lymphoma diagnosis all lymphoma tissues were retrieved and classified according to the latest WHO classification. Clinical data of both GPA and lymphoma were collected from the medical files.

Results:

In all, 24 GPA-patients with malignant lymphoma were identified. 20 of these were B-cell lymphomas, and only two T-cell lymphomas (Table). Only one of the lymphomas was localized to the ENT-area, a diffuse large B-cell lymphoma in the hard palate. The majority of the patients had generalized GPA disease, most (75%) had been treated with cyclophosphamide for their GPA, many for long periods and with high doses; the median cumulative dose was 40g. The mean time from GPA to lymphoma diagnosis was 10 years (0-22). The majority of the lymphomas were aggressive and the median survival after lymphoma diagnosis was only 4 months.

Conclusion:

The findings in this population-based setting indicate that the lymphomas developing in patients with GPA are aggressive with a poor prognosis. T-cell lymphoma or lymphoma localized to the ENT-area are not a prominent finding. The study emphasizes the need for awareness of lymphoma and long-term follow-up of patients with GPA.

1. Watts, R et al. Ann Rheum Dis, 2007

Type of lymphoma	Total (n=24)	Median survival time from lymphoma diagnosis (months)
B-cell lymphoma	20	4
Diffuse large B-cell lymphoma	6	4
Chronic lymphocytic leukemia	3	2
Mantle cell lymphoma	4	1.5
High grade B-cell lymphoma	4	26.5
Low grade B-cell lymphoma	1	0
Undifferentiated B-cell lymphoma	2	6.5
NK/T-cell lymphoma	2	3
High grade T-cell lymphoma	1	2
Peripheral T-cell lymphoma	1	4
Other	2	1.5
Undifferentiated High grade lymphoma	2	2

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Vasculitis Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitides (AAVs), including granulomatosis with polyangiitis (Wegener's, (GPA), eosinophilic granulomatosis with polyangiitis (Churg-Strauss, EGPA), and microscopic polyangiitis (MPA), can face persistent disease activity, disease-associated damage, or adverse treatment effects, all of which may impact on health related quality of life. There is currently no disease-specific patient-reported outcome (PRO) for AAV. The development of a PRO should be in compliance with FDA recommendations and involves: (i) Questionnaire item development; (ii) Item reduction and scale generation; and (iii) Testing scale properties - reliability, validity and responsiveness. Following these principles, a multi-national collaboration of researchers and patient-partners from the UK, USA and Canada has been conducting the first stage of questionnaire item development with the aim of creating a tool with content validity (and cultural/linguistic equivalence) appropriate for use in all three countries.

Methods: Exploratory semi-structured patient interviews were performed in the UK, USA, and Canada. The aim was to identify salient dimensions of quality of life and perceived problems of health status related to having AAV. The overall sample size was determined by the point at which no new themes emerged from interviews (saturation), and was also guided by a purposive sampling framework to ensure a range of participants were included (for example differing disease presentations, age and genders). Researchers (within and across research groups) independently scrutinised interview transcripts for relevant themes. Themes identified from transcripts were then re-cast as candidate questionnaire items. Regular teleconferences maintained equivalence of methods and exchange of relevant themes.

Results: Forty-nine semi-structured interviews of patients with AAV were conducted. After transcription and scrutiny, 60 distinct themes related to having AAV were identified, these included symptoms (related to condition or treatment) and the ways in which these symptoms influenced patients' ability to work, activities of daily living, engagement in social activities, and state of mind. The interaction between these factors is demonstrated in the evolving conceptual framework for the PRO, shown in Figure 1.

Conclusion: A list of themes and candidate items, drawn directly from patient experience, has been used to inform the development of a PRO for AAV. A parallel survey of~500 patients in the UK and US is currently underway and will produce an instrument with appropriate scale structure, measurement properties, and scoring algorithms. This will be followed by a multi-centred prospective validation study.

