Background/Purpose: Smoking is a strong risk factor for myocardial infarction (MI), but not among rheumatoid arthritis (RA) patients. These paradoxical findings may be due to index event bias (a type of selection bias) which arises from selecting a group of patients (e.g., RA) on the causal pathway (e.g., between smoking and MI); thus, true risk factors may appear spuriously null or protective. We sought to identify this paradox, and employ a sensitivity analysis to handle the unmeasured or uncontrolled factor (U) that could partly explain the paradox.

Methods: We used data from The Health Improvement Network (THIN), an electronic medical record database representative of the UK general population, from 1995-2015. We analyzed data from adults (≥ 20 years) free of RA and MI after at least 1 year of enrollment in the THIN database. Follow-up began with first recording of smoking status after the 1-year enrollment and ended at the time of MI, death, loss of follow-up, or the end of the study period, whichever came first. We assessed the effect of smoking on MI using Cox regression in the general population, and restricting on incident RA patients. We conducted a sensitivity analysis to correct for the bias from U, by varying the prevalence of U and its association with MI. Analyses were adjusted for baseline confounders.

Results: Of ~3.7 million subjects (mean age 46 years; 55% women; 28% current-smokers and 19% ex-smokers), 16,061 developed incident RA of which 296 had incident MI. The adjusted hazard ratio (HR) for current smoking and MI among RA patients was 1.56 (95%CI: 1.15, 2.12), whereas the corresponding HR in the general population was 2.42 (95%CI: 2.37, 2.48) (**Table**). On the additive scale, the adjusted rate difference was 1.1 among RA patients, and 2.2 in the general population. For the biased HR of 1.6, the corrected HR estimate ranged from 1.60-2.57 when the prevalence of U was set to 6% among smokers, with the prevalence of U ranging from 20-30% in nonsmokers, and the association between U and MI ranging from 2.0-4.0 **(Figure)**.

Conclusion: We demonstrated that conditioning on RA can bias the association between smoking and MI toward the null, and provided a method to partly correct for this paradox. Since this bias could considerably mislead the conclusion about the contribution of modifiable risk factors to important clinical outcomes, investigators should consider appropriate design and analytic approaches to avoid such biases.

Session Title: ARHP III: Epidemiology and Public Health

Session Type: ARHP Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Low socioeconomic status (SES) is associated with an increased risk of death as well as knee and/or hip osteoarthritis (OA). SES and mortality has rarely been examined in individuals with OA. We therefore sought to explore whether SES at baseline was associated with death before follow-up assessments among those with knee and/or hip OA.

Methods: The association between SES and all-cause death over 25 years was explored in the Johnston County Osteoarthritis Project. We used baseline data from 1,333 individuals aged ≥45 who entered the cohort between 1990-1997 and who had known vital status at all three follow-up periods. Participants had radiographically confirmed knee and/or hip OA at baseline clinical assessment, defined as a Kellgren-Lawrence grade ≥2. Vital status was assessed at 3 follow up points (F1: 1999-2004; F2: 2006-2010, F3: 2013-2015), and deaths were identified through participant provided contacts and obituaries. SES measures at baseline included indicators for high school (HS) education (<HS diploma *vs.* ≥HS diploma), block group poverty (BGP) (≥20% *vs.* <20%), homeownership (own their home *vs.* not), and annual household income (<$30K *vs.* ≥$30K). Multilevel logistic regression models controlling for the primary sampling unit were used to estimate odds ratios (OR) and 95% confidence intervals (CI) for the association between individual SES measures at baseline and whether a death occurred separately for each follow-up point. All models were adjusted for baseline age, race, sex, cohort, education, BMI, use of an assistive walking device, history of smoking, stroke, diabetes, heart disease, high blood pressure and depression, plus additional adjustment for other SES measures.

Results: Mean age at baseline was 65.4 years, with 61.8% women and one-third African American. There were 49.0% with <HS education, 43.9% lived in areas with ≥20% BGP, 28.7% did not own their home and 82.6% had a household income <$30K. There were 234 deaths which had occurred before the F1 assessment (18.1%), 528 deaths before F2 (41.1%) and 680 deaths before F3 (52.9%). Those with <HS education had an increased odds of death that appeared to gain strength at subsequent follow up points (Table 1). By F3, those with <HS education had a 50% increased odds of death (OR=1.52; 95% CI=1.06-2.17). Although failing to reach statistical significance, we observed a similarly elevated OR for BGP ≥20% at each subsequent timepoint.

Conclusion: Among individuals with knee and/or hip OA, low education is associated with death, where odds of death seems to increase at subsequent follow-up periods. Results were independent of comorbidities and sociodemographic measures commonly linked to increased mortality, although lack of time-to-death and cause of death are limitations. Results suggest that those with low education may need more intensive guidance regarding self-management from clinicians.

Session Title: ARHP III: Epidemiology and Public Health

Session Type: ARHP Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Sleep is an important physiological process responsible for regulating several metabolic and hormonal processes; hence, poor sleep may negatively impact health. Reduced sleep duration and restless sleep (i.e., low sleep efficiency) has been related to a higher risk of cardiovascular disease (CVD) in the general population. Individuals with RA commonly report poor sleep quality, and also have greater CVD risk than their healthy counterparts. However, the relationship between sleep quality and CVD risk in RA is not clear. Thus, the aim of the study was to assess associations between objectively measured sleep quality (duration and efficiency) and CVD risk factors in RA.

Methods: This was a secondary, cross-sectional analysis of baseline data from two studies in persons diagnosed with RA based on the ACR classification criteria. Sleep duration and efficiency were measured using a multi-sensor activity monitor, the Sensewear Armband (Bodymedia, Pittsburgh), which has been validated against polysomnography as an accurate measure of sleep duration and efficiency. Sleep efficiency is expressed as a ratio of actual sleep time to lying down time. Subjects wore the monitor for 7 days and average daily sleep duration and efficiency were calculated. Cardiometabolic markers consisted of blood pressure, lipid profile, and insulin resistance measured by homeostatic model of assessment. Demographics, BMI, and disease severity using the DAS-28 were also obtained. Multiple linear regression models were used to determine the association between each cardiometabolic marker and sleep efficiency, and duration after adjusting for age, gender, cohort, BMI and DAS-28 scores.

Results: Complete data for data analysis was available in 89 subjects with RA, (90% female, 58 ± 9 years, BMI 29 ± 7 kg/m^2) who had mild functional limitations (HAQ score 0.8 ± 0.6), moderate disease activity (DAS-28 3.5 ± 1.2), and median RA duration of 15 years. Subjects spent 8.2 ± 1.5 hours lying down and 6.5 ± 1.4 hours in actual sleep, with a sleep efficiency of 80%. Adjusted models demonstrated that greater sleep efficiency significantly associated with lower low-density lipoproteins and higher high-density lipoproteins (p <. 05) (Table). In contrast, sleep duration was not associated with any cardiometabolic markers.

Conclusion: Poor sleep efficiency seems to be more indicative of non-favorable cardiometabolic markers in individuals with RA than sleep duration. Normal circadian rhythms are crucial for regulating several metabolic processes, including lipid metabolism. Hence, it stands to reason that poor sleep efficiency could directly influence certain cardiometabolic markers, independent of body size, and RA severity. Although the current study is limited due to its cross-sectional design, the findings indicate the need to further investigate the influence of sleep quality on CVD risk profile in RA.

TABLE. Associations between Sleep Duration and Efficiency, and Cardiometabolic Markers. Values represent standardized coefficients (β), R^2 change (R2Δ), and p-values from linear regression models.

	Sleep Efficiency			**Sleep Duration**		
Variables	β	$R^2\Delta$	P-value	β	$R^2\Delta$	P-value
Diastolic Blood Pressure, *mmHg*	-.09	.01	.40	.07	.01	.49

Session Title: ARHP III: Epidemiology and Public Health

Session Type: ARHP Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Although there is a higher frequency of adverse maternal outcomes in mother with rheumatoid arthritis, little is known regarding mothers with juvenile idiopathic arthritis (JIA). Our objective was to determine whether women with a history of JIA have more adverse maternal outcomes than mothers who never had JIA.

Methods:

Our cohort study used data from physician billing and hospitalizations covering Québec, Canada. We identified all females with JIA with a first-time birth between 01/01/1983 and 12/31/2010, and assembled a control cohort of first-time mothers without JIA from the same administrative data, matching 4:1 for date of first birth, maternal age and area of residence. We compared maternal outcomes (hypertension, diabetes, preeclampsia/eclampsia) in the JIA versus non-JIA groups, using logistic regression. We adjusted for maternal education, and socioeconomic status (as measured by a geographic deprivation index).

Results:

Mean age at delivery was 24.7 years in the JIA group (n=1681) and 25.0 for the non-JIA group (n=6724). Mothers with JIA were more likely to have hypertension during pregnancy compared with those who did not have JIA (8.5% (95% confidence interval (CI) 7.3,9.9) vs 4.6%, 95% CI 4.2,5.2). The proportion in the JIA group with preeclampsia/eclampsia was 3.8% (95% CI 2.9,4.8)vs 2.8% (95% CI 2.4,3.2) in the non JIA group and the proportion with diabetes during pregnancy was 0.9% (95% CI 0.5,1.5) in the JIA group vs 0.6% in the non JIA group (95% CI 0.4,0.8). Among JIA mothers, 99% who had hypertension during pregnancy also had pre-pregnancy hypertension compared with 57% in the non JIA group. Similarly, 100% who had diabetes during pregnancy had pre-pregnancy diabetes in the JIA group vs. 63% in the non JIA group. In multivariate analyses, women with JIA were more likely to have hypertension during pregnancy (odds ratio (OR) 1.89, 95% confidence interval (CI) 1.55,2.28), but not preeclampsia/eclampsia (OR 1.06, 95% CI 0.80,1.42) compared to control women; the OR for diabetes during pregnancy (1.66, 95% CI 0.91,3.02) was inconclusive. Lower socioeconomic status was associated with all three adverse maternal outcomes in the entire group.

Conclusion:

Mothers with JIA were more likely to have hypertension during pregnancy compared to women without JIA. Further studies would be useful to assess the impact of medications and other factors (e.g. obesity) on maternal outcomes in JIA.

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: ARHP III: Epidemiology and Public Health
Session Type: ARHP Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose:

Osteoarthritis (OA) is a major cause of musculoskeletal pain and disability, and is commonly reported to impair health-related quality of life (HRQoL). We aimed to examine the distribution of clinical OA in the hand-, knee-, and hip joints, and to investigate whether dimensions of HRQoL differ in mono-articular and poly-articular OA.

Methods:

Postal questionnaires regarding musculoskeletal pain, comorbidities and perceived HRQoL, assessed by the 36-item Short Form survey (SF-36), were sent to the general population (n=12.155, response rate 41.1%). Subsequently, those who self-reported OA in the hand-, hip- and/or knee joint(s) (n=1045) were invited to attend a clinical examination. 630 persons attended, of whom 547 participants free of inflammatory rheumatic disease were analyzed. Using the ACR-criteria for clinical OA, the participants were categorized into mono-articular OA (MOA, i.e. OA in one single joint site) or poly-articular OA (POA, i.e. OA in ≥ 2 joint sites) or no clinical OA (NOA). We performed crude and adjusted linear regression analyzes with the OA categories as the independent variable, using NOA as reference category, and the SF-36 eight dimensions as the dependent variable.

Results:

176 participants (32.2%) were categorized into the NOA group, 268 (49%) in the MOA group and 103 (18.8%) in the POA group (mean ± SD age 63.9 ± 8.8 years, 68% women). Clinical hand OA affected 75.5% of the OA population (Figure 1). Participants with POA had higher BMI (mean 29.4 ± 4.9) compared to participants with MOA (27.6 ± 4.7) (p = 0.003). Five out of eight SF-36 subcomponents were significantly poorer in the POA group compared to the NOA group (Figure 2), and remained significant in analyzes adjusted for age, gender, BMI, education and comorbidity: Social Functioning (B = -5.7, 95%CI = -11.2 to -0.1), Vitality (B = -6.7, 95% CI = -11.6 to -1.8), Pain (B = -7.5, 95% CI = -7.5 to -2.7), Physical Role (B = -15.1, 95% CI = -24.7 to -5.5) and Physical Functioning (B = -8.8, 95% CI = -13.6 to -4.0). There were no differences in any of the SF-36 subcomponents between the MOA and NOA groups.

Figure 1:

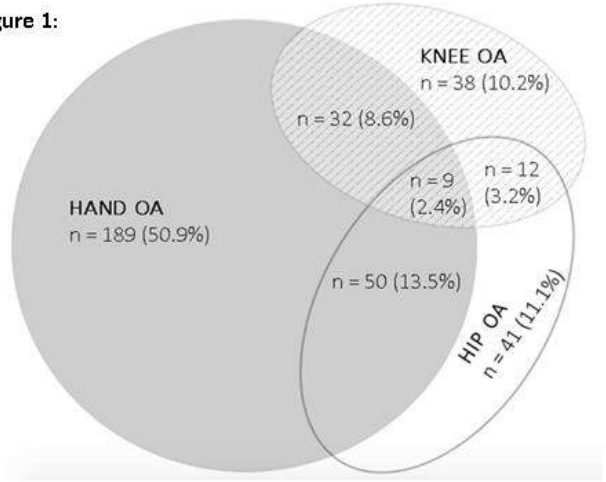

Figure 2:

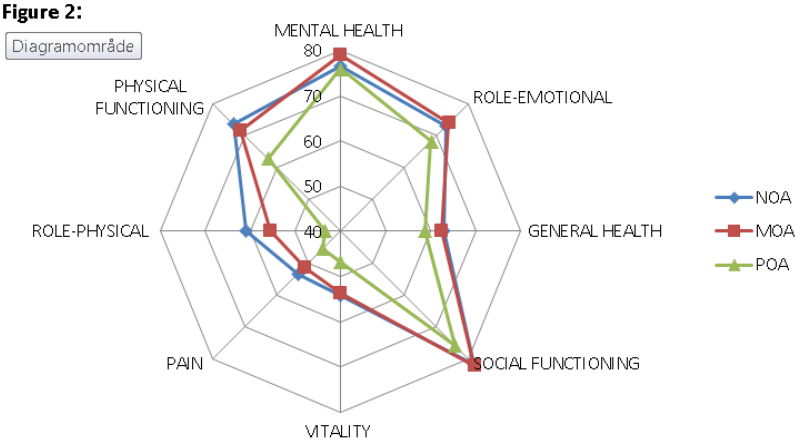

Conclusion:

In a population-based cohort with self-reported OA, approximately one third got the OA diagnosis rejected according to the clinical ACR criteria. MOA, and specifically isolated hand OA without affection of the knees and hips, was the most common localization of clinical OA. POA was less prevalent, but was associated with diminished HRQoL dimensions in terms of poorer vitality, higher pain intensity as well as impaired physical- and social functioning compared to participants without clinical OA.

