The mean age of the patients at the diagnosis of PAI was 28.8± 5.8 SD years and their mean disease duration was 2±1.5 SD years. Five patients had pulmonary artery aneurysms (PAA) and 1 had pulmonary artery thrombosis (PAT). Consolidation treatment consisted of monthly cyclophosphamide pulses and corticosteroids (1.7±1.2 mean±SD years) and this was followed by maintenance with azathioprine. This treatment was successful in ameliorating hemoptysis in all patients except 1 PAA patient who experienced gross hemoptysis necessitating pulmonary artery embolization 2 years later. Hemoptysis recurred in all after a mean interval of 5.8±6.2 SD years (range 1 – 17 years). Thorax CT evaluations did not show any signs for new or worsening of existing PAI. Rather, there was complete resolution of PAA in 4 patients, regression of PAA in 1 patient and regression of PAT in 1 patient. However, enlargement of bronchial arteries and enlarged collaterals were evident in 5 patients. Four of them underwent transcatheter bronchial artery embolization that was complicated by hemiparesis in 1 patient. This procedure was repeated in 1 patient 2 years later because of new enlarged epigastric arteries. This patient still continues to experience occasional and small hemoptysis 3 years after the last procedure. The other 3 patients are currently free of hemoptysis ranging for between 3 months and 8 years after the procedure. The fifth patient died of massive hemoptysis in emergency unit in another center before undergoing embolization. His last CT did not show any evidence of PAI. The source of bleeding could not be demonstrated in the last patient despite repeated bronchoscopies and pulmonary angiography who is now completely symptom free since 4 years and does not take any medications either.

Conclusion:

Enlargement of bronchial arteries and formation of collaterals can complicate the course of PAI during remission and may result in recurrent and potentially fatal hemoptysis in BS patients. Whether this enlargement is only due to the compromised pulmonary circulation or there is also accompanying vasculitis remains to be studied. Transcatheter embolization appears to be successful in controlling hemoptysis in such patients.

Session Title: Vasculitis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Budd-Chiari syndrome (BCS), or hepatic venous outflow obstruction, is a rare and serious complication of Behçet's disease (BD). The aim of this study was to determine the demographic, clinical, laboratory and management characteristics along with the clinical course of BCS associated with BD.

Methods: Forty-four patients with BD with BCS (31 male, 13 female) were identified in 15 rheumatology centers (Group I). A total of 82 consecutive patients (51 male, 31 female) with BD who did not have clinically apparent BCS during the follow-up were evaluated as the control group (Group II). The demographic, clinical, laboratory, management characteristics, and clinical course of these two groups of patients were recorded according to predefined protocol and compared.

Results: Comparison of the demographic and clinical findings between the Group I and the Group II were as follows: Male gender was more frequent in both group I and group II but, there was no significant difference between the two groups. The mean age of disease onset was 23.1 +/- 6.7 years vs. 27.2 +/- 8.3 years ($p=0.04$), mean age at diagnosis was 26.3 +/- 6.9 vs. 31 +/- 8.2 ($p<0.01$), arthritis was 4.5% vs. 28.9% ($p=0.001$) and cardiac involvement was found to be 15.9% vs. 3.6% ($p=0.017$). Skin pathergy test positivity was observed in 40.9% vs. 21.7% of the patients ($p=0.02$), superficial thrombophlebitis was 25% vs. 7.2% ($p=0.006$), and deep vein thrombosis was 47.7% vs. 14.5% ($p<0.01$). The frequency of MTHFR mutation in BD patients with BCS was 25%. On diagnosis 46.7% of BD patients with BCS were classified as Child-Pugh A. Serum albumin level was lower (3.3 +/- 0.6 vs. 4.3 +/- 0.5, $p<0.001$) and serum AST, ALT and ALP levels were higher, and serum INR level was higher (1.4+/-0.5 vs. 1+/-0.2, $p=0.001$) in patients with BCS. Inferior vena cava obstruction was observed in 56.7% and portal vein thrombosis was seen in 6.7% of the patients with BCS. Mortality in BCS patients with BD was 18.2%. BCS related treatment after diagnosis in patients with BD were as follows: 67.4% of patients were treated with monthly cyclophosphamide intravenous pulses, 52.3% received intravenous pulse corticosteroids, 56.8% used azathioprine, 45.5% had warfarine treatment and 47.7% were treated with low

molecular weight heparin.

Conclusion: This study shows a higher frequency of cardiac involvement, skin pathergy test positivity, superficial thrombophlebitis and deep vein thrombosis in BD patients with BCS. Arthritis was observed less common in BD patients with BCS. The mean age onset was lower in patients with BCS. Medical treatment with immunosuppressive agents and anticoagulation appears to be the treatment of choice in BD patients with BCS. The majority of the *patients with BCS were Child-Pugh* class A on diagnosis. The inferior vena cava is frequently involved and, often associated with deep vein thrombosis and cardiac involvement. BCS still remains as an important mortality cause in BD patients.

Abstract Number: 3053

Patients Treated for Behcet Syndrome in the US Have Higher Disease Activity Scores at Presentation If They Fulfill ISG Criteria and If They Are Females, However Have Less Severe Disease Overall

Yusuf Yazici, Hannah Bernstein and Christopher Swearingen, Department of Medicine, Division of Rheumatology, New York University School of Medicine, New York, NY

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Vasculitis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Diagnosis of Behcet's syndrome (BS) is based on clinical signs and symptoms, without the use laboratory or imaging tests and the most commonly used diagnostic criteria are the ISG criteria. Patients have also been diagnosed with BS not meeting ISBD criteria based on the clinical impression of the treating physicians.

Objective:

To determine differences in disease activity among BS patients meeting and not meeting the ISBD criteria.

Methods:

Behcet's patients seen at the NYU Behcet's Center had their demographic, clinical features and outcomes data abstracted. Confirmed BS diagnosis was determined if ISG criteria were met at any time during the course of observation. Multiple linear regression estimated any association between meeting ISG criteria and gender with the patient-reported outcomes Behcet's Syndrome Activity Score (BSAS), Pain Visual Analog Scale (VAS), Fatigue VAS, Patient Global Assessment VAS, and RAPID3 as well as Physician Global Assessment VAS.

Results:

First observation data on 832 subjects were abstracted for this analysis. 504 (63%) met ISG criteria for Behcet's, 616 (74%) were female with an average age of 35 years (+ 13.8). Mean scores for BSAS, pain, fatigue, patient global, RAPID3 and physician global were uniformly higher in those meeting criteria vs not meeting criteria. Meeting ISG criteria was significantly associated with increases in all clinical outcomes independently of gender, ranging from 5 points on the Physician Global VAS to 13 points on the Fatigue VAS (**Table**). Conversely, female gender was only associated with significant increases in BSAS, Fatigue and RAPID3 independent of meeting ISG criteria. Not surprising, meeting ISG criteria was associated with increased odds of eye involvement; CNS or vascular involvement were not associated with meeting ISG criteria, however. Notably, males [N=63 (29%)] were are significantly increased odds of having eye involvement compared to females [N=155 (25%)] [OR=1.6, 95% CI:1.11, 2.41), P=0.013] independent of meeting ISG criteria, race, age and education. No association between gender and CNS [males N=12 (10%) vs female N=45 (12%)] or vascular involvement [males N=3 (2%) vs female N=3 (1%)] was detected.

Conclusion:

Behcet's patients who fulfill ISG criteria have more active disease, based on all measures of disease activity, including patient and physician

based outcomes. Interestingly, females were also at risk for more active disease as measured by composite patient reported outcome measures, reflecting possibly the different character of Behcet's in non-endemic areas, such as the US. Males were more likely to have eye involvement, suggesting that even though females may have more activity overall, males may have more severe disease.

Table. Change in Outcomes Associated with Criteria and Gender

		Met Behcets Criteria			Gender		
Outcomes*	**N**	**Yes**	**No**	**P†**	**Female**	**Male**	**P†**
BSAS	832	47.0 (21.6)	33.6 (19.3)	**<0.001**	43.8 (21.4)	36.9 (21.9)	**0.001**
Function	784	17.8 (19.8)	8.8 (13.5)	**<0.001**	14.7 (18.2)	13.8 (18.4)	0.720

Session Date: Tuesday, November 10, 2015

Session Title: Vasculitis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Takayasu's arteritis (TA) and Behçet's syndrome (BS) are both systemic vasculitis of an unknown etiology, each with unique involvement pattern. TA affects aorta and its main branches causing narrowing or occlusions. BS is characterized by recurrent skin –mucosa lesions and uveitis. Arterial involvement is rare in BS and manifests usually as aneurysms or in situ thrombosis.

We describe here 8 TA patients with concomitant BS.

Methods:

We reviewed the charts of patients diagnosed with BS and TA for information regarding patients' gender, age at diagnosis of BS and TA, BS manifestations, symptoms prior to TA diagnosis, involved vessels and the used drugs. The diagnosis of TA was based on the finding of typical homogenous arterial wall thickening.

Results:

We identified 8 (0.1%) patients among 9000 BS patients. Table summarizes demographic and clinical characteristics of these patients. Their mean age at the time of diagnosis of BS was 31.6 ± 11.5 yrs, and at the time of diagnosis of TA was 37.5 ± 10.8. F/M ratio was 3/1. TA

preceded BS in 4 cases (6, 6, 12, 15 yrs) and occurred simultaneously in the remaining 4. Skin-mucosa lesions were the most common finding, followed by uveitis (5/8), and arthritis (3/8). Initial symptoms of TA were fatigue and fever in 2 patients, absent pulse in 2, fatigue in 1, arm claudication in 1. The remaining 2 were diagnosed as TA while being evaluated for the extent of vascular disease for BS. Subclavian (5/8) and carotid arteries (5/8) were the most commonly involved arteries. In addition to prednisolone, the initial agent was methotrexate in 4 patients, azathioprine in 3 and cyclophosphamide in 1. At the end of follow-up (1, 2, 2, 3, 7, 9, 18, 21 yrs), 4 patients had a stable disease following the first treatment, 3 had to switch to infliximab and 1 had to switch to azathioprine after methotrexate. BS manifestations resolved in 6 patients while recurrent arthritis persisted in 2. Six patients were still on immunosuppressive therapy due to TA, while the other 2 were off treatment. None had died.

Conclusion:

TA may be associated with BS. Similar associations of TA have been reported with ulcerative colitis, Crohn's disease, and ankylosing spondylitis. Whether it is a true association or mere co-existence is always debated. Interestingly, in this hybrid setting, both TA and BS followed their own course: while BS abated in time, TA continued its persistent activity.

Table: Demographic and clinical characteristics of patients with TA and BS

Sex	Age at BS diagnosis (year)	Age at TA diagnosis (year)	BS Manifestations	Initial presentations of TA	Typical vessel involvement due to TA	Medical Treatment
M	27	27	O, G, PAA, STM	None	CAR, BT	AZA
F	27	39	O, G, EN, U	Fatigue	CAR, SBC, BT, ThAo	CYC, AZA
F	44	44	O, G, A	None	CAR, SBC, BT, CT	MTX, INF
F	22	22	O, G, EN, PP, U	Arm claudication	CAR, SBC, RA, CT, SMA	MTX
M	39	39	O, G, A, U	Fatigue, fever	CAR, ThAo	AZA, INF
F	51	58	O, G, PP, U	Absent pulse	SBC	AZA, MTX
F	20	35	O, G, A, U	Fatigue, fever	ThAo	MTX, AZA
F	23	36	O, G, EN	Absent pulse	SBC, SFA	MTX, CYC, INF

A: arthritis; AZA, azathioprine; BT, brachiocephalic trunk; CAR: carotid artery; CT: celiac trunk; CYC: cyclophosphamide; EN: erythema nodosum; F: female; G: genital ulcers; INF: infliximab; M: male; MTX: methotrexate; O: oral ulcers; PP: papulo-pustular lesions, PAA: pulmonary artery aneurysm; RA: renal artery; SBC: subclavian artery; SFA: superficial femoral artery, SMA: superior mesenteric artery; STM: superficial thrombophlebitis; ThAo: Thoracic aorta; U: uveitis.

Session Title: Vasculitis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Assessment of disease activity is one of the major difficulties in patients with TAK during follow-up. To date, no biomarker is universally accepted to be a surrogate for active disease in TAK. In this study, we aimed to investigate plasma Pentraxin-3(PTX-3) level and its correlation with clinical activity in patients with TAK.

Methods: The study included 94 patients (age: 43.3±13.6 years, F/M: 80/14) with TAK and 40 age and sex matched control subjects (age: 41.5±9.3 years, F/M: 28/12). All patients fulfilled the criteria of American College of Rheumatology (ACR). TAK patients were evaluated by physician's global assessment (PGA; active/inactive) and Kerr' criteria(if available). Recently, a new composite index- ITAS2010 (Indian Takayasu Clinical Activity Score) for the clinical assessment of TAK was developed and validated. We also used ITAS2010 to assess clinical

activity. Plasma samples were separated to measure PTX-3. Commercial enzyme linked immuno-sorbent assay (ELISA) kits were used for measurements of plasma PTX-3.

Results: Mean disease duration the patients was 6.8±7.2(0-42) years. Thirty-three (35.5%) patients were clinically active according to PGA. While, Kerr's activity assessment was available in 79 patients, ITAS2010 was available in 88 patients. Twenty-five(31.6%) patients were active according to the Kerr's, 28(31.8%) patients were active according the ITAS2010. Plasma Ptx3 level was significantly higher in TAK compared to healthy controls(3,5±2,5 nanogram(ng)/ml vs. 2,5±1,6 ng/ml, p=0.029). PTX-3 level was found similar between active and inactive patients according to all assessment tools(PGA, Kerr' and ITAS2010)(Table 1). PTX-3 level significantly correlated with only serum CRP level. PTX-3 level was also similar between taking corticosteroid treatment and not taking.

Conclusion: Although plasma PTX-3 levels were higher in patients with TAK compared to healthy controls, we observed no association with disease activity. PTX-3 level was similar between active and inactive patients according to all activity assessment tools such as PGA, Kerr' and ITAS2010. Our results that PTX-3 level has limited role as a biomarker for active disease in TAK.

Table 1: Plasma pentraxin-3 levels according to different activity assessment tools.

		Plasma pentraxin-3 level (ng/ml)	**P value**
PGA	Active	3.2±2.4	
	Inactive	3.6±2.4	**0.442**
Activity by *Kerr et al*	Active	3.7±2.2	
	Inactive	3.6±2.5	**0.981**
ITAS2010	Active	3.9±2.5	
	Inactive	3.3±2.3	**0.214**
ITAS-A	Active	4.2±2.6	
	Inactive	3.3±2.3	**0.147**

Increased Circulating Th17 Cells, Serum IL-17 and Serum IL-23 in Takayasu's Arteritis

Ramnath Misra, Durga Prasanna Misra and Smriti Chaurasia, Clinical Immunology, Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Vasculitis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

The immune mechanisms underlying Takayasu's arteritis (TA) are not clear. Expanded Th17 T cell subset has been demonstrated in Giant Cell Arteritis. Gamma delta T cells (γδT), natural killer cells (NK) and natural killer -T cells (NKT) are also producers of IL-17 besides Th17 cells. Studies have demonstrated an increased number of circulating γδT cells in peripheral blood and in histopathology of arterial biopsies of patients with TA. We therefore enumerated Th17, γδT , NK and NKT cells and serum levels of IL-17 and IL23 in peripheral blood of patients with TA, and looked for its correlation with disease activity and erythrocyte sedimentation rate (ESR).

Methods: 30 patients with TA fulfilling ACR 1990 criteria and 20 healthy controls were included after seeking informed consent. NK cells (CD3-CD56+), NK-T cells (CD3+CD56+) and γδ-T cells (CD3+and γδTCR+) were surface stained in whole blood. For Th17 cells, 500 µl blood+500 µl cRPMI was cultured for 6 hours in presence of 50 ng/ml PMA, 1 µg/ml ionomycin for activation and golgi plug 0.2 µM monansin was added in last 4 hours of culture. Surface staining was done with anti-CD3, CD4, and intracellular staining for IL-17. Frequencies of all cell

types were analysed by flow cytometry. Th17 cells could not be assessed in one patient due to technical difficulties.

IL-17 and IL-23 were measured in serum by ELISA according to manufacturer's instructions. The relation of studied cell populations and serum IL-17 and IL-23 was analysed with disease activity (assessed by Kerr criteria, ITAS2010 and ITASA). Non-parametric tests were used for analysis (results presented as median with inter-quartile range). This study was approved by the institute ethics committee.

Results:

Mean age of patients was 33.47±11.78 years (25 females); mean symptom duration was 7.1±5.3 years. 13 were not on immunosuppressive drugs. 12 patients had ITAS ≥ 4. Compared with normal, the percentage of Th17 cells was significantly expanded in patients with TA. No differences in other cell populations were found. Serum IL-17 and IL-23 (pg/mL) in patients were significantly higher than controls (Table 1).

Subgroup analysis showed that the increased Th17 cells, serum IL-17 and IL-23 did not correlate with ESR, disease activity or medications.

Conclusion:

There is significant expansion of Th17 cells and elevation of serum IL-17 and IL-23 levels in patients with TA as compared to healthy controls. No relationship with disease activity could be demonstrated.

Table 1 – Gamma delta T cells, NK cells, NKT cells, Th17 cells, serum IL-17 and serum IL-23 in patients and controls (median with interquartile range in brackets)

	Patients (30)	**Healthy controls (20)**	**P value**
Serum IL-17 (pg/mL)	6.2 (4.6-8.5)	3.9 (3.9-7.3)	**0.004**
Serum IL-23 (pg/mL)	15 (14.9-26.5)	14.9 (14.9-14.9)	**<0.0001**
Th17 cells (%)	2.1 (1.5-3.2) (n=29)	0.75 (0.32-1.2)	**<0.0001**
Gamma delta T cells(%)	5.5 (3.9-7.1)	6 (2.7-9.9)	0.72
NK cells(%)	5.2 (3.6-8.7)	6.9 (4.3-9.3)	0.39
NKT cells(%)	3.7 (1.9-6.5)	2.4 (1.5-4.9)	0.12

Session Title: Vasculitis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Clinicians can have difficulty in making differential diagnosis between Takayasu and atherosclerosis. This is especially true when laboratory evaluations and FDG PET are inconclusive. In addition o that atherosclerosis load is potentially increased in TA because of the intense vascular inflammation. About 1/3rd of the patients with TA had carotid artery plaques and almost half diffuse aortic calcifications.

We thought that TA might have unique vascular changes distinct from atherosclerosis when evaluated with Doppler ultrasonography (USG). Thus, in this study we investigated the morphologic and hemodynamic changes in the carotid arteries in TA, along with patients with diabetes mellitus and healthy controls.

Methods:

Consecutive patients with TA seen in the department of Rheumatology at Cerrahpasa Medical Faculty were studied. Healthy controls were also included. TA patients and healthy controls were aged between 18 and 50 years. Patients with diabetes mellitus (DM) who were followed by the endocrinology outpatient clinic were also studied. For the purposes of this study, no age limit was set for patients with DM. Only females were studied. Traditional atherosclerotic risk factors were also assessed.

The radiologist scanned the right and left common, internal and external carotids and carotid bulb with the help of Doppler USG. Intima media thickness (IMT) was measured and resistivity index was calculated. The presence of atherosclerotic plaques, turbulence and macaroni sign was

assessed. Macaroni sign was defined as diffuse homogenous IMT thickening of at least 0.9 mm.

Results:

We studied 58 patients with TA (mean age: 43 ±11), 42 patients with DM (mean age: 57 ± 9) and 24 healthy controls (mean age: 41 ± 4). Atherosclerotic risk factors are summarized in Table 1 and carotid artery Doppler findings in Table 2. Patients with DM were significantly older and had significantly more atherosclerotic risk factors compared to patients with TA. Only smoking was significantly more frequent among healthy controls.

Patients with DM had more plaques and had higher IMT when compared to patients with TA, however, macaroni sign and turbulence were observed almost only among patients with TA. Finally the mean resistivity index was only significantly increased in TA.

Conclusion:

This study showed that carotid artery USG may be helpful in differentiating TA from atherosclerosis. Diffuse homogenous increase in IMT, presence of turbulence and higher resistivity index can be considered as suggestive of TA rather than atherosclerosis.

Table 1. Atherosclerotic risk factors

	Takayasu arteritis n= 58	Diabetes Mellitus n= 42	Healthy controls n= 24	P
BMI	25.6 ± 4.4	30.8 ± 5.8	26.7 ± 4.9	<0.001
Smoking, n (%)	12 (22)	11 (28)	16 (76)	<0.001
Diabetes mellitus, n (%)	4 (8)	42 (100)	0	< 0.001
Hypertension, n (%)	31 (56)	30 (77)	1 (5)	< 0.001
Familial history of ischemic heart disease, n (%)	22 (41)	16 (40)	8 (38)	0.978
Post-menauposal status, n (%)	23 (42)	36 (92)	1 (5)	<0.001

Table 2. Morphologic and hemodynamic findings in the carotid artery USG

	Takayasu arteritis n= 58	Diabetes Mellitus n= 42	Healthy controls n= 24	P
Macaroni sign, n (%)	45 (78)	1 (2)	0	<0.001
Atherosclerotic plaques, n (%)	21 (36)	28 (67)	2 (8)	<0.001
Turbulence, n (%)	8 (14)	0	0	0.008
Intima-media thickness, mm	0.90 ±0.36	0.96 ± 0.25	0.40 ± 0.12	<0.001
Resistivity index	0.63 ± 0.10	0.50 ± 0.04	0.56 ± 0.04	<0.001

NMR-Based Metabolomics Provides New Insights into the Inflammatory Processes in Takayasu Arteritis

Ramnath Misra[1], Anupam Guleria[2], Durga Prasanna Misra[1], Avadesh Pratap[3], Durgesh Dubey[4], Atul Rawat[4], Smriti Chaurasia[3], C L Khetrapal[4], Dinesh Kumar[4] and Paul Bacon[5], [1]Clinical Immunology, Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India, [2]Centre of Biomedical Research, Lucknow, India, [3]S.G.P.G.I.M.S, Department of Clinical Immunology, Lucknow, India, [4]Centre for Biomedical Research, Lucknow, India, [5]Rheumatology, Birmingham Universit, Birmingham, United Kingdom

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Vasculitis Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Takayasu Arteritis (TA), a large vessel disease of unknown aetiology, is the orphan of the inflammatory vasculitides with no evidence base for therapy. It often presents with vessel occlusions and biomarkers are needed for this subclinical process. Limited knowledge of its pathogenesis has hindered finding good candidates but PET scans indicate an active metabolic process in the aortic wall. Here, we have applied NMR-based serum metabolomics to gain more basic understanding of this process. The serum metabolic profiles of TA patients, Systemic lupus erythemoatosus (SLE) patients (chosen here as a diseased control group) and normal controls (NC) were obtained and compared using multivariate statistical data analysis.

Methods:

The sera samples were collected from (a) 29 TA patients fulfilling the ACR criteria seen at first presentation in SGPGI, Lucknow and assessed for disease activity and extent using ITAS and DEI.Tak., (b) 30 SLE patients attending the OPD and (c) 30 healthy age/sex-matched normal controls (NC) from the local community. NMR experiments were performed at 298 K on Bruker Avance III 800 MHz NMR spectrometer and metabolic differences between TA, SLE and NC were identified using multivariate statistical analysis.

Results: The projection to least squares discriminant analysis (PLS-DA) showed 100% specificity and sensitivity in differentiating TA from NC regardless of TA type and disease activity. Compared to healthy controls, the TA patients had (a) increased serum levels of choline metabolites, LDL cholesterol, N-acetyl glycoproteins (NAGs), and glucose and (b) decreased serum levels of lactate, lipids, HDL cholesterol, glucogenic amino acids (such as alanine, valine, arginine, proline, histidine, glutamine, etc.). We also accessed the role of disease activity on serum metabolic profiles in 2 ways. Spectra from 12 TA clinically active at 1st visit were not significantly different from 17 inactive (r^2=0.13) but did differ clearly from 6 who had become inactive at follow-up r^2=0.98). PLS-DA model also clearly separated TA from SLE (chosen as a disease control with known vascular inflammatory components suggesting that the TA results do not simply reflect active inflammation. Compared to SLE patients, the serum levels of lipid (mainly VLDL) and choline metabolites were found to be elevated in TA patients indicating the phospholipid and choline metabolism more activated in TA.

Conclusion: NMR based serum metabonomics study revealed a distinctive signature of TA, in particular the choline metabolites were found to be significantly higher in TA as compared to NC and SLE. However, the results of this study are preliminary and need to be confirmed in a prospective study using a larger cohort of TA patients and disease control like small vessel disease (SVV) to assess the specificity and utility of the metabolomic signature.

Abnormal Body Composition in Takayasu Arteritis Patients: Role of Inflammatory Cytokines and Adipokines

Thiago Ferreira da Silva, Mauricio Levy Neto, Valéria Caparbo, Liliam Takayama and Rosa M R Pereira, Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Vasculitis Poster III

Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Chronic inflammatory conditions including rheumatic diseases may alter body composition, especially lean and fat mass. In this process, adipokines and inflammatory cytokines appear to play a key role. The aim of this study is to evaluate the body composition (BC) of TA patients compared to healthy controls (HC), and correlate BC parameters of TA patients with serum adipokines (adiponectin and resistin) and inflammatory cytokines (IL-1a, IL-6 and TNF-α).

Methods: A cross-sectional study was conducted in 45 consecutive women with TA and 47 HC matched by age and body mass index (BMI). BC was measured using dual-energy X-ray absorptiometry (DXA). The fat mass parameters evaluated were: total fat mass (FM), adiposity (percentage of body fat), android and gynoid fat, visceral adipose tissue (VAT) and fat distribution ratio (FDR: FM of the trunk/(FM of arms + FM of legs). Overfat was defined to denote excess body fatness, according to the stratification by age, BMI and ethnicity. Regarding lean mass parameters, total lean mass (LM) and appendicular lean mass index (ALMI: appendicular lean mass/ht^2) were analyzed. Abnormal body composition was defined in the presence of overfat (excess body fatness from DXA), low lean mass (ALMI ≤ 5.45 kg/m^2) or combination of these two variables. Serum adipokines (adiponectin, resistin) and plasmatic cytokines (IL-1a, IL-6 e TNF-α) were determined by Luminex xMAP Technology.

Results: Abnormal body composition (35.56% vs. 6.38%; p<0.001) was more prevalent in TA patients. Adiposity (%) and android fat mass were higher in TA patients compared to HC (33.05 ± 5.39 vs. 30.43 ± 5.63 %; p=0.025 and 1.58 ± 0.73 vs. 1.27 ± 0.62 Kg; p=0.05). Decreased lean mass (ALMI) was more prevalent in TA patients than HC (24.44% vs. 4.25%; p=0.013). LM had negative correlation with IL-6 levels (r=-0.44; p=0.005). ALMI presented negative correlation with erythrocyte sedimentation rate (ESR) (r=-0.36, p=0.017), resistin (r=-0.34, p=0.035), IL-1a (r=-0.44, p=0.006) and IL-6 (r=-0.43, p=0.007) levels. Fat distribution ratio (FDR) and VAT had negative correlation with adiponectin levels (r=-0.44; p=0.004; r=-0.42; p=0.010). (table 1)_Cumulative prednisone dose was not shown any correlations with fat mass or lean mass parameters.

TABLE 1 – Correlations of body composition variables by DXA and inflammatory parameters in TA patients

Cumulative prednisone	0.02	0.888	-0.05	0.731	0.01	0.945	-0.09	0.562	-0.13	0.664	-0.04	0.879
ESR	-0.20	0.178	**-0.36**	**0.017**	0.12	0.406	0.26	0.080	0.17	0.303	0.18	0.288
CRP	0.01	0.946	-0.10	0.494	0.10	0.504	0.19	0.210	0.18	0.277	0.02	0.892
Adiponectin	-0.14	0.369	-0.28	0.084	-0.01	0.933	-0.44	0.004	**-0.42**	**0.010**	-0.19	0.260
Resistin	-0.23	0.140	**-0.34**	**0.035**	0.05	0.747	0.22	0.161	-0.13	0.425	-0.05	0.766
IL-1a	-0.29	0.077	**-0.44**	**0.006**	-0,25	0.123	-0.16	0.331	-0.21	0.207	-0.20	0.225
IL-6	**-0.44**	**0.005**	**-0.43**	**0.007**	-0.26	0.113	-0.06	0.692	-0.15	0.351	-0.19	0.243
TNF-α	-0.23	0.159	-0.20	0.226	-0.25	0.115	-0.07	0.668	-0.11	0.490	-0.25	0.124

Conclusion: Abnormal BC was significantly more prevalent among TA patients compared to healthy women. Appendicular lean mass was negatively correlated with inflammation parameters and visceral adipose tissue with adiponectin serum levels, suggesting a role of inflammation on the parameters of body composition in women with TA.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Vasculitis Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: The aim of this study is to analyze the activity parameters that affect the physicians global opinion (PGO) in TA.

Methods: The data of patients with TA who were followed in the Rheumatology outpatient clinic were retrospectively evaluated. Disease activity was assessed with, National İnstitutes of Healty (NIH) criteria, disease extent index-Takayasu (DEI.Tak), the Indian Takayasu Activity Score (ITAS2010), PGO, radiological activity parameters, and acute-phase reactants. According to the TA follow-up protocol of the Rheumatology and Radiology Board of our hospital, the patients were followed using B-mode/Doppler USG examinations and magnetic resonance angiography (MRA).

Results: 52 patients (48 females; mean age:46.8±13.2 years) who fulfilled the *American College of Rheumatology*(ACR) criteria for TA were enrolled in this study. 40 (76.9%) patients were categorized as having active disease in their first visits according to PGO. In the last visit, 31 (59.6%) patients had inactive disease, 19 (36.5%) had persistent disease and two (%3.9) had active disease. All the patients used the long-term glucocorticoid therapy and DMARDs. Six (%11.5) of them were on the treatment with biologics. Six (11.5%) patients underwent vascular surgery and 26 (50%) were performed endovascular repair for arterial stenosis. In total, 360 visits of patients were evaluated. PGO was that the disease was inactive in the 181 visits, persistan in the 99 visits and active in the 80 visits. The highest aggreement was found between PGO and the results of MRA and also B-mode/Doppler USG. NIH activation, DEI.Tak and ITAS2010 scores also well correlated with PGO. There was a poor agreement between PGO and hs-CRP.

Conclusion: The results of this study suggest that imaging had a significant impact on physician's decision regarding disease activity in TA. Although disease activity scores including radiological activity parameters, NIH, DEI-Tak and ITAS2010 were well correlated with each other, there was a poor agreement between CRP and all the other activity parameters.

Table 1.Agreement rates and correlations of the disease activity parameters with each other and PGO in Takayasu arteritis

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Vasculitis Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Takayasu arteritis (TA) is often refractory to corticosteroids and traditional immunosuppressive agents. Interleukin (IL)-6 plays an important role in the pathogenesis of TA. Tocilizumab (TCZ) is a humanized monoclonal anti-IL6 receptor (IL-6R) antibody.

Objective: Our aim was to assess the efficacy of TCZ in patients with TA refractory to conventional treatment.

Methods:

Retrospective multicenter study of 8 patients treated with TCZ and diagnosed with TA refractory to conventional therapy. We assessed its efficacy (clinical and laboratory parameters) and the reduction in the corticosteroid dose, as well as its side effects. Comparisons were performed between baseline and 1st, 3rd, 6th and 12th months, by means of

Results:

Eight patients (all women) with a mean age of 34±16 years, median 36 years (range: 7-57) were assessed. The main clinical features at TCZ therapy onset were: constitutional symptoms (n=4), fever (n=3), headache (n=2), chest pain (n=1), abdominal pain (n=1), mesenteric ischemia (n=1), myalgia involving the lower limbs (n=1), cerebral vascular insufficiency (n=1), malaise (n=1), upper limb claudication (n=1) and nodular scleritis (n=1). Besides corticosteroids and before TCZ treatment onset, 7 of 8 patients had also received several conventional immunosuppressive and/or biologic agents. Seven patients experienced marked clinical improvement in the first 3 months after the onset of TCZ therapy. After a median follow-up of 15.5 [interquartile range-IQR: 12-24] months, 7 patients were asymptomatic. The median C-reactive protein decreased from 3.09 [IQR: 0.5-12] to 0.15 [IQR: 0.1-0.5] mg/dL (p= 0.018), and median erythrocyte sedimentation rate from 40 [IQ range: 28-72] to 3 [IQR: 2-5] mm/1st hour (p= 0.012). The median dose of prednisone was also tapered from 42.5 [IQR: 25-50] to 2.5 [IQR: 0-7.5] mg/day (p= 0.011). However, TCZ had to be discontinued in 1 patient because she developed a systemic lupus erythematosus, and in another patients due to inefficiency. TCZ dose was reduced in a patient because of mild thrombocytopenia.

Conclusion:

TCZ appears to be effective in the management of patients with TakA, in particular in patients refractory to corticosteroids and/or conventional immunosuppressive drugs.

Frequency, Presentation and Outcome of Takayasu Arteritis in Western Australia

Krista Makin[1], Maxine Garnsey[2] and Johannes Nossent[3], [1]Rheumatology, Fiona Stanley Hospital, Murdoch, Australia, [2]Internal Medicine, Sir Charles Gairdner Hospital, Nedlands, Australia, [3]Medicine, University of Western Australia, WA, Australia
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Vasculitis Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Takayasu Arteritis (TAK) is a systemic large-vessel vasculitis that mostly affects women of childbearing age. The worldwide incidence of TAK varies due to genetic and/or environmental factors. We describe the frequency, clinical features and outcomes of TAK in Western Australia (WA).

Methods: Cohort study of TAK patients identified in the Western Australian population (2.4 million) through multiple sources including hospital discharge codes between 1-1-2000 and 30-5-2015.

Results: Sixteen patients with a clinical TAK diagnosis were identified of whom 11/16 fulfilled 1990 ACR criteria for TAK. All were female and 81% were Caucasian. The median age at diagnosis was 33 years (interquartile range, 27-44 years) with 2 patients (18%) > 40 years at time of diagnosis. The median time to diagnosis was 6 months (interquartile range 2-32 months). Limb claudication was the most common presenting symptom, present in 5/11 patients (45%), followed by fatigue in 4/11 patients (36%). ESR and/or CRP were elevated at diagnosis in only 5 patients (45%). Hata type 2a arteriographic abnormalities were the most common (55%). All patients received corticosteroids as initial treatment and all were commenced on additional immunosuppressant agents (Methotrexate in 73%). There was one death during the study period. Four patients (36%) developed cerebrovascular disease, 3 suffered more than one stroke. Two patients (18%) suffered acute myocardial infarction. Vascular intervention was performed in 3 patients (27%).

Conclusion: TAK prevalence in WA is at least 4.2/million based on ACR criteria. The high morbidity despite immunosuppressive treatment might be related to a long delay to diagnosis and indicates a need for better tools to achieve earlier diagnosis.

Ocular Findings and Ocular Blood Flow Changes in Takayasu Arteritis: A Subclinical Reduction in Blood Flow with a Milder Clinical Course of Retinopathy

Ali Ugur Unal[1], Fehim Esen[2], Fatma Alibaz-Oner[3], Gulce Celik[4], Haluk Kazokoglu[5] and Haner Direskeneli[1], [1]Department of Rheumatology, Marmara University Faculty of Medicine, Istanbul, Turkey, [2]Department of Ophthalmology, Marmara University Faculty of Medicine, Istanbul, Turkey, [3]Department Rheumatology, Marmara University Faculty of Medicine, Istanbul, Turkey, [4]Department of Internal Medicine, Marmara University Faculty of Medicine, Istanbul, Turkey, [5]Department of Ophtalmalogy, Marmara University Faculty of Medicine, Istanbul, Turkey
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Vasculitis Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Ocular involvement in Takayasu arteritis (TAK) mainly arises due to complications related with altered ocular blood flow or side effects of the treatments. In this study, we aimed to document ocular complication rates, ocular blood flow status and the association of ocular blood flow parameters with clinical outcome of the Takayasu arteritis patients followed in a tertiary rheumatology clinic.

Methods: We have included 65 Takayasu arteritis patients followed at Marmara University Medical School, Rheumatology Division (F/M:60/5

, mean age: 41.8 ±12.9 years) and 51 healthy subjects (F/M: 50/1, mean age: 37.4 ±12.9 years) in this study. All of the participants had a detailed ophthalmological examination with optical coherence tomography scan of the macula, retinal nerve fiber layer and choroid. Ocular blood flow in ophthalmic and central retinal arteries was evaluated with Color Doppler ultrasonography. The rheumatology examination data was provided from the last rheumatology visit at which the patients were referred to the ophthalmology clinic.

Results: The most common ocular complication was hypertensive retinopathy (33.9%). Only 4 patients had retinal findings related with Takayasu retinopathy (6.2%). Thirteen eyes had posterior subcapsular cataract (10%) and 7 eyes were pseudophacic (5.4%). None of the patients suffered from a reduction of visual acuity due to ischemic neovascular complications. There was no statistically significant difference between the TAK patients and healthy subjects for the central macular thickness, foveal volume, retinal nerve fiber layer thickness and subfoveal choroideal thickness. TAK patients had an increase of resistivity index in the ophthalmic artery (0.75 vs. 0.66, p=0.002) and central retinal artery (0.75 vs. 0.67, p=0.001). Patients with hypertensive retinopathy had a significantly longer disease duration compared to the group with no retinopathy (7.9 years vs. 4.7 years, p=0.016), while there was no statistically significant difference between the groups for upper extremity blood pressure values. The resistivity index of the ophthalmic artery was higher in patients with ipsilateral radial artery pulselessness compared to the patients who had no pulselessness (0.77 vs. 0.68, p=0.031). The patients with carotid artery bruits did not have a significant change in the ocular blood flow parameters compared to the patients without carotid artery bruits. There was also no significant difference for ocular blood flow parameters between the patients with long (>5 years) or short disease duration (<5 years).

Conclusion: The prevalence of Takayasu arteritis was lower in our study compared to previous series. However, while none of the patients complained about visual disturbances, Doppler findings indicate a subclinical reduction in ocular blood flow in these patients.

Cardiac Manifestation of Takayasu Arteritis

Jin Wan, rheumatology and immunology, Beijing Anzhen Hospital affiliated to Capital Medical University, Beijing, China
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Vasculitis Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: To explore cardiac manifestation of Takayasu arteritis and independent risk factor.

Methods: We retrospectively analyzed manifestations and helpful tests in 55 TA patients.

Results: Fifty-five patients(55/85,64.7%)with TA complicated by cardiac involvement were seen over 10 years£®The male to female ratio was l©U5.87, and the mean age at onset of TA was 24 years. There was no statistically significant difference between TA with and without cardiac involvement groups in terms of gender,clinical type,cardiac symptoms, except confirmed diagnosis time[36(9,168)months vs 12(6,24)months, *P*=0.001], chest pain[27.3%(15/55)vs 6.7%(2/30),*P*=0.023]and blood pressure difference >10 mmHg between right-to-left sides[69.1%(38/55) vs 46.7%(14/30),*P*=0.043]. Cardiac disease included hypertensive heart disease (30 patients,54.5%),cardiomyopathy(6 patients,10.9%),valvular disease(36 patients,65.5%),coronary artery disease(9 patients,16.4%),and pulmonary hypertension (7 patients,12.7%)£®At onset age in patients renal artery involvement was significantly younger in hypertensive heart disease[(28±14)years vs(44±14)years,*P*=0.006]. LVEF[(34±8)% vs(66±7)%, *P*=0.000]and age at onset [(15±13)years vs(25±11)years, *P*=0.030] were statistically significant between patients in TA with and without cardiomyopathy. Multivariate analysis showed that higher CRP was independent risk factor for pulmonary hypertension(*OR*=0.082,*95%CI:0.007-0.965,P*=0.047),mitral valve regurgitation(*OR*=0.192,*95%CI:*0.040-0.929,*P*=0.031)and tricuspid regurgitation(*OR*=0.093,95%*CI:*0.011-0.761,*P*=0.018).

Conclusion: We should pay attention to cardiac manifestation of Takayasu's Arteritis complicated by cardiac involvement to improve its early diagnosis.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Vasculitis Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: To facilitate clinical care and research, validated algorithms are needed to accurately identify patients with Takayasu's arteritis (TAK). This study sought to evaluate and validate case-finding algorithms for TAK in 2 large healthcare administrative databases.

Methods: All adult patients with the International Classification of Diseases version 9 (ICD9) code for TAK (446.7) were identified from 2 large healthcare systems (102 from site 1 and 85 from site 2). 26 case-finding algorithms were constructed using a combination of ICD9 code, encounter type (1 inpatient ICD9 code on 3 consecutive days or 2 outpatient ICD9 codes 3 months apart), physician specialty (Rheumatology, Cardiology, or Vascular Surgery), use of immunosuppressive medications, age, and sex. The diagnosis was confirmed by chart review using the ACR classification criteria or the Chapel Hill Consensus Conference definitions for TAK.

Results: 102 patients from the first healthcare system (site 1) and 85 patients from the second system (site 2) were included in the analysis. 47/102 (46%) patients had a confirmed diagnosis of TAK at site 1 and 35/85 (42%) patients at site 2. Table 1 shows the positive and negative predictive values of the studied algorithms in each healthcare system. An algorithm including the encounter type, physician specialty, age, and immunosuppressive medications had the highest average positive predictive value (PPV: 76.9% and 88.2 % respectively). An algorithm including only the physician specialty had the highest average negative predictive value (NPV: 90.2% and 100% respectively).

Conclusion: Case-finding algorithms can accurately identify patients with TAK using large administrative databases. A simple algorithm including the encounter type, physician specialty, age, and immunosuppressive medications had the highest positive predictive value. Similarly, an algorithm including only the physician specialty had the highest negative predictive value. These algorithms can be used to assemble a population-based cohort of patients with TAK and facilitate future research in healthcare use, outcomes, and comparative effectiveness.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Vasculitis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Some cases with Takayasu arteritis (TAK) complicated with ulcerative colitis (UC) have been reported. We previously performed a multi-center surveillance of TAK patients complicated with UC (Terao et al., Arthritis Rheumatol 2015) and reported that 30 of 470 TAK patients (6.4%, CI: 4.3-9.0%) were coincident with UC. We also found that the onset of TAK symptoms was approximately 6 year earlier in TAK+UC patients than in TAK-only patients (p=0.007), implying that stronger genetic backgrounds might underlie in TAK+UC patients. In this study, we investigated detailed clinical features of TAK+UC cases in a single center.

Methods: We referred to medical records of 122 Japanese TAK patients in Kyoto University Hospital, and examined their HLA-B genotypes, ages of onsets, symptoms associated with TAK or UC, and treatments.

Results: 7 of 122 TAK patients (5.7%, CI: 2.3-11.5%) had UC. HLA information was available in 6 TAK+UC patients and 77 TAK only patients. All of TAK+UC patients and 38 (49%) TAK only patients had HLA-B52 (p=0.027). In 4 TAK-preceding patients, the onset of TAK was 5.5 ± 4.5 (1-10) years earlier than that of UC, and all of them noticed bloody stool and/or diarrhea as the first symptom of UC. In 3 UC-preceding patients, the onset of UC was 4.0 ± 3.0 years (1-7) years earlier than that of TAK, and 2 of them noticed neck pain as the first symptom of TAK. We did not find particular clinical features of symptoms and signs between TAK-preceding and UC-preceding patients. Biologic agents were used in 43% (3/7) of TAK+UC, whereas in only 7.0% (8/115) of TAK-only patients. Both diseases were well controlled in the 3 TAK+UC patients when treated with biologics (2 with infliximab and 1 with ustekinumab).

Conclusion: While association of HLA-B52 had been reported both in TAK and UC, HLA-B52 was considered as a major genetic background underlying in TAK+UC patients. When stool abnormality is seen in TAK patients with HLA-B52, possible complication of UC could be considered. Biologics may be a therapeutic consideration to control both diseases.

Session Title: Vasculitis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Takayasu's arteritis (TAK) is a chronic vasculitis of large-vessels, mainly affects the aorta and its branches in the middle-aged females. There are reports regarding the concurrence of inflammatory bowel disease (IBD) and TAK. Microscopic colitis (MC) has been demonstrated in inflammatory rheumatic diseases such as spondylarthropathies which has been linked to an ethiopathogenetical association between two diseases. MC as an IBD subgroup has not been investigated in TAK, so far. We aim to assess the presence of MC in TAK patients who have no clinically overt IBD symptoms.

Methods: We cross-sectionally assessed TAK patients, between the ages of 18-65, who were diagnosed according to ACR criteria. Disease activity was evaluated by Kerr's criteria. Age and sex matched irritabl bowel syndrome (IBS) patients were selected as control group. Study subjects who have been on MC inducing medications, such as NSAIDs, PPI, anti-physchotic or anti-depressant and having co-morbidities were excluded. All patients and controls have been interviewed for IBD and IBS symptoms by the questionnaires of WHO guideline and Rome III criteria, respectively. Lower endoscopic procedure was performed with at least 5 random biopsies taken from different colonic segments and terminal ileum within the following 2 weeks after the research visit. A blinded expert pathologist evaluated the specimens for the thickness of the collagen band, the degree of inflammatory infiltration in the lamina propria, and the number of intraepithelial lymphocytes according to an algorythm proposed for MC assessment by Langner C et al.[1]. Lymphocytic and collagen colitis were defined as the subgroups of MC. Incomplete colitis has also been defined in the algorythm.

Results:

Thirty TAK patients (29 female) with the mean age of 35±11 (20-59), total disease duration of 107±79 months (3-286) and 10 female IBS controls with the mean age of 38±13 were included into the study. Type 2 vascular involvement was the most common (64%) pattern in the cohort. Nine of 30 (30%) TAK patients have active disease at the time of endoscopic procedure. MC was not demonstrated in any patients with IBS. All but one TAK patients had normal endoscopic findings. Erythema on the entire colonic mucosa as the only pathological endoscopic finding was demonstrated in one patient. The examination of terminal ileum was found normal in both TAK and control groups. Three patients (10%) were full-filled LC criteria of MC. Incomplete LC was determined in additional 6 patients (20%). LC was found significantly higher among the patients with active TAK subgroup compared with inactive patients (p= 0.03, OR= 5,7).

Conclusion: MC was found significantly high in TAK patients who had no overt IBD symptoms/diagnosis. This preliminary report from this ongoing study supports that this association might have a pathopyhsiological relevance.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Vasculitis Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: This study aimed to describe disease-related damage in Takayasu's arteritis (TAK) and evaluate damage assessment tools using data from a large longitudinal cohort.

Methods: Patients with TAK enrolled in a prospective, multicenter, longitudinal study were included. Measures of disease damage, including the Vasculitis Damage Index (VDI) and the Large-Vessel Vasculitis Index of Damage (LVVID), were assessed at baseline and follow-up visits. LVVID was developed specifically for large-vessel vasculitis. **Results** from patients with a diagnosis of TAK made within 6 months prior to study entry were also separately analyzed.

Results: The study included 129 patients with TAK: 94% female, 89% Caucasian with a median duration of follow-up 3.5 years (1.9, 6.2). At entry in the cohort, 113 patients (88%) had at least one damage item recorded on VDI (mean score ± SD: 2.5±1.8) and 113 (88%) on LVVID (mean score: 3.0±2.5). During follow-up 49 patients (38%) accrued at least one new damage item as measured by VDI (mean increase in score: 1.8±1.0) and 47 patients (36%) as measured by LVVID (mean increase in score: 2.0±1.9). 31/129 patients had a diagnosis of TAK made within 6 months prior to study entry, 81% of them had at least 1 item documented on VDI at entry with a mean score of 2.2±1.5 items and 81% on LVVID with a mean score of 2.7±2.1 items.

Organ systems affected by damage at baseline and follow-up are outlined in the **Table**. The cardiac, peripheral vascular, and the "other" sections, including weight gain, accounted for most of the damage captured at baseline and follow-up. The accrued damage items were mostly related to the disease (cardiac and peripheral vascular) rather than treatment (weight gain). There were 25 items never scored on VDI and 8 items never scored on LVVID. The unscored items were mostly related to the skin, ear, nose, and throat, pulmonary, and renal systems.

Conclusion: Damage from vasculitis is present in the majority (>80%) of patients with TAK even within 6 months of diagnosis. Approximately 40% of patients continue to accrue a new damage item, mostly related to disease, with a mean of 2 items per patient. The cardiac, peripheral vascular, and "other" sections capture most of the damage in TAK. LVVID appears to document more damage items overall than VDI. Revision of the VDI or adoption of the LVVID, along with data-driven approaches to item reduction and weighting, may improve damage assessment in TAK.

Major organ systems damage in 129 patients with Takayasu's arteritis as captured by VDI and LVVID

Session Title: Vasculitis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Takayasu arteritis (TA) is a chronic arteritis of the aorta and its major branches. Patients may require endovascular repair in long term follow up. The aim of this retrospective study was to report our long term follow up results of endovascular repair in the management of arterial stenosis caused by TA.

Materials and Methods: We retrospectively analyzed the outcome of endovascular interventions including angioplasty and angioplasty with stenting in patients with arterial stenosis caused by TA. The patients were followed-up in the Rheumatology out-patient clinic at 3 monthly intervals. Each visit included the evaluation of clinical symptoms, acute-phase reactants and regulation of the medical treatment including glucocorticoids and immunosuppressive drugs. For the evaluation of outcome of the interventional procedure, patients underwent Doppler ultrasonography and MR angiography routinely at every 6 months. Catheter angiography was performed if there was any suspicion of restenosis or occlusion.

Results: This study included 35 patients with TA (31 female, mean age: 42.5 years) who fulfilled the American College of Rheumatology 1990 Criteria for the diagnosis of TA. All patients had symptomatic arterial stenosis proven by catheter angiography. A total of 67 endovascular procedures were performed for 49 arterial stenotic lesions of the patients. Clinical inactivity of the disease was provided with immunosuppressive treatment before any interventions. Treatment of recurrent stenosis by a second endovascular procedure was performed in 11 (22.5%) lesions. The mean follow-up interval after endovascular procedure was 81 months (range 12-144 months). Twenty two (33%) of total 67 endovascular interventions resulted in restenosis or occlusion. Among all 49 arterial lesion, only four (8%) lesions (one common iliac, one renal, one celiac and one thoracic aortic) were occluded at the time of the final evaluation. Kaplan-Meier survival analyses of the renal arterial lesions showed that the overall 1- and 8-year restenosis-free survival rates of renal arterial interventions were 74% and 57%, respectively.

Conclusion: This study suggests that long term patency of TA lesions is related with control of the disease activity by optimal immunosuppressive therapy before and after the initial endovascular procedure. Performing reinterventions with close monitoring of the arterial lesion should not be avoided for better outcomes.

Session Title: Vasculitis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Takayasu arteritis (TA) is a large-vessel vasculitis that affects young women of childbearing age. We aimed to analyze the outcome of pregnancies in TA patients and to identify the factors associated with maternal and neonatal prognosis.

Methods: We conducted a French nationwide retrospective study of pregnancies occurring in patients with a TA diagnosis.

Results: Forty-one pregnancies occurred in 31 TA women between 1999 and 2015. Steroids were used in 25 pregnancies (61%), azathioprine in 9 (22%) and anti-TNF- agonist in 1 (3%). Nineteen pregnancies (46%) were complicated by at least one obstetrical adverse event: 14 gravida arterial hypertension (34%) with 3 pre-eclampsia (7%), 1 HELLP syndrome (2%), 6 intrauterine growth restriction (15%), and 2 post-partum hemorrhage (5%). Delivery was vaginal in 22 (54%) and by cesarean section in 19 pregnancies (46%).There were 40 live births (98%) with a median term of 38 [27-42] weeks of gestation with 8 premature birth (20%). The median birth weight was 2985 [1050-4310] grams with 7 neonates <2500 gr (17%). Four children required intensive care units (10%) and one died at 2 days of life. Maternal chronic arterial hypertension increased the risk of gravida arterial hypertension (p=0.01), of pre-eclampsia (p=0.04) and of cesarean delivery (p=0.01). The presence of renal artery stenosis before pregnancy increased the risk of fetal growth restriction (p=0.04). The presence of renal artery stenosis before pregnancy as well as the presence of infra-diaphragmatic vasculitis both increased the risk of low birth weight (p=0.03 and p=0.023 respectively).

TA disease activity was observed in 8 pregnancies (20%), including 2 flares in previously inactive patients. The risk of flare or of TA activity was higher if TA had been active in the 6 months before pregnancy: 6 active disease in 10 pregnancies (60%) if TA had been active before pregnancy versus 2 in 31 (6%) if TA had been inactive (p=0.0011).

Conclusion: We observed a high rate of obstetrical complications in this large series of pregnancies occurring in patients diagnosed with TA**.** The presence of chronic hypertension, infra-diaphragmatic vasculitis, renal artery stenosis or active disease before pregnancy were associated with poor pregnancy outcome. TA activity did not seem to be strongly influenced by pregnancy.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Vasculitis Poster III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

To assess the relation between Takayasu's arteritis (TA) and pregnancy outcome.

Methods: This study included 240 pregnancies in 96 patients fulfilling ACR and/or Ishikawa criteria. Obstetrical and maternal outcomes in pregnant women before or concomitant with or after TA diagnosis were analyzed. Factors associated with complicated pregnancy were assessed.

Results:

One hundred and forty two pregnancies occurred in 52 patients before TA diagnosis [median age at pregnancy 26 [23-30] years] and 98 pregnancies occurred in 52 patients concomitantly or after TA diagnosis [median age at pregnancy 28 [26-31] years]. Pregnancies concomitant with or after TA diagnosis had 13 times higher rates of obstetrical complications compared to pregnancies before TA diagnosis (OR=13, 95% CI [5-33], $p<0.0001$). TA was associated with 40% obstetrical complications and include preeclampsia/eclampsia [n=24, (24%)], prematurity [n=8 (8%)] and intrauterine fetal growth restriction or death [n=5 (5%)]. Specific TA complications during pregnancy occurred in 39% and include mainly new onset or worsening hypertension [n=26, (26%)]. In multivariate analysis, smoker (OR=6.15 [1.31-28.8]) and disease activity of TA (i.e. NIH score >1) (OR=28.7 [7.89-104.7]) were independently associated with obstetrical and maternal complications.

Conclusion:

TA negatively impacts pregnancy outcomes. Disease activity increases the risk of obstetrical and maternal complications mainly due to arterial hypertension.

Childhood Takayasu Arteritis – A Single Center Experience

Background/Purpose: Takayasu Arteritis is a large vessel vasculitis that rarely affects children. Data on childhood TA (cTA) are scarce.

Methods: A single-center retrospective review of all consecutive patients fulfilling the EULAR/PRINTO/PReS criteria for cTA between 1986 and 2015 was performed. Clinical, laboratory and imaging features at presentation, treatment and flares (new symptoms and/or increased inflammatory markers necessitating therapy escalation or new angiographic lesions after 2 months of inactive disease) were captured. Disease activity was retrospectively assessed by Paediatric Vasculitis Activity Score (PVAS), damage by Paediatric Vasculitis Damage Index (VDI). Active disease was defined as PVAS>1 and/or increased inflammatory markers not explained by other causes or active disease on imaging (new lesions, evidence of vessel wall inflammation); inactive disease was defined as a PVAS=0 and normal inflammatory markers or inactive disease on imaging. Outcome measurements included death, disease activity and VDI at last follow-up.

Results: Twenty-nine patients were identified; an overview and presenting features are shown in Table 1. Most frequently involved vessels were the abdominal aorta (86%), the renal (66%) and carotid arteries (55%). Data on induction treatment are presented in Table 2. Seven patients were considered in a non-inflammatory disease status at diagnosis and therefore not treated. Overall flare rate was 28%. Patients flared after a median of 12.5 months after diagnosis (range 9–73.7 months). Follow-up data were available for 27 patients with a median follow-up time of 2.1 years (range 0.2–11.7). At last follow-up median VDI was 4 (range 2–7); 48% of patients had active disease and 17% inactive disease while on treatment. Another 21% had inactive disease without treatment. Two children died within the first 6 months of diagnosis (mortality rate 7%).

Conclusion: In this cTA cohort mortality in early disease phase and relapse rate after induction treatment were high. At last follow-up half of the children had active disease. We observed a discrepancy between clinical (PVAS) and biochemical measures of disease activity, which has to be considered regarding treatment management.

Table 1: Demographic and presenting features of our cohort. Arterial hypertension = systolic/diastolic pressure >95th percentile for height. Blood pressure discrepancy >10mmHg in any of the four limbs. ESR: erythrocyte sedimentation rate, CRP: C-reactive protein, BP: blood pressure.

Patient characteristics	Patients (n = 29)

Session Title: Vasculitis Poster III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Takayasu arteritis (TA) is the most common large vessel vasculitis and may presents in childhood. Different angiographic classification systems based on adults with TA have been proposed. However, in clinical practice many children with TA do not fit into any of these classification categories. We sought to study the vascular involvement patterns in children with TA using unsupervised data-driven pattern recognition techniques to better characterize homogeneous subgroups of children with TA.

Methods: 29 children with TA were included from a single-center cohort. Non-negative matrix factorization (NMF) was conducted on baseline imaging data (MR angiography or conventional angiogram) to identify unique factors that distinguish between various types of vascular involvement in children. A feature of NMF is that the factors naturally give rise to clusters of children.

Results: NMF identified 3 factors and clusters characterized by the following distinct pattern of vessel involvement: (1) widespread vessel involvement including the aortic arch/ascending aorta, coronary artery, neck vessels, upper extremity vessels, abdominal aorta, renal and iliac arteries (7 patients); (2) the abdominal aorta its branches (coeliac trunk, superior mesenteric artery, bilateral renal) and the iliac arteries (14 patients); and (3) the entire aorta and its left-sided neck vessels (subclavian, carotid and vertebral artery), and involvement of the superior mesenteric and bilateral pulmonary arteries. The renal arteries are spared (8 patients).

Conclusion: Our data-driven, assumption-free analysis recovered unique patterns of vascular involvement that are distinct from the current adult-based angiographic classifications. These patterns may help to define homogeneous subgroups of children with TA and to guide the challenging management.

Figure 1: Contributions of individual arteries to factors. Shades of gray indicate the degrees to which individual arteries (y-axis) contribute to factors (x-axis). Shades nearer black indicate stronger contributions. Traces (lines represent 0 loadings and dots indicating absolute loadings) provide an alternative means of visualizing the loadings. Arrows indicate the side of body.

Session Date: Tuesday, November 10, 2015

Session Title: ACR Plenary Session III: Discovery 2015

Session Type: ACR Plenary Session
Session Time: 11:00AM-12:30PM

Background/Purpose:

Large-scale genomic studies have identified many genetic associations with autoimmune diseases, but the precise pathogenetic mechanisms by which the associated genes impact disease susceptibility remain unclear in most cases. Furthermore, interpretations may be skewed by the ethnic mix of the samples. RA is linked to particular *HLA-DRB1* alleles. In the current understanding, based largely on studies of Caucasians, alleles associated with ACPA-positive RA share a conserved motif at amino acid positions 11, 13, 71 and 74 of DRβ termed the "shared susceptibility epitope (SE)". His/Phe13β is associated with ACPA-positive RA, while His13βSer polymorphisms are associated with ACPA-negative RA and RA-protection. Indigenous North American (INA) RA patients have a high prevalence of ACPA. In this population, *HLA-DRB1*04:04* and *14:02* are implicated as risk factors for RA. While *HLA-DRB1*04:04* has a typical SE His/Phe13β, *HLA-DRB1*14:02* unexpectedly has a His13βSer polymorphism. Therefore, we aimed to determine the molecular mechanism explaining the association of *HLA-DRB1*14:02*with ACPA+ RA in INA.

Methods: Competitive HLA-DR binding assays compared citrullinated and native vimentin peptide binding against HA(305-319) indicator peptide. HLA-DRB1*14:02 molecules with their class II-associated invariant peptide (CLIP) were expressed and purified, then loaded with Vimentin-64Arg(59-71) or Vimentin-64Cit(59-71), and the structure was solved using x-ray crystallography. Single CD4+ T cells were sorted from peripheral blood mononuclear cells (PBMC) of 5 HLA-DRB1*1402+ ACPA+ RA patients and 5 of their HLA-DRB1*1402+ ACPA+ non-RA first-degree relatives, based on staining with fluorescent vimentin-64Cit(59-71)-specific and vimentin(59-71)-specific pHLA tetramers. Paired TCRα/β chains were analyzed using multiplex, nested PCR and sequencing.

Results: In binding studies, HLA-DRB1*14:02 displayed no preference for citrulline residues in the P4 pocket. Structures of HLA-DRB1*14:02 complexed with Vimentin-64Arg(59-71) or Vimentin-64Cit(59-71) showed that both citrulline and arginine were accommodated in the P4-pocket of HLA-DRB1*14:02, in contrast to HLA-DRB1*0401/0404 where citrulline but not arginine was accommodated within the electro-positive P4-pocket. When bound to HLA-DRB1*04:01/04 or HLA-DRB1*14:02, citrulline was upright and TCR-exposed. In contrast, arginine was buried in the P4 pocket of HLA-DRB1*14:02. T cell receptor repertoires of citrullinated and native vimentin-sorted CD4+ T cells were distinct among PBMC of HLA-DRB1*14:02+ ACPA+ RA patients and relatives.

Conclusion:

Together, these findings based on SE alleles prevalent among Caucasians and INA suggest a new model for the *HLA-DRB1* association with ACPA+ RA, in which the SE shapes the molecular orientation of citrulline and thus the autoreactive citrulline-specific TCR repertoire required for the development of ACPA.

Session Date: Tuesday, November 10, 2015
Session Title: ACR Plenary Session III: Discovery 2015
Session Type: ACR Plenary Session
Session Time: 11:00AM-12:30PM

Background/Purpose:

Patients with primary Sjögren's Syndrome (pSS) have an increased risk of non-Hodgkin's lymphoma, predominantly of the Mucosa Associated Lymphoid Tissue (MALT) type, which commonly occur in the parotid glands. MALT lymphomas in general, express Fc receptor-like 4 (FcRL4/IRTA1/CD307d)[1]. Normally FcRL4 is expressed on a very small subset of mucosa-associated B-cells. $FcRL4^+$B-cells might be closely related to the MALT lymphoma cells. Therefore, we assessed whether $FcRL4^+$B-cells are present in the inflamed salivary gland tissue of pSS patients, and whether these cells are targeted by biological therapy.

Methods:

Forty nine parotid gland MALT lymphomas, 30 parotid gland biopsies, 24 labial gland biopsies and parotid gland biopsies before and after treatment with rituximab (18 patients) or abatacept (15 patients), all obtained from pSS patients, were stained for FcRL4 expression. As control served parotid gland biopsies of 8 non-pSS sicca patients and 5 non-sicca patients. FcRL4 mRNA was isolated from 8 non-pSS sicca patients, 9 pSS patients and 11 pSS MALT lymphoma patients.

Results:

Nearly all (96%) parotid gland MALT lymphomas expressed FcRL4 (Fig. 1). Low numbers of $FcRL4^+$B-cells were detectable in parotid glands of most (90%) pSS patients. Intensely stained $FcRL4^+$B-cells were in close relation to lymphoepithelial lesions with some $FcRL4^+$B-cells within the surrounding infiltrate. Even lower numbers of $FcRL4^+$B-cells were discernible in the labial glands. Levels of FcRL4 were significantly increased in parotis gland tissue of pSS patients, compared to non-pSS sicca patients. These levels further increased significantly in pSS patients with MALT lymphomas in the parotid glands. Treatment with rituximab significantly reduced the number of $FcRL4^+$B-cells in the parotid glands, whereas abatacept treatment did not affect $FcRL4^+$B-cells in the glandular tissue (Fig. 2).

Conclusion:

$FcRL4^+$B-cells are found in the salivary glands of pSS patients and are likely the cells from which MALT lymphomas arise. The observation that $FcRL4^+$B-cells are enriched in the parotid glands may explain why MALT lymphomas preferentially develop in these glands. Our treatment studies reveal that $FcRL4^+$B-cells can be targeted by anti-CD20 therapy and that these cells are maintained in a CD28- independent manner.

Interferon Gamma (IFNg) Is the Driving Mediator of Secondary Hemophagocytic Lymphohistiocytosis (sHLH) in TLR9-Mediated Pathogenesis in Mice and Is Correlated to Disease Parameters in Children

Session Date: Tuesday, November 10, 2015

Session Title: ACR Plenary Session III: Discovery 2015

Session Type: ACR Plenary Session

Session Time: 11:00AM-12:30PM

Background/Purpose:

Life-threatening hyperinflammatory syndromes caused by severe hypercytokinemia include primary (p) and secondary (s) hemophagocytic lymphohistiocytosis (HLH). Increased circulating levels of interferon gamma (IFNg) in pHLH and sHLH patients suggest a central role for this cytokine in the development and maintenance of hypercytokinemia observed in HLH.

Methods:

C57BL/6 mice were injected i.p. on days 0, 2, 4, 7 and 9 with 50 µg of CpG-ODN 1826. Anti-mouse IFNg neutralizing mAb (XMG1.2) and rat IgG1 isotype-matched control mAb (mAb35) were injected intravenously at 100 mg/kg. Q-PCR was used to analyze inflammatory gene expression. Luminex multiplex technology was used to detect serum cytokines. Blood parameters were measured using a haematological counter. Serum concentrations of total IFNg were determined by an ELISA method developed for purpose. Serum samples were taken from 14 sHLH patients, with underlying infection demonstrated in 7 patients, (age at onset 8.6 years, interquartile range (IQR) 4.1-12.9 years; female 36%), seen at the Ospedale Pediatrico Bambino Gesù, Italy. All patients met the 2004-HLH diagnostic guidelines.

Results:

Using a model that mimics an infection-driven sHLH, TLR9 agonism resulted in a multi-phasic production of IFNg evidenced by a spike in serum cytokine levels following each CpG-ODN injection. Therapeutic blockade of IFNg reduced body weight loss, splenomegaly, normalized white blood cell counts, significantly reversed the decrease in other laboratory parameters (e.g. platelets, haemoglobin and red blood cells) and controlled hyperferritinemia. Our study reveals that total IFNg levels, originating within organs, are 500- to 2,000-fold higher than those present in blood. Expression of IFNg induced inflammatory genes demonstrated that spleen and liver are major sites of IFNg production. Furthermore, the IFNg signature gene products, CXCL9 and CXCL10, correlate with disease severity. In patients with sHLH, sampled during active full blown disease, levels of IFNg (median 34.7 pg/mL, IQR 23.9-170.1) and IFNg inducible chemokines (CXCL9: 33598 pg/mL, IQR 3083-127687; CXCL10; 4420 pg/mL, IQR 799-8226) were markedly higher than those of patients sampled during remission following effective treatment (IFNg <3.5 pg/mL, IQR <3.5-6.5; CXCL9: 745 pg/mL, IQR 469-1098; and CXCL10; 132 pg/mL, IQR 74-157). Similar to what was found in TLR9-induced sHLH in mice, IFNg levels significantly correlated with levels of CXCL9 and CXCL10. Furthermore, levels of IFNγ, as well as of CXCL9 and CXCL10, correlated with laboratory parameters of HLH including neutrophil and platelet counts, ferritin, LDH and ALT levels.

Conclusion:

IFNg production in the tissues is central to the hypercytokinemia causing the manifestations of the disease in mice following recurrent TLR9 repeated stimulation. Taken together with data in patients with sHLH, our observations demonstrate that IFNg appears to be the driving mediator of sHLH, support the role of CXCL9 and CXCL10 levels as a marker of the production of IFNg and indicate that the neutralization of IFNγ should be investigated as a therapeutic approach also in secondary forms of HLH.

Session Date: Tuesday, November 10, 2015
Session Title: ACR Plenary Session III: Discovery 2015
Session Type: ACR Plenary Session
Session Time: 11:00AM-12:30PM

Background/Purpose: Patients with recurrent pericarditis either do not respond or are intolerant to treatment with NSAIDs drugs, corticosteroids and colchicine. We aimed to assess the safety and efficacy of anakinra in patients with cortico-dependent idiopathic recurrent pericarditis.

Methods: We did a double-blind randomised controlled withdrawal trial between June2014 and June2015. We enrolled 21 patients aged 45.4 years (7 males) from 3 Italian centres, who had a history of idiopathic recurrent pericarditis with at least 2 previous recurrences, CRP elevation during recurrence (>1 mg/dL) and on therapy with corticosteroids. 20 adults patients took 100 mg of anakinra subcutaneously daily for 2 months, 1 child received 2 mg/kg/day. 11 patients were then randomly assigned to continue anakinra for additional 6 months or until a flare of the pericarditis and 10 were randomly assigned to receive placebo at the same dose and timing. Primary endpoint: time to flare of pericarditis. Flare was defined as recurrence of typical pain and CRP elevation. We analysed all patients who were treated as per protocol. The trial is registered (NCT02219828)

Results: Mean n° of recurrences in the patients before this study was 6.6 with a clinical history of recurrent pericarditis lasting 27.7 months on average. All patients completed successfully the open lead-in course with a complete response to the treatment, CRP normalization and discontinuation of all the other drugs. Flares of pericarditis occurred in all the 10 patients randomized to placebo and none of the 11 patients randomized to anakinra during the double-blind treatment ($p<0.0001$). Median time to flare of pericarditis was 48.2 days for patients given placebo; insufficient events had occurred in the anakinra group for median time to flare to be assessed ($p< 0.00001$). During study the frequency of adverse events differed in the two treatment groups. The most common side effect was a local reaction at the injection site, observed in 20 of 21 cases (95.2%) during the initial open-label phase; generally disappeared over one month, and only one patient discontinued the study for this side effect. Two serious events were reported, both in the anakinra treated patients ($p=0.47$): 1 patient developed skin herpes zoster during the open-label phase, 1 developed ischemic optic neuropathy at the fifth month of the double-blind period; she is a 70 years old woman, hypertensive and with hypercholesterolemia, but the exact mechanism of the optic neuropathy is debatable.

Conclusion: Inhibition of IL1 with anakinra is a rational alternative treatment for selected patients with severe cortico-dependent recurrent pericarditis and multiple failure of conventional therapies with colchicine.

ABCG2 rs2231142 predicts Poor Response to Allopurinol in Patients with Gout

Lisa K. Stamp[1], Mary Wallace[2], Tony R. Merriman[3], Amanda Phipps-Green[4], Ruth Topless[4,5], Jill Drake[6], Paul Tan[7], Nicola Dalbeth[8] and Rebecca Roberts[4], [1]Medicine, University of Otago, Christchurch, Christchurch, New Zealand, [2]Surgical Sciences, University of Otago, Dunedin, New Zealand, [3]Biochemistry Dept, PO Box 56, University of Otago, Dunedin, New Zealand, [4]University of Otago, Dunedin, New

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: ACR Plenary Session III: Discovery 2015
Session Type: ACR Plenary Session
Session Time: 11:00AM-12:30PM

Background/Purpose: Many patients fail to reach target serum urate (SU) on allopurinol. Although the most common causes of inadequate response are non-adherence and low dosing in kidney disease, there are a group of adherent patients who fail to achieve target SU and can be considered poor responders to allopurinol. In patients who have undergone allopurinol dose escalation, poor response can be defined as failure to reach the recommended target SU of <6mg/dl on allopurinol ≤300mg/day. A recent GWAS identified the urate raising minor allele of *ABCG2 rs2231142* as a determinant of poor allopurinol response [1]. However, the definition of response used in the GWAS was allopurinol related SU change with only weak assessment of adherence. The aim of our study was to examine the association of *ABCG2 rs2231142* with allopurinol response in a well phenotyped group of patients with gout.

Methods: Patients with gout according to 1977 ARA criteria participating in clinical trials of allopurinol were recruited. Good response was defined as SU <6mg/dl on allopurinol ≤300mg/d and poor response was defined as SU ≥6mg/dl despite allopurinol >300mg/d. Adherence was assessed by plasma oxypurinol concentrations >20umol/l and in the absence of oxypurinol concentration SU reduction with allopurinol dose escalation. Genotyping for *ABCG2* (*rs2231142*) was performed using a pre-designed SNP TaqMan assay. Logistic regression analyses were used to test for an association between poor response to allopurinol and *rs2231142*. Adjustments were made for age, sex, body mass index (BMI) and ethnicity and further separate adjustments were made for eGFR, diuretic use and SU off urate lowering therapy.

Results : Of 264 patients with gout receiving allopurinol, 120 (45.4%) patients were good responders, 68 (25.8%) were poor responders and 76 (28.8%) were either non-adherent or could not be classified. Of the 188 patients included in the responder analysis, 85.6% were male, mean age was 59 years and 32% were receiving a diuretic. The mean BMI was 34.1 kg/m^2 and eGFR 55.5mls/min/1.72m^2. Mean SU prior to urate lowering therapy was 10.1 mg/dl. Mean SU was 5.2 mg/dl in good responders and 7.0mg/dl in poor responders. Mean allopurinol dose was 263 mg/d (100-300) in the good responders and 413 mg/d (350-700) in poor responders. Logistic regression found that the minor allele of *ABCG2 rs2231142* was significantly associated with poor response to allopurinol (Table; OR=2.9, P=1.5x10^{-4}). This association persisted after adjusting for eGFR, diuretic use and SU off ULT (Table).

Conclusion: This study demonstrates that *ABCG2 rs2231142* predicts poor response to allopurinol, as defined by SU ≥6mg/dl despite allopurinol >300mg/d. *ABCG2* genotyping may allow identification of people with gout for whom standard doses of allopurinol are unlikely to lead to therapeutic target serum urate levels.

Session Title: ACR Plenary Session III: Discovery 2015

Session Type: ACR Plenary Session

Session Time: 11:00AM-12:30PM

Background/Purpose:

PAH associated with CTD (PAH-CTD) has a worse prognosis than idiopathic/familial PAH. Here we report a prospective subgroup analysis of patients with PAH-CTD from the PATENT studies of the soluble guanylate cyclase stimulator, riociguat.

Methods:

PATENT-1 was a 12-week, randomized Phase III trial in which patients with PAH received either riociguat individually dose-adjusted up to 2.5 mg tid (2.5 mg–maximum group), riociguat up to 1.5 mg tid (1.5 mg–maximum group; exploratory), or placebo. The primary endpoint was change from baseline in 6-minute walking distance (6MWD). Long-term safety and survival were assessed during the PATENT-2 open-label extension.

Results:

In PATENT-1, 111 patients had PAH-CTD (systemic sclerosis [SSc; n=66, including diffuse SSc and limited SSc], non-SSc CTD [n=39], and unspecified CTD [n=6], derived post-hoc from the medical history using MedDRA preferred terms). Seventy PAH-CTD patients were pretreated with PAH-specific therapy, of whom 59 were receiving endothelin receptor antagonists. Of the overall group of PAH-CTD patients, 71, 15, and 25 were randomized to riociguat 2.5 mg–maximum, riociguat 1.5 mg–maximum, and placebo, respectively. At baseline, mean±SD 6MWD was 348±70 m in the riociguat 2.5 mg–maximum group and 361±88 m in the placebo group. At Week 12, there was an improvement in 6MWD in the 2.5 mg–maximum riociguat group (+18 m) and a deterioration in the placebo group (–8 m) (Figure 1; PAH-CTD population; intention-to-treat, imputed values). Consistent with other studies, the least-squares mean treatment difference between riociguat and placebo (+28 m) in patients with PAH-CTD was lower than that observed in the overall study population (+36 m). In the SSc subgroup the placebo-corrected mean treatment difference in change from baseline was mostly based on the deterioration in exercise capacity on placebo (Figure 1). At the March 2014 cut-off for PATENT-2, 70 patients with PAH-CTD had been receiving treatment for ≥2 years. In PATENT-2, efficacy in 6MWD was maintained over 2 years in patients with PAH-CTD receiving riociguat. Clinical worsening events were experienced by <30% of patients with PAH-CTD in the PATENT-2 study, with a higher rate of events occurring in the SSc subcategory, which was driven by patients needing to start new PAH-specific treatments. At 2 years, similar survival rates (95% CI) were observed for patients with PAH-CTD, SSc, idiopathic/familial PAH and the overall population: 93% (85–97%), 94% (82–98%), 93% (89–96%), and 93% (90–95%), respectively. Riociguat had a similar safety profile in patients with PAH-CTD as observed in the overall population.

Conclusion:

In patients with PAH-CTD, riociguat was associated with long-term improvements in exercise capacity. The 2 year survival rates in riociguat-treated patients with PAH-CTD were high and similar to patients with idiopathic/familial PAH.

Histone H2AX Phosphorylation As a Measure of DNA Double Strand Breaks and a Marker of Environmental Stress and Disease Activity in Lupus

Rajaie Namas, Paul Renauer, Mikhail Ognenovski, Pei-Suen Tsou and Amr H. Sawalha, Division of Rheumatology, University of Michigan, Ann Arbor, MI

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: 2015 Rheumatology Research Foundation Edmond L. Dubois, MD Memorial Lectureship

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Studies suggested that defective or inefficient DNA double strand break (DSB) repair results in failure to preserve genomic integrity leading to apoptotic cell death, a hallmark of lupus. Compelling evidence linked environmental factors that increase oxidative stress with lupus risk and the formation of DSBs. Histone H2AX is robustly phosphorylated in the chromatin micro-environment at DSB loci resulting in the accumulation of essential repair proteins. The aim of this study is to measure DSB levels as a marker linking the effect of environmental stressors and the chromatin micro-environment in lupus.

Methods: Peripheral-blood mononuclear cells were isolated by Ficoll-Paque density gradient centrifugation from lupus patients and age-, sex-, and ethnicity-matched healthy controls. Flow cytometry using intracellular staining was used to measure H2AX phosphorylation levels in monocytes, CD4+ T cells, and CD8+ T cells. Median fluorescence intensity of anti-phospho-H2AX represents relative accumulation of DSBs within cells. Propidium iodide DNA staining was simultaneously used to assess cell cycle phase. A dose and time-effect relationship of hydrogen peroxide (H_2O_2) exposure, as an extrinsic environmental stressor, on the formation of DSBs was studied. Statistically significant differences ($P < 0.05$) between patients and controls were determined using a two-tailed *t*-test, and correlation analysis with lupus disease activity as measured by SLEDAI was assessed by Pearson's correlation coefficient.

Results: We observed increased DSBs in monocytes, CD4+ T cells, and CD8+ T cells in lupus patients compared to healthy controls (P=0.0008, 0.001, and 0.001, respectively). This difference in DSBs between patients and controls was independent of the cell cycle phase. A significant positive correlation between DSB accumulation and SLEDAI scores was observed among lupus patients (CD4+ T cells: r^2= 0.64, P= 0.03; CD8+ T cells: r^2= 0.64, P= 0.009; Monocytes: r^2= 0.57, P= 0.01). SLEDAI also correlated positively with DSB in lupus patients during all cell cycle phases in T cells and monocytes. A time-dependent effect (0, 2, 5, 10, 30 and 60 min, n=4) of 0.5uM H_2O_2 revealed a significant increase of DSBs with time in both patients and controls in all cell types, and a significantly greater accumulation of DSBs in lupus CD4+ T cells compared to healthy controls. A similar trend was also observed in lupus CD8+T cells and monocytes.

Conclusion: Our data indicate that DSBs occur more frequently and independent of the cell cycle in lupus monocytes and T cells compared to controls, and that accumulation of DSBs in lupus correlates with disease activity. Further, lupus T cells are more sensitive and accumulate more DSBs upon exposure to extrinsic oxidative stress compared to healthy T cells.

IRF5 Deletion Prevents the SLE-like Disease Initiated By Dendritic Cell-Specific Loss of Caspase 8

Carla M. Cuda[1] and Harris R. Perlman[2], [1]Rheumatology, Northwestern University, Chicago, IL, [2]Feinberg School of Medicine, Northwestern University, Chicago, IL

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: 2015 Rheumatology Research Foundation Edmond L. Dubois, MD Memorial Lectureship

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Previous studies implicate dendritic cells (DCs) in the initiation and persistence of systemic lupus erythematosus (SLE). While DCs from SLE patients exhibit elevated activation, the factors responsible remain unknown. Gain-of-function polymorphisms in the transcription factor IRF5 have been linked to SLE susceptibility. Moreover, mice with an underlying defect in Fas (MRL/lpr) on an IRF5-deficient background were protected from disease. We have shown that DC-specific loss of caspase 8, an enzyme in the Fas pathway classically linked to apoptosis initiation and necroptosis suppression, induces a SLE-like disease that originates from heightened DC activation. Immune complexes containing self nucleic acids activate endosomal TLRs, which require the adaptor MyD88 for subsequent up-regulation of proinflammatory gene expression, in part through the action of IRF5. The increased activation of caspase 8-deficient DCs is controlled by a MyD88-dependent mechanism, as DC-specific loss of MyD88 reduces disease, and caspase 8-deficient DCs display a hyperresponsiveness to endosomal TLR ligation with increased DNA binding activity of IRF. To this end, we have examined the interaction between DC-specific caspase 8 and IRF5 in disease development.

Methods: Mice lacking caspase 8 specifically in DCs were generated ($Cre^{CD11c}Casp8^{flox/flox}$) and crossed with $IRF5^{flox/flox}$ mice ($IRF5^{flox/flox}Cre^{CD11c}Casp8^{flox/flox}$). Flow cytometric analysis was used to characterize cell populations. ELISA and Luminex bead-based assays detected serum antibody and cytokine levels. Immunohistochemical and immunofluorescent analyses were used to evaluate spleen and kidney pathology.

Results: $Cre^{CD11c}Casp8^{flox/flox}$ develop a SLE-like disease characterized by splenomegaly, lymphadenopathy, autoantibodies, elevated serum cytokines, glomerulonephritis, immune complex deposition in the kidney and proteinuria. Further, caspase 8-deficient DCs are highly activated, leading to lymphocyte hyperactivation in a paracrine manner. Moreover, we observe a disruption of the splenic architecture in $Cre^{CD11c}Casp8^{flox/flox}$ mice, with a severe reduction in the marginal zone and metallophilic macrophage populations. Strikingly, DC-specific deletion of IRF5 in $Cre^{CD11c}Casp8^{flox/flox}$ mice prevents development of nearly all of the above inflammatory phenotypes.

Conclusion: Our previous studies showed that DC-specific loss of MyD88 reduced SLE-like disease pathogenesis associated with DC-specific deletion of caspase 8. We now reveal that deletion of IRF5 in caspase 8-deficient DCs inhibits onset of almost all SLE-like disease phenotypes observed in $Cre^{CD11c}Casp8^{flox/flox}$ mice. These data substantiate a novel DC-specific mechanism whereby caspase 8 interacts withand regulates the action of MyD88 and IRF5 to control DC activation and subsequent autoimmune disease development, thereby highlighting potentially useful targets for therapy.

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Treatment of autoimmune diseases is still based on the use of general immunosuppressive drugs which invariably cause severe side effects. This fact has compelled searches for more specific or targeted delivery of drugs. Calcium/ calmodulin- dependent protein kinase IV (CaMK4) is involved in the suppression of IL-2 and enhancement of IL-17 production and its pharmacologic or genetic inhibition limits disease progression in lupus-prone mice and mice subjected to experimental allergic encephalomyelitis (EAE).

Methods: EAE and lupus prone (MRL/lpr) mice were treated with KN93 (an inhibitor of Camk4)- loaded nanolipogels (nlg) targeted into CD4+ cells, and analyzed for immunologic and clinical.

Results: KN93 delivered with nlg directly to CD4+ cells at an equivalent of one twentieth of the dose required systemically, is clinically equally effective for both lupus and EAE. Specific delivery of the CaMK4 inhibitor did not deplete T cells and did not suppress autoantibody production but it effectively blocked Th17 cell expansion in the spinal cord and the kidney of mice developing EAE or lupus respectively.

Conclusion: Inhibition of molecules proven to be involved in the expression of autoimmunity only in relevant cells is a highly promising way to advance treatment in autoimmune diseases.

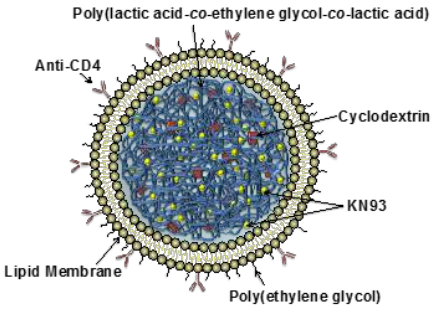

Figure 1. The schema of the structure of KN93 loaded nanolipogels (nlg) used in this work.