Abstract Number: 871

Clinicians' Perspective on Aspects of ANCA-Associated Vasculitis That Influence Patients' Function and General Health: A Delphi Exercise Based on the International Classification of Function, Disability and Health

Nataliya Milman[1], Peter Tugwell[2], Annelies Boonen[3] and Peter A. Merkel[4], [1]Division of Rheumatology, University of Ottawa, Ottawa, ON, Canada, [2]Center For Global Health, Institute of Population Hlth, Ottawa, ON, Canada, [3]Maastricht University Medical Center, Maastricht, Netherlands, [4]Penn Vasculitis Center, Division of Rheumatology, University of Pennsylvania, Philadelphia, PA
First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Vasculitis Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

ANCA-associated vasculitis (AAV) is a multisystem condition that results in significant level of morbidity and functional limitations for many patients. Previous studies showed that patients and clinicians prioritize aspects of AAV differently. This study was conducted to determine which aspects of AAV are considered by clinicians most relevant to determining patients' function and general health.

Methods:

International vasculitis experts were identified by consulting with 3 major vasculitis societies and invited to participate in an email-based three-round Delphi exercise. The International Classification of Function, Disability and Health (ICF) was used to describe the studied aspects of AAV. The ICF is a general health status framework that describes health in terms of hierarchically organized categories from 4 interacting "components": body functions (BF), body structures (BS), activities and participation (AP), and contextual factors (personal (PF) and environmental (EF)).

In the first open-ended round of the exercise participants were asked to list up to 30 items they considered most relevant to determining patients' overall health for each of the ICF's 4 components of health. The participants of the second and third rounds selected those aspects of AAV they consider most important, given the results of the previous rounds. Categories identified by at least 80% of participants of either of the 3 rounds were selected as representative of the clinicians' perspective.

Results:

82 clinicians were invited to participate in this study and 44 responded; 27 clinicians participated in the first Delphi round, 30 in the second, and 36 in the third. Participants came from 17 countries and several relevant medical specialties (rheumatology, nephrology, pulmonology, otorhinolaryngology, internal medicine, immunology, and allied health professions).

After the third round 20 ICF categories were identified as important by > 80% of participants: 6 BF (energy level, seeing, hearing, pain, respiratory functions and renal function), 7 BS (eyes, ears (especially middle ear), nose (especially saddle nose and nasal crusting specifically), sinuses, lungs (also subglottic stenosis), kidneys, and peripheral nerves, 2 AP (carrying out daily routine and remunerative employment), and 3 EF (side effects of medications, support and relationships, and health services, systems and policies).

Conclusion:

This study identified aspects of AAV considered by clinicians as most relevant for determining the overall health of affected patients. The use of the standardised ICF classification allows comparison of these results across different perspectives. Among the categories identified in this study, "side effects of medications" is the only aspect of AAV that is not sampled by currently accepted core set of outcome measures for AAV which was recently subjected to an ICF-based analysis. An ongoing ICF-based study of the patient perspective on the most important aspects of AAV will allow for direct comparison of perspectives of patients and clinicians and help revise and enhance disease assessment in AAV for use in clinical research and routine care.

Work Limitations and Disability in Patients with Systemic Vasculitis

Emma Ali Bateman[1], Sherry Rohekar[2], Christian Pagnoux[3] and **Lillian Barra**[1], [1]Medicine, Division of Rheumatology, Western University, London, ON, Canada, [2]Western University, London, ON, Canada, [3]Mount Sinai Hospital, Toronto, ON, Canada
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Vasculitis Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Despite recent advances in the treatment of systemic vasculitis (SV), direct consequences of the disease leading to impairments in physical and mental function can cause disability, which is an understudied aspect of SV. The objective of this research was to assess work limitations and disability in patients with SV.

Methods:

Patients aged >18 years old with SV (anti-neutrophilic cytoplasmic antibody-associated vasculitis (AAV), polyarteritis nodosa, large vessel vasculitis, IgA vasculitis, Behcet's syndrome or cryoglobulinemic vasculitis) were recruited from a tertiary care Rheumatology clinic (London, Canada). Work disabled (WD) was defined as not working, early retirement, or reduced hours at work due to SV. Participants who were working at the time of enrolment completed the Work Limitations Questionnaire (WLQ). Other work-related measures were self-reported by questionnaire. At the time of enrolment, the Vasculitis Damage Index (VDI) was also obtained.

Results: 103 participants completed the study (mean age 58±17, 60% females, 48% with AAV, 26% LVV and 26% other). 52 (51%) subjects were WD or retired for reasons other than SV and were excluded from further analyses; 22 (21%) were WD secondary to SV and 29 (28%) did not report any disability. SV-related WD subjects were more likely to have a diagnosis of AAV and a lower level of education ($p<0.01$) than non-WD subjects. Mean VDI scores were higher in SV-related WD vs. non-WD subjects (1.9±2.7 vs. 2.9±1.4; $p=0.015$). Involvement of musculoskeletal, peripheral vascular, ocular and neuropsychiatric systems was more common in WD. 38 subjects were working and completed the WLQ; their productivity loss was 8.9±7.2%, higher than control patients from the same center with Rheumatoid Arthritis and Ankylosing Spondylitis (4.5% and 5.8%, respectively).