Impact of Smoking on Patient-Reported Disease Status and Symptoms Among Women with Lupus

Patricia P. Katz[1], Eliza Chakravarty[2], Robert S. Katz[3] and Kaleb Michaud[4], [1]Medicine/Rheumatology, University of California San Francisco, San Francisco, CA, [2]Arthritis and Clinical Immunology, Oklahoma Medical Research Foundation, Oklahoma City, OK, [3]Rush University Medical Center, Chicago, IL, [4]Internal Medicine, University of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: ARHP III: Epidemiology and Public Health

Session Type: ARHP Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Smoking appears to be associated both with an increased risk of rheumatoid arthritis and with more severe symptoms. The impact of smoking on patient-reported disease status and symptoms in lupus has not been reported.

Methods: Data were from the National Data Bank for Rheumatic Diseases (NDB), for which participants complete questionnaires every 6 months. Only women with lupus who responded to at least one of the two most recent completed questionnaires were included (n = 481). Self-reported lupus status was assessed with the Systemic Lupus Activity Questionnaire (SLAQ)[1], the Brief Inventory of Lupus Damage (BILD)[2], global assessment of health status (rating from 0 [doing very well] – 10 [doing very poorly]), and assessment of lupus activity (rating from 0 [not active] – 10 [very active]). Patient-reported symptoms were assessments of pain, fatigue, and sleep problems, each rated 0 – 10 with higher ratings reflecting worse symptoms, and depressive symptoms assessed with the PHQ-8. Bivariate and multivariate linear regression analyses estimated the relationship of current and former smoking on outcomes. Multivariate analyses controlled for age, low education, Medicaid or no health insurance, number of rheumatology visits, duration of lupus, obesity, Rheumatic Disease Comorbidity Index (RDCI)[3], and prednisone use.

Results: Mean age was 58 ± 13 years, 22% had education ≤ high school, and 15% had Medicaid or no health insurance. Mean disease duration was 21 ± 12 years, 34% were obese, and mean score on the RDCI was 2.7 ± 1.8. Means of each lupus status and symptom measure are shown in the Table. Six percent were current smokers, 31% were former smokers, and 63% had never smoked. In unadjusted analyses, current smokers had significantly worse scores than never smokers on all measures except the BILD (Table), and former smokers had worse scores on the SLAQ and ratings of lupus activity. After adjustment, the elevated scores of current smokers compared with never smokers remained for all measures except the BILD.

Conclusion: While current smoking was not common, it was associated with significantly worse patient assessments of lupus status and worse symptoms. Findings underscore the importance of assessing smoking and supporting smoking cessation efforts among women with lupus.

Session Date: Tuesday, November 10, 2015

Session Title: Antiphospholipid Syndrome: Basic Science

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Antiphospholipid syndrome (APS) is a systemic autoimmune disease characterized by recurrent thrombotic events, pregnancy complications, and the presence of antiphospholipid antibodies. The pathogenesis of primary APS is incompletely understood. We aimed to investigate the role of neutrophils in primary APS.

Methods: We studied 19 patients with primary APS and 19 healthy controls matched for age, sex, and ethnicity. Neutrophils were extracted from peripheral blood samples using density gradient centrifugation followed by flow cytometry to confirm neutrophil purity. A comprehensive transcriptome analysis was performed using paired-end 100bp mRNA sequencing reads generated on an Illumina HiSeq 2000 instrument. A genome-wide DNA methylation analysis was performed using Infinium HumanMethylation450 BeadChip arrays. RNA sequencing data were normalized and analyzed following quality control assessment and filtering using EdgeR software package in the R programming environment. Differential gene expression between patients and controls was defined using a fold difference of >2 and a false discovery rate <0.01. DNA methylation analysis was performed using GenomeStudio (Illumina) and differentially methylated loci between patients and controls were identified using an absolute methylation difference of at least 10% and a P value <0.01 after correction for multiple testing. Bioinformatics analysis was performed using the Database for Annotation, Visualization, and Integrated Discovery (DAVID), and Ingenuity Pathway Analysis.

Results: RNA sequencing analysis identified 593 overexpressed and 769 underexpressed genes in neutrophils from primary APS patients compared to age, sex, and ethnicity matched healthy controls. Neutrophils in primary APS are characterized by a pro-inflammatory phenotype defined by prominent transcriptional overexpression of interferon-regulated genes such as IFIT1 (8-fold), IFIT3 (5-fold), IFI6 (5-fold), MX1 (5-fold), HERC5 (5-fold), IFIT2 (5-fold), and ISG15 (4-fold), among many others. Neutrophils from primary APS patients are also characterized by activation of the Toll-like receptor signaling pathway with overexpression of TLR4, TLR5, and TLR8 (2-3 folds). In addition, neutrophils from patients overexpressed several Fc-gamma receptors including FCGR1A, FCGR1B, FCGR2A, FCGR3A, and FCGR3B (2.5-3.5 folds). P-selectin glycoprotein ligand-1 (PSGL-1) and L-selectin (CD62L), which play an important role in neutrophil adhesion to the vessel wall and neutrophil degranulation, were both also overexpressed in primary APS neutrophils. DNA methylation analysis in neutrophils from primary APS suggests an epigenetic architecture that is unique and very distinct from lupus neutrophils. Indeed, DNA methylation profiles in a small number of specific CG sites are very sensitive and specific to stratify patients with primary APS versus lupus with an area under the ROC curve of ≥0.90.

Conclusion: Neutrophils in patients with primary APS are activated and likely play an important role in disease pathogenesis. Further, the DNA methylation signature in primary APS neutrophils suggests a unique epigenetic architecture that is distinctly dissimilar from lupus.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Antiphospholipid Syndrome: Basic Science

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Antiphospholipid Syndrome (APS) is an autoimmune disease characterized by antiphospholipid antibodies (aPL) associated with thrombosis and/or pregnancy morbidity. Although initially described in patients with systemic lupus erythematosus (SLE) it can occur in patients with no autoimmune disease. The standard treatment for thrombotic APS is anticoagulation with vitamin K antagonists. The prothrombin time (PT) and its corresponding INR (International English Normatized ratio) is the laboratory test used to target anticoagulation. Because inadequate anticoagulation therapy may be hazardous, a strict monitoring is needed. The CoaguCheck XS is a simple and prompt device that allows INR monitoring providing the result in seconds. Despite studies comparing CoaguCheck XS and PT analysis presented favorable correlation, there are scarce studies evaluating the use of CoaguCheck in APS patients. Purpose: Evaluate accuracy of CoaguCheck XS in APS patients, comparing it with standard method for plasma prothrombin time (PT). Furthermore, we analyzed other clinical and laboratorial features to check if they could interfere with CoaguCheck results.

Methods: This is a single center cross-sectional study with 94 APS patients from a rheumatology clinic tertiary hospital included from august 2014 to march 2015. All patients fulfilled APS Sydney´s criteria and all APS associated with SLE fulfilled ACR SLE criteria. The comparison of Coagucheck XS results versus standard laboratory practice for monitoring anticoagulant therapy was evaluated using the coefficient of determination (r) followed by the Bland-Altman test. Paired T test was also applied.

Results: The comparison between INR values from 94 patients measured with CoaguCheck XS and the standard PT resulted in a coefficient of correlation (r) of 0.95. The mean INR (S.D.) was 2.94 (1.41) with CoaguCheck XS and 2.43 (0.86) with standard PT. Dividing the INR values in into four ranges (INR < 2, INR 2-3, INR 3-4 and INR>4) we found that INR>4 group presented a poor correlation (r=0.64) compared to the other ranges ($p<0.05$). Although CoaguChek XS and standard PT are highly correlated, the INR values were not equal. In general CoacuCheck shows higher values than the standard PT test, with an average of 0.42 ± 0.54. Therefore we propose a simple linear regression model in order to predict the PT standard values using values obtained from CoaguChek. The model showed a R^2 of 87%, indicating a good quality of forecast, for INR<2.5. None of the clinical or laboratory variables evaluated interfered with CoaguCheck results. There was no difference in testing performance in primary APS and APS associated with SLE patients.

Conclusion: CoaguCheck XS is a simple and acceptable way of monitoring anticoagulation in APS patients presenting a good correlation with standard PT test if INR is <4. These results corfim previous reports from anticoagulated patients with no antiphospholipid syndrome.

The Ability of Recombinant Domain I of Beta-2-Glycoprotein I to Inhibit Lupus Anticoagulant Effect of IgG from Patients with APS Is Enhanced By Pegylation

Session Date: Tuesday, November 10, 2015

Session Title: Antiphospholipid Syndrome: Basic Science

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Antiphospholipid Syndrome (APS) is an autoimmune rheumatic disorder in which antiphospholipid antibodies (aPL) cause clinical events including vascular thrombosis (VT) and pregnancy morbidity (PM). In clinical practice aPL are detected by three tests, the anti-cardiolipin and anti-beta-2-glycoprotein I (beta2GPI) ELISAs and the lupus anticoagulant (LA) test. The LA test measures prolongation of clotting time caused by aPL present in the serum of patients. LA positivity is strongly associated with thrombosis and is the strongest predictor of PM in patients with APS. In testing potential efficacy of new therapeutic agents for APS it would therefore be very useful to be able to assay their ability to inhibit the LA effect of polyclonal IgG aPL in samples from patients. Here we describe a novel method for carrying out such tests and its application to testing PEGylated human recombinant domain I (DI) of beta2GPI. Recombinant DI has previously been shown to block binding and pro-thrombotic properties of purified IgG antibodies from patients with APS. PEGylation (chemical addition of polyethylene glycol) can increase half-life and reduce immunogenicity of small molecules, enhancing their potential for development as therapeutic agents.

Methods:

We used a Sysmex-CA coagulometer with a dRVVT Plus kit. The principle of the assay is that the sample to be tested is allowed to clot either in the presence or absence of a reagent containing excess phospholipid (two step test). aPL that cause an LA effect prolong clotting time in the LA sensitive test (LS) but not in the LA resistant test (LR) containing excess phospholipid. Thus the ratio of LS to LR clotting time is a measure of LA effect. We purified IgG from serum of patients with APS (n=4, all fulfilling Sydney criteria and known to be LA-positive) and added it to normal human plasma at a concentration of 500mcg/ml. These samples were then tested in the coagulometer assay either with or without pre-incubation with DI alone or DI PEGylated with three different sizes of PEG (20kDa, 30kDa and 40kDa).

Results:

The figure shows results for all four patients individually. In each case, purified IgG in the absence of inhibitor gave LS/LR ratio > 1.1, showing an LA effect. For all patients, addition of PEGylated DI reduced the LA effect on LS/LR ratio and the effect of PEGylated DI was greater than the effect of non-PEGylated DI in 3 out of 4 cases. This finding is particularly interesting because PEGylation generally reduces biological effects of small molecules. PEG alone has minimal effect.

Conclusion:

Using this assay, we demonstrated that it is possible to test ability of a putative therapeutic agent for APS to inhibit the LA effect. PEGylation of DI did not reduce its ability to inhibit the LA effect of IgG purified from patients with APS but actually increased inhibition. This finding may be beneficial in development of PEG-DI as a therapeutic.

Session Date: Tuesday, November 10, 2015

Session Title: Antiphospholipid Syndrome: Basic Science

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Antiphospholipid Syndrome (APS) is an autoimmune rheumatic disorder in which antiphospholipid antibodies (aPL) cause clinical events including vascular thrombosis (VT) and pregnancy morbidity (PM). The key antigen in APS is beta-2-glycoprotein I (beta2GPI), which consists of five domains. The N-terminal domain (DI) carries the main immunodominant epitope. We previously showed that recombinant human DI blocks binding of serum IgG from patients with APS (APS-IgG) to whole beta2GPI in ELISA and inhibits thrombosis induced by APS-IgG in a mouse model. A modified variant containing two point mutations (DI(D8S,D9G)) was a stronger inhibitor than wild-type DI. Small molecules such as DI require modification to make them viable as therapeutic agents. Chemical addition of polyethylene glycol (PEGylation) is one such modification , which increases half-life and reduces immunogenicity. Conversely, PEGylation can also reduce binding to ligands/receptors and biological activity. Larger PEG sizes may enhance half-life more but reduce activity more. Therefore, we investigated whether PEGylated DI of various sizes retain the ability to inhibit beta2GPI -binding of serum IgG and IgA from patients with APS.

Methods:

DI was expressed in E.Coli and PEGylated on its disulphide bonds. Three different PEGylated variants carrying 20kDa, 30 kDa and 40 kDa PEG were produced as well as non-PEGylated DI. Serum samples from four patients with APS, all fulfilling the Sydney classification criteria, were tested in an inhibition ELISA. This ELISA tests for binding of IgG or IgA to beta2GPI in the presence or absence of 100mcg/ml inhibitor. **Results** are expressed as the retained binding in presence of each inhibitor compared to binding with no inhibitor (defined as 100%).

Results:

Figure 1 shows results for IgG. All PEGylated and non-PEGylated variants of DI significantly inhibit binding to beta2GPI by between 43-55% ($P<0.05$). Figure 2 shows results for IgA. All PEGylated and non-PEGylated variants of DI significantly inhibit binding to beta2GPI by between 40-55% ($P<0.005$). There were no significant differences between results for the different DI variants, showing that PEGylation does not alter inhibitory capacity of DI in this binding assay.

Similarly we showed that DI (D8S,D9G) carrying 20kDa PEG inhibits binding to beta2GPI of serum IgG ($P<0.01$) and IgA ($P<0.005$) from patients with APS. PEG alone shows <10% inhibition.

Conclusion:

PEGylation of DI and DI (D8S,D9G) allows retention of their ability to inhibit binding of both IgG and IgA from APS patients to beta2GPI, an important step in potential development as a therapeutic agent.

Session Date: Tuesday, November 10, 2015

Session Title: Antiphospholipid Syndrome: Basic Science

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

β_2GPI represents the major antigenic target for antiphospholipid antibodies (aPL), the hallmark of antiphospholipid syndrome (APS). β_2GPI contains five homologous domains, with domain I (DI) being identified as the main antigenic epitope for pathogenic anti-β_2GPI. Antibodies targeting β_2GPI-DI (anti-DI) represent a key pathogenic sub-population of aPL, thus their detection may allow the identification of patients at highest clinical risk. It has been reported that β_2GPI *in vivo* exists in two interconvertible biochemical redox dependent configurations. The reduced form has a circular configuration maintained by interaction between the first and fifth domain thus potentially hiding the epitope on DI, whilst the oxidised protein has an open and linear shape in which the DI is exposed. It is known that the proportion of β_2GPI in the oxidised form is elevated in patients with APS. Thus, one hypothesis is that the oxidative state of β_2GPI might alter the exposure of neo-epitopes on DI thus providing an antigenic drive for anti-DI antibodies production. In this study we investigated the association between circulating oxidised form of β_2GPI and presence of anti-DI in APS patients.