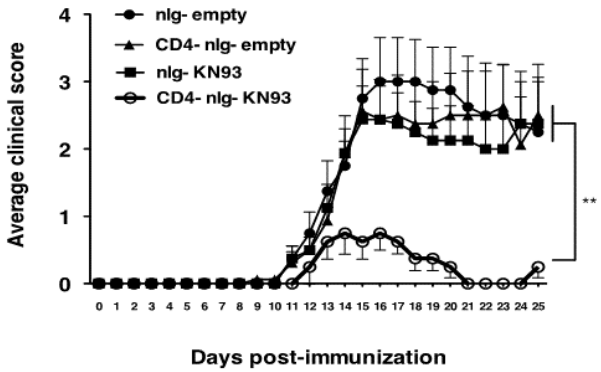

Figure 2. Average clinical score of the mice treated with nlg- empty, anti CD4 antibody coated nlg- empty (CD4- nlg- empty), nlg- KN-93 and CD4- nlg- KN-93 on EAE model (n = 8 mice in each group). The each nlg were injected weekly. Error bars represent the mean ± SEM. **P<0.01 by 2way ANOVA.

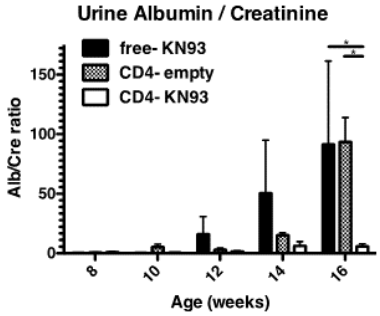

Figure 3. The mean ratio of urine albumin and creatinine from the MRL/lpr mice treated with free- KN-93, anti CD4 antibody coated nlg- empty (CD4- empty) and anti CD4 antibody coated nlg- KN93 (CD4- KN-93) (n = 4 mice in each group. Urine samples were obtained biweekly and determined by albumin and creatinine ELISA. Error bars represent the mean ± SEM. *P<0.05 by 2way ANOVA.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: 2015 Rheumatology Research Foundation Edmond L. Dubois, MD Memorial Lectureship
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose:

Given that early detection of renal involvement in systemic lupus erythematosus (SLE) and prompt management of the disease can have a significant impact on disease outcome, accurate diagnosis of lupus nephritis (LN) becomes absolutely critical. The current gold standard is to perform a renal biopsy in order to assess renal pathology. However, this procedure cannot be repeated serially, and is associated with untoward side-effects. Hence, there is an urgent need to identify biomarkers of LN that enable early detection of this disease.

Methods:

We have used serum samples from 22 SLE patients and matched healthy controls to hybridize to antibody-coated glass slide arrays that interrogated the level of 274 human proteins. Based on these screens, promising markers were further validated using single ELISA assays in independent cohorts of serum samples from lupus patients.

Results:

Whereas AXL, ferritin and sTNFRII were significantly elevated in patients with active LN relative to SLE patients who were quiescent, other molecules such as OPN, sTNFRI, sTNFRII, IGFBP2, SIGLEC5, FAS and MMP10 exhibited the capacity to distinguish SLE from healthy controls with ROC AUC exceeding 90%, all with $p<0.001$ significance.

These serum markers were next tested in a cohort of 45 LN patients where serum was obtained at the time of renal biopsy. In these patients, sTNFRII exhibited the strongest correlation with eGFR ($r=0.50$, $p=0.0014$) and serum creatinine ($r=0.57$, $p=0.0001$), though AXL, FAS, and IGFBP2 were also correlated with these clinical measures of concurrent nephritis. When concurrent renal biopsies from these patients were examined, serum FAS, IGFBP2 and TNFRII showed significant positive correlations with renal pathology activity index , while sTNFRII displayed the highest correlation with concurrently scored renal pathology chronicity index ($r=0.57$, $p=0.001$).

Finally, in a longitudinal cohort of 7 SLE patients examined at ~3-monthly intervals, AXL, ICAM-1, IGFBP2, SIGLEC5, sTNFRII and VCAM1 demonstrated the ability to track with concurrent disease flare, with significant subject to subject variation. To sum,

Conclusion:

Collectively, these studies suggest that serum levels of AXL, FAS, ferritin, ICAM-1, IGFBP2, SIGLEC-5 and sTNFRII are potential indicators of active LN and/or concurrent renal pathology indices or disease flares, worthy of further validation studies.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: 2015 Rheumatology Research Foundation Edmond L. Dubois, MD Memorial Lectureship
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disease causing inflammation throughout the body and cardiovascular involvement is a significant contributor to morbidity and mortality in this patient population. We have previously identified data demonstrating impaired left ventricular function using cardiac magnetic resonance (CMR) with quantitative T2 mapping in patients with SLE during a flare, which is suggestive of subclinical myocardial inflammation. With the early stages of cardiac disease clinically silent, understanding the underlying pathogenic contributions of autoimmune-mediated inflammation would enable more effective therapeutic intervention. Thus, the objective of this study was to establish a T2 mapping protocol in an animal model of lupus to examine cardiac function longitudinally in order to better understand the pathobiology of SLE on cardiovascular disease.

Methods: Kidney function was assessed by weekly blood urea nitrogen (BUN) testing in NZM2410 mice, which develop severe lupus-like glomerulonephritis at 22-40 weeks of age. Quantitative analysis of *in vivo* physiological cardiac function was performed using a high-frequency ultrasound system. Myocardial edema was quantitatively measured *in vivo* with T2 CMR mapping on the BioSpec 94/30 microMRI imaging system. Heart tissue was collected for H&E and Masson's trichrome staining.

Results: For comparative analysis in this study, wild-type mice were examined along with NZM2410 mice with early-stage or late-stage lupus, as determined by weekly monitoring of BUN levels. Echocardiograms revealed differences in cardiac output, diameter, ejection fraction, fractional shortening, and stroke volume, which indicates decreased cardiac function in late-stage NZM2410 mice. CMR analysis of sagittal heart sections showed progressive thickening of the myocardium with a prominent left ventricular hypertrophy. T2 CMR mapping showed prolonged T2 signals, consistent with edema, in early and late stage lupus hearts compared to wild type mice. To examine histopathology, heart tissue was collected from early and late-stage NZM2410 mice for staining with H&E and Masson's trichrome. Evidence of myocarditis and fibrosis was observed in mice with late-stage disease.

Conclusion: Our results suggest an association of SLE disease progression with the development of cardiac abnormalities resulting from inflammation in NZM2410 mice. Therefore, this animal model could be used to further characterize the pathophysiological correlation, relationship, and interplay between lupus and cardiovascular disease in longitudinal studies. Future work will involve identification of biomarkers related to cardiac involvement and will further develop CMR with quantitative T2 mapping as a clinical tool to assess inflammation in patients with SLE.

Session Date: Tuesday, November 10, 2015

Session Title: 2015 Rheumatology Research Foundation Edmond L. Dubois, MD Memorial Lectureship

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Patients with systemic lupus erythematosus (SLE) are at increased risk for widespread endothelial dysfunction, vascular thromboses, and premature cardiovascular disease. Enhanced platelet activation and interaction with the vascular endothelium may represent a common predisposition. This study was initiated to evaluate platelet phenotype and effect on endothelial cell function in SLE and healthy subjects.

Methods: Platelet phenotype was assessed using assays of platelet aggregation and markers of platelet activity in 50 SLE patients (mean age 41.1 ± 13.0, 81% female and 46% white) and age/sex matched healthy controls off antiplatelet therapy. SLEDAI ranged from 0 to 22 (mean 5.3 ± 4.0). Serum was collected for circulating soluble P-selectin and RANTES (chemokines from activated platelets). Agnostic (array) and candidate (qPCR) gene transcripts were identified following cotreatment of resting and thrombin-stimulated platelets from SLE patients and controls with normal endothelial cells (HUVECs).

Results: Compared to healthy controls, SLE patients had increased monocyte platelet aggregation, leukocyte platelet aggregation, light transmission platelet aggregation both with and without submaximal ADP, collagen, and arachidonic acid ($P<0.05$ for each comparison). Platelet activation did not associate with any ACR criteria or concomitant SLEDAI. However, patients with active renal disease compared to those without renal disease had significantly higher values of both sP-selectin (37.0 ± 18.6 ng/ml vs 20.6 ± 13.7, P=0.01) and RANTES (45.2 ± 13.7 ng/ml vs 29.9 ± 7.6, P=0.03) reflecting in vivo platelet activation. Predicted by serum levels, in ex vivo experiments using healthy platelets, SLE sera increased P-selectin expression (35.9%±8.6 vs. 28.0%±7.0, SLE vs control, $P<0.01$). Based on agnostic RNA array on HUVECs incubated with resting platelets from SLE vs healthy controls, endothelial adhesion molecules SELE, VCAM1, ICAM1, and cytokine IL8 and chemokine CXCR7, were among the top ten upregulated genes. KLF2 (0.69 + 0.02), a repressor of NFkB transcription factor was attenuated compared with CD146, a pan endothelial cell marker, 1.04 +0.08, p=0.034). Decreased expression of genes encoding proteins with immunomodulatory function including HMOX1, PROCR, HDAC5, and CALML4 were also noted following incubation of SLE platelets compared to controls. Validation by qPCR confirmed that cotreatment of HUVECs with resting platelets from SLE vs controls resulted in a mean fold increase in IL-8 gene expression (12.46 ± 2.55 (SE) and 4.23 ± 0.74, respectively, $P<0.01$) and ICAM-I (3.02 ± 0.5 vs. 1.31 ± 0.3, P =0.02). ICAM1 gene expression trended higher in patients with SLEDAI >4 compared to those with SLEDAI ≤4 (3.42 ± 0.7 vs 2.25 ± 0.19 , P=0.09).

Conclusion: Platelet activity measurements are increased in SLE, irrespective of accompanying disease activity which supports observations that premature atherosclerosis is not fully explained by overt clinical activity. Platelets from subjects with SLE increase pro-inflammatory gene expression by endothelial cells, suggesting a role for the platelet-endothelial interface in the pathogenesis of the more insidious vascular manifestations of disease.

Session Title: Fibromyalgia: Clinical Issues

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: An MDHAQ/RAPID3 (Multidimensional Health Assessment Questionnaire/Routine Assessment of Patient Index Data) is a 2 sided, 1 page questionnaire which is completed by patients in 5-10 minutes, while waiting to see the doctor in the waiting room in routine clinical care. RAPID3 is an index which is informative in RA and other rheumatic diseases. MDHAQ also includes a 0-10 visual analog scale for fatigue and a 60 symptom checklist, which may provide clues to recognize comorbid fibromyalgia (FM) (1). Comorbid FM is seen in about 10-25% of patients with RA and may complicate assessment and management. Formal criteria for fibromyalgia are included in many research studies, but generally are not assessed in busy clinical settings, in which primary or secondary FM generally is diagnosed according to "gestalt," narrative, non-quantitative descriptions. A simple quantitative tool to recognize and document clues to comorbid FM could be of value in routine care in busy clinical settings.

Methods: MDHAQ is completed by all patients seen by a rheumatologist in routine care. MDHAQ includes scores for physical function (0-10), pain (0-10), patient global assessment (0-10), RAPID3 (0-30 sum of physical function, pain, and patient global estimate), fatigue (0-10), and total number of symptoms (0-60). Mean MDHAQ scores were compared in patients with primary diagnoses of either RA or osteoarthritis (OA) who did or did not have a secondary diagnosis of comorbid FM. Statistical significance of differences in patients with no FM vs with comorbid FM was analysed using 2-tailed t-tests, with significance at $p<0.05$.

Results: A total of 82 RA patients – 75 with no FM and 7 with FM, and 64 OA patients - 49 with no FM and 15 with FM, were studied (Table). The mean number of symptoms reported by patients with a clinical diagnosis of FM was significantly higher than reported by those who did not have secondary FM - RA 19.5 vs 7.97 P=0.0001; OA 19.5 vs 8.3 P<0.0001. The mean fatigue scores of patients with and with no secondary FM also differed significantly - RA 6.8 vs 3.86 P=0.004; OA 6.39 vs 3.82 P=0.0049. The mean physical function, pain, patient global estimate and RAPID3 scores did not differ significantly between patients with and with no secondary FM in either diagnostic group.

Conclusion: MDHAQ scales for fatigue and number of symptoms, which are found on the questionnaire to assess RAPID3 in patients with rheumatic diseases as part of routine clinical care, can provide clues to identify comorbid FM. Recognition and documentation of comorbid FM in patients with primary RA or OA may support the complexity of rheumatology visits and assist in management decisions in busy clinical settings.

Cell Bound Complement Activation Products in Multianalyte Assay with Algorithm Have Utility in Distinguishing Primary Fibromyalgia from Systemic Lupus Erythematosus

Daniel Wallace[1], Stuart L. Silverman[2], Derren Barken[3], John Conklin[4] and Thierry Dervieux[5], [1]Cedars-Sinai/UCLA, Los Angeles, CA, [2]OMC Clinical Research Center, Beverly Hills, CA, [3]Exagen Diagnostics, Vista, CA, [4]1261 Liberty Way Suite C, Exagen Diagnostics, Vista, CA, [5]Research and Development, Exagen Diagnostics, Vista, CA

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Fibromyalgia: Clinical Issues
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose : Our objective was to prospectively establish the performance characteristics of a cell bound complement activation products (CB-CAPS) in a multi-analyte assay with algorithm (MAAA) laboratory test currently offered in the United States as decision tool assisting rheumatologists with the differential diagnosis of systemic lupus erythematosus (SLE).

Methods : The population of subjects enrolled in this validation cohort consisted of 75 consecutive primary fibromyalgia syndrome (FMS) (96% females, mean age 48 years) and 75 consecutive adult SLE (88% females, mean age 53 years). All subjects fulfilled their respective American College of Rheumatology classification criteria of disease. The subjects were enrolled at two rheumatology practices located in Southern California, and each patient provided informed consent following appropriate Ethic Committees approval. Venous blood was collected and shipped overnight to our reference clinical laboratory conducting routine diagnostic immunology testing for CB-CAPS (erythrocyte and B-lymphocyte C4d) and other autoimmune markers including antinuclear antibodies (ANA) as determined using solid phase assay and indirect immunofluorescence (IIF), anti-dsDNA antibodies (all confirmed by Crithidia Luciliae IIF) and additional cellular autoantibodies. The CB-CAPS in MAAA combining these autoimmune markers relies on two consecutive tiers of analysis as currently approved by the Department of Health in the State of NY and reported as positive or negative. Test performances in this validation cohort were assessed using sensitivity, specificity, positive and negative likelihood ratio (LR). Post-test probability of SLE disease versus primary fibromyalgia was determined using standard 20% prior probability. All testing laboratory personnel were blinded to subject diagnosis during the pre-analytical, analytical and post-analytical phase of testing.

Results : ANA was positive in 33% FMS (67% specific) and was 80% sensitive for SLE (LR+=2.8). Anti-dsDNA was negative in all FMS (100% specific) but yielded low sensitivity in SLE (17%; LR+>13). High CB-CAPs as defined by EC4d or BC4d levels above the 95th percentile established among normal healthy individuals were infrequently detectable among FMS patients (4% positives, 96% specificity) but were detectable in 60% SLE (LR+>43)(Table). Using these performances characteristics, a positive CB-CAPS in MAAA assessment would raise the probability (post-test) for SLE compared to FMS from 20% (pre-test) to higher than 92%. Conversely, a negative CB-CAPS in MAAA test result would reduce the post-test probability of SLE from 20% to 9%.

Conclusion : Our data indicate that CB-CAPS in MAAA can distinguish FMS from SLE.

Table: Positive and negative Likelihood ratio and post-test probabilities of SLE and Fibromyalgia

	Likelihood ratio		Post-test probability (20% prior)	
	Positive	Negative	Positive result	Negative result
ANA by IIF and ELISA	2.8 (1.8 to 4.1)	0.36 (0.24 to 0.54)	41% (31% - 51%)	8% (6%-12%)
Anti-dsDNA confirmed by IIF	> 13.0 (1.8-98.2)	0.83 (0.75-0.92)	> 76% (31%-96%)	17% (16%-19%)
High CB-CAPS	11.0 (3.5-34.2)	0.59 (0.48-0.72)	73% (47%-90%)	13% (11%-15%)
CB-CAPS in MAAA	> 43.8 (6.2-310)	0.40 (0.30-0.54)	> 92% (61%-99%)	9% (7%-12%)

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Fibromyalgia: Clinical Issues

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

Currently there are three drugs approved by the FDA for the treatment of fibromyalgia (FM), and there appears to be a paucity of drugs in development. We recently completed a study with the major aim of discovering biological disease markers that could shed light on the molecular mechanisms that drive FM. Herein we report FM associated genes that are targets of known drugs

Methods:

We analyzed gene expression from the RNA isolated from blood of 70 women with FM and 70 healthy age/gender-matched controls.

Results:

The average FM patient was aged 45.5±7.7 years and had symptoms 17.2±12.2 years. Differentially expressed genes and their known targets of available drugs are displayed below:

Symbol	Gene function	Associated Drug	Disease target
MS4A2	IgE activity	Omalizumab	Allergic asthma
IL3RA	Cytokine receptor	Gm-CSF	Bone marrow stimulation
COL4A6	Type IV subunit	Collagenase	Skin debridement
MUT	Vit B12 metabolism	Cyanocobalamin	Pernicious anemia
NPY2R	Appetite regulation	Peptide YY 3-36	Appetite regulation
CPT1A	Mitochondrial transport	Perhexiline	Angina pectoris
ITGA4	Cell surface adhesion molecule	Natalizumab	Multiple sclerosis
GGPS1	C20-prenylation of proteins	Zoledronic acid	Osteoporosis
CA3	Carbonic anhydrase gene	Thiazide diuretics	Hypertension
VWF	von Willebrand factor gene	Factor 8	Hemophilia
ALDH5A1	Aldehyde dehydrogenase gene	Valproic acid	Anticonvulsant
HRH4	Histamine receptor gene	Triprolidine	Nasal allergies
YES1	Tyrosine kinase gene	Dasatinib	Chronic myeloid leukemia

Conclusion:

Overall, genes associated with immune/inflammatory responses were up-regulated as were genes associated with neuronal development and neurotransmitters. Conversely, genes associated with allergic responses were down-regulated. There were 14 differentially expressed kinase molecules, 21 transcriptional regulators and 21 transporter molecules that have never been previously reported in FM. These represent opportunities for novel drug targets. There were 13 genes differentially expressed in FM that are known targets of already available drugs. These data contribute new targets for the further exploration of both existing drugs and development efforts to identify new candidate therapies based on molecular markers that may underlie FM disease mechanisms.

Session Title: Fibromyalgia: Clinical Issues

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Chronic diseases involve cognitive and emotional aspects of patients. One relevant cognitive factor is the learned helplessness (LH), defined as an inadequate perception of the disease, generating feeling of defenselessness, behaviors of passivity, loss of self-esteem and belief that nothing you do can improve your situation. Another important cognitive factor is perceived self-efficacy (SE), which is defined as the individual's abilities to cope with the disease. It has been reported that patients with higher LH, have more pain and functional disability. On the other hand, patients with high levels of SE have less pain, LH and functional disability. The relationship of these cognitive aspects has not been fully studied in fibromyalgia (FM). Our purpose was to evaluate LH and SE in patients with fibromyalgia and compared them with patients with rheumatoid arthritis (RA), and to assess their association with functional disability and level of perceived pain and fatigue in both groups of patients.

Methods: Consecutive patients, older than 18 years, with diagnosis of RA (2010 ACR/EULAR criteria) and with diagnosis of fibromyalgia (1990 or 2010 ACR criteria) seen at the outpatient rheumatology unit between March 2014 and June 2015, were included. During the inclusion visit the following data were collected: HAQ-A (Health Auto Questionnaire-simplified Argentinean validation); pain (VAS); fatigue (VAS); LH measured with Rheumatology Attitudes Index (RAI) and SE measured by Arthritis Self-auto-efficacy Scale. Descriptive statistics were calculated and compared between both groups. Correlations were calculated between LH and SE and pain, fatigue and HAQ-A, using Pearson tests.

Results: One hundred and fifteen patients with RA and 57 patients with FM were included. Patient's characteristics are shown in table 1. Patients with FM had significantly more pain, more fatigue, more LH, and less SE than RA patients (table 1). There was a significant positive correlation between LH, and pain (RA: r=0.67; p<0.001; FM: 0.59; p<0.001); HAQ-A (RA: r=0.65; p<0.001; FM: r=0.52; p= 0.0004), and fatigue (RA: r=0.54; p<0.001; FM: r=0.49; p= 0.0010); and a negative correlation between SE and pain (RA: r= - 0.47; p<0.001; FM; r= -0.59; p<0.001); HAQ-A (RA: r= -0.47; p<0.001; FM: r= -0.42; p= 0.0112) in both patient's groups.

Conclusion: Patients with FM had more LH, pain and fatigue than RA, and less SE. There was a significant correlation between these psychological assessments and pain, functional capacity and fatigue. LH and SE are potentially modifiable cognitive factors that correlated with functional disability and patients related outcomes. This might have clinical implications.

Characteristics	RA (n=115)	FM (n=57)	P value
Female , n (%)	94 (82)	55 (96.5)	0.007
Age, years, mean (DS)	58 (13)	59 (14)	0.727
Time from diagnosis (years), mean (SD)	12 (10)	2 (2.8)	<0.0001
HAQ-A, mean (DS)	0.75 (0.76)	0.73 (0.59)	0.832
Pain (VAS,0-100), Mean (SD)	31 (28)	61 (25)	<0.0001
Fatigue (VAS, 0-100), Mean (SD)	26 (28)	66 (26)	<0.0001
Learned helplessness, Median (IQR)	10.4 (4.8)	14.5 (6.1)	<0.0001
Self-efficacy, Mean (SD)	61 (15.4)	48 (18.6)	<0.0001

Session Date: Tuesday, November 10, 2015
Session Title: Fibromyalgia: Clinical Issues
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: The prevalence of fibromyalgia (FM) is 10-20% in rheumatoid arthritis (RA) patients, compared to 2-3% in the general population. Previous studies have shown that RA patients with FM have higher disease activity, greater medical costs and worse quality of life compared to RA patients without FM. However, these studies were limited due to their cross-sectional design. In this study, we determined the impact of FM on 2-year changes in functional status of RA patients in a prospective study.

Methods: Subjects in a single center RA registry were enrolled in a 2-year prospective observational substudy examining characteristics of FM. Subjects completed questionnaires every 6 months and underwent physical examination and laboratory tests yearly. The primary outcome was change in the Multidimensional Health Assessment Questionnaire (MDHAQ) score from baseline to 2 years. The MDHAQ was scored on a scale of 0-3, with 3 indicating the worst functional status. The primary predictor was FM status, a dichotomous variable derived from the FM survey scale, with a threshold of ≥13 indicating FM. The FM survey scale is a validated, self-report measure based on the ACR 2010 preliminary diagnostic criteria. It consists of 2 scales, assessing widespread body pain and somatic symptoms. Multivariable linear regression models were used to examine the association between FM status and change in MDHAQ score, adjusted for age, gender, race, baseline MDHAQ score, disease duration, RF/CCP seropositivity, disease activity and anxiety/depression. In secondary analyses, we also examined the association between the baseline FM survey score, as a continuous variable, and change in MDHAQ score over 2 years.

Results: Of the 156 included RA subjects, 134 (85.9%) were female, and 145 (93.6%) were Caucasian. Mean age was 58.5 ± 11.0 years. Mean disease duration was 15.4 ± 9.2 years, and 111 (72.1%) were seropositive. Twenty-six patients (16.7%) had FM, while 130 patients (83.3%) did not. Compared to RA patients without FM, RA patients with FM had significantly higher baseline MDHAQ scores (RA with FM: 0.74 ± 0.40, RA alone: 0.43 ± 0.39; $P < 0.001$) and Hospital Anxiety and Depression Scale scores (RA with FM: 13.65 ± 6.74, RA alone: 8.22 ± 5.75; $P < 0.001$). In a multivariable linear regression model adjusted for the covariates listed above, RA patients with FM had a 0.15 unit greater 2-year increase in MDHAQ score than RA patients without FM ($P = 0.012$). In secondary analyses examining the association between continuous FM survey score and change in MDHAQ, higher FM survey scores were significantly associated with greater 2-year increases in MDHAQ score (β-coefficient 0.014; $P = 0.005$).

Conclusion: RA patients with FM experience significantly greater 2-year worsening of functional status compared to RA patients without FM. The difference in the increase in MDHAQ score was 0.15 units higher over 2 years in the RA with FM group compared to those with RA alone. This difference is striking given that MDHAQ scores typically only increase 0.01-0.016 units per year in stable RA patients. Future studies are needed to determine if treatments for FM can reduce functional status decline among individuals with established RA.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Fibromyalgia: Clinical Issues
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: : Fibromyalgia (FM) is characterized by chronic widespread pain, sleep disturbance, and fatigue. Pregabalin is approved in the US in adults for the management of FM at 300-450 mg/day.

Methods: This was a 15-week, randomized, double-blind, placebo-controlled study of flexible-dose pregabalin (75-450 mg/day) in adolescents (aged 12-17 yrs) with FM. Patients met the Yunus and Masi diagnostic criteria for FM, and had a mean numeric daily pain rating scale (NRS) score of ≥4 (0–10, 24 hour recall period). Patients were randomized 1:1 to pregabalin or placebo. Pregabalin or placebo doses were optimized over 3 weeks based on efficacy and tolerability to 75, 150, 300, or 450 mg/day. Patients remained at these doses for an additional 12 weeks.. The primary outcome was change from baseline in mean pain score (NRS). Secondary outcomes included change in pain score by week, change in pain score at week 15 (with a 1 wk recall period), and Patient Global Impression of Change (PGIC). Exploratory measures were Parent Global Impression of Change (Parent GIC), a version of the PGIC completed by the patient's parent, and Fibromyalgia Impact Questionnaire-Children (FIQ-C).

Results: A total of 107 patients were randomized (54 pregabalin, 53 placebo) and 80 completed the study (44 pregabalin, 36 placebo). The percentages of pregabalin-treated patients at each optimized dose were: 25%, 19%, 15%, and 40% at 75, 150, 300, and 450 mg/day, respectively. Improvement in mean pain score at endpoint with pregabalin vs placebo was not statistically significant, treatment difference (95% CI), -0.66 (-1.51, 0.18), P=0.121. There were statistically significant improvements with pregabalin vs placebo in change in weekly mean pain score (P<0.05 for 10 of the 15 weeks); change in pain score at week 15 (1 week recall), treatment difference (95% CI), -0.87 (-1.68, -0.05), P=0.037; PGIC with 53.1% vs 29.5% very much or much improved (P=0.013); and Parent GIC with pregabalin 51.0% vs 25.0% (P=0.011). Tolerability was consistent with the known profile of pregabalin with the exception of a higher rate of mild nausea with pregabalin; 22.2% had nausea of any severity, vs 7.8% in adults with FM in previous studies. The most frequently reported adverse events with pregabalin were dizziness, nausea, headache, weight increase, and fatigue. Two serious adverse events occurred in one pregabalin treated patient (cholelithiasis, major depression). In each treatment group, 4 subjects discontinued due to adverse events.

Conclusion: In this study, pregabalin did not significantly improve the primary measure of mean pain score compared with placebo at endpoint in adolescent patients with FM. However, the treatment difference was similar to those observed in the adult FM studies. The adolescent study employed lower doses (75-450 mg/day) than are approved for adults with FM (300-450 mg/day; starting dose 150 mg/day). There were significant improvements in secondary endpoints measuring pain and global impression of change. Pregabalin was well tolerated in this study. The safety profile observed in this study was generally consistent with the known profile for pregabalin with the exception of nausea, which was mostly mild.

Session Date: Tuesday, November 10, 2015

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects III: Miscellaneous Pediatric Rheumatic Diseases

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

The deficiency of adenosine deaminase II (DADA2), first described in 2014, is an autosomal recessive disease caused by mutations in *CECR1* and is characterized by intermittent fevers, early-onset lacunar strokes, livedoid rash, hepatosplenomegaly, immune deficiency and systemic vasculopathy. An additional report by others included patients with cutaneous polyarteritis nodosa. We now present clinical follow-up on our 5 reported patients and an additional 9 patients.

Methods:

We evaluated the 14 patients at the National Institutes of Health. We performed whole-exome sequencing in the initial 3 patients and their unaffected parents and candidate-gene sequencing in the other 11 patients. Clinical information and radiographic and laboratory testing were obtained at each visit.

Results:

All patients had 2 mutations in *CECR1*. 11/14 patients reported recurrent fevers. Ten had a history of at least one ischemic stroke. The age of onset of the first stroke ranged from 5 months to 8 years, with 8/10 before the age of 5 years. MRI of the brain showed evidence of acute or chronic small subcortical infarcts involving the deep-brain nuclei and brain stem, consistent with small-vessel occlusions (lacunar strokes). 8/10 patients with ischemic stroke had at least one occur in the thalamus; other involved areas included the midbrain (4/10), pons (4/10), internal capsule (3/10) and basal ganglia (3/10). One patient had an anterior thoracic-lumbar spinal cord infarct that resulted in the development of a neurogenic bladder. Three patients had hemorrhagic strokes in addition to their ischemic strokes. One patient developed posterior reversible encephalopathy syndrome (PRES) in relation to hypertension. Subsequent MRI revealed complete reversal of the PRES. In 10/10 patients magnetic angiography showed no evidence of cerebral vasculitis.

All 14 patients demonstrated livedo racemosa. Erythematous papules or nodules were seen in 11 of these patients. Hepato-and/or splenomegaly was observed in 10/14 with 3 patients demonstrating portal hypertension. One patient developed a perforated small bowel requiring resection.

Hypertension was noted in 2 patients. Prolonged QT was reported in 3 patients. 12/14 demonstrated hematologic abnormalities including anemia, leukopenia, and/or thrombocytopenia. Elevation of acute phase reactants was reported in 13/14. Low serum iron was noted in 8/10 patients tested. 10/13 presented with hypogammaglobulinemia, however this may reflect prior treatment with cyclophosphamide in 3 patients.

Most patients received a number of medications over the course of their disease. It was our practice to discontinue aspirin and/or anticoagulation in all DADA2 patients. We observed striking improvement in CRP, ESR, CBC, and serum iron in 10/12 patients receiving anti-TNF agents.

Conclusion:

We have expanded the clinical picture in patients with DADA2 to include multiple strokes, livedo racemosa, cutaneous PAN, portal hypertension, hematologic abnormalities, vascular pathology and mild immunodeficiency. In addition, we have demonstrated both clinical and laboratory improvement following treatment with anti-TNF agents.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects III: Miscellaneous Pediatric Rheumatic Diseases
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Cryopyrin Associated Periodic Syndromes (CAPS) are a rare, clinically heterogeneous group of devastating inflammatory illnesses. *NLRP3*gene gain-of function mutations result in unceasingly raised IL1 secretion and the clinically highly variable phenotype of severe systemic and organ inflammation. Early diagnosis is crucial, since rapid start of IL1 inhibition controls inflammation and prevents organ damage in children and adults with CAPS. The aim of the study was to develop and validate diagnostic criteria for CAPS.

Methods: An innovative, rigorous model development process was followed including a) interdisciplinary, international team building including pediatric and adult subspecialists plus methods experts for rare diseases, b) item generation: systematic literature review, item review of CAPS registries, CAPS expert survey and consensus conference for item refinement and agreement, c) item reduction and weighting using 1000minds decision analysis software. The resulting CAPS criteria were validated in a large cohort CAPS cases and true CAPS controls (autoinflammatory controls – FMF, sJIA, other and inflammatory controls – Schnitzler, Kawasaki, others) from clinical registries using correspondence analysis to identify items consistently associated with CAPS. Resulting variables were used to evaluate diagnostic models using sensitivity analyses. Subanalyses were performed for all CAPS subtypes and evidence of NLRP3 mutations.

Results: The CAPS team included 18 CAPS and methods experts. Systematic literature and CAPS registry review identified 32 CAPS-typical items; the consensus conference refined these to 11 items plus “NLRP3 mutation”. The 1000minds exercise ranked these 12 variables based on importance for the diagnosis CAPS, demonstrating excellent correlations between experts. Validation: Correspondence analysis determined variables consistently associated with the diagnosis of CAPS using 284 cases and 873 controls removing infrequently observed variables such as “amyloidosis”. The remaining seven variables were found to high significantly associated with the diagnosis CAPS ($p<0.001$ for all). Different modeling approaches were explored resulting in a “coupling model” as the best fit. The best CAPS diagnosis criteria model: “Raised inflammatory markers (CRP/SAA) plus ≥ two of six CAPS typical signs/symptoms including urticara-like rash, cold/stress triggered episodes, sensorineural hearing loss, musculoskeletal symptoms of arthralgia/arthritis/myalgia, chronic aseptic meningitis, skeletal abnormalities of epiphyseal overgrowth/frontal bossing” with a sensitivity of 81% and a specificity of 94%. It performed equally well for all CAPS subtypes and in subgroups with and without evidence of germline NLRP3 mutations.

Conclusion: The CAPS diagnosis criteria model enables a rapid diagnosis and initiation of treatment for children and adults with CAPS, a rare, heterogeneous inflammatory disease. The novel approach integrated traditional methods of evidence synthesis with expert consensus, web-based decision tools and innovative statistical methods and may serve as a model for the diagnosis of other rare diseases.

Dose Adjustment of Anakinra (Kineret®) Based on Clinical Response in Patients with Severe Cryopyrin-Associated Periodic Syndromes

Bengt Hallen[1], Torbjörn Kullenberg[1], **Mika Leinonen**[2], Margareta Wiken[1], Raphaela Goldbach-Mansky[3] and Hans Olivecrona[1], [1]Swedish Orphan Biovitrum, Stockholm, Sweden, [2]4Pharma AB, Stockholm, Sweden, [3]Translational Autoinflammatory Diseases Section, NIAMS, NIH,

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects III: Miscellaneous Pediatric Rheumatic Diseases
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Cryopyrin-Associated Periodic Syndromes (CAPS) include a group of rare inherited autoinflammatory diseases consisting of Familial Cold Autoinflammatory Syndrome (FCAS), Muckle-Wells Syndrome and the most severe form, Neonatal-Onset Multisystem Inflammatory Disease (NOMID). Anakinra is an IL-1-receptor antagonist blocking the biologic activity of naturally occurring IL-1 which has been proven effective and safe in the treatment of severe CAPS[1,2]. The objective of the present analysis was to describe anakinra dose adjustments in patients with severe CAPS.

Methods: A prospective, open-label, single arm 60-month study of anakinra was conducted at the National Institutes of Health and the main efficacy and safety findings have been reported earlier[1,2]. The patients were stratified by age at anakinra treatment initiation: infants/toddlers (<2 years), children (2-11 years), adolescents (12-18 years) and adults (>18 years). The initial starting dose of 1-2 mg/kg/day of anakinra was either maintained or adjusted during the study depending on clinical response. For patients with inadequate clinical response or a disease flare, the dose could be increased by 0.5-1 mg/kg for up to a maximum of 10 mg/kg/day. The dose increases were estimated with a Mixed Model for Repeated Measures (MMRM).. References: [1]Goldbach-Mansky et al. NEJM. 2006;355:581-92. [2]Sibley et al. Arthritis Rheum. 2012;64:2375-86.

Results: 43 patients (13 infants/toddlers, 18 children, 12 adolescents/adults) were included in the study and exposed to anakinra: 26 started on doses <1.5 mg/kg/day and 17 on ≥1.5 mg/kg/day. For 90% of the patients enrolled during the first 3 years of the study the starting dose was <1.5 mg/kg/day, while for the majority of the patients enrolled later (68%) the starting dose was ≥1.5 mg/kg/day. During the study, the treatment doses increased and the estimated mean maintenance dose at Month 60 was similar across age groups, ranging from 3.0 to 3.8 mg/kg/day (mean 3.3 mg/kg/day). On average, the dose was increased by 0.5 mg/kg/day for the first time at Month 6 and thereafter at Month 18 and 36. The actual dose range during the study was 0.9-7.6 mg/kg/day, with the highest dose maintained for 15 months followed by a decrease thereafter. The doses were not only increased for preventing disease flares e.g. rash, fever and elevated CRP but also to preserve organ function, e.g. hearing and vision. Comparable numbers of adverse events were reported for low (<3.5 mg/kg/day; total anakinra exposure 128.0 patient years) and high (≥3.5 mg/kg/day; total anakinra exposure 31.9 patient years) doses; 7.9 events per patient year for low doses and 6.8 for high doses. There was no correlation between development of anakinra anti-drug antibodies and dose adjustments.

Conclusion: Anakinra doses were adjusted based on clinical response in order to achieve systemic inflammatory remission and absence of organ inflammation. In one patient doses up to 7.6 mg/kg/day were needed to control CNS inflammation. Dose adjustments were well tolerated with adverse event reporting rates similar in patients on doses <3.5 and ≥3.5mg/kg/day.

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects III: Miscellaneous Pediatric Rheumatic Diseases

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Juvenile localized scleroderma (jLS) is a chronic inflammatory and fibrosing disease that causes severe morbidity, including growth defects, cosmetic deformities, seizures and arthropathy. Optimal therapy is not known. The LS Children's Arthritis and Rheumatology Research Alliance (CARRA) subgroup has been working towards conducting comparative effectiveness studies with the aim of improving long-term outcome. We report our initial findings from a pilot study to evaluate the feasibility of conducting such studies.

Methods:

We conducted a multi-center 12 month prospective observational cohort study of jLS subjects treated with one of 3 methotrexate (MTX)-based standardized treatment regimens (consensus treatment plans, CTPs), chosen by the treating physician. Each CTP included MTX administered for 1 year; two included corticosteroids (CS), either intravenous (IV) for 3 months or oral for 48 weeks (tapering schedule). The CTP options are based upon best available evidence and reflect the current treatment practices of CARRA members (Li et al., Arthritis Rheum 2012; 64:1175). Data were entered into a web-based registry (InForm), including activity and damage assessments, global assessments (GA), adverse events (AE), and medications.

Results:

The target enrollment (50 subjects) was reached. Median age at enrollment was 13 years, majority of subjects were Caucasian (92%), female (70%), had the linear subtype (82%) and had never been treated with MTX or CS (82%). Fourty percent of subjects had a head lesion, 72% had extracutaneous involvement.

Participating sites showed strong CTP preferences, with 50% choosing only 1 and 40% 2 CTPs. Half the subjects were enrolled into MTX + IV CS, 14 into MTX alone, and 11 into MTX + oral CS CTPs. Ninety percent of subjects were followed for at least 6 months, 80% completed the full 12 months.

Among subjects followed for at least 6 months, 49% were considered to have a major and 31% a moderate improvement in activity level compared to baseline. Subjects in the MTX + CS CTPs were more likely than those in the MTX alone CTP to be rated as having a major improvement (57% vs 22%). Thirty two percent of subjects had a major deviation from their starting CTP with the most common reasons being AE (28%) and lack of response (28%). The AEs most commonly associated with deviations were severe gastrointestinal symptoms, mood issues, and infections. There was 1 SAE: one subject required hospitalization for viral gastroenteritis. Mycophenolate mofetil and/or IV CS were the most commonly employed therapies when there was a lack of response. Subjects that deviated from initial CTP had a higher physician GA of disease activity and patient/parent GA of disease impact at baseline compared to those that did not.

Conclusion: Our pilot study shows the feasibility of conducting jLS comparative effectiveness studies across multiple centers. Despite a high rate of deviation from the CTPs, the majority of subjects were rated as having moderate or major improvement. Centers showed strong biases in their treatment preferences highlighting the need to have sufficient site variability and CTPs to enable comparative effectiveness studies.

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects III: Miscellaneous Pediatric Rheumatic Diseases

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: A vast body of evidence in animals and humans points to a pivotal pathogenic role of IFNγ, in primary HLH. The role of IFNg in HLH secondary to rheumatic diseases, usually referred to as MAS, remains to be established. We have previously reported high levels of IFNg and of the three IFNγ-related chemokines, CXCL9, CXCL10 and CXCL11 in patients with active MAS, in the context of systemic Juvenile Idiopathic Arthritis (sJIA) (1). Indirect evidence in mice suggests that IFNγ is mostly produced in peripheral tissues and blood concentrations may be relatively low.

Methods : Circulating levels of IFNγ, CXCL9, CXCL10, CXCL1, IL-1b and IL-6 in patients with sJIA (n=54) of whom 20 had MAS at time of sampling were measured by Luminex multiplexing assay. We evaluated the correlation between serum levels of IFNg and of the three IFNg related chemokines with themselves and with laboratory parameters of disease activity in active MAS.

Results: Levels of IFNγ and of the 3 IFNγ-related chemokines were significantly elevated in active MAS compared to active sJIA without MAS at sampling (all p-values <0.005). In patients with active MAS, but not in patients with active sJIA without MAS at sampling, laboratory parameters of disease severity (ferritin, neutrophils, platelets, alanine aminotransferase and lactate dehydrogenase) were significantly correlated with IFNγ and CXCL9, and to a lesser extent with CXCL10 and CXCL11 (Table1). No correlation with IL-6 levels was found. In active MAS IFNg levels were significantly correlated with levels of CXCL9 (r=0.69; r^2=0.48; p=0.001), but not with those of CXCL10 (r=0.54; r^2=0.29; p=0.015), or CXCL11 (r=-0.04; r^2=0.0016; p=0.887).

Conclusion: High levels of IFNγ and of CXCL9 during active MAS were significantly correlated with laboratory parameters of disease severity. Since CXCL9 has been shown to be induced only by IFNg and not by other interferons (2), our findings support the conclusion that CXCL9 is a potential biomarker of IFNg production in MAS.

Innovative Approach for the Identification of an Appropriate Dose Regimen of a Targeted Treatment, NI-0501, an Anti-Interferon Gamma (IFNg) Antibody, in Patients with Hemophagocytic Lymphohistiocytosis (HLH)

Cristina De Min[1], Philippe Jacqmin[2], Christian Laveille[3], Robert Nelson[1], Florence Guilhot[1], Maureen Deehan[1], Marie Kosco-Vilbois[1], Walter Ferlin[1] and Genevieve Lapeyre[1], [1]NovImmune S.A., Geneva, Switzerland, [2]SGS Exprimo, Mechelen, Belgium, [3]SGS Exprimo NV, Mechelen, Belgium

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects III: Miscellaneous Pediatric Rheumatic Diseases

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

Based on the growing evidence that IFNg plays a pivotal role in HLH, NI-0501, an anti-IFNg monoclonal antibody, is being developed as the first targeted treatment of HLH. Since a dose-finding study could not be performed in this fragile population, an innovative, individualized-dosing approach is being investigated in a pilot study, with the objective of achieving, as quickly as possible, a complete IFNg neutralization.

Methods:

The pilot study foresees the recruitment of 10 pediatric patients receiving NI-0501 either as first or second line HLH treatment. The NI-0501 dose required for reaching and maintaining, for a defined period of time, complete IFNg neutralization depends on the amounts of cytokine produced in various body compartments.

On the basis of calculated neutralizing NI-0501 concentrations, NI-0501 PK parameters in healthy volunteers and PK information from use of recombinant IFNg in humans, we predicted, by means of PK modelling and simulation, the dose neutralizing existing and *de novo* IFNg production over 3 days. The initial interval between NI-0501 infusions was 3 days. Guided by close PK monitoring, modifications of NI-0501 dose or frequency of administration were allowed.

Results:

A dose of 1 mg/kg achieved the desired NI-0501 concentration in the 7 patients enrolled thus far in the study. NI-0501 elimination kinetics was linear at high concentrations and appeared non-linear, due to target mediated drug disposition, at lower drug concentrations. After reaching steady state, up to a 7-day administration frequency could be applied. Kinetics was not affected by the numerous therapeutic interventions (blood transfusions, hemofiltration or hemodialysis, bone marrow transplantation). IFNg neutralization in serum was confirmed *ex vivo* via the use of STAT-1 bio-assays and *in vivo* through down-modulation of IFNg-inducible proteins, such as CXCL9 and CXCL10.

Conclusion:

The adequacy of the originally planned dosing regimen was demonstrated in all patients enrolled to date in the pilot study. NI-0501 treatment has shown to be effective in improving or even abrogating all relevant clinical and laboratory features of HLH such as fever, splenomegaly, cytopenia, hyperferritinemia, hypofibrinogenemia, and also CNS disease. All infusions were well tolerated and no safety concerns emerged.

Session Title: Rheumatoid Arthritis - Clinical Aspects IV: Biomarkers, Disease Progression and Treatment Response

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

The inflammatory cell infiltrate in RA synovium has been recognised to organise into lymphocytic aggregates (Ags) with data to suggest that these structures are immunologically competent and can support chronic inflammation. However, their clinical significance has been controversial with conflicting publications reporting diverse associations with disease outcome. Therefore the aim of this study was to determine whether synovial pathotypes associate with clinical phenotype and predict radiographic damage at 12 months in early RA.

Methods:

A cohort of 119 consecutive DMARD-naïve early RA patients (<12 months duration, 2010 ACR/EULAR criteria) were recruited as part of the MRC-funded Pathobiology of Early Arthritis Cohort (PEAC) http://www.peac-mrc.mds.qmul.ac.uk/at Barts and the London Hospital and underwent a pre-treatment baseline US-guided synovial biopsy. Baseline demographics (including ESR, CRP, RF, ACPA and DAS28) and US score (0-3, synovial thickness (ST) and power doppler (PD) of biopsied joint and 12-joint total US score (10 MCP and 2 wrist joints), at baseline were determined. Furthermore, baseline and 12 month hand/feet radiographs underwent Sharp/van der Heijde scoring (SHS). All patients were treated with DMARD combination therapy +/- oral steroids with a treat to target approach (DAS<2.6). Paraffin embedded sections of synovial tissue underwent routine immunohistochemical staining for CD20+ B cells and CD68+ macrophages. Patients were then categorised as aggregate (AG) if grade 2/3 CD20+ Ags were identified and following semi-quantitative scoring (0-4) for CD68+ sublining macrophages into pauciimmune (PI) (≤ 2 CD68+) or diffuse (D) (>2 CD68+, +/- grade 1 Ags). Finally significant differences in clinical parameters at baseline and progression in SHS (≥1) score at 12 months between the 3 synovial pathotypes was determined.

Results: (Table)

At baseline a significantly higher DAS28 score (p=0.02) was seen in the AG vs D or PI pathotype. The number of patients sero + for RF and ACPA was also significantly higher (p=0.029, 0.038) in the AG group. Furthermore US-ST and US-PD scores of the biopsied joint were significantly higher and a trend for higher total US-ST and US-PD scores was also seen in the AG group. Finally a significantly higher number of radiographic progressors were seen in the AG group (p=0.02).

Conclusion:

The significant association between synovial lymphocytic Ags and high disease activity/ sero positivity in patients with early RA suggests a critical role for these structures in RA pathogenesis. Furthermore in this cohort despite a treat to target approach patients with an AG pathotype were significantly more likely to develop progressive radiographic damage. Such data suggests the potential for early patient stratification in order to target effective therapies according to clinical need.

Table 1: Clinical, US and radiographic characteristics according to synovial pathotype

Differential Effects of IL-6 Blockade Tocilizumab and TNF Inhibitors on the Reduced Angiogenesis and Lining Layer Degeneration in Synovial Tissues from Patients with Rheumatoid Arthritis

Hirohata Shunsei[1], Asami Abe[2,3], Akira Murasawa[3], Tetsuya Tomita[4] and Hideki Yoshikawa[4], [1]Rheumatology and infectious diseases, Kitasato University School of Medicine, Kanagawa, Japan, [2]Rheumatplogy, Niigata Rheumatic Center, Shibata, Japan, [3]Rheumatology, Niigata Rheumatic Center, Shibata, Japan, [4]Department of Orthopedics, Osaka University Graduate School of Medicine, Suita Osaka, Japan

Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects IV: Biomarkers, Disease Progression and Treatment Response
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory disease characterized by hyperplasia of synovial tissues, leading to the destruction of joint structures. TNF inhibitors, including anti-TNF-a antibodies and soluble TNF receptors, have been shown to result in characteristic discoid fibrosis in the deep lining layer of the synovium, probably by their action on synovial cells thereof. Whereas IL-6 blockade tocilizumab has comparable beneficial effects in the treatment of RA, its detailed mechanism actions have not been fully understood. Since angiogenesis plays a pivotal role in the pathogenesis of RA, the current studies were carried out to compare the influences of tocilizumab and TNF inhibitors on the angiogenesis in synovial tissues of RA patients.

Methods: Synovial tissues were obtained during the joint surgical operations from 13 RA patients who had been treated with tocilizumab for at least 4 months (4-47months), 7 of whom had been previously received TNF inhibitors. As a control, synovial tissues were similarly obtained from 13 RA patients who had received TNF inhibitors and from 10 RA patients who had not been given only non-biological DMARDs. Synovial tissues were fixed in formaldehyde and embedded in paraffin. The sections were evaluated by hematoxylin and eosin stain as well as by immunohistological staining with anti-CD31 in which the microvessel densities (MVD) were quantitated under microscopy. Synovial histopathology was evaluated and scored for lining layer proliferation, stromal proliferation and inflammatory changes.

Results: The most remarkable change in the synovium from RA patients treated with tocilizumab was the reduced angiogenesis as well as the degeneration of lining layers in the synovium. irrespective of the previous use of TNF inhibitors. Thus, MVD in patients treated with tocilizumab with or without previous TNF inhibitors were significantly decreased compared with those in patients with TNF inhibitors alone or in patients with non-biological DMARDS (Figure). Moreover, MVD was significantly correlated with lining layer scores, but not with synovial stromal proliferation or inflammatory changes.

Conclusion: These results disclosed that inhibition of angiogenesis is a primary action of tocilizumab. Moreover, the data also suggest that the proliferation of synovial cells in the lining layers might be closely associated with angiogenesis in the sublining layers.

Session Title: Rheumatoid Arthritis - Clinical Aspects IV: Biomarkers, Disease Progression and Treatment Response

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

Antibodies against RA33 (hnRNP A2/B1) were one of the earliest antigen specificities identified in rheumatoid arthritis (RA). Unlike the erosive disease associated with anti-citrullinated proteins antibodies (ACPAs) and rheumatoid factor (RF), anti-RA33 antibodies have been uniquely associated with a milder disease phenotype. In preliminary studies, we identified that RA33 is citrullinated in RA synovial fluid (SF), and targeted as citrullinated protein in RA. Here, we define the clinical utility of antibodies against unmodified (native) and citrullinated RA33

(citRA33) in a longitudinal cohort of patients with RA.

Methods:

RA33 splicing variants (hnRNP A2/B1/A2b and B1b) were cloned from RA SF cDNA, and recombinant proteins citrullinated in vitro using human rPAD4. Antibody reactivity against native and citrullinated splicing variants of RA33 was compared by ELISA using ACPA-positive RA sera. Patient sera from a cohort study of subclinical cardiovascular disease in RA (n=196) and healthy control sera (n=56) were assayed for antibodies against native and citrullinated B1b by ELISA. Antibody specificities were confirmed by immunoprecipitation and immunoblotting. Antibody positivity was defined based on seroreactivity above the 95th percentile of controls, and correlated with markers of disease activity and radiographic progression.

Results:

Anti-citRA33 antibodies were identified in 86 patients (44%) with RA, while anti-native RA33 antibodies (anti-RA33) were detected in 21 patients (11%) at first visit. Analysis of the fine specificities recognized by these antibodies in patients with RA demonstrated that RA33 is targeted in three ways: (1) exclusively as a citrullinated antigen (n=75); (2) both as a native and citrullinated antigen (n=11); and (3) exclusively as a native antigen (n=10). Patients with anti-citRA33 specific antibodies had a median baseline Sharp-van der Heijde score (SHS) that was 3.4-fold higher than antibody negative patients (17 vs. 5 units, p=0.006). In contrast, anti-RA33 specific antibodies identified patients with the lowest systemic inflammatory burden as measured by CRP and IL-6 levels, and with erosion scores similar to those without either antibody (1.2-fold increase; p=0.81). Minimal longitudinal progression of erosive damage was observed among patients with anti-RA33 alone or anti-citRA33 alone (SHS change/year 0.0 and 0.6, respectively). In contrast, the subset of patients with reactivity against both RA33 and citRA33 (anti-RA33DR) demonstrated a significantly higher rate of radiographic progression (SHS change/year 2.3; p=0.035).

Conclusion:

Anti-citrullinated and anti-native RA33 antibodies identify distinct clinical subsets in RA that differ in disease duration and phenotype. Anti-RA33DR antibodies characterize a unique group of patients with markedly accelerated progression of erosive disease.

Receptor Activator of Nuclear Factor Kappa-B Ligand (RANKL) and Sclerostin Are Related to Joint Destruction in Early Rheumatoid Arthritis Unrelated to Polymorphisms of the Genes

Antonia Boman[1], Heidi Kokkonen[2], Ewa Berglin[1], Lisbeth Ärlestig[1] and **Solbritt Rantapaa-Dahlqvist**[3], [1]Public Health and Clinical Medicine/Rheumatology, Umeå University, Umeå, Sweden, [2]Public Health and Clinical Medicine/ Rheumatology, Umeå University, Umeå, Sweden, [3]Department of Public Health and Clinical Medicine/ Rheumatology, Umeå University, Umeå, Sweden

Session Title: Rheumatoid Arthritis - Clinical Aspects IV: Biomarkers, Disease Progression and Treatment Response
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Rheumatoid arthritis (RA) is characterized by joint inflammation and destruction of cartilage and bone. The destructive process is related to autoantibodies, genetic polymorphisms involving proteins in the Wingless related MMTV integration site (Wnt) pathway and markers of inflammation, cartilage and bone. We have analysed the relationships of receptor activator of nuclear factor kappa-B ligand (RANKL) and sclerostin to radiological destruction and progression in early RA.

Methods: Patients with early RA (n=414, symptom duration <1 year) (ARA criteria) with radiological examinations at inclusion and after 24 months were consecutively included. Disease activity score, swollen (SJC) and tender (TJC) joint count, ESR, CRP and treatment were regularly registered. Concentrations of sclerostin (EIA, TECOmedical group, Sissach, Switzerland), RANKL (ELISA, BioVendor, Karasek, Czech Republic) and anti-CCP2 antibodies (ELISA, Euro-Diagnostica AB, Malmö, Sweden) were analysed at baseline. Data on gene polymorphisms were extracted from Immunochip analysis (Uppsala, Sweden).

Results: RANKL concentration was significantly higher in patients compared with controls ($p < 0.001$). Anti-CCP positive patients had significantly higher concentration of RANKL compared with anti-CCP negatives, median (Q1-Q3) 763.7 (347.3-1325.0) pmol/L and 241.5 (137.8-474.1) pmol/L. Sclerostin was significantly increased in patients 0.63 (0.49-0.78) ng/mL versus controls (0.51 (0.4-0.7) ng/mL ($p < 0.01$). After stratification for sex the difference was only significant in females, 0.59 (0.47-0.74) ng/mL compared with controls.

RANKL concentration was related to Larsen score at baseline ($p<0.01$), and after 24 months ($p<0.001$) and to radiological progression after 24 months ($p<0.001$). After adjustments (age and SJC), RANKL was only related to Larsen score at baseline. Sclerostin was significantly ($p< 0.05$) related to radiological progression after 24 months adjusted for sex, Larsen score and ESR at baseline and 24 months' treatment response.

The less frequent type of three SNPs (rs41848320, rs41887440, rs41931102) encoding RANKL was associated with increased concentrations, particularly in the RA-patients, although unrelated to radiological findings. The levels of sclerostin were not related to any of the SNPs.

Conclusion: The concentration of RANKL was related to Larsen score at baseline, whilst the concentration of sclerostin was related to radiological progression during the first 2 years. Measurement of sclerostin at baseline could be a valuable predictor of radiological progression during the first 2 years. Polymorphisms of three SNPs showed increased concentrations of RANKL but were unrelated to radiological findings.

Session Title: Rheumatoid Arthritis - Clinical Aspects IV: Biomarkers, Disease Progression and Treatment Response
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Higher levels of circulating adiponectin have been linked to radiographic progression in RA in observational studies, but never studied in the context of early RA with multiple treatment strategies.

Methods: We studied enrollees in the Treatment of Early Aggressive RA (TEAR) Trial. Participants had early, active RA, were seropositive, or had ≥2 baseline erosions. All received methotrexate and either etanercept [immediately (IE) or as step-up therapy (SE)] or sulfasalazine + hydroxychloroquine (i.e triple therapy) [immediately (IT) or as step-up therapy (ST)]. Radiographs (baseline, and wks 48 and 102) were

obtained and Sharp-van der Heijde scores (SHS) calculated blind to sequence. Available stored baseline and 48wks serum samples from patients with complete radiographic data were assayed for total adiponectin using a bead-based Luminex assay (R&D Systems). Assays were optimized, run in duplicate, and blocking for RF was used. Multivariable (MV) generalized linear modeling was used to model SHS change according to baseline and change in adiponectin level, adjusting for relevant confounders.

Results: A total of 288 patients were studied. Baseline characteristics (mean age=51 yrs; 70% female; 74% non-Hispanic White; 91% seropositive for RF or anti-CCP; median RA duration=1.2 months; mean DAS28-ESR=5.8) were similar to those of the entire trial cohort. Baseline radiographic damage was observed in 86%, with a median SHS of 2.5 units. Median baseline adiponectin was 8.6 mg/L, and higher levels at week 48 were observed in 46% of patients. Factors significantly associated with increasing adiponectin included female sex, lower baseline adiponectin, EULAR good response at 48 weeks, and randomization to the IT group. Radiographic progression (≥2 unit increase in SHS) was observed in 10% at 48 wks. MV factors significantly associated included higher age, higher baseline ESR and swollen joint count (SJC), longer RA duration, and increase in adiponectin. Seropositivity, baseline erosions, baseline adiponectin, BMI, and changes in DAS, ESR, or SJC were not associated. For adiponectin, each mg/L increase from baseline to 48wks was associated with a 10% higher odds of radiographic progression (OR=1.10; p=0.009), an effect not altered with adjustment (Figure). Interestingly, this effect was observed only in patients without a 48wk EULAR good response (Figure), and was seen regardless of randomized treatment allocation (Figure). Similar effects were observed for predicting radiographic progression at 102wks.

Conclusion: Rising adiponectin in the setting of treatment non-response was a potent factor associated with radiographic progression among RA patients at highest risk for joint damage in the early phases of disease. Additional mechanistic studies are needed to define the physiologic basis for these findings.

Session Title: Rheumatoid Arthritis - Clinical Aspects IV: Biomarkers, Disease Progression and Treatment Response

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Anti-carbamylated protein antibody (anti-CarP) is seen in 45% of rheumatoid arthritis (RA) patients [1]. The precise target antigen (Ag) of anti-CarP had not been elucidated, since the authors of the first report used fetal calf serum (FCS) as target Ag which contains various kind of proteins. Although several proteins have been reported to be target Ags of anti-CarP, the repertoire of anti-CarP has not

been fully understood. In addition, all reported carbamylated Ags are also known as citrullinated Ags, and carbamylation-specific Ag has not been reported. Since the largest fraction of FCS is albumin, we hypothesized that human albumin (ALB) is one of target Ags of anti-CarP. The purpose of this study is to demonstrate whether anti-carbamylated ALB antibody (anti-car-ALB) is detected in RA and to evaluate its clinical importance.

Methods: ALB and FCS were carbamylated by potassium cyanate. ALB was also citrullinated by peptidyl arginine deiminase. We established in house ELISA systems of anti-carbamylated FCS antibody (anti-car-FCS), anti-car-ALB, and anti-citrullinated ALB antibody (anti-cit-ALB) as previously described [1]. Sera and clinical data of 455 RA patients were obtained from KURAMA database which was established to store clinical information and specimens from RA patients in Kyoto University. Inhibition ELISA was done by 8 representative sera, in which they were pre-incubated with increasing concentration of unmodified FCS, car-FCS, car-ALB, or cit-ALB and tested for reactivity against car-FCS.

Results: The sensitivity of anti-car-FCS, anti-car-ALB, and anti-cit-ALB were 27.0%, 44.2%, and 7.3%, respectively (Table 1). Positive result of anti-car-ALB was related to bone damage and smoking (Table 2). Inhibition ELISA showed anti-car-FCS was inhibited by car-ALB, but not by cit-ALB (Figure 1A). Strength of inhibition by car-ALB was different among sera (Figure 1B). The titer of anti-car-FCS and anti-car-ALB showed good correlation (rho=0.63), but anti-CCP did not correlate with anti-car-ALB (rho=0.28) or anti-cit-ALB (rho=0.16).

Conclusion: Anti-car-ALB was more sensitive than anti-car-FCS for diagnosing RA and correlated with bone damage and smoking. Car-ALB is one of the target Ags of anti-CarP. This is the first report of carbamylation-specific Ag.

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis III

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Rheumatoid arthritis (RA) fibroblast-like synoviocytes (FLS) mediate disease pathogenesis by invading the joint extracellular matrix. The *PTPN11* gene, encoding the tyrosine phosphatase SHP-2, is overexpressed in RA FLS compared to osteoarthritis (OA) FLS and promotes RA FLS invasiveness. Here we sought to elucidate the molecular basis for *PTPN11* overexpression in RA and explore

whether pharmacologic inhibition or genetic deficiency of its expressed protein, SHP-2, reduces RA FLS aggressiveness and arthritis severity.

Methods: FLS were obtained from arthroplasty RA and OA synovium. Dexamethasone (DEX)-induced DNA binding of the glucocorticoid receptor (GR) in RA FLS was assessed by chromatin immunoprecipitation (ChIP)-PCR. Arthritis severity in the K/BxN serum transfer model was assessed by measuring ankle swelling. Contribution of *PTPN11* in FLS to arthritis severity was assessed by reconstitution of irradiated wild type (WT) or *Ptpn11*$^{-/+}$mice with bone-marrow from WT mice.

Results: Potential regulatory regions of *PTPN11* were identified in the UCSC genome browser and the ENCODE database. Based on the co-localization of histone marks and transcription factor binding motifs, we identified a possible 1.4 kb enhancer in intron 1 of *PTPN11* containing a glucocorticoid receptor (GR)-binding motif. To confirm function of the enhancer, the region was subcloned into a luciferase reporter construct and transfected into FLS. The FLS were stimulated with DEX (100 nM) and ChIP-PCR showed that GR binding to the enhancer increased 5.6±0.4-fold ($p<0.01$) and increased luciferase expression by 13±5-fold ($p<0.05$). We then showed that DEX increased *PTPN11* expression 1.4-fold higher in RA than OA FLS ($p<0.05$). To determine why *PTPN11* expression is higher in RA, we pyrosequenced the 8 enhancer CpG sites near the GR-binding site. We found 2 hypermethylation sites in RA FLS compared to OA FLS: chr12 112860522 (28±4.1% in RA and 8.2±0.7% in OA; $p<0.01$) and chr12 112860601 (30%±3.6 in RA and 17%±2.4 in OA; $p<0.05$). Deletion of the two CpGs reduced enhancer activity by 40±9% ($p<0.05$), showing they are required for enhancer function. Having discovered that *PTPN11* dysregulation is associated with abnormal enhancer DNA methylation in two CpGs, we examined functional consequences of high *PTPN11*. Using a transwell assay, a small molecule SHP-2 inhibitor reduced RA FLS migration by 83±8.3% ($p<0.0001$). Furthermore, heterozygous deletion of *Ptpn11* in radioresistant cells (e.g., fibroblasts) attenuated passive K/BxN arthritis severity in mice (54±3.4% reduction, $p<0.05$). Treatment of mice daily with 7.5 mg/kg SHP-2 inhibitor reduced arthritis severity by 20±5% (AUC, $p<0.05$).

Conclusion: We identified a new intronic GR-responsive enhancer that is abnormally methylated in RA FLS, resulting in increased expression of the pathogenic gene *PTPN11*. Blocking function of its encoded protein, SHP-2, reduces RA FLS aggressiveness and arthritis severity. Our findings show how the interplay of abnormal epigenetics with a pathogenic gene determines FLS behavior and joint inflammation. SHP-2 inhibition could be an important new strategy that targets FLS invasiveness in RA.

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis III

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: We recently reported an advance in modeling the human immune system in mice, (Kalscheuer et al. Sci Transl Med 2012) involving maturation of patient immune systems from marrow hematopoietic stem cells (HSCs) in NOD/SCID/IL-2 receptor γ chain^{null} immunodeficient mice receiving partially HLA-matched human fetal thymic tissues to recreate the adult donor's functional and diverse T and B cell repertoires. These resemble the donor repertoire in tolerance of self and non-self recognition, but predominantly consist of naïve phenotype T cells. Since HSCs contain the genetic information to recreate a replica of each individual's unique immune system, this Personalized Immune Mouse (PIM) affords a powerful and novel opportunity to recreate a functional human immune system of a patient with a systemic autoimmune disease, generated through thymic (for T cells) and bone marrow (for B cells) selection *de novo* from adult HSCs.

Methods: We explored the feasibility of creating replicas of RA patient immune systems to study early events during formation of their immune system. 120 RA patients meeting classification criteria were sequence-based typed for HLA-ABC and DRB1alleles to identify those who matched similarly HLA-typed available fetal thymic tissue by at least one HLA-A allele and one shared epitope-encoding HLA-DRB1 allele.

After informed consent, 15-25 mls of RA donor marrow was aspirated yielding ~$2x10^6$ CD34+ cells isolated by magnetic beads. ~$2.5x10^5$HSCs were injected intraosseously into each mouse in a cohort of replicates irradiated with 2Gy, that had the T cell-depleted thymic fragment implanted under the renal capsule.

Results: To date, HSC preparations from 3 RA patients, aged <34 yrs, were studied. The third donor generated an RA immune system that at 12 weeks resembled those established from healthy controls in having 12-20 % of circulating hCD45+ cells of human origin, of which 2/3 were hCD19 and 1/3 hCD3. At week 14 the thymic grafts contained 2-$9x10^6$human thymocytes, ~70% double positive. However, in marked contrast to reconstitutions with healthy control HSCs, where 80-90% of circulating CD4 T cells typically exhibit the CD45RA+CD45RO- naïve phenotype, in RA-PIM 5-25% of the CD4 T cells expressed HLA-DR and from 50 to 90% of circulating CD4 T cells had lost expression of CD45RA, reflecting activation and memory-effector differentiation. By week 14, 5-30% of bone marrow and splenic T cells were terminally differentiated to CD28-CD45RA+ and similar proportions expressed CD57, CD69, and HLA-DR, T cell phenotypes long recognized to occur in RA patients. The proportion of immature RA-PIM marrow B cells was also reduced compared to healthy controls, reflecting enhanced differentiation to naïve and transitional B cells.

Conclusion: In the initial weeks of immune cell development from HSC, replicas of RA immune systems exhibit marked CD4 T cell activation and T and B cell differentiation, suggesting their intrinsic hyperactivity compared to quiescent cell populations comparably generated from healthy controls. These results suggest that there may be genetically-predetermined defects in the selection or regulation of lymphocytes in RA that can be replicated and analyzed in PIM.

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis III

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Aberrant expression of microRNAs (miRs) has shown to be critical for the pathogenesis of rheumatoid arthritis (RA). Apoptosis signal regulating kinase-1 (ASK1), a member of MAP3K family upstream of p38 and JNK MAPK has recently been associated with RA pathogenesis. Here we studied the regulation of ASK1 by miR-17 in human RA synovial fibroblasts (RA-FLS) and correlated their expressions in human RA and adjuvant induced arthritis (AIA) and collagen induced arthritis (CIA) models of RA.

Methods: Bioinformatics analysis was performed to identify miRs predicted to targets ASK1 3'UTR. ASK1 and miR-17 expressions were correlated in FLS/synovial tissue (ST) from RA (n=15), osteoarthritis (OA; n=11), or non-diseased (NL; n=8) donors using Western blotting and qRT-PCR. Effect of IL-1β (10 ng/ml) or TNF-α (20 ng/ml) with or without ASK1 inhibitor (TC-ASK-10; 12.5 μM) or ASK1 siRNA was studied on the expression of phospho-p38 (p-p38), p-JNK, IL-6, and IL-8. Luciferase assay was performed using ASK1 3'UTR construct and pre-miR-17 to verify miRNA:mRNA interaction. Effect of miR-17 overexpression and inhibition on ASK1 was evaluated by transfection of RA-FLS with pre-miR-17/anti-miR-17. Findings from human FLS were validated in AIA and CIA models. Serum miR-17 levels in RA patients, AIA and in CIA models were quantified using qRT-PCR. Effect of miR-17 overexpression on matrix metalloproteinases (MMPs) was determined in the conditioned media using MMPs protein array. $p<0.05$ was considered significant.

Results: Bioinformatics analysis predict miR-17 binding site in the 3'UTR region of ASK1 mRNA. Expression of miR-17 was down-regulated (70%) in RA-FLS compared to NL-FLS and inversely correlated with a significant increase in ASK1 mRNA (2.3-fold) and protein. Similar inverse correlation of miR-17 and ASK1 was also observed in RA-ST compared to NL-ST. No significant correlation was observed between miR-17 and ASK1 expression in OA-FLS or OA-ST. IL-1β or TNF-α stimulation further suppressed miR-17 expression, with a concomitant increase in ASK1 mRNA (2.2-12.5 fold) and protein in RA-FLS. Co-transfection of RA-FLS with the ASK1 reporter construct and pre-miR-17 significantly suppressed the luciferase activity (34%). Overexpression of miR-17 inhibited ASK1 protein, whereas its inhibition enhanced ASK1 protein in RA-FLS. Interestingly, inhibition of ASK1 using TC-ASK-10 resulted in a marked attenuation of p-p38, p-JNK MAPK, IL-6, and IL-8 expression in RA-FLS. Knockdown of ASK1 or overexpression of miR-17 inhibited TNF-α-induced IL-6 and IL-8 production in RA-FLS. Overexpression of miR-17 also inhibited MMP-1, -3, and -13 production in IL-1β stimulated RA-FLS. miR-17 levels were significantly lower in the serum of RA patients, AIA and in CIA models compared to controls with increased in arthritis score. In AIA and CIA studies,

ASK1 expression increased with the disease progression, and correlated with lower miR-17 expression and enhanced p-p38, p-JNK, IL-6, and IL-8 expression in arthritic joints.

Conclusion: This study provides evidence for the role of ASK1 in RA pathogenesis and a novel mechanism of its regulation by miR-17 in human RA-FLS and in two different models of RA.

Investigating the Ameliorating Effect of Pregnancy on Rheumatoid Arthritis Using Whole Transcriptome Analysis

Anuradha Mittal[1], Lior Pachter[2], J. Lee Nelson[3], Hanne Kjaergaard[4], Mette Smed[4], Vibeke Zoffmann[4], Jørn Olsen[5], Merete Lund Hetland[6], Ingileif Hallgrimsdottir[2] and Damini Jawaheer[1], [1]Children's Hospital Oakland Research Institute, Oakland, CA, [2]University of California, Berkeley, Berkeley, CA, [3]Immunogenetics, Fred Hutchinson Cancer Rsch, Seattle, WA, [4]Juliane Marie Center, Copenhagen, Denmark, [5]Aarhus University, Aarhus, Denmark, [6]On behalf of all Depts of Rheumatology in Denmark, DANBIO, Glostrup Hospital, Glostrup, Denmark

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis III
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Pregnancy is known to induce a natural improvement of Rheumatoid Arthritis (RA) symptoms in 50-75% of patients as gestation progresses. However, the underlying mechanisms are not well understood. In this study, we aimed to identify genes that demonstrate altered expression in RA during pregnancy through analysis of transcriptome profiles before pregnancy and at the third trimester from women with RA who show pregnancy-induced improvement in Clinical Disease Activity Index (CDAI) scores, and from healthy women (controls).

Methods: Blood was drawn from 7 women fulfilling the 1987 ACR criteria for RA and from 5 healthy women, before conception and at the third trimester. Total RNA was isolated and used to prepare cDNA libraries which were sequenced on an Illumina HiSeq2500 instrument at an average depth of 60 million reads (100bp). The raw RNA sequencing (RNA-seq) data was pre-processed and aligned to the reference Human transcriptome using Bowtie2. Gene expression levels were quantified using eXpress. Genes differentially expressed between groups (between RA cases and controls or between time-points) were identified with edgeR using a fold-change cutoff of 2 and significance threshold $p<0.05$ (FDR corrected). Functional category enrichment analysis was performed using the DAVID bioinformatics resource.

Results: Before pregnancy, 1,311 genes were differentially expressed in RA cases (CDAI: 11.1 ± 8.9) vs controls. In contrast, in the third trimester of pregnancy when there was improvement in RA disease activity (CDAI: 3.0 ± 2.4), differential expression between RA cases and controls was limited to only 38 genes, showing a dilution of the pre-pregnancy RA gene expression signature. Among the genes demonstrating RA-associated expression before pregnancy, those showing differential expression among healthy women in the third trimester vs before pregnancy – i.e. genes with expression levels modulated by pregnancy in the absence of RA – were found to be enriched in biological processes such as translational elongation, inflammatory response, immune response and leukocyte activation. Interestingly, in the third trimester, a subset of these pregnancy-modulated genes no longer displayed differential expression between cases and controls, even though they were over-expressed in RA cases compared to controls before pregnancy. These included genes such as CEACAM8, OLFM4, CAMP, ELOF1 and SLPI, some of which have been implicated in RA and some in pregnancy.

Conclusion: These pre-pregnancy and third trimester transcriptional signatures in RA suggest that the set of genes that show altered expression among cases during pregnancy may have a role in the pregnancy-induced changes in RA disease activity.

Serum 14-3-3eta Are Elevated in Indigenous North Americans with Rheumatoid Arthritis and May Predict Imminent Synovitis in Their at-Risk First Degree Relatives

Carol Hitchon[1], Irene Smolik[2], Xiaobo Meng[1], David Robinson[2] and Hani S. El-Gabalawy[1], [1]University of Manitoba, Winnipeg, MB, Canada, [2]Arthritis Center, University of Manitoba, Winnipeg, MB, Canada

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis III

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

Indigenous North Americans (INA) have high prevalence rates of severe erosive rheumatoid arthritis (RA). We have established a cohort of unaffected first degree relatives (FDR) of INA RA patients who are at high risk for future RA in order to evaluate the preclinical events leading to disease. 14-3-3 eta, an extracellular ligand that activates intracellular signalling pathways associated with RA, is found in seropositive erosive RA and may predict future RA in subjects with arthralgia. In this study, we sought to evaluate 14-3-3eta in INA with RA, and in asymptomatic FDRs prior to the onset of synovitis.

Methods: FDRs are reviewed annually for the development of synovitis. Serum 14-3-3eta levels were measured by commercial ELISA in 22 INA RA subjects and in serial samples from 19 FDR (10 who developed synovitis(FDR-S)). Titers higher than 0.16 ng/ml were considered positive. Anti-citrullinated peptide antibodies (ACPA) were measured by ELISA and rheumatoid factor (RF) by nephlometry. Percent positive or median with interquartile range (IQR) are reported. Subject groups were compared using Chi square tests and odds ratios with 95% confidence limits (CL) reported and using Mann Whitney U tests. Correlations were assessed by spearman tests. Changes in titers over time were assessed by Wilcoxon signed rank tests.

Results:

INA with RA were more likely to have elevated serum levels of 14-3-3eta than their FDRs (15/20(75%) vs 3/19(16%) OR 16 CL 3.2-78.9) p<0.001). Titres ranged from 0.16-20ng/ml (median (IQR) RA 1.24(6.4))vs FDR 0.16 (0.05)ng/ml p=0.001). In RA, 14-3-3eta positivity was not associated with ACPA (4/5 (80%) without ACPA vs 12/16 (75%) with ACPA p=ns), RF (13/16 (81%) with RF vs 3/5(60%) without RF p=ns) nor with CRP or joint counts. Titers of 14-3-3 correlated modestly with RF titer (spearman rho 0.44 p=0.05) but not with other clinical activity indices. Three pre-disease serum samples were tested for each FDR-S; 2 for each non-transitioning FDR. RF and ACPA positivity generally preceded 14-3-3eta positivity. Five FDR-S initially negative for 14-3-3eta became positive up to 46 months prior to or at disease transition; one FDR-S was positive at all three visits. In FDR-S, 4 developed ACPA and 14-3-3 at the same time, 2 developed ACPA before 14-3-3eta. The two FDR initially positive for 14-3-3eta at a low titer (both <0.25) were negative on repeat testing and have not developed synovitis after 3 and 8 years. Significant changes in 14-3-3eta titer between first and last sample (taken at time of transition) were seen for FDR-S (median (IQR)0.16 (0) vs 0.37 (2.54) ng/ml p=0.04) but not for FDRs who remained arthritis-free.

Conclusion:

In this cohort of INA RA and their at risk FDRs, 10 FDR developed clinical synovitis. 14-3-3eta was found primarily in the setting of disease but did not associate with RA activity. In pre-clinical RA 14-3-3eta was usually preceded by RF and/ or ACPA and 14-3-3eta positivity generally occured at or near the time of disease onset suggesting it may be a useful predictor of imminent RA.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis III
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: In management of rheumatoid arthritis (RA), initiating effective treatment as soon as possible within the so-called therapeutic "window of opportunity" is the strategy, and disease remission is a primary goal. Recent work from our group demonstrated that pre-treatment serum type I IFN- β/α ratio > 1.3 can predict non-response to anti-TNF-alpha therapy in RA patients. The cellular mechanisms that underlie the IFN-β/α ratio that predicts response are not known. Effects of IFN on single immune cells and uncommon cell populations may be masked in whole blood or mixed cell populations.

Methods: To better understand the underpinnings of the pre-treatment IFN-β/α ratio, we used single cell expression analysis to investigate whether monocyte gene expression differs significantly between RA patients according to their pre-TNF-α inhibitor serum IFN-β/α ratio. Single classical (CL) and single non-classical (NCL) blood-derived monocytes were isolated from 15 seropositive RA subjects prior to biologic therapy. An IFNα gene score was calculated from the expression level of 10 genes induced in healthy control blood-derived monocytes after in vitro stimulation by IFNα. An IFNβ gene score was calculated from the expression level of 10 genes found to be induced by IFNβ while excluding the possibility of influence of IFNα. Subjects were grouped by pre-TNF-α inhibitor serum IFN-β/α ratio into two groups, IFN-β/α > 1.3 (n=6) and IFN-β/α < 1.3 (n=9). Comparisons between groups were by Mann-Whitney. Hierarchical clustering of 87 target genes was done to determine if there were functional gene expression differences between groups.

Results: Hierarchical clustering revealed striking differences of expression of gene sets in CL monocytes between patients with IFN-β/α < 1.3 and IFN-β/α > 1.3, the groups which correspond to response/non-response to anti-TNF-α agents. This same clustering was not observed in NCL monocytes, and the differentiation between anti-TNF-α response patient groups was lost when hierarchical clustering was done on total monocytes (CL and NCL). Two major gene sets which differentiated subjects with IFN-β/α > 1.3 (non-response to anti-TNF-α group) in CL monocytes included TLR and IFN pathway genes, cell surface markers and cytokines as follows: cluster 1 (GMCSF, TLR7, STAT2, ILT7, MYD88) and cluster 2 (TLR2, CD16, JAK1, IFI27, IL1A, and MAVS).

Conclusion: These within-cell expression patterns demonstrate biological differences in CL monocytes of RA patients with an IFN-β/α > 1.3, the ratio of type I IFNs previously found to be predictive of non-response to anti-TNF-α therapy. Differentiation by gene expression among the response/non-response patient groups is lost when comparing gene expression in single NCL monocytes and single mixed population monocytes (CL and NCL), suggesting that further study of CL monocytes will likely illuminate molecular differences that determine treatment response to TNF-α inhibition in RA. This work will help to develop a more individualized approach to therapy in RA based upon the underlying biology of disease in a given patient.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis-Small Molecules, Biologics and Gene Therapy V: Immunogenecity
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose:

As many as one third of patients show insufficient response to their first TNF inhibitor (TNF-insufficient response, TNF-IR). The lack of efficacy of one anti-TNF drug does not preclude the potential efficacy of another anti-TNF drug. Alternatively, switching to a non-TNF-targeted therapy is also a rationale strategy. These 2 strategies (a second anti-TNF agent or a non-TNF targeted therapy) have only been compared in scarce observational studies in TNF-IR patients. However, no randomized controlled trial has compared the efficacy of a non-TNF-targeted biologic and a second anti-TNF drug in TNF-IR patients. We previously presented the preliminary results at 6 months. We now present the final 12 month-results of the trial.

Methods:

The “Rotation of anti-TNF Or Change of class of biologic” (ROC) trial (NCT01000441) is a multicenter,investigator-initiated, open, parallel-group, randomized controlled trial. Patients with inadequate response to a first anti-TNF were randomly assigned in a 1:1 ratio to receive a non-TNF-targeted biologic or a second anti-TNF agent. The choice of the biologic prescribed within each randomized group (ie, non-TNF-targeted biologic or a second anti-TNF agent) was left to the treating clinician. The study duration was 48 weeks.

Results:

- Week 12

At week 12 (W12), for patients randomized to a non-TNF-targeted biologic (n=146) or a second anti-TNF agent (n=146), 64.2% and 47.8%, respectively, achieved a good or moderate EULAR response (good response: 27.7% and 13.2%, respectively; moderate response: 36.5% and 34.6%, respectively) (OR 2.01, 95% CI [1.23; 3.32], p = 0.005).

- Week 24

At W24 (primary outcome), 69.7% and 52.1%, respectively, achieved a good or moderate EULAR response (good response: 39.4% and 21.1%, respectively; moderate response: 30.3% and 31.0%) (OR 2.12, 95%confidence interval [95% CI] [1.31; 3.46], p=0.003). At W24, DAS28-ESR was lower for patients with the non-TNF-targeted biologic than second anti-TNF drug (difference adjusted to baseline value -0.43, 95% CI [-0.72; 0.14], p= 0.004). The proportion with low disease activity was 44.6% and 27.9%, respectively (OR 2.09, 95%CI [1.27; 3.43], p= 0.004).

- Week 48

At W48, 60.0% of patients treated with a non TNF-targeted biologic and 43.2% of those treated with a second anti-TNF were EULAR responders (good response: 37.7% and 21.2%, respectively; moderate response: 22.3 and 22.0%, respectively) (OR 1.97 (95%CI [1.21; 3.24], p = 0.007). DAS28-ESR was lower for patients with the non-TNF-targeted biologic than second anti-TNF drug (difference adjusted to baseline value -0.38, 95% CI [-0.69; 0.08], p= 0.013). The proportion with low disease activity was 40.8% and 23.5%, respectively (OR 2.24, 95%CI [1.32; 3.82], p= 0.003). The proportion with DAS28-ESR remission was 26.9% and 13.6%, respectively (OR 2.34, 95% CI [1.24; 4.39], p= 0.009. Ongoing comparison of radiographic progression and safety will be also presented at ACR.

Conclusion: This randomized controlled trial demonstrated a better efficacy of a non-TNF-targeted biologic than a second anti-TNF agent for TNF-IR patients. This superiority was consistent over time and across numerous outcome criteria.

Abstract Number: 3111

Long-term Safety and Efficacy of Mavrilimumab, a Fully Human Granulocyte-Macrophage Colony-Stimulating Factor Receptor-α (GM–CSFR-α) Monoclonal Antibody, in Patients with Rheumatoid Arthritis (RA)

Gerd Burmester[1], IB McInnes[2], JM Kremer[3], P Miranda[4], J Vencovský[5], A Godwood[6], M Albulescu[6], D Close[6] and Michael Weinblatt[7], [1]Department of Rheumatology and Clinical Immunology, Charité - Universitätsmedizin Berlin, Berlin, Germany, [2]Glasgow Biomedical Research Centre, Glasgow, United Kingdom, [3]The Albany Medical College, Albany, NY, [4]Centro De Estudios Reumatológicos, Santiago, Chile, [5]Institute of Rheumatology and Department of Rheumatology, Charles University, Prague, Czech Republic, [6]MedImmune, Cambridge, United Kingdom, [7]Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Boston, MA
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis-Small Molecules, Biologics and Gene Therapy V: Immunogenecity
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Modulating macrophage function through GM–CSF is a novel therapeutic approach for RA. Mavrilimumab, a fully human monoclonal antibody, which targets GM–CSFR-α, has demonstrated efficacy and an acceptable safety profile in prior 12- and 24 week studies.[1,2]This analysis evaluated the long term (LT) safety and efficacy of mavrilimumab through 74 weeks of treatment.