Conclusion: SV-related work disability occurred in 21% of patients and was associated with a diagnosis of AAV, lower levels of education, higher disease activity and damage scores.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Vasculitis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Damage related to active disease or its treatment is an important outcome measure in ANCA-associated vasculitis (AAV). The Vasculitis Damage Index (VDI), the principal damage measure in AAV, was not designed specifically for AAV. The VDI may also underestimate toxicity from therapies for vasculitis, particularly glucocorticoids (GC). The AAV Index of Damage (AVID) was designed to be a more comprehensive tool for the assessment of damage in AAV, both due to disease and its treatment. We compared the performance of AVID to that of the VDI in the context of a large randomized, double-blind, placebo-controlled trial.

Methods:

We analyzed the VDI and AVID in 197 patients enrolled in the Rituximab in AAV (RAVE) trial. Disease damage was measured prospectively at baseline, 6, 12, 18 months, and end of follow-up by both the VDI and AVID.

The VDI is composed of 11 categories (e.g., musculoskeletal, pulmonary) and 64 individual damage items. The AVID has 12 categories and 112 items (Table 1). Twenty-five of the AVID items pertain to treatment-related damage (20 related to GC toxicity), compared to only 13 in the VDI (9 related to GC toxicity). Each item was counted as one point in the total score.

Results:

AVID captured 184 more damage-related items at baseline compared with the VDI. During the course of the trial, AVID identified 358 new items compared with only 201 identified by the VDI (Table 1). Renal and ear/nose/throat categories accounted for the most damage in both instruments. 188 (27%) of the new AVID items pertained to GC-associated damage as compared to 81 (18%) of the VDI items (Table 2).

The sum of GC-related AVID items was greater among the patients in the highest quartile of cumulative GC use (mean dose 9.2g) compared to the lowest quartile (mean dose 3.7g) (51 versus 22, $p<0.01$). In contrast, there was no significant difference in VDI scores between these two groups (24 versus 14, $p=0.08$). Changes in neither the AVID, nor the VDI scores correlated with baseline disease severity, the number of relapses during follow-up, or changes in quality-of-life as measured by the Short Form 36 Health Survey.

Conclusion:

In this prospective, head-to-head comparison of the AVID and VDI, AVID captured substantially more items of damage caused by either active AAV or its treatment. GC-related damage was captured more comprehensively by AVID, which was able to differentiate between high and low GC users. The inclusion of item weighting may improve the correlation of disease damage scores with baseline disease severity and patient quality-of-life scores.

Table 1 – VDI and AVID scores by category

	VDI		AVID

Abstract Number: 874

The Short Term Damage Burden in Vasculitis and Vasculitis Mimics As Measured By the

Vasculitis Damage Index

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Vasculitis Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Damage in vasculitis, which is due to both the vasculitic process itself and the complications of treatment, accumulates over time and accounts for significant morbidity across a variety of organs and body systems. It is not known whether comparator conditions mimicking vasculitis are associated with a similar spectrum and extent of damage. The aim of this study was to compare short term damage accrual in vasculitis and vasculitis mimics using the Vasculitis Damage Index (VDI).

Methods: We used data available from patients recruited into the ACR/EULAR Diagnostic and Classification Criteria in Vasculitis Study (DCVAS). VDI is recorded at 6 months from diagnosis in patients with vasculitis and also in patients with comparator conditions. We analysed total VDI score, system scores, and individual damage items in granulomatosis with polyangiitis (GPA), eosinophilic granulomatosis with polyangiitis (EGPA), microscopic polyangiitis (MPA), polyarteritis nodosa (PAN), giant cell arteritis (GCA), Takayasu's arteritis (TAK), and their clinical context-specific comparator conditions. The diagnosis supplied by the recruiting physician (with recorded confidence > 75%) was used as the gold standard. We used predetermined criteria to identify comparator conditions for each of the vasculitides; some of the comparators were used for analyses with more than one type of vasculitis. Comparator conditions for each vasculitis are shown in table 1.