Methods:

Serum samples from 44 patients who fulfilled the revised classification criteria for APS were tested (38 primary and 6 secondary APS). The samples were screened for IgG anti-DI, anti-β_2GPI and anti-cardiolipin (anti-CL). A sandwich ELISA for quantifying total β_2GPI levels within serum was performed for all samples. Biochemically reduced β_2GPI was detected via labelling free thiols within serum proteins with a biotinylated free-thiol binding reagent and then, via coating on a streptavidin plate, detecting

the presence of labelled β_2GPI with an anti-β_2GPI antibody, based on published methods. For the *in vivo* studies, male Sprague Dawley rats were injected intravenously with 1 mg of IgG purified pooled from 4 healthy individuals or 2 APS anti-DI positive patients (n=6 rats per IgG pool). Blood samples were collected 24-hour after IgG injection and assayed for reduced β_2GPI.

Results:

A negative correlation was found between the reduced proportion of β_2GPI and IgG anti-DI levels (Spearman r = -0.535, p = 0.0002). Furthermore, the proportion of reduced β_2GPI was lower in anti-DI positive than anti-DI negative APS patients (p = 0.0178). The relative amount of reduced β_2GPI was no different between patients who were positive or negative for anti-β_2GPI (p=0.757) or anti-CL (p=0.062). The reduced proportion of β_2GPI was no different within serum samples collected from healthy rats injected with purified anti-DI positive IgG from APS patients versus healthy controls (p=1.000).

Conclusion:

This study demonstrates that IgG anti-DI are strongly associated with the oxidative state of β_2GPI as compared to anti-CL and anti-β_2GPI antibodies. Furthermore, the *in vivo* injection of APS derived IgG did not affect the redox state of β_2GPI in the experimental rat-model employed. Though not proof, this study further supports the hypothesis that epitope exposure on DI of β_2GPI defined by the redox state of the protein might affect the antigenic drive of pathogenic anti-DI antibodies.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Antiphospholipid Syndrome: Basic Science

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

The spectrum of the vascular pathology affecting SLE patients with secondary antiphospholipid syndrome includes vasculopathy with endothelial cell hyperplasia as in APS nephropathy. Previous studies established a role for endothelial cell activation via the mammalian target of rapamycin (mTORC) but were limited to IgG fractions of primary APS patients. We extend this finding by studying SLE patients with secondary APS and demonstrate that this activity resides in both IgG and IgA fractions.

Methods:

Endothelial cell phenotypes were assessed using an immunofluorescent assay to report the mTORC biomarker, phospho-S6 ribosomal protein (S6RP) using the human microvascular cell line (serum starved HMEC1 with β2GP1 pretreatment) in the presence and absence of purified human IgG, IgGFab2, and IgA with or without LY294002, a mTORC inhibitor (5 min). We studied 8 SLE patients with secondary APS (mean age 46.8 ± .3, 89% female and 67% white), 4 disease controls that were either

SLE without APS or asymptomatic Ro+, and 3 controls. Purified IgG and IgA fractions were used as follows: SLE patients 4 IgG and IgA, 3 IgG and I IgA; 4 diseases controls 4 IgG and 2 IgA; and controls 2 IgG and 1 IgA. Immunofluorescence (IgG TRITC and Hoechst 33342) was reported using both intensity (1-3+) and a staining scale reflecting % positive cells (3 fields) with 1, <10%; 2, 10-30%; 3, 40-50%; and 4 >50%.

Results:

The phenotype of the endothelial cells which were co-incubated with the IgG fractions of 3 (of 8) patients were diffusely positive for phospho-S6RP (i.e. 3+ intensity, >3 on the scale of % positive cells), which was attenuated by co-incubation with LY294002 (1+, 1 % positive cells). Moreover, endothelial cells co-incubated with Fab2 subfraction retained the diffuse stain for phospho-6SRP. In addition, treatment of endothelial cells with IgA fractions from the same individuals resulted in an increase of phosphorylation of S6RP, suggesting the importance of both IgG and IgA APS isotypes. The patient with the greatest intensity and highest staining with both IgG and IgA fraction is triple and full house positive (eg positive for LAC as well as very high titer IgG, IgA and IgM ACA and β2GPI). For the total group of 8 SLE patients with APS antibodies however, there were no associations with APS titers and the ability to elicit the biomarker in HMEC1. The expression of phospho- S6RP by HMEC1 were within the ranges reported for no treatment (1+, <3 to report % positive cells) for IgG fractions isolated from disease controls, healthy controls, and IgG Fab2 from a disease control and a control IgA.

Conclusion:

These data support the novel finding that both IgG and IgA fractions from SLE patients with secondary APS activate endothelial cells via the mTORC pathway as demonstrated by S6RP phosphorylation.

Session Date: Tuesday, November 10, 2015

Session Title: Antiphospholipid Syndrome: Basic Science

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Systemic Lupus Erythematosus (SLE) patients display high levels of the cell-bound complement activation factor C4d deposits on erythrocytes, B lymphocytes and platelets. In particular, complement activation on platelets has been suggested to play a crucial role in the pathogenesis of thrombosis in SLE, especially in aPL positive patients. Several in vitro and in vivo studies have demonstrated an increased C4d deposition on platelets, that have been associated with stroke or other thrombotic complications in SLE.

Recently, the addition of purified anti-cardiolipin antibodies from Antiphospholipid antibody syndrome (APS) patients has been

demonstrated to increase C4d deposition on activated fixed platelets.

Thrombosis is an hallmark of APS and both platelets and complement have been suggested to be involved in the pathogenic pathways. However few data on complement activation and C4d deposition on platelets in Primary APS patients have been reported in the literature. Aim of the study was to evaluate C4d deposition on platelets, erythrocytes and B lymphocytes of Primary APS patients (PAPS) in comparison to aPL neg SLE patients and healthy donors (NHS).

Methods:

11 active SLE (SLEDAI 3-14) and 18 PAPS patients attending our Rheumatology Unit were consecutively enrolled. C4d deposition on platelets, erythrocytes and B lymphocytes was assessed by flow cytometry, using an anti-human C4d monoclonal antibody associated with specific lineage markers. **Results** were expressed as C4d positive cell percentage, mean and Standard Error Mean. Statistical analysis was performed by Mann Whitney test with significant limit $p<0.05$.

Results:

The proportion of C4d positive cells was higher in PAPS than SLE in all cell populations, with statistical significance for B cells ($p=0.005$) (fig 1). Comparing PAPS vs NHS, significant differences were detected for all cell types ($p<0.005$), while only erythrocytes C4d deposits were significantly higher in SLE patients than in NHS.

Conclusion:

we show for the first time that PAPS patients display higher levels of cell bound C4d in comparison to both NHS and SLE. These in vivo data suggest that: i) complement is activated in PAPS in spite of normal C3/C4 plasma levels: ii) increased complement activation on platelets may play a role in causing thrombocytopenia in PAPS. The increased C4d deposition on B lymphocytes deserves further investigation. As a whole our finding does suggest that cell-bound complement split products may represent a potential tool to characterize APS clinical subtypes.

Session Title: Antiphospholipid Syndrome: Basic Science
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Antiphospholipid syndrome (APS) is a multisystemic autoimmune disease characterized by recurrent thrombotic and adverse obstetric events in the presence of antiphospholipid antibodies (aPL). Compelling data indicate a key role for aPL-mediated induction of tissue factor (TF) expression in monocytes and endothelial cells in the pathogenesis of APS. Recent in-vivo data from our group utlizing low TF producing mice demonstrated the importance of TF in aPL-mediated thrombosis. There is however limited in-vivo data demonstrating the source of TF in the vessel wall in thrombosis resulting from aPL activity.

The aim of this study was to determine the major sources of TF expression in the arterial wall of mice subjected to passive aPL administration.

Methods:

CD1 male mice (n=5 per group) were inoculated with either purified whole IgG from an APS patient (IgG-APS) with high IgG aPL and documented aterial and venous thrombosis or with whole IgG from normal human serum (IgG-NHS). Antibodies were purified from serum using diethylaminoethanol (DEAE) sepharose and adjusted to the appropriate concentration in phosphate buffered saline and any endotoxin present was removed by a commercially available column (Thermo Scientific). Mice were treated with the IgG solutions twice intraperitoneally, the second inoculation given 48 hours after the first, and surgery to measure thrombus dynamics of thrombi induced by a standardized pinch injury to the femoral vein and to collect the aorta was done 72 hours after first inoculation. Staining for TF in the aortic wall was performed by immunohistochemistry using an anti-TF primary antibody, an Alexa-Fluor 586 conjugated secondary antibody and 4',6-diamidino-2-phenylindole(DAPI) counterstain on formalin fixed and paraffin embedded aorta specimens.

Results:

The mean thrombus size was significantly larger in IgG-APS treated mice (1747.4±362.6 um^2) compared to those given IgG-NHS (613.6±127.3um^2) ($p<0.001$). Staining for TF in the aortic wall of IgG-NHS mice revealed minimal staining in the media and moderately more intense staining in the adventitia. In IgG-APS treated mice, there was consistently intense TF staining in the adventitia and moderate staining in the media, noticeably greater than that seen in NHS treated mice.

Conclusion:

In this mouse model, IgG aPL induced significantly larger thrombi than control IgG and was associated with a noticeable increase in adventitial and medial TF, with the adventitia being the major source. Further study is needed to determine the specific cellular sources of TF important in aPL-mediated thrombosis.

Increased Risk of Livedo Reticularis Associated with Antiphospholipid Antibodies in Patients with Systemic Lupus Erythematosus: A Systematic Review and Meta-Analysis

Ersilia M. DeFilippis[1], Denis Wahl[2] and Stephane Zuily[2], [1]Department of Medicine, Brigham and Women's Hospital, Boston, MA, [2]CHU de Nancy, Vascular Medicine Division and Regional Competence Center For Rare Vascular And Systemic Autoimmune Diseases, Nancy, F-54000, France; Inserm, UMR_S 1116, Nancy, F-54000, France; Université de Lorraine, Nancy, F-54000, France, Nancy, France

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Antiphospholipid Syndrome: Clinical

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose : Livedo reticularis (LR) is present in patients with systemic lupus erythematosus (SLE), and the role of antiphospholipid antibodies (aPL) is controversial. Therefore our objective was to estimate the risk of LR associated with aPL in patients with SLE.

Methods : Studies were selected if they investigated the association between aPL and LR in SLE patients and if aPL-negative patients were included for comparison. Data sources were Pubmed, Embase, Cochrane Library, hand search, congress abstracts, and reference lists of studies, without language restrictions. Risk estimates were independently extracted by 2 investigators. Pooled effect estimates were obtained by using the Mantel-Haenszel method (random effects).

Results: Of 919 identified abstracts, 28 primary studies (4 cohorts, 5 case-control, 19 cross-sectional) met inclusion criteria, including 3413 SLE patients according to ACR criteria and 564 cases of LR. Prevalence of LR in aPL-positive vs. aPL-negative SLE patients was 26.5% (n=320/1207) vs. 11.1% (n=244/2206), respectively. Compared with SLE patients without LR, the overall pooled odds ratios (OR) for LR in aPL-positive SLE patients was 3.36 (95% confidence interval [CI], 2.49-4.55) (Figure 1). The risk of LR was the highest for lupus anticoagulant (LA) (5 studies, OR=4.65 [95% CI, 2.35-9.20]), anti-β_2-glycoprotein I antibodies (3 studies, OR=3.40 [95% CI, 1.53-7.52] and IgG anticardiolipin antibodies (aCL) (7 studies, OR=3.26 [95% CI, 2.18-4.88]) while IgM aCL (3 studies, OR = 1.66 [95% CI, 0.97-2.85]), anti-β_2-glycoprotein I IgM antibodies (1 study, OR 2.12 [95% CI, 0.65,6.94]) and anti-β_2-glycoprotein I IgG antibodies (2 studies, OR 2.90 [95% CI, 0.65,12.92]) did not reach statistical significance.

Conclusion : In SLE patients, aPL-positivity is associated with a significant 3- to 4-fold increased risk for livedo reticularis. These findings a) confirm that an aPL-related small vessel involvement can contribute to LR in SLE patients and b) suggest that LR could be associated with aPL in SLE patients.

Session Date: Tuesday, November 10, 2015

Session Title: Antiphospholipid Syndrome: Clinical

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

It is well known that anti-phospholipid antibodies (aPL) are associated with an increased risk of arterial and venous thrombosis and pregnancy loss/morbidity. However, anticoagulation of aPL positive individuals is not routine due to risk of bleeding complications. The adjusted global anti-phospholipid syndrome score (aGAPSS) takes into consideration both criteria aPL and conventional cardiovascular risk factors to predict both thrombotic and pregnancy morbidity risk and may better identify patients who need more aggressive monitoring or therapy. The aGAPSS has not been evaluated in ethnically diverse subjects. This study describes the clinical relevance of aGAPSS in a Chinese APS cohort.

Methods:

This study included 98 consecutive patients who attended the rheumatology clinic at People's Hospital of Beijing University Health Science Center. All patients fulfilled the 2006 revised APS criteria. The criteria aPL profiles [anticardiolipin (aCL), anti-β2glycoproteinI (anti-β2GPI) and lupus anticoagulant (LA)] were assessed with an in-house assay. Hypertension was classified based on 8thJoint National Committee (JNC-8) guideline. Hyperlipidemia was defined as fasting total cholesterol >200 mg/dl. aGAPSS was calculated for each patient by adding points corresponding to the risk factors previously reported by Bertolaccini (3 points for hyperlipidemia, 1 point for hypertension, 5 points for aCL IgG/IgM, 4 points for anti-B2GPI IgG/IgM, 4 points for LA). Pearson Chi-squared or Fisher's exact test univariate analysis with two tailed P value was used to evaluate correlation between aGAPSS and clinical manifestations.

Results:

Patients with APS showed a baseline aGAPSS of 8.5+/-3.3 (Mean +/- SD, range 4-16). Primary and secondary APS patients showed aGAPSS of 8.0+/- 3.4 (range 4 -14) and 8.7 +/- 3.3 (range 4-16) respectively. There is no statistical difference in aGAPSS between primary and secondary patients, p=0.3021. No difference in aGAPSS was observed between male 8.6 +/- 3.2, (range 4-14) and female 8.5+/-3.4, (range 4-16) APS patients, p=0.86. Higher aGAPSS values were seen in patients who experienced thrombosis 9.4 +/- 3.2, (range 4-16) compared to those with pregnancy morbidity 6.7 +/- 2.8, (range 4 -14), p=0.0001. Patients who experienced both thrombosis and pregnancy morbidity showed higher mean aGAPSS when compared to those with pregnancy morbidity alone, but it was not statistically different, p= 0.087. There is no difference in aGAPSS score among patients who experienced thrombotic recurrence [8.7+/- 3.6, (range 4-14)] compared to those without recurrence [9.7 +/- 3.0, (range 4 – 16)], p= 0.19.