Methods: This open-label extension (OLE) study (NCT01712399) enrolled adult RA patients (pts) who had completed the EARTH EXPLORER 1[2] and 2 (NCT01715896) Phase IIb studies or were rescued as inadequate responders at a predefined time point. Pts received subcutaneous mavrilimumab 100 mg every other week (eow), consistent with the highest dosage in the Phase IIa study.[1]The primary objective was to assess the LT risk:benefit ratio of mavrilimumab via evaluation of i) Treatment emergent adverse events (TEAEs), TE serious AEs (TESAEs), and pulmonary function tests (PFTs), and ii) Exploratory LT efficacy endpoints (DAS28–CRP/ACR responses). AEs with onset date after mavrilimumab had been started are presented. Change from baseline (BL) in modified Total Sharp Score (mTSS) was used to explore radiographic progression in pts previously included in EARTH EXPLORER 1.

Results: At the 74 week (includes original study) cutoff, 391 pts had been enrolled in the OLE study. Of these, 329 (84.1%) continued on treatment and 62 (15.9%) discontinued (due to withdrawal of consent, 9/391 [2.3%]; death [cardiopulmonary failure], 1/391 [0.3%]; adverse event, 7/391 [1.8%]; non study-related site closure, 20/391 [5.1%]; other, 24/391 [6.1%]; lost-to-follow-up, 1/391 [0.3%]). Between the Phase IIb and OLE studies, 440 pts received mavrilimumab, with a safety exposure of 603 pt years (yr) and median (min–max) duration of 1.6 (0.1–2.4) yr. Most common TEAEs (n [/100 pt yr]) were nasopharyngitis (51 [8.45]), bronchitis (36 [5.97]) and hypertension (32 [5.30]); the serious infection rate was 1.82/100 pt yr. PFT demonstrated a generally transient 20% reduction to < 80% of predicted in a few pts (Table). Mavrilimumab demonstrated sustained efficacy with DAS28–CRP <3.2 and <2.6 rates of 57.3% and 38.5%, respectively (Table). After 74 weeks of treatment, 68% of pts showed no radiographic progression (<0.5 change in mTSS vs. BL) (Table).

Conclusion: Mavrilimumab continues to demonstrate a sustained efficacy and safety profile in pts with moderate to severe RA, over the 74 week treatment duration reported. No significant pulmonary signals were observed. Although mavrilimumab 100 mg eow is suboptimal compared with 150 mg eow in DMARD-IR pts,[2] efficacy results are comparable with those of previous studies,[1,2]further validating the use of mavrilimumab to target the GM–CSFR-α.

Table: Long term safety data and efficacy data at 74 weeks (48 weeks in OLE)

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis-Small Molecules, Biologics and Gene Therapy V: Immunogenecity

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Treatment with biologics can elicit unwanted immune responses such as antidrug antibodies (ADA), which may decrease their clinical efficacy and increase adverse events. However, use of different assay methods and inconsistent sample collection times has made direct comparison difficult.

To assess incidence of ADA for etanercept (ETN), adalimumab (ADL), and infliximab (IFX), and to correlate it with trough drug concentration, efficacy, and patient health outcomes in a real world setting.

Methods: This non-interventional, cross-sectional study was conducted in 57 centers across Argentina, Australia, Bulgaria, Turkey and the United States. Adult patients with rheumatoid arthritis, treated with ETN, ADL, or IFX continuously for 6–24 months were eligible. ADA, using RIA, and trough drug concentrations, using ELISA, were measured in samples collected on one occasion ≤2 days prior to the next scheduled dose. All assays were performed at the same laboratory. Efficacy was measured as Disease Activity Score 28-joint count (DAS28), Clinical Disease Activity Index (CDAI), Simplified Disease Activity Index (SDAI), C-reactive protein (CRP) levels, erythrocyte sedimentation rate (ESR) and health outcomes measures, eg, HAQ-DI, EQ-5D, SF-36. History of injection site or infusion reactions, serum sickness, and thromboembolic events while on the current biologic were also assessed.

Results: A total of 595 eligible patients (ETN: n=200; ADL: n=199; IFX: n=196) were enrolled in the study. Baseline demographics were similar across all groups. The mean duration of treatment was 14.6, 13.5, and 13.1 months for ETN, ADL, and IFX, respectively. None of the patients receiving ETN tested positive for ADA, whereas 62 (31.2%) and 34 (17.4%) of patients treated with ADL and IFX, respectively, tested positive for ADA ($p<0.0001$). In ADL- or IFX-treated patients, those with ADA had significantly lower trough drug levels. Efficacy and health outcomes are summarized in the table. DSR28-ESR LDA and remission rates are higher in patients without ADA. There was a correlation noted in objective measurements of inflammation in patients with ADA. All 3 treatments were well tolerated with regard to reporting targeted medical events.

Conclusion: ADA were not detected in ETN-treated patients. Statistically significant higher proportion of patients in the ADL/IFX treatment groups was positive for ADA. Patients with ADA had lower serum concentration of the drug and showed a higher value for CRP and ESR. Patients without ADA showed statistical differences in clinical and health outcomes between groups compared with patients with ADA. This is a cross-sectional study recruiting patients currently on continuous treatment of tumor necrosis factor α inhibitors. A prospective longitudinal study may be needed to further evaluate the impact of ADA on efficacy.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis-Small Molecules, Biologics and Gene Therapy V: Immunogenecity
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Anti-drug antibodies (ADAs) might result in loss of efficacy to anti-TNF. The impact of ADAs to a 1st anti-TNF on subsequent response to a second biologic has never been assessed in the setting of a randomized controlled trial. The "Rotation of anti-TNF Or Change of class of biologic" (ROC) trial showed a better efficacy at 6 months of a non-TNF-targeted biologic than a second anti-TNF. In a post-hoc analysis, we investigated the potential usefulness of assessing anti-drug antibodies to guide the choice of the second biologic in TNF-IR patients.

Methods: The ROC trial (NCT01000441) is a multicenter,investigator-initiated, open, parallel-group, randomized controlled trial. Patients with inadequate response to a first anti-TNF were randomly assigned in a 1:1 ratio to receive a non-TNF-targeted biologic (abatacept, rituximab or tocilizumab) or a second anti-TNF agent. Anti-TNF drug concentration in serum was measured using solid phase ELISA assays based on the capture of infliximab, adalimumab, golimumab, certolizumab with plate-bound recombinant TNF-a. For infliximab and adalimumab, the detection of anti-drug antibodies (ADAb) was performed by a homemade assay based on the ability of anti-idiotypic antibodies to neutralize anti-TNF drug activity and inhibit its capture by TNF-alpha (Candon S, et al. 2006). For the other anti-TNF, commercial tests were used. (Shikari, Eurobio for anti-etanercept ADAs, Lisa-Tracker kits (Theradiag, France) for anti-golimumab and anti-certolizumab ADAs).

Results: ADAs were assessed in 278 patients. In 19 (6.8%) patients, ADAs could not be detected because of persistent levels of the 1st anti-TNF. No ADA was detected in 227 (81.7%) patients. Presence of ADAs was detected in 32 (11.5%) of patients (anti-adalimumab: 20 patients ; anti-certolizumab : 2 patients ; anti-golimumab : 1 patient ; anti-infliximab: 9 patients). In all these patients with ADAs, blood levels of the 1st anti-TNF were very low or indetectable. Among the 120 patients randomized to a 2d anti-TNF and assessed for ADAs, 12 had ADAs and 108 had no ADA. Among the 139 patients randomized to a non-TNF targeted biologic and assessed for ADAs, 20 had ADAs and 119 had no ADA. In patients with ADAs, change in DAS28-ESR at 6 months adjusted on baseline DAS28-ESR was similar between patients randomized to a second anti-TNF and those randomized to a non-TNF-targeted biologic (median change of 0.45 and 0.45, respectively, P=0.96). In patients without ADA, change in DAS28-ESR at 6 months adjusted on baseline DAS28-ESR was lower in patients randomized to a second anti-TNF than in those randomized to a non-TNF targeted biologic (median change -0.22 and -0.36, respectively, P= 0.003).

Conclusion:

In the ROC trial, only a minority (~ 10%) of TNF-IR patients had ADAs. Interestingly, in TNF-IR patients with an immunogenic response against TNF inhibitors, the response to a second TNF inhibitor did not differ from response to a non-TNF-targeted drug. Therefore, the assessment of ADAs might contribute to guide the choice of a second biologic in TNF-IR patients.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis-Small Molecules, Biologics and Gene Therapy V: Immunogenecity
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Intravenous (IV) and subcutaneous (SC) formulations of tocilizumab (TCZ) are available for treatment of adult RA based upon the efficacy and safety outcomes of the Phase III and IV trials and their open-label, long-term extensions. The objective of this study was to provide an overview of the immunogenicity profile of TCZ-SC and TCZ-IV as monotherapy or in combination with DMARDs, including the incidence of anti-TCZ antibodies and their impact on safety and efficacy in patients with RA.

Methods: In the TCZ-IV (4 or 8 mg/kg every 4 weeks) studies, patients were monitored for up to 5 years, and for TCZ-SC (162 mg weekly or every other week), up to 2 years. Blood samples were taken at baseline and regularly prior to TCZ dosing throughout the studies for anti-drug antibody (ADA) assessment. All samples were screened using a bridging enzyme-linked immunosorbent assay method for ADAs, and samples that tested positive were analyzed by a confirmation assay for specificity. Those samples that were confirmation assay positive were further characterized for neutralizing potential and the immunoglobulin E (IgE) isotype (SC studies only). Safety and efficacy measures were evaluated in association with ADA development.

Results: For patients who received TCZ-SC, the proportion that developed ADAs postbaseline was low and comparable to that for TCZ-IV (2.0% vs 1.2%; Table). Overall, the incidence of ADA development was ≤2.0% and similar between patients who received TCZ monotherapy (1.3%) or TCZ+DMARDs (1.4%), regardless of formulation. No anaphylaxis or serious hypersensitivity reactions were observed in patients who received TCZ-SC monotherapy, TCZ-SC+DMARDs or TCZ-IV monotherapy and developed ADAs. Of the patients who had anaphylaxis, serious hypersensitivity or clinically significant hypersensitivity (n=131), 7.6% developed ADAs. Of the 63 patients who received TCZ-IV+DMARDs and developed ADAs, 5 had anaphylaxis; 1 additional patient had a serious hypersensitivity reaction and 4 additional had clinically significant hypersensitivity reactions. One patient who received TCZ-IV monotherapy and developed ADAs had a clinically significant hypersensitivity reaction. Three patients who received TCZ-SC+DMARDs and developed ADAs had injection site reactions (ISRs), and no ISRs occurred in patients who received TCZ-SC monotherapy and developed ADAs. Among patients who developed ADAs with neutralizing potential, none experienced loss of efficacy, regardless of formulation or concomitant DMARDs.

Conclusion: TCZ-SC and TCZ-IV have a low risk of immunogenicity potential, with no impact on safety or efficacy. For patients who received TCZ-SC, the proportion that developed anti-TCZ antibodies was comparable to that for TCZ-IV. TCZ had low and comparable immunogenicity to that of monotherapy or in combination with DMARDs.

Neutralization assay +[f]	N/A	25 (1.7)	4 (0.5)	50 (1.0)
IgE assay +[g]	5 (2.9)	6 (0.4)	N/A	N/A
Anaphylaxis[b]	0	0	0	5 (0.1)
Clinically significant hypersensitivity[c]	0	0	1 (0.1)	9 (0.2)
Serious hypersensitivity[d]	0	0	0	6 (0.1)
Injection site reactions[e]	0	3 (0.2)	N/A	N/A

ADA, anti-drug antibody; DMARD, disease-modifying antirheumatic drugs; IV, intravenous; mono, monotherapy; SC, subcutaneous; TCZ, tocilizumab.

TCZ-SC was dosed at 162 mg weekly or every other week. TCZ-IV was dosed at 4 or 8 mg/kg every 4 weeks.

[a] Denominator is total patients screened.

[b] Anaphylactic reactions were defined using Sampson criteria (Sampson HA, *J Allergy Clin Immunol,* 2006).

[c] In the MUSASHI study, hypersensitivity events were defined as adverse events (AEs), excluding ISRs, that occurred during or within 24 hours of an infusion or injection and were judged as a hypersensitivity event by the clinical expert. In all other studies, hypersensitivity events were defined as all AEs, excluding injection site reactions, that occurred during or within 24 hours of an infusion or injection and were not judged "unrelated"' to treatment by the investigator; those events may or may not be consistent with hypersensitivity clinically. Clinically significant hypersensitivity events were hypersensitivity events that also led to withdrawal from treatment.

[d] Serious hypersensitivity events were defined as hypersensitivity events that were reported as serious AEs.

[e] Injection site reactions were AEs occurring at the local injection site.

[f] The neutralization assay was not performed in MUSASHI. The denominator used for this does not include the MUSASHI population.

[g] IgE assay was not performed in the TCZ-IV studies.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis-Small Molecules, Biologics and Gene Therapy V: Immunogenecity

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: So far no mechanism for non response to biologicals targeting TNFα has been described despite one third of rheumatoid arthritis patients treated are non-responders. A link to the gut mirobiota its ability to drive an autoimmune disease. Immunity. 2010 Jun 25;32(6):815-27 can be made vie segmented filamentous bacteria (SFB) that cooperate to generate potent IgA and Th17 cell responses. Immunity. 2014 Apr 17;40(4):608-20. We investigated the differences in seroreactivity of patients responding and not responding to TNF therapies prior and after therapy and identified diagnostically applicable IgA autoantigenicity set to identify non response

Methods: Screening with patient sera were conducted with 5 different roteins candidates which were identified by protein maroarray screening (Anal Biochem. 1999 May 15;270(1):103-11.9) expressed recombinantly in *E. coli*, purified and further stratified with a large well defined patient cohort by ELISA. Baseline sera form PREDICT trial treated with Enbrel) and patients treated with Humira in the HIT HARD (Ann Rheum Dis. 2013 Jun;72(6):844-509 trial and 66 baseline sera from Charite in addition treated with (Cimzia ,Infiximab) were ivestigated by Pre. mark TNF ELISA from DRDx GmbH.

Results: Pretreatment sera from patients with diagnosis of RA based on the ACR classification criteria who were initiated on therapy with TNFalpha inhibitors were analyzed with five markers from the biomarker set of highest priority (RAB11B, PPP2R1A, KPNB1,Cog 4, FTFT1) using an ELISAs assay. . In total, analyses of 203 patients were carried out, of which 162 were clearly defined as Responder and 41 were clearly defined as non-Responder after 6 month treatment. 81% of Non-responder could be clearly identified with the pre.markTNF Test. The assay has currently a specificity 94%. Moreover, 80 baseline serum samples from the PREDICT study with Enbrel and 57 baseline sera from an early intervention trial Hit Hard (Ann Rheum Dis. 2013 Jun;72(6):844-509) with Humira were analysed. In early subset, all 3 non-responder were identified and the specificity of the assay was 98 %. In the PREDICT study Enbrel non responders were identified with 68.8 % sensitivity and a specificity of 92.5 %. The amount of IgA produceing B cell in the synovia differs significantly between the patients which is not seen with IgG produceing B cells. Moreover the potent IgA response is linked to Th17 cell response. A dual pathomechnism of local TNF produceing IgA B cells in RA synovial tissue and TNF produceing macrophages is proposed

Conclusion: These data suggest that non-response to anti-TNFα biologicals might be predicted based on frequency and magnitude of autoantibodies to specific IgA autoantigens. SFB can stimulate multiple intestinal homeostatic IgA and Th17 cell responses and specific IgA and TNF producing B cells might be important for disease persistence in TNFα non responders

High Level of Inflammation Predicts the Development of Diabetes Mellitus in Patients with Psoriatic Arthritis

Lihi Eder[1], Vinod Chandran[1], Richard J. Cook[2] and Dafna D. Gladman[1], [1]Rheumatology, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, [2]Statistics and Actuarial Science, University of Waterloo, Waterloo, ON, Canada

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment: Psoriatic Arthritis - CoMorbidities
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: To estimate trends in the prevalence of diabetes mellitus (DM) in patients with psoriatic arthritis (PsA) in comparison to the general population in Ontario, Canada and to assess whether the levels of disease activity and inflammation over time predicts the development of DM in these patients.

Methods: A cohort analysis was conducted in patients followed in a large PsA clinic from 1978 to 2013. The collected information included demographics, lifestyle habits, medical history and disease-related outcomes. DM was defined as the use of medications for DM or elevated blood glucose or HbA1C levels. The prevalence of DM in patients followed up in the cohort was compared with data obtained from the Canadian Community Health Survey (CCHS), a cross sectional examination of health status conducted from 1995 to 2013 in Ontario. Age-standardized morbidity ratio (SMR) of DM was calculated for years with available CCHS data. For the assessment of risk factors for DM, patients with an existing diagnosis of the disease at clinic entry were excluded. The following time-weighted arithmetic mean (AM-) levels were assessed as predictors of incident DM: tender and swollen joint counts, number of dactylitic digits, psoriasis area and severity index (PASI) and erythrocyte sedimentation rate (ESR). Cox proportional hazard models stratified by age-group at clinic entry and controlled for sex, cumulative steroid dose, duration of PsA and body mass index were used to compute the multivariate relative risk (RR) for incident DM.

Results: A total of 1305 patients were included in the analysis. The standardized prevalence of DM in 2013 was 11.3% (95% Confidence Interval (CI) 8.9%, 13.7%) and the SMR compared to the general population was 1.43 (95% CI 1.2, 1.7, p=0.002). An increase in the point-prevalence of DM over the past two decades was observed (Figure 1). Of the 1065 patients who were included in the time to event analysis, 73 patients developed incident DM. This cohort had a total of 11006 person-years of follow-up, with a mean of 10.3± 8.9 years per person. On multivariate analysis AM- tender joint count (RR 1.68, 95% CI 1.2-2.36, p=0.003) and AM-ESR (RR 1.21, 95% CI 1.04-1.41, p=0.01) predicted the development of DM.

Conclusion: The prevalence of DM is increased in patients with PsA compared to the general population with a gradual increase in the prevalence over the past decades. The risk of developing PsA is predicted by exposure to elevated levels of inflammation over time.

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment: Psoriatic Arthritis - CoMorbidities
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Cardiovascular risk in patients with psoriatic disease is partly attributed to the high prevalence of traditional cardiovascular risk factors in these patients. This study aimed to estimate the proportion of under-treatment of cardiovascular risk factors in an international multicentre cohort of patients with psoriasis and psoriatic arthritis (PsA).

Methods: A cross-sectional analysis of patients with psoriatic disease from the International Psoriasis and Arthritis Research Team (IPART) cohort was conducted. The presence of traditional modifiable cardiovascular risk factors (diabetes, hypertension, dyslipidemia, smoking and central obesity) and the use of appropriate therapies were determined based on patients' report, physical examination and laboratory tests. The 10-year cardiovascular risk was calculated according to the Framingham Risk Score (FRS). Adherence with guidelines for the treatment of dyslipidemia (Stone et al. Circulation 2014;129:S1-45) and hypertension (James et al. JAMA 2014;311:507-20) was assessed. Chi-square and Cochran-Armitage trend test were used to compare categorical variables across groups.

Results: A total of 2254 patients (58.9% PsA, 41.1% psoriasis alone) from 8 centres in Canada, US and Israel were included. Their mean age was 52±13.8 years and 53% were males. 83.2% of the patients had at least one modifiable cardiovascular risk factor. Based on the FRS classification 30% of patients were in a high risk and 18% were in a moderate risk category. 6.1% of the patients had ischemic heart disease, 45.1% hypertension, 71.1% dyslipidemia, 12.6% diabetes, 54.3% central obesity and 17.3% were current smokers. A significant proportion of under-treatment of hypertension and dyslipidemia was found. 455 (20.4%) patients had uncontrolled blood pressure (43% of them were not on antihypertensive medications). Uncontrolled hypertension was associated with low level of education ($p<0.001$) and severe psoriasis (PASI≥10, $p<0.001$). 850 (37.9%) patients had an indication for statin therapy but were not using these medications. Under-treatment of dyslipidemia was more frequent in patients with PsA ($p=0.005$), those with low-level of education ($p<0.001$) and patients with severe psoriasis ($p=0.03$).

Conclusion: In a real-world setting, a large proportion of patients with psoriasis and PsA were undertreated for hypertension and hyperlipidaemia.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment: Psoriatic Arthritis - CoMorbidities

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Psoriatic arthritis (PsA) is a type of inflammatory arthritis that is commonly comorbid with the skin condition, psoriasis. A major contributor to the severity and burden of psoriatic disease is the extent of skin lesions. The objective of this study was to characterize the demographic and clinical characteristics of PsA patients with >3% versus ≤3% of body surface area (BSA) affected by psoriasis and evaluate the association with outcomes such as minimal disease activity (MDA) and disability, measured by health assessment questionnaire (HAQ) in a large national observational cohort of patients with PsA and spondyloarthritis (Corrona).

Methods: All PsA patients ≥18 years enrolled in the Corrona registry and had data on BSA were included in this study. Descriptive analyses of patient characteristics, disease activity, and functionality measures at registry enrollment were assessed for patients with >3% versus ≤3% BSA. Regression models were used to evaluate the associations of BSA level with the outcome measures MDA and HAQ (0-3); adjusted for age, gender, race, BMI, disease duration, history of csDMARD use, history of biologic use and history of prednisone use at enrollment.

Results: Of the 1,240 PsA patients that were included in the analysis, 451 (36.4%) had >3% and 789 (63.6%) had ≤3% BSA. Patients with BSA>3% were younger with a mean (SD) age of 52.2 (13.4) years [vs 54.4 (13.2)], with 49.4% women [vs 52.1%], 89.1% Caucasian [vs 91.5%], with mean (SD) BMI 32 (7.5) [vs. 31.2 (7)] and mean (SD) disease duration of 9 (9.4) years [vs 8.7 (8.6)]. There were slightly higher rates of cardiovascular disease (61.25% vs. 59.4%), cancer (9.1% vs. 6.6%), and serious infections (5.1% vs. 4.4%) in the patients with BSA >3% vs. those with BSA ≤ 3% respectively. About 60% of patients in both groups used a biologic therapy and approximately 21% of patients with BSA>3% were in MDA vs. 30 % of patients with BSA ≤3%. Adjusted models showed that patients with BSA >3% were 1.79 times (OR=1.79, 95% CI=1.30, 2.47) more likely to not be in MDA relative to those with BSA ≤3%. Sensitivity analysis evaluating the associations between BSA >3% and ≤ 3% and a modified MDA (5/6 criteria excluding BSA) showed consistent results (OR=1.71, 95% CI=1.21, 2.41). Similarly, adjusted models showed a significant difference in mean HAQ in patients with >3% BSA (mean difference=0.21 units higher; 95% CI=0.13, 0.29) compared to patients with BSA≤3%.

Conclusion: Data from the Corrona registry showed that PsA patients with >3% of BSA affected by psoriasis were significantly more likely to not be in MDA and more likely to be disabled than patients with ≤3% BSA at enrollment. Even at the low cutoff of >3% BSA affected used in this analysis, the extent of psoriasis lesions confers a significantly greater burden of disease in PsA. These findings underscore the importance of assessing and effectively managing psoriasis in patients with PsA.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment: Psoriatic Arthritis - CoMorbidities
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Venous thromboembolism (VTE), the combined endpoint of deep venous thrombosis (DVT) and pulmonary embolism (PE), is a common and potentially deadly medical problem with an annual incidence between 1-3/1,000. While rheumatoid arthritis (RA) has been linked to an increased incidence of VTE, few studies have examined the risk associated with psoriasis and psoriatic arthritis (PsA). The objective of this study was to determine the risk of VTE among patients with PsA, psoriasis and RA compared with the general population.

Methods: A longitudinal cohort study was conducted in The Health Improvement Network (THIN), a primary care medical record database in the United Kingdom, to determine the risk of VTE, DVT only and PE only using data from 1994-2014. Patients aged 18-89 were selected if they had a diagnosis of PsA, RA, or psoriasis. Diagnosis codes for PsA, RA, psoriasis, DVT and PE have been validated in THIN. Up to 5 unexposed controls matched on practice and start date within the practice were selected for each exposed patient. Cox proportional hazards models were used to calculate the relative hazards for each outcome. Multivariable models were constructed to include confounders which changed the main effects by >10% (e.g., hospitalization, cancer, hypertension, hyperlipidemia, liver disease, oral glucocorticoid use, NSAID use, body mass index, smoking, and alcohol use). An interaction with disease modifying anti-rheumatic drug (DMARD) was hypothesized a priori and was significant. Adjusted hazard ratios (aHR) stratified by DMARD are presented. Severe psoriasis was defined as a prescription for a DMARD specific to psoriasis or phototherapy.

Results: Patients with PsA (N=12,447), RA (N=51,949), psoriasis (N=194,639) and unexposed controls (N=1,247,933) were identified. Patients with RA (with and without a DMARD) and patients with psoriasis without a DMARD prescription had a significantly elevated risk of VTE (See Table: aHR 1.50, 1.40, and 1.19 respectively). This risk was elevated but not statistically significant among patients with severe psoriasis and PsA with a DMARD (aHR 1.16 and 1.22 respectively) and not elevated in patients with PsA without a DMARD. While the findings were similar for DVT, the aHR were different for PE. Patients with RA (with and without DMARD) and patients with PsA prescribed a DMARD had a significantly higher risk of PE than controls. Adjusted HR for patients with psoriasis were not statistically significant. These results were robust to several sensitivity analyses.

Conclusion: Patients with RA had a significantly increased risk of VTE compared with the general population even after accounting for risk factors for VTE. VTE and DVT were not significantly elevated in PsA. However, patients with PsA on a DMARD had a substantially increased risk of PE. Further investigation of the increased risk for PE in patients with PsA on a DMARD is needed.

Table. Incidence and Hazard Ratios for Venous Thromboembolism, Deep Venous Thrombosis, and Pulmonary Embolus

		N	VTE Incidence (per 10,000 PY)	VTE HR (95% CI)	DVT HR (95% CI)	PE HR (95% CI)
Controls		1,247,933	29.43*	Ref	Ref	Ref
Psoriatic Arthritis	No DMARD	8,989	23.52	0.81 (0.62-1.07)	0.83 (0.61-1.12)	0.78 (0.41-1.51)
	DMARD	3,458	27.38	1.22 (0.86-1.74)	1.06 (0.71-1.60)	2.16 (1.16-4.02)
Rheumatoid Arthritis	No DMARD	25,183	67.41	1.40 (1.29-1.51)	1.35 (1.24-1.47)	1.64 (1.39-1.92)
	DMARD	26,766	77.32	1.50 (1.40-1.61)	1.44 (1.34-1.56)	1.91 (1.66-2.19)
Psoriasis	No DMARD	188,506	34.98	1.19 (1.14-1.24)	1.21 (1.16-1.26)	1.05 (0.96-1.16)
	DMARD	6,133	35.99	1.16 (0.93-1.44)	1.10 (0.86-1.40)	1.51 (0.98-2.32)

*The incidence of VTE in the UK is 30/10,000 person years. Incidence as shown is unadjusted.

Models were adjusted for age, sex, history of malignancy, hypertension, hospitalization in the baseline period, liver disease, oral steroid and NSAID use in the baseline period, body mass index category, smoking and alcohol intake, joint replacement surgery.

Patients could be included in more than one category (e.g. patients with both psoriasis and PsA were included in both analyses)

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment: Psoriatic Arthritis - CoMorbidities

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Psoriasis, psoriatic arthritis (PsA), and rheumatoid arthritis (RA) are associated with an increased risk for cardiovascular disease (CVD). While management of traditional CVD risk factors improves outcomes, it is unclear to what degree CVD risk factors are recognized and managed in patients with these inflammatory diseases. The objectives of this study were the following: 1) to determine the prevalence and incidence of hypertension (HTN), hyperlipidemia (HL), and diabetes mellitus (DM) among patients with PsA, psoriasis and RA compared to the general population, and 2) to examine the treatment of incident HTN, HL, and DM among patients with RA, PsA, and psoriasis compared to the general population.

Methods: A retrospective cohort study was performed in The Health Improvement Network (THIN), a medical record database in the United Kingdom, among patients with PsA, psoriasis, RA and controls from the general population matched on general practice and start date (1994-2014). Logistic regression analysis was used to examine the relative prevalence of HTN, HL, and DM (defined by diagnosis codes) in RA, PsA, and psoriasis compared to controls after adjusting for age and sex. Cohort studies were performed to determine the incidence of HTN, HL, DM, the hazard ratios for each outcome adjusting for potential confounders, and the receipt of appropriate therapy within one year following these diagnoses.

Results: Study subjects included 12,666 patients with PsA, 193,053 with psoriasis, 54,890 with RA and 1,319,542 matched controls. In patients with PsA, the age/sex-adjusted prevalence of HTN (OR 1.43; 95% CI 1.37-1.49), HL (OR 1.30; 95% CI 1.23-1.36), and DM (OR 1.42; 95% CI 1.35-1.51) were significantly increased compared to controls (see Table). In contrast, in patients with RA, only the age/sex-adjusted prevalence of DM (OR 1.03; 95% CI 1.01-1.06) was significantly increased. The age/sex-adjusted prevalence of HTN, HL, and DM was significantly increased in both mild and severe psoriasis, although higher among patients with severe psoriasis compared to mild psoriasis. The frequency of receipt of therapy among patients with incident diagnoses of HTN, HL, and DM was not significantly different between the disease groups and controls; approximately 80%, 50%, and 60% of patients received prescriptions for HTN, DM, and HL respectively.

Conclusion: In this study, the age-and-sex adjusted prevalence of diagnosed HTN, HL, and DM was higher in psoriasis and PsA compared to RA and controls. Treatment of HTN, DM, and HL was similar between those with inflammatory diseases and controls. This study examined only "diagnosed" HTN, HL and DM and did not examine lifestyle modification or potential under-diagnosis of CVD risk factors. Future work should investigate strategies to manage CVD risk factors in these inflammatory conditions.

	Prevalence	Age/Sex Adj OR (95%CI)	Incidence[2] /10,000 PY	Adjusted-HR[3] HR (95%CI)	Treatment

Severe Psoriasis	759 (12.0%)	1.52 (1.41-1.65)	76	1.34 (1.16-1.54)	53.9%
HYPERLIPIDEMIA					
Control	182557 (13.8%)	REF	118	REF	57.1%
PsA	1996 (15.8%)	1.30 (1.23-1.36)	152	1.34 (1.21-1.48)	57.2%
RA	8924 (16.3%)	0.86 (0.84-0.88)	157	1.08 (1.04-1.12)	63.2%
Mild Psoriasis	24,553 (12.7%)	1.05 (1.04-1.07)	117	1.10 (1.08-1.13)	57.6%
Severe Psoriasis	961 (15.2%)	1.31 (1.22-1.41)	143	1.19 (1.05-1.35)	64.7%

1) Severe psoriasis was defined as patients with psoriasis and a code for either a disease modifying drug or phototherapy.
2) Incidence was specified per 10,000 person years. Incident diagnoses were defined as cases in which the first diagnosis for HTN, HL, or DM occurred after registration with the practice, software implementation ("Vision") date, and diagnosis of the disease (which was assigned for controls).
3) Hazard ratios are adjusted for age, sex, and baseline covariates including charlson comorbidity index, number of visits in the baseline period, body mass index category, smoking status, cardiovascular disease, and the remaining two of hypertension, hyperlipidemia, and diabetes (those with a previous diagnosis of the primary outcome were excluded).

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment: Psoriatic Arthritis - CoMorbidities
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Gender is an important patient characteristic that may potentially be used to predict clinical presentation, disease progression and therapeutic response. In recent studies, women with psoriatic arthritis (PsA) have reported less favorable function, increased fatigue, and decreased quality of life compared to men. Less is known about gender differences with other patient reported outcomes (PROs) such as pain, joint counts, and work limitations. Our purpose was to characterize gender differences in PROs, in participants of the Utah Psoriasis Initiative Arthritis Registry.

Methods: Baseline demographics, PsA characteristics, and PROs were compared between men and women enrolled between January 2010 and November 2014, using student's t-test, Wilcoxon rank sum test, or Chi-square test. Work limitations were assessed in participants working for pay at the time of enrollment. Multivariate logistic regression was used to adjust for age, erythrocyte sedimentation rate (ESR) and PsA severity, as measured by the number of lifetime disease modifying anti-rheumatic drugs (DMARDs).

Results: Participants included 115 men and 138 women. Compared to men, women were older, had higher mean ESR, and were exposed to more DMARDs (Table 1). Women had less favorable unadjusted PROs for pain, fatigue, joint count, physical demands at work, work output, and function as measured by both Health Assessment Questionnaire (HAQ) and the Psoriatic Arthritis Screening and Evaluation (PASE) function subscale (Table 2). After adjustment for age, ESR, and number of lifetime DMARDs, these differences persisted for fatigue and HAQ.

Conclusion: Women experienced PsA differently than men, with higher fatigue and more functional limitations. The etiology of the gender differences in PsA are unclear, and further research is indicated to better understand the role of hormones, gene expression, and other potential pathophysiologic differences between men and women.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment V: Neuropsychiatric Lupus
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Patients with lupus nephritis (LN) may have improvement or deterioration in renal status over time. To capture bidirectional change we used a reversible multistate Markov model to study transitions in glomerular filtration rate (GFR) and proteinuria (PrU) in a prospective, international, inception cohort of SLE patients receiving standard of care.

Methods: Patients were evaluated at enrollment and annually. LN was identified from the ACR classification criteria and/or renal biopsy. Data included medications, estimated GFR (eGFR) and PrU (ePrU), disease activity (SLEDAI-2K), organ damage [(SLICC)/ACR damage index (SDI)] and lupus autoantibodies including IgG anticardiolipin (aCL) and lupus anticoagulant (LAC). GFR states were defined: state 1 (eGFR: >60 ml/min); state 2 (eGFR: 30–60 mL/min); and state 3 (eGFR: <30 ml/min). Similarly, PrU states were defined: state 1 (ePrU: <0.25 gr/day); state 2 (ePrU: 0.25–3.0 gr/day); and state 3 (ePrU: >3.0 gr/day). Multistate models were used to provide estimates of relative transition rates and state occupancy probabilities for various time periods.

Results: Of 1,826 SLE patients, 89% were female, 49.2% Caucasian with mean±SD age 35.1±13.3 years. The mean disease duration at enrollment was 0.5±0.3 years and follow-up was 4.6±3.4 years. LN occurred in 700/1,826 (38.3%) patients. There was no observed change in eGRF state for 2303/2430 (94.8%), 136/255 (53.3%) and 26/55 (47.3%) visits when the previous eGFR state was 1, 2 and 3 respectively. The corresponding values for ePrU states were 1167/1460 (79.9%), 547/983 (55.6%) and 59/205 (28.8%). For both outcomes the likelihood of improvement (states 2 to 1 and 3 to 2) was greater than deterioration (states 1 to 2 and 2 to 3). The transition from state 3 to ESRD was more likely with eGFR (54%) than ePrU (9%). Probability estimates of transitioning between eGFR and ePrU states, ESRD and death at 1, 2 and 5 years were determined. At year one the highest probability was for patients to remain in the initial eGFR (95%, 55%, 42%) or ePrU (81%, 56%, 31%) state. Following 2 and 5 years, the estimated probability for improvement in either eGFR or ePrU was higher than deterioration. Multivariate analysis identified older age ($p<0.001$), race/ethnicity (Hispanic, Asian and African ancestry) ($p<0.001$), higher ePrU state ($p<0.001$), higher renal biopsy chronicity score ($p=0.013$) and baseline aCL antibodies ($p=0.039$) as predictors for deterioration in eGFR states and male sex ($p=0.04$) for improvement. For ePrU, multivariate analysis identified race/ethnicity (Hispanic, Asian and African ancestry) ($p=0.009$), corticosteroid use ($p=0.031$), higher eGFR state ($p=0.011$) and higher renal biopsy chronicity score ($p=0.015$) as predictors for deterioration. Positive LAC ($p=0.006$) and ISN/RPN class V nephritis ($p=0.013$) were associated with lower improvement rate.

Conclusion: Multistate modeling in patients with LN generates probability estimates of transitions between disease states that reflect improvement or deterioration in renal outcomes. This approach can identify predictors of change in renal status and can inform clinical trial design by providing minimum expectations for benefit from new therapeutic interventions for LN.

Session Date: Tuesday, November 10, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment V: Neuropsychiatric Lupus

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

Neurocognitive dysfunction is a common manifestation of childhood-onset Systemic Lupus Erythematosus (cSLE). Murine models suggest that loss of the blood-brain barrier (BBB) integrity allows brain-reactive proteins to enter the CNS and contribute to SLE-associated pathology. Contrast magnetic resonance imaging (MRI) can provide a measure of BBB integrity, but has risk associated with gadolinium use. We have previously identified multiple areas of gray matter (GM) loss on structural MRI in cSLE patients with neurocognitive deficits. Our aim was to evaluate safe, non-invasive MRI-methods of measuring regional BBB permeability and its relationship with neurocognitive function and regional GM volume in cSLE.

Methods:

Twelve cSLE patients and 12 healthy controls (age, gender, race and socioeconomic status matched) were enrolled. Those with diseases or medications (except prednisone) affecting neurocognitive function were excluded. Cognitive performance was assessed using the *cSLE Neurocognitive Battery*, which probes four cognitive domains: working memory, psychomotor speed, attention, and visuoconstructional ability. Performance in each of these was standardized and expressed as a Z-score. We almost concurrently performed arterial spin labeling (ASL) and diffusion-weighted imaging to measure regional BBB permeability. Voxel-based morphometric analysis was done to measure regional GM volume. Voxel-wise comparisons of capillary permeability were made between the cSLE and control groups. Correlation analysis was performed between regional BBB permeability and cognitive performance Z-scores, as well as local GM volume for the cSLE group.

Results:

Among the cSLE patients (11 females, 7 African American, mean age 18 ± 6.8 years), 9 were treated with prednisone (median dose 5 mg/d). None was diagnosed with active neuropsychiatric SLE. Group comparison revealed clusters of voxels with significantly greater BBB permeability for cSLE patients than controls, in three regions as shown in **Figure 1**. Correlations between BBB permeability and regional GM volume or overall and individual domain Z-scores for neurocognitive performance were not statistically significant, although locations of significant increases in permeability for cSLE closely match our previously identified areas of GM loss and functional changes associated with clinically overt neurocognitive impairment.

Conclusion:

We present imaging evidence of altered regional BBB permeability in cSLE, using a novel non-invasive MRI technique. The absence of correlation with GM volume or cognitive performance Z-scores, yet similar location to GM loss in previous work in our cSLE cohort suggests that BBB breakdown may precede clinically overt neurocognitive impairment and brain tissue loss. Longitudinal studies are needed to confirm the change in GM volume in relation to BBB permeability over time.

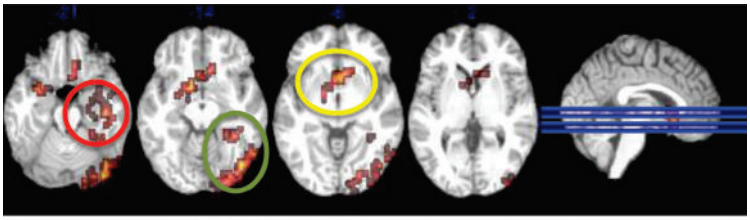

Figure 1: Select slices of a group difference T map for Blood-Brain Barrier permeability (SLE>controls). The three identified significant clusters (< 0.05 family-wise error corrected) are shown with legend.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment V: Neuropsychiatric Lupus

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

MicroRNAs (miRNAs) are small noncoding RNAs that modulate protein translation and regulate numerous immunologic and inflammatory pathways. Certain miRNA profiles have been associated with several diseases, including atherosclerosis. Patients with systemic lupus erythematosus (SLE) are known to have a high prevalence of atherosclerosis and a recent study has shown that circulating miRNAs are systematically altered in SLE.

Therefore, our objective was to investigate the association between markers of atherosclerosis and cell-free circulating microRNAs in patients with systemic lupus erythematosus.

Methods:

120 SLE patients were screened for atherosclerosis by means of cardiac CT demonstrating coronary artery calcification (CAC) and carotid ultrasound visualizing intima-media thickness (IMT) and plaque. Atherosclerosis was defined as either CAC > 99U, carotid IMT>1.00mm and/or carotid plaque. Total RNA was purified from plasma, and 46 specific miRNAs were determined using quantitative real time PCR on a dynamic microfluidic array. Patients with atherosclerosis were compared to those without in terms of expression of cell-free circulating miRNAs.

Results:

Six miRNAs were expressed differently in plasma from SLE patients with atherosclerosis compared to those without. The expression of miR-125b, miR-29b-3p, miR-375, miR-101, miR- 122-5p and miR-20a were all decreased in SLE patients with atherosclerosis.

Unsupervised hierarchical clustering identified miRNA profiles (an 8-miRNA signature) that differentiated a group of SLE patients from the rest. This patient group (n=16) had significantly increased frequencies of recorded venous thrombotic events (p=0.045), a higher prevalence of β_2-glycoprotein 1 IgG antibodies (p=0.029), and significantly lower platelet counts (p=0.024).

Conclusion: Six circulating miRNAs are for the first time shown to be associated with atherosclerosis in a cross-sectional SLE cohort. Furthermore, an 8-miRNA signature was associated with the phenotype of the antiphospholipid syndrome with the patients having a history of venous thrombotic events, β2-glycoprotein 1 antibodies and lower platelet counts. The findings warrant further prospective studies of the putative association between specific circulating miRNAs and vasculopathy in SLE patients.

Session Date: Tuesday, November 10, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment V: Neuropsychiatric Lupus
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Magnetization transfer ratio (MTR) can be used to detect microstructural cerebral changes in normal-appearing brain tissue of neuropsychiatric systemic lupus erythematosus (NPSLE) patients. Our aim was to assess white matter (WM) and grey matter (GM) magnetization transfer ratio histogram peak heights (MTR-HPHs) in different subsets of NPSLE patients with a non-remarkable 3T-brain-MRI and to evaluate whether these values could highlight different clinically suspected underlying pathogenic processes, recognize the clinical NPSLE status or be associated with a specific NPSLE syndrome.

Methods: Sixty-four SLE-patients with neuropsychiatric symptoms were included. The initial NPSLE diagnosis and suspected pathogenic underlying process were established by multidisciplinary evaluation. Furthermore, we performed a re-evaluation of the disease course and confirmation of the diagnosis 6-18 months later. Thirty-three patients with central nervous system (CNS) NPSLE and 31 SLE patients with neuropsychiatric complaints non-related to SLE (NP-non-SLE) were included. Twenty SLE patients without neuropsychiatric complaints and 36 healthy controls were included for comparison. Differences of mean WM and GM MTR-HPH values between different NPSLE subgroups (inflammatory or ischemic NPSLE phenotype), the clinical changes after treatment and the relation with NPSLE syndromes were evaluated.

Results: The mean and standard deviation of the WM and GM MTR-HPHs are presented in Table 1. Inflammatory NPSLE patients have significantly lower WM MTR-HPH than healthy controls ($P < 0.001$), SLE ($P < 0.001$) and NP-non-SLE patients ($P < 0.05$) (Figure 1). Cognitive disorder, mood disorder and psychosis were related to lower values and cerebrovascular symptoms to higher values of WM MTR-HPH ($P < 0.05$). Furthermore, we show how the mean WM MTR-HPHs increased when the clinical status of the NPSLE patients improved ($P < 0.001$) (Figure 1).

Conclusion: WM MTR-HPH has potential to identify inflammatory NPSLE with CNS involvement corroborating the usefulness of this technique to detect cerebral changes in NPSLE patients and to assess clinical changes after treatment.

Table 1. Comparison of white matter and grey matter MTR-HPHs in the study groups					
	Healthy controls (n=36)	SLE (n = 20)	NP-non-SLE (n = 31)		
				Phenotype	
				Inflammatory NPSLE (n=22)	Ischemic NPSLE (n = 11)
WM MTR-HPH µ	43.37 ± 5.11†	42.74 ± 6.22†	38.35 ± 4.64‡	32.22 ± 7.76	39.42 ± 4.21†
GM MTR-HPH µ	10.01 ± 2.51	10.02 ± 1.92‡	9.81 ± 3.68	7.71 ± 3.25	10.25 ± 2.85

CNS: central nervous system; GM: grey matter; MTR-HPH: magnetization transfer ratio histogram peak height; NP-non-SLE: SLE patients with neuropsychiatric complaints non associated with CNS involvement due to SLE; NPSLE: neuropsychiatric SLE; SLE: systemic lupus erythematosus; WM: white matter.

* Values are the mean ± standard deviation.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment V: Neuropsychiatric Lupus

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Cytokines and neuronal injury markers act as crucial mediators in the bidirectional signaling between the immune system and the brain and may be biomarkers for brain damage. The aim of this study was to determine the prevalence of hyperintense white matter (WM) lesions and to elucidate the possible relationship between biomarkers such as Th1 (IL-12, IFN-γ, TNF-α), Th2 (IL-4,6,10) cytokines and S100β, subunit of high molecular weight neurofilament (NF-H) and antiribosomal P protein antibodies (anti-P) and WM lesions in systemic lupus erythemathosus (SLE) patients.

Methods: Consecutive SLE patients followed at the Rheumatology unit of the State University of Campinas were enrolled in this study. Healthy volunteers, matched by age and sex, were included as control group. A complete clinical, laboratory and neurological evaluation was performed in all subjects. Neurological manifestations were analyzed according to the ACR classification criteria. SLE patients were further assessed for clinical and laboratory SLE manifestations, disease activity [SLE Disease Activity Index (SLEDAI)], damage [Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index (SDI)] and current therapy. WM lesions were analyzed in T2-weighted images (3T Phillips®scanner) using a semiautomated computer program (Neuroline®). Th1, Th2 cytokines and S100β, NF-H and anti-P were measured by ELISA using commercial kits. Data were compared by non-parametric tests.

Results: One hundred fifty SLE patients (138 women; mean age of 42.03±11.37; range 24-73) and 56 (50 women; mean age of 41.35±12.44; range 18-69) healthy controls were included. WM lesions were identified in 121 (80.67%) SLE patients and in 4 (7.4%) healthy controls (p=0.001). In SLE patients, we observed, predominantly, subcortical lesions (74.67%), followed by periventricular (65.33%), deep WM (59.33%) and cortical (26.67%) lesions. Both the number (N=6549 *vs* N=27; p=0.001) and the volume of lesions (244109.94cm^3 *vs* 994.65cm^3; p<0.001) were significantly increased in SLE patients compared to controls. Significantly increased sera levels of Th1 [IL-12 (p=0.026), IFN-γ (p=0.021), TNF-α (p<0.001)], Th2 [IL-4 (p=0.006), IL-6 (p=0.008) and IL-10 (p<0.001)], S100β (p=0.006), NF-H (p<0.001) and anti-P (p<0.001) were observed in SLE patients compared to controls. We observed an association between the presence of subcortical lesions and IL-10 (p=0.018) and TNF-α (p=0.014). The presence of deep WM lesion was associated with IFN-γ (p=0.04). We also identified an indirect correlation between the volume of subcortical lesions and IL-10 (r=-0.26; p=0.027). We did not observe an association between WM lesions and neuronal injury markers, current corticosteroid dose or any other clinical or laboratory manifestations.

Conclusion:

TNF-α, IFN-γ and IL-10 levels are associated with WM lesion in SLE, suggesting that peripheral inflammation contributes to WM by triggering an inflammatory response in the microglia. Both Th1 and Th2 cytokines may be useful as biomarkers for brain damage in SLE, once they play a critical role in the interface between the systemic circulation and the brain.

Session Date: Tuesday, November 10, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment V: Neuropsychiatric Lupus

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

Peripheral neurologic syndromes and central nervous system (CNS) manifestations are recognized as primary disease manifestations in systemic lupus erythematosus (SLE). Neuropsychiatric SLE (NPSLE) involves a wide range of nervous system disorders, and can affect 50% or more of SLE patients(1). There is no single diagnostic test specific for NPSLE; rather, the diagnosis is currently based on the combined use of serological testing, functional and/or structural neuroimaging, and standardized neurological and neuropsychological assessments(1). A sensitive and specific serological biomarker for NPSLE would be very helpful in the management of lupus patients. Using a novel antigen microarray platform, unique multivariate classification models were developed to distinguish between patients with NPSLE and SLE patients without active neuropsychiatric manifestations (non-NPSLE).

Methods:

Thirty-eight SLE serum samples were obtained from the Einstein Lupus Cohort at the Albert Einstein College of Medicine (Bronx, NY) and tested using the ImmunArray iCHIP®(2), printed with a set of 225 antigens associated with SLE and/or brain injury. All SLE samples satisfied the ACR classification criteria. Twelve of the 38 patients were diagnosed as positive for NPSLE based on the use of a validated questionnaire

(3). Two independent classification methods were developed. Classifier training and testing were performed based on 5-fold cross validation on all samples.

Results:

Both classification methods differentiated between the lupus patients with and without neuropsychiatric symptoms. The support vector machine (SVM) classification model performed with sensitivity greater than 99% and specificity of 88%. The logistic regression method separated the populations with 83% sensitivity and 96% specificity. Several auto-antigens were shared between the two models, increasing the confidence in the selected antigen lists.

Conclusion:

In a proof of concept study, classification methods based on autoantibody profiles from the ImmunArray iCHIP® were able to successfully distinguish between lupus patients with and without neuropsychiatric symptoms. Our preliminary results based on 38 patients are very promising and warrant additional validation in a larger cohort of NPSLE patients.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics II

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: The etiology and mechanisms underlying the wide variation in disease heterogeneity and severity in systemic sclerosis (SSc) remain unknown. To assess the role of DNA methylation in SSc risk and clinical heterogeneity while controlling for genetic background, we performed a genome-wide DNA methylation analysis in whole blood and skin fibroblasts of twin pairs discordant for SSc. We also performed gene expression analysis from the same fibroblasts to investigate the relationship between the DNA methylation changes and mRNA expression levels.

Methods: Genome-wide methylation was assessed on approximately 480,000 CpG sites using genomic DNA isolated from 1) whole blood from 20 twin pairs discordant for limited cutaneous SSc (lcSSc) and 10 twin pairs discordant for diffuse cutaneous SSc (dcSSc), and 2) skin fibroblasts cultured from dermal punch biopsies of 7 twin pairs discordant for dcSSc and 5 twin pairs discordant for lcSSc. Total RNA was extracted from fibroblasts in passage 3 for gene expression profiling of 47,000 transcripts. An efficiency analysis was performed with caGEDA to determine best normalization and feature selection methods and to identify differentially methylated probes and differential gene expression between unaffected and affected twins. Ingenuity Pathway Analysis was used for pathway analysis.

Results: A total of 68 CpGs were differentially methylated in whole blood from patients with SSc compared with their healthy twin. In the disease subsets, 206 and 409 CpGs were differentially methylated in the twin pairs discordant for lcSSc and dcSSc, respectively. Only 1% of

differentially methylated genes were common between both subsets. In the dermal fibroblasts, 103 CpGs were differentially methylated in patients with SSc compared with their healthy twin. In the disease subsets, 110 and 220 CpGs were differentially methylated in lcSSc and dcSSc, respectively. 7% of differentially methylated genes were common between both subsets. In each disease subset, less than 2% of differentially methylated genes were observed in blood and fibroblasts. Despite the enrichment of different pathways and biological functions in each cell type and disease subset, most of these pathways can be placed into broader categories implicating an overall involvement of cancer functions. On the other hand, gene expression data from fibroblasts revealed 20% of genes shared between disease subsets. There were common and unique pathways enriched in disease subsets, also implicating an involvement of cancer functions. There were no genes simultaneously differentially methylated and expressed in either disease subset.

Conclusion: The distinct methylation patterns observed in blood and fibroblasts between lcSSc and dcSSc corroborate a similar observation reported in skin fibroblasts and suggest that subset-specific epigenetic signatures may be, at least in part, responsible for the clinical heterogeneity of the disease. These data also support a role for DNA methylation differences in mediating susceptibility to SSc.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics II

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Gastrointestinal tract (GIT) dysfunction is a leading cause of morbidity in patients with systemic sclerosis (SSc). However, the etiology of SSc-related lower GIT dysfunction remains elusive. The purpose of the present study was to compare colonic microbial composition of SSc patients and healthy controls and to determine whether certain microbial genera are associated with SSc-GIT symptoms.

Methods: Adults SSc patients who had no contraindication to colonoscopy were eligible to participate. Patients were excluded if they were on chronic antibiotic therapy. Healthy controls were age- and gender-matched to SSc patients (1:1). Cecum and sigmoid mucosal lavage samples were obtained during colonoscopy. SSc patients completed the GIT 2.0 questionnaire to assess GIT symptom severity at the time of colonoscopy. The microbiota from these samples were determined by Illumina HiSeq 2000 16S sequencing, and operational taxonomic units (OTU) were selected using the Greengenes database at 97% identity. Linear Discriminant Analysis (LDA) Effect Size was used to identify the genera that showed differential expression in SSc versus controls. Multivariate Association with Linear Models (MaAsLn) was used to identify specific genera associated with GIT symptoms.

Results: Among 17 patients with SSc (88% Female; Median age 52.1 years), the mean (SD) total GIT 2.0 score was 0.7 (0.6). Principal coordinate analysis illustrated significant microbial community differences in SSc versus healthy controls in the cecum ($p=0.001$) and sigmoid ($p=0.001$) regions (Figure 1). Similar to inflammatory disease states, SSc patients had decreased commensal genera, such as *Faecalibacterium* and *Clostridium* and increased pathogenic genera, such as *Fusobacterium*, *Erwinia* and *Trabsulsiella* compared with healthy controls. However, SSc patients had increased *Bifidobacterium* and *Lactobacillus*, which are typically reduced in inflammation. Increased *Erwinia* and *Trabsulsiella* levels were associated with increased scores on the constipation and diarrhea domains of the GIT 2.0.

Conclusion: This study demonstrates a distinct colonic microbial signature in SSc patients compared with healthy controls. This unique ecological change may perpetuate immunological aberrations and contribute to clinical manifestations of SSc.

Figure 1. Significant differences in the beta diversity of the SSc and healthy samples as demonstrated by principal coordinate analysis plots of the unweighted UniFrac distance for the cecum (top panel) and sigmoid (bottom panel) samples. Each dot represents a sample from a SSc patient (closed circle) or a healthy control (open circle).

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics II

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

Monocytes from patients with systemic sclerosis (Scleroderma, SSc), are characterized by the increased expression of IFN-regulatory genes, implicating dysregulation of the innate immune response in activation of these cells. However, what triggers and sustains monocyte activation in SSc remains unclear. Since Epstein-Barr virus (EBV) mRNA and proteins were found in fibroblasts and endothelial cells in SSc skin, we sought to determine whether EBV might also infect monocytes and contribute to their activation in SSc.

Methods:

Monocytes were isolated from peripheral blood mononuclear cells (PBMCs) depleted of CD19+ cell fraction, using CD14/CD16 negative depletion (CD14-) (Human Monocyte Enrichment Kit without CD16 Depletion,EasySep, StemCell). Circulating monocytes from diffuse cutaneous SSc (dcSSc) (n=8) and healthy donors (HDs) (n=6), were examined for the presence of EBV lytic proteins using Immunofluorescence (IF). EBV-p2089 recombinant virus was used to infect dcSSc and HDs monocytes. Gene expression of IFNs, TLRs (TLR7/8/9) and innate immune mediators (IRF5/7) was evaluated in EBV-p2089 infected dcSSc and HD monocytes using real-time PCR, and proteins examined by IF staining and Western Blot. Flow cytometry was performed on dcSSc and HD PBMCs labeled with phycoerythrin (PE), allophycocyanin (APC), fluorescein isothiocynate (FITC) and PE-cyanine7 (PE-Cy7) conjugated mouse monoclonal antibodies (mAb) against human CD14, CD16, CD163, CD206, CD169/siglec1, CD4, CD8, CD20, CD19, CD23. THP1 monocytes were stimulated with TLR7 (R837) and TLR8 synthetic ligands (cpd14b, R848).

Results:

We found that EBV lytic proteins (Zebra, BFRF1 and gp-350/220), were expressed in skin macrophages and in circulating monocytes from SSc patients, while no expression of lytic EBV was detected in monocytes/macrophages from HDs. Infection of SSc monocytes by EBV-p2089 strongly induced TLR8 expression, while no induction of TLR7 and TLR9 was observed in the infected cells. EBV also significantly induced markers of activated monocytes, such as IRF7, IRF5, Siglec1 and IL-6. Further supporting the importance of TLR8 activation in SSc, expression of TLR8 was significantly increased in freshly isolated monocytes from dcSSc patients compared to HDs. Furthermore, distinct monocyte subsets (CD14+/CD16++) and activation markers were identified in dcSSc PBMCs compared to HDs by FACS analysis. Activation of TLR8 by synthetic ligands mimicked EBV effects on TLR8, inducing IRF7 and inflammatory cytokines, whereas the TLR7 agonist did not induce monocyte inflammation markers on THP1 cells.

Conclusion: These data suggest that dcSSc monocytes are carrying an EBV lytic infection. Activation of TLR8 by EBV RNA might represent a novel mechanism in mediating monocyte inflammation in SSc by which EBV triggers the innate immune response in infected cells.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics II

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: A recent global gene expression profile study in a large early SSc patient samples revealed a type I interferon (IFN) signature. Type I IFN and associated genes might serve as biomarkers of more severe disease. Interferon regulatory factors (IRFs) are transcriptional regulators of type I IFN and IFN-inducible genes. Furthermore, IRF7 gene polymorphisms are associated with SSc susceptibility. In our most recent global gene expression study, IRF7 was the most prominent transcription factor in SSc skin (manuscript in press). However, the specific role of IRF7 in SSc pathogenesis has not been identified.

Methods: Early passage SSc fibroblasts (n=20) and age-, gender-, and ethnicity- matched control fibroblasts (n=20) were investigated. SSc and healthy control skin biopsies (14 SSc patients and 14 healthy controls) were used to quantify IRF7 expression by qPCR and protein expression by immunohistochemistry (IHC) analyses. IRF7 expression and activation were also determined in bleomycin induced SSc mouse model. Lesional murine skin tissues were examined by IHC analysis. To better understand the role of IRF7 in SSc pathogenesis, we utilized the bleomycin animal model with a loss-of-function approach. IRF7 KO (n=10) and wild-type mice (n=10) received daily subcutaneous bleomycin injection for 7 or 28 days. The lesional skin was harvested and processed for analysis. For *in vitro* experiments, we used IRF7 KO and wild-type fibroblasts to further investigate the role of IRF7 in fibroblast biology.

Results: IRF7 mRNA and protein levels were significantly up-regulated in SSc skin biopsies compared to control subjects. Furthermore,

compared to control subjects, IRF7 activation was prominent in fibroblasts and macrophages in SSc skin. Explanted skin fibroblast results further confirmed IRF7 mRNA up-regulation (SSc vs control; fold change = 2.37; p=0.024) and protein activation (IRF7 phosphorylation) in SSc. Interestingly, IRF7 showed complex dimerization with SMAD3 in vitro which is a major transcription factor of the TGF-b driven fibrosis signaling. In the bleomycin animal model studies, IRF7 KO mice demonstrated attenuated dermal thickness (IRF7 KO vs wild-type: 162.8 ± 13.6 µm vs 251.3 ± 24.5 µm; p=0.004) as well as inflammatory response and other fibrosis features compared to C57BL/6 wild-type mice after receiving bleomycin for 7 or 28 days. TGF-β1 (IRF7 KO vs wild-type: 1.98 ± 0.76 vs 3.09 ± 0.14 fold changes; p=0.025) and IL6 mRNA expression were significantly abrogated in IRF7 KO mice skin tissue compared to wild-type mice exposed to bleomycin for 7 days. Interestingly, Col1a2 (IRF7 KO vs wild-type: 1.23 ± 0.13 vs 2.36 ± 0.68 fold changes; p=0.008), α-SMA (p=0.035) and CTGF (p=0.046) mRNA expression were also significantly abrogated in IRF7 KO mice skin tissue compared to wild-type mice of 28 days bleomycin injection. Furthermore, IRF7 KO dermal fibroblasts showed reduced collagen and a-SMA protein levels compared to wild-type mice fibroblasts.

Conclusion: Up-regulation and activation of IRF7 in SSc might play a pivotal role in the IFN driven inflammatory response as well as the TGF-ß-driven fibrotic process. IRF7 may therefore represent as a promising novel therapeutic target in SSc.

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics II

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

Scleroderma (SSc) is a complex disease characterized by inflammation, vascular complications, and excessive deposition of extracellular matrix. Vascular dysfunction represents a disease initiating event in SSc. Indeed, endothelial cell (EC) damage is thought to trigger a self-fueling process that results in tissue fibrosis. Recent data suggest that epigenetic dysregulation impairs normal angiogenesis and can result in abnormal blood vessel growth patterns in various disease conditions. Studies have shown that histone deacetylases (HDACs) control EC proliferation and participate in EC migration. Specifically, HDAC5 appears to be anti-angiogenic through the repression of pro-angiogenic factors such as basic fibroblasts growth factors (bFGF), vascular endothelial growth factor (VEGF), and epherin B2. The phenotypic and functional abnormalities of SSc ECs are stable *in vitro*over multiple generations of tissue culture, suggesting that persistent epigenetic changes might play a role in EC dysfunction in SSc. We hypothesized that HDAC5 contributes to impaired angiogenesis in SSc by repressing pro-angiogenic factors in ECs.

Methods:

Dermal ECs were isolated from biopsies from patients with diffuse cutaneous SSc. HDAC5, VEGF, and ephrin B2 expression were determined by qPCR. HDAC5 was knocked down using HDAC5 siRNA. Angiogenesis was assessed by an *in vitro*Matrigel tube formation assay. bFGF and VEGF in culture media were measured using ELISA. A paired t-test was used to compare differences between groups, and a p-value of <0.05 was considered significant. An assay for transposase-accessible chromatin using sequencing (ATAC-seq) was performed to assess and localize genome-wide effects of HDAC5 knockdown on chromatin accessibility.

Results:

The expression of HDAC5 was significantly increased in SSc ECs compared to normal ECs (0.0058 ± 0.0017 vs. 0.0028 ± 0.0003, $p<0.05$) while pro-angiogenic ephrin B2 was down regulated (0.0021 ± 0.0011 vs. 0.0096 ± 0.0005, $p<0.05$). Cells transfected with HDAC5 siRNA showed 87% knockdown in SSc ECs. Silencing of HDAC5 in SSc ECs restored normal angiogenesis, as reflected by a significant increase in tube formation on Matrigel compared to sham-transfected cells. After HDAC5 knockdown, ephrin B2 mRNA decreased 50% compared to sham-transfected group in SSc ECs. In contrast, SSc ECs released increased amounts of VEGF and bFGF into the cell culture media (2 and 1.2 fold for

VEGF and bFGF). In addition, VEGF mRNA increased significantly after HDAC5 knockdown (2.9 fold, $p<0.05$). ATAC-seq was used to identify additional HDAC5-regulated targets in EC, which will help to further mechanistically understand the anti-angiogenic effects of HDAC5.

Conclusion:

By knocking down HDAC5 in SSc ECs, we were able to restore the tube-forming ability of these cells. Our data indicate that overexpression of HDAC5 in SSc gears ECs to an anti-angiogenic state via repressing pro-angiogenic factors such as VEGF and bFGF. This appears to be a complicated process, as HDAC5 knockdown decreased pro-angiogenic ephrin B2. We provided a link between epigenetic regulation and impaired angiogenesis in SSc, and present a novel mechanism for the dysregulated angiogenesis that characterizes this disease.

The Anti-Fibrotic Effect of Endostatin-Derived Peptide Is Mediated By the Urokinase Pathway Via Binding to Enolase-1 and Urokinase Plasminogen Activator Receptor

Session Title: Systemic Sclerosis, Fibrosing Syndromes and Raynaud's - Pathogenesis, Animal Models and Genetics II

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Fibroproliferative disorders such as systemic sclerosis (SSc) have no effective therapies and result in significant morbidity and mortality. We recently demonstrated that the C-terminal domain of endostatin known as E4 prevented and reversed both dermal and pulmonary fibrosis. Our goal was to identify the E4 receptor and the mechanism by which E4 abrogates fibrosis.

Methods: To identify E4 binding, we conducted a pull down assay using biotinylated-E4 and neutravidin-beads. Proteins that bound E4 in fibroblasts were identified by mass spectrometry. Binding was confirmed using immunoblotting. To assess the mechanism by which E4 exerts anti-fibrotic effects *in vitro*, lung fibroblasts were treated with TGF-b with vehicle or E4. The expression levels and activity of urokinase plasminogen activator (uPA) and plasminogen activator inhibitor-1 (PAI-1), an inhibitor of uPA, were evaluated by immunoblotting and activity assays, respectively. Since MMP-1 and MMP-3 are downstream effectors of plasminogen activation, we assessed MMP-1 and -3 activity using collagen and casein zymography, respectively. *In vivo*, bleomycin with vehicle or E4 was administered intratracheally to C57BL/6J male mice to induce lung fibrosis. Bronchoalveolar lavage fluid (BALF) was collected on days 3, 5, 7, and 14 post treatment, and the levels and activity of uPA and PAI-1 were measured. Furthermore, the mRNA levels of uPA and PAI-1 in human whole lung tissue and primary lung fibroblasts from 9 healthy controls (HC) and 32 SSc patients were measured using real-time PCR.

Results: Proteins bound to biotinylated-E4 were identified as enolase-1, known as a plasminogen receptor, and urokinase plasminogen activator receptor (uPAR). TGF-b reduced uPA levels and increased PAI-1 levels in primary fibroblasts. E4 abrogated these effects and increased the uPA/PAI-1 ratio. Moreover, E4 increased MMP-1 and MMP-3 expression and activity. Knockdown of uPAR abolished the anti-fibrotic activity of E4. Plasminogen exerted anti-fibrotic activity similarly to E4 treatment. *In vivo*, bleomycin reduced uPA levels and activity, and increased PAI-1 levels and activity in BALF. E4 reduction of PAI-1 preceded the increase in uPA activity, suggesting that a release from inhibition may explain in part the increase in uPA activity. Finally, the uPA:PAI-1 ratio was decreased in both SSc patient lung tissues and fibroblasts, compared to HC. The lowest uPA:PAI-1 ratio was detected in SSc patients with pulmonary fibrosis.

Conclusion: Our findings show that E4 binds enolase-1 and uPAR, suggesting that E4 bridges enolase-1 and uPAR, likely to facilitate activation of enolase-bound plasminogen by uPAR-bound uPA. The anti-fibrotic effect of E4 is mediated, in part, by its increase uPA and activation of plasminogen. Further, E4 induces MMP-1 and MMP-3 levels and activity, thus promoting extracellular matrix degradation. In SSc patients, the uPA/PAI-1 balance shifted toward PAI-1. Taken together, our findings suggest that E4 exerts its anti-fibrotic effects via regulation of the urokinase pathway. Thus, E4 is a promising therapeutic agent for SSc.

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's - Clinical Aspects and Therapeutics II

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Interstitial lung disease (ILD) is a common and serious complication of systemic sclerosis (SSc). Pirfenidone, a novel antifibrotic agent, has been shown to be safe and effective in the treatment of idiopathic pulmonary fibrosis (IPF). The LOTUSS study was designed to assess the safety and tolerability of pirfenidone in patients with SSc-ILD.

Methods: This is an open-label, 16-week study. Patients were randomized to a 2- or 4-week titration to the target dose of 2403 mg/day. Eligibility required a diagnosis of SSc ≤7 years from first non-Raynaud's symptom, HRCT-confirmed ILD, FVC ≥50% and DL_{co} ≥40%, absence of clinically significant pulmonary hypertension or severe GERD. Stable treatment with mycophenolate mofetil (MMF) or oral cyclophosphamide was permitted. Safety assessments included collection of treatment emergent adverse events (TEAEs), vital signs, ECGs and laboratory tests. Though the study was not designed or powered to evaluate efficacy, FVC %-predicted, DL_{co} %-predicted, modified Rodnan skin score (mRSS), Mahler BDI/TDI, and UCLA SCTC GIT 2.0 were recorded at baseline and 4 months.

Results: Of the 63 patients enrolled, the mean (SD) age was 50.6 (12.3) years; the majority were female (82.5%) and white (76.2%). The mean (SD) SSc duration was 38.3 (26.0) months. Forty patients (63.5%) were on MMF and the rest (36.5%) were not receiving any immunosuppressants. The mean (SD) mRSS, %FVC and $\%DL_{co}$ at baseline were 11.4 (9.6), 76.0 (14.2) and 59.7 (16.5), respectively.

The frequency and type of TEAEs were similar for both titration groups. The safety results are summarized below. No clinically significant changes in vital signs, ECGs, or laboratory tests were observed.

At week 16, the median change from baseline in %FVC was -0.5% (range -42% to 12%); 10 patients (16.7%) had an increase ≥5% whereas 5 (8.3%) had a decrease >5% at week 16. Median change from baseline in $\%DL_{co}$ was 1.5% (range -24.0% to 40.0%); 19 subjects (31.7%) had an increase ≥5% vs. 10 (16.7%) had a decrease >5% at week 16. Minor changes (mean±SD) were observed in Mahler TDI (1.0±3.41) and mRSS (-0.4±3.71). No change was noted in the GI symptoms on UCLA SCTC GIT 2.0.

Conclusion: In the 16-week, open-label trial of pirfenidone in SSc-ILD, pirfenidone was safe and generally well-tolerated in SSc-ILD patients, despite pre-existing co-morbidities, including underlying GI disease, and concomitant use of MMF. The AEs were expected and consistent with those previously seen in IPF trials. The data support further investigation of pirfenidone in SSc-ILD.

Safety Summary	
	All Patients (N=63)
Total Number of TEAEs	521
No. of Patients with Any TEAEs	61 (96.8%)
No. of Patients with TEAEs by Maximum Intensity	
Mild TEAEs	19 (30.2%)
Moderate TEAEs	30 (47.6%)
Severe TEAEs	12 (19.0%)
Most Common TEAEs (>=10% of Patients)

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's - Clinical Aspects and Therapeutics II
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose:

Systemic sclerosis (SSc) is a rare and clinically heterogeneous autoimmune disorder characterised by fibrosis and microvascular obliteration of the skin and internal organs, particularly the heart, lungs, kidneys and the digestive tract. Organ involvement mostly manifests after a variable period of the onset of Raynaud's phenomenon (RP). Using data from the large, multinational EUSTAR cohort, we aimed to map the incidence and predictors of pulmonary, cardiac, gastrointestinal (GI) and renal involvement in the early course of SSc.

Methods:

Patients from the EUSTAR cohort with early SSc, defined as those who had a visit within the first year of RP onset were studied. Outcome measures were analysed as a function of time after RP onset using Kaplan-Meier methods, and Cox regression analysis was used to evaluate predictors of incident organ manifestations.

Results:

Of the 695 SSc patients in the EUSTAR database who had a baseline visit within one year after RP onset, the incident non-RP manifestations (in order of frequency) were: skin sclerosis (75%), GI symptoms (71%), impaired diffusing capacity for carbon monoxide of <80% predicted (65%), digital ulcers (34%), cardiac involvement (32%), impaired forced vital capacity (FVC) of <80% predicted (31%), increased resting systolic pulmonary artery pressure estimated by echocardiography (PAPsys)>40mmHg (14%), and renal crisis (3%; Figure 1).

Diffuse skin involvement was a significant predictor of incident FVC impairment (Figure 2; Table 1), older age and male sex were predictors of incident PAPsys>40mmHg (Figure 2; Table 1), and anti-topoisomerase positivity and older age were predictors of incident cardiac manifestations (Table 1). Incidence rates were highest for diastolic dysfunction, followed by conduction blocks and pericardial effusion. Male sex, anti-RNA-polymerase-III positivity and older age were predictors of renal crisis (Table 1).

Conclusion:

In SSc patients presenting early after RP onset, approximately half of all incident organ manifestations occur within 2 years. These findings may have implications for the design of new diagnostic and therapeutic strategies aimed to ‘widen' the still very narrow ‘window of opportunity'. They may also enable physicians to counsel and manage patients presenting early in the course of SSc more accurately.

-

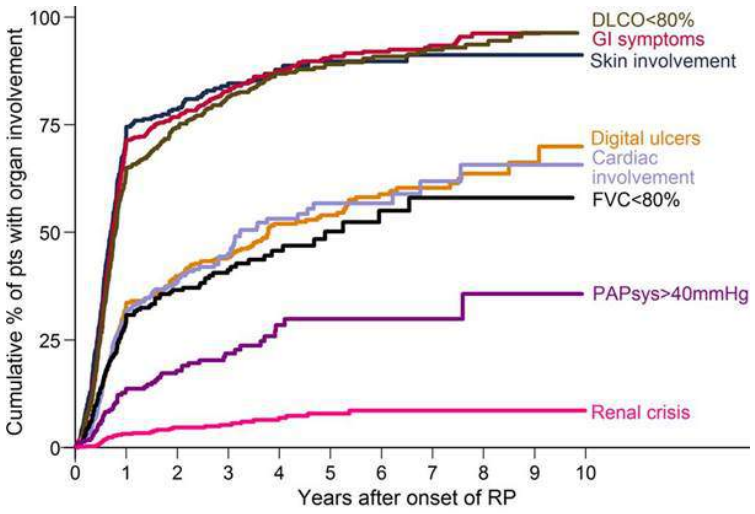

Figure 1 Kaplan-Meier curves of incident organ involvement in SSc patients after RP onset.

RP - Raynaud's phenomenon; Pts - patients; DLCO - single breath diffusing capacity for monoxide; GI symptoms - gastrointestinal symptoms - defined as a history of either dysphagia, reflux, early satiety, vomiting, diarrhoea, bloating or constipation; Skin involvement - defined as a modified Rodnan skin score of ≥2 at any part of the body; Cardiac involvement - defined as either the presence of diastolic dysfunction, conduction blocks, a left ventricular ejection fraction (LVEF) < 50%, or a pericardial effusion; FVC - forced vital capacity; PAPsys - systolic pulmonary artery pressure as estimated by echocardiography.

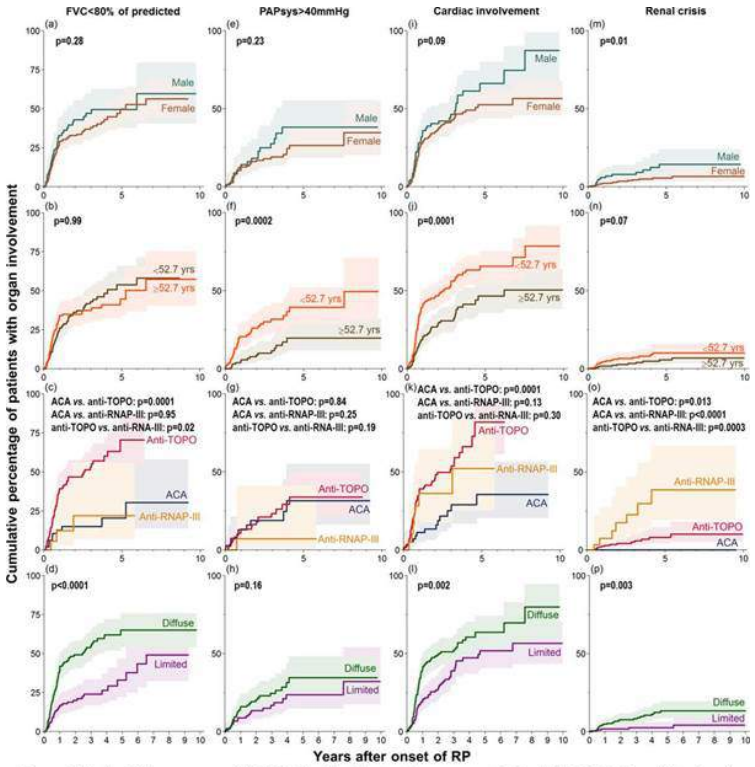

Figure 2 Kaplan-Meier curves with 95% CI of incident pulmonary restriction (FVC<80% of predicted; a-d), suspected pulmonary hypertension (PAPsys>40 mmHg; e-h), cardiac involvement (i-l) and renal crisis (m-p) after RP onset in SSc patients; stratified by sex (a/e/i/m), the median age at RP onset (b/f/j/n), autoantibody status (c/g/k/o) and extent of skin involvement within the first year after RP onset (d/h/l/p).

CI - confidence interval; FVC - forced vital capacity; PAPsys - systolic pulmonary artery pressure as estimated by echocardiography; cardiac involvement - defined as either the presence of diastolic dysfunction, conduction blocks, a left ventricular ejection fraction (LVEF)<50%, or a pericardial effusion; RP - Raynaud's phenomenon; yrs – years; ACA - anti-centromere autoantibodies; Anti-TOPO - Anti-topoisomerase-I autoantibodies; Anti-RNAP-III - anti-RNA-polymerase-III autoantibodies.

Impact of Prokinetic Agents on Systemic Sclerosis-Associated Gastrointestinal Disease: A Systematic Review

Annaliese Tisseverasinghe[1], Ahmad Kadhim[2], Ambica Parmar[2], Louis Liu[2] and Sindhu R. Johnson[1], [1]Toronto Scleroderma Program, Division of Rheumatology, Toronto Western Hospital, Mount Sinai Hospital, Institue of Health Policy, Management and Evaluation, University of Toronto, Toronto, ON, Canada, [2]Division of Gastroenterology, Toronto Western Hospital, University of Toronto, Toronto, ON, Canada

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's - Clinical Aspects and Therapeutics II

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: More than 90% of patients with Systemic Sclerosis (SSc) have gastroinstestinal (GI) involvement, commonly dysmotility causing complications such as gastroesophageal reflux and constipation. Treatment with prokinetic drugs is mostly modelled on their use in the general population, despite pathophysiological differences between GI disease in SSc and other etiology. Thus, our goal is to identify and appraise all studies evaluating the impact of prokinetics on GI outcomes in patients with SSc.

Methods: Three databases (Cochrane Central Register of Controlled Trials, Ovid MEDLINE, and Embase) were searched until November 27, 2013 using permutations of the terms “scleroderma” and “systemic sclerosis” combined with “prokinetic”, “anti-emetic”, and generic and trade names of individual drugs. Studies were included if they evaluated the impact of a prokinetic on any GI outcome in at least 5 adults (age > 18 years) with SSc, regardless of language or study type. Two reviewers independently evaluated all studies, and conflicts were resolved by a third.

Results: Of 492 search results, 21 studies from 12 countries met our criteria (Figure 1). The sample sizes ranged from 5 to 64, with 362 participants in all (83% women), ranging in age from 30 to 80 years. Using Cochrane guidelines, 7 studies had high risk of bias in at least one domain for at least one outcome measure (Table 1). Six prokinetics were evaluated: cisapride in 9 studies, metoclopramide in 6, octreotide in 2, erythromycin in 2, and mosapride and clebopride in 1 study each. Only 2 studies evaluated >1 prokinetic. Outcomes included GI motility as evaluated by manometry (ex. esophageal sphincter pressure), scintigraphy (ex. gastric emptying time), and hydrogen breath tests; serum levels of motility-altering peptides (ex. motilin); and symptoms (ex. Index of Gastrointestinal Status). Each prokinetic was associated with a favourable

outcome in at least half the studies that evaluated it, without serious adverse effects, except diarrhea with octreotide in one study. The heterogeneity in treatment administration, outcomes, and comparator groups precluded any meta-analyses.

Table 1: Summary of Included Studies
Legend: RCT = randomized controlled trial, NRCT = non-randomized controlled trial, B&A = before & after study, * = cross-over design, E = esophagus, G = gastrum, SB = small bowel, LB = large bowel, GB = gall-bladder, SZM = Shenzhe Zhuyun mixture, LESP/UESP = lower/ upper esophageal sphincter pressure, QOL = quality of life, PW = peristaltic wave, Sx = symptoms, PP = pancreatic polypeptide, L = low, H = high, M = mixed, with high risk of bias for patient reported outcomes (i.e. Sx), and low risk of bias for all other outcomes

Conclusion: Available studies suggest a favourable side-effect profile and impact of prokinetics on SSc-associated GI disease, but are limited by small numbers, lack of uniform outcome measures, and risk of bias. Evaluation of prokinetics in larger SSc cohorts using validated and standardized outcome measures are needed to assess the generalizability of these findings, and to determine the ideal type, dose, and duration of prokinetics for a given GI dysfunction in SSc.

Abstract Number: 3137

Scleroderma Hand Contracture Study

Joyce Joseph, Rheumatology, Univeristy of Teas Health Science Center at Houston, Houston, TX
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's - Clinical Aspects and Therapeutics II
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: To investigate the progression of hand contractures in patients with systemic sclerosis and to identify disease features predictive of contractures. A sub-group analysis was also performed on patients with less than or equal to 2 years since disease onset.

Methods: Patients enrolled in the GENISOS cohort were assessed for disease features predictive of hand contractures. Such variables are included in Table 1.

Linear mixed model was used to analyze longitudinal measurements of each hand separately given the potential for variation in the extent of contracture development. The time variable is the date of first non-Raynaud's symptom.

A subgroup analysis was also performed with the same disease variables to assess for predictive features and to assess if the rate of decline was faster earlier in disease.

Results: 1108 sets of hand measurements were evaluated over a median follow-up period of 8.8 years. 219 patients were included in the analysis and 62 patients in the subgroup analysis. In the right hand, ATA and MRSS scores were predictive of a decrease in hand extension. ATA positive patients showed a decrease in right hand extension by 0.24 cm/year while ATA negative patients showed a decrease in hand extension by 0.075 cm/year. A similar decrease in hand extension was observed in the left hand for ATA positive patients.

A unit increase in the MRSS score was predictive of faster decline in right hand extension by 0.006 cm/yr.

In the subgroup analysis, disease type and ACA were predictive of contracture development in the right hand. Patients with diffuse disease were found to have a decrease in right hand extension by 0.64 cm/year. ACA negative patients were found to have a decrease in hand extension by 0.21 cm/yr in the right hand.

In the left hand, ATA, ACA and digital ulcers were predictive of contracture development. ATA positive patients showed a decrease in left hand extension by 1.54 cm/year while ATA negative patients showed a decrease in hand extension by 0.08 cm/year. Further, the absence of digital ulcers was also predictive of decrease in hand extension in the left hand.

Conclusion: This is the largest and longest reported prospective study assessing disease features predictive of hand contractures in patients with systemic sclerosis.

ATA and MRSS scores were predictive of hand contracture development in the right hand. ATA was also predictive of hand contracture development in the left hand. Discrepancy in skin score as a predictor between the two hands may be related to hand dominance.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's - Clinical Aspects and Therapeutics II

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

Heart involvement is common during Systemic Sclerosis (SSc), even if often clinically silent, and represents the leading cause of death in about one third of patients. Arrhythmias, in particular, are a frequent event and portend a bad prognosis, accounting alone for 6% of SSc total deaths.

We performed a prospective cohort study to define the role of 24h-ECG-Holter in the identification of patients at high risk of life-threatening arrhythmias and sudden cardiac death(SCD) in Systemic Sclerosis.

Methods:

100 SSc-patients with symptoms and/or signs suggestive of cardiac involvement underwent 24h-ECG-Holter. The primary end-point was a composite of SCD or the need for implantable cardioverter defibrillator(ICD). A mean follow-up of 23.1±16.0 months was reached.

Results:

Fifty-six patients(56%) had 24h-ECG-Holter alterations and 24(24%) presented frequent ventricular ectopic beats(VEBs), classified as polymorphic in 11 (26.2%). The mean number of VEBs was strikingly high (2046.1 ± 6027.8//24h), with a maximum of 33615/24h. Supraventricular ectopic beats (SVEBs)>1000/24h were also frequent (19%), with a mean number of 798.9±1835.6 per day; seventeen patients (17%) presented runs of SVEBs. Fourteen patients (14%) presented episodes of supraventricular paroxysmal tachycardia (SVPT), with a maximum of 36 beats, while 11 patients (11%) exhibited runs of NS-VT, the longest of 34 beats. The number of VEBs correlated with cardiac troponin T(cTnT) levels (R=0.4,p<0.001) and inversely correlated with left ventricular ejection fraction(LV-EF) on echocardiography (R=-0.4,p<0.001). Furthermore, the number of VEBs directly correlated with severity index and with the extension of skin involvement evaluated by the mRSS (p=0.3 for both correlations).

During the follow-up, 5 patients died of SCD and two required ICD-implantation for life-threatening arrhythmias. The 7 patients who met the composite end-point had a higher number of VEBs, higher levels of cTnT and NT-proBNP and lower LV-EF(p=0.001 for all correlations), while in all of them a pulmonary arterial hypertension was ruled out by right heart catheterization. All 7 patients had frequent ventricular ectopy at baseline ECG-Holter, while LV-EF range in patients who met the primary end-point was wide and LV-EF was not reduced in all. At ROC curve, VEBs>1190/24h showed 100% of sensitivity and 83% of specificity to predict the primary end-point (AUROC=0.92,p<0.0001). Patients with VEBS>1190/24h had lower LV-EF and higher cTnT levels compared to patients with VEBs<1190/24h.

Conclusion:

VEBs are frequent in SSc and correlate with cardiac damage; VEBS>1190/24h identify patients at high risk of major arrhythmic complications. 24h-ECG-Holter need to be considered as a part of routine evaluation in SSc-patients with suspicious cardiac involvement and it could be an additional risk-stratification technique for selection of SSc-patients at high-risk of SCD, in whom an ICD-implantation could represent a potential life-saving intervention.

Screening Algorithm for Pulmonary Hypertension in Systemic Sclerosis – Comparison of Predictive Accuracy of Three Algorithms

Vivek Nagaraja[1], Scott H. Visovatti[2], Heather Gladue[3], Veronica J. Berrocal[4], Jennifer Serrano[5], Vallerie McLaughlin[2] and Dinesh Khanna[6], [1]Department of Medicine [Division of Rheumatology], University of Toledo, Toledo, OH, [2]Internal Medicine, Division of Cardiology, University of Michigan, Ann Arbor, MI, [3]Rheumatology, Emory University, Atlanta, GA, [4]Div of Rheumatology, University of Michigan, Ann Arbor, MI, [5]University of Michigan, Ann Arbor, MI, [6]Division of Rheumatology, University of Michigan, Ann Arbor, MI
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's - Clinical Aspects and Therapeutics II
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Pulmonary arterial hypertension (PAH) is the leading cause of mortality in systemic sclerosis (SSc), and is associated with a 3-year survival of approximately 50%. Early screening for SSc-PAH may improve survival. We compared the predictive accuracy of three recently published screening algorithms - DETECT 2013, Australian Scleroderma Interest Group (ASIG) 2012, Cochin risk prediction score (RPS) 2011 - for SSc-PAH.

Methods: We included consecutive SSc patients with suspected PAH undergoing right heart catheterization (RHC). The inclusion criteria were based on 2013 recommendations for screening PAH (Khanna D. Arthritis Rheum. 2013). The three screening models were applied to each

patient. For each model, contingency table analysis was used to determine sensitivity, specificity, and positive (PPV) and negative (NPV) predictive values for PAH [defined as mean pulmonary artery pressure (mPAP) > or = 25, pulmonary capillary wedge pressure (PCWP) < or = 15, and no/mild interstitial lung disease (ILD) on high-resolution CT scan of chest (HRCT), or FVC > or = 70%], WHO group 2 pulmonary hypertension (PH defined as mPAP > or = 25, PCWP >15, and no / Mild ILD on HRCT, or FVC > or = 70%), and WHO group 3 PH (defined as mPAP > or = 25, PCWP < or = 15, and moderate / severe ILD on HRCT, or FVC <70%).

Results: Of the 108 patients screened for PAH, 77 met the recommendations, and 60 patients had the RHC. The prevalence of PAH was 18%. Figure 1 provides a flowchart of patients screened for PAH. There were no significant differences in the baseline clinical characteristics between the PH and non-PH patients. Majority of the patients were females (60% vs 57%), had telangiectasia (70% vs 78%) and about a third of the patients had anticentromere antibody (35% vs 38%). DETECT and ASIG algorithms performed similarly in detecting PAH with sensitivities and NPV of 100 % (Table 1). Approximately 1/3 of patients who met the criteria had PAH (PPV 32-38%). In detecting group-2 PH, DETECT and RPS algorithms had sensitivities and NPV of 100% (Table 1).

Conclusion: In this cohort, the DETECT and ASIG algorithms were comparable in detecting PAH in the SSc patients.

Figure 1: Flowchart of patients screened for PAH

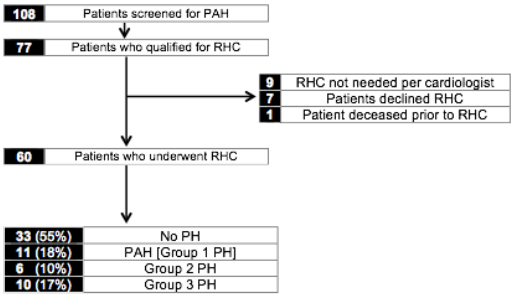

Table 1: Summary of the predictive accuracies (in percentage) of the screening models for PAH in SSc patients

	ASIG			DETECT			RPS

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Vasculitis III
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Large-vessel vasculitides (LVV) comprise giant cell arteritis (GCA) and Takayasu arteritis (TAK). They are characterized by self-sustaining inflammatory damage of the wall of large-sized vessels such as the aorta. Using previously published Immunochip data, we carried out an inter-disease meta-analysis of these two disorders in order to identify common susceptibility genetic factors predisposing to LVV development.

Methods: Two cohorts from Spain (759 cases/1,505 controls) and Italy (238 cases/1,270 controls) included in an Immunochip study on GCA, were combined with two additional cohorts from Turkey (327 cases/481 controls) and USA (110 cases/558 controls) included in an Immunochip study on TAK. In total, 1,434 LVV cases and 3,814 unaffected controls were analysed. We compared in every cohort the variation frequencies of cases and controls by logistic regression under a fixed-effects model using the ten first principal components as covariates. We then used the inverse variance weighted meta-analysis method to test for common association signals. Only those variants showing a nominally significant association with both diseases separately ($P<0.05$), as well as no significant heterogeneity in the overall meta-analysis ($Q>0.05$), were considered as putative shared risk variants.

Results: Strong association signals were observed within the HLA class II region (lead SNP rs9268923, P=6.50E-16, OR=1.49), although associations at the genome-wide level of significance were also detected in HLA class I (rs10947210, P=2.25E-08, OR=1.66). The highest non-HLA peak corresponded to a genetic variant nearby the *IL12B* gene (rs6871626, P=4.67E-07, OR=1.28), which is in complete linkage disequilibrium ($r^2=1$) with the reported TAK-associated *IL12B* SNP rs56167332. Other suggestive signals were observed within *GRIN2A* (rs1448258, P=2.69E-06, OR=1.24), a member of the glutamate-gated ion channel protein family, and *GPSM1* (rs28489139, P=1.38E-05, OR=1.45), a receptor-independent activator of G protein signaling.

Conclusion: A strong contribution of HLA class I and II variants to LVV predisposition was evident. Outside the HLA region, our data indicated that *IL12B* may be a common susceptibility factor for both GCA and TAK, and suggested other putative shared loci between these vasculitides including *GRIN2A* and *GPSM1*.

Session Title: Vasculitis III
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: In large vessel vasculitis (LVV), inflammatory infiltrates typically accumulate within the mural layers of the aorta and its

major branches and are composed of macrophages, T cells and dendritic cells. Before T cells can reach the site of inflammation, they have to extravagate from the circulation and interact with endothelial cells (EC). How this interaction shapes disease-relevant T cell functions is not understood.

Methods: Peripheral blood T cells were isolated from healthy donors and patients with aortitis who had a positive biopsy for GCA and cultured on EC monolayers that had previously been treated with the patient's serum for 24 hours. Four days later CD4 T cells were analyzed for the expression of the lineage-determining transcription factors RORγt, T-bet, GATA-3 and FoxP3 and for intracellular cytokine stores.

Results: Serum pretreated EC changed the differentiation program of the interacting T cells and upregulated RORγt (P=0.03) and T-bet (P<0.001), while suppressing GATA-3 (P<0.001) and FoxP3 (P<0.001). The shift in transcription factor expression was associated with the expansion of Th1 and Th17 cells and the loss of Th2 and Treg cells. This effect required serum pretreatment and was not observed if the serum derived from patients with the inflammatory disease rheumatoid arthritis (P>0.1). To identify underlying molecular pathways, the T cell-EC cocultures were treated with small molecule inhibitors to block intracellular signaling networks. The γ-secretase inhibitor DAPT, which disrupts the NOTCH signaling pathway, was able to abrogate the shift in T cell differentiation (P<0.001). Flow cytometry confirmed that GCA T cells express the NOTCH receptor NOTCH1 and GCA serum-treated EC express the NOTCH ligand Jagged1 (P=0.003).

Conclusion: In patients with GCA, EC acquire expression of Jagged1, which enables such cells to actively communicate with T cells and interfere with their differentiation program. Signal-sending Jagged1$^+$ EC bias T cell differentiation towards proinflammatory effector functions, including the production of IFN-γ and IL-17 and loss of anti-inflammatory Tregs. In LVV, EC not only facilitate the entrance into the arterial wall, they actively participate in swaying T cell immunity.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Vasculitis III
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose : CD4+ T helper (Th) 17 cells, Th1 cells, and regulatory T-cells (Treg) contribute to the pathogenesis of giant cell arteritis (GCA). Interleukin (IL)-6, a key mediator in the differentiation of both Th17 and Treg cells, is up-regulated in this disease. Preliminary use of the IL-6 receptor antagonist tocilizumab (TCZ) has shown encouraging results in patients with GCA. However, the mechanism of action of TCZ in this disorder is unknown. We aimed to characterize the effector and regulatory CD4+ T-cell compartments in the peripheral blood of patients with GCA treated with TCZ

Methods: We evaluated 39 patients with GCA classified into one of three categories (**Table 1**): 1) active disease (aGCA, n=11); 2) disease remission on corticosteroid (CS) monotherapy (rGCA-CS, n=17); and 3) disease remission on TCZ therapy (rGCA-TCZ, n=11). Thirteen healthy controls (HC) were also included. Using flow cytometry, we determined the percentages (%) of IFNg+IL-17- (Th1), IL-17+IFNg- (Th17), IL21+, CD25high (Treg), and CD45RA-Foxp3high (activated Treg, aTreg) cells within the CD4+ T-cell population. In addition, we determined the % of Foxp3+ cells expressing the proliferation marker Ki67, and the activation markers CCR4 and CTLA4. We assessed Treg function in suppression assays. Serum levels of IL-12, IFNg, IL-6, IL-1β, IL-23, IL-21, TNF-α, CCL20, IL-17A, and IL-10 were measured by Luminex. Univariate and multivariate analyses were completed.

Results: The frequency (mean %) of Treg cells was equivalent across groups. However, the frequency of aTregs was significantly higher in rGCA-TCZ patients (1.3%) compared to rGCA-CS patients (0.6%; p<0.01) (**Figure 1**). The significant difference in aTregs persisted in age-, sex-, and CS-dose-adjusted analysis. Moreover, the number of Ki67+ Tregs was significantly higher in rGCA-TCZ patients (31.7%) as opposed to rGCA-CS patients (16.4%; p<0.01) and aGCA patients (15.5%; p<0.01). Multivariate analyses demonstrated that compared to rGCA-CS

patients, Tregs from rGCA-TCZ patients expressed CCR4 and CTLA4 significantly more often (**Figure 1**). Tregs were functional in all groups. The frequency of Th1 cells was equivalent across groups. The frequency of CD21+CD4+ T-cells was significantly higher in aGCA patients compared to patients with GCA in remission. The frequency of Th17 cells was significantly higher in GCA patients compared to HC. IL-10 levels were significantly increased in the serum of aGCA patients

Conclusion: The therapeutic effects of TCZ in GCA could be mediated by changes in the activation and proliferative potential of Tregs

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Vasculitis III

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: The arterial wall is nourished by microvessels (vasa vasorum), which are a potential route of entry for inflammatory cells in vasculitis. Little is known about the anatomy of temporal artery vasa vasorum or their relationship to the inflammatory neovessels in giant cell arteritis.

Methods: Temporal arteries from consenting patients were serially sectioned (5µm) and stained with haematoxylin and eosin (H&E). Slides were scanned at 0.5µm/pixel generating 'virtual copies'. Virtual slides were registered (aligned) and segmented (annotated). Area and circularity (isoperimetric quotient) were calculated for microvessels (vasa vasorum and neovessels). 2D segmentations were connected throughout the virtual case using Medical Image Manager (Heterogenius Ltd, Leeds), creating 3D iso-surfaced images.

Results: Vasa vasorum (red) formed a dense plexus within the adventitia of the normal temporal artery (lumen in yellow), becoming smaller and more numerous towards the internal elastic lamina. In a completely-occluded temporal artery with panarteritis, microvessels penetrated all layers of the vascular wall. Leukocyte aggregates surrounded some of the adventitial vasa vasorum. In a temporal artery with partial luminal occlusion, the segment with greater occlusion had a greater number of neovessels (innermost neovessels shown in green). In GCA, median microvessel area (834 (IQR 421-1881)um^2 and 150 (90-289)um^2 in the first and second GCA specimens respectively) was smaller than that of the normal vasa vasorum (1177 (555-2822)um^2); $p<0.001$. Median microvessel circularity (0.62 (IQR 0.37-0.84) and 0.45 (0.46-0.87)) was also reduced in each GCA specimen compared to normal vasa vasorum (0.69 (0.46-0.87)); $p<0.001$.

Conclusion: The vasa vasorum of the temporal artery form a dense plexus. Inflammatory neovessels are smaller and have reduced circularity compared to vasa vasorum. This method could be used to visualise 3D relationships of microvessels and skip lesions in vasculitis.

Session Date: Tuesday, November 10, 2015

Session Title: Vasculitis III

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: IL-6 is a pivotal cytokine in PMR pathogenesis, yet the efficacy of IL-6 blockade with tocilizumab (TCZ) for treatment of PMR is unknown. The aim of this study was to assess the efficacy and safety of TCZ for treatment of newly diagnosed PMR.

Methods: In a single-center open-label study, subjects with newly diagnosed PMR (Healey criteria) and prior treatment with <1 month (mo) of corticosteroids (CS) were treated with TCZ 8mg/kg IV monthly for 12 mos plus a rapid CS taper. Subjects were followed for 15 mos. Those with concurrent GCA or those treated with >30mg prednisone were excluded. Primary endpoint was the proportion of subjects in relapse-free remission off CS at 6 mos. A cohort of consecutively evaluated patients with newly diagnosed PMR who declined participation in the trial or failed to meet inclusion criteria served as a control group. These patients were treated contemporaneously by a single rheumatologist with expertise in PMR and received CS alone, tapered at the treating physician's discretion.

Results:

Primary endpoint: Ten subjects were enrolled. All 10 also met ACR/EULAR 2012 Provisional Classification Criteria for PMR. One subject withdrew after 2 mos due to a mild infusion reaction, leaving 9 subjects in whom primary endpoint was assessed. 9/9 subjects achieved the primary endpoint of relapse-free remission off CS at 6 mos. Of the 7 subjects who have reached 12 mos in the study to date, all remained in remission without relapse, as did all 4 of those who have thus far completed their 15 mos of follow-up. No flares in subjects treated with TCZ were observed throughout the study.

Ten controls were identified who had been seen consecutively with newly diagnosed PMR. Controls did not differ from study subjects with regard to age, gender, acute phase reactants, or mean baseline CS dose [Table 1]. No controls were in remission off of CS at 6 mos. At 12 mos, a 60% relapse rate was observed in controls.

Steroid-sparing effects: 8/9 TCZ-treated subjects were able to discontinue CS following the third TCZ dose; one subject tapered off CS following the fourth TCZ dose. No subjects receiving TCZ required resumption of CS once they had been tapered off. Cumulative prednisone dose in subjects was 1085±301mg compared to 2562±1356mg in controls (p-value 0.01). Total duration of steroid exposure was significantly less in subjects (3.9±0.9 mos) compared to the controls (14.1±6.0 mos), p-value 0.002 [Table 1].

Safety: 22 adverse events were observed in subjects on TCZ (1 infusion reaction, 5 URIs, 5 episodes of mild neutropenia); only one SAE observed (subject hospitalized after motor vehicle accident).

Conclusion: In this study**,** TCZ was an effective, safe and well-tolerated treatment for newly diagnosed PMR with a robust steroid-sparing effect compared to contemporaneously-treated controls. Subjects treated with TCZ received on average <4 mos of CS and enjoyed relapse-free remission out to 15 mos.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Vasculitis III

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Polymyalgia rheumatica (PMR) is characterized by persisting proximal pain and morning stiffness of the neck, shoulder and hip girdles of 2 weeks' duration, an acute-phase response, and a rapid clinical response to glucocorticoids. Modified release (MR) prednisone improves oral prednisone treatment strategies, at least in RA, by adapting glucocorticoid release to endogenous cortisol rhythms and symptom severity, both of which have their peaks during the early morning hours. We assessed the efficacy and safety of MR prednisone compared to immediate release (IR) prednisone in patients with newly diagnosed PMR previously untreated with glucocorticoids.

Methods: Patients meeting the 2012 EULAR/ACR classification criteria for PMR (excluding US) were randomized to double-blind MR prednisone or IR prednisone 15 mg/day for 4 weeks. MR prednisone/placebo was taken at approx. 10pm and IR prednisone/placebo was taken between 5am and 9am. Patients recorded duration of morning stiffness and symptoms of PMR, global pain, shoulder pain and fatigue on visual analog scales (VAS) in a daily diary. CRP, ESR and IL-6 were measured at study visits. The primary efficacy endpoint was the percentage of complete responders (CRs, defined as ≥70% reduction in PMR VAS, duration of morning stiffness and CRP [or CRP <2 x ULN]) at Week 4,

analyzed using a logistic regression model. Non-inferiority was concluded if the lower limit of the 95% CI for the treatment comparison (MR vs. IR prednisone) was above -15%.

Results: The study randomized 62 patients; 66% female, mean age 69 years. The percentage of CRs at Week 4 was 54% for MR prednisone and 41% for IR prednisone in the per protocol population (PPP) (53% and 33%, respectively, in the full analysis population [FAP]). Non inferiority of MR vs. IR prednisone was not proved in the primary analysis on the PPP (N=48; treatment difference: 12.22% in favour of MR prednisone; 95% CI: -15.82%, 40.25%) as the lower 95% CI was less than 15%, but sensitivity analysis on the FAP showed a trend in favour of MR prednisone (N=62; treatment difference: 15.56%; 95% CI: -9.16%, 40.28%). There was a clear consistent trend for a stronger effect of MR compared with IR prednisone across most secondary efficacy endpoints at Week 4 (Table 1), with a discernible treatment difference observed as early as Week 1. MR prednisone showed a larger efficacy in reducing IL 6 levels. The incidence of treatment-related adverse events was relatively low and the events reported were generally consistent with the known safety profiles of used doses of MR and IR prednisone.

Conclusion: Although the primary analysis of non-inferiority was not met, the consistently positive and clinically meaningful results for MR prednisone compared with IR prednisone observed in this study provide an indication of a beneficial clinical effect of MR over IR prednisone in patients with PMR, with improvements observed as early as Week 1.

Session Date: Tuesday, November 10, 2015
Session Title: ACR/ARHP Combined Abstract Session: Pediatric Rheumatology
Session Type: ACR/ARHP Combined Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Improvement of health-related quality of life (HRQOL) is a central aim in treatment of patients with JIA. The primary

aim of the study is to acquire knowledge about HRQOL in JIA patients, 30 years after disease onset.

Methods: From a total of 336 JIA patients, first time referred to Oslo University Hospital between 1980-85 and reassessed after 15 years, 176 participated in a study mean 29.7 (± 2.3) years after disease onset. HRQOL was assessed by SF-36, physical disability by Health Assessment Questionnaire Disability Index (HAQ-DI) and pain by Visual Analogue Scale (VAS pain). Patients, mean age 37.8 (± 4.5), male 27%, were matched to 90 controls selected randomly from the Norwegian population register.

Results: At 30 year follow-up 102 patients (58%) were in remission off medication (table 1). Differences in PCS, HAQ-DI and VAS pain between JIA subtypes were found.

Compared to controls, patients had reduced HRQOL according to the SF-36 physical component summary score (PCS) including all subscales of SF-36 except mental health after 30 years (table 2). Between patients with active disease and patients in remission a difference was found in PCS and HAQ-DI, but both groups had reduced PCS compared to controls.

From 15 to 30 year follow-up PCS decreased and HAQ-DI increased (Δ 1.5, p-value 0.046, & Δ 0.08, p-value 0.024, respectively). All disease activity variables (core set recommended by ACR) assessed at 15-year, except ESR, correlated with PCS at 30-year follow-up (table 3). In a multiple linear analysis, HAQ-DI and VAS pain after 15 years predicted PSC after 30 years.

Conclusion: JIA has a detrimental effect on HRQOL 30 years after disease onset; also in patients in clinical remission. HRQOL worsened from 15 to 30 year follow-up. Physical disability (HAQ-DI) and pain (VAS) after 15 years predicted physical health assessed by PCS after 30 years. However, substantial unexplained variance in HRQOL exists in adults with JIA.

Inter-Provider Reliability in Scoring the Physician Global Assessment of Disease Activity Among Patients with Juvenile Idiopathic Arthritis Patients Who Met the ACR Provisional Criteria for Clinical Inactive Disease

Janalee Taylor[1], Edward H. Giannini[1], Daniel Lovell[2] and Esi M. Morgan DeWitt[1], [1]Division of Rheumatology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]PRCSG, Cincinnati Children's Hospital Medical Center, Cincinnati, OH

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: ACR/ARHP Combined Abstract Session: Pediatric Rheumatology
Session Type: ACR/ARHP Combined Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: With the advent and implementation of advanced drug therapy clinical inactive disease (CID) has become an attainable

target in the treatment of juvenile idiopathic arthritis (JIA). As a result CID is becoming an endpoint in clinical trials and a goal of quality improvement efforts. The ACR Provisional Criteria that describe CID include the physician/provider's global assessment (PGA), which must be scored as zero on a scale of 0 (indicating no disease activity) to 10 (most disease activity) or ≤ 1 when using the Juvenile Arthritis Disease Activity Score. Scoring of the PGA is not standardized and considerable inter-provider variation is known to exist. Our goal was to measure the degree of this variation when scoring patients who were known to meet the ACR provisional criteria of CID, (intended for systemic, oligo- and polyarthritis) and determine clinical and/or laboratory parameters that contribute most to the non-uniformity in the assessment of the PGA in clinical practice.

Methods: Twenty patient profiles from the JIA registry at Cincinnati Children's Hospital Medical Center (CCHMC) who met the ACR provisional criteria for CID were given to a total of 51 providers who were members of the clinical faculty of the Rheumatology division of CCHMC, the Childhood Arthritis and Rheumatology Research Alliance (CARRA), or of the Pediatric Rheumatology ─ Care and Outcomes Improvement Network (PR-COIN). Using Delphi questionnaire and nominal group techniques for consensus building we determined the intra-class correlation (ICC) for the entire provider group, and asked what variables most strongly influenced their scoring of the PGA.

Results: The twenty cases included systemic 0, oligoarthritis 6, polyarthritis 7, psoriatic 3, ERA 3, arthritis associated with IBD 1. Two patients had uveitis. A total of 51 providers participated in the exercise with a total of 1022 PGA scores. The ICC was 0.15. The standard deviation (SD) due to patient differences was 0.127, and SD due to different raters of the patients was 0.697, suggesting that differences in physician-ratings accounted for most of the variability. Variables that influenced scoring were presence of pain, questionable TMJ involvement, joint loss of motion, morning stiffness, psoriasis, and past history of uveitis.

Conclusion: Combined data from 3 groups of experienced pediatric rheumatologists reveal that substantial variation in scoring the PGA continues to exist when scoring JIA patients with very low disease activity. JIA is a heterogeneous collection of conditions, with various extra-articular manifestations that providers consider in making assessments. Due to the complexity of the conceptual framework of the PGA, standardization is likely not feasible. This implies that other disease states, other than CID, that do not require the PGA to equal zero may be more suitable for clinical trial endpoints and when setting goals of quality improvement efforts.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: ACR/ARHP Combined Abstract Session: Pediatric Rheumatology

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Physical activity has health benefits for all children and adolescents, including those with juvenile idiopathic arthritis (JIA). Our study aimed 1) to determine whether the physical activity level of children and adolescents with JIA met Canadian health guidelines, 2) to compare the physical activity levels of children and adolescents with JIA to those without JIA, and 3) to identify disease-related, personal and environmental factors associated with time spent in moderate to vigorous physical activity (MVPA).

Methods: We analysed data on physical activity obtained objectively through accelerometry for 76 children and adolescents with JIA between the ages of 8 to 17 years followed at the Montreal Children's Hospital, McGill University Health Center. Data obtained from a study of healthy children and adolescents devoid of JIA or other joint problems (ages 8 to 14 years) was used as a control group. All participants were asked to wear an accelerometer for 7 consecutive days. The disease characteristics related to JIA were abstracted from the child's medical file (JIA sub-type, active joint count, age of diagnosis), pain perception and functional status were obtained through self-report. Participants with JIA and their parents completed a series of questionnaires to gather information on the child's socio-demographic characteristics, mastery motivation,

self-concept, activity preference, and perceived social support. Hierarchical regression analysis was used to explore factors associated with MVPA in children and adolescents with JIA.

Results: Mean daily MVPA for all participants with JIA was 24.0 minutes (SD = 14.6). Only 2.9% of those with JIA met international recommendations of 60 minutes of daily MVPA. Having JIA was associated with significantly less time (minutes/day) spent in MVPA (β=-12.25, 95% CI= -17.70, -6.81), p<0.0001) compared with controls. Only younger age, being a boy and identifying as Canadian (versus other cultural backgrounds) were identified as predictors of increased MVPA.

Conclusion: Most children and adolescents with JIA did not meet international health recommendations of engaging in 60 minutes of daily MVPA and were less active than those without JIA. In light of the known health benefits of physical activity, it should be encouraged in children and adolescents with JIA to potentially improve disease symptoms, as well as limit development of comorbidities. The identification of personal and environmental factors associated with physical activity may help guide the development of strategies to promote physical activity in JIA.

Abstract Number: 3149

Predictors of Longitudinal Quality of Life Impact in Pediatric Localized Scleroderma

Kaveh Ardalan, Christina Kelsey and Kathryn S. Torok, Pediatric Rheumatology, Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: ACR/ARHP Combined Abstract Session: Pediatric Rheumatology
Session Type: ACR/ARHP Combined Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Localized scleroderma (LS) is an autoimmune disease characterized by inflammation and fibrosis of the skin and a wide range of extracutaneous manifestations (ECMs). The longitudinal impact of this disease on children's quality of life (QoL) is not currently known. The aim of this study was to longitudinally assess predictors of QoL impact in a cohort of pediatric LS patients.

Methods: Subjects who were 4-16 years old at the time of enrollment into the National Registry for Childhood Onset Scleroderma were included in analysis. Children's Dermatology Life Quality Index (CDLQI) scores at baseline and follow-up clinic visits were dichotomized; scores of 0 or 1 indicated minimal QoL impact, and a score of >1 was considered significant impact.

Hierarchical generalized linear modeling was used to determine predictors of QoL impact, first assessing univariably (alpha = 0.10) and then including all univariably significant variables in the final model (alpha = 0.05). Variables included initially were gender, age at diagnosis, time from initial visit, presence of disease flare, the activity and damage portions of the physician-scored Localized Scleroderma Cutaneous Assessment Tool (i.e. the modified Localized Scleroderma Skin Severity Index (mLoSSI) and the Localized Scleroderma Damage Index (LoSDI) respectively), presence of facial lesion(s), use of systemic immunosuppressive medications, total number of body sites affected, medication side effects, and number of ECMs.

Results: Eighty subjects with a total of 616 visits were included for analysis, with median follow-up of 29.5 months (IQR: 14.0-50.3 months) per subject. Demographics were representative of typical LS populations (see Table 1). Five univariably significant variables were included in the final model: time from initial visit, mLoSSI, LoSDI, gender, and number of ECMs. Males were less likely to have QoL impact than females (*OR*: 0.12, $p = 0.002$). Each month after the initial visit yielded 5% lower odds of QoL impact (*OR*: 0.95, $p < 0.001$). Two thirds of participants reported at least one ECM, with musculoskeletal, orofacial and neurologic ECMs being the most common. Each additional ECM increased the likelihood of QoL impact by 37% (*OR*: 1.37, $p = 0.019$). mLoSSI and LoSDI did not reach significance in the final model. Unit-specific and population-average models were found to be similar; the addition of an over-dispersion factor to the final model did not meaningfully alter the results.

Table 1: Demographic and Visit Descriptive Statistics	
Female Sex, n (%)	58 (73%)
Race - White, n (%)	74 (93%)
Median Age at Disease Onset (years), (IQR)	7.8 (4.9-10.3)
Median Age at Diagnosis (years), (IQR)	9.5 (7.2-11.9)
Median Age at Initial Study Visit (years), (IQR)	10.4 (8.0-13.2)
LS Subtype, n (%)	
Linear (limb/trunk)	27 (33.8%)
Linear (Head/Face)	14 (17.5%)
Generalized Morphea	11 (13.8%)
Superficial Circumscribed	8 (10%)
Deep Circumscribed	4 (5%)
Mixed Subtype	16 (20%)
Lesion Location, n (%)	
Face/Neck	28 (35%)
Trunk	43 (54%)
Limb	50 (63%)
Extracutaneous Manifestations	
ECM(s) Present, n (%)	53 (66%)
Median # ECMs (IQR)	1.5 (0-3)
Treatment, n (%)	
# Visits on Immunosuppressive Treatment	420 (68%)
# Visits with Med Side Effects	337 (55%)
Disease Activity, n (%)	
# Visits with "Inactive Disease"*	480 (78%)
# Visits with "Active Disease"*	106 (17%)
"Active Disease Visits" Considered "Flare"	26 (25%)
# Visits with QoL Impact (CDLQI Score > 1), n (%)	299 (49%)

*30 visits (5%) missing disease activity status

Conclusion: This study is the first longitudinal assessment of predictors of QoL impact in pediatric LS. Female sex and presence of ECMs significantly increase the likelihood of negative QoL impact. In addition, the odds of QoL impact decrease with time from initial visit, suggesting that factors such as effective immunosuppressive treatment, physical/occupational therapy, and patient/family coping mechanisms may mitigate the QoL impact.

Session Title: ACR/ARHP Combined Abstract Session: Pediatric Rheumatology
Session Type: ACR/ARHP Combined Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose:

Juvenile Idiopathic Arthritis (JIA) is a common chronic disease that results in physical and emotional symptoms as well as difficulties in social and role functioning that negatively impact health-related quality of life (HRQL). Many youth with JIA are isolated, having never met another person with JIA and most do not receive comprehensive support to develop self-management skills. The Virtual Peer-to-Peer (VP2P) Program aims to fill this gap by providing peer mentoring via the Internet to improve the *accessibility* and *acceptability* of self-management programs while providing essential peer support for adolescents with JIA.

Methods:

The VP2P program was developed in a phased approach. First, a needs assessment was completed in youth with JIA. Second, a systematic review of peer support programs for adolescents with chronic disease was conducted in order to highlight essential components of successful peer interventions. Third, the VP2P program was developed for adolescents with JIA, informed by results of the systematic review, and included a 2.5-day peer mentor training session. Fourth, using a waitlist pilot randomized control trial (RCT) design, young adult peer mentors (16-25 years; successfully managing their JIA) were matched to adolescent participants (12-18 years; diagnosed with JIA, English speaking, access to a computer with Internet) to provide peer support (emotional, informational, and appraisal) and education for effective self-management of JIA. All mentors and adolescents met American College of Rheumatology criteria for JIA. Mentors and adolescents connected 10 times over the 8-week study period using Skype video calls. Primary outcomes focused on implementation of the VP2P program and included measures of feasibility and acceptability. Secondary outcomes focused on effectiveness of the VP2P program and included measures of self-management, self-efficacy, pain, social support and HRQL.

Results:

Thirty adolescents (mean age 14.3±1.7 years, range = 12-17 years, 97% female) completed participation in the pilot RCT (intervention n = 16, control n = 14). *Primary outcomes:* Over half (64%) of adolescents who were approached agreed and consented to participate; 13% dropped out prior to beginning the intervention or did not complete the 10 full sessions; and 70% of participant-mentor pairings completed the program within 2 months. Median program length was 63.5 days. Average call length was twice the required amount with median call lengths of 45.2±17.2 minutes. Participants reported satisfaction with the program and all reported that they would recommend it to a friend. Participants reported median engagement levels of 8/10 (range = 7.5-10). *Secondary outcomes:* Participants who completed the VP2P program demonstrated significant improvements in their perceived ability to manage JIA ($p = 0.04$), improvements in social support ($p = 0.03$) and disease knowledge ($p = 0.01$) compared to controls.

Conclusion:

The VP2P program is a promising intervention that improves accessibility and acceptability of self-management and peer support treatments for adolescents with JIA. Findings were used to inform a full-scale multi-site RCT of the VP2P program for adolescents with JIA.

Validation of Patient-Reported Outcomes Measurement Information System (PROMIS®) Modules for Use in Childhood-Onset Lupus

Jordan T. Jones[1], Janet Wootton[2], Jun Ying[3], Brianna Liberio[4], Jiha Lee[5], Adam Carle[6], Laura Schanberg[2] and Hermine I. Brunner[6], [1]Division of Rheumatology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Pediatrics, Duke Medical Center, Durham, NC, [3]University of Cincinnati, Cincinnati, OH, [4]University of Cincinnati College of Medicine, Cincinnati, OH, [5]Rheumatology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [6]Cincinnati Children's Hospital Medical Center, Cincinnati, OH
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: ACR/ARHP Combined Abstract Session: Pediatric Rheumatology
Session Type: ACR/ARHP Combined Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Childhood-onset lupus (cSLE) has a substantial negative impact on health-related quality of life (HRQoL). Patient-reported outcomes (PROs) that accurately assess HRQoL and are responsive to change can contribute to improvements in clinical care, and treatment decisions. The PRO Measurement Information System (PROMIS®, http://nihpromis.org) is a publicly available system, supported by the National Institute of Health that measures PROs. Although several accepted legacy HRQoL measures exist for cSLE, the goals of PROMIS are to decrease respondent burden, increase comparison diseases, and increase responsiveness of measured domains. Our objectives were to investigate the validity and responsiveness of the pediatric PROMIS short forms in cSLE in a clinical setting.

Methods: In a longitudinal study 100 cSLE patients completed pediatric PROMIS short forms (anger, anxiety, depressive, fatigue, mobility, upper extremity function, pain interference, peer relations) and legacy HRQoL measures (Pediatric Quality of Life Inventory™ Generic Core [GC] & Rheumatology Modules [RM], Childhood Health Assessment Questionnaire [CHAQ], Functional Disability Inventory [FDI], and parents completed Child Health Questionnaire [CHQ]) at three study visits approximately three to six months apart. We used legacy measures, physician reported health status change, cross-sectional correlations, and path analyses to evaluate construct validity and responsiveness to change for PROMIS scores.

Results: Participants (80% female; 33% White, 48% Black, 8% other) had a mean age of 15.8 years (SD 2.2) and SLEDAI score of 6.0 (SD 5.9). Completion of the PROMIS short forms averaged seven minutes in total (legacy measures 5 to15 minutes each). Validity of the pediatric PROMIS short forms is supported by moderate to high correlations (Pearson's $r \geq 0.5$) with the scores of various legacy measures (Table 1), and with similar PROMIS domains, respectively, and dissimilar PROMIS domains having low correlations (Pearson's $r \leq 0.4$). Path analyses showed that physician reported changes (e.g., improvement from visit 1 to visit 2) corresponded to parallel change in PROMIS scores (see Table 2). Moreover, the changes were largest for HRQoL scores more closely aligned with clinical change.

Conclusion: The pediatric PROMIS short form measures of HRQoL demonstrated construct validity, and responsiveness to change in a sample of children with cSLE. PROMIS measures can be utilized by clinicians treating cSLE for a more efficient, responsive measure of HRQoL while reducing respondent and clinician time burden.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: B cell Biology and Targets in Autoimmune Disease: Novel B cell roles in RA and SLE

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: B cells have been implicated in the development of rheumatoid arthritis (RA) based on their production of autoantibodies and cytokines as well as the therapeutic response to B cell depletion therapy. The maturation of B cells occurs in the germinal center and is influenced by multiple factors including T cell dependent CD40-CD40L signals, toll-like receptor signals and cytokines including BAFF and IL-21. Each of these is a potential therapeutic target in RA. In this study we examined the response to IL-21 as measured by phosphorylation of STAT3 (pSTAT3), to better understand its potential role in RA.

Methods: We utilized frozen PBMC from a cohort of RA subjects and healthy controls obtained from the BRI Rheumatic disease Registry. Samples were thawed, rested for 1 hour and were stimulated with cytokine; IL-21 (50 ng/mL and 15 pg/mL) for 15 and 45 minutes (n=20 per group); IL-10 for 10 min at 10 ng/mL (n=20 per group); or IL-4 at 100 ng/mL for 15 min (RA n=10, Control n=12). Response to IL-21 and IL-10 was measured as mean fold change in phosphorylation of STAT3 (pSTAT3) and for IL-4 pSTAT6. IL-21R, the common gamma chain and total STAT3 expression were determined through flow cytometric analysis.

Results: We determined that RA subjects exhibit enhanced IL-21 signaling in total B cells ($p = 0.02$), memory B cells ($p = 0.0096$), IgM+ memory B cells (0.01), naïve B cells ($p = 0.02$) and transitional B cells (0.005) but not in the more mature switched memory B cells as compared to controls. We observed no significant differences in IL-10 or IL-4 stimulations. Further, IL-21 signaling in total B cells of RA subjects as measured by pSTAT3 positively correlated with the expression of IL-21R ($p = 0.0004$, $r = 0.70$). Similarly we found a significant correlation with the common gamma chain level of expression ($p = 0.01$, $r = 0.55$). When we measured total STAT3 we observed no significant differences between RA and control subjects.

Conclusion: We found that the response to IL-21 is enhanced in the B cells of subjects with RA in comparison to healthy age and gender matched controls. This is unique to IL-21 and not other cytokines; IL-4 which signal through the common gamma chain nor IL-10 which signaling via STAT3, suggesting a link with the IL-21R specifically. Consistent with this we found an increase in the expression of the IL-21R on the cell surface. This heightened response has the potential to enhance or alter the maturation of B cells leading to alterations in antibody and cytokine production in RA. Characterizing the response to IL-21 in RA B cells is important as it relates to disease pathogenesis but also is vital as therapeutics that target this cytokine and its signaling pathway are currently under development. Thus this work may have implications with respect to how best to use such drugs in the setting of RA.

Session Title: B cell Biology and Targets in Autoimmune Disease: Novel B cell roles in RA and SLE

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: MicroRNA-155(miR-155) has been shown to be a key regulator of B cell biology by PU.1 regulation. However, the role of miR-155 in the activation of B cells in Rheumatoid Arthritis(RA) has not been explored. This study aimed to investigate miR-155 expression in RA B cells and its association with B cell driven pathologies such as levels of antibodies against citrullinated peptides(ACPA) and follicular structures in the synovial tissues(ST).

Methods: 60 RA patients underwent ST biopsy. Based on immunostaining for CD68, CD21, CD3 and CD20 cells, ST samples were categorized as diffuse or with follicular pattern. MiR-155 expression in RA ST and synovial B cells was evaluated by in situ hybridization(ISH). B cells from peripheral blood(PB) and matched synovial fluid(SF) of RA and PB of healthy controls(HC) were isolated by $CD19^{+}$micro-beads. IL-6 and BAFF levels in PB and SF were measured by ELISA. MiR-155 and PU.1 expression in B cells from PB and SF of RA; and in ST samples of osteoarthritis(OA) and RA patients was determined by qPCR. Finally, PB-derived B cells were cultured with or without IL-6(30ng/ml) or BAFF(20ng/ml) and miR-155 and PU.1 expression was assessed by qPCR.

Results: 29 out of 60 RA patients(49.2%) had follicular pattern in the ST biopsy. These patients were more likely ACPA positive compared to RA with a diffuse pattern(p=0.04). Moreover, ACPA plasma levels directly correlated with the synovial aggregate grade(r=0.39;p=0.01). IL-6 and BAFF levels were higher in SF than in PB of RA regardless of the synovial infiltrate pattern(p=0.001 for both). PB B-cells from ACPA positive RA showed higher miR-155 expression compared to ACPA negative RA(p=0.02) and HC(p=0.001). Furthermore, ISH showed that miR-155 was highly expressed in ST of follicular RA compared to diffuse RA(p=0.03). Double staining revealed that the majority of B cells within synovial follicular structures were miR-155 positive. qPCR further confirmed that miR-155 was significantly increased in ST of follicular RA compared to diffuse RA(p=0.03) and OA(p=0.03), respectively. Consistently, the expression of miR-155 target in B cells, PU.1 was found to be lower within synovial aggregates in RA. At the cellular level, miR-155 was highly expressed in PB-derived B-cells of RA compared to HC(p=0.0002). In addition, miR-155 was over-expressed in SF B-cells compared to matched PB B-cells(p=0.05) in RA. This was associated with reciprocal lower expression of PU.1 in SF-derived B-cells and within ST follicular structures compared to matched PB B-cells(p=0.001) and ST with a diffuse pattern, respectively. Finally, *in vitro*stimulation of HC B-cells with IL-6 and BAFF induced miR-155(p=0.04 and p=0.03) and decreased PU.1(p=0.01 and p=0.03) expression.

Conclusion: B-cells of RA show high expression of miR-155 that is associated with ACPA positivity, follicular synovial pattern and low expression of PU.1. IL-6 and BAFF that are significantly increased in the SF environment and induce miR-155 expression in B-cells *in vitro* are likely candidates for maintaining high levels of miR-155 in the synovial B cells. Thus, miR-155 may represent a key regulator of B-cells in RA patients.

Session Date: Tuesday, November 10, 2015

Session Title: B cell Biology and Targets in Autoimmune Disease: Novel B cell roles in RA and SLE

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose:

We previously showed that anti-citrullinated peptide/protein antibodies (ACPA) targeting citrullinated antigens contained in neutrophils extracellular traps (NETs) can be manufactured within ectopic germinal center-like structure (GC-LS) in the rheumatoid arthritis (RA) synovium. Here, we aimed to characterise **a)** whether the RA synovial anti-NETs antibodies had undergone antigen-driven affinity maturation, **b)** the importance of somatic hypermutations (SHM) within the V_H and V_L chain for their binding and **c)** whether the presence of N-glycosylation sites in the variable domains introduced by SHM can modulate the reactivity towards NETs.

Methods:

82 full recombinant monoclonal antibodies (RA-syn-rmAbs) were generated from single CD19+ B cells FACS-sorted from fresh GC-LS+ synovial cell suspensions following IgV_H+V_L genes cloning. RA-syn-rmAbs for reversion experiments (n=9) were chosen according to their level of reactivity towards NETs. Reversion of the IgV genes into germ-line (GL) and generation of hybrid clones (where V_H, V_L or selected CDRs/FRs were reverted into GL, n=5) was performed by overlap-PCR. Further characterization of the mature vs GL RA-syn-rmAbs sequence was performed by structural alignment via an *in silico*prediction model using the root-mean-square-deviation (RMSD) score to measure the similarity between the mature and GL structures (1). Anti-NETs immunoreactivity was detected using cell-based immunoassays with activated peripheral blood or RA synovial fluid neutrophils.

Results:

Structural alignment showed some differences in the 3D structure between mature vs GL sequences in 3 RA-syn-rmAbs suggesting that SHM is critical for antigen binding. Accordingly, the anti-NETs immunoreactivity of the RA-syn-rmAbs was dependent on affinity maturation within GC-LS and was completely abrogated when the full IgV_H+V_L genes were reverted to GL. Conversely, when only the IgV_L gene was reverted to GL, 2 out of 5 RA-syn-rmAbs displayed a residual reactivity toward NETs suggesting that in some clones the V_H chain plays a dominant role in conferring the reactivity towards NETs. Preliminary data also showed that the increased molecular weight observed in selected anti-NET antibodies, likely due to the presence of Fab-linked N-glycans sites (2), was lost in the GL counterpart.

Conclusion:

Importantly, our data showed that SHM is necessary for the development of high-affinity NETs-binding antibodies in synovial GC-LS. The importance of defining the contribution of individual CDRs and FRs to the affinity of antigen-binding sites may help to engineer new therapeutic Abs and design of CDRs/FRs-specific peptides for tolerogenic strategy.

Session Title: B cell Biology and Targets in Autoimmune Disease: Novel B cell roles in RA and SLE

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Rheumatoid arthritis (RA) is a prototypic autoimmune disease characterized by a prominent humoral autoimmunity. Of particular relevance is the local production of autoantibodies and the presence of ectopic lymphoid neogenesis (ELN) in the rheumatoid synovium. However, the mechanisms underlying break of B cell tolerance and local autoantibody production remain poorly understood. In this study we aimed to identify cellular and molecular pathways implicated in RA-specific humoral autoimmunity.

Methods: Gene expression profiling was performed on synovial tissue from individuals with RA and inflammation-matched non-RA controls without known autoantibodies. Expression of Bob1 was validated on three independent cohorts of synovium by qPCR and immunohistochemistry. Bob1-positive cells were analysed by triple-color immunofluorescence. B and T cell subsets were FACS-sorted from tonsils. Effects of Bob1-deficiency on collagen-induced arthritis (CIA) model were examined using Bob1-deficient mice ($Bob1^{-/-}$) and RAG-1-*null* mice after adoptive transfer of WT and $Bob1^{-/-}$B and T cells. Anti-collagen type II (CII) antibodies (Abs) were assessed by ELISA. Germinal center (GC) formation was analysed in the inguinal lymph nodes of immunized mice by FACS.

Results: Transcriptional profiling in RA synovium revealed a prominent B cell signature with the B cell-specific transcriptional co-activator Bob1 and its transcriptional target BCMA among the most upregulated genes. Further validation by qPCR and immunohistochemistry confirmed the microarray data and demonstrated elevated expression of Bob1 in RA synovium at the early phase of the disease. Triple immunofluorescence analysis of RA synovium revealed expression of Bob1 in B cells and in a subset of T cells. Subsequent Western blot analysis of tonsillar T cell subsets confirmed expression of Bob1 in T follicular helper (T_{FH}) cells. Interestingly, expression of Bob1 in RA synovium was strongly correlated ($r=0.91$; $p<0.0001$) with expression of CD21L, a molecular marker of ELN, linking highest levels of Bob1 to the presence of GCs. In addition, functional analysis in mice showed that $Bob1^{-/-}$mice failed to produce pathogenic anti-CII Abs and were completely protected from CIA. Adoptive transfer of different combination Bob1-deficient and sufficient B and T cells to RAG-1-*null* mice demonstrated that only mice which received Bob1-sufficient B cells developed CIA. The susceptibility to CIA was mirrored by the presence of anti-CII Abs in serum and GC B cells in lymph nodes of animals. Mice which received Bob1-deficient B cells were resistant to CIA, did not develop anti-CII Abs and did not have GC B cells despite the ability of transferred Bob1-deficient T cells differentiate into T_{FH}cells and produce IL-21. Finally, increased expression of Bob1 and its correlation with CD21L in salivary glands of patients with Sjögren's Syndrome, but not in Sicca controls, suggest a general role for Bob1 in B cell-driven autoimmunity.

Conclusion: Aberrant high Bob1 expression in RA synovium and failure of Bob1-deficient B cells to form GCs and produce autoantibodies indicate that Bob1 may contribute to humoral autoimmunity in RA.

Session Title: B cell Biology and Targets in Autoimmune Disease: Novel B cell roles in RA and SLE
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: The early stage transitional B cell has been shown to be the key peripheral B-cell tolerance control point defect in SLE patients. Anti-RNP Abs can occur before the onset of SLE, but the mechanism underlying tolerance loss to RNPs is unclear. Our previous B cell RNP Ag tetramer analysis indicates abnormal maturation of La_{13-27} epitope reactive transitional T1 B cells in autoimmune BXD2 mice. As B-cell signaling strength and NF-kB p-p65 signaling play an important role in T1 B cell maturation, the purpose of this study was to determine the contribution of elevated IL-17R mediated NF-kp-p65 signaling in autoreactive transitional B cell development.

Methods: Using a La-peptide specific tetramer, La_{13-27} autoreactive B cells from the spleens of B6, autoimmune WT BXD2, and BXD2-*Il17r*$^{-/-}$ mice were analyzed by FACS for the development of $CD93^+$ transitional B cell subsets. T1 B cells were co-transferred into WT vs. BXD2-*Il17r*$^{-/-}$. B cell proliferative responses to anti-IgM and PMA/Ionomycin were determined by the Dojindo assay, and NF-kB p-p65 and p-Tyr levels were determined by phospho-flow.

Results: Tetramer analysis of $CD93^+$ transitional B cells revealed a 2-fold accelerated development of $La_{13-27}{}^+$ T3 transitional spleen B cells ($CD23^-IgM^{hi}$) in BXD2 (38%±5%) compared to that in B6 (18%±3%) mice (n=8, p≤0.01). Interestingly, we have identified that there was mislocalization of $IgM^{hi}CD93^+$ T1 B cells in the follicles of BXD2 mice. However, in normal B6 mice, T1 B cells are located in the peri-follicular region. IL-17R signaling was previously shown to stabilize B-cell retention in the germinal center light zone. Follicular mislocation of T1 B cells was normalized in BXD2-*Il17r*$^{-/-}$ mice. Interestingly, a deficiency in IL17R signaling in BXD2-*Il17r*$^{-/-}$ mice prevented the abnormal maturation of T1 to T3 $La_{13-27}{}^+$ B cells (T3=14±2% vs 38±5%, n=8, p≤0.01). *In vivo* co-transfer of WT and BXD2-*Il17r*$^{-/-}$ into WT or BXD2-*Il17r*$^{-/-}$recipients support a role for IL-17R signaling in transitional B cell development in BXD2 mice. Phospho-flow experiments suggest IL-17R mediated elevated NF-kB p-p65 activation at the T1 stage in BXD2 compared to B6 mice. This elevation was associated with increased protein kinase C (PKC) activation and proliferation in BXD2 B cells stimulated *in vitro* with anti-IgM and PMA/ionomycin (p≤0.01). A deficiency of IL-17R normalized these responses in BXD2-*Il17r*$^{-/-}$ mice.

Conclusion: The present data suggest that follicular exclusion of T1 B cells promotes peripheral tolerance, whereas follicular translocation and retention of T1 B cells promotes maturation. Furthermore, IL-17 can promote NF-kB signaling in T1 B cells that have entered the follicle, bypassing tolerance checkpoint two in BXD2 mice. This provides a mechanistic basis for checkpoint two defects. As anti-La autoAbs can occur before the onset of SLE, these mechanisms may play a key role in initiation of disease.

B Cell Profile As a Biomarker of Disease Segmentation and Flare Prognosis in SLE

Chungwen Wei[1], Bridget Neary[2], Jamie Biear[3], Jennifer Barnard[3,4], Michelle Petri[5], Alex Rosenberg[6], Jennifer H. Anolik[7] and Ignacio Sanz[1], [1]Rheumatology, Emory University, Atlanta, GA, [2]Emory University, Atlanta, GA, [3]Rheumatology, University of Rochester, Rochester, NY, [4]Allergy, Immunology and Rheumatology, University of Rochester, Rochester, NY, [5]Rheumatology, Johns Hopkins University Hospital, Baltimore, MD, [6]University of Rochester, Rochester, NY, [7]University of Rochester Medical Center, Rochester, NY

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: B cell Biology and Targets in Autoimmune Disease: Novel B cell roles in RA and SLE
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: B cell abnormalities in SLE are well-established contributors to disease pathogenesis. Perturbation of B cell homeostasis in SLE is often described separately for each affected B cell subset independent of others. Such univariate approaches fail to reveal how collections of subsets and their relative distribution might contribute to patient segmentation. Hence, we sought a global B cell profiling approach in conjunction with comprehensive clinical parameters to identify distinct B cell signatures in SLE.

Methods: PBMCs were analyzed by flow cytometry from healthy controls (HC) (n=25) and SLE patients (n=135). B cell subsets were identified using the following markers: IgD, CD19, CD27, CD38, CD24, CXCR3, CD21, CD24, CD95, MitoTracker Green, CD10, IgM, CD23. Patients met ACR criteria for the classification of SLE. Disease activity and flares were measured by SELENA-SLEDAI and PGA. All clinical and experimental data were imported into a database where multivariate clustering methods were used to seek natural divisions based on the B cell profiles and relationship to clinical parameters. Flare incidence was followed in a subset of patients with no active disease at baseline (n=52).

Results: High dimensional multiparameter analysis identifies three major clusters of SLE patients based on the B cell profiles. Cluster 1 is characterized by expansions of $IgD^{-}CD27^{+}$ switched memory (SM), $IgD^{-}CD27^{-}$ double negative (DN) cells and plasmablasts, with a concomitant reduction of $IgD^{+}CD27^{-}$ naïve and transitional (N+T) B cells. Of the expanded SM and DN subsets, cells that exhibit the activated phenotype ($CD21^{-}$, $CD24^{-}$ or $CD95^{+}$) are particularly in abundance. A fine subset analysis of the contracted N+T population further reveals that, in contrary to the reduction of resting naïve B cells, there is a pronounced increase in activated naïve B cells ($IgD^{+}CD27^{-}MTG^{+}CD24^{-}$). This cluster with an activated B cell profile is significantly enriched with patients who present high SLEDAI, multiple autoantibodies and elevated serum IFNa activity, and who are of African descent. In contrast, patients in cluster 3 exhibit a B cell profile that is similar to that of HC and are least likely to present high disease activity. Cluster 2 is exemplified by a greatly expanded N+T subset with moderate expansions of activated SM and DN. To evaluate the application of B cell profiling in predicting future lupus flare, low-SLEDAI, non-flaring patients from each cluster at baseline were followed for flare incidences over a period of two years. Preliminary results show that such patients in clusters 1 and 2 experience shorter time lag to first flare and higher incidence of flares than the counterparts from cluster 3.

Conclusion: A system-wide view of B cell populations provides a means to segment the lupus patients. Significantly, inactive patients with an activated B cell profile appear to have a higher propensity to develop a flare sooner. Our results provide a proof of concept that, when combined with other informative clinical parameters, B cell profiling offers a systems biology approach to identifying potential biomarkers to estimate risk of disease progression and to initiate early treatment that might halt disease progression or improve long-term outcome.

Impact of Family History of Systemic Lupus Erythematosus on Risk of Autoimmune Diseases: National Cohort Study in Denmark 1977-2012

Constance Jensina Ulff-Møller[1], Jacob Simonsen[2], Søren Jacobsen[1] and Morten Frisch[2], [1]Department of Rheumatology, Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark, [2]Department of Epidemiology Research, Statens Serum Institut, Copenhagen, Denmark

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Epidemiology and Public Health IV: Risk Factors and Comorbidities for SLE and Psoriatic Arthritis
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Systemic lupus erythematosus (SLE) is a complex autoimmune disease (AID), which develops through the interplay of genetic, epigenetic and environmental factors and may cluster within families with other AIDs. Previous studies suggest that 4-12% of SLE patients have a first-degree relative with SLE and 14-27% have a first-, second- or third-degree relative with some AID. However, the relative risk of SLE or other AIDs once a relative has been diagnosed with SLE has so far remained unexamined.

Methods: All Danish citizens born after 1950 and identified through the Civil Registration System were coupled to their relatives through the parental link. Information regarding SLE and other AIDs was obtained through linkage to the National Patient registry. Cohort members were

followed for SLE and other AIDs from 1997-2012 and hazard ratios (HRs) with 95% confidence intervals (CI) were calculated through Cox proportional hazards regression analyses.

Results: The cohort was followed for more than 100 million person-years of follow-up. In that time, 3,612 persons were hospitalized with an SLE diagnosis. During follow-up, 80 first-degree relatives of individuals with SLE developed SLE themselves (HR 10.0, 95% CI 8.0-12.5), while 17 second- or third-degree relatives developed SLE (HR 3.4, 95% CI 2.1-5.5). Overall, first-degree relatives had a slightly increased risk of any AID (HR 1.43, 95% CI 1.30-1.56), which was still significant among second- and third-degree relatives (HR 1.18, 95% CI 1.04-1.34). For rheumatoid arthritis there was a 64% increased risk among first-degree relatives (95% CI 1.35-1.99), but not among second- or third-degree relatives (HR 1.16, 95% CI 0.81-1.65). Furthermore, there was a slightly increased risk of inflammatory bowel disease (HR 1.21, 95% CI 1.02-1.43) and type 1 diabetes mellitus (HR 1.65, 95% CI 1.12-2.42) among first-degree relatives and multiple sclerosis among second- or third-degree relatives (HR 1.62, 95% CI 1.09-2.43).

Conclusion: There is a clearly increased risk of SLE among relatives of SLE patients and to a lesser degree of other AIDs.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Epidemiology and Public Health IV: Risk Factors and Comorbidities for SLE and Psoriatic Arthritis

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Previous studies indicate that individuals with SLE have a high risk of stroke but have not investigated when the highest risk occurs. We aimed to estimate the risk of ischemic stroke (IS) and hemorrhagic stroke (HS) in SLE compared to the general population by

age, sex, and time since diagnosis.

Methods: Adult patients (≥18y) with SLE were identified from the National Patient Register (NPR) to create a population-based and nationwide cohort of individuals with SLE. SLE was defined as ≥2 SLE ICD codes in the inpatient (1969-2013) or outpatient (2001-2013) registers with ≥1 code in a specialist clinic and ≥1 in outpatient care. We included only those who received their first observed SLE ICD code Jan 2003 or later as a proxy for incident SLE. General population comparators were selected from the Total Population Register alive at the SLE patient's estimated diagnosis date (index date) and were matched 5:1 to the SLE population on age, sex, and county. Stroke was identified from the NPR and those with a history of stroke at baseline were excluded. Follow-up was from index date through first of death, stroke, emigration or end of study (Dec 2013). Age- and sex-adjusted Cox models were used to estimate the hazard ratio (HR) for stroke comparing SLE to non-SLE. Models were additionally stratified by sex, age at diagnosis, attained age and time since diagnosis. Effect modification by stratification variables was tested using the likelihood ratio test (LRT). In secondary analyses, we estimated the HR for stroke among individuals with confirmed SLE from two clinical cohorts.

Results: We identified 3 133 individuals with SLE and 15 504 general population comparators. The average age at SLE diagnosis was 49 and 85% were female. We observed 90 strokes in SLE (76 IS, 14 HS) and 198 in the general population (160 IS, 38 HS). The HR for IS comparing SLE to the general population was 2.4 (95%CI 1.9, 3.2) and the HR for HS was 1.9 (95%CI 1.0, 3.5). HRs were higher in analyses using confirmed SLE only (IS 4.2 (95%CI 2.2, 8.0), HS 4.4 (95%CI 1.2, 16.5).

The HR for IS was significantly higher in females than in males (females HR 3.0 (95%CI 2.2, 4.1), males HR 1.5 (95%CI 0.9, 2.6); LRT p=0.01; **Figure**). Younger individuals (18-49y) had the highest risk of stroke (IS HR 10.2 (95%CI 3.5, 29.7), LRT p=0.003; HS HR 7.7 (95%CI 2.2, 27.1), LRT p=0.008). The HR for IS was similar over time since diagnosis whereas the HR for HS was higher the further from diagnosis (LRT p=0.05), although this was based on small numbers.

Conclusion: Individuals with SLE are at high risk of both ischemic and hemorrhagic stroke. The relative risk was especially high in females and below the age of 50. Notably, the risk for IS was high already within the first year of diagnosis and remained constant during the following decade.

Figure. Hazard ratios and 95% confidence intervals for ischemic and hemorrhagic stroke stratified by sex, age and time since diagnosis comparing individuals with SLE to the general population.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Epidemiology and Public Health IV: Risk Factors and Comorbidities for SLE and Psoriatic Arthritis
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Patients with systemic lupus erythematosus (SLE) are at high risk of infections partly from use of immunosuppressives (IS). Clinical trials are powered to detect differences in treatment efficacy and therefore the comparative risks of infections are understudied. We compared the rates of hospitalized infection and all-cause mortality among SLE patients receiving mycophenolate mofetil (MMF) vs. azathioprine (AZA), two commonly and often interchangeably used IS. We hypothesized based on prior small studies that MMF users may be at increased risk of infection and death.

Methods: We used Medicaid data from 47 states and Washington, DC, 2000-2006, to identify adults (18-65 years) with ≥2 SLE ICD-9 codes separated by ≥30 days, who were new users of MMF or AZA with no use of either drug in the prior 183 days of continuous Medicaid enrollment. The index date was the first MMF or AZA prescription fill date. We excluded patients with HIV/AIDS or prior organ transplant. We used multivariable logistic regression to calculate propensity scores (PS) for receipt of MMF vs. AZA. Covariates included sociodemographics, year, comorbidities, lupus nephritis, vaccines, healthcare utilization, hydroxychloroquine and other IS use during the 183 days prior to the index date, and cumulative corticosteroid dose during the 60 days prior to the index date. We matched new users of MMF and AZA by PS (1:1) and conducted as-treated (AT) analyses, censoring at drug discontinuation, gaps >30 days, switch to the comparator drug, death, disenrollment or end of follow-up. In secondary intention-to-treat (ITT) analyses, patients were censored at death, disenrollment or end of follow-up. We identified hospitalized infections using a validated algorithm (PPV 80%) and used Cox proportional hazard regression models to estimate hazard ratios (HR) of first infection and death comparing PS-matched new users of MMF and AZA (referent).

Results: We identified 926 PS-matched pairs of MMF and AZA new users with SLE. Characteristics were well balanced: mean age was 34 (SD 11) years, 92% were female, 45% were Black, 25% White and 20% Hispanic. In AT analyses, the incidence rate (IR) of first hospitalized infection per 100 person-years was 13.95 among MMF users and 11.91 among AZA users (**Table**). The hazard ratio of first infection was similar for new MMF vs. AZA users (HR 1.18, 95% CI 0.80-1.75). Mortality rates per 100 person-years were 2.39 among MMF users and 1.74 among AZA users (HR 1.39, 95% CI 0.53-3.65). Findings of secondary ITT analyses were similar to the AT analyses with no significant differences between groups.

Conclusion: In this large, diverse cohort of SLE patients, while the rates of hospitalized infection and all-cause mortality were marginally higher among MMF vs. AZA new users, there were no significant differences. Further studies are needed to determine whether there are differences in other relevant safety outcomes.

Table. Propensity Score-Matched* Analyses of First Hospitalized Infection and All-Cause Mortality among SLE New Users of Mycophenolate mofetil (MMF) vs. Azathioprine (AZA)

Session Title: Epidemiology and Public Health IV: Risk Factors and Comorbidities for SLE and Psoriatic Arthritis

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Infections are a significant cause of morbidity and mortality in SLE patients. Recent studies show that lupus nephritis patients have more than two-fold higher incidence of serious infections than the overall SLE population. We investigated the burden of hospitalized infections and related mortality among patients with SLE-related end-stage renal disease (ESRD).

Methods: We used the US Renal Data System, the national registry of ESRD patients, 1995-2008, to identify adults ≥18 years with ESRD due to SLE as recorded by nephrologists on the Medical Evidence Report. We ascertained age, sex, race/ethnicity, region, comorbidities, prior insurance, and dialysis type at ESRD onset. For patients with Medicare Parts A and B coverage beginning 90 days following ESRD onset, we used linked claims to determine hospitalizations for infection from primary discharge diagnosis ICD-9 codes. We calculated mortality due to infection, as documented on the ESRD Death Notification Form, among patients with SLE-related ESRD regardless of Medicare coverage. We calculated incidence rates (IR) of first hospitalization for infection after ESRD onset, and mortality due to infection. We used multivariable Cox proportional hazard regression to determine the hazard ratio (HR) of first hospitalized infection and mortality from infection by race/ethnicity and sex, adjusting for demographics, comorbidities, and dialysis type.

Results: We identified 12,533 patients with SLE-related ESRD and 6,064 with linked Medicare claims. The mean age for the linked cohort was 41.8 years (SD 16.5), 81% were female, 52.4% Black, 42.3% White, and 4.2% Asian, and 15.2% were Hispanic. Mean follow-up was 4.0 years (SD 3.3). The majority (84%) received hemodialysis. The IR of first hospitalization for infection after ESRD onset was 25.9 per 100 person-years. In adjusted models, the risk was lower among males compared to females (HR 0.83, 95% CI 0.76-0.91) and higher among Blacks (HR 1.16, 95% CI 1.11-1.27) and Native Americans (HR 1.40, 95% CI 1.04-1.88) compared to Whites. The risk of infection was higher among patients receiving peritoneal dialysis compared to hemodialysis (HR 1.19, 95% CI 1.07-1.32). Among all patients with SLE-related ESRD, there were 4,428 deaths; 865 (19.5%) were from infection, the majority from septicemia (79.9%). Infection-related mortality was 1.77 per 100 person-years, significantly higher among Blacks compared to Whites (HR 1.20, 95% CI 1.02-1.42), and not statistically different for other racial/ethnic groups or by sex.

Conclusion: In this cohort of patients with SLE-related ESRD, we observed a high burden of hospitalization for infection and related mortality with similar infection rates to pre-ESRD lupus nephritis patients. Female, Black and Native American patients were at increased risk of infection. Further studies are needed to compare these rates to non-SLE patients with ESRD.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Epidemiology and Public Health IV: Risk Factors and Comorbidities for SLE and Psoriatic Arthritis

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Rheumatoid arthritis (RA), psoriatic arthritis (PsA), ankylosing spondylitis (AS) and systemic lupus erythematosus (SLE) are immune-mediated disorders and are associated with a number of comorbidities, including cardiovascular disease. However, reported rates may depend on study design, control population and exposure data. The aim of this study was to assess the rate of comorbidities in patients with RA, PsA, AS and SLE compared to the general population without these rheumatological conditions using data from a large national study.

Methods: This study was conducted using UK Biobank data from over 500,000 people aged 40-70 years in the UK. At entry, participants completed a touchscreen questionnaire on lifestyle, sociodemographics, and health and medical history, followed by a verbal interview with a research nurse. Health history questions captured the occurrence of cardiovascular, pulmonary, allergic and metabolic comorbidities (Table 2). Patients reporting non-specific arthritis were excluded from the total population. Indirect standardization was used to adjust the comorbidity prevalence rates in each of the four rheumatological populations separately (i.e. RA, PsA, AS, SLE) using the age and gender rates in the population without these conditions. The Standardized Incidence Ratios (SIR) were estimated by dividing the observed number of comorbidity events by the "expected" number of events.

Results: 498,611 participants were included in this study, cohort characteristics are summarised in Table 1. The incidence rates of all cardiovascular diseases were significantly higher in the RA and SLE population compared to the general population. Although not significant, similar trends were observed for the AS and PsA population. Rates of allergies were similar between the populations with rheumatological conditions and those observed in the general population without these conditions. Moreover, the incidence rate of emphysema was significantly higher in all populations with rheumatological compared to the general population. Finally, the rate of diabetes in RA patients was higher compared to the general population. However, this was not observed in the other rheumatological conditions (Table 2).

Conclusion: In this cross-sectional study, prevalence rates of cardiovascular diseases and lung disorders are especially increased in people with RA, AS and SLE. This study is unique in that it captures morbidities in a similar way across several rheumatic conditions in a large national-based study.

Session Title: Epidemiology and Public Health IV: Risk Factors and Comorbidities for SLE and Psoriatic Arthritis

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Smoking is a strong risk factor of psoriasis, but a previous study has suggested that smoking protects against the development of psoriatic arthritis (PsA) among psoriasis (PsO) patients. These paradoxical findings occur because of two possibilities. First, a type of selection bias called index event bias arises from selecting a group of patients (e.g. PsO) on the causal pathway (e.g., between smoking and PsA). Second, the causal net effect (**i.e.,** *total effect*) of smoking cannot be validly estimated using conventional methods **(Figure a)**. We sought to evaluate the impact of smoking on the risk of PsA among PsO patients (index population), and clarify the paradox using a counterfactual mediation analysis.

Methods: We used 1995-2015 data from The Health Improvement Network (THIN), an electronic medical records database representative of the UK general population. We analyzed data from adults (age ≥ 20 years), free of PsO and PsA after at least 1 year of enrollment into the THIN database, and with available data on factors of interest. Follow-up began with first record of smoking status (exposure) after the 1-year enrollment period and ended at time of PsA diagnosis, death, disenrollment in THIN, or the end of the study period, whichever came first. Using Cox regression, we assessed the effect of smoking on incident PsA in the general population, and restricting on incident PsO patients. We then clarified the paradox using marginal structural models (MSM) for mediation analysis to partition the total effect of smoking on PsA into its *indirect effect* (via its effect on PsO) and its *direct effect* not through PsO. All analyses were adjusted for known confounders.

Results: There were ~3.7 million subjects without PsO and PsA at baseline (mean age 47 years; 54% females; 27% current smokers, and 20% ex-smokers). Of those, 46,372 developed incident PsO of which 715 developed incident PsA. The adjusted hazard ratio (HR) for smoking and the risk of PsA among PsO patients was 0.85 (95%CI: 0.70, 1.04), but the corresponding HR for PsA in the general THIN population was 1.19 (95%CI: 1.06, 1.33) (**Table**). Using MSM, the *indirect effect* of current smoking compared with non-smoking on risk of PsA was 1.20 (95%CI: 1.12, 1.28); the *direct effect* was 0.99 (95%CI: 0.92, 1.06) and the *total effect* was 1.19 (95%CI: 1.06, 1.33) (**Table**).

Conclusion: We showed that conditioning on PsO can reverse the association between smoking and PsA, and that the effect of smoking on the risk of PsA may be mediated almost entirely through smoking's effect on PsO. Conditioning on an index event may bias conclusions about the contribution of modifiable risk factors; therefore investigators should consider study designs that are free of such bias **(Figure b,** analysis assessing the impact of exposure status change or analogous randomized trials in the index population).

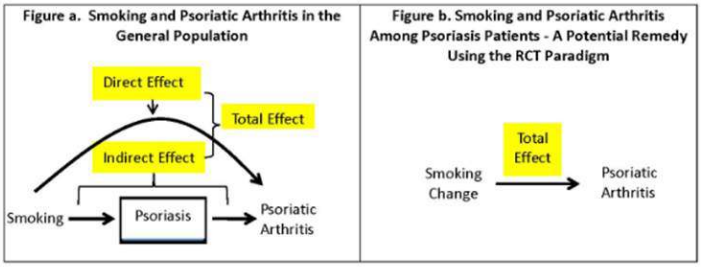

Table 1. Association between SMOKING and Psoriatic Arthritis in the General Population and Among PsO Patients

	Non-Smokers	Ex-smokers	Current Smokers

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Title: Calcium Pyrophosphate Deposition Disease and Associated Medical Co-Morbidities in the Veteran Population.

Background/Purpose: Precipitation of calcium pyrophosphate dihydrate (CPP) crystals in articular tissues results in a variety of clinical presentations collectively called CPP crystal deposition disease (CPPD). The cause of CPPD remains unknown and no evidence-based treatments are available. Some risk factors for CPPD have been identified including aging, prior joint trauma, and various metabolic conditions. The objective of this study was to identify patient characteristics and medical conditions associated with CPPD in the veteran population using

data from the Veteran Affairs' (VA) Corporate Data Warehouse using previously validated ICD-9 codes.

Methods: This cross-sectional case control study included patients seen at any VA medical center from 2010 through 2014 with ICD-9 codes for CPPD. Cases were age-matched with a control population that also received care at a VA facility in the same time frame and lacked ICD-9 codes for CPPD. Prevalences of various co-morbidities were examined in each cohort. Univariate odds ratios were computed to examine the association between CPPD and each condition.

Results: A total of 54,564 (27,282 CPPD cases; 27,282 Controls) patients were included (Table 1). The conditions having the strongest associations with CPPD included osteoarthritis (OR, 3.71; CI, 3.58 to 3.85), gout (OR, 3.11; CI, 2.97 to 3.26), hyperparathyroidism (OR, 4.31; CI, 3.76 to 4.94), rheumatoid arthritis (OR, 3.43; CI, 3.13 to 3.75), and hemochromatosis (OR, 2.29; CI, 1.86 to 2.81). Hypothyroidism, hypomagnesemia, diabetes, and chronic kidney disease did not appear to be associated with the disease. Knee, shoulder, and hip arthroplasties were more common in the CPPD cohort.

Conclusion: This data set contains the largest study population of CPPD patients examined to date. We confirm known disease associations with conditions such as osteoarthritis, gout, hemochromatosis, and hyperparathyroidism. Interestingly, there was not a significant association between CPPD and hypothyroidism, chronic kidney disease, or diabetes, and the difference in rates of hypomagnesemia was not statistically significant. In contrast, an interesting association with rheumatoid arthritis was noted which could reflect diagnostic mimicry or concomitant disease. CPPD patients also had higher rates of total joint replacements, particularly for knee arthroplasty. We anticipate that this data set could shed additional light on this understudied disease.

Table 1. CPPD Co-Morbid Conditions and Odds Ratios

Condition	Prevalence in CPPD patients n=27,282	Prevalence in Controls n=27,282	Odds Ratio (95% CI)

Do Omega-3 Fatty Acids Reduce Risk of Recurrent Gout Attacks?

MaryAnn Zhang[1], Yuqing Zhang[2], Robert Terkeltaub[3], Clara Chen[4] and Tuhina Neogi[2], [1]Internal Medicine, Boston University School of Medicine, Boston, MA, [2]Boston University School of Medicine, Boston, MA, [3]Medicine-Rheumatology, VA Medical Ctr/University of California San Diego, San Diego, CA, [4]Boston University School of Public Health, Boston, MA

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Metabolic and Crystal Arthropathies II: Mechanisms and Associations
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose:

Current guidelines for gout management, based in part on epidemiologic data for development of incident gout, recommend limiting intake of high-purine fish. However, fatty fish also contain omega-3 polyunsaturated fatty acids (ω-3 FA), which have been shown to have multiple anti-inflammatory effects including reduction of NSAID consumption, morning stiffness, and tender joint counts in rheumatoid arthritis, particularly in early disease. ω-3 FA are known to suppress activation of the NLRP3 inflammasome in vitro in macrophages, and limit experimental IL-1beta mediated inflammatory responses in vivo. Since gouty inflammation is driven by NLRP3 inflammasome-mediated IL-1beta release, we assessed whether ω-3 FA intake is associated with reduction of acute flares in gout.

Methods:

We used data from the Boston University Online Gout Study, an internet-based, case-crossover study conducted from 2003-2012. Each subject acted as his or her own control, allowing for elimination of between-person differences. All subjects were recruited online and had to report at least one gout attack in the prior year, with diagnosis confirmed by medical record review. Participants logged on to the study website at times of gout attacks (hazard periods) and every 3 months for 1 year during gout flare-free periods (control periods) to complete questionnaires regarding exposures (including over-the-counter medications, supplements, and diet) during the 24 and 48 hours preceding the attack or control period. We examined the relation of self-reported ω-3 FA-rich supplements and fish intake in the prior 48 hours to the risk of recurrent gout attacks using conditional logistic regression, adjusting for alcohol and total purine intake, and urate-lowering or flare prophylactic medications (allopurinol, NSAIDs, colchicine).

Results:

Of the 724 participants who experienced ≥ 1 gout attack during the study period and completed ≥1 control period questionnaire, 85% met the 1977 Preliminary ACR classification criteria for acute gout. In the 48 hours prior to attack, 22% of participants reported some form of FA consumption. Of those, 4.6% reported use of supplements (i.e., “fish oil” supplements, “ω-3 FA” supplements, or “cod liver oil” supplements) and 19% was from dietary fish. The adjusted odds ratios (aOR) were 1.01 (95% CI, 0.63-1.60) for all three supplement types combined and 0.77 (95% CI, 0.61-0.96; p=0.02) for ≥1 ω-3 FA-rich fish servings, respectively (**Table**). For any ω-3 FA-rich supplements or fish combined, the aOR was 0.78 (95% CI, 0.63-0.97; p=0.02).

Conclusion:

Dietary ω-3 FA-rich fish consumption had a protective effect for recurrent gout attacks in the community, whereas ω-3 FA supplementation alone, as taken in a self-directed manner, did not. Consumption of specific sources of ω-3 FA for gout flare prevention warrants further study in an adequately powered clinical trial.

Table 1. Association of ω-3 FA-rich Supplements and Fish with Risk of Recurrent Gout Attacks.

Exposure over 48 hours	Control Periods	Case Periods	Adjusted OR* (95% CI)	p-value
ω-3 FA-rich Supplements (any of the three):**				
Not consumed	1830	1362	1.0 (ref)	0.98
Consumed	117	72	1.01 (0.63-1.60)	
ω-3 FA-rich Fish:				
0 servings	1564	1123	1.0 (ref)	
≥1 servings	383	311	0.77 (0.61-0.96)	0.02

*adjusted for alcohol and total purine intake, and urate-lowering or flare prophylactic medications (allopurinol, NSAIDs, colchicine)

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Metabolic and Crystal Arthropathies II: Mechanisms and Associations
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: The acute gout flare results from a localised self-limiting innate immune response to monosodium urate (MSU) crystals deposited in joints in hyperuricaemic individuals. Activation of the inflammasome and secretion of IL-1b by immune cells plays a key role in triggering clinical inflammation. Genome-wide association studies have yielded insights into genetic control of the cause of hyperuricaemia. However very little is known about genetic control of the innate immune response involved in acute gouty arthritis. Therefore our aim was to test functional single nucleotide polymorphism (SNP) variants in the toll-like receptor (TLR)-inflammasome-IL1b axis for association with gout.

Methods: 1,494 cases of European ancestry and 863 cases of New Zealand (NZ) Polynesian (Māori and Pacific Island) ancestry. All people with gout fulfilled the 1977 ARA gout classification criteria. There were 1,030 Polynesian controls and 10,942 European controls from the publically-available Atherosclerosis Risk in Communities (ARIC) and Framingham Heart (FHS) studies. The eleven SNPs were genotyped by Sequenom MassArray in the gout cases and either genotyped by Affymetrix SNP array or imputed in the ARIC and FHS datasets. Allelic association was done by logistic regression adjusting by age and sex with European and Polynesian data combined by meta-analysis. Sample sets were pooled for epistatic interaction analysis, which was also adjusted by sample set.

Results: Eleven SNPs were tested in the *TLR2*, *CD14*, *IL1B*, *CARD8*, *NLRP3*, *MYD88*, *P2RX7*, *DAPK1* and *TNXIP* genes. Nominally significant ($P<0.05$) associations with gout were detected at *CARD8 rs2043211* (OR=1.12, $P=0.007$, risk allele T) *IL1B rs1143623* (OR=1.10, $P=0.020$, risk allele G) and *CD14 rs2569190* (OR=1.08; $P=0.036$, risk allele A). There was significant epistatic interaction between *CARD8* and *IL1B* ($P=0.005$) (Table), with the *IL1B* risk genotype amplifying the risk effect of *CARD8*.

Conclusion: There is evidence for association of gout with functional immune system variants in *CARD8, IL1B* and *CD14*. The gout-associated allele of *IL1B* increases expression of IL1-b – the epistatic interaction with *CARD8* would be consistent with a biological scenario of the amount of pro-IL1-b limiting the amount of mature IL1-b generated in stimulatory conditions.

Table Genotype combinations of *IL1B rs1143623* and *CARD8 rs2043211*

Combination	Cases (n, %)	Controls (n,%)	OR [95% CI]	*P*

Session Title: Metabolic and Crystal Arthropathies II: Mechanisms and Associations

Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Gout is caused by an inflammatory response to monosodium urate (MSU) crystals and is associated with elevated triglyceride and very low density lipoprotein levels. There is evidence that suggests apolipoprotein coating of MSU crytsals modulates the inflammatory response. Association of the apolipoprotein A1-C3-A4 gene cluster with gout has previously been reported. To investigate a possible causal role for this locus in gout we tested the association of genetic variants from *APOA1* and *APOC3* with gout.

Methods: Testing of rs670 (*APOA1)* and *rs5128 (APOC3*) was undertaken in 2452 controls and 2690 clinically-ascertained gout cases of European and of New Zealand Polynesian (Māori and Pacific) ancestry. Data from the publically-available Atherosclerosis Risk in Communities (n=5367) study and the Framingham Heart Study (n=2984) were also analyzed. Multivariate adjusted logistic and linear regression was used to test the association of SNPs with gout risk, serum urate, triglyceride and high-density lipoprotein cholesterol (HDL-C).

Results: In Europeans and Polynesians, consistent with previous studies, both SNPs were associated with HDL-C ($P \leq 0.027$) and *rs5128* was associated with triglyceride levels ($P \leq 0.006$). There was no evidence for association of *rs670* or *rs5128* with the risk of gout in Europeans ($OR_{T\ allele}=1.11$, $P=0.059$; $OR=1.01_{G\ allele}$, $P=0.91$ respectively). In contrast, in Polynesians the T-allele of *rs670* (*APOA1*) increased the risk of gout (OR=1.53, $P=4.88\times10^{-6}$) and the G-allele of *rs5128* (*APOC3*) decreased the risk of gout (OR=0.86, $P=0.026$). Association in Polynesians was independent of any effect of *rs670* and *rs5128* on triglyceride and HDL-C levels. There was no evidence for association of either SNP with serum urate levels in Europeans or Polynesians ($P \geq 0.10$).

Conclusion: The data supports the hypothesis that the apolipoprotein A1-C3-A4 gene cluster plays a causal role in the inflammatory response in gout. The effect was specific to Polynesians in this study and could indicate a pathogenic process, outside of the inherent hyperuricaemia present in Polynesians, that contributes to the increased prevalence of gout in this population group.

Session Title: Metabolic and Crystal Arthropathies II: Mechanisms and Associations
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: We have not found a study determining cardiovascular (CV) risk in the different stages of gout. This led us to use a complex multimodal ultrasonography in order to assess the independent influence of the different stages of gout on parameters associated with CV risk: renal resistive index (RRI), left ventricular mass index (LVMI), Em - reflecting diastolic function of the heart, intima-media thickness (IMT) and common carotid artery resistive index (CCARI).

Methods: A total of 170 patients (pts) were examined cross-sectionally, divided into four groups. Control group - pts with osteoarthritis who were with conventional CV risk factors (arterial hypertension, diabetes mellitus, obesity, dyslipidemia, reduced eGFR, smokers), normal level of serum uric acid and no history of gouty crisis (n=35), 15 males and 20 females aged 61±9.7 years. The other three groups of pts were asymptomatic hyperuricemia (n=41), 23 males and 18 females aged 54.6±15.6 years, gout pts without tophi (n=52), 45 males and 7 females aged 55.9±11.6 years and gouty tophi pts (n=42), 41 males and 1 female aged 58.8±11.4 years. All pts underwent a complex multimodal ultrasonography done by one researcher unaware with clinical and laboratory data. RRI was measured in both kidneys with 3.5 MHz transducer. Echocardiography was done by 2.5 MHz transducer. Carotid arteries were examined with 10 MHz linear transducer. Statistical analyses were performed by ANOVA, Kruskal-Wallis, chi-square tests. We conducted a multiple logistic regression to pts with osteoarthritis. In this way we assessed the independent influence of the three stages of gout and CV risk factors on measured parameters. The cutoff for RRI was >0.70; for LVMI>125 g/m² in males and >110 g/m² in females; for Em<0.08 m/s; for IMT>0.90 mm; for CCARI>0.70.

Results: Of conventional CV risk factors we revealed an association between smoking (p=0.044), dyslipidemia (p=0.006) and the examined groups of diseases. There was no significant difference in the incidence of arterial hypertension (p=0.148), diabetes mellitus (p=0.343), obesity (p=0.539) and reduced eGFR (p=0.145) between the four groups. We established that gout without tophi raised the risk of having thicker intima-media with an OR=6.245 (95% CI; 1.371 - 28.443, p=0.018), gouty tophi markedly raised the risk with an OR=11.509 (95% CI; 2.315 - 57.213, p=0.003), but asymptomatic hyperuricemia did not significantly modify the odds of having abnormal IMT. Arterial hypertension increased the risk of having abnormally high CCARI with an OR=3.217 (95% CI; 1.105 - 9.363, p=0.032), the presence of tophi raised the risk with an OR=11.179 (95% CI; 2.613 - 47.825, p=0.001), while asymptomatic hyperuricemia and gout without tophi did not significantly change the risk of having higher CCARI. The different stages of gout had no independent impact on LVMI, Em and RRI.