Conclusion:

All patients with APS clinical manifestations had an elevated aGAPSS. Higher aGAPSS were seen in patients who experienced thrombosis than those with only pregnancy morbidities. Previously reported differences in aGAPSS among patients with recurrent thrombosis and patients with a single thromboembolic event were not observed in this cohort of Chinese APS patients. aGAPSS may be a potential quantitative tool for APS related clinical manifestations. However, further clinical examination and validation in a large multicenter and multi-ethnicity cohort with control is warranted.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Antiphospholipid Syndrome: Clinical

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The relevance of non-criteria clinical manifestations of antiphospholipid syndrome (APS) has been less studied than its thrombotic and obstetric features. The aim of this study was to evaluate the relationship of APS non-criteria clinical manifestations with antiphospholipid antibodies and damage accrual.

Methods: We retrospectively included 176 patients with APS according to Sydney or Alarcon-Segovia's criteria. We registered demographics, antiphospholipid antibody profile, use of prednisone and immunosuppresors, thrombotic and obstetric

manifestations as well as the following so-called non-criteria clinical manifestations: cutaneous (livedo reticularis, skin ulceration,) hematological (thrombocytopenia, hemolytic anemia), renal (microangiopathy, proteinuria or renal impairment), heart valve disease, and neurological (chorea, migraine, seizures and myelitis). We scored a modified SLICC index where we also included the variables racemous livedo, adrenal insufficiency, placing of Greenfield filter and sclerosis multiple-like disease. We used descriptive statistics and logistic regression and reported OR with 95% CI.

Results: Seventy-eight percent of our patients were women with a mean age of 43.1 ± 14.7 years and median follow-up of 6.7 years. We observed thrombosis in 73%, obstetric features in 20% and 64% had non-criteria clinical manifestations (not exclusive groups). 73 patients (41.4%) had both thrombosis and a non-criteria clinical manifestation (10 concomitant, 42 post-thrombotic and 21 pre-thrombosis).The frequency of the non-criteria clinical manifestation were: hematological 64%, cutaneous 33%, neurological 27%, cardiological 8.2% and renal 6.4%. The univariate analysis showed that the prevalence of LA was higher in the non-criteria clinical manifestation group (53.2% vs. 69.5%, p=0.03). This group also used more prednisone (35.8% vs.1%, <0.0001) and immunosupressors (48.6% vs. 0%, p <0.0001) and had a higher SLICC modified score SLICC (1.69±1.9 vs. 1.1±1.5, p=0.04). Most of the weight of the SLICC score was attributed to the neurologic, pulmonar and peripheral vascular domains. The variables associated with a modified SLICC ≥ 1 were thrombosis (OR 11.5; IC 95% 4.43-30.1; P≤ 0.0001), livedo reticularis (OR 5.45; IC 95% 1.49-19.8; P=0.01) and obstetric features (OR 0.30; IC 95% 0.12-0.7; P=0.01).

Conclusion: The APS non-criteria clinical manifestations are frequent, can precede or follow thrombosis and are associated with LA. Damage accrual was mainly associated with thrombotic events followed by lived reticularis.

Session Date: Tuesday, November 10, 2015

Session Title: Antiphospholipid Syndrome: Clinical

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

The presence of aPL has been associated with pregnancy complications, but the evolution of aPL titers during pregnancy in aPL-positive patients and the utility of repeated testing during pregnancy are unclear. The primary objective of the study was to evaluate whether titers of aCL and anti-β2 Glycoprotein-1 antibodies (aβ2GP1) vary during pregnancy. The second objective was

to determine if aPL variation was associated with pregnancy outcomes.

Methods:

Data were collected from the aPL-positive patients included in PROMISSE Study, a multicenter, prospective, observational study of pregnancy outcome in women with aPL and/or SLE. Demographic and clinical data were collected at screening and patients followed monthly until delivery. aPL were tested in a core laboratory at screening [<18 weeks of gestation (WG)], 2nd trimester (20-23 WG), 3rd trimester (32-35 WG) and 12 weeks post partum (PP). Patients were considered aPL-positive if aCL and/or aβ2GP1 was ³ 40IU IgG or IgM and/or LA was positive in two determinations with at least one during pregnancy. Adverse pregnancy outcome (APO) was defined as one or more of the following: fetal death after 12 WG; neonatal death; delivery prior to 36 WG due to preeclampsia or placental insufficiency; or SGA<5th percentile.

Results:

One hundred and fifty-eight patients fulfilled inclusion criteria. Mean age was 31.9 ± 4.6 years, 84% were white, 57% had clinical APS, and 36% had SLE. During pregnancy, 28% were treated with hydroxychloroquinine, 11% steroids, 66% heparin, and 71% aspirin. At screening, 58% were IgG aCL positive, 18% IgM aCL positive, 30% aβ2GP1 IgG positive, 15% IgM aβ2GP1 positive, and 52% were LA positive. APO occurred in 30% of the patients.

Description of mean aPL titer variation is shown Figure 1. aPL IgG titers decreased through pregnancy, and the mean aCL IgG titer was significantly lower during 2nd and 3rd trimesters compared to screening, but remained in the high positive range. Mean aβ2GP1 IgG titer was significantly lower during 3rd trimester. 80% of APO occurred during the 2nd trimester when IgG titers began to fall. No significant variation in aCL or aβ2GP1 IgM was observed through pregnancy, and titers remained low.

Of note, aPL IgG titers, as well as magnitude of change in titer over the course of pregnancy, were comparable between the patients with or without APO.

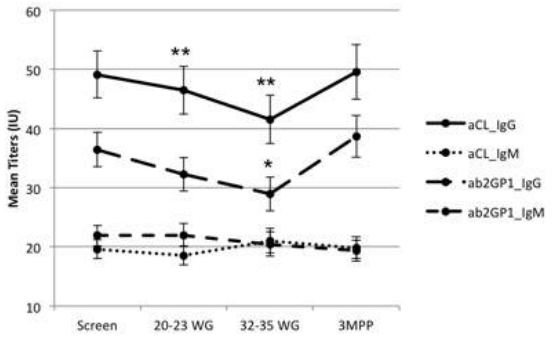

Figure1: Variation in aPL titers through pregnancy in 158 aPL-positive PROMISSE patients. Values represent mean ± SEM. Paired T-Test *p<0.05 **p<0.001 compared to mean value at screening. ab2GP1: anti-β2 Glycoprotein 1 antibodies; WG: Weeks of Gestation.

Conclusion:

In a large, prospective cohort of aPL-positive pregnant women, aCL and aβ2GP1 IgG titers decreased modestly in the course of pregnancy. Potential mechanisms for this decrease include dilutional effect, targeting of aPL to placenta, or decreased autoantibody production. Changes were modest, not clinically meaningful, and not associated with pregnancy outcomes. Our findings suggest that it is not necessary to repeat aPL testing through pregnancy.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Antiphospholipid Syndrome: Clinical
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: With good management, around 70% of pregnant women with Antiphospholipid Syndrome (APS) will deliver a viable live infant.However, current management does not prevent all maternal, foetal and neonatal complications of APS. This observational, retrospective, single-centre cohort study aimed to assess pregnancy outcome in women with antiphospholipid antibody(aPL) treated with hydroxychloroquine (HCQ) in addition to conventional treatment during pregnancy.

Methods: One-hundred and seventy pregnancies in 96 women with persistent aPL were analysed:51 pregnancies occurred in 31 women treated with HCQ for at least six months prior to pregnancy and continued throughout gestation(group A);119 pregnancies occurred in 65 women with aPL not treated with HCQ were included as controls (group B).

Results: HCQ-treatment was associated with a higher rate of live births (67%groupA vs. 57% group B,p=0.05)and a lower prevalence of aPL-related pregnancy morbidity (47% group A vs. 63% B,p=0.004).The association of HCQ with the absence of any complication in pregnancy was confirmed after multivariate analysis (OR 2.2;95%CI 1.2-136;p=0.04). Fetal losses>10thweeks of gestation(2% vs. 11%,p=0.05)and placenta mediated complications (2% vs 11%,p=0.05)were less frequent in group A than B.Pregnancy duration was longer in group A than B(27.6 [6-40] vs. 21.5[6-40] weeks,p=0.03).There was a higher rate of spontaneous vaginal labour in HCQ-treated women compared to group B(37.3% vs. 14.3%,p=0.01).

Conclusion: Despite the heterogeneity in the two groups in terms of SLE prevalence and previous pregnancy history, our results support the concept that women with aPL may benefit from treatment with HCQ during pregnancy to improve pregnancy outcome.The addition of HCQ to conventional treatment is worthy of further assessment.

Anti-Phosholipid Antibodies and Female Infertility: A Systematic Revision of Literature

Cecilia B. Chighizola[1], Guilherme Ramires de Jesus[2] and W. David Branch[3], [1]Department of Clinical Sciences and Community Health, University of Milan, Istituto Auxologico Italiano, Cusano Milanino, Italy, [2]Department of Obstetrics, Universidade do Estado do Rio de Janeiro, Rio de Janeiro, Brazil, [3]Obstetrics and Gynecology, University of Utah and Intermountain Healthcare, Salt Lake City, UT
First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Antiphospholipid Syndrome: Clinical
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Infertility is a common condition, affecting 8-12% of couples in childbearing age. Even though the association of aPL with infertility is highly debated, infertile women are commonly screened for anti-phospholipid antibodies (aPL). Therefore, the aim of this work was to accurately review available evidence.

Methods:

A systematic PubMed search was conducted to retrieve papers addressing the: i) association between aPL positivity and infertility, ii) positivity rate of criteria and non criteria aPL in infertile women and iii) association between aPL positivity and ART outcome. aPL positivity rates in infertile women and controls were calculated as median (25-75 percentiles); differences in aPL positivity rate between patients and controls were evaluated by Wilcoxon matched-pair test. The strength of association between aPL positivity and both infertility and outcome of assisted reproduction technologies (ART) were expressed as the rate of studies confirming a positive association.

Results:

A total of 39 papers were considered in this critical analysis. There was a wide heterogeneity in the selection of study and control populations; only 10% of the studies presented a prospective design. aPL cut-offs conforming to international guidelines were used in less than 25% of studies; aPL positivity was confirmed in 11% of studies. Approximately half of the considered studies assessed non criteria aPL tests. i) According to our best estimates, the overall positivity rate of criteria aPL tests is 6% (2-8.9) among infertile women and 1% (0-2.15) among controls. Non criteria aPL tests were estimated to be positive in 3% (1.5-9) of study women and in 2% (1-7) of controls. **Table 1** reports the calculated frequencies of each of the considered tests in patients and controls. A significant difference in the positivity rate of patients versus controls emerged for anti-cardiolipin antibodies (aCL) only ($p<0.00001$, 95% CI 3.35-8.50). ii) The association rates between each aPL test and infertility are detailed in **Table 2**. iii) Only 5 of the relevant 18 studies (27.7%) reported a detrimental effect of aPL on ART outcome. Of these studies, 4 assayed only criteria aPL tests and one aCL plus non-criteria aPL tests.

Conclusion:

According to our literature revision, aPL are more frequently detected among infertile women than controls; conversely, the association between aPL and ART outcome is not supported by most studies. Data inconsistencies might be ascribed to the lack of a true association or to literature limitations; well-designed studies are warranted to produce strong evidence-based recommendations.

Table 1

aPL test	Number of studies	Number of patients/controls	Positivity rate (patients)	Positivity rate (controls)
Lupus anticoagulant	9	90 (56-137)/ 100 (80-201)	0% (0-2.5)	0% (0-0)

Antiphospholipid Antibodies and the Risk of Damage Accrual in Systemic Lupus Erythematosus

Mara Taraborelli[1], Laura Leuenberger[2], Maria Grazia Lazzaroni[3], Nicole Martinazzi[3], Wei Zhang[4], Jane E. Salmon[2], Franco Franceschini[1], Angela Tincani[3] and Doruk Erkan[2], [1]Rheumatology and Clinical Immunology, Spedali Civili of Brescia, Brescia, Italy, [2]Rheumatology, Hospital for Special Surgery, New York, NY, [3]Rheumatology and Clinical Immunology, Spedali Civili and University of Brescia, Brescia, Italy, [4]Healthcare Research Institute, Hospital for Special Surgery, New York, NY
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Antiphospholipid Syndrome: Clinical
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: A limited number of studies evaluated **t**he impact of antiphospholipid antibodies (aPL) on organ damage in Systemic Lupus Erythematosus (SLE) with contrasting conclusions. The aim of this study was to assess the relative contribution of a significant aPL positivity to organ damage in SLE patients.

Methods: SLE patients (based on American College of Rheumatology [ACR] Classification Criteria) with less than 10 years of disease duration at registry entry and at least 5 years of follow-up were identified from the SLE registry of 2 centers. Clinical information retrieved included: demographics, disease duration at registry entry, organ damage assessed by the Systemic Lupus International Collaborating Clinics/ACR Damage Index (SDI), and aPL profile. A "clinically significant" aPL profile was defined as: positive lupus anticoagulant test, anticardiolipin antibody IgG/M $\geq$ 40U, and/or anti-β_2Glycoprotein-I IgG/M $\geq$ 99thpercentile on two or more occasions, at least 12 weeks apart, within ± 1 year of registry entry. The outcome variables were any increase of SDI at 5, 10 and/or 15 years of follow-up (time 0 was defined as registry entry). For univariate analysis the demographic and clinical characteristics of patients with and without a SDI increase at 5, 10 and 15 years were compared (Chi square or Fisher's exact test for categorical data, Student t test or Mann-Whitney for continuous data as appropriate). The Generalized Estimated Equations (GEE) model was used as multivariate analysis to detect significant factors for increased SDI at 5, 10 and/or 15 years.