Conclusion: Tophi raised the likelihood of having abnormal CCARI three times more than arterial hypertension. CCARI is a well known independent predictor of higher CV risk. We suggest that tophi in gout are independent, commensurable and even stronger risk factor than arterial hypertension.

Session Title: Metabolic and Crystal Arthropathies II: Mechanisms and Associations

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Musculoskeletal ultrasound (US) is a non-invasive option for diagnosing gout. However, little is known about the test characteristics of US for the diagnosis of gout in clinical practice. The objective of this study was to determine the diagnostic performance of ultrasound for the diagnosis of gout using presence of monosodium urate (MSU) crystals as the gold standard.

Methods: A sub study was performed within the Study for Updated Gout Classification Criteria (SUGAR), a large, multi-center observational cross-sectional study in consecutive subjects with at least one swollen joint who conceivably may have gout. Cases were subjects with MSU crystal confirmation and controls had an arthrocentesis negative for MSU crystals. Rheumatologists or radiologists, blinded to the results of the MSU crystal analysis, performed US on an involved joint. US findings of interest were: double contour sign (DCS), tophus, and snowstorm appearance. Sensitivity and specificity were calculated for these features. Multivariable logistic regression models were used to examine factors associated with true positive US results.

Results: Among 982 subjects enrolled in SUGAR, ultrasound was performed in 824 subjects (416 cases and 408 controls). Sensitivity and specificity for DCS, tophi, snowstorm, and any US feature for all subjects, those with early (<2 years since symptom onset) versus late disease (³2 years since symptom onset), and the presence or absence of suspected clinical tophi on examination are shown in the Table. Among subjects with gout, 249 (60%) subjects had a DCS, 189 (46%) had US evidence of tophus, and 125 (30%) had a "snowstorm" appearance on ultrasound. Associations with a true positive DCS result included highest ever serum uric acid (SUA; OR 1.31; 95%CI: 1.13-1.53), tender joint proximal to the ankle (2.02; 1.34-3.04) and any xray feature of gout (3.04; 1.95-4.75). Associations with a true positive US tophus included suspected clinical tophus on exam (7.47; 4.72-11.84), current SUA (1.22; 1.05-1.41), and asymmetrical swelling on joint xray (6.14; 3.93-9.60). Finally, associations with a true positive "snowstorm" included suspected clinical tophus on exam (2.29; 1.40-3.76), cystic changes on X-ray (1.70; 1.06-2.72), and the number of episodes (compared to 1 as the reference, 2-5 episodes OR 0.20; 0.06-0.51 and >5 episodes OR 0.34; 0.15-0.76).

Conclusion: In this study, US features of gout have high specificity (but more limited sensitivity) for gout. This was also true in subjects with early disease and in those without suspected clinical tophi on clinical examination. However, sensitivity of DCS and US tophus was better for subjects with long standing disease compared to those with early disease. The presence of other features of gout (e.g. suspected clinical tophus, elevated SUA or xray features) increased the likelihood of achieving a true positive result.

Table. Sensitivity and Specificity of US Features of Gout				
	Cases	**Controls**	**Sensitivity**	**Specificity**
Ultrasound: DCS				
All subjects	249/414 (60%)	35/408 (9%)	60.1%	91.4%
Early disease (<2 yrs)	55/108 (51%)	15/195 (8%)	50.9%	92.3%

Peripheral Osteoblastogenesis in Rheumatoid Arthritis Is Enhanced after TNF Blocker

Treatment, Irrespective of Systemic Inflammation

Mie Jin Lim[1], Won Park[2], Seong-Ryul Kwon[2], Kyong-Hee Jung[2] and Min Jung Son[3], [1]Division of Rheumatology, Department of Internal Medicine,, Inha University Hospital, Incheon, South Korea, [2]Division of Rheumatology, Department of Internal Medicine, Inha University Hospital, Incheon, South Korea, [3]Inha University Hospital, Incheon, South Korea

Session Title: Osteoporosis and Metabolic Bone Disease - Clinical Aspects and Pathogenesis
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose:

We investigated osteoclastogenesis and osteoblastogenesis in peripheral blood before and 6 months after TNF blocker treatment in seropositive RA patients.

Methods:

Seventeen seropositive RA patients who received TNF blocker treatment including infliximab, adalimumab and etanercept were enrolled. Peripheral blood mononuclear cells (PBMCs) were collected at baseline and 6 months after TNF blocker treatment. For osteoblast culture, PBMCs were cultured and stained with alizarin S to detect calcified nodules. The optical density (OD) of alizarin S was measured for quantitative analysis. We also evaluated serum level of bone formation markers including osteocalcin, bone specific alkaline phosphatase (BSALP) using enzyme linked immunosorbent assay (ELISA). For osteoclast culture, PBMCs (1×10^6 cells/well) were cultured and stained with tartrate resistant acid phosphatase (TRAP). TRAP positive cells with more than 3 nuclei were regarded as osteoclasts. To assess resorption potential of osteoclasts, PBMCs were cultured on bone slices and resorption pits were visualized with 0.1% toluidine blue. The areas of pits were quantified using our own devised computerized image analysis program (Fig. 1). Inflammatory markers including erythrocyte sedimentation rate (ESR), c-reactive protein (CRP) and IL-6 were measured.

Results:

The OD of calcified nodules and bone formation markers including osteocalcin and BSALP all increased after TNF blocker treatment (Table 1). There was a positive correlation between differences of osteocalcin and that of BSALP ($p = 0.002$, $r = 0.696$). The number of cultured osteoclasts and the area of resorption pit by osteoclasts decreased after treatment. The difference of numbers of circulating monocytes showed negative correlation with difference of BSALP ($p = 0.008$, $r = -0.617$) and that of osteocalcin ($p = 0.005$, $r = -0.651$). Inflammatory markers did not respond to the treatment.

Conclusion:

Increase both in bone formation markers and optical density of calcified nodules by cultured osteoblasts showed improved peripheral osteoblastogenesis after TNF blocker treatment. The tendency of peripheral osteoclastogenesis which is responsible for osteoporosis and bone erosion in RA was in downstream after treatment. Although inflammatory markers did not respond to TNF blocker, the peripheral osteoblastogenesis was markedly enhanced. There was a negative correlation between changes of circulating monocytes, the osteoclast progenitor cells and that of bone formation markers, suggesting a strong tie between bone formation and resorption.

Table 1.

	At Baseline	6 months after treatment	*p*
Bone formation markers in serum			
osteocalcin	**5.81 ± 1.94**	**8.6 ± 3.23**	**< 0.001**
BSALP	**22.17 ± 6.99**	**25.82 ± 8.89**	**0.007**
ex vivo culture			
OD of calcified nodule (mmol/well)	**205.7 ± 196.27**	**752.5 ± 671.93**	**0.024**
Number of osteoclasts (per well)	**565 ± 294.5**	**304 ± 120.9**	**0.007**
Bone resorption pit by osteoclasts (μ±)	**0.18 ± 0.113**	**0.08 ± 0.076**	**0.007**
Inflammatory markers			
ESR (mm/hr)	33 ± 19.9	25 ± 26.6	0.06

Session Title: Osteoporosis and Metabolic Bone Disease - Clinical Aspects and Pathogenesis
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose:

Patients with RA and other rheumatologic disorders are at increased risk for osteoporotic fractures. Biologic DMARDs are an important treatment option for these patients. However, they are associated with increased infection risk. It is well known that combining biologic DMARDs increases the risk of serious adverse effects, including infections. Considering its mechanism of action, there has been concern that denosumab (Dmab) may increase infection risk when combined with biologic DMARDs. Here we report the results of a retrospective chart review in an outpatient rheumatology practice that evaluated and compared the rates of serious infections in patients receiving Dmab alone, biologic DMARDs alone, Dmab with biologic DMARDs, and bisphosphonates with biologic DMARDs.

Methods:

We performed a retrospective chart review of 389 patients, of whom 159 received Dmab alone, 193 biologic DMARD alone, 10 Dmab + biologic DMARD, and 27 bisphosphonate + biologic DMARD. Data were collected from Jan 2010 through May 2015. The primary endpoint was to compare the rate of serious infections in the Dmab + biologic DMARD group to the biologic DMARD alone group. Rates were calculated for each group and then compared. Chi-square test and relative risk estimates were used for statistical analysis. 95% CI and P values were calculated for each group.

Results:

The Dmab + biologic DMARD group had a higher rate of serious infections compared to the biologic DMARD alone group (RR=12, 95%CI 2.41-68.52, P=0.002). The rate of serious infections for the Dmab + biologic DMARD group was also significantly higher compared to the

Dmab alone group (RR=10.60; 95% CI:1.99-56. P=0.005). No difference in serious infections was observed between the Dmab + biologic DMARD and bisphosphonate + biologic DMARD groups (RR 1.80, 95% CI 0.35-9.2 P=0.48). The Dmab + biologic DMARD group was older (76; SD 7.7) than the biologic DMARD alone group (56; SD 16), and bisphosphonate + biologic DMARD group (63; SD 10), but similar to the Dmab alone group (77; SD 9.9). Gender was female predominant in all 4 groups, 94% in Dmab alone, 100% in Dmab + biologic DMARD, 68% in biologic DMARD alone, and 88% in bisphosphonate + biologic DMARD. The types of serious infections requiring hospitalization were not significantly different between the 4 groups. These included community acquired pneumonia (n=3), post surgical wound infection (n=1), infectious bursitis (n=1), skin and soft tissue infections (SSTI) (n=2), Lyme disease (n=1), and Chikungunya (n=1).

Conclusion:

We observed a greater rate of serious infections in patients receiving combination treatment with Dmab + biologic DMARD compared to biologic DMARD alone and to Dmab alone. The Dmab + biologic DMARD group was older compared to biologic DMARD alone group, which may contribute to the higher rate of serious infections observed. No other significant differences were observed among the 4 treatment groups, including duration of exposure. In summary, the findings of this retrospective study suggest that combination treatment with denosumab and biologic DMARD may increase the risk of serious infections, particularly in an older patient population. Caution should be exercised when considering combination therapy.

Session Title: Osteoporosis and Metabolic Bone Disease - Clinical Aspects and Pathogenesis

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Recently it has been described that anti citrullinated protein antibodies (ACPA) can induce differentatiomn and activation of osteoclasts even before arthritis onset (1,2). The aim of this study was to analyze the effect of ACPA on periarticular and systemic bone mineral density (BMD) in a large population from an early arthritis (EA) clinic.

Methods: We analyzed data from patients belonging to PEARL (Princesa Early Arthritis Longitudinal) study. Demographic, clinical, laboratory and treatment data were collected per protocol. BMD was meaasured at the first visit of the following up through dual X-ray absorptiometry (DXA) (Hologic ©QDR-4500) at lumbar spine (LS), hip, forearm and hand. ACPAs were determined by ELISA. Multivariable analysis was performed adjusting for coufinding variables such as sex, age and body mass index (BMI) was performed using generalized linear models with the command glm of STATA 12.

Results: We analyzed data from 474 patients (39.6% ACPA positive, 80% women). 56.1% of patients fullfiled the Rheumatoid Arthritis (RA) 2010 Criteria at start of follow up. The other patients were undifferentiated arthritis, spondyloarthritis , connective tissue disease and other diagnostics. Median age at disease onset was 54 years [43 - 66 (p25 - p50)]. Symptom duration until BMD measurement was 5 months [6-8 (p25-p50)]. Median DAS28 in patients who fullfilled RA criteria was 4.98 [4-6 (p25-p50)] and 3.6 [3-4 (p25-p50)] in remaning patients. Likewise, HAQ score was higher in RA patients (median 0.750 vs 1.125 in non-RA group). However, neither of these two variables was significantly associated with baseline bone mass. We found ACPA positive patients had lower BMD in LS (beta coefficient - 0.025; p=0.051), femoral neck (coef. beta: -0.02; p=0.053) and total hip (coef. beta. - 0.017; p=0.1). This association was not observed in the nondominant hand or forearm.

Conclusion: Our data provide further support Schett at al suggesting that ACPA may induce systemic osteoporosis even at very early stages of the disease in absence of a long term inflammatory state. Subsequently, bone loss mass would extend to more localized areas in relation to the persistence of inflammatory activity.

Session Title: Osteoporosis and Metabolic Bone Disease - Clinical Aspects and Pathogenesis

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Osteoporotic (OP) fractures and falls are a growing global problem as the population ages. One third of all falls related deaths are attributable to low bone density. Yet OP is poorly managed despite effective treatments being available. A potential reason for not prioritizing OP treatment may be the lack of awareness of the increased mortality due to OP fractures. The aim of this analysis was to determine mortality risk with all fragility fractures in community-dwelling older women and men in New South Wales, Australia.

Methods: Baseline questionnaire data from the 45 & Up Study, a prospective population-based cohort of 238,673 older women (125,174) and men (113,499), were linked to the Emergency Department Data Collection (EDDC), Admitted Patient Data Collection (ADPC- including all hospital admissions, procedures and diagnoses within NSW), Registry of Births, Marriages and Death (RBDM). Fractures were identified from the EDDC and ADPC using the ICD 9, 10, SNOMED and procedure codes. Participants were followed from recruitment (2006-2008) till either death or 31 December 2013. Cox proportional hazards models calculated mortality hazard ratios (HR) (adjusted for age, gender, Charlson comorbidity index, prior fracture history) between those who did and did not fracture.

Results: A total of 14,827 fractures (9,145 females (F) and 5,682 males (M)) and 15,621 deaths (5,604 F and 10,017 M) were available for analysis. The mean age of the cohort was 63 yrs with mean follow-up of 5.7 yrs (sd:1.0). In the whole cohort, absolute mortality rate was higher in men (15.7/1000 person yrs) than women (7.9/1000 person yrs). Having an incident fracture increased mortality rates by ~ two-fold in both men: (33/ 1000 person yrs) and women (19/1000 person yrs). This differed by fracture type as demonstrated by adjusted HRs. Mortality was increased for all proximal site but not distal fractures (See Table).

Conclusion: In a large sample of community dwelling older women and men premature mortality risk is significantly increased following all proximal but not distal fractures. The cause of this increased mortality needs to be explored.

Session Title: Osteoporosis and Metabolic Bone Disease - Clinical Aspects and Pathogenesis

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose:

Antiretroviral regimens containing tenofovir disoproxil fumarate (TDF) have been associated with decreases in bone mineral density, and elevations in bone turnover markers (BTM) and intact parathyroid hormone (iPTH) in patients with HIV. Prior cross-sectional studies suggested that a functional vitamin D deficiency may in part explain these changes. To explore this hypothesis further, we measured change in plasma vitamin D binding protein (DBP) levels from baseline to 48 weeks among a cohort of patients treated with TDF/lamivudine(3TC)/efavirenz(EFV) in the context of other serologic markers of vitamin D and bone metabolism.

Methods:

We performed a secondary analysis using plasma samples collected at 0, 24, and 48 weeks after initiation of TDF/3TC/EFV from 140 adult participants enrolled in a multi-center randomized trial. Women over 45 years were excluded to avoid confounding due to menopausal status. Data regarding socio-demographic characteristics, BMI, $CD4^+$ counts, and HIV viral load were obtained as part of the parent study. Laboratory tests included plasma DBP, iPTH, total 25-hydroxyvitamin D (25OHD), the bone resorption marker collagen type 1 cross-linked C-telopeptide (CTX), and the bone formation marker total procollagen type 1 N-terminal propeptide (P1NP). Differences between time points were compared using the paired t-test and Wilcoxin signed-rank test.

Results:

Our sample included 108 men and 26 women with a mean age of 33.6±9.6 years and BMI of 22.3±2.9 kg/m^2. Mean BMI remained stable from 0 to 48 weeks (p=0.47), however median CD4$^+$ count increased significantly from 290.5 (IQR: 201-362) to 424 (IQR: 294-555) cells/mm^3 (p<0.001) and median viral load decreased from 53767 (IQR: 19802 to 136493) to 0 (IQR:0 to 10) copies/mL (p<0.001). Significant increases were observed in DBP levels from 0 to 24 weeks followed by smaller increases from 24 to 48 weeks (see Table). Similar increases were detected in iPTH levels, however 25OHD levels remained stable. BTM levels increased significantly from 0 to 24 weeks followed by a slight decline (CTX) or stabilization (P1NP), however remained significantly higher compared with baseline at 48 weeks.

Conclusion:

Plasma levels of DBP rose significantly in the first 24 weeks after initiation of TDF/3TC/EFV, followed by a more modest increase from 24 to 48 weeks. This change was observed in concert with elevations iPTH and BTMs, despite stable 25OHD levels, supporting a potential role for DBP in bone loss associated with TDF therapy.

Table. Markers of vitamin D and bone metabolism at 0, 24 and 48 weeks after initiation of tenofovir/lamivudine/efavirenz therapy (N=134)

	0 weeks Median (IQR)	24 weeks Median (IQR)	48 weeks Median (IQR)	p 0 to 24 wks	p 24 to 48 wks	p 0 to 48 wks

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Osteoporosis and Metabolic Bone Disease - Clinical Aspects and Pathogenesis
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Romosozumab is a bone-forming agent that inhibits sclerostin. In a phase 2 study (NCT00896532), 12 months of romosozumab increased DXA bone mineral density (BMD) in postmenopausal women with low bone mass (McClung et al. *NEJM* 2014). A subset of these women underwent spine and hip quantitative computed tomography (QCT) imaging, confirming the BMD gains (romosozumab vs teriparatide integral volumetric BMD gains of 17.7% vs 12.9% at the spine and 4.1% vs 1.2% at the hip). To investigate the effects of romosozumab on bone strength, we performed a finite element analysis (FEA) on these QCT scans.

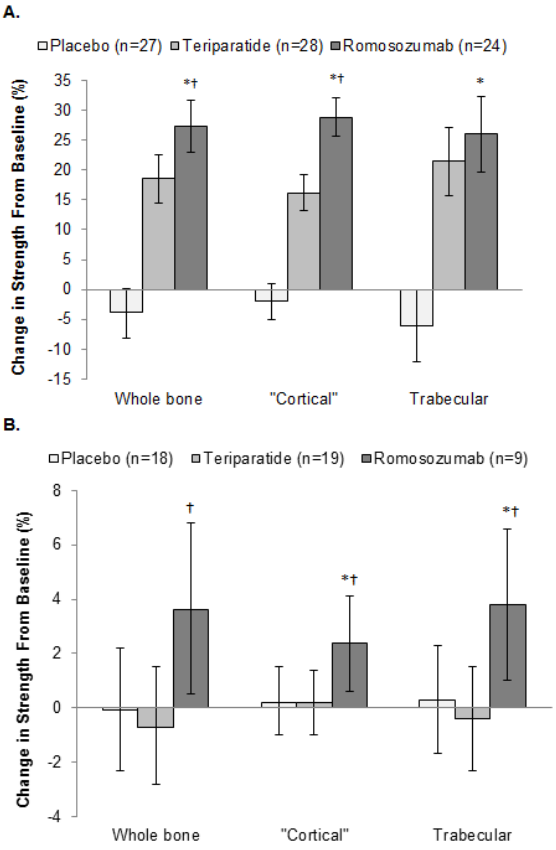
Methods: This international randomized study enrolled postmenopausal women with lumbar spine, total hip, or femoral neck T scores ≤–2.0 and ≥–3.5. In this analysis, subjects received blinded subcutaneous romosozumab 210 mg monthly, placebo, or open-label teriparatide (20 mcg daily). QCT scans were performed at the L1 and L2 lumbar vertebrae and proximal femur at baseline and month 12. Subject-specific vertebral strength for a simulated compression overload and femoral strength for a simulated sideways fall were estimated blinded-to-treatment using a FDA-approved non-linear 3D FEA (VirtuOst, O.N. Diagnostics). Whole-bone and compartment strength changes were estimated. The "cortical" compartment was defined as all bone within 2 mm and 3 mm of the periosteal surface for the spine and hip, respectively, plus any high-density bone (>1.0 g/cm^3 of apparent density); the trabecular compartment was defined as all other bone.

Results: At the spine, romosozumab increased strength from baseline by 27.3% at month 12, which was substantially higher than placebo (–3.9%) and teriparatide (18.5%; Figure A). This strengthening effect was due to contributions from both the "cortical" and trabecular

compartments. At the hip, despite a small sample size for the romosozumab group, strength increased compared with baseline for romosozumab (3.6%), but did not change for placebo or teriparatide (Figure B). Again, both "cortical" and trabecular compartment changes contributed to the overall strengthening observed with romosozumab.

Conclusion: Romosozumab increased strength at the spine and hip over 12 months, with strength improving in the "cortical" and trabecular compartments at both sites. These strength improvements, documented using a validated method for assessing fracture risk and monitoring treatment, confirm and extend existing data and support romosozumab evaluation in the ongoing phase 3 clinical program.

Figure. Percentage Change (95% CI) in FEA-Estimated Strength at Month 12 for the Lumbar Spine (A) and Hip (B)



*P<0.05 compared with placebo; †P<0.05 compared with teriparatide.

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects IV: Imaging and Novel Clinical Interventions
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Structural damage is the main disease outcome to be avoided in JIA. The gold standard to assess joint damage in JIA is X-ray, which is however limited by its late detection of erosions. Alternatively, MRI is sensitive, but distinction between normal variants and bone erosions secondary to the disease is a real challenge. We posit that only bony depressions whose size increases over time should be considered true bone erosions. To test this hypothesis, we developed software to co-register and compare baseline and follow-up MRIs. The aim of this study was to assess the performance of this novel method in detecting bone erosion progression.

Methods: 66 JIA patients with active wrist arthritis who participated in a prospective trial, were enrolled. The baseline and 1 year follow-up MRI of the wrists were assessed separately according to the OMERACT RAMRIS score. Erosive progression was defined as a change between the baseline and 1-year follow-up MRI bone erosion score of at least two points. The novel computer-assisted MRI technique allows to visualize simultaneously two consecutive MRIs and to overlap each of the carpal bones, distal radius, distal ulna and metacarpal bones. Two independent readers assigned 0 or 1 points to each bone indicating absence or presence of progression, respectively. Structural damage progression was defined as progression in at least one bone. The baseline and last X-ray available for each patient were scored according to the Sharp-Van der Heijde method with a difference of at least 2 points indicating joint damage progression. This score served as reference standard for the MRI scores. Inter-reader reliability of the new method was assessed by Cohen's kappa. Of both MRI scores, the diagnostic properties and correlation with clinical variables were evaluated.

Results: Median disease duration at baseline was 4.9 years. The last X-ray was available in 43 patients after a median time of 4.2 years from baseline. 23 (35%) patients showed radiographic progression of joint damage, while 14 (21%) and 32 (48%) patients showed progression of bone erosions using the RAMRIS score and computer-assisted technique, respectively. Inter-reader agreement for detecting erosive progression using the novel software was substantial, with Cohen's kappa ranging from 0.63-1 for the individual bones and equaling 0.79 for the total score. The novel method was accurate with a sensitivity of 0.83, specificity of 0.78, positive predictive value (PPV) of 0.83 and negative predictive value (NPV) of 0.78, whereas the RAMRIS bone erosion score performed poorly with a sensitivity of 0.17, specificity of 0.74, PPV of 0.44 and NPV of 0.42. As expected, the novel method did not correlate with traditional measurements of disease activity, while it was correlated with validated measurements of damage such as conventional radiography (Spearman's rho = 0.60).

Conclusion: The novel method outperformed the RAMRIS bone erosion score and allowed a reliable and accurate evaluation of structural damage progression in JIA, with the potential to select patients who are eligible for a more aggressive treatment.

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects IV: Imaging and Novel Clinical Interventions
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose:

Although the prognosis of JDM has significantly improved during the past decade, some patients still experience persistent active disease, which potentially leads to irreversible damage and permanent disability. In patients with longstanding disease muscle weakness may be due to a combination of ongoing muscle inflammation, muscle atrophy, fatty replacement and steroid-induced myopathy; MRI allows to define the role of each of these components in the patients' weakness and to overcome the limits of the clinical evaluation. The aim of this study is to estimate the frequency and distribution of muscle damage in JDM, using Whole-Body MRI (WB-MRI) and to investigate its feasibility and validity in the assessment of damage.

Methods:

WB-MRIs were obtained from 50 JDM patients (22M;28F, mean age 10.88 years, mean disease duration 3.86 years) and 50 age and sex-matched controls, using a 1.5 T MRI scanner. Muscular atrophy and fatty replacement were assessed on T1 W sequences and scored in 39 muscular groups using a 0-2 and a 0-1 point scales respectively. WB-MRI and clinical assessments were performed concurrently and the results compared. Validation procedures included analysis of reliability, construct validity and discriminative validity.

Results:

WB-MRI revealed muscle atrophy in 43/50 patients (86%) and fatty replacement in 17/50 patients (34%). Quadriceps and ileopsoas muscles were more frequently affected. The inter-reader agreement for WB-MRI scores ranged from moderate to excellent (with Cohen's kappa ranging from 0.556-1 for the individual muscular group and intra-class correlation coefficient 0.96 for the total muscular damage score). Correlations between MDI and muscle atrophy ($rs=0.4$, $p< 0.01$) and fatty replacement ($rs=0.51$, $p= 0.0007$) were moderate and, as expected, MRI muscular damage score did not correlate with traditional measurements of disease activity. Unexpectedly, MRI damage scores did not correlate with disease duration or steroid therapy. None of controls showed signal changes in muscle revealing an excellent discriminant validity of the WB-MRI score.

WB imaging allowed to detect abnormalities in other organ and systems, including osteonecrosis (6/50 patients, 12%), vertebral fractures (7/50, 14%) and calcinosis (14/50, 28%). Other incidental findings detected by WB MRI were a renal cyst and a thyroidal lesion which resulted to be a papillary thyroid carcinoma.

Conclusion:

WB-MRI represents a promising tool to estimate the overall spectrum of damage in JDM. An accurate discrimination between the persistent disease activity and the disease damage burden is crucial to guide treatment decision.

Background/Purpose:

To assess the efficacy of Tocilizumab (TCZ) in refractory uveitis associated to juvenile idiopathic arthritis (JiA).

Methods:

Multicenter study of uveitis related to JiA and refractory to at least **a)** one standard synthetic immunosuppressive drug and, **b)** one anti-TNFα drug**.**

Results:

We studied 13 patients/24 eyes (11 women/2 men) with a mean age of 20.38±9 years (range 8-38). The most frequent ocular pattern was anterior uveitis (n=11), bilateral (n=11), and chronic (n=13).

Besides corticosteroids and before TCZ onset, they had received methotrexate (n=11), cyclosporine A (n=5), mycophenolate (n=1) and leflunomide (n=1). The first biological treatment was: adalimumab (ADA) (n=6) (40 mg/sc/2 weeks), infliximab (IFX) (n=3) (5 mg/kg/i.v./every 6-8 weeks) and etanercept (ETN) (n=4). Before TCZ onset they were switched to other biologic drug (n=11) (most of them due to inefficacy), a third (n=5), fourth (n=3) and a fifth biologic therapy (n=1). TCZ was used at a conventional dose (8 mg/kg/4 weeks) in most cases and combined in all cases (MTX=7, LFN=4, CsA=1, MMF=1). Improvement from baseline to 1 year was observed in: a) Visual acuity: from 0.46±0.35 to 0.52±0.37 (p=0.007); b) Anterior chamber cells from a median [IQR] of 1 [0.5-2] to 0 [0-0] (p=0.001), c) vitritis from 0 [0-1] to 0 [0-0] (p=0.06) and d) Macular thickness from a mean of 277±127 to 234±32 microns (p=0.04). After a mean follow-up of 15.2±8.3 months, ocular remission was achieved in 9 of 13 patients and adverse events were severe thrombocytopenia (n=1), pneumonia (n=1), viral conjunctivitis and bullous impetigo (n=1).

Conclusion:

Tocilizumab seems to be effective and relatively safe in refractory uveitis related to JiA.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects IV: Imaging and Novel Clinical Interventions

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose:

Childhood primary small vessel CNS vasculitis (SVcPACNS) is an increasingly recognized inflammatory brain disease with high morbidity and mortality mandating an elective brain biopsy to confirm the diagnosis. The aim of the study was to systematically review biopsies of SVcPACNS patients and inflammatory and epilepsy controls and to determine characteristic features defining the diagnosis of SVcPACNS.

Methods:

A previously developed, standardized brain biopsy review instrument was applied to consecutive full thickness brain biopsies of pediatric cases and controls collected at a single center. Standardized stains including Hematoxyllin & Eosin, histochemistry of immune cell subsets plus electron microscopy. Nine North American expert neuropathologists were blinded reviewed to the patient’s presentation, diagnosis and therapy. All biopsies were de-identified and scored independently by two reviewers. Univariate analyses compared variable between groups;

correspondence analysis determined the multi-dimensional relationship of histological variables and patient diagnoses.

Results:

A total of 31 brain biopsy specimens of children with SVcPACNS, 12 with epilepsy and 11 with non-vasculitic inflammatory brain disease controls were included. Correspondence analyses revealed distinct clusters of the three diagnoses based on dimensions of location of infiltrate and subtype/ severity of inflammation. Significant histological characteristics found to set apart SVcPACNS from controls included angiocentric ($p<0.01$) and/or perivascular infiltrates ($p=0.04$), evidence of endothelial cell activation ($p<0.01$) and inflammation in both grey and white matter ($p<0.01$). The infiltrate was found to be primarily T-cell mediated (CD3+ 86%, CD8+ 90%) only 27% of SVcPACNS biopsies had evidence of B cells. Features reported in adult PACNS including granulomas, necrosis or fibrin deposits were absent in all biopsies. Leptomeningeal inflammation was non-diagnostic.

Conclusion:

Distinct histological features were identified on brain biopsies of SVcPACNS and may help defining the disease. These were absent in biopsies of children with epilepsy and non-vasculitic inflammatory brain diseases and allow for the development of diagnostic criteria.

Session Date: Tuesday, November 10, 2015

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects IV: Imaging and Novel Clinical Interventions

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Juvenile Idiopathic Arthritis (JIA) is a frequent childhood disease with a prevalence of 1 per 1000 children. The introduction of the biological agents including have greatly improved the outcome. However a proportion of these children remains refractory to all of these drugs. We were the first to show earlier that using another form of cellular therapy, autologous SCT, was effective in some 50% of such children, even after 8 years of follow up. Given the immunosuppressive effects of Mesenchymal Stromal Cells (MSC) and clinical responses observed in animal models and human studies show that MSC could be an attractive and safe option for this group with the poorest clinical outcome. Infusion of MSC is quite simple compared to haemopoietic stem cell transplantation. It can be performed as a short-stay procedure and does not require hazardous treatment with myelo-ablative drugs. We believe that intravenous injection of MSC in therapy refractory JIA will be tolerated and will enable us to estimate the effect to plan for further studies.

Methods: Phase 2 pilot safety study in 6 therapy-refractory JIA patients with a maximum of 3 MSC-infusions according to the scheme (figure 1). Visit 1 starts at week 0, the next visit (visit 2) will be after 4 weeks, visit 3 at 8 weeks and so on. The main objective is to offer a safe alternative for therapy-resistant JIA patients as measured by the total number of adverse events in the 3 months after MSC infusion compared to 3 months before. Secondary aims: Effectiveness as measured by the active joint count, by the Juvenile Arthritis Disease Activity Score (JADAS) an by the erythrocyte sedimentation rate (ESR). Does infusion of MSC induce remission of inflammation as seen on MRI?

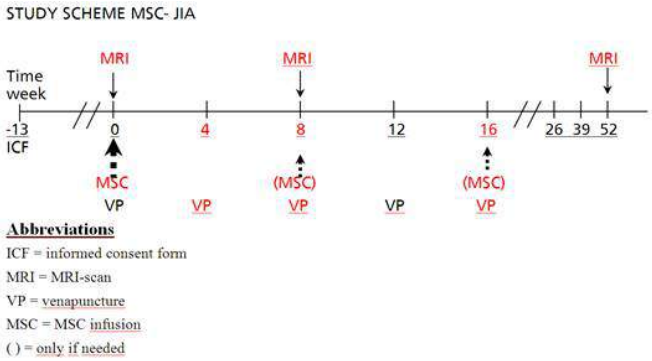

Figure 1.

Results: Currently, 3 of the 6 patients have been enrolled with now 4 MSC administrations given. Patient 1 is now at week 16 of the study (visit 4); patient 2 in week 12 (visit 3) and patient 3 in week 4 (visit 2). No new adverse events were yet observed during or after administration MSC. In all 3 patients, there was a decline in the number of active joints at final follow-up compared with study start. The same improvement was seen in JADAS (figure 2) with the ESR coming down after each MSC-infusion. The second follow-up MRI's of the first two patients had shown (slight) improvement in inflammation, but the pre-existing cartilage-damage did not improve.

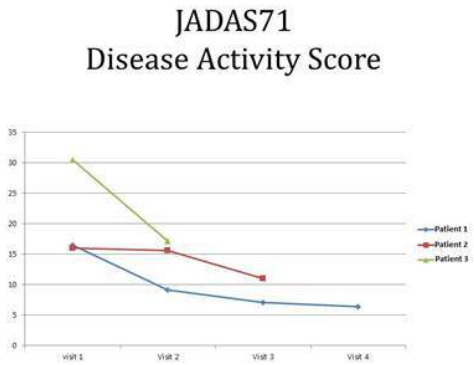

Figure 2.

Conclusion: The preliminary results of a Phase 2 pilot safety study show that MSC infusion in 3 therapy refractory JIA patients was safe. Furthermore there was a trend to improvement of the JIA in active joint count, disease activity score, ESR and improvement as seen on the MRI of an active joint.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects IV: Imaging and Novel Clinical Interventions

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Patients with JIA are at risk of disability, pain and joint damage in the longer-term. Treating toward clinically inactive disease (ID) has the potential to improve outcomes and standardise the quality of care provided across different clinical settings. A number of ID definitions have been developed for JIA. Few studies have compared the frequency of achieving ID across definitions in a single patient population.

Methods: Children were recruited to the Childhood Arthritis Prospective Study (CAPS), a JIA prospective inception cohort established in 2001. Single and composite definitions of ID and composite definitions of minimal disease activity (MDA) were applied to the cohort at one year following first presentation (Table 1). Composite definitions included Wallace's preliminary criteria and cut-offs on Juvenile Arthritis Disease Activity Score (JADAS) measures. Multiple imputation was used to account for missing variables at baseline and at one year.

Results: A total of 1415 children were included. At baseline, the median age was 7.7 years and 65% were female. The most common ILAR subtypes were oligoarticular (50%) and RF-negative polyarticular (21%) at one year. Median baseline JADAS71 score was 11.

At one year, 1331 patients remained in the study. Sixteen (1.1%) patients had been discharged due to low disease activity and a further 68 had been discharged for other reasons or lost-to-follow-up. At least one state of ID was achieved by 69% of patients (Table 1). Estimates of ID ranged from 20% using Wallace's preliminary criteria to 48% using parental remission on JADAS71. Physician, parent and child-driven JADAS cut-offs resulted in similar remission frequencies, with between 45% (Physician JADAS10) and 48% (Parental JADAS71) of patients achieving these states. There was very little difference between the frequency of remission using JADAS10 and JADAS71 tools, with a 1% maximum discrepancy using corresponding cut-offs.

MDA was achieved slightly more frequently than ID, with 51% patients achieving MDA on JADAS71. Other MDA definitions could only be applied to specific ILAR subtypes. In persistent oligoarticular JIA, 66% achieved MDA although the frequency in patients with extended oligoarticular, polyarticular or systemic JIA was lower at 50%. However, only 47% achieved MDA using cJADAS which excludes the systemic disease course.

Conclusion: The frequencies of patients achieving MDA and ID varied greatly between definitions, although a large proportion of children still had active disease one year following diagnosis. Estimates from the JADAS71, JADAS10 and cJADAS10 were similar supporting the use of the more clinically feasible JADAS tools. However the disparity in rates between the majority of measures has implications for research and clinical practice, where distinctly different disease states are being used as treatment targets in patients with JIA.

Session Title: Rheumatoid Arthritis - Clinical Aspects V: Goal = Remission

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: High BMI has been associated with worse disease severity and lower rates of sustained remission (susREM) in early rheumatoid arthritis (ERA). In this study, we examined the relationship of increased BMI on time to susREM in patients with ERA.

Methods: Patients from the multicenter, prospective cohort study, CATCH (Canadian Early Arthritis Cohort) were analyzed. Patients with ERA (symptoms ≤12-months and fulfilling American College of Rheumatology 1987 and/or 2010 RA criteria), available BMI data, and at least 2 consecutive DAS-28 measurements met inclusion criteria. Underweight patients (BMI ≤18.5) were excluded due to small sample size (n=24). Patients were stratified into 3 BMI groups: normal (18.5-24.9), overweight (25-29.9), and obese (≥30), and time to sustained remission (time from 1st visit to DAS28≤2.6 at two consecutive visits) was assessed. A Kaplan Meier survival plot was generated along with the log-rank test to compare the time to susREM among the three BMI groups. Cox proportional hazard regression was performed to quantify the relationship between BMI groups and the hazard ratio for achieving susREM, after adjusting for statistically significant variables from univariate analysis and other identified potential confounders.

Results: Of 1066/2626 patients with available BMI, 348 (33%) had a normal BMI, 369 (35%) were overweight, and 348 (33%) were obese. Both Kaplan Meier curves (Figure 1) and log-rank test ($p<0.001$) showed the difference in the survival functions among the 3 BMI groups. The difference remained significant in the multivariate cox regression analysis. Specifically, patients in obese and overweight groups were less likely to achieve susREM quickly compared to those with normal BMI (HR=0.63, p=0.0008 and HR=0.75, p=0.03 respectively). Additionally, achieving DAS28≤3.2 by 6 months (HR 4.209, $p<0.01$), higher education (1.608, p=0.05), and use of methotrexate in the1st 3 months (1.401, p=0.02) were more likely to achieve susREM, while higher BMI, number of comorbidities (0.911, $p<0.01$), and use of steroids in 1st 3 months (0.761, p=0.01) were less likely to achieve susREM.

Conclusion: Overweight and obesity impact time and ability to achieve sustained remission. In addition to lower rates, patients with high BMI take longer to achieve sustained remission in ERA. Early methotrexate use is associated with shortened time whereas early steroid use is associated with prolonged time to sustained remission, independent of BMI. These findings support a growing body of evidence to include weight management interventions in ERA treatment plans.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects V: Goal = Remission
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Treat to target guidelines recommend achieving a state of remission or low disease activity for rheumatoid arthritis (RA) patients. However, the benefit of lower disease activity for reduction of adverse events and costs is not clear. Our objective was to evaluate clinical outcomes and economic costs associated with RA disease activity states.

Methods: We used CORRONA data linked to national Medicare data to identify RA patients and their disease activity, measured using the Clinical Disease Activity Index (CDAI) captured at each registry visit. CDAI was modeled using a time-varying, area under the curve approach. Follow-up began at the date of the 2nd registry visit and the analysis was censored at time of the first event, 12/31/2012. Outcomes included all cause hospitalization, a composite of hospitalization or ED visits, mortality, and paid monthly healthcare costs. Outcome-specific Cox proportional hazards models evaluated the adjusted hazard ratios (aHR) between disease activity and outcomes, controlling for potential confounders. Costs were analyzed with mixed models using a Gaussian distribution with log transformation.

Results: Slightly depending on outcome, 4593 RA patients contributed up to 14,756 person years. Mean (SD) age was 69.8 (9.3) years, 75% women. At baseline, 59% of patients were in remission or low disease activity (LDA); 43.8% were on biologics. There was a strong dose-response relationship between the four categories of RA disease activity (remission, low, moderate, high) and incidence rate for hospitalization (13.7, 19.0, 23.1, 29.9 per 100py). For hospitalization, all aHR were significant: 0.65 (remission), 0.81 (low), and 1.16 (high) referent to

moderate. Similar crude and adjusted trends were observed for other outcomes. The crude difference in monthly costs between remission ($956/mo) and moderate disease activity ($1607/mo) was $651; the adjusted difference was -441.60 (-563.96, -319.24) per month.

Conclusion: Lower disease activity states in RA were associated with incrementally reduced risks of all-cause hospitalization, ED visits, mortality, and healthcare costs in a dose-dependent fashion.

Table 2a: Crude Rates* of Outcomes, by RA Disease Activity Associated with Cumulative, Time-Averaged CDAI

Disease Activity Category by CDAI	Hospitalization	ED Visit or Hospitalization	Death	Costs, $ per 30 days
Events, n Person-time, years	1,833 9,084.81	2,353 7,151.41	315 13,290.4	
Remission (<=2.8)	13.7 (12.0, 15.5)	26.3 (23.7, 29.3)	1.5 (1.1 2.1)	956.39 (895.08,1017.71)
Low (2.8-10)	19.0 (17.7, 20.4)	30.4 (28.6, 32.4)	2.3 (1.9, 2.7)	1269.27 (1228.46,1310.07)

Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects V: Goal = Remission
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: A Treat-to-Target approach (T2T), treating patients with RA towards a target, either remission or low disease activity (T2T-REM or T2T-LDA), is nowadays recommended. However it has never been assessed whether such a strategy in daily clinical practice really leads to more patients meeting that target.

Methods: Two-year data from BIODAM were used. BIODAM is a prospective cohort including RA patients in daily practice from 10 countries, who were started or changed on DMARD and/or anti-TNF treatment and were followed-up every 3 months. Participating physicians were required to practice treat-to-target per protocol. Per visit was decided whether a patient was treated according to T2T-REM or not. The T2T-REM principle was considered met: i) if a patient had already a disease activity score below the target (DAS28-CRP≤2.6) at a certain time point; or ii) if treatment was intensified (by increasing dosage or adding drugs) upon a DAS28>2.6. T2T-LDA was computed using the benchmark for low disease activity (DAS28≤3.2). The main outcome was the presence or absence of ACR/EULAR-boolean remission 3 months after T2T-REM or T2T-LDA. The relationship between T2T and ACR/EULAR Boolean remission 3 months later was investigated using generalized estimating equations with auto-regression.

Results: In total 3084 visits of 539 patients were included (mean (SD) age: 56 (13) years, 76% female, disease duration 6 (8) years, 49% DMARD-naive). In 68% of the visits, T2T-REM was applied (in 79% of the visits T2T-LDA was applied). ACR/EULAR-boolean remission was reached in 15% of the visits, DAS28 remission in 39%, DAS28-LDA in 53%, CDAI remission in 16% and SDAI in 18%. Appropriate application of T2T-REM led to a 52% higher likelihood of ACR/EULAR-boolean remission 3 months later than not applying T2T-REM (OR (95%CI): 1.52 (1.20; 1.93)). Both T2T-REM and T2T-LDA strategies led to lower disease activity (with an exception of DAS28 remission or DAS28-LDA)(see table). Only 9% of the treatment intensifications followed upon a DAS28 between 2.6 and 3.2, and 79% of the intensifications were applied upon a DAS28>3.2. The effect of T2T-REM on ACR/EULAR-boolean remission was stronger in DMARD-naive patients (OR: 2.10 (1.45; 3.03) than in DMARD-experienced patients (OR 1.20 (0.86; 1.66))(P-value for the interaction:<0.05).

Table - Effect of treat-to-target approach on disease activity outcomes 3 months later

		ACR/EULAR boolean remission (OR (95% CI))	DAS28 remission (OR (95% CI))	DAS28-LDA (OR (95% CI))	CDAI remission (OR (95% CI))	SDAI remission (OR (95% CI))
T2T-REM	Unadjusted	**1.49 (1.19; 1.86)**	0.99 (0.85; 1.15)	1.10 (0.94; 1.29)	**1.47 (1.18; 1.83)**	**1.62 (1.32; 2.00)**
	Adjusted*	**1.52 (1.20; 1.93)**	0.96 (0.82; 1.13)	1.09 (0.93; 1.27)	**1.49 (1.18; 1.88)**	**1.62 (1.30; 2.02)**
T2T-LDA	Unadjusted	**1.95 (1.46; 2.61)**	**1.37 (1.14; 1.64)**	**1.30 (1.09; 1.56)**	**2.24 (1.66; 3.01)**	**2.53 (1.90; 3.38)**
	Adjusted*	**2.14 (1.56; 2.95)**	**1.36 (1.12; 1.64)**	**1.30 (1.08; 1.56)**	**2.46 (1.77; 3.43)**	**2.74 (2.00; 3.76)**

* Adjusted for age, gender and disease duration

T2T-REM: treat-to-target with remission (DAS28≤2.6) as benchmark; T2T-LDA: treat-to-target with low disease activity (DAS28≤3.2) as benchmark

Conclusion: A treat-to-target approach, even with a modest benchmark (DAS28=3.2), works instantaneously and leads to higher ACR/EULAR-remission rates. T2T is more effective in DMARD-naïve than in DMARD-experienced patients. Rheumatologists should be encouraged to follow a treat-to-target approach in order to improve the outcome of their patients.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects V: Goal = Remission

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: We report the results of a cluster-randomized behavioral intervention trial designed to assess the impact of implementing a treat-to-target (T2T) approach vs usual care (UC) in a large, US-based, observational cohort of rheumatoid arthritis (RA) patients.

Methods: Thirty-one rheumatology practices from the Corrona network were randomly assigned to either T2T (n=16) or UC (n=15) between July 29, 2011 and July 30, 2013. Eligible RA patients with moderate or high disease activity (Clinical Disease Activity Index [CDAI>10]) were followed for 12 months. In the T2T group, encounters associated with a CDAI>10 were to result in treatment acceleration (e.g., a new initiation or dose increase of a prescribed biologic or nonbiologic DMARD) when deemed appropriate, with a follow-up appointment in 4 weeks. In contrast, UC patients were seen at least every 3 months with treatment changes and follow-up visits decided by the treating provider. Co-primary endpoints were achievement of low disease activity (LDA; CDAI≤10) and measures of feasibility, most importantly treatment acceleration conditional on CDAI>10. Baseline characteristics of the T2T and UC groups were compared using standardized differences. An intent-to-treat analysis was performed adjusting for clustering by site and covariates associated with standardized differences >0.10.

Results: There were 246 patients in the T2T practices and 286 from UC practices enrolled. The 2 groups were similar in terms of mean age, gender and race, but not Hispanic ethnicity (**Table 1**). Patients had similar clinical features (disease duration, rheumatoid factor seropositivity, prior medications and current medications) at baseline. During the 12-month study period, 19.9% of the T2T group and 16.4% of the UC group dropped out (p=0.457). Median (IQR) number of visits in the T2T group was 7.0 (5.2-9.7) compared to 4.6 (3.8-6.7) in the UC group, adjusting for clustering and varied person time (p<0.001). Rates of treatment acceleration and achievement of LDA were similar in the 2 groups (**Table 2**). There were no differences between the 2 arms in terms of trends in LDA over time (p=0.20).

Conclusion: This first US-based T2T behavioral intervention in RA patients was not associated with an increased likelihood of achievement of LDA, and acceleration occurred only ≈50% of the time, despite providers being instructed to have more frequent visits and accelerate therapy based upon disease activity in the T2T arm. Further analysis is ongoing to better understand patient, provider and healthcare factors associated with T2T implementation.

Table 1. Baseline Demographic and Clinical Characteristics of the T2T and UC Study Populations

Characteristic	Population Comparisons		Standardized Differences
	T2T Population N=246	UC Population N=286	
Age, mean (SD), years	57.0 (12.8)	58.0 (13.1)	0.08

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects V: Goal = Remission

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Previous cross-sectional data revealed disease activity (DA) measures that omit foot joint assessment inadequately capture foot synovitis in in apparent remission at 6 months[1]. We sought to determine whether foot synovitis is associated with adverse radiographic and functional outcomes after 3 years in an inception cohort receiving treat-to-target combination DMARD therapy.

Methods: Patients with early RA (<1 year; fulfilling ACR 1987 and/or 2010 classification criteria) were included. Remission was assessed using DAS28, clinical disease activity index (CDAI) and simplified disease activity index (SDAI); radiographic outcomes by annual hand and feet radiographs scored by the van der Heijde modified Sharp score and quality of life by SF-36. The prevalence of remission by different DA criteria and presence of foot synovitis was estimated using marginal binomial generalised estimating equations and transition between disease remission and non-remission states using a multi-state Markov model. Changes in radiographic scores were analysed using negative binomial mixed regression log-link model. SF-36 data were transformed to a norm-based scale (NBS) using population matched data and analysed by mixed effects linear regression.

Results: Baseline DA in 266 patients was 5.43 (SD 1.27). Dynamic correlation revealed DA scores that omit foot joint scores were modest in their ability to capture foot synovitis over time. Despite relative stringency of SDAI and CDAI as remission criteria, a significant proportion of patients in remission had foot synovitis, ranging from 25-36% (Table 1). In patients in apparent remission, foot synovitis predicted transition from remission into relapse by up to 2-fold (Table 2), and the sustainability of remission markedly influenced progression of erosion scores (p=0.006) After adjustment for DA, foot synovitis was associated with significantly worse SF-36 physical functioning subscale (p=0.025).

Table 1. Proportion of patients in remission

	DAS28 (CRP)	DAS28 (ESR)	SDAI	CDAI
Patients in remission, with or without foot synovitis (95%CI)	0.47 (0.11, 0.51)	0.43 (0.10, 0.47)	0.28 (0.05, 0.32)	0.27 (0.05, 0.31)
Patients in remission with foot synovitis (95% CI)	0.35 (0.29, 0.41)	0.36 (0.30, 0.42)	0.24 (0.18, 0.30)	0.25 (0.19, 0.32)

Table 2. The effect of foot synovitis on transition from remission to non-remission and vice versa

Transition Hazard Ratio (95% CI)	**DAS28(CRP)**	**DAS28(ESR)**	**SDAI**	**CDAI**
Non-remission to Remission	0.68 (0.42, 1.10)	0.70 (0.45, 1.10)	0.70 (0.40, 1.24)	0.68 (0.39, 1.17)
Remission to Non-remission	1.47 (0.84, 2.57)	1.81 (1.03, 3.17)	2.06 (1.00, 4.26)	2.08 (1.03, 4.18)
Likelihood Ratio test p-value	0.015	0.002	0.0004	0.0002

Conclusion:

DA measures that omit foot joints capture foot synovitis poorly. When used to define remission, a substantial proportion have foot synovitis which predicts relapse into non-remission and worse physical function. Foot synovitis influences sustainability of remission which in turn markedly influences radiographic progression. Presence of foot synovitis regardless of remission status should warrant consideration of escalation of therapy to improve long-term outcomes.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects V: Goal = Remission

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: The timing and severity of relapse and likelihood of "recapturing" remission following a relapse in RA is not well known. We aimed to describe time-to-relapse, as well as factors associated with relapse and subsequent remission after disease relapse.

Methods: We performed a longitudinal analysis of patients enrolled in the Ontario Best Practices Research Initiative (OBRI), a clinical registry of RA patients in routine care. First clinical remission according to DAS28-ESR <2.6 following cohort entry was determined. Patients achieving remission with >/= 1 follow-up visit were observed for the average time until relapse (DAS28 >2.6). Disease activity at relapse as well as the prevalence and timing of subsequent remission was examined. Cox proportional hazards models calculated the hazard of remission and relapse adjusted for baseline variables and time-varying disease activity and medication changes.

Results: The total cohort (N=2591) was 78% female with mean age 57 (13) years. Remission was achieved in 1258 patients (60%) with median time-to-first-remission of 314 days (IQR 153,552). Early RA was the only positive predictor of remission (Table). Among the remission group, 1117 had follow-up and 776 (69%) went on to experience a relapse. Median time-to-relapse was 204 days (IQR 129-390) and the majority switched from a state of remission to mild or moderate disease activity, in contrast to moderate or severe levels of disease activity they experienced at baseline. In the multivariable analysis, relapse was significantly associated with female sex, higher DAS28 preceding relapse and use of biologic DMARD (bioDMARD) monotherapy and/or corticosteroids in the interval between remission and relapse; combination conventional synthetic DMARD (csDMARD) appeared to protect against the risk of relapse (Table). 452 (58%) patients regained remission after spending a median of 209 days (IQR 126-386) in a state of relapse. Similar variables associated with first remission, including disease duration and receipt of combination csDMARD or bioDMARD after relapse, were negatively associated with regaining remission (Table).

Conclusion: Clinical remission in routine care is achievable but relapses to states of low or moderate disease activity are common and may last several months. High disease activity and need for biologics or corticosteroids may predict those at highest risk for relapse. Recapturing remission after a relapse appears possible but occurs at a lower frequency than initial remission. Additional investigation about the optimal timing, dosing and sequence of DMARD therapy needed to maintain and recapture remission will inform how to best manage and prevent disease flares.

Table. Multivariable analysis with hazard ratios and 95% confidence intervals of time-to-remission and time-to-relapse.

Inhibition of Lymphatic Muscle Contraction By Lymphatic Endothelial iNOS Impairs Lymph Drainage from Arthritic Joints in TNF-Tg Mice and Is Prevented By Herbal Drugs

Qianqian Liang[1], Yan Chen[1], Jinlong Li[1], Wensheng Wang[2], Li Zhang[1], Hao Xu[1], Ronald Wood[2], Brendan Boyce[2], Edward Schwarz[3], Yongjun Wang[1] and Lianping Xing[4], [1]Longhua Hospital, Shanghai University of Traditional Chinese Medicine, Shanghai, China, [2]University of Rochester, Rochester, NY, [3]Orthopedeatrics, University of Rochester, Rochester, NY, [4]University of Rochester Medical Center, Rochester, NY

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis Animal Models II
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: We reported previously that inflammation in TNF-Tg mice, a model of rheumatoid arthritis (RA), inhibits lymphatic vessel maturation, resulting in decreased lymphatic smooth muscle cell (LSMC) coverage and lymph leakage, thereby reduced draining function. Here, we investigatedthe mechanisms responsible for LSMCdysfunction in TNF-Tg mice and if existing drugs could be used asnew lymphatic-based therapy for RA.Wetestedthe hypotheses:1) chronic jointinflammation stimulateslymphatic endothelial cells(LECs) to produce iNOS, leading to reduced draining functionvia inhibition of LSMC contraction; and 2)Ferulic acid (FLA) andPanaxNotoginsengSaponins(PNS), herbal drugs that have been used to treat patients with vascular diseases, reduce LEC iNOSand restoreLSMC/lymphatic vessel function toattenuate RA.

Methods: TNF-Tg mice and WT littermates were used. 1)iNOS expression was examined by qPCR in synovial LECs that were purified with anti-Podoplanin Ab-conjugated beads, and by immunostaining in the collecting lymphatic vessels. (2) The effect of LECs on LSMCs that were isolated from rat mesenteric lymphatic vessels were assessed by pre-treating LECs with TNF on glass coverslips, transferring LECs to LSMC cultures, and measuring expression of functional muscle genes in LSMCs by qPCR and Western blot. 3)TNF-Tg mice were treated with the herbal drugs,FLA orPNS, or vehicle for 3 months. Lymphatic draining function, including clearance and pulse,was measured by indocyanine green near-infrared lymphatic imaging, and tissue damage was determined by histology. 4) The effects of FLA and PNS on LEC inhibition of LSMCs were tested in co-cultures, as in (3).

Results: 1) Synovial LECs from TNF-Tg mice expressed higher levels of *nos2*thanWT LECs (8.4+2.7 vs. 1+0.4) and these were greater than those observed for*nos1*and *tnf*(*nos1*: 2.4+SD,*tnf*: 3.8+0.7). Low levels of TNF (0.1ng/mL) stimulated the expression of *nos2*,but not *nos1*and *tnf*, in LECs (*nos2:* 40+11, *nos1*: 6.5+2.5, *tnf:*2.4+0.9). Immunostainingrevealedthat LECs in the collecting lymphatic vessels from TNF-Tg mouse leg stained strongly positively for iNOS.2) TNF pre-treated LECssignificantly decreased expression of multiple functional muscle genes (*h1-calponin, sMYH11, SMα2* and *SMα22*)in LMSCs at mRNA and protein levels, which was blocked by a NO inhibitor. 3) FLA and PNS significantly improved lymph clearance of ankle tissues, restored lymphatic pulses, and markedly reduced joint inflammation, bone erosion and cartilage loss inTNF-Tg mice in comparison with vehicle-treated TNF-Tg mice. 4) FLA and PNS blocked the inhibitory effects on expression of LSMC functional genes in LECs withpre-treated TNF.

Conclusion: In the setting ofchronic inflammation in TNF-Tg mice, LECs express high levels of iNOS and produce NO, which negatively affects the structure and contractile function of LSMCs, leading to impaired lymphatic drainagefrom collecting lymphatic vessels, and exacerbates inflammation and tissue damage in afferent joints.Herbal drugscommonly used to treat patients with vascular diseases have potential as anti-RA agents based on theirinhibition of NO production and preservation of lymphatic function.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis Animal Models II

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Joint destruction in rheumatoid arthritis (RA) progresses via the hyperproliferation of the synovium and secretion of MMP-3/RANKL from fibroblast-like synoviocytes (FLS). In tumors, we previously reported that the expression of mitochondria-related genes is low and increased numbers of mitochondria enhance cell apoptosis. However, the relationship between mitochondrial biogenesis and joint destruction in RA remains unclear. To elucidate this relationship, we measured the expression levels of mitochondria-related genes and mitochondrial DNA in RA-FLS and osteoarthritic (OA)-FLS. We then tested the effects of AICAR (5-Aminoimidazole-4-carboxamide ribonucleotide), an enhancer of mitochondrial biogenesis, on MMP-3/RANKL secretion in RA-FLS and on joint destruction in collagen-induced arthritis (CIA) mice.

Methods: Quantitative PCR was used to assess the expression levels of mitochondria-related mRNA (PGC-1a, NRF-1, and TFAM) and number of mitochondrial DNA (mtDNA) in RA- and OA-FLS. The effect of AICAR (2 mM) on mitochondrial biogenesis in RA-FLS was assessed in the same way. Cell viability was assessed using WST assay, and MMP-3/RANKL secretion was measured using an immunoassay (immunoblot and ELISA) with/without IL-1b or TNFa stimulation. For evaluating the effect of AICAR (500 mg/kg) on joint destruction in CIA mice, micro-CT was used.

Results: The expression of NRF-1 and TFAM and the levels of mtDNA were lower in RA-FLS than in OA-FLS (Fig. 1). In RA-FLS, the levels of mtDNA and mRNA expression of mitochondria-related genes were enhanced by AICAR (Fig. 2a, 2b). AICAR inhibited cell viability and IL-1b- or TNFa-induced MMP-3/RANKL secretion in inflammation-induced RA-FLS (Fig. 2c, 2d). Moreover, AICAR reduced the arthritis score and joint destruction in CIA mice (Fig. 3).

Conclusion: Downregulation of mitochondrial biogenesis is related to the disease state of RA, and enhancement of mitochondrial biogenesis resulted in the suppression of disease activities of RA, such as reducing RA-FLS viability, secretion of MMP-3/RANKL from RA-FLS, and joint destruction in CIA mice. A novel therapeutic approach by changing mitochondrial biogenesis is proposed.

Session Title: Rheumatoid Arthritis Animal Models II

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Rheumatoid arthritis (RA) is an autoimmune disease that causes chronic inflammation and destruction of the joints and some extra-articular tissues. Netrin-1 is a laminin-like matrix protein that acts as a chemorepulsant and which is expressed during and required for osteoclast differentiation. In other settings Netrin1 has been reported to play a pathogenic role during inflammation by preventing macrophage egress from inflamed sites. Therefore, we asked whether blockade of Netrin-1 or its receptors Unc5b and DCC may be useful therapeutic targets in the treatment of inflammatory arthritis.

Methods: The K/BxN serum transfer model was used. 8wk old C57Bl/6 mice were injected ip with 0.2ml K/BxN serum at day 0 and 2, and at the same time murine monoclonal antibodies against Netrin-1, Unc5b or DCC (10μg/mice) were injected ip (n=10 each). Antibodies were administered weekly for up to 4 weeks. Clinical signs like paw swelling and thickness were measured daily using a caliper. The scores of all four paws were added for a composite score. Animals were sacrificed 2 and 4 weeks after serum transfer, and legs were prepared for microCT and histology.

Results: Serum transfer induced an increase in paw inflammation that was maximal 2 weeks after injection, and weekly ip injection of anti-Netrin-1 or anti-Unc5b antibodies significantly reduced paw inflammation (clinical score of 9.8±0.8 and 10.4±0.9 respectively vs. 16±0 for control, $p<0.001$, n=10) whereas anti-DCC antibodies had no effect (13.5±0.5 vs. 16±0 for control, p=ns, n=10). The same results were observed for changes in paw thickness; weekly ip injection of anti-Netrin-1 or anti-Unc5b antibodies significantly reduced the change in paw thickness from baseline 2 weeks after serum transfer (0.4±0.05mm and 0.3±0.4mm respectively vs. 0.7±0.02mm for control, $p<0.001$, n=10) and anti-DCC antibodies had no effect (0.6±0.04 vs. 0.7±0.02 for control, p=ns, n=10). microCT analysis showed bony erosions in untreated or anti-DCC treated mice whereas there were no erosions in anti-Netrin-1 and anti-Unc5b treated animals. TRAP staining demonstrated a marked decrease in osteoclasts in anti-Netrin-1 and anti-Unc5b treated animals but not in anti-DCC treated or control mice (4±1 3±1 and 9±2 cells/hpf respectively vs.12±1 cells/hpf for control, $p<0.001$ and p=ns, n=5). Immunofluorescence staining revealed decrease Cathepsin K and CD68-positive cells in bones and joints of anti-Netrin-1 and anti-Unc5b treated animals but not in anti-DCC treated or control mice but Alkaline Phosphatase immunostaining for osteoblasts was not affected by any of the treatments.

Conclusion: Blockade of Netrin-1 and its receptor Unc5b by treatment, *in vivo*, with murine monoclonal antibodies prevents bone destruction and K/BxN serum transfer-induced arthritis. Netrin-1 may be a novel therapeutic target for inflammatory bone destruction and other forms of osteoclast-mediated bone resorption.

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis Animal Models II

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Siglecs (Sialic acid-binding immunoglobulin-type lectins) are type1 transmembrane proteins and expressed on cell surface of various immunocytes. Siglec9 is a member of CD33 related Siglecs which down-regulate both innate and acquired immune response. In our earlier studies, soluble Siglec9 was identified in the culture supernatant fluid of pulpal cells as a powerful anti-inflammatory element and has been found to be effective in several inflammatory diseases. The aim of this study is to investigate the efficacy of Siglec9 on murine collagen induced arthritis (CIA) model *in vivo* and the activation of cultured murine macrophage *in vitro*.

Methods: To initiate CIA model, DBA/1J mice were immunized subcutaneously with bovine type II collagen emulsified with adjuvant. Recombinant Siglec9 (5 or 50ng/gm body weight) was administered intravenously to the mice with CIA weekly from day 23 (primary immunization in day 0) to day 42. The arthritis score and the histologic score were evaluated using the parameters described in a previous report. The serum concentration of TNFα was measured using an ELISA assay. In vitro, murine macrophage cell-line RAW264.7 was cultured in monolayers, stimulated with 10 ng/ml of IFNγ, and concurrently treated with Siglec9 (0–10ng/ml) for 12 hours. Total RNA was extracted and subjected to real-time polymerase chain reaction (PCR) analysis to determine the mRNA expression of TNFα, IL-6, iNOS, as M1 markers, and CD206, Arginage-1, as M2 markers and GAPDH for RAW264.7. The effect of Siglec9 on the expression levels of TNFα, IL-6, and iNOS

protein in RAW264.7 was evaluated by ELISA and Western blot analysis. To clarify whether sialic acid are necessary for Siglec9 to demonstrate inhibitory effect, we used sialidase to remove sialic acid. RAW264.7 was pre-incubated with sialidase for 1 h before stimulation protocols were administered.

Results: Treatment with Siglec9 in CIA mice significantly suppressed the incidence rate and severity of arthritis (based on the arthritis score) in a dose-dependent manner. The beneficial effect was maximal in mice treated with 50ng/gm of Siglec9. Serum TNFα level was significantly inhibited in groups treated with Siglec9 compared with control group. Treatment with Siglec9 significantly reduced the histologic score in both knee and ankle joints. RT–PCR analysis revealed that treatment with Siglec9 decreased the mRNA expression of TFNα, IL-6, and iNOS in RAW264.7 stimulated with IFNγ in a dose-dependent manner. However, we could not find significant increase in mRNA expression of M2 marker such as CD206, arginaze-1, fizz1 by treatment with Siglec9. The protein expression of each M1 markers were also suppressed by treatment with Siglec9. Sialidase treatment canceled the inhibitory effect which was seen in treatment group with Siglec9.

Conclusion: Siglec9 reduced disease activity of arthritis and suppressed histological inflammation and joint destruction, and in vitro, M1 markers (TNFα, IL-6, iNOS) were remarkably suppressed by treatment with Siglec9 in dose dependent manner. The inhibitory effect of Siglec9 was canceled by removing sialic acid with sialidase.

KCa3.1 Ion Channel in the Pathogenesis of Rheumatoid Arthritis: KCa3.1-/- Mice Do Not Develop CIA

Siba Raychaudhuri[1], Smriti K. Raychaudhuri[2] and Heike Wulff[3], [1]Med/Rheumatology, Univ California Davis/VA Sacramento, Davis, CA, [2]Rheumatology/Immunology, VA Sacramento Medical Center, Davis, CA, [3]Pharmacology, UC Davis School of Medicine, Davis, CA
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis Animal Models II
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: KCa3.1 is a Ca^{2+}-activated K^+ channel that modulates Ca^{2+}-dependent signaling processes such as activation and cellular proliferation. KCa3.1 is expressed in $CCR7^+$ naïve and central memory T cells, in mast cells, macrophages, fibroblasts and endothelium. Given this expression pattern, KCa3.1 is likely to play a critical role in the pathogenesis of rheumatoid arthritis (RA). Here using KCa3.1 knockout mice ($KCa3.1^{-/-}$) we are reporting that functional KCa3.1 channels are critical for induction of collagen induced arthritis (CIA).

Methods: CIA mouse model is a well established tool to study the pathogenesis of RA and mostly DBA/1 mice are used for this model. $KCa3.1^{-/-}$ mice are on the C57BL/6 background so we used C57BL/6 mice to induce CIA as per the protocol of Inglis et al (*Arthritis Research & Therapy* 2007, **9**:R113). CIA was induced in $KCa3.1^{-/-}$ mice (n=10) and in C57BL/6 wild mice (n=10). Mice were observed for development of arthritis for 60 days. Arthritis was evaluated by clinical score (weekly); histopathological score and PET imaging of the joints was performed before sacrificing the mice on day-60.

Results: $KCa3.1^{-/-}$ mice did not develop any clinical evidence of arthritis and did not have histological evidence of joint inflammation. Whereas, about 60% of the wild-type C57BL/6 mice developed clinical and histological evidence of arthritis. Both clinical scores and histopathological scores for arthritis on day-60 was zero in the $KCa3.1^{-/-}$ mice; in wild-type mice the respective scores were 2.5 ±0.5 and 6±1.5. Further evidence of arthritis was confirmed by micro-PET imaging (Fig 1). CD3+ T cell proliferation in response to mouse collagen type II by CFSE dilution FACS study was significantly higher in the C57BL/6 wild mice compared to $KCa3.1^{-/-}$ mice .

Conclusion: Using the CIA model here we have demonstrated that wild-type C57BL/6 mice developed clinical, histopathological, immunological and radiological evidence of inflammatory arthritis whereas $KCa3.1^{-/-}$ mice did not. These results substantiate a critical role of the KCa3.1 potassium channel in the pathogenesis of RA. Since small molecule-based interference with KCa3.1 such as TRAM-34 is well tolerated, further evaluation of KCa3.1 channel blockers in models of RA may be a promising approach to identify new pharmacological targets

and develop new therapeutic strategies for this debilitating disease.

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis Animal Models II

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Chikungunya virus (CHIKV) is a rapidly emerging arthritogenic mosquito-borne alphavirus that has infected more than 1 million individuals in the Western Hemisphere since 2014. CHIKV arthritis can persist for months to years, but little is known about potential therapies for this epidemic polyarthritis. We previously reported that CHIKV arthritis and rheumatoid arthritis (RA) exhibit similar clinical features as well as peripheral T cell phenotypes, suggesting immunological overlap in the pathogenesis of CHIKV arthritis and RA. However, the effects of immunosuppression during CHIKV arthritis are unknown. Here, we describe the clinical and virological effects of immunosuppressive and antiviral therapies in a mouse model of CHIKV arthritis.

Methods: Two hundred and eighty C57BL6/J mice were infected with the La Reunion strain of CHIKV, followed by treatment on day 3 after infection with either neutralizing anti-CHIKV monoclonal antibodies or with one of seven immunomodulatory therapies: CTLA4-Ig, tofacitinib, anti-CD20, etanercept, methylprednisolone, naproxen, and methotrexate. Clinical disease was assessed by measuring footpad thickness over time. Viral titers at day 7 were measured by qRT-PCR.

Results: Treatment with CTLA4-Ig, tofacitinib, or with anti-CHIKV monoclonal antibodies effectively reduced arthritic swelling at day 7 after infection without major effects on viral titers in the affected joints. Administration of anti-CD20 or etanercept exacerbated CHIKV arthritis, distinguishing CHIKV arthritis from RA.

Conclusion: CHIKV arthritis is clinically ameliorated by tofacitinib, CTLA4-Ig or neutralizing monoclonal antibodies directed against the CHIKV E2 envelope protein. By contrast, blockade of TNF-alpha and depletion of CD20+ B cells had deleterious effects. Our results demonstrate novel potential therapies for CHIKV arthritis in a preclinical model. Additional studies are required to determine the safety and efficacy of these therapies in human patients with CHIKV arthritis since immunosuppression may still pose serious risks, especially during the acute phase of infection.

Oral to Subcutaneous Methotrexate Dose-Conversion Strategies in the Treatment of

Rheumatoid Arthritis

Michael Schiff[1] and Peter Sadowski[2], [1]Division of Rheumatology, University of Colorado, Denver, CO, [2]Antares Pharma Inc., Minneapolis, MN

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis-Small Molecules, Biologics and Gene Therapy VI: Strategies

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose:

Methotrexate (MTX) is the cornerstone of rheumatoid arthritis (RA) therapy[1] but absorption saturation limitations compromise oral MTX bioavailability (BA). Subcutaneous (SC) MTX has a dose-proportional, linear absorption profile compared to oral MTX, which plateaus at doses >15 mg.[2] Differences in the relative BA of oral vs SC MTX demonstrate the need for guidance on successful dose-conversion strategies.

Methods:

In a phase 2, 12-week, open-label, crossover study, 49 adults with RA already receiving MTX for ≥3 months were given 10, 15, 20, or 25 mg MTX based on their current MTX dose and disease control, and then randomized 1:1:1 to oral MTX, SC MTX (abdomen; $MTXAI_{ab}$), or SC MTX (thigh; $MTXAI_{th}$). Blood samples for pharmacokinetic (PK) analysis were collected pre-dose and at 13 time points 0.25 to 12 h post-dose; samples were analyzed by liquid chromatography–mass spectrometry. Mixed model analysis derived area under the curve (AUC), maximum observed concentration (C_{max}), and time to maximum concentration (T_{max}) PK parameters. Dose-normalized parameter ratios were calculated.

Results:

Mean age was 61 y, mean body mass index was 30.7 kg/m^2, and mean disease duration was 13 y; 63% of patients were female. PK analysis of $MTXAI_{th}$ vs oral MTX showed that BA of $MTXAI_{th}$ was consistently greater at all dose levels (Figure 1). $MTXAI_{th}$ and $MTXAI_{ab}$ PK measures were similar. Although oral MTX plateaued at 15 mg, MTXAI had no plateau, resulting in higher exposure than comparable oral doses. Relative BA (AUC of $MTXAI_{th}$ vs AUC of oral MTX) at 10, 15, 20 and 25 mg were 121%, 114%, 131%, and 141% respectively (Table 1). Ratios of the dose-normalized AUC_{0-24} [90% CI] and C_{max} [90% CI] of MTXAI vs oral MTX were 127.61 [122.30, 133.15] and 94.88 [87.95, 102.37]. Equivalence between oral and SC MTX doses was determined based on BA (Table 2). SC MTX was safe and well-tolerated in subjects with RA.

Conclusion:

A dose conversion method was established based on the BA of MTX from oral and SC administration. SC administration provided higher exposure of MTX than the same dose given orally.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis-Small Molecules, Biologics and Gene Therapy VI: Strategies
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose:

The variable response to anti-TNF therapy in patients with rheumatoid arthritis (RA) remains largely unexplained, and biomarkers for treatment response are scarce. We previously investigated whole blood micro-RNA (miRNA) as predictors of anti-TNF response. In this study we aimed to investigate association between plasma miRNAs and treatment response in 180 DMARD naïve early RA patients enrolled in the OPERA Study, a prospective, double-blinded, placebo-controlled study.

Methods:

Patients were randomized to methotrexate, intra-articular glucocorticoids plus either adalimumab or placebo. All patients had RA (ACR 1987 criteria). Plasma samples for total RNA purification were collected pre-treatment and at 3-month. 91 specific miRNAs were investigated by quantitative RT-PCR on a microfluidic dynamic array. Cq values were normalized with spiked-in synthetic miRNAs and further normalized using means of all endogenous expressed miRNAs. Means were compared (Welch's *t*-test) of pre-treatment miRNAs and of the 3-month change in miRNA expression for the groups of responding and non-responding patients. Response was defined by 12-month ACR/EULAR Boolean remission.

Results:

We successfully profiled 76/91 miRNAs in 180 pre-treatment samples and in 170 (94%) 3-month samples. Pre-treatment expression of six miRNAs (Table 1), and altered change in expression of eight miRNAs (Table 2) were associated ($p<0.05$) with remission to adalimumab treatment. In the placebo group, pre-treatment expression of 12 miRNAs, and altered change in expression of four miRNAs were associated with remission. Adalimumab treated responders had increased pre-treatment miR-27a-3p ($p=0.004$), which decreased after 3 months compared to non-responders ($p=0.0001$). Placebo treated responders had increased miR-27a-3p compared to adalimumab responders ($p=0.03$). miR-146a decreased ($p=0.01$) in adalimumab responders vs. non-responders consistent with previous data on miR-146a as a putative marker of disease activity. Placebo responders vs. non-responders did not differ with respect to miR-146a changes. In our previous study of whole blood, miR-23a was also associated with remission in the adalimumab group.

Conclusion:

In this well-characterized cohort we have identified miRNAs predictive of treatment response. Our results suggest miR-27a-3p as particular promising as both predictor and biomarker of response to adalimumab treatment. The results should be interpreted with some reservation due to the large number of associations investigated, and need validation in independent prospective studies.

Table 1. Pre-treatment expression in remitting RA patients

miRNA	Adalimumab + DMARD Remission (n=43) vs no-remission (n=43)	p-value	Placebo + DMARD Remission (n=29) vs no-remission (n=54)	p-value

Session Title: Rheumatoid Arthritis-Small Molecules, Biologics and Gene Therapy VI: Strategies

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: In early rheumatoid arthritis (eRA), a clinically significant proportion of patients may respond to first-line treatment with methotrexate (MTX). A priori identification of patients with high or low likelihood of response to MTX would enhance therapy strategies. Previously, we have presented data on the multi-biomarker disease activity (MBDA) score, based on twelve biomarkers, from the Swedish Farmacotherapy (SWEFOT) trial. The objective of this study was to investigate these biomarkers at baseline (BL) separately and in simple combinations as predictors of response to MTX monotherapy.

Methods: Analyses were done on a subset of 298 patients with eRA from the SWEFOT population (104 responders [DAS28≤3.2] and 194 non-

responders [DAS28>3.2] to MTX) who had complete data on the 12 biomarkers from the MBDA score at BL and DAS28 at Month 3. The categories of these biomarkers (low, moderate and high) were defined using tertiles with the exception of CRP, where the following cutoffs (mg/L) were applied: ≤10 for low, >10-30 for moderate and >30 for high. For the comparison of proportions of responders and non-responders between patients with different categories of the biomarkers, the χ^2 test was used. Each individual biomarker was analyzed as a predictor (without correcting for multiple comparisons), followed by a study of combinations of the most strongly predictive biomarkers.

Results: In MTX-responders versus non-responders, out of the 12 biomarkers at BL, the medians of CRP and IL-6 were significantly lower (15 vs 20, p=0.038, and 49 vs. 67, p=0.049), and TNF-RI and VCAM-1 were significantly higher (1.9 vs 1.7, p=0.005, and 0.70 vs. 0.64, p=0.006), respectively. Of patients with both low CRP AND high TNF-RI at BL (n=19), or low IL-6 AND high TNF-RI (n=27) higher proportions were responders compared with the rest (79% vs 32%, p<0.001, and 74% vs 31%, p<0.001, Figures 1A and B respectively). In contrast, patients with low/moderate VCAM-1 AND high CRP (n=61) or low VCAM-1 AND moderate/high IL-6 (n=55) were more likely not to respond to MTX than the others (85% vs 60%, p<0.001; Figures 1C and D). All 19 patients with low VCAM-1 AND high CRP AND moderate/high IL-6 were MTX-non-responders.

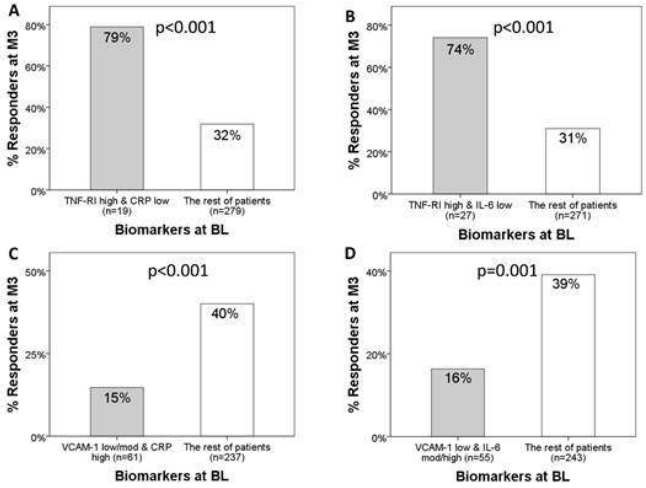

Figure 1. Association of different biomarkers with response to MTX therapy. Patients grouped using combination of TNF-RI with CRP **(A)**, TNF-RI with IL-6 **(B)**, VCAM-1 with CRP **(C)** and VCAM-1 with IL-6 **(D)**. M3 – Month 3, BL – baseline.

Conclusion: We identified individual biomarkers and 2-biomarker combinations that were associated, positively or negatively, with the clinical response to MTX monotherapy. If reproduced in other study populations, these results suggest that biomarkers and their combinations might be helpful in decision-making on the initial therapy of patients with early RA.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis-Small Molecules, Biologics and Gene Therapy VI: Strategies

Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Recently published randomized controlled trials (RCTs) have demonstrated similar outcomes in rheumatoid arthritis (RA) patients treated with triple therapy [methotrexate (MTX), sulfasalazine (SUL) and hydroxychloroquine (HCQ)] in comparison to patients receiving MTX plus etanercept, a tumor necrosis factor inhibitor (TNFi). Competing strategies examined in RCTs have included the addition of TNFi or concomitant SUL/HCQ to MTX in patients experiencing suboptimal improvement in MTX alone. This study aims to compare adherence and persistence rates between combination treatments in US Veterans who added TNFi or concomitant SUL/HCQ to MTX.

Methods: Veteran's Affairs clinical and administrative data from January 1, 2006 to December 31, 2012 was used for this retrospective cohort study. Veterans with ICD-9-CM codes for RA transitioning from MTX monotherapy to MTX-TNFi or triple therapy, the latter characterized by simultaneous addition of HCQ/SUL, were examined for the 12-month period following combination initiation. For the primary outcome, persistence required that all drugs in each treatment be continued over the 12-month period without a ≥90 day gap in refilling of any drug. Two alternative outcomes were examined: 1) allowed discontinuation of any one DMARD in triple therapy or MTX in the MTX-TNFi group, provided no new DMARDs were initiated or 2) permitted switching between drugs within the TNFi class and non-biologic DMARD. Adherence was calculated using proportion of days covered (PDC), defined as PDC ≥ 80% at 12 months.

Results: The MTX-TNFi patients (n=2,125) had higher adherence and persistence compared to triple therapy patients (n=171) (p<0.001 for all outcomes). The primary persistence outcome demonstrated that 45% were persistent on MTX-TNFi and 18% were persistent on triple therapy (p<0.001) (Figure, Table). 12 month adherence (PDC) was higher for the MTX-TNFi group (26%) than the triple therapy group (11%). While the relatively small sample size of the triple therapy group made controlling for all potential confounders difficult, adjustment for observed covariates did not significantly alter persistence and adherence.

	Crude Model				Matching Weights Adjusted Model			
Outcomes (% of patients)	MTX-TNFi N=2,125	Triple Rx N=171	P Value	Relative Risk (95% CI)	MTX-TNFi N=170	Triple Rx N=171	P Value	Relative Risk (95% CI)
Primary Outcome	960 (45.2%)	30 (17.5%)	<0.0001	2.6 (1.8, 3.6)	73.4 (43.1%)	30.0 (17.6%)	<0.0001	2.5 (1.7, 3.6)
Persistent Alternative #1	1115 (52.5%)	56 (32.8%)	<0.0001	1.6 (1.3, 2.0)	85.6 (50.3%)	56.0 (32.8%)	0.0022	1.5 (1.2, 2.0)
Persistent Alternative #2	1235 (58.1%)	58 (33.9%)	<0.0001	1.7 (1.4, 2.1)	97.2 (42.9%)	58.0 (33.9%)	<0.0001	1.7 (1.3, 2.2)
Adherence Outcome	547 (25.7%)	18 (10.5%)	<0.0001	2.4 (0.1, 3.8)	43.0 (25.3%)	18.0 (10.5%)	<0.0001	2.4 (1.4, 4.0)

Conclusion: Real-world persistence and adherence in VA patients were higher in RA patients receiving MTX-TNFi therapy compared to triple therapy. Findings were robust to varying outcome definitions and controlling for potential confounders. While potential effects of channeling bias cannot be excluded, these findings suggest that the patterns and benefits of use of triple therapy in clinical practice may be different than that seen in RCTs.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis-Small Molecules, Biologics and Gene Therapy VI: Strategies
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: ACT-iON was a global, multicenter, observational, 52-wk, clinical practice study of the effectiveness of tocilizumab (TCZ) vs anti–tumor necrosis factor (aTNF) agents prescribed as first biologic therapy after inadequate response to DMARDs (DMARD-IR).

Methods: Eligible patients were DMARD-IR with moderate to severe RA (1987 ACR criteria) for ≥24 wks who were prescribed TCZ or aTNF as their first biologic, in accordance with local label, within 6 weeks of enrollment. The study comprised a 52-wk observation period. No study-specific medication or dosing regimen was stipulated. The primary effectiveness measure was change in $DAS28_{ESR}$ from baseline to wk 24. Data were analyzed by treatment group based on the first administered biologic. Safety was assessed in patients receiving ≥1 dose of biologic. Effectiveness was assessed in patients with a disease activity assessment <60 days before first biologic dose (effectiveness population). Missing data were not imputed, and no correction for multiple testing was applied.

Results: Of 1250 patients screened, 1225 were enrolled; 1216 received ≥1 dose of biologic (safety population: TCZ, 423 [34.8%]; aTNF, 793 [65.2%]), and 1083 were included in the effectiveness population (TCZ, 390 [36.0%]; aTNF, 693 [64.0%]). Overall, 158/1216 (13.0%) patients discontinued the study (lack of efficacy: TCZ, 0.9%; aTNF, 2.0%; adverse events [AEs]: TCZ, 2.1%; aTNF, 1.6%). Drug survival was higher with TCZ than aTNFs (p<0.001; Table). TCZ vs aTNF patients had shorter disease duration and started their biologic more often as monotherapy (28.1% vs 16.0%; Table). Oral corticosteroids were used in a higher proportion of TCZ patients. Although baseline $DAS28_{ESR}$ was similar between groups, TCZ patients had a significantly larger change from baseline in $DAS28_{ESR}$ than aTNF patients (difference in adjusted means [95% CI]: wk 24, –0.9 [–1.1, –0.6]; wk 52, –0.9 [–1.2, –0.6]; p<0.001 at wks 24 and 52). Changes from baseline at wks 24 and 52 for other effectiveness parameters were also significantly better with TCZ (Table). Sensitivity analysis restricting validated baseline assessments to 2 weeks before first biologic dose confirmed these results. AEs and serious AEs (SAEs) occurred in 49.2% and 5.2% of TCZ patients and 56.6% and 8.1% of aTNF patients. Infections were the most common AEs (TCZ, 20.8%; aTNF, 25.9%) and SAEs (TCZ, 1.9%; aTNF, 3.3%). Three (0.7%) TCZ patients and 6 (0.8%) aTNF patients died; 1 death in each group (both due to pneumonia) was deemed treatment related.

Table. Demographics and Baseline, Wk 24, and Wk 52 Effectiveness Parameters

	TCZ	aTNF	Difference
Baseline Demographics and RA Disease Characteristics[a]	**n = 423**	**n = 793**	
Age, years, mean (SD)[b]	54.3 (12.8)	55.2 (13.1)	p=0.171
Disease duration, years, mean (SD)[b]	7.8 (7.3)	9.4 (9.0)	p=0.014
Initiated biologic as monotherapy, n (%)	119 (28.1)	127 (16.0)	p<0.001[g]
MTX, n (%)[c] [median dose in mg/wk][d]	219 (72.0) [15.0]	537 (80.6) [15.0]	—

HAQ-DI change from baseline to wk 24, adjusted mean (95% CI)[f]	−0.6 (−0.7, −0.5)	−0.4 (−0.5, −0.4)	−0.1 (−0.3, −0.0) p=0.020
HAQ-DI change from baseline to wk 52, adjusted mean (95% CI)[f]	−0.6 (−0.7, −0.5)	−0.4 (−0.5, −0.3)	−0.2 (−0.3, −0.0) p=0.020

[a]Safety population.
[b]p value based on Wilcoxon rank-sum test.
[c]Percentages based on number of patients who initiated biologic in combination with DMARDs.
[d]For MTX dose: TCZ, n = 233; aTNF, n = 541.
[e]Primary effectiveness population (N for specific analyses are lower).
[f]p value based on analysis of covariance with change from baseline as dependent variable; therapy (monotherapy/combination), site country, and treatment as fixed effects; and baseline value as covariates.
[g]p value based on Chi-square test for comparison of monotherapy and combination therapy between both treatment groups.

Conclusion: In DMARD-IR patients starting a biologic for the first time in real-life settings, TCZ was initiated as monotherapy more often than aTNFs. Safety profiles of TCZ and aTNFs were comparable and similar to the safety profiles from clinical trials. TCZ was associated with better drug survival and was possibly associated with better improvements in DAS28, CDAI, and HAQ-DI than aTNFs.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis-Small Molecules, Biologics and Gene Therapy VI: Strategies

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose:

In RA patients, different randomized clinical trials have showed that the efficacy of reduced dose of RTX either initially and for subsequent courses (DANCER, SERENE MIRROR trials), or for retreatment after an initial full dose (SMART trial) did not differ from standard dose, with the advantage of a lower cost and a possible better safety.

Objective

To investigate the maintenance of RTX in patients retreated with reduced doses after an initial full-dose compared with RTX to standard doses at each infusion in real life setting.

Methods:

Patients of AIR registry (a nationwide prospective study investigating the long-term safety and efficacy of RTX in real life) were included in this specific study if they were retreated at least once with RTX for RA and had at least 6 months of follow-up. According to RTX retreatment regimen, three groups were defined. Group A: patients treated with 2 infusions of 1000 mg for all courses, group B: patients treated by 2 infusions of 1000 mg for the first course and reduced dose from the second course of RTX and thereafter and group C: patients treated by 2 infusions of 1000 mg for more than 1 course and reduced dose at a later course of RTX. Regimen of RTX was very variable in group C and will need specific analyses. Thus, this work focus on comparison of group A and B. Non maintenance was defined by the scientific committee of the registry as either death, lack of efficacy defined by introduction of a DMARD, switch to another biologic agent, increase in corticosteroid dose (≥10 mg at 2 times during follow-up), or according to physician judgment, or for side effect. Patient follow-up was censored at 3 years. Maintenance of group B was compared to that of group A using Kaplan Meier analyses and Hazard Ratio were calculated using Cox proportional Hazard model.

Results:

In total, 1233/1986 patients from the registry fulfilled inclusion criteria: group A (n=841), group B (n=175) and group C (n=217). Comparison of patient characteristics between groups did not revealed major difference. However, the patients of the group B were more likely to have erosive disease and a lower DAS28 at time of retreatment compared to group A. Maintenance of Rituximab did not significantly differ between groups A and B (median= 38 vs 40 months; hazard ratio [HR]= 0.79 [0.62-1.02], p= 0.0972). Overall, the mean time between 2 courses was lower in group B compared to group A (6.5 months vs 7.5, $p< 0.001$), but the cumulative RTX dose for retreatment measured in mg/year were decreased by 36% in group B compared to group A (1400 vs 2500 mg, $p< 0.001$).

Conclusion:

Maintenance therapy at 3 years in RA patients treated with RTX did not differ between patients treated with full-dose at each course or with reduced dose since the second course. Also the total dose of RTX / year may be decreased by 36% leading to economic and possibly safety benefits without interfering with effectiveness.

SESSION INFORMATION

Session Title: Sjögren's Syndrome II: Clinical Discoveries

Session Type: ACR Concurrent Abstract Session

Background/Purpose: Autoimmune diseases are often preceded by subclinical serologic and functional abnormalities that predate diagnosis by several years. The insidious and progressive nature of these incomplete syndromes results in a lag in diagnosis, preventive and therapeutic strategies, and likely contributes to damage accrual.

Methods: : To explore possible markers of transition from incomplete Sjögren's Syndrome (iSS) to complete Sjögren's Syndrome (SS), 467 iSS patients were compared to 364 SS (SS) meeting AECG classification criteria in a multi-disciplinary sicca clinic. All subjects were evaluated for AECG classification measures, clinical and serological features (25 autoantibodies), and gene expression profiling of 64 interferon (IFN)-inducible genes. We developed an IFN-score based on the most informative 14 genes, which were differentially expressed ($p<0.05$, fold-change>2, and log2[SD(expression)]<1.75 for each group) in nine controls from previous microarray and RNASeq experiments

with known high (n=4) and low (n=5) IFN-signature expression. A logistic regression model was created to calculate the probability of having a high interferon level for each iSS case; the resulting probability output is the IFN score.

Results: Nineteen iSS subjects had anti-Ro antibodies (4.1%), and 33 (7.1%) were biopsy (+); the remaining 415 had nonSS-sicca. Ro (+) iSS constituted a distinct subgroup from all Ro (-) iSS: they were younger (*p=0.001*), less white (*p=1.95E10-7*), more anti-La (+) (*p=8.8E10-6*), and had more hypergammaglobulinemia (*p=0.02)* and lymphopenia (*p=0.009)*; 14/19 had extraglandular manifestations. These same statistically significant clinical differences were also observed when Ro (+) iSS to biopsy (+) iSS and Ro (-)/biopsy (-) iSS. Subsets of Ro (-) iSS subjects were (+) for other autoantibodies associated with SLE or Scleroderma: 14 had anti-Cenp-B and 10 had anti-dsDNA. Quantitatively, IFN-inducible gene expression occurs in a gradient: non-SS sicca patients have low IFN scores, biopsy (+)/Ro (-) have intermediate scores, and Ro (+) have high IFN scores, which are similar to those identified in autoantibody (+) pSS patients. High IFN-scores correlated with presence of any autoantibodies (*p=1.08E-08*), Ro (+) iSS (*p=4.53E-06*), and biopsy (+) iSS (*p=6E-03)*, but only marginally with reduced salivary flow (*p=0.018*). There was no significant difference in IFN scores between SS and Ro (+) iSS, but SS had higher IFN scores than both biopsy (+) iSS and non-SS sicca (*p=8.6E-3* and *1.95E-30*, respectively).

Conclusion: Patients with iSS may represent a *forme frustre* of SS, but it is plausible that some subsets, in particular Ro (+) iSS and dsDNA(+) iSS, will progress to SS, SLE, or overlap syndromes, respectively. The fact that they present similar IFN-signatures as those observed in SS further supports this notion, and therefore, iSS patients warrant careful follow up to characterize the transition to full-blown SS. Understanding the early events of disease has the strongest potential to lead to improvements in prevention, early diagnosis, and therapeutics.

SESSION INFORMATION

Session Title: Sjögren's Syndrome II: Clinical Discoveries

Session Type: ACR Concurrent Abstract Session

Background/Purpose:

In primary Sjögren's syndrome (pSS) B cell hyperactivity including autoantibody secretion and lymphoma development are hallmark immunopathological features. Specific lymphoid organization (including germinal centers) is associated with increased risk for development of extraglandular manifestations and lymphoma. Thus better understanding of the cellular and molecular pathways that underlie formation of ectopic lymphoid structures is of pivotal importance. T follicular helper (Tfh) cells, expressing ICOS and cytokines like IL-21 play a critical role in the formation of such structures and in activation of B cells. Recently, a novel subset of CD4+ T cells found to have Tfh-like characteristics was found to be specifically attracted to mucosal sites by CCL25, the ligand for CCR9. Our objective was to investigate the role of CCR9+ T cells and CCL25 in pSS.

Methods:

Levels of CCL25 and 103 other soluble targets were measured in serum and washouts from labial salivary gland (LSG) biopsies by Luminex. CCL25 mRNA in LSG was quantified by qPCR. CCR9-expressing cells were assessed in the LSG by immunohistochemistry. Circulating CCR9-expressing cells were assessed by flow cytometry and cultured to assess functional properties (cytokine production).

Results:

Increased CCL25 was measured in serum of pSS and nSS patients as compared to HC (median pSS, nSS, HC 2.75, 2.61 and 1.99 ng/mL, sicca

patients vs HC: p=0.04, nSS vs pSS: ns). CCL25 serum levels in pSS correlated with chemokines involved in formation of ectopic lymphoid structures CXCL13 and CCL19, and proinflammatory cytokines IL-12 and TWEAK. In addition, pSS patients displayed around an increase in CCL25 mRNA levels in LSG (p=0.04) and increased CCL25 protein levels in LSG washouts as compared to nSS patients (median 1.24 vs 0.97 ng/mL, p=0.04). pSS patients showed enhanced numbers of CCR9-expressing cells in the salivary gland (mean pSS 9.2, nSS 3.8 cells/mm2, p=0.006). Interestingly, CCR9+ Th cells from pSS patients express increased levels of PD-1 and ICOS (both $p<0.05$). In addition, CCR9+ T cells expressed significantly higher levels of IL-7Rα as compared to CXCR5 Tfh precursor cells ($p<0.01$) and secreted strongly increased levels of IFN-y, IL-10, IL- 17, IL-6, IL-21 but not CXCL13 upon stimulation with IL-7 as compared to CXCR5+ Tfh cells.

Conclusion:

Enhanced expression of CCL25 could significantly contribute to the increased numbers of CCR9+ cells in particular CCR9-expressing Tfh-like cells in labial salivary glands from pSS patients. Considering the increased expression of ICOS and IL-7Rα on CCR9+ Th cells and the capacity of IL-7 to induce pro-inflammatory and Tfh-like cytokine secretion this suggests that the CCL25/CCR9-axis might play a significant role in lymphoid neogenesis and immunopathology of pSS, representing a novel therapeutic target in this disease.

SESSION INFORMATION

Session Title: Sjögren's Syndrome II: Clinical Discoveries

Session Type: ACR Concurrent Abstract Session

Background/Purpose:

Sjögren's syndrome (SS) is a chronic autoimmune inflammatory disease characterized by bilateral hypofunction of lacrimal and salivary glands leading to keratoconjuctivitis and xerostomia. The hallmark of SS is presence of antibodies against Ro (SS-A) and La (SS-B). Recent studies showed the presence of antibodies against M3 muscarinic acetylcholine receptor (M3R), a receptor found in endocrine and exocrine glands including salivary and lacrimal glands. M3R is a seven transmembrane GPCR having 3 extracellular and 3 intracellular domains/loops, responsible for smooth muscle contraction and glandular secretion. We hypothesized that antibodies derived from salivary gland against extracellular domains of M3R are functional and are responsible for decrease in salivary and lacrimal flow observed in Sjögren's syndrome.

Methods:

Production of monoclonal antibodies (MAbs): Patients meeting the American College of Rheumatology (ACR) classification criteria for primary Sjögren's syndrome (pSS) were evaluated at OMRF Sjögren's Research Clinic (OSRC). Control patients do not meet the criteria (DNMCs). A single cell suspension was prepared from labial salivary gland tissue obtained following biopsy. Antibody secreting cells (ASCs) having CD3- CD4- CD8- CD19+ $CD27^{high}$ $CD38^{high}$ IgG+ were sorted by fluorescence-activated single cell sorting. Recombinant MAbs were produced from ASCs by sequencing the V, D, J and CDR of the heavy and light chains amplified by RT-PCR and nested PCR, cloned into an expression vector, transfected to human cell line, expressed and purified. MAbs derived from pSS and DNMCs were 51 and 18 respectively.

M3R experiments: Peptides encoding the 2^{nd} (a.a. 213-228) and 3^{rd}(a.a. 514-527) ECL of M3R were employed in an ELISA to detect antibodies against these domains. FRET agonist/antagonist functional assays for MAbs using chimeric CHO-K1 NFAT bla cells, engineered to express human M3R along with beta lactamase reporter gene under control of NFAT response element, were carried out. CHO-K1 cells were incubated with 100 µg/ml mAb following incubation with either assay media or with carbachol at EC80 followed by substrate and fluorescence detection.

Results:

MAbs from pSS patients were highly reactive to 2nd as well as 3rd ECL as compared to DNMCs. We found significantly high O.D. values (> 4) in MAbs derived from pSS as compared to DNMCs. In MAbs from pSS, 9/51 were positive for 2nd ECL and 5/51 were positive for 3rd ECL. Where as in DNMCs none of the MAbs were positive for 2nd ECL however two of the MAbs were found positive for 3rdECL (cut-off 2 S.D. above DNMCs average O.D.). From the functional assays we have tested eight MAbs so far and found significant inhibition ranging from 14-66 % of the total stimulated response. None of these antibodies were found to be stimulatory.

Conclusion:

Anti-M3R antibodies have become a center of interest in rheumatology because of its possible pathogenesis and detection in SS as well as borderline SS patients. This data suggests inhibitory role of anti-M3R antibodies in producing SS symptoms. Second extracellular loop could play an antigenic role for anti-M3R antibodies. Our further studies will test whether passive transfer of MAbs into mice could induce Sjögren's like disease.

First publication: September 29, 2015

SESSION INFORMATION
Session Title: Sjögren's Syndrome II: Clinical Discoveries
Session Type: ACR Concurrent Abstract Session

Background/Purpose: Primary Sjögren's syndrome (pSjS) is characterized by chronic inflammation of the lacrimal and salivary glands, as well as frequent extraglandular involvement and increased risk of B cell lymphoma. Several lines of evidence implicate the lymphotoxin (LT) pathway in the pathogenesis of this disease. Baminercept inhibits the LT pathway, which is important in lymphoid tissue organization and chronic inflammation. This study tests the clinical efficacy and safety of baminercept in pSjS.

Methods: We randomized subjects in a 2:1 ratio to receive 24 weekly subcutaneous injections of baminercept 100 mg or placebo. Eligible subjects met the 2002 American-European Consensus Group classification criteria for pSjS, had a pilocarpine-stimulated whole salivary flow (SWSF) of ≥ 0.1 mL/min, and had ≥ 1 systemic manifestations. The primary endpoint was the change in SWSF between baseline and week 24. Secondary endpoints included the safety of baminercept and the changes in unstimulated whole salivary flow (UWSF), Schirmer-I-test, ocular staining, fatigue, joint pain, overall dryness, and the EULAR SjS Disease Activity Index (ESSDAI). Subjects that received at least one dose of study medication constituted the modified intent-to-treat (mITT) population. Subjects were followed for 48 weeks.

Results: Only 52 of the planned 72 subjects were enrolled due to study drug expiration. Of the 52 eligible subjects, 33 and 19 subjects were randomized to the baminercept and placebo treatment groups, respectively. Ten of the 52 (19%) participants withdrew from treatment (adverse event, 4; subject decision 3; > 4 missed doses, 1; investigator decision, 1; other, 1). In the mITT population (n=52), we found no difference between the baminercept and placebo groups in the change in SWSF (adjusted mean: -0.01 vs. 0.06 mL/min; p=0.37). However, the ESSDAI improved significantly more in the baminercept than the placebo group (adjusted mean change: -1.6 vs. -0.25; p=0.043). In addition, there were no significant differences between treatment groups in the change in UWSF, Schirmer-I-test, ocular staining, fatigue, joint pain, and overall dryness. Lymphocyte numbers increased during baminercept treatment compared to the placebo group (p < 0.0001), an expected effect of baminercept on cellular trafficking. Baminercept treatment was not associated with any significant changes in the serum levels of CXCL13, LIGHT, IP10, and BAFF. Seven subjects had a serious adverse event (SAE), including 2 subjects (baminercept group) with grade 3 hepatic injury who recovered without sequela. Transaminase abnormalities (>ULN) occurred more frequently in the baminercept group (10 subjects [30%], 15 events) than the placebo group (3 subjects [16%], 5 events), including the 2 subjects with SAEs who had grade 3 abnormalities; the

remainder had grade 1 elevations.

Conclusion: Baminercept therapy was no more effective than placebo for increasing salivary flow or reducing ocular dryness, and was accompanied by an imbalance in transaminase elevations and 2 cases of reversible grade 3 hepatic injury. The finding that baminercept therapy was associated with improvement in the ESSDAI warrants further study.

Hypoechoic Lesions on Parotid Gland Ultrasound Are a Surrogate Marker of Focal Lymphocytic Sialadenitis on Minor Salivary Gland Biopsy in Sjögren's Syndrome

Thomas Grader-Beck[1], Joel Fradin[2], Jean Kim[3], Esen Akpek[4], Brendan Antiochos[5], Julius Birnbaum[6] and Alan N. Baer[7], [1]Medicine Div of Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD, [2]Department of Radiology and Radiological Science, Johns Hopkins University School of Medicine, Baltimore, MD, [3]Otolaryngology, Head & Neck Surgery, Johns Hopkins University, Baltimore, MD, [4]Ophthalmology, Johns Hopkins University School of Medicine, Baltimore, MD, [5]Medicine-Division of Rheumatology, Johns Hopkins University, Baltimore, MD, [6]Medicine (Rheumatology), Johns Hopkins University School of Medicine, Baltimore, MD, [7]Division of Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Sjögren's Syndrome II: Clinical Discoveries

Session Type: ACR Concurrent Abstract Session

Background/Purpose: To determine whether hypoechoic lesions on parotid gland ultrasound can serve as a surrogate marker for a focus score ≥1 on minor salivary gland biopsy in patients with suspected Sjogren's syndrome (SS)**.**

Methods: We analyzed 220 parotid gland salivary gland ultrasounds that were obtained on 220 patients being evaluated for possible or known SS at the Johns Hopkins Sjogren's Center between 2012 and 2015. All scans were performed and interpreted by a radiologist (JF) with expertise in ultrasonography. The presence of hypoechoic lesions within the parotid gland parenchyma was determined in each scan. Sjogren's syndrome (SS) was diagnosed according to AECG or preliminary ACR criteria. Statistical analyses were performed using Fisher's exact and Student's t-test.

Results: Among the 220 patients, 116 fulfilled classification criteria for SS. The remaining patients were labeled as "sicca controls". Hypoechoic lesions were significantly more frequent in SS patients versus controls (55/116 versus 3/104; $p < 0.0001$) resulting in a sensitivity of 47% and specificity of 97% for SS. A minor salivary gland biopsy was performed in 64 patients with SS and showed a focus score ≥ 1 in 51 (80%). The presence of hypoechoic lesions on ultrasound was highly associated with FLS ≥1 (23/24 versus 28/40, OR 9.9; 95% CI 1.2-81.5). The mean focus score was not significantly different in SS patients with hypoechoic lesions compared to SS patients without hypoechoic lesions (3.22 versus 2.39, p=*ns*). Positive autoantibody status (anti-SSA/SSB/rheumatoid factor, hypergammaglobulinemia) as well as leukopenia, monoclonal gammopathy and salivary gland swelling were significantly more frequent in SS patients with hypoechoic lesions, whereas there was no difference in frequency of C3 and C4 hypocomplementemia or symptom duration. Other features on parotid gland ultrasound, including heterogeneity, calcifications and presence of cysts did not predict FLS ≥ 1 as accurately as hypoechoic lesions. Moreover, addition of submandibular gland ultrasound data did not add additional predictive value.

Conclusion: Hypoechoic lesions on parotid gland ultrasound strongly correlate with the presence of a focus score ≥1 on minor salivary gland biopsy. Larger studies are needed to determine whether ultrasound imaging may replace a diagnostic lip biopsy in subsets of patients evaluated for SS.

SESSION INFORMATION

Session Title: Sjögren's Syndrome II: Clinical Discoveries

Session Type: ACR Concurrent Abstract Session

Background/Purpose: T cell-dependent B cell hyperactivity is a characteristic pathogenetic feature of primary Sjögren's syndrome (pSS). This is illustrated by the finding that treatment of pSS patients with either abatacept or rituximab improves disease activity [1-2]. However, the mode of action of both treatment modalities in pSS remains elusive. The current study assessed the impact of abatacept or rituximab treatment on circulating $CD4^+$memory T cell subsets in pSS patients.

Methods: Fifteen pSS patients treated with abatacept and twenty-four pSS patients treated with rituximab were included in this study [1-2]. Percentages of $CD4^+$memory T cell subsets were assessed by flow cytometry analysis of peripheral blood mononuclear cells from patients at baseline, during treatment and after treatment. Expression patterns of CD45RA, CXCR3, CCR6, CCR4, CXCR5, programmed death-1 (PD-1), inducible costimulator (ICOS) and FoxP3 were used for distinction of Th1, Th2, Th17, T follicular helper (Tfh) and T regulatory (Treg) subsets. Generalized estimating equations were used to analyze the presence of different subsets over time within patients, viz. on treatment (week 0-24) and off treatment (week 24-48).

Results: Treatment with abatacept or rituximab results in a decrease in absolute numbers of Tfh cells ($CXCR5^+PD\text{-}1^+$) ($p<0.001$ for both treatments). Furthermore, expression levels of the activation marker ICOS by Tfh cells became concomitantly lower ($p<0.001$ for both treatments). Absolute numbers of Treg cells ($FoxP3^+$) were only reduced by abatacept ($p<0.001$). In contrast, other $CD4^+$memory T cell subsets (Th1, Th2, Th17 cells) were unaffected. Off treatment (week 24-48), changes in Tfh cells, ICOS expression and Treg cells reversed to baseline levels.

Conclusion: Treatment of pSS patients with abatacept or rituximab primarily affects Tfh cells. The lower numbers of Tfh cells may lead to reduced T cell-dependent B cell hyperactivity and contribute to the beneficial clinical effects of both treatment modalities in pSS patients. These findings indicate that Tfh cells may play a central role in the pathogenesis of pSS.

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment: Clinical Aspects, Imaging and Biomarkers

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: In patients with axial spondyloarthritis (axSpA), clinical disease activity measures (DA) have been longitudinally related to radiographic progression. Interestingly, a gender disparity has been observed in this relationship, but the reason for this is unclear. Here, we investigate whether such a gender disparity also exists with respect to the relationship between DA and inflammatory lesions on magnetic resonance imaging (MRI) of the sacroiliac joints (SI) and the spine.

Methods: Two-year follow-up data from 167 patients fulfilling ASAS axSpA criteria in the DESIR cohort with at least two MRIs of SI and/or spine available during this period were analyzed. Baseline characteristics of patients included were: 50% males, mean (SD) age: 33 (9) years, 81% HLA-27 positive and symptom duration: 18 (11) months. The association between inflammatory lesions on MRI of SI/spine (measured by SPARCC/Berlin score, respectively) and DA (ASDAS, BASDAI, patient«s global disease activity, night pain, CRP and ESR) was investigated using generalized estimating equation (GEE) models: i) a model of absolute-scores; and ii) a model of change-scores. All models were adjusted for age, symptom duration and HLA-B27.

Results: The relationship between inflammatory lesions on MRI and DA was different in males than in females. MRI-scores of SI/spine (i) were statistically significantly associated to most of the DA in males, but not in females (Figure 1A&1B). In the model of changes (ii), ASDAS was significantly associated with inflammatory lesions on MRI of either SI (Fig 2A) or spine (Fig 2B) in males, but not in females. Similar effects were seen with different DA measures.

Conclusion: In male, but not in female patients with axSpA, clinical disease activity is longitudinally associated with inflammatory lesions on MRI. This observation supports the hypothesis that some aspects of axSpA are different in males compared to females.

Figure: Longitudinal relationship between clinical disease activity measures and inflammation degree (SPARCC/Berlin) on MRI-SI/spine stratified for gender. Markers and surrounding lines represent beta values and 95%CI, respectively.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment: Clinical Aspects, Imaging and Biomarkers

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose:

Little is known of the characteristics of psoriatic spondyloarthritis (PsSpA). A study was conducted to determine the: (i) prevalence of PsSpA in a psoriatic arthritis (PsA) cohort; (ii) clinical and radiographic characteristics of PsSpA.

Methods:

A prospective single-centre cross-sectional observational study was conducted, recruiting consecutive patients: 201 PsA (CASPAR+) and 201 ankylosing spondylitis (AS; modified New York, mNY+). Participants were examined clinically, completed patient reported outcome measures, and their axial radiographs (cervical, lumbar, pelvis) were scored. Multivariate Poisson regression analyses are presented.

Results:

The 402 enrolled cases were reclassified on the basis of radiographic axial disease and psoriasis: 118 PsSpA, 127 peripheral-only PsA (pPsA), and 157 AS cases (40, 7, and 89% were *HLA-B27*+, respectively). The prevalence of PsSpA in this SpA cohort was 118/245 (48%).

CASPAR criteria were fulfilled by 49/201 (24%) AS cases, and mNY criteria by 48/201 (24%) PsA cases.

Symptomatically-silent PsSpA (radiographic but no recall of symptoms) was present in 30/118 (25%) of PsSpA cases. Of 118 PsSpA cases: 45/118 (38.14%) had sacroiliitis and spondylitis; 34/118 (28.81%) had sacroiliitis alone; and 39/118 (33%) had spondylitis without sacroiliitis.

Younger age at arthritis symptom onset (p=0.01) and psoriatic nail crumbling (adjusted incidence risk ratio, aIRR 2.86; 95%CI 1.67, 5.00; p<0.001) predicted the occurrence of PsSpA.

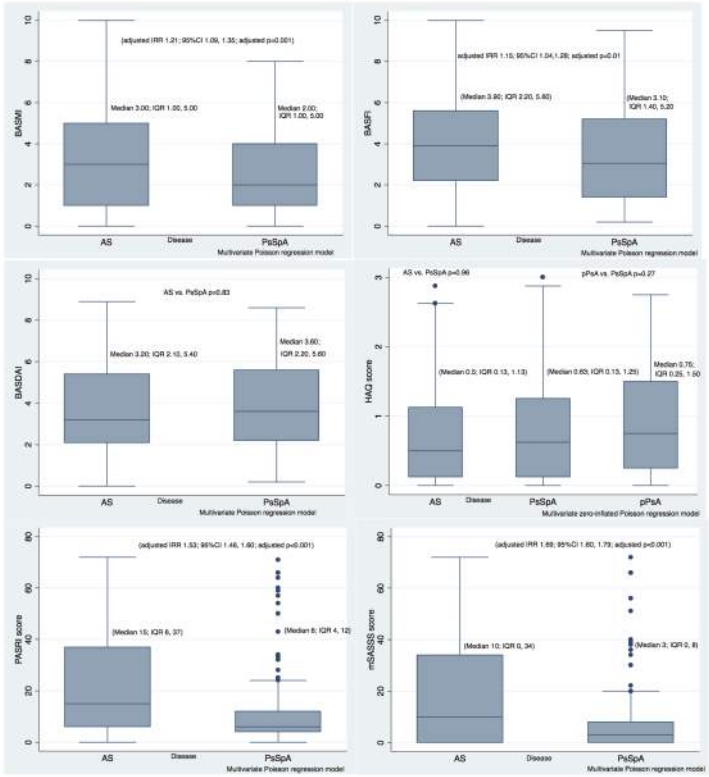
PsSpA cases had similarly high disease activity (ASDAS, BASDAI) to that seen in the AS cases (*Figure 1)*. Disability (HAQ) was no different across the three groups. Function (BASFI, aIRR 1.15; 95%CI 1.05, 1.28; p=0.01) and axial metrology (BASMI, aIRR 1.21; 95%CI 1.09, 1.35; p=0.001) were poorer in AS than PsSpA cases.

Both AS and PsSpA cases predominantly have bilateral symmetrical-grade sacroiliitis, and both cervical vertebral and facet spondylitis. Complete SIJ ankylosis (aOR 4.35; 95%CI 2.26, 8.36; p<0.001) and bridging syndesmophytes (aOR 2.78; 95%CI 1.49, 5.18; p<0.001) were more likely in AS than PsSpA cases. Radiographic severity was higher in AS compared with PsSpA cases (mSASSS score, aIRR 1.69; 95%CI 1.60, 1.79; p<0.001; PASRI score, aIRR 1.53; 95%CI 1.46, 1.60; p<0.001).

Conclusion:

PsSpA was more prevalent than expected. Symptomatically-silent PsSpA, and spondylitis without sacroiliitis are important considerations when classifying PsSpA. PsSpA has as severe a clinical impact as AS, but is radiographically less severe. Bridging syndesmophytes and complete SIJ fusion appear to best radiographically differentiate PsSpA from AS.

Figure 1. **Clinical and radiographic composite indices in PsSpA, AS and pPsA cases**



Multivariate modelling, adjusted as required for: sex, age at clinical / radiographic assessment, disease duration at clinical / radiographic assessment, synthetic and biological DMARD use, smoking, and body mass index.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment: Clinical Aspects, Imaging and Biomarkers
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: The development of radiographic damage over time has been investigated in patients with AS, but not yet in early axial spondyloarthritis (axSpA). We have recently shown that the modified Stoke in Ankylosing Spondylitis Spine Score (mSASSS) is the most sensitive and adequate scoring method in (early) axSpA. Our aim was to analyse the development and progression of radiographic damage in the spine in patients with IBP and early axSpA.

Methods: Patients with IBP for <3 years and with a clinical suspicion for axSpA were included in DESIR. Yearly cervical and lumbar radiographs from the first 2 years of follow-up were used in this analysis. Patients with radiographs available allowing the estimation of at least one (1-year or 2-year) progression interval were included in this analysis. Two trained readers independently scored the radiographs according to the mSASSS (0-72). Scores per vertebral corner were averaged between the readers. One-year (M0-M12) and two-year (M0-M24) progression scores were computed. Progression was assessed in each of the different subgroups of patients defined at baseline according to the fulfillment of the ASAS axSpA criteria, imaging arm (modified New York Criteria (mNYC) +/- and MRI positivity (according to the ASAS definition)), clinical arm only (+/- positive CRP). In addition, patients were grouped according to presence of baseline syndesmophytes.

Results: In total, 608 patients (mean age 36.0 (SD 8.8) years, 47% males, 74% fulfilling ASAS axSpA criteria) were included. At baseline, the average mSASSS was 0.36 (1.49). From these patients, 571 one-year mSASSS progression intervals could be obtained and 441 two-year progression intervals. Patients fulfilling the ASAS axSpA criteria had on average 0.29 (1.73) mSASSS-units progression in 2 years, whereas those not fulfilling the criteria showed a progression of 0.06 (1.00) units. Patients fulfilling the imaging arm had a progression of 0.42 (2.21) mSASSS-units per 2 years. Within this subgroup of patients, patients fulfilling the mNYC and with a negative MRI had the highest progression, followed by those mNYC+ and MRI+ and lastly those mNYC- but with MRI+ (Table). Patients fulfilling only the clinical arm of the ASAS criteria had a progression of 0.11 (0.60) mSASSS-units per 2 years. Patients with baseline syndesmophytes (across all subgroups) had a 2-year progression of 1.16 (4.31) mSASSS-units.

Table - Progression of spinal radiographic damage over 2 years (1-year and 2-year intervals)

	Subgroup	1-year mSASSS progression (M0-M12) n=517 mean (SD)	2-year mSASSS progression (M0-M24) n=441 mean (SD)
ASAS criteria	ASAS +	0.11 (1.15), n=366	0.29 (1.73), n=322
	ASAS -	0.08 (0.69), n=147	0.06 (1.00), n=116
ASAS criteria Imaging arm	MRI+ mNYC+	0.20 (2.11), n=96	0.36 (2.38), n=88
	MRI+ mNYC-	-0.02 (0.26), n=76	0.18 (0.93), n=63
	MRI- mNYC+	0.17 (0.47), n=41	1.02 (3.21), n=34
ASAS criteria Clinical arm	Clinical arm only CRP+	0.05 (0.22), n=20	0.14 (0.50), n=21
	Clinical arm only CRP-	0.10 (0.59), n=130	0.10 (0.62), n=112
Baseline syndesmophytes	Baseline syndesmophytes +	0.38 (3.15), n=34	1.16 (4.31), n=30
	Baseline syndesmophytes -	0.08 (0.68), n=483	0.16 (1.12), n=411

Conclusion: Development of spinal radiographic progression can be captured in a cohort of patients with early axSpA within a 2-year follow-up. Progression is higher in patients fulfilling the mNYC and also in patients with baseline syndesmophytes.

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment: Clinical Aspects, Imaging and Biomarkers

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Ultrasound has been shown to detect subclinical synovitis in in rheumatoid arthritis and psoriatic arthritis (PsA in clinical remission.). The value of power Doppler ultrasound (PDUS) to predict flares in patients with PsA in remission or minimal disease activity has not been fully studied.

Objective: To determine whether PDUS assessment of synovitis predicts short term relapse in patients with PsA in clinical remission or minimal disease activity.

Methods: consecutive PsA patients in clinical minimal disease activity (MDA) and/or remission (fulfillment MDA criteria or Disease Activity Score in 28 joints [DAS28] <2.6, respectively) underwent PDUS examination of 18 joints (second and third metacarpophalangeal joints, second and third proximal interphalangeal joints, wrist, knee, ankle and second and fifth metatarsophalangeal joints). US assessment were performed by the same rheumatologist, blinded to clinical data, usig a MyLab 70 machine (Esaote) provided with a 6-18 MHz multifrequency broad band linear transducer. PD signal was graded on a semi-quantitative scale from 0 to 3. PD synovitis was defined as the presence of intraarticular PD signal ≥1, and was treated as a dichotomous variable. On the same day a complete clinical assessment was performed by another rheumatologist. All patients were followed-up for 6 months. Flare was defined as the requirement of a change in disease modifying antirheumatic drugs (DMARDs) (increasing dose, adding or changing DMARDs or biologics therapy) by the treating rheumatologist, who was blinded to the US findings. Relative risks (RR) with their 95% CI for flare among patients with and without PD signal were calculated. Multivariable analysis using logistic regression with flare as the outcome variable, and PD signal, demographic characteristics, and baseline disease activity as independent variables were also calculated.

Results: Fifty four patients were included: 47 patients fulfilling MDA criteria, 36 DAS28 remission criteria (DAS28<2.6) (29 patients fulfilled both criteria). Baseline patients' characteristics are shown in the table. Among the 54 patients on MDA or DAS28 remission, 15 (28 %) experienced a flare within the next 6 months,15/47 (32%) of patients in MDA, 10/36 (28%) of patients in DAS28 remission, and 10/29 (35%) patients fulfilling both criteria. Thirteen (87%) of the 15 patients with flares had baseline PD synovitis, compared with 7/39 (35%) patients without flares (RR= 11; 95% CI: 2.8-44; p<0.0001).). On logistic regression analysis the only variables associated with short term flares were baseline positive PD signal (OR: 119;p=0.001), and baseline use of non-biologics DMARDs (OR: 5.9; p=0.038).

Conclusion: Among PsA patients on clinical remission and/or MDA, synovial inflammation determined by the presence of a positive PD signal, was a strong predictor of short term flare.

Table: Patients' characteristics.

Feature	Patients on remission (n=54)
Male, no. (%)	33 (61)
Mean age (SD) years	54.5 (14)
Median disease duration (IQR) months	36 (10-60)
DMARDs use, no. (%)	35(65)
TNFi use, no. (%)	12 (22)
erythrocyte sedimentation rate, median (IQR)	14 (7-22)
Swollen joint count 66, mean (SD)	0.3 (0.65)
Tender joint count 68, mean (SD)	0.3 (0.68)
DAS28 remission, no. (%)	36 (67)
Mean DAS28 (SD)	2.26 (0.7)
Minimal disease activity, no. (%)	47 (87)

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment: Clinical Aspects, Imaging and Biomarkers

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Evaluation of sacroiliac joints (SIJ) on pelvic radiographs according to the modified New York criteria (mNYc) is considered the gold standard for classification of axial spondyloarthritis (SpA). However, agreement among trained readers was consistently limited with kappa values around 0.5 [1-4]. The goals of this study in chronic back pain patients suspected of having SpA were: to determine the reproducibility of radiographic SIJ evaluation among 7 readers with varying levels of experience; to identify potential drivers to disagreement in classification among 5 predefined radiographic lesion types.

Methods: The study sample comprised 104 (38% male) consecutive patients aged 18-40 years with low back pain ≥3 months' duration, who met the Assessment of Spondyloarthritis International Society (ASAS) definition for a positive SIJ MRI (n=92) or were HLA B27 positive (n=12) and had ≥1 SpA related clinical/laboratory feature according to the ASAS classification criteria for axial SpA. All readers (2 musculoskeletal (MSK) radiologists; 2 junior and 3 senior rheumatologists) were calibrated by reference images covering all mNYc grades. The rheumatologists additionally had 3 training sessions comprising independent evaluation of unrelated pelvic radiographs. 7 blinded readers classified pelvic radiographs according to the mNYc and then recorded 5 lesion types in both SIJ: erosion, sclerosis, ankylosis, joint space widening and narrowing. Reproducibility of the mNYc classification among 21 reader pairs was assessed by Cohen's kappas and percent agreement. Potential drivers of disagreement were identified as proportions of concordant lesion types among patients with discordant classification. Finally, a generalized linear mixed logistic regression model was computed to explore to which extent discordance in lesion type was associated to discrepant mNYc classification.

Results: Kappas (percent concordance) for classification by mNYc were: 0.39 over 7 readers; 0.46 (79.8%) between 2 MSK radiologists; 0.55 (86.5%) and 0.36 (77.9%) among the most experienced rheumatologist and the 2 MSK radiologists.

Figure 1 Proportion of concordant lesion types among patients with discordant classification among 21 reader pairs

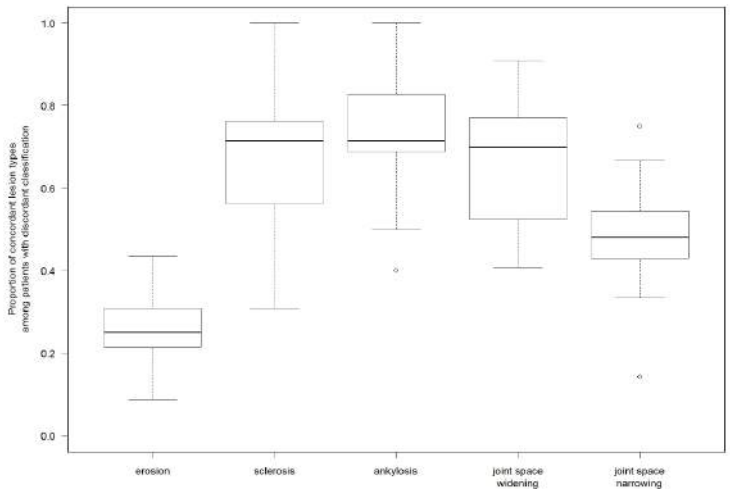

Table 1 Odds ratio for disagreement in classification in relation to lesion type among 21 reader pairs

Discordance in lesion type	Odds ratio for disagreement in mNYc	95% confidence interval	P-value
Erosion	13.5	9.1 to 20.1	<0.0001
Sclerosis	0.9	0.6 to 1.3	0.49
Ankylosis	4.8	2.7 to 8.3	<0.0001
Joint space widening	5.6	3.4 to 9.2	<0.0001
Joint space narrowing	3.0	2.0 to 4.6	<0.0001

Conclusion: Reproducibility of SIJ classification by mNYc was fair to moderate among 7 readers with varying experience in assessing pelvic X-rays. Erosion was the main driver of discordant classification.

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment: Clinical Aspects, Imaging and Biomarkers

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Smoking has been associated with radiographic severity and progression in SpA although there is little understanding of the mechanism. Prospective MRI data indicates that ankylosis develops following an intermediary phase of fat metaplasia, which follows resolution of inflammation in subchondral bone and at sites of erosion, when it is termed backfill[1]. We aimed to determine whether smoking influences the propensity to develop fat metaplasia as a potential mechanism for its association with progression in SpA.

Methods: In the FOllow-up Research Cohort in AS (FORCAST), AS patients from Northern Alberta attending community and academic practices are assessed for clinical and laboratory outcomes every 6 months, MRI is performed at baseline, at 3-6 months for patients starting anti-tumor necrosis factor alpha (anti-TNFα), and annually. MRI scans are scored independently by 2 readers and adjudicated by a third reader according to pre-specified rules. MRI inflammation is assessed on short tau inversion recovery (STIR) scans using the Spondyloarthritis Research Consortium of Canada (SPARCC) Sacroiliac Joint (SIJ) and 23-DVU Spine scores while structural change is assessed independently on T1-weighted (T1W) scans using the SPARCC SIJ Structural Score (SSS) score for fat metaplasia, erosion, backfill, ankylosis, and the Fat AS Spine Score (FASSS). We used univariate and multivariate regression to assess associations between smoking (current (yes/no, <10/ ³10 years), past, never, pack per day, pack year) and MRI parameters.

Results: The cohort includes 730 patients: mean age 41.3 years, 72.7% males, 78.6% B27 positive, mean disease duration of 17.5 years. Of 517 patients reporting smoking history, 105 (20.2%) were current smokers, 148 (29.0%) past smokers, and 264 (51.8%) never smoked. MRI scans were available on 250 cases in the cohort. In univariate analyses, current but not previous smoking, especially intensity (from 0.25 to 1 pack/day) and duration of current smoking (³10 years vs <10), was associated with spinal (FASSS: β=11.1, p=0.03)) and SIJ fat metaplasia (SSS backfill: β=2.4, p=0.01; SSS fat ³2: OR 2.4, p=0.03), SIJ ankylosis (β=4.5, p=0.01), and spinal inflammation (SPARCC 23-DVU (β=8.3, p=0.02). In multivariate models that included age, sex, B27, smoking, ASDAS, and selected according to the best goodness of fit Akaike Information Criterion (AIC), current smoking (intensity and/or duration) was independently associated with several MRI parameters (Table).

Conclusion: Current, but not past smoking, and its intensity and duration is associated with the degree of fat metaplasia and ankylosis on MRI of the SIJ suggesting that it may influence the tissue response to inflammation.

Session Date: Tuesday, November 10, 2015

Session Title: Systemic Lupus Erythematosus - Animal Models

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose:

The genetic analysis of the lupus prone NZM2410 mouse has identified a suppressor locus, *Sle2c2,* which confers resistance to both spontaneous and chronic graft-vs.-host disease (cGVHD) induced lupus. We hypothesized that a non-synonymous polymorphism in the granulocyte colony stimulating factor (G-CSF) receptor 3 (*Csf3r)* gene in *Sle2c2* is responsible for providing protection. G-CSF acts as a pleiotropic growth factor and mediates its biological functions including granulopoiesis by binding specifically to G-CSF-R. Exogenous G-CSF restored cGVHD susceptibility in *Sle2c2*, suggesting that the *Csf3r* rs13377964 coding SNP results in a loss-of-function in signaling modulating the expression of targets in myeloid cells expressing G-CSF-R, including neutrophils and dendritic cells, and thus mediating lupus resistance.

Methods:

We investigated the functional differences between the wild type B6 and congenic *Sle2c2* alleles of *Csf3r* transduced in the murine Csf3r-negative myeloblast- like 32d.cl3 cell line with a lentiviral vector. G-CSF-R signaling was measured using phospho-flow staining and gene expression assays in transduced 32d.cl3 cells stimulated with mouse G-CSF. Furthermore, the assays were repeated using primary bone-marrow derived dendritic cells, splenocytes and peripheral blood leukocytes of B6 and congenic B6.*Sle2c2*mice. In addition, the progression and activation of G-CSF-R expressing myeloid cells throughout the entire course of cGVHD was compared between B6 and congenic mice by flow cytometry.

Results:

32d.cl3 cells expressing the *Sle2c2* allele of G-CSF-R showed a reduced expression of Jak and Src targets in response to G-CSF with both phospho-flow and gene expression assays. The *Sle2c2* allele of G-CSF-R induced a reduced phosphorylation of STAT3, ERK and p38 and lowered the expression of genes such as SOCS3, cFOS, Fcgr3, IRF1 compared to B6 allele. The effects of phospho signaling associated with Jak-STAT and ERK pathways were recapitulated with ex-vivo experiments using primary BM derived DCs as well as total splenic and blood

neutrophils. Differences in frequency of G-CSF-R positive neutrophils and splenic dendritic cell subsets as well as levels of G-CSF-R expression during the course of cGVHD further suggest the functional relevance of the G-CSF-R SNP in lupus.

Conclusion: Our results show that the coding rs13377964 SNP affects G-CSFR signaling, supporting the hypothesis that it could confer resistance to lupus. The defective signaling observed downstream of G-CSF-R primarily within the Jak and Src pathways in both primary cells and cell lines transduced with *Csf3r* alleles suggest the functional relevance of the polymorphism. Both Jak and Src kinase pathways are involved in differentiation, proliferation and survival of myeloid progenitor cells and activation of neutrophils. Future experiments aimed at elucidating the differences in functions of these pathways using cell lines and myeloid cells such as neutrophils and dendritic cells will enhance our understanding of the GCSFR axis in lupus pathogenesis.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Systemic Lupus Erythematosus - Animal Models
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Defective phagocytosis of dead cells is seen in SLE patients' monocytes. Pristane-induced lupus causes accumulation of dead cells in tissues resembling that in SLE patients. However, the extent to which this reflects increased cell death vs. impaired removal of dead cells is unclear. The present studies addressed the clearance of dead cells in pristane-lupus

Methods: Clearance of dead cells from human bone marrow (BM) was examined by immunohistochemistry. The distribution of pristane in mouse tissues was detected by oil red staining and mass spectrometry. Murine macrophage (Mϕ) subsets were identified by flow cytometry ($F4/80^+CD11b^+Ly6G^-$). Gene expression in sorted cells was determined by real-time PCR. Phagocytosis of pHrodo red-labeled thymocytes by Mϕ from pristane-treated (develop lupus) vs. mineral oil (MO)-treated (do not develop lupus) mice was assessed in vitro and in vivo by flow cytometry. Autophagy was quantified by Cyto-ID green staining.

Results:

Tissues from SLE patients and pristane-treated mice contained numerous dead cells (activated caspase-3^+). In non-SLE patients undergoing BM ablation and massive cell death prior to stem cell transplantation, dead cells were found only within resident BM Mϕ, not free as in lupus BM, consistent with a high capacity to clear dead cells. After i.p. injection in mice, pristane was transported to the lung and BM and could be detected by oil red staining and mass spectrometry along with numerous dead cells. We hypothesized that exposure of Mϕ to pristane causes a phagocytosis defect that predisposes to lupus. Consistent with that model, resident $Tim4^+$ peritoneal Mϕ disappeared within hours of either pristane or MO injection and were replaced by BM-derived neutrophils and Mϕ. Peritoneal Mϕ from pristane-treated mice were poorly phagocytic vs. those from MO-treated controls and cells from pristane-treated mice were deficient in the class A scavenger receptor Marco. Marco is known to mediate phagocytosis of apoptotic cells, and the $Marco^+$ Mϕ subset from control mice efficiently took up dead cells. The uptake of dead cells by peritoneal Mϕ from MO-treated mice was inhibited by anti-Marco antibodies. Expression of *Marco* mRNA is regulated by the transcription factor Nrf2 and was low in pristane- vs. MO- treated mice. Autophagy, which has been found to regulate phagocytosis by modulating Nrf2-mediated Marco expression, was increased in pristane-treated mice.

Conclusion:

Pristane may cause lupus by inducing a phagocytosis defect. The mechanism appears to involve modulation of phagocytosis due to increased autophagy, resulting in decreased activation of Nrf2, decreased scavenger receptor expression, and impaired clearance of dead cells.

Bim Suppresses the Development of SLE By Limiting Macrophage Inflammatory Responses

Session Date: Tuesday, November 10, 2015

Session Title: Systemic Lupus Erythematosus - Animal Models

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: The Bcl-2 family guards the mitochondrial apoptotic pathway. Among numerous Bcl-2 antagonists, only the loss of Bim in mice leads to the development of SLE-like disease, suggesting Bim's unique state that exerts dominance in several pathways that are vital for the development of SLE. We have shown that reduction of Bim alters macrophage function thereby preventing the break in tolerance. We hypothesize that Bim limits inflammatory responses in macrophages and therefore prevents SLE-like disease development independent of its role in apoptosis.

Methods: We generated mice lacking Bim specifically in myeloid cells ($Cre^{LysM}Bim^{fl/fl}$) and assessed mice at 8 months of age for characterization of SLE-like disease. Macrophage turnover/proliferation and activation were examined *in vivo* using flow cytometric analyses and luminex based assays.

Results: $Cre^{LysM}Bim^{fl/fl}$ mice displayed splenomegaly, lymphadenopathy, hypergammaglobulinemia, IC deposition in the kidney, proteinuria, GN, and early mortality as compared to $Bim^{fl/fl}$ and mice lacking Bim in either lymphocyte compartments. Bim functions independently of its role in apoptosis in macrophages and monocytes, because we did not detect any differences in the rate of EdU incorporation in tissue-resident macrophages and monocyte-derived populations from $Bim^{fl/fl}$ and $Cre^{LysM}Bim^{fl/fl}$ mice. $Cre^{LysM}Bim^{fl/fl}$ splenic macrophages also displayed an enhanced activated phenotype that may not be due to an endogenous TLR that requires MyD88, as loss of MyD88 in $Cre^{LysM}Bim^{fl/fl}$ mice did not reverse disease phenotype. Mixed bone marrow chimera mice showed reduced disease activities, indicating that macrophages from the wild type mice are sufficient to suppress autoimmunity caused by loss of Bim in macrophages. Loss of Bim in macrophages is sufficient to induce SLE-like disease, as adoptively transferring wild type lymphocytes to $Cre^{LysM}Bim^{fl/fl}Rag^{-/-}$ mice increased glomeruli size and leukocyte infiltrates in the kidneys compared to $Rag^{-/-}$ mice receiving wild type lymphocytes. The BH3 domain and JNK phosphorylation site of Bim, which are essential for apoptotic functions, are necessary for the disease development, because replacing BH3 domain or mutating the phosphorylation sites resulted in the development of SLE-like disease. Lastly, kidney macrophages can be accurately identified by multi-parameter flow cytometry, which increased in number in $Cre^{LysM}Bim^{fl/fl}$ mice. Gene expression profiling revealed that kidney macrophages from $Cre^{LysM}Bim^{fl/fl}$ exhibited M2 phenotype that is associated with collagen deposition and fibrosis in the kidney.

Conclusion: The expression of Bim in macrophages is sufficient to inhibit SLE-like pathogenesis. These data suggest that Bim acts as a molecular rheostat controlling macrophage functions through its BH3 domain and JNK phosphorylation site, which is independent of its role in apoptosis. Bim mediates macrophage inflammatory responses not only in secondary lymphoid organs (spleen), but also in end-organs (kidney). These studies are crucial for understanding the development SLE, and for translational studies leading to the development of new targets for SLE.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Systemic Lupus Erythematosus - Animal Models
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: T cells from patients with systemic lupus erythematosus (SLE) express reduced amounts of the critical CD3 zeta signaling chain, and are poor producers of the vital cytokine interleukin (IL)-2. Using a discovery approach (mass spectrometry analysis of proteins "pulled-down" by a CD3 zeta mRNA-defined oligonucleotide), we identified the splicing regulator serine arginine-rich splicing factor 1 (SRSF1). We showed that SRSF1 promotes generation of a full-length CD3 zeta transcript over a short spliced unstable isoform to promote normal expression of CD3 zeta chain in human T cells. Recently we showed that overexpression of SRSF1 into SLE T cells rescues IL-2 production. SRSF1 expression levels are decreased in SLE T cells, more so in patients with worse disease. Although these findings suggest that SRSF1 deficiency is important in the expression of SLE T cell dysfunction, it remains unknown whether SRSF1 contributes to immune-mediated disease. To this end, we generated mice with a T cell-restricted deletion of SRSF1 to evaluate the mechanistic role of SRSF1 in T cell dysfunction and the development of immune-mediated disease *in vivo*.

Methods: We used the Cre-lox recombination strategy to cross *Srsf1* "floxed" B6/129 mice with *Lck.Cre* (distal promoter) transgenic mice to delete SRSF1 specifically in mature T cells and generate the T cell Srsf1 conditional knockout (*Srsf1*-cko) mice. Mice were euthanized at 10-16 weeks of age, or aged to >1 year. Central (thymus) and peripheral (spleen, lymph nodes) lymphoid organs were analyzed for immune cell phenotype and function by flow cytometry, enzyme-linked immunosorbent assay (ELISA) and intracellular staining. Serum and urine were collected at monthly intervals to assess autoantibody levels and proteinuria respectively. Lymphoid tissues from aged mice were analyzed for immune cell phenotype and function by flow cytometry. Non-lymphoid (lung, liver, kidney) tissues were fixed, sectioned and stained with hematoxylin and eosin to evaluate histopathology.

Results: The *Srsf1*-cko mice exhibit T cell lymphopenia, with a striking reduction in the CD8 compartment. The CD4 T cells exhibit increased proportions of activated (CD69hi) cells, and produce increased amounts of IFN-γ and IL-17 upon *ex vivo* stimulation. The *Srsf1*-cko mice develop increased levels of anti nuclear autoantibodies (ANA), and exhibit increased proteinuria compared to control mice. Tissue histopathology displays glomerular capillary hyperplasia, glomerular hyperproliferation and interstitial infiltration of mononuclear cells in the kidneys. These results indicate that lack of SRSF1 leads to a reduction of CD8 T cells, aberrantly increased inflammatory cytokine production, autoantibody development and renal pathology.

Conclusion: Our results reveal that the splicing factor SRSF1 is a novel regulator of T cell homeostasis and function, and its deficiency leads to autoimmunity and kidney damage. Therefore, deficiency of SRSF1 may represent a molecular defect that contributes to the pathogenesis of systemic autoimmune disease.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Systemic Lupus Erythematosus - Animal Models

Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Kidney and skin involvement are common in systemic lupus erythematosus (SLE). Nephritis is seen in up to 60% of patients, and contributes significantly to morbidity and mortality. Approximately 80% of patients manifest some form of cutaneous lupus erythematosus (CLE), and there is a strong correlation between rash and ultraviolet light-B (UVB) exposure. Macrophages contribute to the pathogenesis of nephritis and are correlated with poor outcomes. Furthermore, following UVB exposure, macrophages are increased in the skin where they contribute to keratinocyte apoptosis.

Methods: To evaluate the role of macrophages in the pathogenesis of kidney and skin disease in murine SLE, we depleted macrophages using GW2580, a kinase inhibitor specific for colony stimulating-factor 1 receptor (CSF-1R). CSF-1R is found almost exclusively on macrophages and is important for their survival, recruitment, and activation. Lupus-prone female MRL/lpr mice (10 weeks of age) were treated with GW2580 (n=9) (or control, n=10) for 6 weeks via oral gavage. We tracked the development of kidney disease by measuring proteinuria, and assessed kidney function at 17 weeks of age by measuring serum BUN levels. In a separate cohort, female MRL/lpr mice (10 weeks of age) were exposed to two doses of UVB irradiation (50 mJ/cm^{2}each), 24 hours apart, following 2 weeks of GW2580 or control treatment (GW2580, n=5; PBS, n=6). Histology was blindly scored to assess skin damage.

Results: Macrophage depletion in MRL/lpr mice ameliorated kidney disease. Proteinuria in GW2580-treated mice was significantly lower, at multiple time points, than that seen in PBS-treated mice (13 weeks, GW2580=18±9.6 mg/dl, PBS=82±22 mg/dl, p-value=0.02; 15 weeks, GW2580=40±11.1 mg/dl, PBS=168±39.3 mg/dl, p-value=0.006). Macrophage depletion treatment also led to improved kidney function, with lower BUN levels in GW2580 as compared to control-treated mice at 17 weeks of age (GW2580=90±4.5 mg/dl, PBS=110±6.6 mg/dl, p-value=0.02). Anti-double stranded DNA antibody levels did not differ between the two groups of mice. Following macrophage depletion and subsequent UVB irradiation, MRL/lpr mice treated with GW2580 developed less severe skin lesions than those treated with PBS (mean skin scores: GW2580=2.3±0.12, PBS=4.6±0.2, p-value=0.0001). Classic characteristics of lupus-associated cutaneous disease such as hyperkeratosis and acanthosis were less prevalent in GW-treated mice.

Conclusion: Our studies support a role for macrophages in the pathogenesis of both kidney and skin disease in SLE. As current therapies are largely immunosuppressive and non-specific, these cells may represent a promising therapeutic target for LN and CLE treatment.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment VI: Novel Therapies
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: To assess the efficacy and safety of belimumab (BEL) administered subcutaneously plus standard SLE care (SoC) in patients with active SLE.

Methods:

BLISS-SC (BEL112341; NCT01484496) is a randomized, double-blind, placebo-controlled trial.

Patients with SLE with SELENA-SLEDAI (SS) score ≥8, receiving stable SLE therapy for ≥30 days were randomized (2:1) to receive weekly BEL 200 mg or placebo (PBO), administered subcutaneously (using a prefilled syringe), plus SoC. The primary endpoint was SLE Responder Index 4 (SRI4; ≥4 point reduction in SS, increase of <0.3 in Physician's Global Assessment and no new BILAG A organ domain score or 2 new BILAG B organ domain scores, all compared with baseline) response rate at week 52. Secondary endpoints included time to severe flare and reduction in corticosteroid dose. Safety was assessed using adverse events (AEs).

Results:

839 adults enrolled; 3 patients were randomized but did not receive study drug and were removed from the intent-to-treat population. Baseline disease characteristics were similar between groups: mean (standard deviation [SD]) age was PBO 39.6 (12.61), BEL 38.1 (12.10) years; median (range) SLE disease duration was PBO 4.6 (0–38), BEL 4.3 (0–35) years; mean (SD) SS was PBO 10.3 (3.0), BEL 10.5 (3.2). SRI4 response at week 52 was: PBO 48.7% vs BEL 61.4%, odds ratio 1.65, p=0.0009 (95% CI 1.23, 2.22), with each individual component achieving statistical significance (all p≤0.0247). SRI4 response was significantly greater with BEL compared with PBO as early as week 16 and was sustained for 52 weeks. SRI5 response was significantly greater with BEL compared with PBO from week 12 and SRI6, 7 and 8 responses were significantly greater from week 8; all were sustained for 52 weeks (p≤0.0002, week 52). The BEL group was 50% less likely to experience a severe flare (hazard ratio = 0.50, p=0.0003) relative to the PBO group; time to severe flare for subjects experiencing a flare was PBO 116.5 vs BEL 170.0 days. More BEL patients were able to reduce steroid dose by ≥25% to ≤7.5 mg/day during weeks 40–52, but this did not achieve statistical significance: PBO 11.9% vs BEL 18.2%, odds ratio 1.65, p=0.0732 (95% CI 0.95, 2.84). Treatment compliance with the subcutaneous injections according to patient diaries was ≥96% in both groups.

Overall study withdrawals (PBO 23.6%, BEL 16.7%) included: AEs PBO 8.9%, BEL 7.2%; subject request PBO 5.4%, BEL 2.2%; lack of efficacy PBO 3.6%, 2.7% BEL. Serious AEs (PBO 15.7%, BEL 10.8%) included: infections/infestations PBO 5.4%, BEL 4.1%; renal/urinary PBO 2.5%, BEL 1.4%; nervous system PBO 2.1%, BEL 1.4%. The incidence of depression/suicide/self-injury was PBO 3.6%, BEL 3.1%. Five deaths occurred: PBO 0.7% (one each of hematologic and vascular), BEL 0.5% (three infections).

Conclusion:

BEL 200 mg administered weekly via subcutaneous injection plus SoC significantly improved SRI response and decreased time to severe flare compared with PBO plus SoC, and safety with BEL plus SoC was similar to that with PBO plus SoC.

Disclosures: GlaxoSmithKline (GSK) and Human Genome Sciences (HGS) sponsored and conducted this clinical trial. Katie White, PhD, Fishawack Indicia Ltd, UK, provided editorial support, funded by GSK.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment VI: Novel Therapies

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Arsenic Trioxide (ATO) is approved for the treatment of acute promyelocytic leukemia, increasing oxidative stress with selective apoptosis of leukemia cells. In *MLR/lpr* model of SLE, ATO demonstrated a dramatic improvement. Given the promising results of experimental models, we conducted this study in patients with SLE

Methods: The primary objective of this phase I/IIa proof-of-concept study was to evaluate the safety and tolerability of IV ATO in patients with SLE. Efficacy and pharmacokinetics were also evaluated. Patients with mild-to-moderate SLE, defining as SELENA-SLEDAI score of ≥ 4 at baseline and corticosteroid dosage > 10 mg/day with active disease despite standard-of-care treatment, including hydroxychloroquine (HCQ) were enrolled. Concomitant therapy with methotrexate (MTX), mycophenolate (MMF), and azathioprine (AZA) were allowed at constant doses during the study. Patients with severe active renal or CNS disease were excluded. Patients received 10 IV infusions of ATO from day1 to day 4 than at day 8, 11, 14, 17, 21 and 25, with escalading dose from 0.10 mg/kg to 0.20 mg/kg, and follow-up for 20 weeks. The primary outcome measure was safety assessment with recording of adverse events (AEs) according to NCI Common Terminology Criteria for Adverse Events. Major secondary endpoint included disease activity measures, assessed by SLE Responder Index (SLEDAI, Physician's Global Assessment (PGA) and BILAG : combination of SLEDAI response ≥ 4 points, no BILAG A or 2 x B flares and no PGA score worsening, corticosteroid sparing.

Results: 11 patients (all on HCQ) are included to date in this ongoing study, and were evaluated for safety and toxicity. Five among 11 received MTX, 1 AZA, 1 thalidomide and 2 MMF. Dose of ATO was 0.10mg/kg/day in 4 patients, 0.15mg/kg/day in 4 and 0.2 mg/kg/day in 3. Two severe AEs occurred in 2 patients (0.15 and 0.2 mg/kg, receiving also MMF) with transient (<5 days) asymptomatic grade 3 neutropenia (at day 15). ATO was discontinued in these patients without MMF interruption. Mean SLEDAI at baseline was 8 and decreased to 4 at Month 2 and 3 at Month 4, with steroid sparing (Figures). Six patients among 8 had SRI response, generally without improvement of anti-dsDNA antibodies and C3/C4.

Conclusion: In this proof-of-concept phase 1/IIa study, 4 weeks IV ATO treatment with 20 weeks follow-up, demonstrated an acceptable safety and tolerability profile (except in patients treated by MMF) with a clinical efficacy, supporting further evaluation in larger clinical trials.

Session Date: Tuesday, November 10, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment VI: Novel Therapies

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Anifrolumab is a fully human IgG_1 κ monoclonal antibody directed against subunit 1 of the type I interferon receptor (IFNAR1). A Phase IIb randomized, double-blinded, placebo-controlled, multicenter clinical trial of adult patients with systemic lupus erythematosus (SLE) has been conducted for anifrolumab. Our project aimed to provide an initial assessment of downstream effects of anifrolumab on serum protein markers and pathophysiologic pathways in SLE patients.

Methods: A total of 305 patients with moderate to severe SLE were randomized in a 1:1:1 ratio to receive a fixed intravenous dosage of placebo or anifrolumab (300 or 1000 mg) in addition to standard of care every 28 days for 1 year. Type I IFN status was assessed by a 4-gene type I IFN signature. Sera were procured at baseline, Day 85, and 169 days post-administrations of placebo, 300- or 1000-mg anifrolumab. Samples were tested for 138 selected proteins using a multiplex luminex immunoassay. Protein concentrations in different patient groups were compared using Student's *t*-test with multiple testing adjustments.

Results: Serum proteomics results were obtained for 304 SLE patients at baseline: 229 had an elevated type I IFN gene signature (IFN-high) and 75 did not (IFN-low). Forty-five proteins were significantly greater in sera of IFN-high vs. IFN-low patients ($p<0.05$), of which 27 are type I

and/or II IFN-inducible. Effects of anifrolumab on serum protein concentrations were assessed by paired comparison between patient-matched pre- and post-treatment sera concentrations, as well as comparisons between anifrolumab and placebo. Anifrolumab administration was associated with significant suppression of 15 serum proteins at Days 85 and/or 169 compared with placebo ($p<0.05$), of which 10 are type I and/or II IFN-inducible. Fourteen of these proteins had greater serum concentrations in IFN-high vs. IFN-low patients at baseline. Of these 15 proteins, CCL2, CCL8, and CCL19 are involved in the recruitment of T cells, monocytes, dendritic cells, and other immune cells to inflammation sites. CXCL10 and CXCL11 are ligands of CXCR3 that recruit activated CD4+ and CD8+ T cells, while CXCL13 is a chemoattractant for B cells. IL-18 is a Th1 cytokine and CD163 is a marker for monocyte/macrophage activation. Anifrolumab-driven suppression of these proteins indicates reduction in T-cell, B-cell, and monocyte activation and movement, compared with placebo. Further, decreased concentration of FCN3, an initiator of the lectin pathway of complement, indicates inhibition of complement system activation by anifrolumab.

Conclusion: This preliminary data set indicates that anifrolumab elicits a potent effect on multiple serum biomarkers in SLE compared with placebo. Suppression of both immune cell dysregulation and complement system may be key contributors to the mechanism of action of anifrolumab in SLE.

Session Date: Tuesday, November 10, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment VI: Novel Therapies

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose:

Systemic lupus erythematosus (SLE) is a chronic autoimmune disease with multi-system involvement, associated with an imbalance between effector and regulatory CD4+ T cells. The development and activation of these T cell subsetsis critically regulated by interleukin-2 (IL-2) which is impaired in SLE patients. Using animal models and human samples, we characterised precursor Tfh cells in blood with a $CXCR5^{+}CCR7^{low}PD1^{high}$ phenotype. The increase of the early memory Tfh cells in blood represents the active Tfh cell differentiation and correlates with the disease activities of systemic lupus erythematosus (SLE). We hypothesized that low-doseIL-2 treatment of SLE would result in selective expansion of regulatory CD4+ T (Treg) cells, while suppressing follicular helper T (Tfh) cells and IL-17-producing helper T (Th17) cells. Our study was to assess the safety and efficacy of low-dose IL-2 therapy in active SLE.

Methods:

Forty patients with active SLE were recruited to a prospective open label study; 38 patients completed three cycles of 1 million IU recombinant human IL-2 (rhIL-2), administered subcutaneously every other day for 2 weeks, followed by a 2-week break. Both clinical and immunological responses were assessed. The primary end points were the SLE Responder Index (SRI) and safety at week 12. Secondary end points were the effects of the therapy on Treg, Tfh and Th17 cells.

Results:

An SRI response was seen in 34/38 patients (89.5%) at week 12. Disease activity measured using the Safety of Estrogens in Lupus Erythematosus National Assessment version of the SLE Disease Activity Index (SELENA-SLEDAI) improved significantly, from a median (range) of 11 (8 - 23) to 4 (0 – 12) ($p<0.001$). At week 12, resolution of clinical activity present at baseline was observed in multiple domains, including rash (20/24 patients), alopecia (13/14), arthritis (10/11), fever (3/3), leukopenia (18/19) and thrombocytopenia (4/4).No severe adverse events were observed. Significant reductions of anti-dsDNAtitres ($p<0.001$) and proteinuria ($p=0.005$), and increased levels of C3 ($p<0.001$) and C4 ($p<0.001$), were observed at week 12. Immunological analysis revealed that low-dose rhIL-2 administration was associated with selective expansion of Treg cells ($p<0.001$) and conversely with reductions of Tfh andTh17cells ($p=<0.001$), but had not effect on Th1 and Th2 cells.

Conclusion:

Low-dose IL-2 was efficient and well tolerated in active SLE. The improvements in disease activity were associated with selective modulation of $CD4^+$ T cell subsets.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment VI: Novel Therapies

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose:

CD40 ligand (CD40L) regulates interactions between T cells, B cells, and antigen presenting cells. Considerable evidence suggests CD40L blockade might provide an effective treatment for systemic autoimmune disorders.

In previous studies, some evidence of efficacy was seen using monoclonal antibodies (hu5c8) to CD40L; however, the program was halted due to thromboembolic events, possibly mediated by Fc interaction with platelet Fc gamma RIIA receptor. DZP (formerly CDP7657) is a PEGylated anti-CD40L Fab' fragment with no Fc.

Methods:

This 32-week randomized, double-blind, multicenter study (NCT01764594) evaluated the efficacy of repeat IV administration of DZP in patients with SLE with a SELENA SLEDAI score ≥4. Patients were documented as positive for anti-dsDNA antibodies or antinuclear antibodies and, if taking immunomodulatory therapies, were on a stable dose throughout the study. Patients with active severe glomerulonephritis or renal flare in the last 6 months, or history of thromboembolism within a year were excluded from the study.

After screening (up to 4 weeks), patients (n=24) were randomized 2:1 to DZP (loading dose 30 mg/kg then 5 doses of 15 mg/kg every 2 weeks) or placebo (PBO), stratified by presence or absence of antiphospholipid antibodies. Patients were subsequently followed for 18 weeks.

The primary objective was to evaluate DZP safety and tolerability; disease activity measures were exploratory variables. Two composite measurements for SLE disease activity: BILAG-based Composite Lupus Assessment (BICLA) and Systemic Lupus Responder Index (SRI-4) were analyzed separately. These responses were determined on a subset of patients with ≥1 BILAG A or B (BICLA) or SLEDAI ≥6 (SRI-4) at baseline.

Results:

DZP and PBO groups had similar demography and SLE disease status at baseline.

Variable	Statistics	PBO N=8	DZP N=16	Total N=24
Gender (female, male)	n (%)	8 (100), 0 (0)	13 (81), 3 (19)	21 (87.5), 3 (13.5)
Age (years)	Mean (SD)	40.55 (15.19)	42.41 (9.5)	41.79 (11.4)
BMI (kg/m^2)	Mean (SD)	25.67 (5.08)	24.07 (6.06)	24.61 (5.69)
Duration of disease (years)	Median (Min, Max)	7.08 (1.0, 31.6)	8.88 (0.6, 24.7)	8.30 (0.6, 31.6)
SELENA SLEDAI total score	Median (Min, Max)	8.0 (4, 14)	9.0 (2, 14)	8.0 (2, 14)
Physician's Global Assessment of Disease	Median (Min, Max)	31.0 (0, 68)	28.5 (0, 67)	29.0 (0, 68)
BILAG total score	Median (Min, Max)	10.0 (2, 21)	13.0 (2, 21)	12.0 (2, 21)
At least 1 BILAG Grade A or B at baseline	n (%)	7 (87.5)	14 (87.5)	21 (87.5)

There were no serious treatment emergent adverse events (TEAEs) and no deaths occurred. There were no thromboembolic events and no laboratory findings suggestive of such. Nasopharyngitis was the most common TEAE, reported for 6 patients in the DZP group and none in the PBO group. The majority of TEAEs observed were mild or moderate in intensity, transient, and resolved without intervention. There was 1 withdrawal due to a TEAE of infection in the DZP group.

Preliminary evidence of clinical activity was seen in the DZP group.

		Week 12		Week 28	
		Treatment group			
		PBO	DZP	PBO	DZP
BICLA	N	7	11	6	10
	Responders, n (%)	1 (14.3)	5 (45.5)	1 (16.7)	3 (30.0)
	Non-responders, n (%)	6 (85.7)	6 (54.5)	5 (83.3)	7 (70.0)
SRI-4	N	7	12	6	11
	Responders, n (%)	1 (14.3)	5 (41.7)	1 (16.7)	4 (36.4)
	Non-responders, n (%)	6 (85.7)	7 (58.3)	5 (83.3)	7 (63.6)

Conclusion:

Multiple administrations of DZP over 12 weeks in patients with mild to moderate SLE were well tolerated and the safety profile supports further development. Exploratory analyses show greater improvement in clinical measures of disease activity in the DZP group vs PBO.

Session Date: Tuesday, November 10, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment VI: Novel Therapies
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: The efficacy and safety of anifrolumab (ANIFR), a type I IFN receptor antagonist, were assessed in a Phase II, randomized, double-blind, placebo-controlled study in SLE (NCT01438489).

Methods: Three hundred and five adults with seropositive moderate to severe SLE despite standard of care medication were randomized and received intravenous (iv) ANIFR (300 mg, 1000 mg) or placebo (PBO) every 4 weeks for 48 weeks. Patients were stratified by SLEDAI score, oral corticosteroid (OCS) dose, and IFN gene signature (IFN high vs. IFN low) based on a 4-gene expression assay. Disease activity was assessed by SLEDAI-2K, BILAG 2004, Physician's Global Assessment, CLASI, BICLA, and 28-joint count. The primary endpoint was a composite of SRI(4) response at Day 169 with sustained reduction of OCS (<10 mg/day and ≤Day 1 dose maintained between Days 85 and 169). Two secondary efficacy endpoints were assessed at Day 365: A) Composite of SRI(4) response at Day 365 with sustained reduction of OCS maintained between Days 281 and 365; B) Reduction of OCS to ≤7.5 mg/day by Day 365 in those taking ≥10 mg/day at baseline. Other efficacy measures of systemic and organ-specific disease activity and safety were also assessed at Day 365.

Results: The primary endpoint at Day 169 was met by a greater proportion of ANIFR-treated patients vs. PBO (PBO: 17.6%; 300 mg: 34.3%, p=0.014; 1000 mg: 28.8%, p=0.063). At Day 365, the secondary SRI endpoint was met by 25.5% of PBO, 51.5% of 300 mg (p<0.001) and 38.5% of 1000 mg (p=0.048) patients. OCS reduction to ≤7.5 mg/day at Day 365 was achieved by 26.6% of PBO, 56.4% of 300 mg (p=0.001) and 31.7% of 1000 mg (p=0.595) patients. ANIFR demonstrated consistent benefit across multiple global and organ-specific measures at Day 365 (Table), as well as lower rates of BILAG moderate/severe flares/patient-year (PBO: 0.611; 300 mg: 0.266; 1000 mg: 0.391). 75% of patients were IFN high at baseline. The ANIFR efficacy observed in the entire cohort was similar or more pronounced in IFN high patients. Median suppression of 21 IFN-regulated genes was ~90% for both doses of ANIFR. Serious adverse events were reported in 18.8% of patients on PBO and 16.7% of patients in the pooled ANIFR groups. A higher frequency of influenza (most unconfirmed) (PBO: 1.0%; 300 mg: 6.1%; 1000 mg: 7.6%) and a dosage-dependent increase in *Herpes zoster* (PBO: 2.0%; 300 mg: 5.1%; 1000 mg: 9.5%) occurred in the ANIFR arms.

Conclusion: Anifrolumab significantly reduced disease activity compared with PBO across multiple clinical endpoints. Enhanced effects in IFN high patients support the pathobiology of this treatment strategy. The lack of dose response can be explained by the nearly similar degrees of IFN gene signature inhibition achieved with the two anifrolumab doses. These data strongly support further development of anifrolumab.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Vasculitis IV

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Recurrent oral aphthous ulcers are the common manifestation of the Behçet's disease (BD), and they are indistinguishable from ulcers of recurrent aphthous stomatitis (RAS). There is no reliable biomarker reflecting disease activity in BD, and systemic acute phase reactants are not helpful in evaluation of active disease, especially in patients with predominantly mucocutaneous activity. We aimed to assess the potential of salivary interleukin-1 alpha and beta (IL-1α and IL-1β) concentrations as well as two S100 proteins, namely S100A12 (calprotectin) and S100A13 in comparison to their serum levels in BD, RAS, and healthy controls.

Methods: A total of 67 patients with BD, 43 patients with RAS, and 22 healthy controls with no history of aphthous ulcers or other oral mucosal disorders (NA) comprised the study group. BD patients fulfilled the ISG criteria for the diagnosis, and patients with active systemic disease were excluded. Patients with BD and RAS were classified as active and inactive according to the presence or absence of aphthous ulcers at the time of sample collection. Unstimulated saliva and serum samples were collected after overnight fasting. IL-1α, IL-1β, S100A13 and calprotectin levels were measured by ELISA, and concomitant measurements of ESR and serum CRP levels of BD patients were recorded.

Results: At the time of sample collection, 38 BD patients (18 male, mean age: 39,1±10,3) were classified as active and 29 patients (18 male, mean age: 38,9±10,5) as inactive. Similarly, 19 patients with RAS (11 male, mean age: 36,6±8,7) were active and 24 patients (7 male, mean age: 36,7±10,1) were inactive state. Mean values of salivary and serum ELISA measurements are given in Table 1. Salivary IL-1α and IL-1β, levels were higher in BD patients compared to RAS and NA even during inactive state (IL-1α $p<0.001$ for RAS and $p<0.001$ for NA, IL-1β $p<0.001$ for RAS and $p=0.003$ for NA). There was a correlation between IL-1α and IL-1β levels, but IL-1α increase was more prominent in

active BD patients. No correlation was detected between salivary IL-1α and S100A13 levels. Serum CRP and ESR were within normal range in BD patients, and they showed no correlation with salivary measurements.

	SALIVA				SERUM			
	IL-1α (pg/ml)	IL-1β (pg/ml)	S100A12 (ng/ml)	S100A13 (ng/ml)	IL-1α (pg/ml)	IL-1β (pg/ml)	S100A12 (ng/ml)	S100A13 (ng/ml)
BD active (n=38)	2147	5.1	49.1	1.8	13.9	17.8	57.7	0.6
BD inactive (n=29)	1492	4.7	48.4	1.5	12.4	18.3	67.1	0.9
RAS active (n=19)	1324	2.3	60.1	1.8	35.2	22.8	110.0	1.9
RAS inactive (n=24)	282	0.7	37.0	1.9	28.5	23.2	146.0	1.7
Healthy controls (n=22)	361	1.8	30.3	1.3	31.4	23.3	188.0	1.2

Conclusion: These results suggest a role for IL-1α and IL-1β in the development of oral aphthous ulcers. S100A13 is known to be involved in controlled secretion of IL-1α. Increased IL-1a levels without an increase in S100A13 levels may suggest that pyroptosis or other causes of cellular damage is the main source of salivary IL-1α. Further studies are necessary both to improve saliva collection and analysis methods and to search the biomarker potential of salivary IL-1α and IL-1β concentrations in the management of mucocutaneous and systemic manifestations of BD.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Vasculitis IV

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Behcet's disease (BD) is a systemic inflammatory disease characterized by recurrent oral and genital ulcers, skin lesions, uveitis, and other organ complications such as vascular, central nervous system, and gastrointestinal involvement. The etiology and pathogenesis of BD are poorly understood. Despite the identification of multiple common genetic variants associated with BD, rare genetic variants have been less explored. We performed whole exome sequencing (WES) in a European-derived cohort of BD patients to investigate the role of rare protein-coding variants in this disease.

Methods: Whole exome sequencing was initially performed in 14 BD patients of European descent. Exome enrichment was performed using the TrueSeq Exome Enrichment Kit (Illumina), then paired-end 100bp reads were sequenced on an Illumina HiSeq 2000 instrument. Sequence alignment, quality assurance measures, and data analysis were performed using the DNA-Seq Analysis Package (SVS 7) implemented in Golden Helix. Sanger sequencing and Sequenom technology genotyping were performed in the original patient set and two additional independent European-derived sets for validation and replication. Protein damaging potential for non-synonymous coding variants was assessed using SIFT, Polyphen, Mutation Taser, Mutation Assessor, and FATHMM.

Results: We identified 77 protein-coding non-synonymous variants in 74 genes detected in at least 2 out of 14 re-sequenced BD patients, with a minor allele frequency (MAF)<0.01 in 6,500 control individuals included in the NHLBI Exome Sequencing Project, and predicted to have

protein damaging effect. Sanger sequencing in selected variants confirmed our exome sequencing results. Genotyping was successfully performed and passed quality control measures in 61 variants in two additional sets of 49 and 129 European-derived BD patients from Germany and Italy, respectively. Genetic analysis was performed in BD cases compared to 503 European-derived controls included in the 1000 Genomes Project. Two rare protein-coding non-synonymous genetic variants were significantly associated with BD with a Bonferroni-corrected *P* value of $<8X10^{-4}$. We detected an association with non-synonymous potentially damaging variants in *LIMK2* which is involved in actin cytoskeleton organization, and the DNA repair gene *NEIL1*.

Conclusion: We used whole exome sequencing in BD for the first time, and identified rare non-synonymous protein-coding variants associated with this disease.

Session Title: Vasculitis IV

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose:

Behcet's Disease (BD) is a chronic inflammatory disease characterized by recurrent oral and genital ulcers, skin lesions, uveitis, and arthritis. Although the etiology of BD still remains to be elucidated, several autoantibodies including anti-alpha-enolase (ENO1) antibodies (AEA) have been associated with BD. AEA are directed against endothelial cells and might contribute to vasculitis leading to subsequent oral ulcer formation. This study was aimed to investigate the association between AEA and clinical manifestations of BD.

Methods:

In this study 64 BD patients and 30 age/sex matched healthy controls (HCs) were enrolled. Western blot with recombinant ENO1 proteins were performed to detect the presence of AEA in serum from BD patients and HCs. Subsequently, enzyme-linked immunosorbent assay (ELISA) was performed to determine the serum levels of AEA. The association between BD manifestation and AEA levels were examined.

Results:

AEA were present in 14 (82.4%) of 17 BD patients as compared to 6 (66.7%) of 9 HCs on Western blot. Serum levels of AEA tended to be increased in BD patients compared to HCs. (Mean ± SE : 1543 ± 160 vs. 1067 ± 144, p= 0.06). Number of oral ulcers tended to correlate with serum levels of AEA (r = 0.238, p = 0.06 by Spearmann). BD patients with oral ulcers were grouped into a mild (number of oral ulcer is less than or equal to 2) and a severe (number of oral ulcer is greater than 2) disease based on the cumulative number of oral ulcers in the preceding 4 weeks prior to blood sampling. AEA levels differed between HCs, the BD patients mild and those with extensive oral ulcers (p = 0.04 Kruskal-Wallis). Patients with extensive oral ulcers exhibited significantly higher levels of AEA than those with mild oral ulcers (1722 ± 178 vs. 1416 ± 257, p = 0.03), and HCs (1722 ± 178 vs. 1067 ±144, p < 0.01). Skin lesions, uveitis, and arthritis had no association with serum AEA levels.

Conclusion:

BD patients with severe oral ulcers have increased serum levels of AEA than those with mild oral ulcers and HCs, suggesting a possible pathogenic role of AEA in the oral ulcer formation. A treatment targeting AEA might offer a new therapeutic option for BD associated severe oral ulcer.

Identification of Novel Protein-Coding Genetic Variants Associated with Takayasu Arteritis

Paul Renauer[1], Patrick Coit[1], Peter A. Merkel[2] and Amr H. Sawalha[1], [1]Division of Rheumatology, University of Michigan, Ann Arbor, MI, [2]Penn Vasculitis Center, Division of Rheumatology, University of Pennsylvania, Philadelphia, PA

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Vasculitis IV

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Takayasu arteritis is a rare large vessel vasculitis of unclear etiology. Previous studies identified associations between Takayasu arteritis and genetic variants within HLA class I and II, *FCGR2A*/*FCGR3A*, *IL12B*, *RPS9*/*LILRB3*, *IL6*, and chromosome 21q22. The purpose of this study was to uncover protein-coding genetic risk variants in Takayasu arteritis.