Results: We identified 262 patients with less than 10 years of disease duration, at least 5 years of prospective follow-up and a complete aPL profile (76% Caucasian, 8% African-American, 6% Asian, and 86% female). Mean age at diagnosis was 31 years (±12) and mean age at registry entry was 33 years (±12) with a mean disease duration of 1 year (±2). Eighty-eight (33%) patients had a clinically significant aPL profile. Twenty-one percent, 42%, and 57% of patients had new organ damage in 5, 10, and 15 years, respectively. On the univariate analysis: a) a significant aPL profile (p:0.02) and a older age at diagnosis (p:0.04) were significantly associated to any increase of SDI at 5 years; b) a shorter disease duration was significantly associated to any increase of SDI at 10 years (p:0.003) and 15 years (p:0.008); and c) male gender showed a tendency for any increase of SDI at 15 years without reaching significance (p:0.054). The GEE model showed that patients with a significant aPL profile (p:0.006,Odds Ratio, [OR]:1.9, 95% Confidence Interval,[CI]:1.2-3.1), older age at diagnosis (p:0.007, OR: 1.02, 95%CI 0.006-0.04) or male sex (p:0.017,OR: 1.9,95%CI 1.1-3.3) were more likely to experience an increase of SDI during the follow-up.

Conclusion: Our data demonstrate that: a) one-third of SLE patients have clinically significant aPL profiles; b) 21%, 42% and 57% of SLE patients have new organ damage in 5, 10 and 15 years; c) clinically significant aPL-profiles, older age at diagnosis, and male sex are associated with an increased risk of organ damage accrual during a fifteen year follow-up.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Antiphospholipid Syndrome: Clinical
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: APS ACTION "Registry" was created to study the natural course of disease over 10 years in persistently antiphospholipid antibody (aPL)-positive patients with/without other systemic autoimmune diseases. Given that risk-stratified prospective data on the first or recurrent thrombosis risk in persistently aPL-positive patients are limited and controversial, our objective was to describe the thrombotic events identified during the follow-up of APS ACTION "Registry" patients, and also to determine the one-year first and recurrent thrombosis risk.

Methods: A web-based data capture system is used to store patient demographics, aPL-related history, and medications. The inclusion criteria are positive aPL (lupus anticoagulant test [LA], anticardiolipin antibody [aCL], and/or anti-β_2Glycoprotein-I antibody [aβ_2GPI]) based on the Updated Sapporo Classification Criteria at least twice within one year prior to enrollment. Patients are followed every 12±3 months with clinical data and blood collection; they also receive advice on cardiovascular disease and thrombosis prevention at each visit. In this descriptive analysis, patients who completed their one year follow-up visits are included.

Results: Of 581 patients included in the APS ACTION Registry, 350 (60%) completed their one year follow-up visits as of June 2015 (aPL/APS without any other autoimmune disease: 241 [no thrombosis: 35; thrombotic APS: 148; obstetric APS: 24; and thrombotic & obstetric APS: 34]; and aPL/APS associated with another autoimmune disease: 109 [no thrombosis: 45; thrombotic APS: 42; obstetric APS: 10; and thrombotic & obstetric APS: 12]). Table demonstrates the demographic, clinical, and laboratory characteristics of patients who had new events during the one year follow-up. Based on five new thrombotic events, the incident thrombosis risk was 1.7% and 0% per year in patients with and without history of thrombosis, respectively.

Baseline Data				One Year Follow-Up Data		
Age*/Sex/ Race	Other AIDx	aPL Profile	APS Manifestations	Recurrent Event**	aPL-related Medications*	Concomitant Thrombosis Risk Factors
18 /M/W	No	Triple aPL	DVT/PE	DVT/PE (13m)	Warfarin x 13m (INR: 2.1*)	None
46/F/A	SLE	LA, aCL	Stroke, TP, aPLN	Stroke (14m)	Cilostazol x 11m	HL, HTN, RF, Immob/postSx
47/F/UK	No	Triple aPL	DVT/PE, Critical Ischemia (lower limb), TP	DVT (arm) with IJVT (21m)	Statin Warfarin x 23m (INR<2)	Malignancy, Immob/postSx, HTN, DM, HL, Obesity, Vascular Procedure
47/F/W	SLE	Triple aPL	Stroke, DVT, Obs. APS, TP, AIHA	Stroke (180m)	Self-stopped 3m prior	PFO, RF, HL, FMHx CVD
55/F/W	No	Triple aPL	DVT	DVT (47m)	ASA x 20m	Long Flight - FMHx CVD

* At the time of the recurrent event
** The duration between the last thrombotic and recurrent event is listed in parenthesis

AIHA: autoimmune hemolytic anemia; **AIDx:** autoimmune disease; **aPLN:** aPL nephropathy; **ASA:** aspirin; **CVD:** cardiovascular disease; **DM:** diabetes mellitus; **DVT:** deep vein thrombosis; **F:** female; **HL:** Hyperlipidemia; **HTN:** hypertension; **IJVT:** internal jugular vein thrombosis; **Immob/Sx:** immobilization & postsurgical; **INR:** international randomization ratio: **M:** male; **Obs:** obstetric; **PE:** pulmonary embolism; **PFO:** patent foremen ovale; **RF:** renal failure defined as GFR < 60 ml/min; **SLE:** systemic lupus erythematosus; **TP:** thrombocytopenia defined as < 100.000/mm^3; **UK**: Unknown (unable to record due to country regulations).

Conclusion: The one year incident thrombosis risk is relatively low and commonly associated with triple aPL-positivity as well as non-aPL thrombosis risk factors in our multi-center international cohort. Annual and risk stratified analysis of APS ACTION registry will better determine the risk of thrombosis in persistently aPL-positive patients based on different risk profiles.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Antiphospholipid Syndrome: Clinical

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: APS ACTION International Clinical Database and Repository was created to study the natural course of disease over 10 years in persistently aPL-positive patients with/without other systemic autoimmune diseases. The protocol involves testing for anticardiolipin antibodies (aCL) and anti-β2glycoprotein I antibodies (aβ2GPI) at five different international core laboratories in samples collected at multiple sites. Although all core laboratories use the same ELISA kits, APS ACTION core laboratory directors agreed that an exchange of samples to assess intra- and inter-laboratory variability is crucial to establish whether an acceptable agreement among the core labs can be achieved. As part of the this validation exercise, two different assays were used.

We designed this study to assess between-laboratory agreement obtained with a novel antiphospholipid (aPL) chemiluminescence immunoassay (CIA), and compare the results to those obtained with ELISA assays.

Methods: Blinded serum samples from aPL positive patients and controls (n=30) were distributed to the five APS ACTION core laboratories. All samples were tested for IgG, IgM and IgA aCL and aβ2GPI with the FDA cleared QUANTA Flash® CIA and QUANTA Lite® ELISA kits (Inova Diagnostics). For every sample, the average, SD and %CV of the values were calculated. Between laboratory precision was considered acceptable if %CV was less than 20%.

Results: Categorical agreement between the two methods was 100%, 97% and 77% for IgG, IgM and IgA aCL, respectively, and 87%, 93% and 77% for IgG, IgM and IgA aβ2GPI, respectively. The correlation between quantitative results was good (Spearman rho 0.917, 0.809 and 0.893 for IgG, IgM and IgA aCL, respectively; rho 0.938, 0.766 and 0.78 for IgG, IgM and IgA anti-β2GPI. All p values <0.0001). Only CIA met the <20% total CV acceptance criteria for all the samples with all the assays. %CV was higher for ELISA and, in some cases, well outside the acceptable range (Table).

	aCL		aβ2GPI	
	CIA	ELISA	CIA	ELISA
IgG	11% [0%-19%]	22% [7%-36%]	7% [0%-20%]	22% [8%-38%]
IgM	7% [4%-8%]	45% [30%-68%]	9% [4%-16%]	15% [3%-22%]
IgA	8% [3%-13%]	34% [25%-43%]	10% [4%-18%]	34% [4%-53%]

Conclusion: IgG and IgM aCL and aβ2GPI results showed good agreement between CIA and ELISA. Agreement was lower for IgA assays due to borderline samples being positive for CIA (a very sensitive test) and negative for the ELISA. Based on the evaluations performed in the APS ACTION Core Laboratories**,** CIA and ELISA tests displayed substantially equivalent performance for the detection of aCL and aβ2GPI. QUANTA Flash® CIA, a fully automated assay, however, showed higher level of reproducibility, making inter-laboratory comparisons more reliable.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Antiphospholipid Syndrome: Clinical

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose : Renal lesions have been described in patients with antiphospholipid antibodies (aPL), however their associations with aPL are inconsistent among studies. Therefore our objective was to investigate associations between aPL and renal lesions among SLE patients.

Methods : Studies were selected if they determined the association between aPL and acute (thrombotic microangiopathy including “glomerular thrombosis” and “intra-renal thrombosis”) and/or chronic (e.g. fibrous intimal hyperplasia, focal cortical atrophy) vascular renal lesions in SLE patients and if aPL-negative patients were included for comparison. Data sources were Pubmed,

Embase, Cochrane Library, hand search, congress abstracts, and reference lists of studies, without language restrictions. Risk estimates were independently extracted by 2 investigators. Pooled effect estimates were obtained by using the Mantel-Haenszel method (random effects).

Results: Of 1820 identified records, 25 published studies and 1 abstract (5 cohorts, 5 case-control, 16 cross-sectional) met inclusion criteria, including 2128 SLE patients according to ACR criteria and 482 cases of renal lesions. Prevalence of renal lesions in aPL-positive vs. aPL-negative SLE patients was 31.9% (n=243/761) vs. 17.5% (n=239/1367), respectively. Compared with SLE patients without renal lesions, the overall pooled odds ratios (OR) for renal lesions in aPL-positive SLE patients was 2.85 (95% confidence interval [CI], 1.88-4.32) (Figure 1). The risk of renal lesions was the highest for lupus anticoagulant (LA) (9 studies, OR=4.70 [95% CI, 2.36-9.36]) and IgG anticardiolipin antibodies (aCL) (4 studies, OR=3.13 [95% CI, 1.09-8.98]) while IgM aCL (2 studies, OR=1.51 [95% CI, 0.03-88.59]) and anti-β_2-glycoprotein I antibodies (aβ_2GPI) (4 studies, OR=1.66 [95% CI, 0.54-5.11] did not reach statistical significance. Furthermore, among all aPL assays, LA was the only test to be significantly associated with both acute (4 studies, OR=2.89 [95% CI, 1.10-7.60]) and chronic renal lesions (2 studies, OR for LA=3.56 [95% CI, 1.05-12.08]).

Conclusion : In SLE patients, aPL-positivity is associated with a significant 3- to 5-fold increased risk for renal lesions. This risk is mainly driven by LA and IgG aCL. While acute thrombotic renal lesions are known to be associated with aPL, our findings suggest that chronic renal lesions could be associated with aPL but with a lower level of evidence.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Antiphospholipid Syndrome: Clinical

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose : Thrombocytopenia is present in patients with systemic lupus erythematosus (SLE), and the role of antiphospholipid antibodies (aPL) is controversial. Therefore our objective was to estimate the risk of thrombocytopenia associated with aPL in patients with SLE.

Methods : Studies were selected if they investigated the association between aPL and Thrombocytopenia in SLE patients and if aPL-negative patients were included for comparison. Data sources were Pubmed, Embase, Cochrane Library, hand search, congress abstracts, and reference lists of studies, without language restrictions. Risk estimates were independently extracted by 2 investigators. Pooled effect estimates were obtained by using the Mantel-Haenszel method (random effects).

Results: Of 2530 identified abstracts, 83 primary studies and 2 abstracts (24 cohorts, 18 case-control, 43 cross-sectional) met inclusion criteria, including 11877 SLE patients according to ACR criteria and 2399 cases of thrombocytopenia. Prevalence of thrombocytopenia in aPL-positive vs. aPL-negative SLE patients was 30.5% (n=1261/4128) vs. 14.7% (n=1138/7749), respectively. Compared with SLE patients without thrombocytopenia, the overall pooled odds ratios (OR) for thrombocytopenia in aPL-positive SLE patients was 2.76 (95% confidence interval [CI], 2.39-3.20) (Figure 1). The risk of thrombocytopenia was the highest for lupus anticoagulant (LA) (25 studies, OR=3.43 [95% CI, 2.59-4.54]). Risk of thrombocytopenia was also significantly increased in SLE patients with either IgG or IgM anticardiolipin antibodies (aCL) (27 studies, OR= 1.97 [95% CI, 1.58-2.44]; 17 studies, OR= 1.68 [95% CI, 1.34-2.12], respectively) and IgG or IgM anti-β_2-glycoprotein I antibodies (5 studies, OR=2.04 [95% CI, 1.22-3.41]; 3 studies, OR=2.68 [95% CI, 1.44-4.99], respectively). Finally, while high titers aCL were associated with an increased risk of thrombocytopenia (3 studies, OR=3.86 [95% CI, 1.05-14.23]), low titers aCL did not reach statistical significance (2 studies, OR= 0.56 [95% CI, 0.12-2.64]).

Conclusion : In SLE patients, aPL-positivity is associated with a significant 2- to 4-fold increased risk for thrombocytopenia. These findings a) confirm that an aPL-related mechanism can contribute to thrombocytopenia in SLE patients and b) suggest that thrombocytopenia could be associated with aPL in SLE patients.

Title: Increased Risk of Hemolytic Anemia Associated With Antiphospholipid Antibodies in Patients With Systemic Lupus Erythematosus: A Systematic Review and Meta-Analysis.

Background/Purpose : Hemolytic anemia (HA) is present in patients with systemic lupus erythematosus (SLE), and the role of antiphospholipid antibodies (aPL) is controversial. Therefore our objective was to estimate the risk of HA associated with aPL in patients with SLE.

Methods : Studies were selected if they investigated the association between aPL and HA in SLE patients and if aPL-negative patients were included for comparison. Data sources were Pubmed, Embase, Cochrane Library, hand search, congress abstracts, and reference lists of studies, without language restrictions. Risk estimates were independently extracted by 2 investigators. Pooled effect estimates were obtained by using the Mantel-Haenszel method (random effects).

Results: Of 1992 identified abstracts, 38 primary studies and 1 abstract (16 cohorts, 4 case-control, 19 cross-sectional) met inclusion criteria, including 7967 SLE patients according to ACR criteria and 974 cases of HA. Prevalence of HA in aPL-positive vs. aPL-negative SLE patients was 22.4 % (n=488/2177) vs. 8.4% (n=486/5790), respectively. Compared with SLE patients without HA, the overall pooled odds ratios (OR) for HA in aPL-positive SLE patients was 3.22 (95% confidence interval [CI], 2.40-4.32) (Figure 1). Of note, in studies explicitly reporting a positive Coombs test, the risk of HA was significantly increased (10 studies, OR=3.17 [95% CI, 1.93-5.20]). The risk of HA was the highest for lupus anticoagulant (LA) (12 studies, OR=4.58 [95% CI, 2.62-8.04]) and IgG anti-β_2-glycoprotein I antibodies (4 studies, OR=3.95 [95% CI, 1.46-10.71]). Risk of HA was also significantly increased in SLE patients with either IgG or IgM anticardiolipin antibodies (aCL) (10 studies, OR=2.27 [95% CI, 1.71-3.00]; 12 studies, OR=2.89 [95% CI, 2.16-3.87], respectively) and IgM anti-β_2-glycoprotein I antibodies (3 studies, OR=3.00 [95% CI, 1.48-6.07]).