Methods: We analyzed 230,050 exonic protein-coding genetic variants included on the Illumina Human Exome BeadChip array in a European-American cohort consisting of 134 patients with Takayasu arteritis and 1051 healthy controls. Genotyping data were subjected to rigorous quality control assessment and filtering prior to genetic analysis.

Results: Outside of the HLA region, 4 nonsynonymous protein-coding variants associated with increased risk for Takayasu arteritis were identified ($P<5X10^{-5}$). The most significant genetic associations were with missense genetic variants in *TXK* (OR= 1.95, $P= 7.75X10^{-6}$) and *CCDC91* (OR= 3.69, $P= 2.11X10^{-5}$). *TXK* encodes a non-receptor tyrosine kinase that plays an important role in T cell function and differentiation. *CCDC91* encodes P56 which interacts with the trans-Golgi network and is involved in regulating protein trafficking. Evidence for gene-gene epistatic interaction was detected between the two genetic variants in *TXK* and *CCDC91* and the risk for Takayasu arteritis (interaction OR= 3.09, $P= 2.38X10^{-2}$). Two additional missense variants within the collagen gene *COL11A2* and the acyl-coenzyme A synthetase gene *ACSM5* were also associated with Takayasu arteritis ($P= 3.27X10^{-5}$ and $3.41X10^{-5}$, respectively).

Conclusion: Missense protein-coding variants associated with increased risk for Takayasu arteritis were identified. A larger cohort will be necessary to confirm these associations with a genome-wide level of significance.

Disclosure: P. Renauer, None; **P. Coit**, None; **P. A. Merkel**, None; **A. H. Sawalha**, None.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Vasculitis IV
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Hepatitis C virus (HCV) is the etiologic agent for most cases of cryoglobulinemia vasculitis (Cryovas). Interferon–containing regimens are associated with important side effects and may exacerbate the vasculitis. We evaluated the safety and efficacy of an oral interferon-free regimen, sofosbuvir plus ribavirin, in patients with HCV-Cryovas.

Methods: We enrolled 24 patients [median age of 56.5 years and 46% of women] with HCV-Cryovas. Sofosbuvir (400mg/day) was associated to ribavirin (200-1,400mg/day), for 24 weeks. Selection of the initial ribavirin dose and subsequent dose modification for anemia were at the investigator's discretion. The primary efficacy end point was a complete clinical response of the Cryovas at the end of treatment (week 24).

Results : Main clinical features of Cryovas included purpura and peripheral neuropathy (67%), arthralgia (58%), glomerulonephritis (21%), and skin ulcers (12%).Twenty one participants (87.5%) had a complete clinical response at week 24. Complete clinical response was achieved in 6 (25%) patients at week 4, 4 (16.6%) at week 8, 7 (29.2%) at week 12, 3 (12.5%) at week 16 and 1 (4.2%) at week 20. Purpura, skin ulcers and arthralgia disappeared in all cases. Kidney involvement improved in four out of five (80%) patients. Peripheral neuropathy improved in 16 out of 17 (94%) cases. The cryoglobulin level decreased from 0.35 (0.16-0.83) at baseline to 0.15 (0.05-0.45) g/l at week 24. The C4 serum level increased from 0.10 (0.07-0.19) to 0.17 (0.09-0.23) g/l at week 24. Seventy four percent of patients had a sustained virological response at week 12 post treatment. The most common side effects were fatigue, insomnia and anemia. Two serious adverse events were observed leading to treatment discontinuation. Thirteen patients (54%) received erythropoietin and three required blood transfusion.

Conclusion: Treatment with sofosbuvir plus ribavirin for 24 weeks was associated with a high rate of complete clinical response and a low rate of serious adverse events among HCV-Cryovas patients.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Vasculitis IV
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Previous genome-wide association studies of granulomatosis with polyangiitis (Wegener's, GPA) identified common genetic variants associated with susceptibility to GPA. However, since GPA is a rare disease, we hypothesize that rare genetic variants may be more strongly associated with disease susceptibility. Therefore, we conducted an exome-sequencing study to identify rare, deleterious exonic variants associated with GPA.

Methods: Seventy-seven individuals with GPA underwent exome sequencing using the Illumina HiSeq platform and the Nimblegen SeqCap EZ exome enrichment protocol. All cases of GPA were of European descent, c-ANCA/anti-PR3 positive, and fulfilled either the ACR Classification Criteria or the Chapel Hill Consensus Conference definition of GPA. Exome sequencing reads were processed according to the Genome Analysis Toolkit Best Practices for DNA sequencing. Variants were annotated and filtered with ANNOVAR and Variant Tools. Functional effects of the variant were assessed using *in silico* bioinformatics algorithms and databases of known pathogenic variants. We applied a gene burden test to identify genes that were enriched with deleterious variants in patients with GPA when compared to publicly available data from the 1000 Genomes and the National Institutes of Health-funded Exome Sequencing Projects. Pathway analysis was performed using the Gene Set Enrichment Analysis Molecular Signatures database.

Results: After quality control filtering and bioinformatics analysis, we identified 4,306 exonic, non-synonymous, deleterious variants in the 77 cases of GPA, of which 3,812 were rare (minor allele frequency <1%). After applying gene burden tests, we identified 153 genes not previously associated with GPA that were enriched with deleterious variants in GPA cases compared to controls. These genes fell into the following 3 groups (with overlap): 1) 98 genes were enriched with rare deleterious variants, 2) 35 genes with homozygous rare deleterious variants not present in controls, and 3) 42 genes enriched with common deleterious variants. Genes with the strongest evidence of enrichment for rare, deleterious variants include *FOXD4L1*, *UMODL1*, and *PNKP*. Pathways over-represented by the 153 genes include the metabolism of lipoproteins and extracellular matrix organization. Lastly, we found enrichment for 6 variants in 3 genes previously associated with GPA (*ITGB2, RXRB, SERPINA1*).

Conclusion: Our initial results indicate that exome sequencing can identify novel genetic associations with GPA beyond what has been previously observed in genome-wide association studies. These associations implicate new biologic pathways that may contribute to the pathogenesis of disease. To our knowledge, this is the first study to utilize next-generation sequencing to assess for genetic variants associated with GPA susceptibility. The results from this study can be used to inform future genomic and translational investigations of this and other systemic vasculitides.

Perceived Barriers in Care for Arthritis

Elizabeth M. Badley[1], Lynn Moore[2] and Monique A.M. Gignac[3], [1]Toronto Western Research Institute, Toronto, ON, Canada, [2]The Arthritis Society, Toronto, ON, Canada, [3]Instititue for Work and Health, Toronto, ON, Canada
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: ARHP IV: Clinical Practice and Patient Care
Session Type: ARHP Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: To examine current arthritis treatments, barriers to treatment, and perceptions of health care decision making, especially preferences for patient-physician shared input.

Methods: A poll of people with arthritis was commissioned to gather data on patient perceptions with the purpose of improving information on the web site of The Arthritis Society of Canada. Respondents were asked for their disease diagnosis; impact of arthritis (e.g., pain, fatigue, disability with activities and social roles); challenges in getting care; and preferences for physician involvement in care decisions. Most questions were on a 1 to 5 scale ranging from 1 = no impact/importance to 5 = extreme impact/importance. Scores are reported as means or percentages unless otherwise stated.

Results:

Of the 1514 respondents, 558 reported only osteoarthritis (OA) and 1043 reported inflammatory arthritis (IA) (rheumatoid arthritis 499, psoriatic arthritis 235, ankylosing spondylitis 227, lupus 156). 69% were female; 69% were aged <65 years; 65% were married and 46% had completed post-secondary education. Mean disease duration was 12.9 years. There were few differences in findings by disease. Mean pain intensity was 6.0 (95% CI: 5.9-6.1) (1 to 10 scale). Mean number of joints (out of 13) was 4.3 (95% CI: 3.9-4.8), slightly less for OA (mean 3.8; 95% CI:3.6-4.0). The impact on daily activities was moderate with mean scores in the range of 2.6 to 4.0. The greatest impact was for intimate relations (4.0) and exercise (3.4). Respondents reported controlling pain, mobility and fatigue as being of high importance (mean score range 4.1-4.4). 52% reported taking medication orally; 15% by injection or infusion (mainly respondents with IA). Overall, 75% of respondents reported at least one challenge in getting treatment. The top 3 challenges were lack of affordable treatment (27.5%), long wait times for appointments (28.8%), and a perceived absence of beneficial treatments (e.g., "don't think anything can be done") (21.2%). Costs for treatments like physiotherapy and medication were noted in particular. Younger respondents tended to report more challenges. A sizable minority reported that nothing could be done for their arthritis (range 16.2 % to 26.3 % by disease). Respondents rated highly the importance of physician input when making decisions related to prescription medication (mean = 4.4) and surgery or physiotherapy (mean = 4.4). They expressed lower importance of seeking physician input on treatments like diet and exercise (mean = 3.7) and over-the counter-medications (mean = 3.8).

Conclusion: Despite pain, a moderate impact on valued roles and activities, and a high importance of controlling a range of symptoms, most respondents reported challenges with getting treatment, including costs not covered by the health care system. Of concern is the perception of some that little was available in the way of efficacious care. There is a need for better patient information on what can be done to control arthritis and for interventions to minimize barriers in accessing appropriate treatments. Additional research on decision-making preferences would be beneficial in addressing a patient-centered approach to care.

Session Title: ARHP IV: Clinical Practice and Patient Care

Session Type: ARHP Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Recently, we witnessed a steep increase in the amount of mobile applications (apps) in the category of "Health & Fitness". Most popular examples of such apps are RunKeeper GPS Track Run Walk, HealthTap, Sworkit Workout Trainer and iTriage Health. These apps all have between 1 and 50 million downloads and a rating of 4.4 or more out of 5, significantly higher than the average 3.9 rating for this category of apps. Possibly, this above average rating can be explained by their usage of so-called persuasive design techniques to engage users in using the app. The same principles can be employed for apps that target a specific disease. The aim of this study is to investigate which of these persuasive design principles are prevalent in apps that aid in the management of arthritis. It is our aspiration that these insights may help experts and app developers to build more effective patient support and may result in increasing the use of apps in arthritis management.

Methods: A systematic search was conducted in all three major app stores (Google Play, iTunes App Store and Windows Phone Store) using keywords related to arthritis. Criteria for inclusion were that the app (1) should target one or more arthritis related diseases, (2) provides tracking or monitoring of arthritis related disease factors or provides information about arthritis, (3) targeted adult patients. Exclusion criteria were (1) apps intended for medical personnel, (2) magazines, general pain trackers or food guides in app format. There were no language restrictions. Apps were coded by two independent raters using an adapted version of the Persuasive System Design (PSD) model by Harjumaa and Oinas-Kukkonen (2009) and the taxonomy of behavior change by Abraham and Michie (2008).

Results: Twenty-eight apps met the inclusion criteria. The most used task support principle (n=15) was to solely provide information to patients. Other common task support principles were reduction (reducing complex behavior into simple tasks) and self-monitoring (being able to (re)view your own data); many apps (n=11) offer reduction as the calculation of the Disease Activity Score (DAS) and visualized to evolution as self-monitoring. Goal setting and ways to support self-efficacy beliefs (e.g. recognition, rewards) were less prevalent (n=2). In addition, principles to influence system credibility were limited to offering a level of surface credibility and perceived expertise in the information provided but lacked other system credibility measures such as figures of authority and third-party endorsements. Surprisingly, techniques to influence normative beliefs or to include social support were lacking.

Conclusion: The results of this study are an indication that current apps for arthritis patients are mostly designed to calculate DAS scores and convey information on the disease. There is a remarkable lack of other persuasive principles to engage patients in digital management of their disease. Although these persuasive principles such as social support and dialogue support contribute to the success of other fitness and health apps, apps for arthritis patients rarely use them.

The Comparative Efficacy of Kinesio Taping and Local Steroid Injection in Patients with Subacromial Impingement Syndrome

Hamit Goksu[1], **Pinar Borman**[2], Figen Gokoglu[3] and Seher Kocaoglu[2], [1]Clinic of Physical Medicine and Rehabilitation, Ankara Training and Research Hospital, Ankara, Turkey, [2]Department of 1st Physical Medicine and Rehabilitation, Ministry of Health Ankara Education and Research Hospital, Ankara, Turkey, [3]Dept of Physical Medicine and Rehabilitation, Ahi Evran University, Medical Faculty, Kýrþehir, Turkey
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: ARHP IV: Clinical Practice and Patient Care
Session Type: ARHP Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: There are several approaches in the treatment of subacromial impingement syndrome (SIS). The aim of this study was to compare the therapeutic effects of kinesio taping (KT) and local subacromial injection in patients with SIS, in regard to pain, range of motion (ROM) and disability.

Methods:

Sixty-one patients with subacromial impingement syndrome were enrolled into the study. Demographic and clinical characteristics including age, sex, duration of disease were recorded. The patients were randomized into two treatment groups receiving either a single corticosteroid and local anesthetic (LA) injection, or kinesio taping performed three times by intervals of 3 day. Visual analog scale (VAS) was used to assess pain intensity, shoulder abduction, flexion and rotation range of motion (ROM) degrees were recorded and Shoulder Pain and Disability Index (SPADI) was performed to evaluate functional disability, before treatment, at the first and fourth weeks after therapies. Both groups were educated for home exercise programme.

Results:

Forty-eight female and 13 male patients (mean age, 42.4+6.48 years; mean disease duration, 2.35+0.79 months) were included in the study. There were no differences between the groups regarding demographic variables on entry to the study. Pain, functional outcome measures were determined to have improved significantly in both groups at the end of therapies at first and fourth weeks, but these improvements were more significant in the injection group than in kinesio taping group ($p>0.05$). The improvements in pain at rest, shoulder abduction degrees, and SPADI scores at first and fourth weeks were statistically higher in injection group than in kinesio taping group.

Conclusion:

We imply that single dose subacromial injection and three times of kinesio taping by 3 day intervals, in addition to exercise programme have favorable effects on pain and functional status in the early period (up to one month) of subacromial impingment syndrome. Although the improvement in pain intensity at rest, abduction ROM measures and disability were better with local injection, KT may be an alternative non-invasive method for patients suffering from subacromial impingement syndrome in the early period.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: ARHP IV: Clinical Practice and Patient Care
Session Type: ARHP Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Emerging models of care in rheumatology are using non-physician health care professionals to assess patients with suspected inflammatory arthritis with the aim to improve early detection and access to care. Such models of care have been recently implemented for early identification of axial spondyloarthritis (SpA). The primary objective of this study was to compare the clinical impression and confidence of advanced practice physiotherapists (APP), having specialized training in inflammatory arthritis, with rheumatologists experienced in axial SpA according to: 1) the evaluation of patients with chronic back pain being assessed for axial SpA and 2) MRI recommendation for further investigation of the above patients.

Methods: Patients with more than 3 months of back pain with onset prior to the age of 45 years and attending community primary care or high risk clinics (e.g. gastroenterology or ophthalmology) were referred for axial SpA evaluation. Two APPs and three rheumatologists evaluated each patient's history, physical examination, laboratory studies and plain radiographs. Patients were classified as either axial SpA or mechanical back pain (MBP) based on the above clinical and investigative findings. Level of confidence in the clinical impression and recommendation for obtaining an MRI for further investigation were noted. Agreement between assessors was evaluated using percent agreement and Cohen's Kappa coefficient.

Results: Of 57 patients assessed, 56% were referred through community care pathways. The majority (56.1%) of patients was male and the mean (±SD) age was 38.5 years (±12.2). Overall interobserver agreement of clinical impression for all raters was moderate (K=0.52). Agreement of clinical impression between the APPs and rheumatologists ranged between 71.2% (K=0.41; 95% CI: 0.17-0.67) and 79.7% (K=0.57; 95% CI: 0.35-0.79). Agreement of clinical impression amongst rheumatologists ranged from 74.1% (K=0.49; 95% CI: 0.26-0.71) and 79.7% (K=0.58; 95% CI: 0.37-0.8). All rater agreement for recommendation of MRI showed fair agreement (K=0.37). The APP agreement with rheumatologist for MRI recommendation ranged from 64.2% (K-0.31, 95% CI: 0.13-0.55) and 75% (K=0.48, 95% CI: 0.23-0.72). Agreement to recommend MRI amongst rheumatologists ranged from 62.9% (K=0.27, 95% CI: 0.02-0.52) and 74% (K=0.47, 95% CI: 0.24-0.71). Confidence in clinical impression was similar amongst all practitioners (APPs median score 7/10; rheumatologists median score 6/10).

Conclusion: APPs with specialty training in inflammatory arthritis demonstrate comparable case ascertainment as rheumatologists in the assessment of axial SpA. Utilization of such advanced practice roles may assist in improving the early detection of axial SpA, thereby facilitating early treatment and improving overall outcomes in this patient population.

Table 1: Interobserver agreement between advanced practice physiotherapists and rheumatologists			
	Percent Agreement	Cohen's Kappa	95% Confidence Interval

Roadblocks Perceived By Canadian Dermatologists for Referring Patients with Suspected Psoriatic Arthritis

Renise Ayearst[1], Daniel Pereira[1], Charles Lynde[2], Holly Etchegary[3] and Vinod Chandran[1], [1]Rheumatology, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, [2]University of Toronto, Toronto, ON, Canada, [3]Memorial University of Newfoundland, St.John's, NF, Canada

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: ARHP IV: Clinical Practice and Patient Care

Session Type: ARHP Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: The current system of referral by Canadian dermatologists of patients who may have psoriatic arthritis (PsA) to rheumatologists is suboptimal. Hypothesizing that knowledge level, attitude and confidence in being able to refer appropriately impacts the ability of dermatologists to refer patients who may have PsA to a rheumatologist, we aimed to define their current awareness of, and practices relating to, the diagnosis and referral of PsA.

Methods: Based on recommendations from our advisory group comprising rheumatologists, dermatologists, methodologists and patient-partners, questions for structured interviews and focus groups with practicing dermatologists were developed. Dermatologists from across Canada at different stages of their career were recruited via electronic mail. Telephone or face-to-face interviews and focus groups were conducted by

trained research associates. The interviews and focus groups were recorded, transcribed, and analyzed by 2 experts and key themes identified.

Results: 8 interviews and 2 focus groups involving a total of 20 dermatologists in community practice (10 males, mean years in practice 18.4) were conducted and data saturation reached. The following themes were identified- (1) **Self-perceived knowledge** of psoriasis and associated co-morbidities was fairly high [mean of 8.5 (out of 10) across the interviews and 7.1 across focus groups]. (2) The **number of patients** with psoriasis seen was quite variable, 30-50 weekly on average. Of these, the percentage with PsA or suspected PsA ranged from 5%-50%. (3) **Co-morbidities**, including PsA, diabetes, obesity, heart disease, depression, metabolic syndrome, and hypertension were consistently mentioned. (4) **Red flags** noted for PsA included morning stiffness and joint pain**.** Fewer mentioned nail lesions and joint swelling. (5) All dermatologists recognized the **importance of identifying PsA early**, both for the patient and for the broader healthcare system. (6) There was a notable divide between their **perceived role in screening for PsA and in making the diagnosis**. A minority of respondents felt comfortable managing PsA if it was mild without confirmation by a rheumatologist. (7) If arthritis is perceived to be mild, dermatologists perceive an ongoing **role in patient management**. Other aspects of the healthcare system that affected dermatologists' perception included the nature of the local healthcare context, access to rheumatologists, and the role of primary care.

Conclusion: This qualitative study shows that dermatologists have high self-perceived knowledge of psoriasis, PsA and its associated comorbidities, and recognize the importance of identifying PsA early. However, the nature of the local healthcare context and access to rheumatologists are significant road blocks to appropriate referral.

Session Title: ARHP IV: Clinical Practice and Patient Care

Session Type: ARHP Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Medication nonadherence accounts for more than $100 billion in preventable healthcare costs annually in the US. Nonadherence to disease-modifying antirheumatic drugs (DMARDs) among patients with rheumatic diseases likely results in significant morbidity. We investigated the association between demographic, disease-related and psychosocial factors and nonadherence to recently initiated DMARDs; the long-term goal is to better tailor interventions to target patients at highest risk for nonadherence.

Methods: English or Spanish-speaking patients ≥18 years old who recently started an oral DMARD for a systemic rheumatic disease were invited to participate. The study took place between 2013 and 2015 at an academic medical center. We identified patients using electronic medical record review and obtained permission to contact the patients from the treating rheumatologist. Medications and demographic factors were ascertained using electronic medical record queries. Trained bilingual research assistants administered baseline surveys by phone or in person. We measured self-reported adherence to oral DMARDs using the eight-item Morisky Medication Adherence Scale (MMAS). We determined disease activity for rheumatoid arthritis (RA) and other inflammatory arthritis with the Rheumatoid Arthritis Disease Activity Index (RADAI). Anxiety and depression were assessed with the Mental Health Inventory (MHI-5) and perceived illness severity using the Brief Illness Perception Questionnaire. We used descriptive statistics to compare demographics and survey findings by degree of adherence.

Results: We administered surveys to 92 patients. The mean age was 56.1 years (SD 16.2), 95% were female, 72.8% were White, 5.4% Black, 2.2% Asian and 19.6% not reported;17.4% identified as Hispanic. 80.4% had RA or other inflammatory arthritis, 7.6% lupus, and 4.3% other systemic rheumatic diseases. In terms of medication use, 52.2% recently started methotrexate, 20.7% hydroxychloroquine, 10.9% sulfasalazine, 6.5% leflunomide, 3.3% azathioprine, and 3.3% tofacitinib. The mean RADAI was 14.7 (SD 9.1). 89.8% of patients had depressive symptoms (MHI-5<70). The mean adherence score was 6.6 (SD 1.4); 23.9% reported poor adherence to their prescribed DMARD (MMAS <6), 53.3% borderline (MMAS 6 to <8) and 22.8% high (MMAS=8). Patients with poor adherence were more likely to be younger (p=0.01), have more active RA (p=0.05), and more depressive symptoms (p=0.02) (**Table**).

Conclusion: In this cross-sectional analysis, the majority of patients who recently started an oral DMARD had borderline or poor adherence and a significant burden of depressive symptoms. Increased disease activity, depression and younger age were associated with poorer adherence. Interventions that target these individuals at high risk for nonadherence are being tested to determine whether clinical outcomes improve.

Session Type: ACR Concurrent Abstract Session

Session Time: 9:00AM-10:30AM

Background/Purpose: Rheumatoid arthritis (RA) is characterized by chronic inflammation and the dysregulated expression of pro-inflammatory cytokines / chemokines (CK). Chronic inflammation has also been implicated in cancer pathogenesis, particularly through the intercommunication of immune and cancer cells mediated by CK signaling. In this study we sought to test the hypothesis that circulating CKs predict cancer mortality in RA.

Methods: Male participants in the Veterans Affairs RA registry were followed from enrollment until death or December 2013. Using banked serum from enrollment, CKs were measured using a bead-based multiplex assay. CK scores were calculated from individual CKs. Both CK scores and individual CKs were examined in quartiles and as log transformed values. Vital status and cause of death were determined through the National Death Index. Associations of CK score and individual CKs with cancer mortality were examined using multivariable competing-risks regression adjusting for age, race, smoking status, body mass index, comorbidity, visit frequency, nodules, RF concentration, enrollment DAS-28, baseline DMARDs and prednisone use.

Results: There were 1,294 RA patients included with 71 cancer deaths occurring over 5,585 patient-years of follow-up. Patients were older (mean 65 ± 11 years), had established disease (mean 12 ± 12 years), were seropositive for RF (80%) or anti-CCP antibody (77%), and had frequent smoking history (82% current or former). Lung cancer was the most common cause of cancer deaths (n = 30, 42%), followed by leukemia (n = 7) and lymphoma (n = 6). Adjusted associations of CK score with overall and lung cancer mortality are shown in Table 1. After MV adjustment, log-transformed CK score was associated with mortality from all cancers (HR 1.65, 95% CI 1.40 to 1.94, P < 0.001) and lung cancer (HR 1.81, 95% CI 1.47 to 2.22, P < 0.001). Fifteen of the 17 CK analytes examined were associated with cancer mortality after multivariable adjustment. In sub-analyses, excluding those with prevalent cancer at enrollment (n=190), CK score remained associated with overall cancer mortality (HR 3.82, 95% CI 2.19-6.65, P < 0.001 for highest quartile vs. lowest; P trend < 0.001) and lung cancer mortality (HR 9.47, 95% CI 0.85-105.90, P = 0.068 for highest quartile vs. lowest; P trend = 0.001).

Table 1. Multivariable Associations of CK Score with Overall and Lung Cancer Mortality in RA.

CK Score Quartile	Overall Cancer Mortality	Lung Cancer Mortality
	Hazard Ratio (95% Confidence Interval)	
Quartile 1 (Lowest)	1.00	1.00
Quartile 2	1.34 (0.39-4.61)	1.83 (0.35-9.58)
Quartile 3	1.83 (0.50-6.71)	2.85 (0.43-18.88)
Quartile 4 (Highest)	3.29 (1.63-6.67)	4.44 (0.83-23.77)
	P-trend < 0.001	P-trend = 0.018

Conclusion: Circulating CK concentrations are strongly associated with future cancer mortality in men with RA, an association that is independent of multiple factors including RA disease activity and medications. In addition to highlighting the potential value of CK as a predictive biomarker, these findings suggest that CK expression could act as a crucial link between RA and cancer. Further studies are needed to investigate the role of specific CKs in cancer development and the impact that therapies targeting CKs could yield in reducing cancer burden in RA.

Session Title: Rheumatoid Arthritis - Clinical Aspects VI: Death Be Not Proud-Mortality and Treatment Outcomes in RA (Includes 2014 Lee C. Howley, Sr. Prize for Arthritis Research Introductory Talk)

Session Type: ACR Concurrent Abstract Session

Session Time: 9:00AM-10:30AM

Background/Purpose: Rheumatoid arthritis (RA) is associated with increased cardiovascular (CV) morbidity and mortality as compared to the general population. Recent prospective studies with limited follow-up suggest a trend towards decreasing CV fatality in RA. Longitudinal studies of CV mortality trends in RA patients diagnosed in the recent years are lacking, and the trends in the relative CV mortality in RA versus the general population are not fully understood. We aimed to assess trends in CV mortality in patients with incident RA in 2000-2007 compared to the previous decades, and to evaluate trends in relative CV mortality in RA compared to non-RA subjects.

Methods: The study population comprised a retrospectively identified population-based incidence cohort of patients with RA (age≥18 years, 1987 ACR criteria met in 1980-2007). A comparison cohort included non-RA subjects from the same underlying population with similar age, sex and calendar year of index. All subjects were followed until death, migration, or Jan. 1, 2014. Underlying causes of death were obtained from state and local death certificates as well as the National Death Index Plus and grouped according to ICD-9 and ICD-10 chapters. Kaplan-Meier methods were used to estimate CV mortality rates. Cox proportional hazards models, adjusting for age and sex, were used to compare CV mortality by decade.

Results: The study included a total of 813 RA patients (mean age 55.9 years; 68% female; 66% rheumatoid factor [RF] positive) and 813 non-RA subjects (mean age 55.9 years; 68% female). Figure shows CV mortality by decade of RA incidence/index date and the table summarizes these data. In patients with incident RA during the 2000–2007 period, the 10-year overall CV mortality was 2.8% (95% confidence interval [CI]: 0.4%, 5.2%); coronary heart disease (CHD) mortality was 1.2% (95% CI: 1.0, 1.4%), suggesting significant improvement compared to those diagnosed in 1990–1999 (hazard ratio [HR] for overall CV death: 0.43; 95% CI: 0.19, 0.94; p=0.035; CHD death: HR 0.21; 95% CI: 0.05, 0.95; p=0.042). Furthermore, 10-year overall CV mortality and CHD mortality in 2000-2007 RA incidence cohort did not differ from non-RA subjects (p=0.95 and p=0.79, respectively), which has not been observed in RA patients diagnosed in the prior decades.

Conclusion: Our findings suggest significant improvement in overall CV mortality, particularly CHD mortality, among patients with incident RA in 2000-2007 versus patients with incident RA in the previous decades. Furthermore, we have shown significant improvement in the relative 10-year CV mortality, including CHD mortality, in patients with incident RA in 2000-2007 versus the general population. These findings represent an important milestone in CV disease management in RA with significant implications for understanding determinants of improvement of CV disease in RA and in the general population.

Session Title: Rheumatoid Arthritis - Clinical Aspects VI: Death Be Not Proud-Mortality and Treatment Outcomes in RA (Includes 2014 Lee C. Howley, Sr. Prize for Arthritis Research Introductory Talk)

Session Type: ACR Concurrent Abstract Session

Session Time: 9:00AM-10:30AM

Background/Purpose: Tumor-necrosis-factor-α inhibition (TNFi) was assumed to be a relevant mechanism for the treatment of sepsis[1]. However, randomized controlled trials failed to show a survival benefit caused by TNFi in patients with diagnosed sepsis[2].

Methods: We investigated the outcomes of serious infection (SI, N=1,170) reported in 947 patients in the German biologics register RABBIT (**R**heumatoid **a**rthritis: o**b**servation of **bi**ologic **t**herapy) as: (i) no complication of SI, (ii) sepsis following SI (≤30d), and (iii) death after SI (≤90d). We applied a GEE model for multinomial responses in longitudinal data [3] to evaluate the risks of sepsis and death (accounting for age at SI, sex, physical function, comorbid heart failure or renal disease, glucocorticoid (GC) dose and the disease-modifying anti-rheumatic drug (DMARD)). Biologic (b)DMARDs were grouped as TNFi or other classes of bDMARDs. Sensitivity analyses were applied: [a] in a subset of

patients with pneumonia (N=298), [b] by restricting the conventional synthetic (cs)DMARD group to biologic naive patients and [c] by incorporating patients with incomplete data.

Results: 135 of 947 patients with an SI developed sepsis 137 times, 85 of 135 patients died due to sepsis. 53 patients died without known sepsis within 90 days after SI. The adjusted risk (odds ratio (OR)) of sepsis was significantly higher in older patients and in patients with chronic renal disease (Table). Patients with an SI who were exposed to bDMARDs and those with better physical function had a significantly lower risk to develop sepsis (Table). Risk factors of death after SI were higher age, glucocorticoids in high doses and heart failure, patients treated with bDMARDs and those with better physical function had a significantly lower risk of death after SI. Results remained consistent in sensitivity analyses [a-c].

Table: Results of multinomial regression. Adjusted odds ratios (OR) show increase or decrease of the risks of sepsis or death. Reference group: patients with SI but no further complication.

	Sepsis		Death	
	OR	95% CI	OR	95% CI
Age (by 10 years)	1.41	[1.15; 1.74]	2.47	[1.61; 3.79]
Sex (male vs female)	0.99	[0.63; 1.55]	1.45	[0.74; 2.83]
% of physical function (10% improvement)	0.92	[0.84; 1.00]	0.86	[0.76; 0.98]
Glucocorticoids (<5 mg/d=Referenz)				
Glucocorticoids (5- <10 mg/d vs. Ref.)	1.26	[0.82; 1.93]	0.93	[0.47; 1.83]
Glucocorticoids (≥10 mg/d vs. Ref.)	1.66	[0.96; 2.88]	2.40	[1.04; 5.55]
csDMARDs (reference)				
TNFi	0.64	[0.42; 0.97]	0.48	[0.24; 0.95]
Other bDMARDs	0.45	[0.25; 0.80]	0.16	[0.05; 0.54]
Heart failure (yes vs. no)	1.38	[0.74; 2.56]	3.56	[1.73; 7.33]
Chronic renal disease (yes vs. no)	1.93	[1.19; 3.14]	1.51	[0.72; 3.17]

Conclusion: Our results suggest a protective effect of bDMARDs in terms of lowering the risk of sepsis after SI if patients were already exposed to bDMARDs at the SI. Further investigation is needed for each class of bDMARDs and separately for bacterial and viral SI.

Session Date: Wednesday, November 11, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects VI: Death Be Not Proud-Mortality and Treatment Outcomes in RA (Includes 2014 Lee C. Howley, Sr. Prize for Arthritis Research Introductory Talk)

Session Type: ACR Concurrent Abstract Session

Session Time: 9:00AM-10:30AM

Background/Purpose:

Methotrexate (MTX) is considered as the anchor drug for the treatment of patients with rheumatoid arthritis (RA). MTX has been shown to reduce disease activity and decrease radiographic progression and mortality. Response to MTX treatment is known to predict long term outcomes over some years. However, it is not clear whether this effect becomes weaker in the long-term.

Methods:

We analysed data of one of the earliest MTX-cohorts in Europe (Evangelisches Fachkrankenhaus Ratingen, Germany)[1]. From 1980 to 1987, all patients starting treatment with MTX (n=271) were enrolled in a prospective observational study. One year after baseline, response to MTX-treatment was determined (improvement or no improvement of at least 20%). Re-evaluations were performed 10, 18, and 30 years after baseline. In 2015, outcomes of 192 patients (71%) could be assessed. Cox regression was applied to estimate risks for increased mortality. The Cox model included age, gender, rheumatoid factor, signs of disease activity at baseline (number of swollen joints, ESR), patient global assessment at baseline, and response to MTX treatment after one year.

Results:

30 years after baseline, 167 patients were deceased. A positive effect on mortality was seen for the response to MTX treatment after one year (hazard ratio (HR) 0.60; 95%-confidence interval (CI): 0.42-0.89, p = 0.007) (Table 1). Furthermore, in the group of patients still alive ten years after baseline continued MTX-treatment was associated with lower mortality (HR 0.95 per mg; 95%-CI: 0.91-0.98, p = 0.003) in the next 20 years.

Table 1. Predictors of all-cause mortality for the entire observation period

Variable	Hazard ratio	95% confidence interval	Chi-Square	p-value
Improvement ≥20% after the first year of MTX treatment	0.60	0.42 to 0.87	7.37	0.007
Age	1.09	1.07 to 1.11	76.3	<0.001
Female gender	0.76	0.52 to 1.10	2.11	0.146
RF positivity	1.20	0.71 to 2.02	0.44	0.507
No. of swollen joints at baseline (0 – 32)	1.01	0.99 to 1.03	0.77	0.379
ESR at baseline	1.00	0.99 to 1.01	2.40	0.121
Patient global assessment at baseline	1.20	0.80 to 1.81	0.80	0.370

RF: rheumatoid factor; MTX: methotrexate; ESR: erythrocyte sedimentation rate.

Conclusion:

In this cohort, response to MTX after one year of treatment was a predictor of lower mortality during the next 30 years. Continued MTX treatment after ten years was positively associated with lower mortality in the following 20 years.

Session Title: Rheumatoid Arthritis - Clinical Aspects VI: Death Be Not Proud-Mortality and Treatment Outcomes in RA (Includes 2014 Lee C. Howley, Sr. Prize for Arthritis Research Introductory Talk)

Session Type: ACR Concurrent Abstract Session

Session Time: 9:00AM-10:30AM

Background/Purpose: All-cause mortality in UK has been decline by almost 20% over the past two decades. While rheumatoid arthritis (RA) is associated with an increased risk of mortality [1], it is unknown whether RA patients has experienced similar trend of reduced mortality or even a greater reduction of mortality owing to the improvement of clinical management of RA (e.g., biologics use since middle of 2000's). To address this knowledge gap, we evaluated mortality trends among RA patients between January 1, 1999 and December 31, 2012 in a general population context.

Methods: Using The Health Improvement Network, an electronic medical record database representative of the UK general population, we identified individuals with incident cases of RA and up to 5 non-RA controls matched on sex, age, and year of RA diagnosis, between 1999 and 2012 (i.e., ≥ 1 year before the end of our dataset to allow for follow-up). The RA cohort was then divided in two cohorts based on the year of RA diagnosis (i.e., 1999-2005 and 2006-2012) to evaluate changes in mortality. The follow-up time of early cohort ended at the end of 2005 and late cohort ended at the end of 2012. We calculated hazard ratios for death using a Cox-proportional hazards model and the rate differences using an additive hazard model, adjusting for potential confounders (i.e., number of GP visits, body mass index, smoking, alcohol and Charlson Comorbidity Index). We tested if the effect of RA mortality varied according to time period by adding an interaction term (i.e., RA*period) into regression model.

Results: Among the early cohort (1999-2005) RA patients had considerably higher mortality rates than the late cohort (2006-2012) (i.e., 23.8 vs. 15.7 cases per 1000 person-years), as compared with only a moderate improvement in the general population between the two periods (14.1 vs. 11.1 cases per 1000 person-years). The adjusted mortality rate differences between two comparison cohorts was 9.7 (95% CI, 7.2-12.2) cases per 1000 person-years in the early cohort and 4.7 (95% CI, 2.9-6.4) cases per 1000 person-years in the late cohort (p for interaction <0.01). The corresponding HRs for all-cause mortality were 1.51 (95% CI, 1.33-1.72) in the early cohort and 1.21 (95% CI, 1.05-1.39) in the late cohort, respectively (p for interaction=0.027), suggesting that mortality reduction over time is more apparent among RA patients than that in the general population.

Conclusion: This study shows that survival of RA patients has improved over the past decade, suggesting that new treatments and improved management of complications and associated comorbidities may be providing substantial benefits.

Do Boosters Support Long-Term Physical Activity Maintenance after an Intervention? a Systematic Review

Kathryn Remmes Martin[1], Chloé Charlotte Schröder[1,2] and Daniel Whibley[1], [1]Musculoskeletal Research Collaboration (Epidemiology Group), University of Aberdeen, Aberdeen, United Kingdom, [2]Faculty For Human and Health Sciences, University of Bremen, Bremen, Germany
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Wednesday, November 11, 2015
Session Title: ARHP V: Physical Activity
Session Type: ARHP Concurrent Abstract Session
Session Time: 9:00AM-10:30AM

Background/Purpose: Physical activity (PA) is an important health behaviour, particularly for individuals with rheumatic and musculoskeletal disease (RMD). While PA interventions can successfully increase PA levels, they often reduce over time post-intervention. One strategy for supporting PA maintenance is the introduction of a booster after an initial intervention, though this is less studied. This current review aims to identify whether evidence exists that supports the efficacy of booster components to support PA maintenance.

Methods: A systematic review was undertaken and used a search strategy designed to broadly detect articles focused on PA interventions and long-term maintenance. Eligibility criteria: randomized control trials including healthy community dwelling adults or those with RMD aged 25 years or older. Trials had to include a PA intervention at baseline for all subjects with subsequent randomization to either a booster or non-booster arm, and a PA outcome measure. Cohorts comprised exclusively of non-RMD clinically defined populations (e.g., cancer, diabetes) were excluded. Six electronic bibliographic databases were searched, including Medline and Cochrane Library, with no date restrictions (date of last search December 2014). Study quality and risk of bias were assessed in accordance with the *Scottish Intercollegiate Guidelines Network*. All stages were independently undertaken by reviewer pairs and consensus was reached after discussion for any discrepancy. A

narrative synthesis of results was undertaken.

Results: 16,664 unique studies were identified. After screening by journal, title and abstract, 47 full-text articles were assessed for eligibility, with eight included in the final synthesis. Of these, two were in the workplace, three focused on older adults, and one consisted of individuals with lower-extremity OA. Study duration ranged from 2 to 18 months and employed diverse PA outcome measures, including self-report questionnaires and/or objective markers (e.g., accelerometry). PA interventions included website, mail, in-person counselling, and exercise training sessions. Booster components included mail, email, telephone counselling calls. No identified studies reported significant differences between PA levels between booster and non-booster groups at long-term follow-up. Issues of low sample size/power and sources of bias found in quality assessment suggest definitive conclusions cannot be made.

Conclusion: A limited number of studies have compared boosters to a control group after a cohort has received the same PA intervention. There is a particular paucity of research focused on those with RMD and what is available is heterogeneous and of questionable quality. Evidence strongly supports PA as beneficial to those with RMD, however further research is required to elucidate the role of boosters in the role of supporting long-term maintenance. Attention should be given to the development and rigorous testing of boosters following intervention to support long-term maintenance of PA in RMD populations for sustained health and symptom benefit.

A Comprehensive Method for Using Sensewear MiniTM Monitors to Explore Differences in Ambulatory Activities in People Living with and without Early Rheumatoid Arthritis: Moving Beyond Measuring Total Steps

Lynne Feehan[1,2,3], Jake McIvor[4], Ju Young Yoo[3] and Linda Li[3,5], [1]University of British Columbia, Vancouver, BC, Canada, [2]Rehabilitation Program, Fraser Health Authority, Surrey, BC, Canada, [3]Arthritis Research Canada, Richmond, BC, Canada, [4]Consultant, Arthritis Research Canada, Richmond, BC, Canada, [5]Physical Therapy, University of British Columbia, Vancouver, BC, Canada

First publication: September 29, 2015

SESSION INFORMATION
Session Date: Wednesday, November 11, 2015
Session Title: ARHP V: Physical Activity
Session Type: ARHP Concurrent Abstract Session
Session Time: 9:00AM-10:30AM

Background/Purpose: Measures of daily steps does not allow for examination of how steps are accumulated from different type or intensity of ambulatory activity, which is important information for designing physical activity interventions to support people living with arthritis to be more physically active. Our study aimed to: 1) introduce an approach for more comprehensive evaluation of ambulatory activities using Sensewear Mini ^{TM} (SW) monitor data, and 2) demonstrate how this analytical approach could be used to explore differences in intensity of ambulation across 1-year in people living with and without early rheumatoid arthritis (RA).

Methods: RA participants had a physician diagnosis of RA within the last year and were matched with age and gender peers living without RA. All participants wore the SW monitor for 7-days at baseline and 12 months later. Off body and non-ambulatory minutes are excluded to allow for evaluation of minutes of ambulatory activity, including: 1) daily ambulation, 2) intensity of ambulation, 3) type of ambulation, and 4) time of ambulation (Figure 1). To demonstrate how this analytical approach could be used we explored difference in daily ambulation and intensity of ambulation with Paired T-tests at baseline and 12 month follow up.

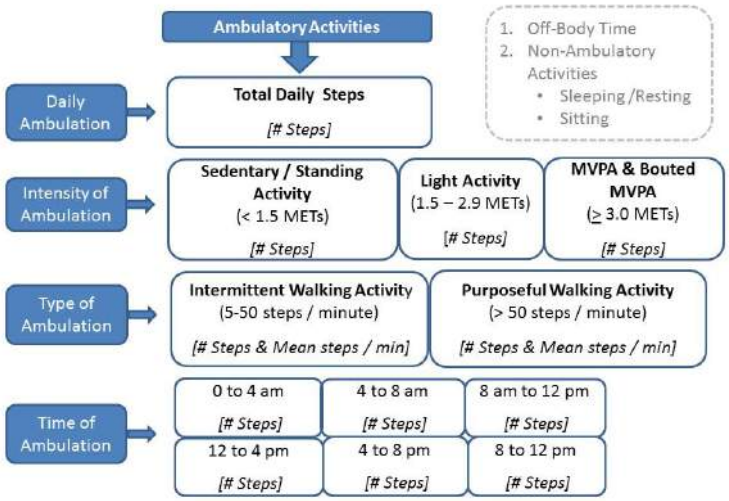

Figure 1: Ambulatory Activity Evaluation Framework (SenseWearMini™ Monitor)

Results: At baseline RA participants [n=27, Age: mean 53 y (21-73 y). Female: 22] acquired significantly fewer total daily steps than their peers (n=27). However, when examined across intensity of activity RA participants actually had markedly more steps acquired from sedentary and light ambulatory activity and significantly fewer steps from moderate to vigorous intensity ambulatory activity. One year later differences in total daily steps between RA and Non-RA participants (n=46, 23 pairs) was no longer significant. However, when examined across intensity of activity similar trends for differences in ambulatory activity seen at baseline remained (e.g. RA more sedentary / light vs less MVPA steps), with the most notable difference being RA acquiring significantly more steps from light intensity ambulatory activity (Table 1).

Table 1: Summary of Selected Comparisons of Ambulatory Activity (Paired T-Test, two tailed) in People Living With and Without Early Rheumatoid Arthritis (RA) [Baseline and 12-month follow up]

Ambulatory Activity Examined	Non-RA [Mean (SEM)]	RA [Mean (SEM)]	* Difference (Non-RA-RA). [Mean (SEM)]	P value
Selected Ambulatory Activity Comparison: (n=54, 27 Pairs) - Baseline				
Total Daily Steps (#)	9819 (744.9)	6855 (598.2)	2964 (893.5)	<0.001
Sedentary - Standing Steps (#)	741 (88.7)	1186 (185.1)	- 445 (230.5)	0.07
Light – Steps (#)	2441 (137.5)	3073 (312.4)	-632 (358.0)	0.09
MVPA 3+ METs – Steps (#)	6581 (783.0)	2509 (437.5)	4072 (891.5)	<0.001
MVPA 3+ METs Bouted (>=10 min,±2) – Steps (#)	5540 (737.9)	1805 (399.3)	3735 (826.7)	<0.001
Selected Ambulatory Activity Comparison: (n=46, 23 Pairs) – 12 Month Follow-up				
Total Daily Steps (#)	8716 (698.4)	8075 (794.7)	641 (1039.2)	0.54
Sedentary - Standing Steps (#)	833 (119.1)	1080 (170.9)	-247 (213.0)	0.26
Light – Steps (#)	2313 (131.2)	3511 (400.1)	-1198 (428.6)	0.01
MVPA 3+ METs – Steps (#)	5444 (723.1)	3592 (729.3)	1852 (1030.0)	0.09
MVPA 3+ METs Bouted (>=10 min,±2) – Steps (#)	4607 (672.3)	2633 (683.5)	1974 (939.9)	0.05

* Negative value indicates Non-RA less than RA. No correction for multiple comparisons

Conclusion: A more comprehensive evaluation of ambulatory activities allows for examination of differences (or change) in ambulatory activities that would not otherwise be detected with measures of total daily steps. Moving beyond measuring daily steps to evaluations of intensity, type and timing of ambulatory activities can inform clinical and research initiatives aimed at supporting individuals living with arthritis to move more and sit less.

A Randomized Controlled Trial for a Physical Activity Intervention for RA Fatigue

Patricia P. Katz[1], Mary Margaretten[2], Steven Gregorich[1], Sandi Kaplan[3], Stephanie Rush[4] and Laura Trupin[1], [1]Medicine, University of California San Francisco, San Francisco, CA, [2]Medicine, University of California, San Francisco, San Francisco, CA, [3]Arthritis Research Group, University of California, San Francisco, CA, [4]University of California, San Francisco, San Francisco, CA
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Wednesday, November 11, 2015
Session Title: ARHP V: Physical Activity
Session Type: ARHP Concurrent Abstract Session
Session Time: 9:00AM-10:30AM

Background/Purpose: Fatigue is a major problem for people with RA. Physical inactivity is an indirect risk factor for fatigue[1]. We tested the effect of a simple pedometer-based physical activity intervention to reduce fatigue in people with RA.

Methods: Individuals with rheumatologist-diagnosed RA were recruited from previous studies or rheumatology clinics. Eligibility criteria were: English- or Spanish-speaking, able to walk, able to return for study visits, at least moderate level of fatigue, and not currently engaged in regular exercise. Eligible individuals completed baseline questionnaires and received activity-monitoring devices for a one-week baseline step count. After one week, subjects returned and were randomized into one of three groups: (1) Education only (control), (2) Pedometer and step diary, or (3) Pedometer, step diary, and step targets. Step targets were based on the baseline step counts with the goal of increasing steps by 10% every two weeks. Groups 2 and 3 received phone calls every two weeks to collect step diary information and, for Group 3, to assign new step targets. Follow-up assessments were made at Week 10 (by phone) and Week 21 (in person). The primary outcome was fatigue measured with the PROMIS Fatigue short-form. Changes in the number of steps and in fatigue were tested within each group using paired t-tests and across groups with linear regression using Group 1 (education only) as the reference group.

Results: 359 individuals were approached to participate; 91 refused before screening, 150 were ineligible, and 22 were eligible but refused, leaving 96 participants. Mean ±SD age of participants was 54 ±13 years, 88% were female, and 21% were Spanish-speaking. Mean RA duration was 14 ±13 years. At baseline, mean RA Disease Activity Index (RADAI) was 4.1 ±1.9, mean HAQ was 1.34 ± 0.65, 59% were currently using glucocorticoids, and 60% were currently receiving biologics. Overall, the median of the average number of daily steps at baseline was 3710 (<5000 is considered “sedentary”) and mean fatigue score was 59.0 ±6.9. At 21 weeks, both intervention groups had significant increases in mean daily steps compared to the control group ($p<.05$; table). Only Group 3 achieved a significant increase in steps as a proportion of baseline. Both intervention groups had significant and meaningful decreases in fatigue ($p<.05$, table). Across all groups, decreases in fatigue were correlated with the percentage increase in average daily steps ($r = -0.37$, $p = .005$).

Conclusion: A low-resource, pedometer-based physical activity intervention yielded significant increases in physical activity and significant decreases in fatigue among individuals with RA. Results suggest that increasing physical activity by prescribing a pedometer can be effective for reducing fatigue, particularly among individuals with very low activity levels initially.

Session Date: Wednesday, November 11, 2015

Session Title: ARHP V: Physical Activity

Session Type: ARHP Concurrent Abstract Session

Session Time: 9:00AM-10:30AM

Background/Purpose: *Walk with Ease* (*WWE*) is the Arthritis Foundation's (AF) 6-week evidence-based walking program for adults with arthritis that can be offered in 2 formats: 1) a group led by a trained instructor; 2) or self-directed using only the workbook. Both formats have been shown to improve physical function, pain, stiffness, fatigue and self-efficacy in non-Hispanic (NH) white and black individuals with arthritis. The AF translated and modified the workbook for Hispanics, *Camine con Gusto* (*CCG*). The purpose of this study was to examine

feasibility (recruitment), tolerability (retention, adherence), safety (adverse events), acceptability (satisfaction), and efficacy (effect sizes [ES]) of the self-directed version of *CCG*.

Methods: A simple pre and post 6-week evaluation with no usual care comparison group was conducted in 285 Hispanics in North Carolina (NC). Self-reported outcomes including symptoms (pain, stiffness, and fatigue visual analog scales [VAS]), performance of activities of daily living (HAQ), perceived helplessness (RAI), and self-efficacy in arthritis management (ASE) were evaluated. Means and effect sizes (ES) with 95% confidence intervals were computed for changes in symptoms between baseline and 6 weeks, adjusted for gender, age, education, body mass index (BMI), comorbidities, and baseline outcome. Multiple imputation was carried out for covariates due to a large amount of missing data for BMI (22%).

Results: The mean age of the participants was 46.9 years, 44% had less than a high school degree, 2% were born in the USA, 60.1% spoke only Spanish, 74.7% were female, 44.6% had a BMI ≥ 30. Feasibility was demonstrated by recruitment and retention of 255 (84% completed 6 week questionnaires) participants, safety established with no adverse events, acceptability with 98% of participants reporting program satisfaction, and promise with moderate ES of 0.50 for pain, 0.75 for fatigue, 0.49 for stiffness, 0.33 for the HAQ, 0.26 for RAI, and 0.24 for ASE (see Table). Efficacy was greatest for individuals who reported walking at least 5 days per week (data not shown).

Conclusion: The self-directed CCG showed promise of self-reported outcomes in Hispanics comparable to those noted in NH white and black individuals with self-reported arthritis.

Table 1. *CCG* baseline characteristics of participants who completed the 6-week follow-up*

SESSION INFORMATION
Session Date: Wednesday, November 11, 2015
Session Title: ARHP V: Physical Activity
Session Type: ARHP Concurrent Abstract Session
Session Time: 9:00AM-10:30AM

Background/Purpose: The purpose of this study was to examine factors associated with physical activity (PA) in children with JIA. PA is important for the physical, psychological and social development of all children. In children with JIA, PA can also improve disease sequelae, yet previous literature has reported that this population has lower PA levels than their healthy peers. There is little research regarding what keeps children with JIA from being active outside of disease-related physical impairments, such as pain and stiffness. There is a large body of research on healthy children that supports a biopsychosocial analysis of PA and suggests the importance of physical, psychological and social factors. The present study examined the relationship between PA in children with JIA and three modifiable factors—gross motor proficiency (GMP), perceived physical competence and parent-perceived physical competence of the child—which were derived from a biopsychosocial model reported in the literature on healthy children.

Methods: This cross-sectional study sampled 40 children with JIA between 8-12 years old. Demographic and clinical variables were collected through self-reports. GMP was collected using the Bruininks-Oseretsky Test of Motor Proficiency, 2nd edition. The results were compared to a normative sample using a one-sample t-test. The revised 38-question Child Health Assessment Questionnaire was used as a measure of perceived physical competence using a self-report for the child and a proxy-report for the parent. PA level was collected using the Intensity Score of the Children's Assessment of Participation and Enjoyment. Spearman's rho correlations examined associations between variables and logistic regression examined the associations of the independent variables with PA level. The relationships of weight percentile, pain level and disease duration with PA in the sample were examined for use as covariates.

Results: The study subjects had significantly impaired GMP compared to a normative sample ($p<0.001$). Of the three independent variables, only GMP was associated with PA levels in the sample ($p=0.01$). GMP was also related to the parent's perception of the child's physical competence ($p=0.04$), but not related to the child's self-perceived competence. The perception of physical competence of the parent and the child were related to each other ($p=0.001$), but significantly different ($p=0.04$). Weight percentile, disease duration and pain level were not associated with PA.

Conclusion: This study found GMP was both significantly impaired as well as strongly associated with PA levels. These findings may have developmental and safety implications in this population. Although the perception of physical competence of the parent and the child were not directly related to the outcome, significant associations among the independent variables suggest that they may still influence PA in this population. Future researchers should continue to build upon these results and explore what other variables may influence PA in children with JIA using a biopsychosocial approach, which may be different from what affects the healthy population.

Does Loss of a Community Walking Speed Lead to More Symptoms of Depression in Knee OA? a Trajectory Analysis from the Osteoarthritis Initiative

Daniel White[1], Tuhina Neogi[2], Yuqing Zhang[3], Jingbo Niu[4] and Patricia P. Katz[5], [1]Department of Physical Therapy, University of Delaware, Newark, DE, [2]Clinical Epidemiology, BUSM, Boston, MA, [3]BUSM, Boston, MA, [4]Clinical Epidemiology Research and Training Unit, Boston University School of Medicine, Boston, MA, [5]Rheumatology, UCSF, SF, CA
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Wednesday, November 11, 2015
Session Title: ARHP V: Physical Activity
Session Type: ARHP Concurrent Abstract Session
Session Time: 9:00AM-10:30AM

Background/Purpose: Knee osteoarthritis (OA) is a well-known risk factor for major depression. While major limitations, e.g., inability to walk, are thought to mediate this relationship, it is not known to what extent minor limitations, i.e., not walking at a community speed, may

contribute to depressive symptoms. The purpose of this study was to investigate the association of minor and major limitations in walking speed with trajectories of depressive symptoms among people with or at high risk of knee OA.

Methods: We utilized data from the Osteoarthritis Initiative (OAI) to describe trajectories of depressive symptoms over 84-months. Depressive symptoms were measured annually with the Center for Epidemiologic Studies Depression Scale (CES-D) which ranges from 0 to 60, with higher scores representing more depressive symptoms. We included only participants with CES-D < 16, which represents those without major depression. Gait speed was measured from the 20-meter walk test at baseline. We categorized 'No limitation' as ≥ 1.2 meters/second (m/s) which represents the minimum time needed to walk across a timed crosswalk, i.e., a community walking speed; 'Minor limitation' as < 1.2 m/s and ≥ 1.0 m/s; and 'Major limitation' as < 1.0 m/s which is associated with persistent functional limitation, hospitalization, and death. To describe trajectories of depressive symptoms, we used a group-based method (PROC TRAJ) to agnostically identify homogeneous clusters of developmental trajectories in OAI. We then examined the relation of gait speed categories with depressive symptom trajectories using multinomial logistic regression adjusting for age, sex, BMI, race, education, radiographic knee OA, and intensity of knee pain.

Results: From the 3801 participants included (age 61.4 ± 9.1, BMI 28.4 ± 4.7, 57.5% women, 64% college degree), we identified five depressive symptom trajectories. The first three trajectories were stable over time and had baseline values < 6, on average, and included 74% of the sample. The 4th and 5th trajectories had worsening scores, increasing 0.4 and 1.0 points/year on the CES-D and included 19% and 7% of the sample, respectively. Study participants with minor limitation had 1.7 and 1.9 times the adjusted risk of being in the 4th and 5th trajectory groups, respectively. Compared with those without limitation, those with major limitation had 2.7 and 3.6 times the adjusted risk of being in the 4th and 5th trajectory groups, respectively. (Table)

Conclusion: Loss of the ability to walk a community speed appears to signal risk for worsening worsening depressive symptoms over time in people with or at high risk of knee OA. Maintaining walking speeds adequate to cross the street safely in the community may be important to consider in order to maintain psychological well-being among people with knee OA.

Association of gait speed with depressive symptoms trajectory groups among those with with CES-D < 16 at baseline. Adjusted* Odds Ratio (OR) and 95% Confidence Interval (CI). Gait speed was categorized as no limitation >1.2 m/s; minor limitation 1.0 m/s to 1.2 m/s; and major limitation < 1.0 m/s.

Trajectory Group (n=3810)	No limitation[%]	Minor limitation[%]	Major limitation[%]	Adjusted* OR [95% CI] Minor vs No limitation	Major vs No limitation
1: 17%	84.6	13.2	2.2	1.0 Ref	1.0 Ref
2: 30%	78.1	17.9	4.1	1.3 [1.0, 1.7]	1.6 [0.8, 2.9]

Session Date: Wednesday, November 11, 2015
Session Title: Pain: Clinical Aspects
Session Type: ACR Concurrent Abstract Session
Session Time: 11:00AM-12:30PM

Background/Purpose:

Chronic pain is common in RA and considered as the major disease burden from the patients' perspective. Earlier data suggest that omega-3 fatty acids, vitamin D and vitamin C are anti-inflammatory and can decrease disease activity in RA. Also, excessive intake of omega-6 fatty acids has been linked with inflammation. However, little is known how these dietary factors may affect pain in RA. Our aim was to study the association between diet and pain, in spite of inflammation, after three months of MTX treatment in early RA patients.

Methods:

We included newly diagnosed RA patients with MTX monotherapy from Epidemiological Investigation of Rheumatoid Arthritis (EIRA) linked to clinical data in the Swedish Rheumatology Quality register (SRQ). Dietary data based on food frequency questionnaires were linked with data on pain after three months of MTX treatment. Pain in spite of inflammatory control (remaining pain) was defined based on the patient acceptance of symptoms scale (PASS) (1) together with low systemic inflammation (VAS>40 + CRP<10) at the three months follow-up. Associations between dietary nutrient intake and remaining pain were analyzed with logistic regression, adjusted for age, sex and BMI.

Results:

This study included 628 RA patients. 70.1% were females and the median age was 55 years. 68.0% were ACPA positive. Mean values for clinical measures: DAS28 5.1, VAS pain 53.8 and HAQ 1.0. All patients received MTX monotherapy and the mean BMI was 25.8 kg/m^2.

After three months of MTX treatment, 103 patients (16.4%) had remaining pain. Higher intake of omega-3, vitamin D and vitamin C were inversely associated with remaining pain (OR=0.4[95% CI: 0.2-0.7], OR=0.5[95% CI: 0.3-0.8] and OR=0.5[95% CI: 0.3-0.9], respectively), whereas a higher omega-6:3 ratio was associated with increased risk of remaining pain (OR=2.7[95% CI: 1.6-4.7]). Adjustment for ACPA status did not change the ORs markedly.

Conclusion:

Intake of anti-inflammatory fatty acids and antioxidants are known to affect disease activity, and here we show that also pain may be affected, regardless of inflammation. Our findings reflect an inverse association between increased intake of omega-3, vitamin D and vitamin C, respectively and remaining pain. In addition, higher omega-6:3 ratio was found to associate with increased pain. These effects were independent of inflammation. Altogether, our data indicate that omega-3, vitamin D and vitamin C may dampen the development of chronic pain in early RA.

SESSION INFORMATION
Session Date: Wednesday, November 11, 2015
Session Title: Pain: Clinical Aspects
Session Type: ACR Concurrent Abstract Session

Session Time: 11:00AM-12:30PM

Background/Purpose: Joint pain is common in older adults; typically multiple joints are involved. Obesity is an important risk factor in pathogenesis of multi-site joint pain (MSJP). Potential mechanisms include increased physical loading and systemic inflammation, but may also include genetic factors. However, whether the effects of fat mass on pain are related to loading or to systemic inflammation is unclear. There may also be other underlying mechanisms involved in the association between obesity and pain. Therefore, this study aimed to determine longitudinal associations between fat mass and MSJP; and to determine genetic correlation between heritability of body mass index (BMI) and knee pain.

Methods: Longitudinal population-based Tasmanian Older Adult Cohort study of older adults (n=1099). Presence of pain (yes/no) at the neck, back, hands, shoulders, hips, knees and feet was assessed by questionnaire at baseline and after 2.6 and 5.1 years. Fat mass was assessed at baseline using dual energy x-ray absorptiometry. Longitudinal data was analysed using mixed effect models, adjusting for age, sex, physical activity, educational and occupational status, and quality of life. 748 samples typed on the exome chip yielded 266,163 single nucleotide polymorphisms (SNPs). The genetic correlation between BMI and knee pain measured by WOMAC was estimated using genome-wide complex trait analysis software.

Results: Study participants were older adults (average age 63 years; range 51 to 81 years). 58% of participants reported pain at >2 sites. Participants reporting greater number of painful sites had higher baseline fat mass and BMI. Greater fat mass was associated with greater odds of MSJP (odds ratio [OR] 1.007; 95% confidence interval [CI] 1.002, 1.011), pain in lower limbs (knee, hip and feet) (OR= 1.042 to 1.077, all P≤0.002), and hand pain (OR 1.027; 95% CI 1.000 to 1.055), after adjustment for confounders. Results were similar with BMI as the outcome. Estimates of heritability (h2) accounted for by the SNPs were 83% for BMI and 72% for knee pain. The genetic correlation between BMI and knee pain was 8% independent of age, sex and principal components (P=0.003).

Conclusion: High fat mass and high BMI independently predict MSJP, lower limb pain and hand pain, suggesting that systemic inflammatory factors are more important than loading in the pathogenesis of pain at multiple sites. Genetic correlation between BMI and knee pain support the importance of genetic factors in pain pathogenesis.

SESSION INFORMATION

Session Date: Wednesday, November 11, 2015

Session Title: Pain: Clinical Aspects

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00AM-12:30PM

Background/Purpose: Tanezumab (TNZ) significantly reduces pain and improves physical function and Patient's Global Assessment (PGA) in patients with chronic pain. From June 2010 to August 2012 the US FDA imposed a partial clinical hold on noncancer pain-related studies due to unexpected adverse events initially reported as osteonecrosis that required total joint replacement. **Methods:** Four, phase 3 placebo (PBO)-controlled clinical trials of TNZ in patients with moderate-to-severe OA of the knee or hip completed before the clinical hold were pooled to evaluate efficacy and 9 phase 3 controlled OA studies were pooled to evaluate safety. Patients received 1 to 3 injections of intravenous TNZ 2.5, 5, or 10 mg every 8 weeks, naproxen 500 mg twice daily (BID), celecoxib 100 mg BID, oxycodone controlled release 10-40 mg BID, or PBO. Efficacy was assessed using WOMAC pain and WOMAC physical function subscales and PGA of OA as co-primary endpoints; ≥30%, ≥50%, ≥70%, and ≥90% improvement on WOMAC Pain subscale were secondary endpoints. Safety assessments included adverse event documentation and physical and neurologic examinations. Patients who reported abnormal peripheral sensation and/or had clinically significant neurologic exam findings underwent neurologic consultation. Subgroup analyses were also conducted on the pooled populations. **Results:** In the overall population, TNZ 2.5-10 mg provided significant improvement in all efficacy endpoints (p≤0.05; Figure). More patients treated with TNZ 5 or 10 mg reported pain improvement ≥30%, ≥50%, ≥70%, and ≥90% (p≤0.05 for all). Substantial increases in efficacy were not noted for TNZ 10 mg over TNZ 5 mg. Incidence of adverse events in TNZ-treated patients was similar to patients receiving active comparator and increased over PBO-treated patients; rates with TNZ 5 and 10 mg were similar and elevated vs TNZ 2.5 mg. Adverse events of abnormal peripheral sensation were reported more frequently by patients receiving TNZ vs PBO or active comparator. Most TNZ-treated patients whose final neurologic consultations were categorized as having a new or worsening peripheral neuropathy based on clinically significant signs or

diagnostic tests were diagnosed with some form of mononeuropathy, predominantly carpal tunnel syndrome or radiculopathy; few patients were diagnosed with a polyneuropathy. TNZ 10 mg but not 2.5 or 5 mg was associated with a higher rate of rapidly progressive OA than active comparator. **Conclusion:** TNZ provides significant improvement of pain, physical function, and PGA of OA. Non-joint-related safety was similar in patients treated with TNZ 2.5-10 mg versus active comparator but increased versus PBO-treated patients.

Figure. Changes in the primary endpoints for the overall population in 4 pooled studies.

Session Date: Wednesday, November 11, 2015
Session Title: Pain: Clinical Aspects
Session Type: ACR Concurrent Abstract Session
Session Time: 11:00AM-12:30PM

Background/Purpose: Pain sensitization is associated with pain severity in knee osteoarthritis (OA), but its cause in humans is not well-understood. We recently demonstrated that local inflammation at the joint could lead to pain sensitization. Whether inflammation systemically could do the same is not known, and data from animal models are sparse. Knee OA, considered to be a state of potentially low-grade inflammation, is also associated with obesity, which itself can contribute to systemic inflammation through elaboration of adipokines such as leptin and adiponectin, which are expected to have opposite effects to one another. We therefore evaluated whether systemically measured inflammatory cytokines and/or adipokines may be related to pain sensitization in knee OA.

Methods: Participants from the Multicenter Osteoarthritis (MOST) Study, a NIH-funded longitudinal prospective cohort of persons with or at risk of knee OA, had plasma stored and standardized pressure pain threshold (PPT) at the wrist and patellae assessed at the 60-month visit. PPT was assessed with an algometer (1 cm^2 tip, 0.5 Kg/sec) as the point at which the subject felt the pressure change to slight pain. Lower PPT indicates more sensitivity. We measured TNF-α (Linco multiplex), leptin and total adiponectin (R&D ELISA for both) from a random sample of participants who were free of knee replacement. We evaluated the sex-specific cross-sectional relation of each inflammatory marker to PPT using linear regression (PPT was normally distributed) with GEE to adjust for correlations between two knees within a person, adjusting for relevant potential confounders (age, race, BMI, pain medications, depressive symptoms, radiographic knee OA (ROA) in either knee). We repeated analyses stratified by ROA status.

Results: There were 750 subjects randomly selected from the 60-month MOST study visit among those who had bilateral native knees (mean age (SD) 66.8 (7.6), mean BMI 30.3 (5.8), 58% female, 44.8% knees with radiographic knee OA). Plasma levels of TNF-α were not associated with PPT at either site (**Table**). Leptin and total adiponectin were both associated with lower PPT at the patella (more sensitized), while there was no association at the wrist. The results were similar among those with and without ROA.

Conclusion: Although a general marker of systemic inflammation (TNF-α) does not appear to be associated with pain sensitization, adipokines

may be associated with increased pain sensitization and/or sensitivity at the knee. While we expected adiponectin to have an association opposite to that of leptin, total adiponectin may not be an accurate reflection of adiponectin's biologically active form. Nonetheless, the finding of similar effects of these two adipokines on pain sensitization requires further study.

Table: Relation of inflammatory markers to PPT				
Inflammatory Marker	PPT: Adjusted standardized beta (95% CI)			
	Men		Women	
	Patella	Wrist	Patella	Wrist
TNF-α	-0.02 (-0.16, 0.11)	-0.05 (-0.20, 0.10)	-0.14 (-0.31, 0.02)	-0.14 (-0.29, 0.01)
Leptin	-0.76 (-1.14, -0.39)	-0.21 (-0.62, 0.20)	-0.21 (-0.38, -0.05)	-0.01 (-0.16, 0.14)
Total Adiponectin	-0.32 (-0.56, -0.09)	-0.06 (-0.31, 0.19)	-0.14 (-0.27, -0.01)	-0.05 (-0.17, 0.07)

The Relation of Massive Weight Loss to Changes in Knee Pain and Sensitization

Joshua Stefanik[1,2], David T. Felson[3], Jingbo Niu[3], Anyu Hu[4], Caroline Apovian[5], Michael P. Lavalley[6] and Tuhina Neogi[7], [1]Northeastern University, Boston, MA, [2]Clinical Epidemiology, Boston University, Boston, MA, [3]Clinical Epidemiology Research and Training Unit, Boston University School of Medicine, Boston, MA, [4]Clinical Epidemiology Research Unit, Boston University School of Medicine, Boston, MA, [5]Boston University School of Medicine, Boston, MA, [6]Biostatistics, Boston University School of Public Health, Boston, MA, [7]Clinical Epidemiology, Boston University School of Medicine, Boston, MA

SESSION INFORMATION

Session Date: Wednesday, November 11, 2015

Session Title: Pain: Clinical Aspects

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00AM-12:30PM

Background/Purpose: Individuals with chronic knee pain often develop central and/or peripheral sensitization (altered pain processing of the nervous system). Whether improvements in knee pain are accompanied by resolution of pain sensitization is not clear. For example, obesity is related to knee pain, and musculoskeletal pain improves after massive weight loss. As obesity is also associated with systemic low-grade inflammation, which itself may contribute to pain sensitization, weight loss may theoretically lead to a reduction in pain sensitization. However, whether this actually occurs is not known. We sought to determine if knee pain and sensitization improve after massive weight loss in individuals undergoing bariatric surgery.

Methods: Individuals for the current study were part of the Osteoarthritis Before and After Bariatric Surgery (OABS) Study. Individuals aged 25-60 were included if they had BMI ≥35, knee pain on most days of the month and were approved for bariatric surgery (laparoscopic gastric bypass surgery or laparoscopic sleeve gastrectomy). Subjects had knee pain assessed at baseline and one year later in the knee that was more painful at baseline (index knee) using the WOMAC (0-20; 0=no pain) and VAS (0-100; 0=no pain). A pressure algometer applied at 0.5kg/s was used to assess pressure pain threshold (PPT) at the index patella (indicator of peripheral and/or central sensitization) and the right wrist (indicator of central sensitization) as the point at which the pressure first changed to slight pain. Three PPT trials at each anatomical site were averaged. Higher PPTs represent less sensitization or decreased pain sensitivity. To determine the mean change in measures of pain and pain sensitization before and after surgery, we performed a paired t-test.

Results: To date 23 individuals completed baseline and follow-up visits (mean (SD) age 45.7 (8.2), mean BMI 41.6 (3.4), 86% female). The

mean (SD) weight loss was 31.1 (10.3) kilograms (% weight loss 28.1). There were significant mean improvements after surgery for all pain and sensitization measures (see Table).

Conclusion: Similar to previous findings, we found a reduction in knee pain severity after weight loss. For the first time, we report that persons who had bariatric surgery and experienced a major reduction in weight experienced a reduction in pain sensitivity, as evidenced by significant improvements in PPT.

Table. Mean difference in measures of knee pain and sensitization (post-pre) surgery

Outcome	Difference	p-value
VAS Pain	-27.8	<0.01
WOMAC Pain	-5.1	<0.01
PPT Wrist	+105.7	0.04
PPT Patella	+124.5	0.03

Session Title: Pain: Clinical Aspects

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00AM-12:30PM

Background/Purpose: Knee pain is a prominent symptom among patients with knee osteoarthritis (OA), but the impact of knee pain frequency on physical function has been understudied. The purpose of this study was to evaluate whether knee pain frequency at baseline and its trajectory over 72 months were associated with baseline-to-72-month physical function outcome.

Methods: This analysis was based on data from the Osteoarthritis Initiative (OAI). Knee pain frequency was assessed using an item from the Knee Injury and Osteoarthritis Outcome Score (KOOS). Physical function was assessed using self-report measures including the WOMAC function score and the Short Form 12 physical component scale (SF-12). Longitudinal models and mixed effects regression were used to evaluate the relationship between baseline knee pain frequency level and the trajectory of physical function, adjusting for potential body mass index (BMI), sex, and race. KOOS knee pain frequency was aggregated to the following categories: Never/Monthly, Weekly, and Daily/Always. Knee pain trajectory over 72 months was defined based on its changes over this time period as: 1) Maintain Never/Monthly knee pain (reference group); 2) Maintain Weekly knee pain; 3) Maintain Daily/Always knee pain; 4) Monotonic worsening of knee pain frequency; 5) Monotonic improvement of knee pain frequency; and 6) Fluctuating knee pain. We used a random effects model to account for the clustering of two knees within a person.

Results *:* The sample included 4,796 men and women with or at high risk of developing knee osteoarthritis. At baseline, the "Daily/Always" knee pain group had the lowest SF-12 throughout 72 months, with a mean (95% CI) ranging from 41.6 (40.6, 43.8) at baseline to 38.39 (37.4, 39.3) at 72 months; whereas, the group who maintained "Never/Monthly" had the highest SF-12 throughout 72 months, ranging from 53.2 (52.6, 53.8) at baseline to 51.7 (50.9, 52.4) at 72 months. Interestingly, in the "monotone improvement" group, the SF-12 increased significantly over time, while in all other groups SF-12 decreased significantly compared to the "maintain Never/Monthly" group ($P<0.001$). Comparing the knee pain trajectory groups that had worsening SF-12, the SF-12 for the "monotone worsening" group decreased three times more compared to the "maintain Never/Monthly", "maintain Daily/Always", and "fluctuating KP" groups. The results are similar for the knee pain trajectory groups and changes in WOMAC over 72 months.

Conclusion: These findings indicate that higher knee pain frequency at baseline is associated with worsening function over time. In addition, worsening knee pain frequency trajectory is associated worsening function over time, while improving knee pain trajectory is associated with improvement in function.

The Predictive Value of Antibodies to Cyclic Citrullinated Peptide in Two Prospective Early Rheumatoid Arthritis Cohorts 10 Years Apart

Alf Kastbom[1], Michael Ziegelasch[1], Ingrid Thyberg[1], Birgir Arge[2], Klara Martinsson[1], Olle Svernell[3], Åsa Häggström[4], Per Salomonsson[5], Britt-Marie Nyhäll-Wåhlin[6], Sören Transö[7], Claudia Jacobs[8] and Thomas Skogh[1], [1]IKE/Rheumatology, Linköping University, Linköping, Sweden, [2]Rheumatology clinic, Eskilstuna Hospital, Eskilstuna, Sweden, [3]Rheumatology Dpt, Västervik Hospital, Västervik, Sweden, [4]Rheumatology clinic, Kalmar Hospital, Kalmar, Sweden, [5]Rheumatology Clinic, Örebro University Hospital, Örebro, Sweden, [6]Department of Rheumatology, Falun Hospital, Falun, Sweden, [7]Rheumatology Clinic, Ryhov Hospital, Jönköping, Sweden, [8]Rheumatology Dept, Oskarshamn Hospital, Oskarshamn, Sweden

Session Title: Rheumatoid Arthritis - Clinical Aspects VII: Disease Activity and Updates in Measurement

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00AM-12:30PM

Background/Purpose:

Antibodies to cyclic citrullinated peptides (anti-CCP) associate with a more severe rheumatoid arthritis (RA) disease course, and therefore have influence on therapeutic decisions. By comparing two early RA cohorts enrolled 10 years apart, we wished to determine whether the predictive value of anti-CCP has changed in contemporary early RA.

Methods:

Two Swedish multicenter prospective observational early RA cohorts (denoted 'TIRA') enrolled patients with symptom duration <12 months and fulfilling either the 1987 American College of Rheumatology criteria or suffering from morning stiffness >60 min, symmetrical arthritis, and small-joint engagement. TIRA-1 enrolled patients 1996-1999, i.e. when neither anti-CCP tests nor biological therapy were used in clinical routine. TIRA-2 enrolled patients 2006-2009 using the same inclusion criteria as TIRA-1. Both cohorts were followed prospectively over 3 years. Anti-CCP tests (CCP2, EuroDiagnostica AB, Sweden) were performed on baseline serum samples. In TIRA-2, radiological damage was determined by Larsen score.

Results:

Baseline anti-CCP occurrence was similar in TIRA-1 (156/239, 65%) and TIRA-2 (303/444, 68%). In TIRA-1, follow-up disease activity measures related to inflammation (ESR, CRP, swollen joint count (SJC)) were higher among anti-CCP positive patients compared with anti-CCP negative patients (fig 1). In TIRA-2, anti-CCP positive patients had significantly lower 28-joint disease activity score (DAS28), CRP, and SJC at baseline compared with anti-CCP negative patients, while the 3-year follow-up revealed no significant differences regarding ESR, CRP or SJC (fig 1). In both cohorts, anti-CCP positive patients were treated more aggressively. In TIRA-2, baseline anti-CCP occurrence associated with more radiological damage over time ($p = 0.001$ regarding 3-year Larsen score; $p=0.006$ regarding progression). Anti-CCP remained associated with radiological progression also after adjusting for age, sex, baseline DAS28, and baseline Larsen score ($p=0.024$).

Conclusion:

Modern management of early RA attenuates the association between baseline anti-CCP status and disease activity over time, but the radiological progression remains increased. Thus, despite early aggressive therapy, anti-CCP occurrence remains predictive of erosive disease. This supports pathogenetic properties of antibodies to citrullinated proteins with regard to bone destruction, regardless of inflammatory responses reflected by swollen joints or raised CRP/ESR levels.

Session Title: Rheumatoid Arthritis - Clinical Aspects VII: Disease Activity and Updates in Measurement

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00AM-12:30PM

Background/Purpose: When diagnosed with rheumatoid arthritis (RA), patients are especially concerned by the prospect of disability. Predictors of future disability may inform early decision making. Previous studies have sought to identify such predictors, but have been limited to the evaluation of traditional biomedical measures within historical cohorts. This study aimed to evaluate both psychosocial and biomedical factors, within a contemporary RA cohort, in order to identify baseline predictors of significant disability at 1 year. Subsequently, we aimed to develop a clinically useful tool which may support early patient education and decision making.

Methods: Analysis used data from the Scottish Early Rheumatoid Arthritis (SERA) inception cohort, an ongoing prospective multicentre study which began recruitment in September 2011. A forward stepwise multivariable logistic regression model was developed. Exposures were putative psychosocial (e.g. work ability, depression, and anxiety) and biomedical (e.g. DAS28-CRP score, neutrophil count and morning stiffness) baseline predictor variables. The outcome was high functional disability (defined as a Health Assessment Questionnaire [HAQ] score >1) at 1 year. The ability of the model to correctly discriminate between patients at low and high risk of the outcome was assessed using the c-statistic. Finally, a clinical prediction score was created based on the coefficients of the predictors determined by the logistic regression model. Each score was translated into a probability of reporting a high HAQ score at 1 year. As a method of external validation, the score was tested using SERA patient data which had been newly acquired since the initial analysis.

Results: Of 578 participants (64.5% female), 80.6% (466/578) fulfilled the 2010 ACR/EULAR classification criteria and 36.7% (212) exhibited high functional disability at 1 year with a HAQ >1. Independent predictors were baseline high HAQ score (OR 2.67; 95%CI 1.98 – 3.59), depression (2.52; 1.18 – 5.37), anxiety (2.37; 1.33 – 4.21), being in paid employment with absenteeism during the last seven days (1.19; 0.63 – 2.23), not in paid employment (2.36; 1.38 – 4.03) and obesity (1.61; 1.04 – 2.50). The good discriminative performance of the model was evidenced by a c-statistic of 0.78. The clinical prediction score (Table 1) ranged from 0 – 26 and had a good discriminative performance in both the original (c-statistic 0.78) and validation data sets (c-statistic 0.78).

Conclusion: In the context of modern treatment paradigms, predictors of 1 year disability appear to be dominated by psychosocial rather than more traditional biomedical measures. Such information may aid both patients and physicians during initial management planning and alludes to the potential benefit of early non-pharmacological interventions targeting key psychosocial factors such as mental health and work disability.

Table 1 Clinical Risk Score for estimation of functional disability (HAQ-DI score >=1) at one year in RA:

Predictors	Categories and corresponding score					Score
HAQ[1]	<1	>=1	>=1.5	>=2	>=2.5	
	0	**4**	**6**	**9**	**11**	
HADS[2] depression score	Low <11	High >=11				
	0	**5**				
HADS[2] anxiety score	Low <11	High >=11				
	0	**4**				
Employment & Absenteeism	In paid employment without absenteeism during the last seven days	In paid employment with absenteeism during the last seven days	Not in paid employment			
	0	**1**	**4**			
BMI	High <25 kg/m^2	High >=25 kg/m^2				
	0	**2**				
					Total score	

[1]HAQ: Health Assessment Questionnaire. [2]HADS: Hospital anxiety and depression scale.
Score ranges between 0 and 26 points.

Brain White Matter Integrity: A Future Biomarker for Rheumatoid Arthritis Related Fatigue?

Neil Basu[1], Marayam Alsyedalhashem[2], Mariella D'Allesandro[3], Alison D. Murray[2], Daniel J. Clauw[4] and Gordon D. Waiter[2], [1]Musculoskeletal Research Collaboration (Epidemiology Group), University of Aberdeen, Aberdeen, United Kingdom, [2]Aberdeen Biomedical Imaging Centre, University of Aberdeen, Aberdeen, United Kingdom, [3]Muscloskeletal Collaboration (Epidemiology Group), University of Aberdeen, Aberdeen, United Kingdom, [4]Anesthesiology, University of Michigan, Ann Arbor, MI

SESSION INFORMATION

Session Date: Wednesday, November 11, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects VII: Disease Activity and Updates in Measurement
Session Type: ACR Concurrent Abstract Session
Session Time: 11:00AM-12:30PM

Background/Purpose: Fatigue is a major burden among patients with rheumatoid arthritis (RA). The identification of reliable biomarkers would greatly enhance research in this challenging field. Diffusion tensor magnetic resonance imaging (DTI) brain studies have previously reported fatigue specific abnormalities in the white matter integrity of patients with other autoimmune conditions. These studies were however cross-sectional and underpowered. We present the first study to evaluate brain white matter integrity in RA. We specifically aimed to evaluate the responsiveness of this putative biomarker to changing fatigue levels over time in a large sample.

Methods: Consecutive clinic attending RA patients fulfilling ACR/EULAR 2012 criteria were recruited if they reported problems with fatigue >3 months and scored >3 on the Chalder Fatigue Scale (CFS, binary scoring). All participants underwent DTI scanning on 2 occasions, 6 months apart, during which time they received standard care. At both visits they were clinically characterised. This included an evaluation of disease activity (DAS28), depressive symptoms (Hospital Anxiety & Depression Scale), pain (numerical rating scale) and sleep disturbance (Jenkin's scale).

DTI data was acquired by a 3 Tesla, 8 channel phased array head coil and presented as fractional anisotropy (FA) values, where decreased FA reflects reduced white matter structural integrity and raised FA reflects the opposite. Participants were split into 2 groups: those who reported a clinically significant improvement in their fatigue levels (2 point reduction in CFS) and those who did not. Within-group differences between the time-points were analysed using paired Tract-Based Spatial Statistics and corrected for multiple comparisons.

Results: Of the 54 participants who attended both visits (76% female, mean age 55.2 years, mean disease duration 11.35 months at baseline), 22 (40.7%) reported a clinical improvement in fatigue at 6 months (mean 2.64 point reduction in CFS) and 32 (60.3%) reported unchanged fatigue (-0.13 change in CFS). Within the fatigue improver group, statistically significantly reduced FA levels were observed at visit 2 compared to visit 1. The regions of change were diffuse, but much greater in the right hemisphere and specifically the periventricular, internal capsule, thalamus, inferior frontal and parietal areas (figure). The regions were unchanged after adjusting individually for disease activity or sleep, although became focalised following adjustment of depression or pain.

In contrast, no significant differences in FA levels were observed between visits within the fatigue non-improver group.

Conclusion: The striking disparity in white matter integrity changes between the fatigue improver and non-improver groups provides preliminary evidence to support the role of DTI as a future biomarker of RA related fatigue.