Conclusion : In SLE patients, aPL-positivity is associated with a significant 2- to 4-fold increased risk for HA. These findings a) confirm that an aPL-related mechanism can contribute to HA in SLE patients and b) suggest that HA could be associated with aPL in SLE patients.

Anticoagulation and Longterm Outcomes in Patients with Renal Artery Stenosis and Antiphospholipid Syndrome

Alina Casian[1], Shirish Sangle (joint 1st author)[2], Sotiria Manoustathopoulou[3] and David P. D'Cruz[4], [1]Louise Coote Lupus Unit, Guy's and St Thomas' Hospital, London, UK, London, United Kingdom, [2]Louise Coote Lupus Unit, Guy's and St. Thomas' Hospital, London, United Kingdom, [3]Department of Medicine, St. Thomas' Hospital, London, United Kingdom, [4]Louise Coote Lupus Unit, Guy's and St Thomas' Hospital, London, United Kingdom

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Antiphospholipid Syndrome: Clinical

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Our previous data showed renal artery stenosis (RAS) is more prevalent in antiphospholipid syndrome(APS)(26%) compared to the general hypertensive population(8%),and anticoagulation with INR>=3 was associated with initial reduction of chronic kidney disease(CKD) and hypertension.

Methods: We identified 37 patients with RAS and APS fulfilling Sapporo criteria: anticardiolipin IgG/IgM titer>40 units or >99thpercentile (or +lupus anticoagulant) on >=2 occasions >=6 weeks apart AND vascular thrombosis(or pregnancy morbidity). RAS was diagnosed by magnetic resonance angiography(MRA).

Results: 15 patients had APS alone and 22 APS associated with autoimmune conditions (13 lupus, 5 ANCA vasculitis, 4 mixed). Median age at RAS diagnosis was 48 years, 31/37(83.8%) were female and median follow-up was 10.4 years. 25/37(67.6%) had previous thrombosis. 7/37(18.9%) had bilateral RAS, 3 artery occlusion. 6/37(16.2%) had concurrent coeliac stenosis. Recanalization of RAS occurred after hydroxychloroquine in 3/37 and 9/37(24.3%) underwent angioplasty+/-stenting. MRA was repeated in 11/37(29.7%) after 2 years. 23/37(62.2%) were anticoagulated, with 9/37(24.3%) on antiplatelet therapy. 13/37(35.1%) received hydroxychloroquine, 10/22(45.5%) immunosuppressives and 18/37(48.6%) antihypertensives. 9/37(24.3%) died after a median of 10 years since RAS diagnosis. 21/37(56.8%) developed CKD: 6 endstage renal failure(ESRD) and 15 with median eGFR 39 mls/min.

Patient Group	CKD	ESRD	Death
Anticoagulation(23)	15/23	4/23	5/23
No anticoagulation(14)	6/14	2/14	4/14
p value	0.3	1.0	0.7
APS(15)	7/15	3/15	1/15
APS+autoimmune disease(22)	14/22	3/22	5/22
p	0.3	0.7	0.4
Medical therapy(28)	13/28	3/28	7/28
Angioplasty (9)	8/9	3/9	2/9
p	0.05	0.14	1

Conclusion: The majority of patients with RAS and APS were female, developed CKD and did not benefit from angioplasty. Anticoagulation was not associated with longterm reduction of ESRD or death, suggesting a non-thrombotic pathogenic process underlying RAS, e.g.intimal hyperplasia. Treatment of associated vascular risk factors and underlying autoimmune disease is paramount. Anticardiolipin antibodies and renal MRA are useful for screening hypertensive lupus patients.

Session Title: Antiphospholipid Syndrome: Clinical

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Data on the long-term outcome in primary antiphospholipid syndrome (PAPS) patients (pt) are still very limited.The objectives of this work was to assess the prevalence of recurrences, organ damage, severe comorbidities (infections, hemorrhages, cancers), mortality, evolution in connective tissue disease (CTD), in long-standing PAPS.

Methods:

Medical records of PAPS pt followed in 6 centers for ≥15 years were retrospectively reviewed. Chi square for categorical and Student t test for continuous variables were used. P <0.05 was considered significant.

Results:

One hundred and sixteen pt (88% females) with PAPS followed between 1983 and 2014 with mean age at diagnosis of 33 (±10) and mean follow-up of 19 years (±3.5) were studied. Fifty-one pt (44%) had at least a thrombotic event during follow-up. Thromboses were more frequent in pt with previous thrombotic history (p:0.002,OR:4.8, 95% CI:1.6-14.7) and oral anticoagulant (OA) treatment was not protective against recurrences (p: not significant). Six pt (5%) had a catastrophic event. Fifty-two women had 87 pregnancies, that were successful in 78% of cases. Twenty-nine percent of pt had functional damage (permanent loss of function) in at least one system. Damage was significantly associated to a thrombotic history (p:0.004,OR:13.9,95% CI:1.8-288.4) and to arterial events (p<0.001,OR:7.9, 95% CI:2,7-24,3), but not to any demographical, serological or therapeutical variable. An anatomical damage (documented ischemic lesion) was present in 55% of pt. Twenty-four major bleeding episodes were recorded in 18 pt all on OA. Severe infections (4 bacterial, 2 viral) affected 6 pt (5%). A cancer (solid in 100%) was diagnosed in 8 pt (7%) at a mean age of 51 years (±6). One patient (1%) with a chronic bowel ischemia died for sepsis. Fourteen pt (12%) developed a CTD (7 Systemic Lupus Erythematosus,2 Sjogren, 5 Undifferentiated CTD).Compared to diagnosis at the end of the follow up we observed: less pt with anti-cardiolipin IgG (p:0.014) but more with antinuclear antibodies (p:0.01) and C4 reduction (p:0.025); less using estroprogestinics (p<0.001), more with hypercholesterolemia (p:0.043), hypertension (p:0.004), cancer (p:0.02); more using steroids (p:0.04), hydroxychloroquine (p<0.001), immunosuppressants (p<0.01), anticoagulants (p:0.003), anti-hypertensive drugs (p<0.001).

Conclusion:

Despite therapy, a high proportion of pt experienced new thrombotic events, while pregnancy outcome was significantly improved. Organ damage developed in a significant proportion of pt and was associated with arterial events. The risk of evolution in CTD has to be considered.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Antiphospholipid Syndrome: Clinical
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: We investigated the association between the presence of antiphospholipid antibodies (aPL) and/or lupus anticoagulant (LAC) (aPL/LAC+) and all-cause mortality among end stage renal disease (ESRD) patients with and without SLE. We hypothesized that aPL/LAC+ would be associated with increased cause-mortality in ESRD, with elevated risk in SLE vs. non-SLE ESRD.

Methods: We included patients over 18 years old with ESRD, followed at an urban tertiary care center between 1/1/2006 and 1/31/2014 who had aPL measured at least once after initiating hemodialysis. All SLE patients met ACR/SLICC criteria. APL/LAC+ was defined as anti-cardiolipin IgG or IgM > 40 IU, anti-b2glycoprotein I IgG or IgM > 40 IU, or positive LAC. Age, sex, race, comorbidities, anticoagulation, and potential reasons for aPL measurement were ascertained from the medical records. Deaths through 1/31/2014 were captured in linked National Death Index data. Time to death was defined from the first aPL measurement; otherwise, subjects were censored at renal transplant, last visit date, or 1/31/2014. Kaplan-Meier survival curves and Cox proportional hazards model were used to evaluate the effects of aPL/LAC and SLE status on all-cause mortality.

Results: 34 SLE ESRD and 64 non-SLE ESRD were identified. SLE ESRD patients were younger (40.4±12.5 vs. 51.9±18.1 years, p=0.001) and more were women (88.2% vs. 54.7%, p=0.0007) compared to non-SLE ESRD. The frequency of aPL/LAC+ was 24% in SLE and 13% in non-SLE ESRD (p=0.16). Anticoagulation use was not associated with SLE or mortality. Median (IQR) follow-up time was 1.6 (0.3, 3.5) years in SLE, and 1.4 (0.4, 3.2) years in non-SLE, p=0.74. In total, 30 patients died during the study period. The median (IQR) time to death was 0.3 (0.2, 0.8) years in the aPL/LAC+ group, and 1.2 (0.2, 1.9) years in the aPL/LAC- group, p=0.22. Kaplan-Meier curves stratified by SLE and aPL/LAC status are shown in **Figure**. The survival curve for SLE aPL/LAC+ group was significantly different from the SLE aPL/LAC- group (logrank p=0.001). In Cox regression model adjusted for comorbidities, there was a multiplicative interaction between aPL/LAC and SLE with respect to mortality (p=0.05) indicating the differential effect of aPL/LAC+ in SLE and non-SLE. In SLE, the adjusted hazard ratio (HR) for death for the aPL/LAC+ vs. aPL/LAC- was 9.93 (95%CI 1.33, 74.19). In non-SLE, the adjusted HR (95%CI) for aPL/LAC+ vs. aPL/LAC- was 0.77 (0.14, 4.29).

Conclusion: SLE ESRD patients with aPL/LAC have higher risks of all-cause mortality than do SLE ESRD patients without these antibodies and non-SLE ESRD patients with these antibodies. Future studies will examine causes of death. If confirmed in prospective studies, preventive strategies could target this high risk group.

Figure 2. Kaplan-Meier curves for the 4 groups stratified by SLE and aPL status.

Session Date: Tuesday, November 10, 2015

Session Title: Antiphospholipid Syndrome: Clinical

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Antiphospholipid antibodies (aPL) are risk factors for Adverse Pregnancy Outcome (APO). Risk stratification may include several demographic, clinical and serological variables. Still debated is how to apply risk stratification in the therapeutic strategy to adopt in aPL-patients during pregnancy. Here we review the therapeutic approach to aPL-patients during pregnancy over 30 years of experience (1985 -2015) in our center, focusing on first-line treated pregnancies.

Methods: We collected 131 first-treated pregnancies in 131 persistently aPL-positive women (mean age 32 years) that were prospectively followed in our center by a multispecialistic team of Rheumatologists and Obstetricians. Patients were classified as Primary Antiphospholipid Syndrome (PAPS) according to Updated Sapporo criteria or as Incomplete PAPS or aPL carriers according to their clinical history or aPL status. Patients with concomitant systemic autoimmune diseases were excluded. aPL profile was defined as the combination of the 3 criteria tests for aPL. APO was defined as at least one of the followings: miscarriage (<10^{th} week), fetal death (≥10^{th} week), severe preterm delivery (≤34^{th} week) with or without preeclampsia (PE), HELLP syndrome, and perinatal death.

Results: The type of treatment was divided in 3 main categories: combination of low molecular weight heparin (LMWH) and low dose aspirin (LDA) (75, 57%), monotherapy with LDA (34, 26%) and combination of corticosteroids with LDA (22, 17%; medium prednisone-dosage 76 mg/week).

We analyzed the treatment that patients received according to clinical classification and found that those with a diagnosis according to revised criteria (Obstetric and Thrombotic PAPS) compared to Incomplete PAPS/aPL carriers, were more frequently treated with combination therapy of LMWH+LDA (67% vs.39%, p:0.0025). Regarding to serological profile, the combination therapy of LMWH+LDA was more frequently adopted in patients with a triple positive aPL profile vs. single/double positive ones (32% vs.3%, p:0.0001).

We recorded 17 APO (13%): 12 (71%) in the category of LMWH+LDA. Analyzing APO vs. non-APO pregnancies (Table 1), we found no differences in variables that could predict an APO (history of thrombosis, a previous APO or a triple positive aPL profile) in any of the 3 categories . The only predicting variable for APO in the group of LMWH+LDA was the presence of non-criteria aPL manifestations (50% vs.6%, p:0.0007).

Conclusion: Conventional treatment comprising LMWH was preferentially given to patients with recognized clinical and serological risk factors (definite APS according to criteria, triple aPL positivity). The presence of non-criteria aPL manifestations emerged as a risk factor for APO, suggesting that patients with a more severe disease phenotype may deserve additional treatments targeting aPL immunomodulation.

Session Title: Antiphospholipid Syndrome: Clinical

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: APS ACTION Clinical Database and Repository ("Registry") was created to study the natural course of disease over 10 years in persistently antiphospholipid antibody (aPL)-positive patients with/without other systemic autoimmune diseases. The natural post-partum course of APS patients presenting with pure obstetric APS can be complicated by thrombosis; however, the incidence rate as well as the determinants of thrombosis are not well determined. Therefore, our objective was to compare the clinical and laboratory characteristics of the obstetric APS patients with or without thrombosis.

Methods: A web-based data capture system is used to store patient demographics, aPL-related history, and medications. The inclusion criteria are positive aPL based on the Updated Sapporo Classification Criteria at least twice within one year prior to enrollment. For the purpose of this cross-sectional baseline data analysis, we included obstetric APS patients with or without thrombosis after the initial diagnosis of pregnancy morbidity (PM) . We compared variables using Chi-Square and T-test, or non-parametric tests accordingly.

Results: Of 550 patients included in the registry as of May 2015, 173/419 (41.2%) women had any PM and 126/173 (72.8%) fulfilled the obstetric APS criteria, 74/126 (58.7%) with thrombotic APS (venous: 43; arterial: 22; and both: 9). Thrombosis occurred in 47/74 (63.5%) patients following the obstetric APS diagnosis (mean time between PM and first non-gravid thrombosis: 7.6±8.2 years). Table shows the clinical and laboratory characteristics of patients with pure obstetric APS, compared to those with presenting with obstetric APS followed by non-gravid thrombosis. Patients with obstetric APS only, compared to those with obstetric and thrombotic APS, were more likely to "ever" use aspirin and hydroxychloroquine (data not shown).

Conclusion: The cross sectional analysis of the baseline characteristics of a large scale aPL/APS registry demonstrates that: a) approximately 60% of thrombotic APS patients present initially with pregnancy morbidity; and b) earlier age during the first pregnancy morbidity, selected cardiovascular risk factors and non-criteria aPL manifestations, and lupus anticoagulant test positivity may increase the risk of future thrombosis after an aPL-related pregnancy morbidity.

Session Title: Antiphospholipid Syndrome: Clinical

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

To investigate the beneficial effects of *in vivo*ubiquinol (Q, reduced form of CoQ10) supplementation on athero-thrombosis prevention in APS patients, through the implementation of a prospective, randomized, double-masked, placebo-controlled study.