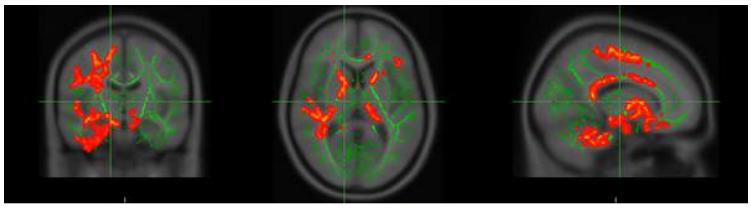

Figure: Significant differences in white matter structural integrity among fatigue improvers.

RED: Regions of the brain where FA reduced at visit 2 compared to visit 1. GREEN: Standardised skeleton of white matter tracts

Session Title: Rheumatoid Arthritis - Clinical Aspects VII: Disease Activity and Updates in Measurement

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00AM-12:30PM

Background/Purpose: In early rheumatoid arthritis (RA), it is not possible to predict response to first line DMARDs (e.g. methotrexate (MTX)) and as such treatment decisions rely primarily on clinical algorithms. The capacity to classify drug naïve patients into those that will not respond to first line DMARDs would be an invaluable tool for patient stratification. Here we report that chromosome conformational signatures (highly informative and stable epigenetic modifications that have not previously been described in RA) in blood leukocytes of early RA patients can predict non-responsiveness to MTX treatment.

Methods: Peripheral blood mononuclear cells were obtained from DMARD naïve early RA patients recruited in the Scottish early rheumatoid arthritis inception cohort. Inclusion in this study was based on diagnosis of RA (fulfilling the 2010 ACR/EULAR Criteria) with moderate to high disease activity (DAS28 $\geq$ 3.2) and subsequent monotherapy with MTX. MTX responsiveness was defined at 6 months using the following criteria: Responders - DAS28 remission (DAS28 <2.6) or a good response (DAS28 improvement of >1.2 and DAS28 $\leq$3.2). Non-responders - no improvement in DAS28 ($\leq$0.6). Initial analysis of chromosome conformational signatures (CCS) in 4 MTX responders, 4 MTX non-responders and 4 healthy controls was undertaken using an EpiSwitch™ array containing 13,322 unique probes covering 309 RA-related genetic loci. Differentiating CCS were defined by LIMMA linear modeling, subsequent binary filtering and cluster analysis. A validation cohort of 30 MTX responders and 30 non-responders were screened for the differentiating CCS using the EpiSwitch™ PCR platform. The differentiating signature was further refined using binary scores and logistical regression modeling, and the accuracy and robustness of the model determined by ROC analysis.

Results: CCS EpiSwitch™ array analysis identified 30 CCS markers with the potential to stratify early RA patients into responders and non-responders. Subsequent evaluation of this signature in our validation cohort refined this to a CCS signature that was able to discriminate responders and non-responders. Prediction modeling provided a probability score for responders and non-responders, ranging from 0.0098 to 0.99 (0 = responder, 1 = non-responder). There was a true positive rate of 92% (95% confidence interval [95% CI] 75-99%) for responders and a true negative rate of 93% (95% CI 76-99%) for non-responders. Importantly, ROC analysis to validate this stratification model demonstrated that the signature had a predictive power of sensitivity at 92% for non-responders to MTX.

Conclusion: We have identified a highly informative systemic epigenetic state in the peripheral blood of DMARD naïve early RA patients that has the power to stratify patients at the time of diagnosis. The capacity to differentiate patients *a priori* into non-responders, using a blood-based clinical test, would be an invaluable clinical tool; paving the way towards stratified medicine and justifying more aggressive treatment regimes in early RA clinics.

The Link Between DAS28 and the Short-Term Risk of Acute Coronary Syndrome in RA, and Its Driving Factors

SESSION INFORMATION

Session Date: Wednesday, November 11, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects VII: Disease Activity and Updates in Measurement
Session Type: ACR Concurrent Abstract Session
Session Time: 11:00AM-12:30PM

Background/Purpose:

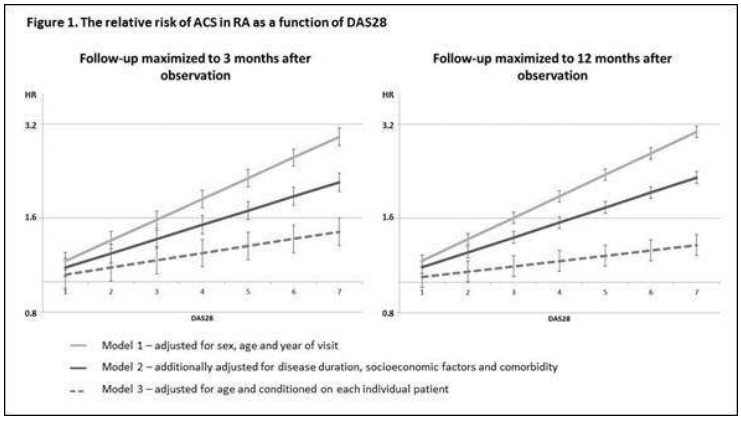
The extent to which a short-term effect of the disease activity adds to the over-risk of coronary events in patients with Rheumatoid Arthritis (RA) is largely unknown. Theoretically, inflammation might affect the vasculature in the long-term by accelerated atherosclerosis, but there have also been indications of effects on shorter-term risks. For instance, inflammatory cytokines and inflammation-driven hypercoagulability could affect the vulnerability of plaques and thrombus formation in the coronaries, i.e., processes underlying unstable ischemic heart disease and myocardial infarctions. In this study we evaluated the risk of acute coronary syndrome (ACS) shortly after disease activity assessment in a large population of patients with RA.

Methods:

We assembled all registrations, Jan 1st 2001 to Dec 31st 2012 from doctor's visits for patients with a diagnosis of RA in the Swedish Rheumatology Quality Register (SRQ). The observations were linked to the Patient Register, the Population Register, and the Cause-of-Death Register to add information on the outcome (ACS; unstable angina and myocardial infarction), vital status, emigration, comorbidity (chronic and acute ischemic heart disease, congestive heart disease, cerebrovascular disease, other atherosclerotic disease, diabetes, and/or hypertension) antedating the observation, and socioeconomic factors (educational level, unemployment, sick leave from work, disability pension). We evaluated the association between DAS28 and ACS risk in three risk windows (0 to 3, 0 to 6, 0 to 12 months after each visit, respectively), using three Cox regression models: 1) adjusted for age, sex and year of visit, 2) additionally adjusted for disease duration, comorbidity and socioeconomic factors, and 3) adjusted for age and conditioned on each individual patient, implicitly adjusting for all factors that are constant within a patient.

Results:

There were 215,135 visits (n patients=31,460, 72.0% women, mean of age at first visit 59.4 SD 14.5 years) during the study period. The crude incidence rates were 9.9 (96% CI 9.1-10.9), 10.0 (9.3-10.7), and 10.2 (9.7-10.8) per 1,000 person-years for the 3, 6 and 12 months follow-up, respectively, with 493, 836, and 1203 ACS events occurring during follow-up. Disease activity score 28-joints (DAS28) was available from 187,659 (87.2%) visits. DAS28 was associated with the risk of ACS in all risk windows in Models 1 and 2, but the association was weakened in Model 3 (Figure 1). The 12 months follow-up provided similar results (Figure 1).



Conclusion:

There is a strong link between clinical disease activity and short-term risk of ACS. Whilst useful for clinical prediction, the association is, however, only partially likely to be causal, since it was attenuated by adjustment for socioeconomic factors and comorbidities, in particular when DAS28 values were compared within each individual.

Session Title: Rheumatoid Arthritis - Clinical Aspects VII: Disease Activity and Updates in Measurement

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00AM-12:30PM

Background/Purpose: The patient rating of global rheumatoid arthritis (RA) disease activity (PtGA) is a key variable in composite measures of disease activity as well as definition of remission (REM). In multimorbid RA patients (RA-MM) the perception of RA disease activity as measured by the PtGA might be impacted by the burden of multiple diseases, leading to higher levels of PtGA. In this study, we aimed to quantify the difference in PtGA between RA-MM and RA-only patients and to determine the factors contributing to this difference.

Methods: We compared mean levels of PtGA between RA-MM and RA-only patients followed in a longitudinal RA cohort at an academic medical center. Multimorbidity was defined as having at least one chronic condition in addition to RA and assessed by the counted multimorbidity index (cMMI ³ 2) [1]. The mean difference in PtGA (ΔPtGA) between RA-MM and a cohort of RA-only patients, matched on swollen and tender joint count (SJC, TJC), evaluator global of disease activity, and disease duration, was assessed. The unique contribution of specific components to the explained variation of ΔPtGA in the matched cohort was calculated as semi-partial R^2 in linear regression models and summarized as the percentage of the total R^2.

Results: Out of a total of 1,040 RA patients, 575 (55.5%) were multimorbid; RA-MM reported higher (worse) PtGA, with a positive linear relationship between number of morbidities and PtGA (linear trend $p<0.01$). This relationship remained significant after adjusting for disease activity, age and disease duration (**Figure 1**). In the matched cohort of 294 RA-MM patients and 294 RA-only patients, the mean PtGA (in mm) was significantly higher for RA-MM (30.5±24.3) versus RA-only patients (25.6±22.9), with a mean difference of 4.9±26.7 ($p<0.01$, paired t-test). Variables contributing to this difference were fatigue (18.2% of total R^2), pain (16.8% of total R^2) and modified health assessment questionnaire (mHAQ; 8.7% of total R^2). Age, gender and level of education were not significantly contributing to the difference in PtGA between RA-MM and RA-only.

Conclusion: RA-MM patients had higher levels of PtGA compared to RA-only patients. The most relevant determinants of this difference in PtGA between RA-MM and RA-only patients are differences in fatigue and pain.

Figure 1. This figure demonstrates higher mean values of patient global of disease activity (PtGA) in groups of patients with higher number of morbidities assessed by the counted multimorbidity index (cMMI). Panel **A** shows unadjusted analyses of variance (ANOVA) testing for linear trend $p<0.001$. Panel **B** shows adjusted estimated marginal means generated by a general linear model considering all covariates set to the cohort's mean (tender joint count= 7.9; swollen joint count = 7.1; evaluator global = 32.2; Age = 56.8; Disease duration = 13.7years).

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's - Clinical Aspects and Therapeutics III

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00AM-12:30PM

Background/Purpose: Previous clinical trials have suggested that immunoablation followed by autologous hematopoietic cell transplantation (HCT) can lead to clinical improvements in systemic sclerosis (SSc). However, global gene expression studies for understanding the molecular basis of these effects were not performed. We aimed at investigating changes in the peripheral blood gene expression patterns ensuing after HCT in the randomized SCOT trial.

Methods: Global transcript studies on Illumina HT-12 arrays were performed in whole blood samples collected at pretreatment baseline and 26 months post-randomization. Sixty-two SSc patients undergoing HCT or receiving 12-month of IV cyclophosphamide (CYC) were investigated . The immune reconstitution after immunoablation is generally completed at 26-months and patients in CYC arm were off treatment for 14 months at that time point. Healthy controls (age, race and gender matched) were also studied (n=62). A false discovery rate < 5% in the multivariable analysis was utilized to identify the differentially expressed genes (DEG). Clinical correlations with long-term outcomes could not be performed as this awaits maturation of follow-up until all subjects have reached the 54 month SCOT primary endpoint.

Results: Compared to controls, the baseline SSc samples showed 3168 DEGs. In agreement with our previous studies, the top three over-represented pathways belonged to interferon (IFN) alpha (p=0.00001), IL22 soluble receptor (p=0.0009), and IFN gamma (p=0.00038) signaling pathways. Restricting the comparison (healthy controls vs. SSc) to 312 IFN inducible genes revealed 160 DEGs (51.2%). A composite score of these IFN inducible genes correlated with the baseline modified Rodnan Skin Score (r=0.28, p=0.027) while there was no significant correlation with the baseline fibrosis score on CT imaging.

Gene expression data on 36 SCOT patients were available at 26 months. In 18 HCT recipients, 2805 DEGs belonging mainly to immune pathways were identified when comparing 26-month to baseline samples. In contrast, no DEGs were detected in a similar comparison in 18 CYC recipients. Restricting the analysis to IFN inducible transcripts revealed 135 DEGs 26-months after HCT while no differentially expressed IFN inducible genes were detected in CYC group. As shown in Figure 1, HCT was associated with a significant decline in the IFN transcript sore compared to baseline (p=0.025), while there was no apparent effect on this composite score 14 months after completion of CYC (p=0.881).

Conclusion: Unique differential gene expression including a decrease in immune regulation anomalies were observed at 26 months after HCT. The IFN signature, which is the most prominent peripheral blood transcript profile, declined significantly after HCT supporting the notion this treatment has the potential of “resetting” SSc patient's immune system.

Increased Frequency of Malignancies Synchronous to the Onset of Systemic Sclerosis in Anti-RNA Polymerase III Antibodies Positive Patients: a EUSTAR Multicentre Study

Background/Purpose:

Several clinical issues have been associated with anti-RNA polymerase III (RNAP) antibodies in patients with systemic sclerosis (SSc), but most data derive from single-centre studies or relatively small positive case numbers. Recently, a temporal relationship between the onset of SSc and malignancy has been described in anti-RNAP+ patients. The analysis of the large EUSTAR cohort may provide further information on the clinical associations of this autoantibody.

Methods:

Patients from the EUSTAR database were included when the item anti-RNAP was fulfilled in at least one visit; data were collected from the last visit available.

In a second phase, 13 EUSTAR centers participated to a case-control study, fulfilling a supplementary form. Anti-RNAP-negative SSc controls were matched for sex, cutaneous subset and disease duration.

Results:

Anti-RNAP status was available in 4,986 of 11,399 patients from EUSTAR database: 223 were anti-RNAP+. After exclusion of 47 patients with multiple autoantibody positivity, 176 anti-RNAP+ patients were compared with 4,763 anti-RNAP-negative patients: multivariate analysis confirmed the association of anti-RNAP with scleroderma renal crisis (SRC) and diffuse cutaneous involvement (Table 1). A multivariate analysis was also performed to compare patients with (n=80) and without SRC (n=4697) (Table 2).

In the case-control study 158 anti-RNAP+ and 199 anti-RNAP-negative patients were collected. We found an association of anti-RNAP with SRC (p:0.0005), arterial hypertension (p:0.006), gastric antral vascular ectasia (p:0.0009), and a shorter time to reach the peak of mRSS (p:0.013, log-rank test). An increased rate of malignancies in anti-RNAP+ patients was accounted for by the increased rate of malignancies synchronous to the onset of SSc (Table 3). Moreover, an increased rate of solid tumors, in particular breast cancer synchronous to the onset of SSc was observed.

Conclusion:

Anti-RNAP antibodies are an important and not always routinely used marker in SSc. They are associated with severe clinical manifestations and cancer, with relevant prognostic implications which should guide the monitoring and follow-up of the patients.

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's - Clinical Aspects and Therapeutics III

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00AM-12:30PM

Background/Purpose:

Radiation oncologists are hesitant to treat scleroderma (SSc) patients with cancer due to concerns about triggering exaggerated fibrosis. In this study, we examined SSc patients with breast cancer to 1) identify the prevalence of radiation complications and 2) examine whether SSc and cancer outcomes differed between SSc patients who received or did not receive radiation therapy (RT) as part of their cancer treatment regimen.

Methods:

Patients with SSc and breast cancer were identified from the Johns Hopkins Scleroderma Center database. Demographics, SSc phenotypic data, cancer treatments and RT outcomes were abstracted from the database and medical record review. Among women exposed to RT, we examined whether erythema, blistering, ulceration, or thickening of the skin developed in the RT port. The following outcomes were compared between patients who did and did not receive RT: 1) changes in mRSS and FVC at 2 years post cancer diagnosis by the Student's t test and 2) percentage of patients cancer free at 1, 2 and 5 years by a chi square test.

Results:

116 female SSc patients with a breast cancer diagnosis were identified. Most patients had limited disease (65.4% vs. 34.6% diffuse) and were white (90.5%). The mean age at SSc onset and cancer diagnosis was 53.4±12.2 and 55.7±10.6 years, respectively. 43 women (37.1%) received RT as part of their cancer treatment regimen: 4/31 with available data developed erythema, 0/31 had blistering, 1/31 developed ulceration, and 16/33 had skin thickening in the RT port. There was not a statistically significant association between skin thickening in the RT port and cutaneous subtype (OR 1.89 for diffuse vs. limited, 95% CI 0.44, 7.85). 3/30 patients with available data developed pulmonary fibrosis that was restricted to the lung fields in the radiation port. While 48.5% of women treated with RT developed localized cutaneous fibrosis, patients treated with RT required less extensive surgery for their breast cancers (66% with lumpectomy in RT group vs 34% in no RT group, $p<0.001$). When comparing patients with and without exposure to RT, there were no statistically significant differences in change in mRSS (mean change 0.6 in RT group (N=5) vs. 0.26 in no RT group (N=19), $p= 0.32$) or change in FVC at 2 years (mean change 5.6% in RT group (N=6) vs. -1.8% in no RT group (N=24), $p= 0.15$). There were no statistically significant differences in the proportion of patients who were cancer free 1, 2, and 5 years post breast cancer diagnosis in patients who received RT versus those who did not. Similarly, there were no significant differences in mortality (34.3% no RT, 34.9% RT).

Conclusion:

While <50% SSc patients with breast cancer developed localized radiation induced cutaneous fibrosis, patients treated with RT were able to avoid more extensive surgery. Cutaneous subtype was not associated with the risk of developing localized radiation fibrosis. While our sample size was limited, SSc and cancer outcomes were similar between the two groups, suggesting that exposure to RT did not exacerbate SSc. These data suggest that among SSc patients with breast cancer, the decision about whether or not to proceed with RT should be an individualized decision based on patient preferences.

Session Date: Wednesday, November 11, 2015

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's - Clinical Aspects and Therapeutics III

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00AM-12:30PM

Background/Purpose:

Microangiopathy in systemic sclerosis (SSc), as visualized by nailfold videocapillaroscopy (NVC) is a dynamic and sequential process[1]. In time, NVC patterns progress from early, to active and finally late SSc pattern. A relation between improvement of NVC pattern and treatment with immunosuppressive drugs has been suggested[2,3]. We aimed to evaluate 1. change of NVC patterns in SSc patients, and 2. influence of

treatment with cyclophosphamide (CYC) and autologous hemopoetic stem cell transplantation (HSCT) on change of NVC patterns.

Methods:

NVC was performed annually in SSc patients participating in a care program. For the current analysis, patients were included if at least two NVCs were performed and qualitatively assessed (normal, borderline changes, or SSc pattern [early, active or late]). Change of NVC pattern was classified as: 1. stable (same pattern at all evaluations), 2. progressive (change from early to active/ late or from active to late) or 3. reverse transition (change from late to early/active, or from active to early) . In order to asses the association between CYC and HSCT with relative rates of transition of NVC patterns a maximum likelihood estimation in a multistate model was used, which, additionally to correction for age, gender and disease duration, corrects for time to transition in relation to drug exposure time.

Results: NVC was performed twice in n=98 patients, 3 times in n= 35 patients and 4 times in n=5 patients. Of these 138 patients, 82% was female, mean age was 51 years, and median disease duration was 3 years. At baseline 6 patients had a normal pattern, n=4 borderline changes, n=13 an early pattern, n=54 an active pattern, and n=61 a late pattern. Over time, NVC pattern was stable in 53%, progressive in 21% and 26% showed reverse transition (table 1). Treatment with HSCT was significantly associated with higher rate of reverse transition (relative transition rates [95% CI] 5.4 [1.0-28.8]). No association between CYC and rate and direction of change of NVC pattern was found.

Conclusion:

Change of NVC pattern was observed in 47% of SSc patients; 26% showed reverse transition. Rapid reverse transition was associated with treatment with HSCT but not with CYC, indicating that more aggressive immunosuppressive treatment can influence microangiopathy in SSc.

SESSION INFORMATION

Session Date: Wednesday, November 11, 2015

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's - Clinical Aspects and Therapeutics III

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00AM-12:30PM

Background/Purpose: Systemic sclerosis (SSc) has far-reaching physical consequences and impacts health-related quality of life. The Patient-Reported Outcomes Measurement Information System (PROMIS)-29 measure includes four items each for domains reflecting physical function, anxiety, depression, fatigue, sleep disturbance, pain interference, and ability to perform social roles, plus a single item on pain intensity (range 0-10). The objective was to explore associations of PROMIS-29 domains with clinical variables in subjects with SSc.

Methods: Adult SSc subjects were enrolled in the Scleroderma Patient-centered Intervention Network (SPIN) Cohort from 19 centers across Canada, the USA and the UK between July 2014 and May 2015. Baseline medical data are provided by the enrolling physician, and SPIN Cohort participants completed the PROMIS-29 at baseline. For all PROMIS-29 domains, t-tests were conducted for gender and dichotomous clinical variables. The standardized mean effect size [95% CI] was calculated to assess the magnitude of the difference between groups. Correlations and effect sizes were interpreted as small (²0.3), moderate (between 0.3 and 0.5), or large (³0.5).

Results: In total, 473 subjects were included in the analyses. Mean age was 55 years (SD=11.9) and mean time since onset of the first non-Raynaud symptom was 11.8 years (SD=8.7). Most subjects were female (n=411, 86.9%) with lcSSc (n=277, 59.1%). The PROMIS-29 domains were 0.1-0.8 SD below general population. The involvement of the gastrointestinal tract was consistently associated with worse outcomes across PROMIS-29 domains (lower scores for function and roles, higher scores for fatigue, pain interference, pain intensity, anxiety and depression), with moderate to large effect sizes in 7 of 8 domains. Other clinical variables with decrements in at least 5 domains included: more skin thickening, diffuse disease, and presence of contractures (Tables 1 and 2). **Conclusion:** SSc is associated with significant impairment in PROMIS-29 domains, with certain disease characteristics more commonly associated than others. These data inform priorities for future patient-centered research.

SESSION INFORMATION

Session Date: Wednesday, November 11, 2015

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's - Clinical Aspects and Therapeutics III

Session Type: ACR Concurrent Abstract Session

Session Time: 11:00AM-12:30PM

Background/Purpose: Hyperimmune caprine serum (HICS) administered by subcutaneous injection over 26 weeks has shown benefit for modified Rodnan skin score in diffuse systemic sclerosis (SSc) in a recent phase II placebo controlled trial[1]. We report multiplex protein analysis of serum samples from the trial to explore mechanisms of action of this novel biological agent and identify potential biomarkers in SSc.

Methods: In a parallel group placebo controlled trial patients were treated with HICS (n=10) or placebo (n=10) over 26 weeks, with a follow up open label treatment for 26 weeks. Serum samples at baseline, 6 weeks, 26 and 52 weeks were analysed using a multiplex assay for 40 cytokines and growth factors (Luminex®) and additional individual solid phase immunoassays for procollagen III N-terminal propeptide (PIIINP), serum IL-2R, cartilage oligomeric matrix protein (COMP), TGF-beta1 and von Willebrand factor (vWF). To explore patterns of change over multiple analytes heat maps were constructed using CIMminer NIH software. Clustering was performed using correlation, and Pearson coefficient and significance analysis of microarrays (SAM) correction.

Results*:* Cluster analysis defined factors that were increased or decreased from baseline after 26 weeks treatment with HICS. **Results** for key analytes are summarised in **Table 1**. Consistent with previous preclinical studies there was evidence for marked upregulation of the hypothalmo-pituitary-adrenal axis from 6 weeks after HCS treatment and this effect was maintained at 26 weeks. This was evidenced by increase in alpha-MSH and ACTH in cases treated with HICS. There were changes in markers of fibroblast biology including changes in bFGF, PIIINP and COMP. Novel findings include consistent increase in PIIINP associated with improved MRSS suggesting that this may be a marker of ECM turnover rather than fibrogenesis. Other factors that were frequently reduced, though not reaching statistical significance, included TIMP2, fractalkine and TGFbeta1 levels.

Conclusion: This study illustrates the feasibility of conducting relatively short term parallel group placebo controlled trials in established dcSSc to target skin fibrosis. The benefit of including multiplex analysis of serum proteins in early phase trials to better understand treatment mechanisms and disease biology is confirmed. This study suggests possible mechanisms of action for HICS, including upregulation of alpha-MSH, that has been shown to be antifibrotic in preclinical studies, and suggests possible serum markers to be included in future trials.

SESSION INFORMATION

Session Date: Wednesday, November 11, 2015

Session Title: ARHP VI: Physical Function and Disability

Session Type: ARHP Concurrent Abstract Session

Session Time: 11:00AM-12:30PM

Background/Purpose: Despite improved treatment, many individuals with inflammatory arthritis (IA) and osteoarthritis (OA) report difficulties working, reduced productivity and elevated absenteeism. Lacking is research on workplace policies and whether they are associated with better health and employment outcomes. This research: 1) examined the availability, need and use of diverse workplace policies, comparing those with arthritis to healthy controls; and 2) contrasted health and work outcomes of participants who reported accommodation needs were unmet to those whose needs were met or whose needs were exceeded (i.e., used more accommodations than needed).

Methods: Participants had osteoarthritis (OA) or inflammatory arthritis (IA) or no disabling health conditions. They were recruited from a

national panel of 80,000 Canadians. Invitations were sent to a sub-sample of individuals aged ≥ 50 yrs to reach a quota of 500 arthritis and 500 healthy respondents. Eligibility included current employment; absence of disabling conditions other than arthritis; and fluency in English/French. A cross-sectional survey was administered on-line or by telephone and assessed demographic (age, gender, education); health (pain, fatigue, workplace activity limitations); work context (job sector, hours, physical work); workplace practices (health benefits, flexible hours, special equipment/adaptations, modified duties, altered work schedules, work-at-home arrangements) and job outcomes (absenteeism, productivity loss, job disruptions). Descriptive statistics and analyses of variance compared groups.

Results: There was a 59% response rate to study invitations and final sample of 631 participants with arthritis (OA>70%; women=53.6%) and 538 with no disabling conditions (healthy controls, 44% women). Groups were similar in demographics, work context and availability of policies to manage work and health. Those with arthritis reported significantly poorer health (pain, fatigue, workplace activity limitations). Yet, there were few differences in their reports of needing or using workplace policies compared to healthy controls. Exceptions were that more individuals with arthritis reported needing and using modified job duties and needing special equipment/adaptations. Comparing the groups revealed similar associations of policy use and job outcomes. Healthy controls and those with arthritis who had unmet accommodation needs reported greater work stress, health variability, productivity loss and job disruptions. Unmet need in those with arthritis also was related to greater fatigue and workplace activity limitations. Respondents whose needs were exceeded had the lowest levels of fatigue, activity limitations, productivity loss and job disruptions.

Conclusion: Despite poorer health, respondents with arthritis often did not take advantage of available workplace policies. Yet using accommodations, even when not needed, was associated with better health and work outcomes. These results need to be replicated with longitudinal data. However, they point to potential benefits of more proactive use of work policies to manage arthritis and employment.

SESSION INFORMATION

Session Date: Wednesday, November 11, 2015

Session Title: ARHP VI: Physical Function and Disability

Session Type: ARHP Concurrent Abstract Session

Session Time: 11:00AM-12:30PM

Background/Purpose: There is concern that an aging workforce results in lost skills and high burden on pension programs. This has resulted in the dissolution of mandatory retirement in many countries and an expectation that older adults will work longer, including in bridge employment (retiring from a main career but continuing to work in a new job/capacity). Previous research finds that many individuals with arthritis leave employment prematurely, but information about retirement plans and sustaining work is scarce. This study examined older workers with arthritis and healthy controls in terms of: 1) retirement plans and bridge employment; and 2) factors associated with bridge employment.

Methods: Participants had osteoarthritis (OA) or inflammatory arthritis (IA) or no disabling health conditions. They were recruited from a national panel of 80,000 Canadians. Invitations were sent to a sub-sample of individuals aged ≥ 50 yrs to reach a quota of 500 arthritis and 500 healthy respondents. Eligibility included current employment; absence of disabling conditions other than arthritis; and fluency in English/French. A cross-sectional survey was administered on-line or by telephone and assessed demographic (age, gender, education); health (pain, fatigue); planned retirement age and expectations, returning to work after retirement (bridge employment) and work context (job sector, hours, physical work, self employment). Analyses of variance and logistic regression examined differences between groups and factors related to retirement.

Results: There was a 59% response rate to study invitations and final sample of 631 arthritis participants (OA >70%; women=53.6%) and 538 healthy controls (44% women) who were on average 59 yrs old. Groups were similar in many demographic and work context factors. Respondents with arthritis reported significantly poorer health (pain, fatigue, workplace activity limitations). Yet, healthy controls and respondents with arthritis were not significantly different in planned retirement age (~65 yrs) or in desiring to remain working full- or part-time after retirement (healthy FT=7.1%, PT=52.4%; arthritis FT=7.6%, PT=50.6%). Arthritis respondents were more likely to believe they might retire sooner than planned (22.1%; healthy 6.8%) and to have retired previously and returned to work (20.3%; healthy 13.0%). Health factors (pain, fatigue, co-morbidities, workplace activity limitations) were significantly associated with expectations of retiring sooner than planned.

Healthy controls working in bridge employment were more likely to be self-employed and working for smaller organizations (<50 people); arthritis respondents were more likely to be in contract or part-time work and to report financial need as a reason for bridge employment.

Conclusion: Previous research has focused on giving up work among those with arthritis. This study highlights that many with arthritis return to bridge employment after retiring and have similar expectations and plans as their healthy counterparts. Research is needed examining types of work that might sustain the employment of those with arthritis.

SESSION INFORMATION

Session Date: Wednesday, November 11, 2015

Session Title: ARHP VI: Physical Function and Disability

Session Type: ARHP Concurrent Abstract Session

Session Time: 11:00AM-12:30PM

Background/Purpose: Pain intensity has been shown to be important in understanding pain related functional disability in adolescents. Additional factors may affect other critical outcomes including functional disability and quality of life. Findings from adult-based studies indicate that contextual factors (e.g. demographics and other patient centered characteristics) may contribute to functional disability beyond that of pain intensity but are less documented in pediatric populations. The purpose of this study was to describe pain distribution and characteristics in adolescents with chronic pain and to explore predictors of functional disability.

Methods: Data were collected from electronic medical records review in a consecutive series of 314 new pediatric pain patients in an academic pain clinic. Available variables included demographics, pain intensity, location, history and frequency, child optimism, anxiety and depression, and the Children's Activity Limitations Interview (CALI) a 21-item measure designed to assess pain-related activity limitations and is a proxy for functional disability in children and adolescents.

Results: The mean (±SD) age at presentation was 15.9±3.27. Participants reported high levels of pain with a typical pain intensity of 5.82 ± 1.98 and worst pain intensity of 8.95 ± 1.33. 42.3% of participants reported experiencing pain in three or greater locations. The most commonly reported pain location included the head (28.5%), abdomen (23.4%), leg (13.6%) and lower back (11.2%) with 78.5% of participants reported experiencing pain at least daily within the last month. 87.6% of participants reported difficulty sleeping related to their pain. The CALI sum scores had a mean of 43.86 ± 17.89. Child/adolescent perception of their ability to cope or deal with their pain was a mean of 4.86. Regression analysis conducted with CALI as independent variable. Stage 1, pain characteristics, contributed significantly to the model and accounted for 18.3% of variance in functional disability. Stage 2, psychological function, explained an additional 10% of variation in functional disability. Stage 3, physical variables, accounted for an additional 3.2% of variance. Stage 4, sleep problems, explained an additional 1.5% of the variance in functional disability. Significant predictors of functional disability included "worst" pain intensity levels, depressive symptoms, physical activity and sleep problems. Together, all independent variables accounted for 32.8% of the variance in functional disability.

Conclusion: In line with previous research, pain characteristics were found to be a significant predictor of functional disability. Novel factors (depressive symptoms, engagement in physical activity and sleep problems) also significantly predicted functional disability after controlling for pain characteristics. Understanding a more comprehensive set of variables that contribute to adolescents' functional disability is an important step in tailoring interventions in adolescents with chronic pain.

Session Title: ARHP VI: Physical Function and Disability

Session Type: ARHP Concurrent Abstract Session

Session Time: 11:00AM-12:30PM

Background/Purpose: People with rheumatoid arthritis (RA) have an increased risk of falls. The consequences of falls include loss of confidence and independence, injury and death. The foot is a common site of pathology in RA and foot problems are reported in up to 90% of people with established disease. Previous studies in non-RA populations have identified that foot and ankle problems are associated with falls in older adults. The aim of this prospective observational study was to determine whether foot and ankle characteristics are associated with falls in people with RA.

Methods: Adults with RA according to the 2010 ACR/EULAR classification criteria were recruited from rheumatology outpatient clinics. RA characteristics, common fall risk factors, and foot and ankle variables were measured at baseline. Foot and ankle measures included deformity, joint swelling and tenderness, sensation, muscle strength, range of motion, gait speed, plantar pressures, postural stability, foot pain and self-reported foot impairment. Participants were then followed for 12 months, to record the occurrence of falls, using monthly falls calendars and telephone calls. The Prevention of Falls Network Europe (ProFaNE) definition of, "an event that results in a person coming to rest unintentionally on the ground or other lower level", was used to identify falls. Univariate parametric and non-parametric analysis compared fallers and non-fallers on all baseline variables to determine significant differences. Logistic regression analysis identified baseline variables which were independent predictors of falls over the 12 month period.

Results: Two hundred and one participants completed the baseline assessment and 196 (98%) completed follow-up to 12 months. Eighty-four (42%) participants fell at least once and 39 (19%) experienced multiple (>1) falls over the 12 month follow-up period. Significant baseline factors associated with falls in univariate analysis are presented in Table 1. Fallers had significantly higher tender joint count, took more medications, were more likely to take psychotropic medication or use an assistive device. Fallers also had increased postural sway with eyes closed, were more likely to have tender joints in the feet or ankles and a 12-month history of falls. In logistic regression analysis, including age and all baseline variables at a level of $p<0.15$ in the univariate analysis, but excluding 12-month fall history, psychotropic medication (odds ratio 2.4, $p=0.03$) and presence of foot or ankle tender joints (odds ratio 2.0, $p=0.03$) were independent predictors of falls.

Conclusion: Psychotropic medications and tender joints in the feet and ankles are independent predictors of falls in people with RA. Clinical assessment of synovitis in the feet and review of psychotropic medications may be of benefit when considering falls prevention in people with RA.

Table 1: Significant factors associated with falls in univariate analysis.
Data are presented as mean (SD) unless specified.

Session Title: ARHP VI: Physical Function and Disability

Session Type: ARHP Concurrent Abstract Session

Session Time: 11:00AM-12:30PM

Trends in prevalence of knee pain among US adults, National Health Interview Survey, 2002-2010

Background/Purpose : Aging of the population as well as the obesity epidemic will play a significant role in future cases of arthritis and other lower extremity orthopedic conditions. The purpose of this study is to examine trends in the prevalence of knee pain among adults age 18 and older, overall and by age and sex.

Methods : The National Health Interview Survey, conducted annually, targets the civilian, non-institutionalized population and gathers data on a variety of health topics. From 2002 – 2010 the adult sample size ranged from 21,781 to 31,428. Adults were asked if they had joint pain in the past 30 days not including the back or neck. For those responding "yes", respondents were then asked what joints were affected. Prevalence (%) and 95% confidence intervals (CI) of knee pain were calculated using design variables and sampling weights to account for the complex survey design. Prevalence was also stratified by age group (18-24, 25-44, 45-64, 65-74, 75+) and sex, and graphed by age to show trends over time. Percent increase was calculated using the formula: (prevalence 2010 – prevalence 2002)/prevalence 2002*100. Statistical significance was determined by non-overlapping 95% CIs.

Results : The overall age-adjusted prevalence of knee pain increased significantly from 16.5% (CI 15.6-17.4) in 2002 to 19.6% (CI 18.5-20.7) in 2010. With a few exceptions, in each year, knee pain prevalence was higher with increasing age and highest for the 75+ age group. (Figure) For most years more than 1 in 4 adults aged 55-64 and 65-74 and 75+ reported having knee painr. Knee pain prevalence increased significantly over the 9 years in all age groups. The age groups with the largest percent increase were 25-44 (+21.4%), 45-64 (+27.7%), and 55-64 (+25.2%). Women had higher prevalence of knee pain than men for all years, but prevalence increased more in men (+23.0%) versus women (+15.3%).

Conclusion : Knee pain prevalence is high and has increased over time for all age groups with adults aged 45-54and 55-64 showing the largest increases. The findings suggest a large burden of knee pain among working age adults. Public health and worksite wellness efforts should consider implementing evidence-based interventions aimed at reducing knee pain such as physical therapy, aerobic and muscle strengthening exercises, and weight loss. The data also support the need for increasing the number of primary care, rheumatology and orthopedic health professionals in the workforce to address the growing burden of knee pain in the population.

SESSION INFORMATION

Session Date: Wednesday, November 11, 2015

Session Title: ARHP VI: Physical Function and Disability

Session Type: ARHP Concurrent Abstract Session

Session Time: 11:00AM-12:30PM

Background/Purpose: Limb length inequality (LLI; paired lower extremities of unequal length) is associated with knee and hip osteoarthritis (OA) and symptoms consistent with OA (pain, aching, stiffness on most days) in adults. Shoe lifts are effective for treating LLI and low back pain, but evidence is lacking for their influence on knee or hip symptoms. This study examined shoe lift therapy as an intervention for LLI and knee or hip symptoms.

Methods: Thirty participants from a large cohort study of OA with current knee or hip symptoms, a minimum score of 6 out of 20 on the Western Ontario and McMasters Universities Osteoarthritis Index (WOMAC) pain subscale, and a LLI $\geq$ 3.2 mm on radiograph were invited to participate in a 3-month trial of shoe lift therapy. Anteroposterior pelvic radiographs were acquired for participants as they stood with equal weight bearing on each limb with knees extended. The difference in height between the most superior aspects of the femoral heads was measured in mm to determine the magnitude of LLI and identify the longer limb. Per protocol, participants began with the minimum amount of lift material (3.2mm) applied to the shoe of the shorter limb, and those with a LLI $\geq$ 6.4 mm had the option of adding lifts in 3.2 mm increments to their shoes every 7-10 days. The magnitude of lift correction did not exceed the magnitude of the LLI; otherwise, participants self-selected their lift based on symptom relief. Participants were randomized to Group 1 (lift therapy for 3 months) and Group 2 (usual care and brochures on joint pain management with the option to begin lift therapy after the study period). Participants completed baseline and 3-month assessments, and the primary outcome was change in WOMAC score. Secondary outcomes were change in time for the 8-foot walk, time for 5 repeated chair stands, and single leg stance time. Means and standard deviations for change in outcomes were calculated and compared using t-tests.

Results: Participant characteristics and study results are summarized in the Table. Characteristics and baseline outcomes were similar between groups, except a greater proportion of participants were African-American in Group 1 than Group 2. All participants completed the 3-month study, and no adverse events related to lift therapy were reported. WOMAC total scores declined meaningfully and significantly more in Group 1 than Group 2 (-13.1 vs. -2.9, $p<0.01$), most notably driven by a decrease in the function subscale score (an improvement in function). The mean 5 repeated chair stand times became faster in Group 1 over 3 months, but slowed on average in Group 2 ($p=0.08$). All participants with 3.2 mm LLI accepted lift correction. Participants with LLI ≥ 6.4 mm self-selected 25-67% lift correction.

Conclusion: This preliminary study suggests that 3 months of shoe lift therapy with self-selected lift height improves function among older adults with knee or hip symptoms of OA and LLI.

Table. Participant Characteristics and Study Results.

Participant Characteristics	Group 1 (N=15) Shoe Lift Intervention	Group 2 (N=15) No Shoe Lift
Age, mean (SD*)	70 (8)	73 (8)

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: ACR Late-breaking Abstract Session
Session Type: ACR Late-breaking Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Giant cell arteritis (GCA) is characterized by a destructive, granulomatous inflammation in the walls of medium and large-sized arteries. Glucocorticoid (GC) treatment controls symptoms and reduces the risk of vascular complications such as vessel occlusion with blindness or rupture with fatal bleeding. Unfortunately, the duration of treatment and frequent relapses lead to high cumulative GC doses with substantial toxicity and morbidity. Tocilizumab (TCZ) is a humanized IgG1k monoclonal antibody directed against the human interleukin-6 receptor, it has been shown to rapidly induce remission in case series. This RCT was designed to evaluate the efficacy and safety of TCZ in the induction and maintenance of disease remission in patients with newly diagnosed or recurrent GCA.

Methods: Single center, randomized, placebo-controlled trial. Participants satisfying the 1990 ACR criteria were randomly assigned between 2011 and 2014 in a 2:1 ratio to receive TCZ (8 mg/kg IV of body weight) + GC (PO) or placebo (IV) + GC (PO). Infusions were given every 4 weeks for 1 year. GC was started at 1mg/kg/d and tapered by 0.1mg/kg/d weekly until week 8, then by 0.05mg/kg/d weekly until week 12 (0.1mg/kg/d). Thereafter, the dosage was decreased by 1mg/d monthly to 0mg.

The primary outcome was the number of patients with complete remission at week 12 (GC dose of 0.1mg/kg/d), reported as crude risk difference and corresponding 95% confidence intervals (CI). *P*-values were derived by Fisher's exact test. The secondary outcome was the number of patients who remained relapse-free at week 52 while the GC dosage was being tapered, plotted as a Kaplan-Meier curve for relapse-free survival for each group. Groups were compared with a Cox proportional hazard model.

Results: Thirty patients, 70% of whom were female were randomized (20 assigned to TCZ + GC, and 10 to Placebo +GC). Sixteen (80%) patients in the TCZ group and 7 (70%) in the placebo group were newly diagnosed. After 12 weeks, 17 patients in the TCZ group and 4 in the placebo group were in complete remission, (85% vs. 40%, respectively; difference, 45 percentage points [95% CI = 11 to 79 percentage points]; $P = 0.030$). At the end of the trial, 17 in the TCZ group and 2 patients in the placebo group had experienced no relapse (85% vs. 20%, respectively; difference, 65 percentage points), with a corresponding hazard ratio = 0.05 (95% CI 0.01 to 0.47), $P = 0.008$ (Figure).

Conclusion: This trial demonstrates the efficacy of TCZ for induction and maintenance therapy in patients with newly diagnosed or relapsed GCA in the context of rapidly tapered glucocorticoids.

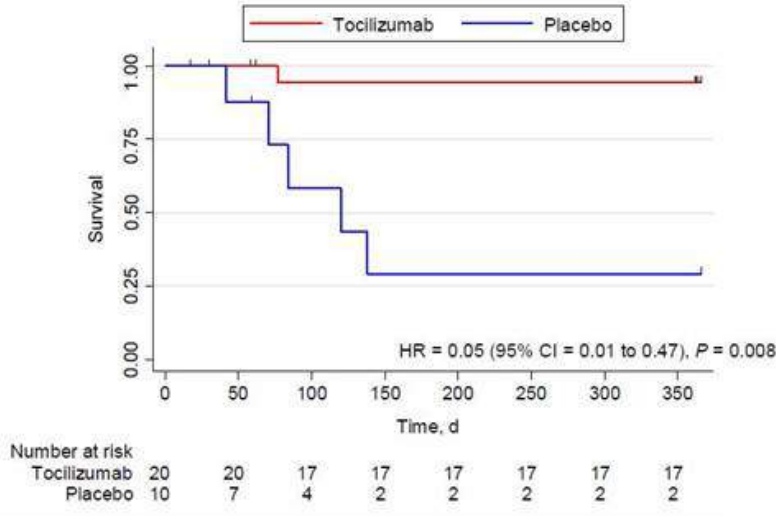

Figure: Kaplan Meier estimate of the time to first relapse after induction of remission.

Session Title: ACR Late-breaking Abstract Session

Session Type: ACR Late-breaking Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: In phase 3 studies, baricitinib (bari) improved disease activity in patients (pts) with active RA and an inadequate response (IR) to conventional synthetic DMARDs[1] or biologic DMARDs[2]. This abstract reports the 24-wk results from a 52-wk, global, phase 3, double-blind, placebo (PBO) and active-controlled study of bari in MTX-IR RA pts.

Methods: Pts with active RA (TJC≥6 & SJC≥6 & hsCRP≥6 mg/L) despite stable background MTX were randomized 3:3:2 to PBO, bari 4 mg once daily (QD), or adalimumab (ADA) 40 mg biweekly (Q2W), stratified by region and baseline joint erosion status. Non-responders were rescued from Wk 16. At Wk 24, pts on PBO switched to bari 4 mg QD. The primary endpoint was ACR20 response at Wk 12 for bari vs. PBO. Major secondary endpoints included comparisons of bari vs. ADA for ACR20 and change in DAS28-CRP at Wk 12.

Results: Of 1305 randomized pts, 89%, 94% and 93% completed Wk 24 in PBO, bari and ADA groups, respectively. Rescue rates were 26%, 7% and 12% for PBO, bari and ADA, respectively. ACR20 response at Wk 12 was higher for bari vs. PBO (70% vs. 40%, p≤.001 – Table 1). At Wks 12 and 24, statistically significant improvements in ACR 20/50/70 & HAQ-DI response rates, and DAS28, CDAI, and SDAI low disease activity and remission rates were seen for bari vs. PBO, many as early as Wk 1. Compared to ADA, bari was superior with respect to measures including ACR20 response and improvement in DAS28-CRP at Wk 12. Compared to PBO, daily diary measures of morning joint stiffness (MJS) duration and severity, worst tiredness, and worst joint pain were significantly improved in pts receiving bari, from as early as Wk 1. Rates of treatment-emergent adverse events (TEAEs), including infections, were higher for bari and ADA compared to PBO (Table 2). Compared to PBO, serious adverse events (SAE) rates were similar for bari and lower for ADA; serious infection rates were similar across groups. Two deaths occurred (bari), 1 pneumonia and 1 duodenal ulcer haemorrhage. Five malignancies were reported, 2 bari and 3 PBO. Three potential opportunistic infections occurred, 2 bari and 1 PBO; none were SAEs. One case of tuberculosis occurred (ADA). There were no GI perforations. Lab abnormalities were consistent with other phase 3 studies[1,2]; few led to discontinuation.

Conclusion: In pts with active RA despite background MTX, once-daily oral bari was associated with significant clinical improvements compared to PBO and to ADA, with an acceptable safety and tolerability profile.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: ACR Late-breaking Abstract Session

Session Type: ACR Late-breaking Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Uveitis associated with Juvenile Idiopathic Arthritis (JIA) is a major cause of morbidity with potentially sight-threatening complications. Despite current screening and (pre-biologic) therapeutic options, 10-15% of children develop bilateral visual impairment. Tumour necrosis factor alpha plays a pathogenic role in JIA-uveitis. No controlled trials have determined the impact of biologic therapy in JIA-associated uveitis. This double blind, randomised placebo-controlled trial assessed the efficacy, safety and cost-effectiveness of adalimumab in JIA-associated uveitis.

Methods: Patients aged 2 to 18 years with active JIA-associated uveitis, despite stable methotrexate (MTX) treatment for at least 12 weeks, were randomly assigned to adalimumab or placebo in a ratio of 2:1. All patients were treated up to a maximum period of 18 months, with follow up of 2 years from randomisation. All patients received a stable dose of MTX and in addition either adalimumab (20 mg for patients weighing <30 kg or 40 mg for patients weighing ≥30 kg, subcutaneous injection every 2 weeks) or placebo.

Primary endpoint was "time to treatment failure" defined by the "Standardisation of the Uveitis Nomenclature" criteria. Ten secondary efficacy endpoints were assessed including quality of life variables and arthritis disease activity measures. Adverse events from both arms were collected. Statistical analysis of the primary outcome used the log rank test to compare treatment groups with a hazard ratio and 95% confidence interval also being reported.

Results: The trial was stopped early for efficacy after 90 patients had been randomised as interim analysis met the pre-specified statistical stopping guidelines. The final analysis of the primary outcome showed positive treatment effect in favour of adalimumab: hazard ratio (HR) 0.27 (95% CI 0.13-0.52); $p<0.0001$. Adverse events were experienced by 88.3% (53/60, 687 events) of patients in the adalimumab group and 90% (27/30, 144 events) of patients in the placebo group. Events were consistent with the known adalimumab profile. 15 serious adverse events (SAEs) most commonly infection (10 events) occurred in 21.7% (n=13) of the patients in the adalimumab group, 3 of these resulted in the patient being withdrawn from treatment and there were 2 SAEs (flare of uveitis) reported in 6.7% (n=2) patients in the placebo group (both patients were withdrawn from the trial).

Conclusion: This trial, the largest of its kind to be conducted in JIA-associated uveitis, provides evidence of efficacy of adalimumab treatment used in addition to methotrexate in this population. The safety profile of adalimumab was consistent with that previously reported for adalimumab.

University Hospitals Bristol NHS Foundation Trust was contracted to receive a sum under data sharing agreement.

This project was funded by the National Institute for Health Research Health Technology Assessment Programme (project 09/51/01) and Arthritis Research UK (grant reference 19612).

Adalimumab was provided by Abbvie which reviewed this abstract and provided comments for author consideration. Trial protocol design and analyses were undertaken independent of AbbVie.

Session Title: ACR Late-breaking Abstract Session

Session Type: ACR Late-breaking Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose:

In phase 2b trials, epratuzumab, a humanized anti-CD22 mAb that modulates B cell signaling without total B cell depletion, significantly improved disease activity in patients (pts) with moderate-to-severe SLE.[1] We report the first data from two phase 3, randomized, double-blind, placebo (PBO)-controlled, multicenter

studies of epratuzumab in active, moderate-to-severe SLE: EMBODY 1™ (SL0009, NCT01262365) and EMBODY 2™ (SL0010, NCT01261793). **Methods:**

Pts were ≥18 years of age from North and South America, Europe, Australia, Asia and Africa. Entry requirements included ANA ≥1:80 and/or anti-dsDNA positivity, ≥4 ACR revised criteria, SLEDAI-2K score ≥6, BILAG-2004 ≥1 A or ≥2 Bs in mucocutaneous, musculoskeletal or cardiorespiratory domains and receipt of stable dose CS (5–60 mg/day prednisone equivalent) for ≥5±1 days prior to baseline (BL). Temporary CS dose increases ≤25% of BL dose were permitted until Week (Wk) 8. Pts with BILAG A grade renal or central nervous system domain scores were excluded.

Pts were randomized 1:1:1 to PBO, IV epratuzumab 600 mg every wk (QW) or 1200 mg every other wk (QOW) in addition to their standard of care (SOC) therapies, stratified by region and BL disease severity. Drug or PBO was administered for a 4-wk period at the beginning of each 12-wk treatment cycle for 4 cycles (48 wks total).

The primary endpoint was the Wk48 responder rate according to the BILAG-based Combined Lupus Assessment (BICLA) definition, requiring all of the following: BILAG improvement and no worsening (all BILAG As at entry improved to B/C/D; all Bs improved to C/D; no new BILAG As and ≤1 new BILAG B), no worsening in SLEDAI score, no worsening in physician's global assessment of disease activity, no disallowed changes in concomitant medications. Secondary efficacy variables included BICLA response at Wks 36/24/12. CS use was evaluated.

Efficacy data are presented for the full analysis set. Missing values were imputed using modified non-responder imputation with missing data incorporated as the worst possible outcome. Safety data were comprehensively assessed.

Results:

In EMBODY™ 1, 793 pts were randomized, 786 (99.1%) received study medication, and 528 (66.6%) completed the study. In EMBODY™ 2, 791 pts were randomized, 788 (99.6%) received study medication, and 533 (67.4%) completed the study. BL characteristics were similar across groups (Table A).

Neither study met the primary endpoint: Wk48 BICLA response rates in epratuzumab+SOC groups were not statistically different from PBO+SOC groups (Table B). No significant differences were seen in other efficacy measures.

No new safety signals were identified (Table B).

Conclusion:

BICLA response rates at Wk48 were no different in SLE patients treated with epratuzumab+SOC compared to PBO+SOC. The safety profile of epratuzumab was similar to previous studies.

Session Date: Tuesday, November 10, 2015

Session Title: ACR Late-breaking Abstract Session

Session Type: ACR Late-breaking Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: This was the first investigation of the effects of tofacitinib (TOFA) in adult patients (pts) with active ankylosing spondylitis (AS). TOFA is an oral Janus kinase inhibitor under investigation for the treatment of AS.

Methods: This was a 16-week (wk), Phase 2, multicenter, randomized, double-blind, placebo (PBO)-controlled, dose-ranging study (NCT01786668) to investigate efficacy, safety, and dose-response of TOFA in pts with AS. Pts fulfilling the modified New York criteria (central read) were randomized 1:1:1:1 to PBO or TOFA 2, 5, or 10 mg twice daily (BID) for 12 wks plus 4 wks follow-up. The primary efficacy endpoint was ASAS20 response rate at Wk 12 using a 3-parameter Bayesian E_{max} model by assuming a monotonic response. Secondary endpoints included ASAS40 response rate, AS disease activity score using C-reactive protein (ASDAS), Bath AS disease activity index 50% (BASDAI50) response rate, Bath AS functional index, Bath AS metrology index (linear method), Spondyloarthritis Research Consortium of Canada (SPARCC) score of sacroiliac (SI) joints and spine. Safety endpoints included adverse event (AE), and laboratory outcomes.

Results: 208 pts were randomized and 207 treated; 196 pts completed the study. 51 pts in the PBO group and 52 in each TOFA group were included in analyses. Baseline demographics and disease characteristics were balanced in general between groups and typical of AS populations (87.4% HLA-B27 positive; 81.2% white; 69.1% male; mean age 42 years; mean disease duration 6.3 years; mean BASDAI 6.7).

The Table summarizes efficacy results. The ASAS20 E_{max} model showed TOFA 10 mg BID had a high response rate and its confidence bounds met a pre-specified efficacy decision rule. Observed ASAS20 response rates were significantly greater with TOFA 5 mg BID vs PBO, compared with 2 or 10 mg BID. All TOFA groups had ASAS40, ASDAS, and BASDAI50 improvements of similar magnitude vs PBO. TOFA 2 mg BID did not differ vs PBO in remaining clinical efficacy measures or SPARCC scores. TOFA 5 and 10 mg BID had greater clinical efficacy vs PBO, with minimal differences between doses, and significantly improved SPARCC SI joint and spine scores vs PBO.

The Table summarizes safety results. No TOFA-related safety issues unique to the AS population or new safety concerns were identified. Two treatment-related herpes zoster cases were reported (1 each with TOFA 2 and 10 mg BID). No cases of tuberculosis, malignancy, gastrointestinal perforation, or death were reported. Dose-dependent changes in laboratory outcomes commonly reported in other TOFA studies were observed and returned to approximately baseline values by Wk 16.

Conclusion: TOFA 5 and 10 mg BID demonstrated greater clinical and imaging efficacy vs PBO in reducing the signs and symptoms of AS in adults with active AS. Safety was similar to that reported for TOFA studies in other indication

Table. Summary of efficacy and safety endpoints

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: ACR Late-breaking Abstract Session

Session Type: ACR Late-breaking Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: In the MEASURE 1 trial (NCT01358175), secukinumab significantly improved the signs and symptoms of patients (pts) with active ankylosing spondylitis (AS) over 52 weeks (wks).[1] Here, we report the effects of secukinumab on radiographic progression up to 104 wks.

Methods: In MEASURE 1, 371 pts with active AS were randomized to secukinumab or placebo (pbo). Pts on secukinumab received a 10 mg/kg i.v. loading dose at baseline (BL), Wks 2 and 4, and then 150 mg s.c. (IV→150 mg) or 75 mg s.c. (IV→75 mg) every 4 wks from Wk 8. Pbo was given on the same schedule. Pbo pts were re-randomized to secukinumab 150 or 75 mg s.c. based on ASAS20 response at Wk 16 (non-responders switched at Wk 16 and responders at Wk 24). Lateral radiographs of the cervical and lumbar spine performed at BL and Wk 104 were read centrally applying the modified Stoke Ankylosing Spondylitis Spinal Score (mSASSS). Two independent readers, blinded to treatment arm and radiograph sequence, scored the digitized images. Pts initially randomized to secukinumab, who had x-rays available at BL and Wk 104 (n=168), were included in this analysis. Only observed data are shown.

Results: Secukinumab data were pooled as there were no major differences between the two doses. Data from pts randomized to secukinumab at BL and those who switched from pbo were analyzed separately. At BL in the secukinumab only group, 104/168 (62%) pts had syndesmophytes, 105/168 (63%) had elevated (>5 mg/L) C-reactive protein (CRP) levels, 42/168 (25%) were smokers, and 123/168 (73%) were men. The mean (±SD) mSASSS at BL was 10.22±16.62; mean change from BL at Wk 104 was 0.30±2.53. There were no major differences between the secukinumab only and pbo→secukinumab groups in terms of mSASSS change through Wk 104. Approximately 80% of pts randomized to secukinumab at BL showed no radiographic progression (mSASSS change ≤0) (Figure). At Wk 104 in the secukinumab only group, new syndesmophytes were found in 3/64 (5%) pts who were without syndesmophytes at BL. Overall, BL mSASSS and mean mSASSS change at Wk 104 in the secukinumab only group were higher in males (mean change 0.38±2.79 vs 0.08±1.58 in females), those with BL syndesmophytes (0.47±3.20 vs 0.02±0.26 in pts with no BL syndesmophytes), or elevated CRP levels at BL (0.47±2.66 vs 0.02±2.27 in pts with normal CRP levels).

Conclusion: The mean change in mSASSS was only 0.30±2.53 in the secukinumab only group, with no major difference between doses. Changes were higher in pts who were male, had BL syndesmophytes, or elevated BL CRP. No radiographic progression was observed in ~80% of the pts receiving secukinumab over 104 wks. This is the first report of interleukin-17A inhibition on structural changes in patients with AS. The changes in mSASSS through 2 years reported here may be lower than those reported in earlier observational and interventional studies in AS.

Session Title: ACR Late-breaking Abstract Poster Presentations

Session Type: ACR Late-breaking Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: Since the 2009 GRAPPA treatment recommendations were published, therapeutic options and management strategies for psoriatic arthritis (PsA) have advanced considerably. We updated

and improved these recommendations through development of overarching management principles and evidence based guidance for treatment of the different manifestations of PsA including associated comorbidities.

Methods: GRAPPA rheumatologists, dermatologists, and patient research partners (PRPs) drafted overarching principles for the management of adult PsA patients by consensus. We updated systematic literature reviews based on data publicly available through November 2014. Six separate literature reviews were performed covering treatment for the key clinical manifestations of PsA (arthritis, spondylitis, enthesitis, dactylitis, skin, and nail disease), and we reviewed a new topic (PsA related comorbidities). Evidence was assessed, and the GRADE system was applied to generate strong or conditional recommendations for therapies within the domain groups and for the management of comorbidities. These recommendations were then incorporated into an overall treatment schema. Consensus for the overarching principles and treatment recommendations was obtained among GRAPPA members with an online questionnaire.

Results: GRAPPA members voted on six overarching principles developed through multiple iterations with significant agreement among both health care professionals (HCPs; n=135, agreement 83.7-92.6% for individual principles) and PRPs (n=10, agreement 80-100%). Evidence was assessed from the published literature reviews and formally evaluated with the GRADE system to provide treatment recommendations (table 1). Based on the evidence, individual groups developed treatment recommendations which were incorporated into an overall schema including principles for management of arthritis, spondylitis, enthesitis, dactylitis, skin, and nail disease, and comorbidities in PsA (figure 1). Consensus amongst the GRAPPA members was 87.2% agreement (n=176) for the treatment recommendations and 87.9% (n=176) for the schema.

Conclusion: Based on the results of the literature review and GRADE assessment of the evidence, we developed updated comprehensive treatment recommendations for the key manifestations of PsA, including related comorbidities. These recommendations are supplemented by overarching principles developed by consensus of GRAPPA members (rheumatologists, dermatologists, other HCPs, and PRPs).

Indication	Recommended Strong	Recommended Weak	Not recommended Strong	No recommendations as lack of evidence
Peripheral Arthritis DMARD Naïve	DMARDs (MTX, SSZ, LEF), TNFi	NSAIDs, oral CS, IA CS, *PDE4i*		IL12/23i, IL17i
Peripheral Arthritis DMARD Inadequately Responsive	TNFi, ustekinumab, PDE4i	NSAIDs, oral CS, IA CS, *IL17i*		
Peripheral Arthritis Biologic Inadequately Responsive	TNFi	NSAIDs, oral CS, IA CS, IL12/23i, *IL17i*, PDE4i		
Axial PsA, Biologic Naïve (based on AS literature)	NSAIDs, Physiotherapy, simple analgesia, TNFi	*IL17i*, CS SIJ injections, bisphosphonates *(IL12/23i)*	DMARDs, IL6i, CD20i	
Axial PsA, Biologic Inadequately Responsive (based on AS literature)	NSAIDs, Physiotherapy, simple analgesia	TNFi, *IL12/23i, IL17i*		
Enthesitis	TNFi, IL12/23i,	NSAIDs, physiotherapy, CS injections (with extreme caution since injecting CS in weight-bearing entheseal sites can lead to rupture of entheses), *PDE4i*, *IL17i*		DMARDs
Dactylitis	TNFi (INF, ADM, GOL, CZP)	CS injections, DMARDs (MTX, LEF, SSZ), TNFi (ETN), IL12/23i, *IL17i (SEC)*, *PDE4i*

Session Title: ACR Late-breaking Abstract Poster Presentations
Session Type: ACR Late-breaking Abstract Session
Session Time: 9:00AM-11:00AM

Background/Purpose:

SB5 is a biologic agent developed as a biosimilar of the adalimumab reference product (ADL). Equivalence in pharmacokinetics (PK) between SB5 and ADL in healthy subjects has been demonstrated[1] in a phase I study. This phase III study was a randomized, double-blind, multicenter study to compare the efficacy, safety, PK, and immunogenicity of SB5 with ADL in patients with moderate to severe rheumatoid arthritis (RA) despite methotrexate (MTX) treatment up to 52 weeks. **Results** up to 24 weeks are presented in this abstract.

Methods:

Patients with moderate to severe RA despite MTX treatment were randomly assigned to receive 40 mg of either SB5 or ADL administered subcutaneously every other week for 24 weeks. At Week 24, patients in ADL group were randomized again to receive 40 mg of either SB5 or ADL for additional 28 weeks. Patients in SB5 group continued to receive SB5. The primary endpoint was the ACR20 response rate at Week 24. Other secondary efficacy endpoints and safety were measured.

Results:

A total of 544 patients were randomized to either SB5 (N=271) or ADL (N=273). Baseline demographic and disease characteristic were comparable between two treatment groups. The ACR20 response rate at Week 24 in the per-protocol set (PPS) was 72.5% (174/240) in SB5 and 72.0% (170/236) in ADL. The 95% confidence interval (CI) of the treatment difference adjusted by region and baseline C-reactive protein was –7.66% to 8.30%, which was within the pre-defined equivalence margin of [–15%, 15%]. The ACR20 response rate at Week 24 was shown to be equivalent in the full analysis set as well (95% CI: -7.03%, 8.56%) when non-responder analysis was applied. The 95% CI of the estimated difference between the time-response curves of SB5 and ADL in the PPS met the pre-defined equivalence margin (Figure). The ACR50 response rates at Week 24 in the PPS were 38.3% vs. 39.8% and the ACR70 response rates were 19.2% vs. 20.3% in SB5 and ADL, respectively. The safety profile of SB5 was generally similar to that of ADL (Table). The overall incidence of anti-drug antibody up to Week 24 was 32.8% in SB5 vs. 31.7% in ADL. The PK profile was also comparable between the two treatment groups.

Conclusion:

SB5 was shown to be equivalent in terms of clinical efficacy when compared with ADL. SB5 was well tolerated with similar safety profile, PK, and immunogenicity to ADL.

Table. Safety Results

Patients with	SB5 (N=268*)		ADL (N=273)

Session Title: ACR Late-breaking Abstract Poster Presentations

Session Type: ACR Late-breaking Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: Giant cell arteritis (GCA) is a large-vessel primary systemic vasculitis. Although glucocorticoids are effective in treating GCA, they are associated with substantial toxicity and relapse of vasculitis occurs in a high percentage of patients. T-cell activation has been implicated in the pathophysiology of GCA. A multi-center, randomized, double-blind, placebo-controlled, withdrawal design trial was conducted to examine the efficacy and safety of treatment with abatacept (CTLA4-Ig) combined

with prednisone in patients with GCA.

Methods: Patients with newly diagnosed or relapsing GCA were eligible for the trial. All patients were treated with abatacept 10 mg/kg IV on days 1, 15, 29, and week 8, together with prednisone. At week 12 patients in remission underwent a double-blinded randomization to continue monthly abatacept or be switched to placebo. Patients in both study arms received prednisone according to a standardized taper schedule that reached discontinuation of prednisone at week 28. Patients remained on their randomized assignment until meeting criteria for early termination or until the common closeout date, 12 months after enrollment of the last patient. The primary endpoint was duration of remission (relapse-free survival, RFS). A planned sample size of 30 or more patients was based on detecting a 30% improvement in RFS utilizing a one-sided alpha = 0.1. Kaplan-Meier curves were constructed and differences in treatment arms compared using the log-rank test in an intent-to-treat analysis.

Results: 49 eligible patients with GCA received study drug with 41 reaching the week 12 randomization. Disease characteristics of the 41 randomized patients are outlined in Table 1.

The RFS at 12 months was estimated to be 48% for those receiving abatacept and 31% for those receiving placebo (p=0.049), Figure 1. A longer median duration of remission was seen with abatacept compared to placebo (abatacept 9.9 months, placebo 3.9 months). Covariate analysis examining those variables that differed between study arms did not impact the results.

129 adverse events occurred in 35 patients, including 23 serious adverse events in 15 patients. There was no difference in the frequency or severity of adverse events between treatment arms, including the rate of infection.

Conclusion: In patients with GCA the addition of abatacept to a standard treatment regimen with prednisone reduced the risk of relapse of vasculitis and was not associated with a higher rate of toxicity compared to prednisone alone. This study provides the first trial-level evidence of a targeted immunomodulatory therapy that has demonstrated efficacy for the treatment of GCA.

Table 1. Baseline characteristics of the study population of patients with giant cell arteritis

		Abatacept N=20	Placebo N=21	
		N (%)	N (%)	p-value
Patient demographics				
Age at enrollment (years), median (range)		63.5 (57.3-80.1)	71.5 (54.3-86.6)	0.052
Age at diagnosis (years), median (range)		62.4 (53.6-80.1)	70.5 (52.4-86.6)	0.043
Sex	Female	16 (80%)	21 (100%)	0.048

Session Title: ACR Late-breaking Abstract Poster Presentations

Session Type: ACR Late-breaking Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: The application of ultrasonography (US) in rheumatology clinical practice is growing. The ARCTIC trial (NCT01205854) was designed to examine if the use of a treatment strategy including information from a structured US assessment would lead to better clinical and radiographic outcomes for patients with rheumatoid arthritis (RA), compared to a conventional strategy based on clinical and laboratory assessments alone.

Methods: The study population consisted of disease-modifying antirheumatic drug (DMARD) naïve early RA patients with <2 years symptom duration, fulfilling the 2010 ACR/EULAR classification criteria and with indication for DMARD therapy. Patients were followed in a tight control regimen with 13 visits over the 2-year follow-up period and randomized 1:1 to A) an US tight control (UTC) strategy targeting DAS < 1.6, no swollen joints and no power-Doppler (PD) signal in any joint or B) a conventional tight control (CTC) strategy targeting DAS<1.6 and no swollen joints. US was performed by experienced sonographers at every visit in the UTC arm, using a validated semi-quantitative scoring system with scores 0-3 for grey scale (GS) and PD in 32 joints (1). Patients in both arms were treated according to the same treat-to-target strategy with a step-up DMARD escalation approach starting with MTX, then triple combination therapy MTX/SSZ/HCQ, then biologic DMARD if target was not reached.

The primary endpoint was the proportion of patients meeting all the 3 following criteria: 1) Sustained clinical remission, defined as DAS<1.6 at 16, 20 and 24 months 2) No swollen joints at 16, 20 and 24 months (44 SJC) and 3) No progression (<0.5 units) in van der Heijde-modified total Sharp Score (vdHSS) between 16 and 24 months. Secondary efficacy endpoints included various measures of disease activity/remission and vdHSS.

Results: A total of 238 patients were randomized, and all patients with at least one follow-up visit were included in the full analysis set (UTC n=118, CTC n=112). 105 patients in the UTC arm and 99 patients in the CTC arm completed the study. The primary endpoint was reached by 26 patients (22.0%) in the UTC and 21 patients (18.8%) in the CTC (p=0.54, mean difference 3.3%; 95%CI -7.1% to 13.7%). Secondary efficacy outcomes are shown in Table 1.

Conclusion: There was no difference in the probability of achieving sustained clinical remission and halt of radiographic progression between the two strategies. Both the strategy adding ultrasonography and the conventional strategy led to early and sustained improvements in clinical outcomes, providing excellent disease control and minimal radiographic progression. The implementation and systematic use of US in the follow-up of early RA patients treated with an aggressive treat-to-target strategy is not justified based on the results of the ARCTIC trial.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: ACR Late-breaking Abstract Poster Presentations
Session Type: ACR Late-breaking Abstract Session
Session Time: 9:00AM-11:00AM

Background/Purpose: Evidence from open-label and observational studies support anti-B-cell therapy in patients with primary Sjogren's Syndrome (PSS). The TRACTISS trial aimed to determine the extent to which rituximab improves symptoms of fatigue and oral dryness in patients with PSS.

Methods: Multicentre, randomised, parallel group, double-blind, placebo-controlled trial. Patients with PSS, and symptomatic fatigue and oral dryness were recruited from 25 rheumatology clinics in the UK from June 2012 to January 2014. At weeks 0, 2, 24 and 26, patients received pre- and post-infusion corticosteroids and either placebo (P) IV or rituximab (R) IV (1000mg in 250mL). Intervention was decided by 24hr central telephone minimisation service. Primary endpoint was the proportion of patients achieving 30% reduction in either fatigue or oral dryness at 48 weeks, measured by Visual Analogue Scale (VAS). Other outcomes included VAS scales for fatigue or oral dryness separately, global assessment of PSS activity, pain, ocular and overall dryness, as well as salivary and lachrymal flow rates, quality of life, EULAR Sjögren's Syndrome Disease Activity Index (ESSDAI) and Patient Reported Index (ESSPRI). Patients and physicians were blinded to the patient's allocation. ISRCTN 65360827

Results:

All patients (n=133) randomised to P (n=66) and to R (n=67) were included in the primary analysis. 55 P and 54 R patients received all 4 infusions in full. Mean age was 54 years, 93% of patients were female, mean ESSDAI was 5.7 and mean time since diagnosis was 5.7 years. Among complete cases at 48 weeks, 21/56 P and 24/61 R patients achieved the primary endpoint. After multiple imputation of missing outcomes, response rates were 36.8% (P) and 39.8% (R) (adjusted odds ratio 1.13, 95% confidence interval 0.50-

2.55). There were no significant differences in any outcome measure, except unstimulated salivary flow: P patients deteriorated compared to R patients with a significant relative difference seen after Week 24. There were more adverse events reported in total for R (275 P vs 325 R), but no difference in serious adverse events. (10 vs 10) One serious infusion reaction (R) and one serious anaphylaxis (P) occurred in one patient each.

Conclusion: TRACTISS is the largest randomised trial of biologic therapy in PSS. No improvement in symptoms was seen in the Rituximab arm (unlike the TEARS study) but modest benefit for Rituximab in salivary flow was observed.

Funding: Funded by Arthritis Research UK.

Session Title: ACR Late-breaking Abstract Poster Presentations

Session Type: ACR Late-breaking Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor for the treatment of rheumatoid arthritis (RA). Clinical guidelines recommend using live zoster vaccine (LZV) to prevent shingles in RA, but this vaccine has not been previously studied in RA patients (pts) and the effect of tofacitinib on humoral or cell-mediated live vaccine responses is unknown.

Methods: To evaluate the effect of tofacitinib upon the immune response and safety of LZV, we recruited pts aged ≥50 years with active RA (≥4 tender/painful joints and ≥4 swollen joints) despite methotrexate (MTX) therapy (≥4 months of treatment with 15–25 mg/week [wk] before screening) (study NCT02147587). Pts with prior history of zoster vaccination were excluded, as were those receiving any vaccine in the 6 wks prior to randomization. After screening, eligible pts were given LZV and then randomized to either tofacitinib 5 mg BID or placebo (PBO) to start 2–3 wks post-vaccination with continuation of background MTX. We measured both humoral (varicella-zoster virus [VZV]-specific IgG via gpELISA) and cell-mediated responses (VZV-specific T cell enumeration via ELISPOT) prior to vaccination (baseline, day of vaccination), and then at 2, 6, and 14 wks post-vaccination. The primary endpoint was an assessment of the geometric mean fold rise (GMFR) in VZV-specific IgG titer at 6 wks post-vaccination. Secondary endpoints included the proportion of patients achieving a ≥1.5 fold rise in VZV-specific IgG titer 6 wks post-vaccination. Exploratory endpoints included the GMFR in VZV-specific T cells (spot-forming cells/10^6 peripheral blood mononuclear cells [PBMCs]) by ELISPOT between baseline and 6 wks post-vaccination. Pts were followed for 12 wks after randomization for safety.

Results: 112 pts were randomized into PBO (n=57) and tofacitinib arms (n=55). Most PBO (93%) and tofacitinib (98%) pts were evaluable for immune response endpoints. Pts were similar with regard to sex, age, baseline disease activity, and baseline VZV immune measures (i.e. IgG, ELISPOT). The GMFR in VZV-specific IgG titer at 6 wks was 2.11 for tofacitinib pts and 1.74 for PBO pts. The GMFRs both in tofacitinib and PBO pts were comparable with the GMFRs in healthy people ≥50 years as indicated in the LZV labels. The proportion of patients developing a 1.5 fold post-vaccination rise in IgG titer at 6 wks trended higher for tofacitinib (57.4%) versus PBO (43.4%). For cell-mediated immune responses, the VZV-

specific T cell GMFR at 6 wks increased similarly for tofacitinib pts (1.50) and PBO pts (1.29). SAEs occurred in 0 (0%) and 3 (5.5%) of PBO and tofacitinib arms respectively. One pt in the study developed cutaneous dissemination with vaccine-strain VZV (Oka strain virus) that occurred 2 days after starting tofacitinib (16 days post-vaccination). Subsequently, this pt was found to lack pre-existing immunity to VZV, consistent with vaccine-induced disease. This event resolved after tofacitinib discontinuation and antiviral therapy.

Conclusion: Pts starting tofacitinib had similar VZV-specific humoral and cell-mediated immune responses to LZV as compared to PBO-treated pts. Vaccination appeared safe in all pts but one who lacked pre-existing VZV immunity.

Session Title: ACR Late-breaking Abstract Poster Presentations
Session Type: ACR Late-breaking Abstract Session
Session Time: 9:00AM-11:00AM

Background/Purpose: Fractalkine (CX3CL1, designated as FKN hereafter) is the sole member of the CX3C-chemokine which leads to dual actions, chemotaxis and cell adhesion for leukocytes expressing the cognate receptor, CX3CR1, during their migration. Accumulating evidence is telling that FKN-CX3CR1 axis plays a pivotal role in leukocyte/lymphocyte accumulation in inflamed tissues in RA[1]. We developed E6011, a novel humanized anti-FKN monoclonal antibody, and its safety and tolerability was assessed in a Phase 1/2, open-label, multiple ascending dose study in RA patients for the first time (NCT02196558).

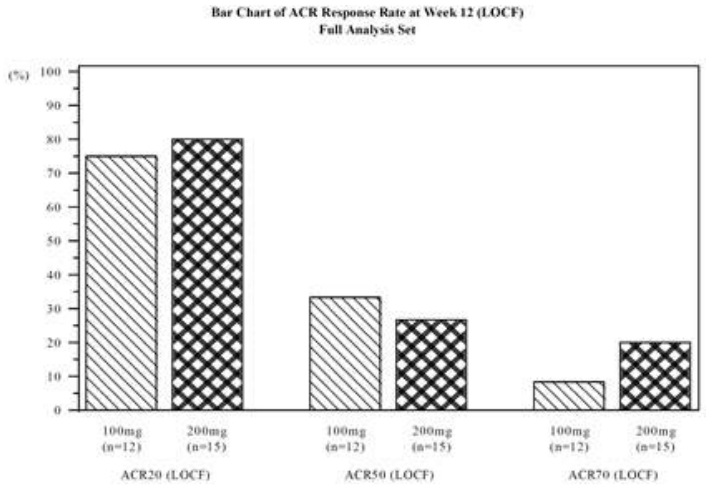
Methods: Active RA patients with inadequate response to MTX or TNF inhibitors were received 7 consecutive doses (subcutaneous) of E6011 at week 0, 1, 2 and thereafter every 2 weeks up to week 10. A hundred and 200 mg of E6011 were chosen for the study as putatively appropriate doses for patients by the PK/PD modeling previously obtained in the Ph1 healthy volunteer study of E6011. The primary objective was safety and tolerability of E6011 in Japanese RA patients while the efficacy of E6011 was also explored.

Results: Twelve subjects were enrolled in the cohort of 100 mg and subsequently 15 subjects were enrolled in the 200 mg cohort, in total, 27 subjects received repeated subcutaneous administrations of E6011. As a result, repeated dose of E6011 was found safe and well tolerated. The incidence of AE, treatment related AE and SAE was 59.3%, 29.6% and 7.4%, respectively. There were no severe AE or deaths, and no significant differences were observed in the incidence or severity of AE between the 100 mg and 200 mg cohorts.

Clinical outcome was also available in the study in which response rates of ACR20, 50 and 70 at week 12 were 75.0%, 33.3%, 8.3% and 80.0%, 26.7%, 20.0% in the cohort of 100 and 200 mg, respectively. At week 12, 33.3% of subjects achieved DAS28-CRP remission in both cohorts, 16.7% and 20.0% for SDAI remission and 8.3% and 26.7% for Boolean remission were observed in the 100 and 200 mg cohorts, respectively.

Category	E6011		
	100 mg (N=12) n (%)	200 mg (N=15) n (%)	Total (N=27) n (%)
All AEs	6 (50.0)	10 (66.7)	16 (59.3)
Treatment-related AEs	3 (25.0)	5 (33.3)	8 (29.6)
Severe AEs	0	0	0
Serious AEs	1 (8.3)	1 (6.7)	2 (7.4)
Death	0	0	0
AEs leading to study drug withdrawal	0	2 (13.3)	2 (7.4)

For each row category, a subject with 2 or more AEs in that category was counted only once.



Conclusion: E6011 was safe and well tolerated, and demonstrated a promising efficacy in active RA patients with MTX or TNFi-IR. While further clinical studies are required, the results obtained indicate that a novel biological DMARD targeting FKN/CX3CR1 interaction will be clinically beneficial for active RA patients.

Session Date: Tuesday, November 10, 2015

Session Title: ACR Late-breaking Abstract Poster Presentations

Session Type: ACR Late-breaking Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose: The safety, efficacy, and dose response of ABT-494, a novel selective JAK1 inhibitor, were characterized vs placebo (PBO) in patients (pts) with moderately to severely active RA and an inadequate response to ≥1 anti-TNF biologic therapy (TNF-IR). **Methods:** This was a phase 2b, 12-week, double-blind PBO-controlled study; TNF-IR pts receiving stable background methotrexate (MTX) were randomized 1:1:1:1:1 to ABT-494 3, 6, 12, and 18 mg twice daily (BID) or matching PBO. The primary efficacy endpoint was the proportion of pts who achieved an ACR20 response at week 12. **Results:** All 276 pts had failed ≥1 anti-TNF therapy prior to enrollment; 28% had received ≥2 anti-TNF biologics and 20% had also received non–anti-TNF biologics. Baseline (BL) characteristics were similar in all treatment groups. The proportion of pts achieving ACR20 at week 12 was significantly higher for all ABT-494 groups vs PBO **(Table 1)**. There was a significant (P<0.01) dose response between PBO and all ABT-494 treatment groups for ACR20 response rates (non-responder imputation) at week 12. ACR50 and ACR70 responses were statistically significantly higher at doses of ≥6 mg BID. Changes in DAS28(CRP) from BL were significantly greater for all doses of ABT-494 vs PBO. Onset of action was rapid, with significant differences in ACR20 and change in DAS28(CRP) from BL at week 2 (P≤0.007) for 6, 12, and 18 mg BID vs PBO. Low disease activity and clinical remission per DAS28(CRP) criteria were achieved statistically significantly more often in the 12-mg BID dose group vs PBO. The incidences of AEs were numerically higher in ABT-494 dose groups, with some trend towards dose dependency **(Table 2)**. The majority of infections were mild. There was one serious infection ("bronchiectasis") in the PBO group and none in the ABT-494 treatment groups were reported. Five pts had non-serious events of herpes zoster: 1 pt each in the ABT-494 3 mg, 12 mg, and 18 mg BID treatment groups, and 2 pts in the PBO group. One pt in the 6-mg BID dose group reported 2 events of non-melanoma skin cancer (basal cell and squamous cell carcinomas). There was 1 report of anemia in the 18-mg BID dose group. No deaths were reported during the study. **Conclusion:** This phase 2b study demonstrated the clinical efficacy of ABT-494 vs PBO when dosed in combination with MTX in TNF-IR pts with active RA. ABT-494 had an acceptable safety and tolerability profile.

Session Title: ACR Late-breaking Abstract Poster Presentations

Session Type: ACR Late-breaking Abstract Session

Session Time: 9:00AM-11:00AM

Background/Purpose:

Idiopathic inflammatory myopathies (IIMs) are a heterogeneous group of rare systemic autoimmune diseases collectively called myositis causing progressive muscle weakness. Interestingly, myositis-specific autoantibodies described in different subsets of IIM are directed against ubiquitously expressed, intracellular proteins and show a lack of muscle specificity. Here we show for the first time that patients with IIM develop autoimmunity to the muscle-specific protein Four-and-a-half-LIM-domain 1 (FHL1). Strikingly, FHL1 is the causative factor for several X-linked hereditary myopathies, collectively called FHL1-related myopathies.

Methods:

Sera from IIM patients (n=141), followed at the Rheumatology Unit, Karolinska University Hospital, were compared to gender- and age-matched healthy controls (n=126) as well as patients diagnosed with other autoimmune disorders (n=186) and patients with non-inflammatory neuromuscular diseases (n=9) by ELISA and immunoblot. For 132/141 patients detailed clinical and laboratory data from patient records were available and the significance of differences between anti-FHL^+ and anti-FHL^- patients was calculated by the Wilcoxon's rank-sum test for continuous variables, and by Pearson's Chi-square test or by the Fischer's exact test for categorical variables. Expression pattern of FHL1 in muscle tissue of affected patients was analysed by confocal microscopy. Functional aspects of an anti-FHL1 autoimmune response was investigated in IIM-susptible MHC class I-overexpressing HT mice.

Results:

Anti-FHL1 autoantibodies were detected in 25% of IIM patients, while patients with other autoimmune diseases including rheumatoid arthritis (RA), systemic sclerosis (SSc) and systemic lupus erythematosus (SLE) or non-inflammatory neuromuscular diseases were largely anti-FHL1-negative. A comprehensive analysis of clinical data on muscular and extra-muscular involvement as well as biopsy characteristics revealed that anti-FHL1 reactivity was predictive for muscle atrophy, dysphagia, pronounced muscle fiber damage characterized by necrosis and connective tissue/fat replacement of muscle tissue, and vasculitis. The targeted autoantigen FHL1 showed an altered expression pattern with focal accumulation in muscle fibers of autoantibody-positive patients compared to a homogeneous expression in anti-FHL1-negative patients and healthy controls. By addressing the question how FHL1-autoimmunity might be initiated, we found that FHL1 is a target of granzyme B. To investigate if FHL1-autoimmunity contributes to muscle damage, we immunized myositis-prone mice with FHL1 and found aggravated muscle weakness, pronounced muscle damage, evidence for T cell infiltrates and increased mortality.

Conclusion:

Our findings provide the first evidence that FHL1 may be involved in the pathogenesis not only of genetic FHL1-related myopathies but also of autoimmune IIM. Importantly, detection of anti-FHL1 autoantibodies in peripheral blood represents a potential biomarker able to identify a subset of severe IIM characterized by a progressive, therapy-resistant disease and poor prognosis.