Methods:

The study was conducted on 20 APS patients randomized to receive either Q (200 mg/day) or placebo for one month. Blood was drawn at time 0 and at the end of the treatment. Studies were performed in plasma and purified leukocytes subsets. Plasma Q levels, various prothrombotic/proinflammatory parameters, and oxidative stress biomarkers were evaluated. Differential expression of miRNAs in monocytes was also determined using Nanostring miRNA arrays and validated by real-time RT-PCR. Ultrastructural evaluation of mitochondria in isolated monocytes was performed by electron microscopy (EM). Endothelial activity analysis was performed by Laser-Doppler measurement of post ischemic reactive hyperemia. Carotid intimae media thickness (CIMT) was measured as an early atherosclerosis marker.

Results:

Seventeen out of 20 patients completed the intervention, which increased significantly plasma Q levels. Endothelial function improved notably, as shown by the amelioration in the highest perfusion value after occlusion was released, expressed as a percentage of change vs rest flow value (RF-PF). Q treatment decreased Tissue Factor (TF), IKK and IL8 protein expression levels in monocytes. A number of other proinflammatory mediators were further reduced in monocytes and neutrophils by effect of Q treatment (VEGF, CCL3, IL-1ß, IL6, and TNFα). Comparing to controls, 57 microRNAs were found significantly altered in APS patients. Among them, 26 were reversed by effect of Q treatment. Functional classification of those miRNAs showed a preponderance of target mRNAs involved in free radical scavenging, inflammatory response, cardiovascular disease, and reproductive system disease. Q supplementation produced a reduction in both the levels of peroxides and the percentage of monocytes with altered mitochondrial membrane potential ($\Delta\Psi m$). EM analyses further indicated that Q treatment promoted an

increase in monocytes' mitochondrial size. Reduced monocyte TF expression after Q treatment was related to decreased peroxides levels, increased plasma Q levels, and improved endothelial function, which further correlated with IL8 levels. Eight out of 11 patients showing atheromatous plaques had also suffered at least one thrombotic recurrence. These pathologic processes were further linked to a poorer endothelial function compared to the remaining APS patients. Q effects were particularly relevant in those APS patients with pathologic CIMT and thrombotic recurrences, who showed a better response to Q treatment with improved endothelial function.

Conclusion:

Q supplementation at 200 mg/d significantly improved endothelial function, and reducedmitochondrial dysfunction, oxidative stress, and the expression of prothrombotic/proinflammatory proteins. Underlying epigenetic mechanisms seem to be involved. Our results support the potential impact of Qin the prevention of atherothrombosis in APS patients.Supported by: CTS-7940, PI12/01511, KANEKA.

Background/Purpose: APS ACTION International Clinical Database and Repository was created to study the natural course of persistently antiphospholipid antibodies (aPL)-positive patients ± autoimmune disorders over 10 years. Cluster analysis (CA) is a data driven method that can group patients in a way that patients in the same group (cluster) are more similar to each other than to those in other groups. Previously, we identified three different clinical phenotypes of aPL-positive patients discriminated by aPL profile, lupus, or cardiovascular (CV) risk factors (Ann Rheum Dis 2015;74(S2):813-4). As a follow-up analysis, our objective was to analyze different clinical phenotypes among female patients with a special focus on obstetric manifestations.

Methods: A secure web-based data capture system is used to store patient demographics, pertinent aPL history, and aPL profile. The inclusion criteria include aPL positivity according to updated Sapporo APS Classification Criteria. CA, using Ward's minimum-variance hierarchical method, was performed on the baseline characteristics; 15 clinical data points were included in the CA to cover a broad spectrum of aPL-positive patients. To identify differences between clusters, ANOVA and χ^2 test of independence were used with adjustment using the Bonferroni correction to identify *predominant* and *discriminant* variables

(Table).

Results: As of June 2015, of 573 aPL-positive patients recruited from 24 centers, 283 were excluded (139 male, 130 without history of pregnancy, and 14 with missing data). Finally, 290 female patients with a history of at least one pregnancy were included. Four main exclusive clusters with different combinations of features were (Table): a) Cluster 1: older female patients with arterial thrombosis and CV risk factors; b) Cluster 2: female patients with pregnancy morbidity only; c) Cluster 3: asymptomatic aPL-positive female patients with aCL/antiβ_2GPI antibodies treated with aspirin; and c) Cluster 4: female patients with venous thrombosis obesity, SLE, lupus anticoagulant, and treated with warfarin.

Conclusion: Our CA identified four different clinical phenotypes of aPL-positive female patients discriminated by pregnancy morbidity, CV risk factors, aPL profile, and lupus. Our results: a) support the heterogeneity of aPL-positive patients; and b) provide a foundation to understand disease mechanisms, create new approaches for APS classification, and ultimately to develop new management approaches.

Table 1

Variables, n (%)	Cluster 1 (n=85)	Cluster 2 (n=69)	Cluster 3 (n=92)	Cluster 4 (n=44)
Demographics

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Antiphospholipid Syndrome: Clinical

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

There is limited data regarding the long-term risk of developing a first-time thrombotic event and prophylactic benefits of aspirin use in asymptomatic aPL-positive carriers. This study was designed to evaluate the long-term risk of thrombosis and the risk factors associated with the development of a first thrombotic event in asymptomatic aPL-positive carriers. We also aimed to assess the preventive effect of aspirin use.

Methods:

One hundred three of 575 patients, who consecutively tested positive in a core laboratory for aCL and/or LA in 2 determinations between 1995 and 2000, were included in a first analysis published in 2008. Patients have been evaluated for thrombosis occurrence and prophylactic benefits of aspirin use during the first study period that ended in 2005. Exclusion criteria included history of previous thrombosis and long-term anticoagulation treatment. In this study, we added data on patient's follow-up during the ten-year period following the first analysis, except for 5 patients who were lost to follow-up. Clinical and biological data were retrospectively collected until time of first thrombotic event or through July 2014 for patients who remained asymptomatic. Survival analyses were performed using Kaplan-Meier method. Cox proportional hazards analysis examined factors associated with thrombosis-free survival.

Results:

Ninety-eight patients were followed during a median follow-up period of 156 months (72-204). Population was composed of 13 men and 85 women. Median age was 40.5 years (28-55). Forty-two had SLE. Sixty-six were treated prophylactically with aspirin. Median treatment duration was 130 months (60-192). At onset, 59 patients had LA, 72 aCL and 39 anti-β2 Glycoprotein 1 antibodies (aβ2GP1) IgG or IgM, 20 were triple positive. At the end of follow-up, 22 were triple positive. A first thrombotic event occurred in 28 patients. The 15-year risk of a first thrombosis was 30%.

The univariate analysis showed that neither gender, SLE status nor biological aPL profile at onset were associated with risk of thrombosis. aCL, LA and aβ2GP1 persistence through follow-up, alone or triple positivity of aPL, were significantly associated with a higher risk of thrombosis. Conversely, aPL disappearance was associated with a lower risk of thrombosis. Despite insignificant association between aspirin prescription at diagnosis and thrombotic risk, a longer period of prescribed aspirin was associated with a lower risk of thrombosis.

In the multivariate analysis, aPL triple positivity persistence through follow-up remained the only predictive factor significantly and independently associated with the risk of thrombosis (HR 2.81; 95% CI: 1.30-6.08, *p=0.009*).

Conclusion:

The risk of developing a first-time thrombosis in asymptomatic aPL-positive carriers is significant and persistent over time. Triple positive-carriers appear to be exposed to a considerable risk of thrombosis and may justify a close follow-up. Prophylactic effects of aspirin against first thrombotic event seem to be attractive but more data are needed.

Session Title: Antiphospholipid Syndrome: Clinical

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Antiphospholipid Syndrome (APS) is an autoimmune rheumatic disorder in which antiphospholipid antibodies (aPL) cause clinical sequelae including vascular events (VE) and pregnancy morbidity (PM). The key antigen in APS is beta-2-glycoprotein I (beta2GPI), which consists of five domains. The N-terminal domain (DI) carries the main immunodominant epitope. Current clinical ELISAs used in APS test for anti-cardiolipin (CL) and anti- beta2GPI antibodies but increasing evidence suggests that anti-DI levels may be more strongly associated with VE and PM. Patients with SLE are often screened using current tests for aPL and up to 40% are positive but the implications of a positive test for future health of the patient are not clear. In this study we retrospectively explored the prevalence of IgG anti-CL, anti-beta2GPI and anti-DI antibodies in stored serum samples that had been collected prospectively within one year of diagnosis in 501 patients with SLE and analysed associations between these serological profiles and clinical outcomes.

Methods:

Samples from 501 patients with SLE, fulfilling revised ACR criteria, had been taken and stored at -20 degrees C within one year of diagnosis. All samples were tested for levels of IgG anti-CL, anti-beta2GPI and anti-DI by ELISA. **Results** were expressed in absorbance units (AU) by comparison with standard positive controls loaded on every plate. A positive test was defined as an AU level > 99th percentile of 100 healthy controls and high positive was defined as double that level. Data on VE (venous or arterial thrombosis or coronary disease) and pregnancy were obtained from medical records and patient interviews. Fisher's exact test was used to analyse statistical associations between particular serological profiles and VE or PM.

Results:

The mean (SD) age of the 501 patients was 30 (12.2) years, 91% were female and 61% white. In the early disease samples, 68 were positive for anti-CL, 24 for anti- beta2GPI and 146 for anti-DI. 30 patients were double-positive for two of these aPL and 9 were triple-positive. Using higher cut-off levels, 31, 6 and 36 were high-positive for anti-CL, anti- beta2GPI and anti-DI respectively. Mean follow-up time post-sample was 12.1 years (max 36 years). Full data on VE and PM were available for 338 and 275 patients respectively. Table 1 shows associations between particular serological profiles and occurrence of VE or PM.

Conclusion:

38% of patients were positive for one or more aPL in early disease but only 15% showed high positivity. Being double or triple-positive was most strongly associated with VE (but not PM) – 40% of the double/triple positive patients suffered VE in the follow-up period. Positivity for anti-beta2GPI was also associated with VE. High positivity for anti-DI showed the strongest association with PM.

Table 1 – Association of different serological profiles in early disease with VE or PM (* signifies statistically significant association<0.05)

aPL profile	P value for association with VE	P value for association with PM
aPL Negative vs. aPL Positive	0.25	0.41
aPL Negative/Single Positive vs. Double/Triple Positive	0.02*	1.00
aPL Negative vs. Single Positive	0.68	0.30
aPL Negative vs. Double Positive	0.09	0.33
aPL Negative vs. Triple Positive	0.04*	0.17
Anti-beta2GPI Negative vs. Anti-beta2GPI Positive	0.02*	0.33
aCL Negative vs. aCL Positive	0.07	0.84
Anti-DI Negative vs. Anti-DI Positive	0.52	0.87
Low aCL Positive vs. High aCL Positive	0.37	0.08
Low Anti-DI Positive vs. High Anti-DI Positive	0.39	0.04*

Session Title: Biology and Pathology of Bone and Joint: Bone Remodeling and Metabolism
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Autophagy and phagocytosis are conserved cellular functions involved in the protein degradation process in immunity. Recently, autophagy-related proteins were shown to regulate osteoclast mediated bone resorption, a critical process in autoimmune diseases such as rheumatoid arthritis. Wdfy3 is a master regulator in selective autophagy for clearing ubiquitinated protein aggregates. In this study, we generated a series Wdfy3 transgenic mice (*Wdfy3*^{lacZ}, and *Wdfy3*^{loxP}) to investigate the function of Wdfy3 in osteoclast development and function.

Methods: Wdfy3 expression in *Wdfy3*^{lacZ} neonatal mice was analyzed by histology and X-gal staining. Bone marrow-derived macrophages from wild type, *Wdfy3*^{lacZ}, and Wdfy3 conditional knockout (*Wdfy3-cKO*) mice (*Wdfy3* $^{loxP/loxP}$*-LysM-Cre*$^{+}$) were differentiated into osteoclasts with macrophage colony-stimulating factor (M-CSF), and receptor activator of NF-κB ligand (RANKL). Wdfy3 expression on osteoclast-like cells was analyzed by X-gal staining and immunohistochemistry. RANKL-induced NF-κB signaling was analyzed by Western blot. Osteoclast-related genes *Ctsk*, *Acp5*, *Mmp9* were measured by qPCR. Osteoclasts were characterized by tartrate-resistant acid phosphatase staining and filamentous actin ring formation assay. Osteoclast function was evaluated by dentin resorption assay.

Results: Our data showed that Wdfy3 is up regulated in osteoclasts in *in vitro* cultures and highly expressed at the growth plate of neonatal mice. Osteoclasts derived from *Wdfy3-cKO*, showed increased osteoclast differentiation and function as evidenced by higher number and enlarged size of TRAP^{+} multinucleated cells. Western blot analysis also revealed up-regulation of TRAF6, enhanced degradation of p-IκBα and increased p-NF-κB p65 in Wdfy3-deficient osteoclasts stimulated with RANKL compared to the control cells. Consistent with these observations Wdfy3 conditional knockout mice also showed an increase in osteoclast-related genes *Ctsk*, *Acp5*, *Mmp9* and an increase of dentine resorption in *in vitro* assays. Importantly, no difference was observed in autophagic flux in Wdfy3 deficient bone marrow-derived macrophages and control cells at basal level or under starvation.

Conclusion: Taken together, our data highlight a novel role for Wdfy3 osteoclast development and function, which can be exploited for the treatment of musculoskeletal diseases.

Tankyrase Regulates Osteoclastogenesis Via SH3BP2 Expression

Tomoyuki Mukai, Shunichi Fujita, Takafumi Mito, Akiko Nagasu, Yumi Sasae, Hiroyasu Hirano and Yoshitaka Morita, Department of Rheumatology, Kawasaki Medical School, Kurashiki, Okayama, Japan

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Biology and Pathology of Bone and Joint: Bone Remodeling and Metabolism
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: SH3BP2, an adaptor protein, is dominantly expressed in immune cells including macrophages and regulates intracellular signaling pathways. Gain-of-function mutations in SH3BP2 cause human genetic disorder cherubism, which is characterized by jaw bone destruction. We have previously reported that SH3BP2 plays an essential role in osteoclastogenesis and controls inflammatory bone destruction in murine arthritis models (Arthritis Rheumatol. 2015, 67(3):656-67; J Bone Miner Res. 2014, 29(12):2618-35). SH3BP2 protein levels are regulated by the degradation process mediated by Tankyrase 1/2. Tankyrase 1/2, poly (ADP ribose)polymerases, has recently been reported to degrade several proteins such as SH3BP2 and beta-

catenin, however the involvement of Tankyrase in osteoclastogenesis is not well clarified. In this study, we investigated the role of Tankyrase in osteoclast differentiation and function.

Methods: Primary murine bone marrow-derived macrophages and murine pre-osteoclastic RAW264.7 cells were treated with either RANKL or TNF in the presence of Tankyrase inhibitors (IWR-1 and XAV-939) and Wnt inhibitors (IWP-2 and C59). SH3BP2 expression levels in the cells were determined by western blotting. Osteoclast differentiation was evaluated by TRAP-positive multinucleated cells (TRAP+ MNCs) formation and osteoclast-associated gene expression. Osteoclastic function was determined by resorption assay. Nuclear localization of NFATc1, a master regulator for osteoclastogenesis, was evaluated by immunofluorescence staining.

Results: SH3BP2 protein levels were elevated in Tankyrase inhibitors-treated cells but not in Wnt inhibitors-treated cells. Tankyrase inhibitors enhanced both RANKL- and TNF-induced TRAP+ MNCs formation and osteoclast-associated genes (Oscar, Acp5, and Ctsk) expression in a concentration-dependent manner. Mineral resorbing activity in response to RANKL was significantly enhanced in Tankyrase inhibitors-treated cells. NFATc1 nuclear localization was significantly induced in the Tankyrase inhibitors-treated cells. The effects of the Tankyase inhibitors on osteoclastogenesis were comparable with the culture of primary bone marrow-derived macrophages from SH3BP2 gain-of-function mouse model (P416R SH3BP2 cherubism mutation knock-in mouse).

Conclusion: These data suggest that inhibition of Tankyrase activity enhances osteoclast differentiation via elevated SH3BP2 expression but not through Wnt pathway. Tankyrase is a novel regulator of osteoclastogenesis, therefore controlling Tankyrase activity could be a therapeutic option for bone destructive disorders including rheumatoid arthritis and osteoporosis.

Inhibition of Dickkopf1 Dampens Anti Osteogenic Effect of Fibroblast-like Synoviocytes

Eiji Sugiyama, Yusuke Yoshida and Satoshi Yamasaki, Department of Clinical Immunology and Rheumatology, Hiroshima University Hospital, Hiroshima, Japan

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Biology and Pathology of Bone and Joint: Bone Remodeling and Metabolism

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Fibroblast-Like Synoviocytes (FLS) play important roles in RA progression. Previous studies have revealed importance of FLS in osteoclast activation, however, the roles of FLS in osteoblast differentiation are not clear. In osteoblast differentiation, Wnt family proteins regulate transcriptions for osteoblast differentiation via stabilization of ß-catenin and TCF activation. It is now known that the Wnt pathway is blocked by several soluble proteins such as Dickkopf1 (DKK1) or Sclerostin (SOST). In this study, we aimed to determine if FLS secrete DKK1 to inhibit Wnt pathway.

Methods: The expressions of DKK1 in synovial tissue were examined by immunohistochemistry. The mRNA and protein expression in cultured FLS were detected by PCR and immuno-precipitation assay, respectively. The concentrations of DKK1 in culture media were measured by ELISA. mRNA expression was quantified by SYBR Green real-time PCR. Activity of Wnt pathway was analyzed by luciferase assay using TCF reporter plasmid that was transfected to U2OS, an osteosarcoma cell line. Anti DKK1 antibodies were used to neutralize DKK1 in FLS culture medium. siRNA was used to knock down the expressions of DKK1 in FLS.

Results: DKK1 is observed in RA synovial tissue. The mRNA and protein expressions of DKK1 in cultured FLS are comparable

to mesenchymal stem cell (MSC), which is a major source of DKK1 in human. TNF clearly induced the DKK1 secretion form FLS, however, IL-1 and IL-6 did not. FLS supernatant inhibited luciferase activities of TCF reporter induced by addition of recombinant human Wnt3a (200ng/mL). The luciferase activities were blocked by addition of anti DKK1 neutralizing antibodies. By using siRNA, we achieved 90% reduction of DKK1 secretion from FLS. As we expected, the supernatant from these siRNA treated FLS exhibited less inhibitory effect on luciferase activities of TCF reporter. Consistent with these data, FLS supernatant inhibited the RUNX2, COL1A1 mRNA expression in MSC.

Conclusion: FLS produce considerable amount of DKK1. Importantly, DKK1 secreted form FLS effectively blocks TCF activity induced by recombinant Wnt3a. Therefore, FLS may inhibit osteoblast differentiation by secreting DKK1, especially in the inflamed joint of RA, because TNF promote DKK1 production. Thus, it is possible that DKK1 inhibition allows Wnt to bind to its receptor for activation of osteoblast to repair bone erosion in RA.

Session Date: Tuesday, November 10, 2015

Session Title: Biology and Pathology of Bone and Joint: Bone Remodeling and Metabolism

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: A body of studies demonstrates the influence of the nervous system on the immune response. We recently described that dopamine, a neurotransmitter of the sympathetic nervous system, is locally produced by synovial fibroblasts of rheumatoid arthritis (RA) patients and influences *in vitro* cytokine release and inflammation. In addition, *in vivo* evidence confirmed the involvement of dopamine receptors (DR) in arthritis, and a subtype of DR was described to be expressed by *in vitro* differentiated human osteoclasts. These studies, together with the clinical evidence of an increased risk of osteoporosis in patients affected by Parkinson's disease, suggest an involvement of dopamine in joint destruction during RA. The aim of this study was therefore not only to investigate the role of the dopamine pathway on bone remodeling in RA patients, but also to unravel new pathways involved in joint destruction.

Methods: Bone tissue was obtained from osteoarthritis (OA, n=5) and RA (n=4) patients during knee joint replacement surgery. Osteoblasts were isolated from the bone spongiosa. Immunohistochemistry of paraffin-embedded bone samples and immunocytochemistry of isolated osteoblasts were performed using antibodies against the five subtypes of DR (D1 to D5). Isolated osteoblasts were treated with specific DR agonists for 24 h or 7 d. IL-6 and IL-8 were quantified after 24 h stimulation by ELISA, and expression of osteoblast activation markers was quantified after 7 d stimulation by real-time PCR. Mann Whitney test was used for statistical data analysis.

Results: Dopamine receptors D1, D3 and D4 could be detected by immunohistochemistry in the bone remodeling zone of RA patients while OA samples did not express these receptors in the bone remodeling zone. Dopamine receptor subtypes D1, D2, D3 and D5 were present on isolated osteoblasts, with stronger expression in RA compared to OA. Stimulation of DR with specific agonists induced a significant dose-dependent increase of IL-6 release in RA compared to the untreated control (D1-like agonist:

+79 ±43%, P<0.005. D2-like agonist: +70 ±49%. n=4), but no significant effects were detectable for OA osteoblasts. IL-8 release was not significantly altered in both, RA and OA osteoblasts. DR activation inhibited mRNA expression of osteocalcin, collagen type I, alkaline phosphatase and osteoprotegerin in RA osteoblasts (up to -10% compared to untreated control, n=2).

Conclusion: Dopamine receptors are upregulated in the bone remodeling zone of RA patients and their activation seems to have proinflammatory effects and to inhibit osteoblast activation. These data suggest an involvement of the dopamine pathway in bone remodeling and joint erosion in RA, and could open future perspectives to target joint destruction.

Session Title: Biology and Pathology of Bone and Joint: Bone Remodeling and Metabolism

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Interleukin-32 (IL-32) has been known to be implicated in the pathogenesis of various inflammatory diseases. Osteoporosis, characterized by low bone density and increases the risk of fracture, was prevalent in systemic inflammatory diseases mediated through the link between chronic inflammation and bone loss. In this study, we try to investigate the effects of IL-32γ in osteoporosis since the role of IL-32 in bone formation as well as bone resorption remains largely unknown.

Methods:

To determine whether IL-32γ affects bone formation, we examined bone volume of transgenic (TG) mice overexpressing IL-32γ by using micro-CT. Ovariectomized mice were used to know the effects of IL-32γ on osteoporosis *in vivo*. In addition, bone formation rate was evaluated by labeling with calcein, a marker of newly formed bone. To elucidate the mechanism of IL-32γ effect on bone metabolism, we measured the levels of Dickkopf-1 (DKK-1), is well-known as having an inhibitory effects on osteoblastogenesis. Further, the concentration of IL-32γ was measured in the peripheral blood from patients with osteoporosis.

Results:

Micro-CT analysis revealed that IL-32γ TG mice had an increased bone volume compared with wild-type (WT) mice. Furthermore, bone loss induced by ovariectomy was substantially attenuated in IL-32γ TG mice compared with that in WT mice. Importantly, IL-32γ TG mice had higher bone formation rate as assessed by the mineral apposition rate compared with WT mice. In addition, the level of DKK-1 was significantly lower in the IL-32γ TG mice than WT mice. Finally, we found that the concentration of IL-32γ was significantly lower in the blood of patients with osteoporosis than in those of healthy individuals.

Conclusion:

Our present study suggested that IL-32γ enhances bone formation through association with the decrease of DKK-1, which contributes to the protective effects on osteoporosis.

Macrophage Migration Inhibitory Factor: A Novel Biomarker in Ankylosing Spondylitis That Can Drive Spinal Fusion

Vidya Ranganathan[1], Ismail Sari[2], Janogini Muralitharan[3], Ammepa Anton[4] and Nigil Haroon[2], [1]University Health Network, Toronto, ON, Canada, [2]Rheumatology, Toronto Western Hospital, University of Toronto, Toronto, ON, Canada, [3]McMaster University, Hamilton, ON, Canada, [4]Rheumatology, University Health Network, Toronto, ON, Canada

Session Title: Biology and Pathology of Bone and Joint: Bone Remodeling and Metabolism

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Ankylosing spondylitis (AS) is a chronic inflammatory arthritis that predominantly affects the axial skeleton. Disease progression in AS is marked by new bone formation in the spine resulting in progressive vertebral fusion. The presence of various immune cell subsets and cytokines at sites of inflammation has been reported. However their specific role in mediating bone fusion is not understood. Macrophage migration inhibitory factor (MIF) is a pro-inflammatory cytokine with pleiotropic functions and has been implicated in a variety of inflammatory diseases. Herein, we intend to identify a role for MIF in triggering bone formation in AS.

Methods: For the initial analysis, AS patients who satisfied the Modified New York Criteria and healthy controls were included. Among AS patients, non-progressors had no increase in the modified Stoke's AS Spinal Score (mSASSS) despite a minimum 4 years of follow up and progressors had ≥2 mSASSS units/year of progression and syndesmophyte formation based on sequential X-rays. MIF levels were estimated by ELISA in stored serum of AS patients and healthy controls and synovial fluid samples from AS, rheumatoid arthritis (RA) and osteoarthritis (OA) patients. The human osteosarcoma cell line Saos-2 was treated with recombinant human MIF in the presence of osteogenic conditions and the extent of mineralization was visualized by Alizarin Red S staining and quantified using Image J analysis. Active β-catenin was detected by western blotting and normalized using Glyceradehyde 3-phosphate dehydrogenase (GAPDH) as control.

Results: AS patients had significantly higher serum MIF levels as compared to healthy controls ($p<0.0001$). Baseline MIF levels were significantly higher in progressors compared to non-progressors ($p<0.04$). Saos-2 cells cultured *in-vitro* in an inflammatory milieu in the presence of recombinant human MIF showed enhanced mineralization in a dose dependent manner ($p<0.03$). Also, we found that MIF levels were markedly elevated in the synovial fluid of AS patients as compared to those suffering from RA or OA ($p<0.04$). Western blot analysis showed an induction of active β-catenin in MIF treated osteoblasts.

Conclusion: Serum MIF levels are significantly higher in AS patients compared to healthy controls. MIF levels in AS synovial fluid is higher than RA and OA. The study identifies a previously unknown role for MIF in bone formation in AS by having a direct stimulatory effect on osteoblastogenesis possibly by triggering the Wnt/β-catenin pathway.

Stimulation of the Adenosine A2A Receptor (A2AR) Regulates the Expression of Netrin-1 (Ntn1) and Its Receptors (Unc5b, DCC) and Inhibits Wear Particle-Induced Inflammatory Osteolysis in a Model of Joint Prosthesis Loosening

Aranzazu Mediero[1], Bhama Ramkhelawon[2], Miguel Perez-Aso[3], Kathryn Moore[2] and Bruce Cronstein[4], [1]Medicine, Divison of Translational Medicine, NYU School of Medicine, New York City, NY, [2]Leon H. Session Date: Tuesday, November 10, 2015

Session Title: Biology and Pathology of Bone and Joint: Bone Remodeling and Metabolism

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Ntn1 is a member of the family of axonal guidance proteins that plays a role in leukocyte function and inflammation and is critical for OC differentiation. Because A2AR ligation, either directly or indirectly following methotrexate treatment, diminishes wear particle-induced inflammatory osteolysis we asked whether A2AR activation might regulate expression of Ntn1 at sites of inflammatory osteolysis.

Methods: 1cm midline sagittal incision was made over the calvaria in C57Bl/6 mice age 6-8 weeks. Mice received no particles (Control) or 3mg of UHMWPE wear particles with 20µl of saline 0.9% or CGS21680 (A2AR agonist, 1µM, n=4 each) at the surgical site every day for 14 days. After sacrifice, calvaria were prepared for immunostaining for Ntn1/Unc5b/DCC. Protein and mRNA expression were studied by RT-PCR and western blot in mouse primary bone marrow-derived OC and OB and in RAW264.7 cells (murine cell line) in the presence/absence of CGS21680 and ZM241385 ($A_{2A}R$ antagonist) 1µM each.

Results: Wear particles stimulated increased expression of Ntn1 and Unc5b, but not DCC, in periosteal inflammatory infiltrates, an effect which was blocked by the A2AR agonist CGS21680. In *in vitro* studies RANKL induced a 25±4 and 3±0.5 fold change, respectively, in Ntn1 and Unc5b mRNA during OC differentiation, changes that were completely blocked by CGS21680 (1.17±0.1, $p<0.001$, n=4). In contrast, DCC mRNA expression did not significantly change during OC differentiation and DCC expression was unaffected by CGS21680 (1.16±0.2 fold increase vs 1.9±0.2 for RANKL, p=ns, n=4). Similar changes were observed in protein expression and secretion. When Ntn1 or Unc5b were knocked-down in RAW264.7 cells using selective shRNA, basal mRNA expression for PKA, EPAC1 and EPAC2 (cAMP signaling molecules activated by A2AR) were increased and vice versa, when PKA, EPAC1 or EPAC2 were knocked down with selective shRNA, Ntn1 and Unc5b basal mRNA levels were increased. NFkB nuclear translocation was decreased in the presence of CGS21680 or in the absence of Ntn1. There was no change in Ntn1 or Unc5b expression during OB differentiation.

Conclusion: Ntn1 expression on macrophages and OC plays a central role in wear particle-induced osteolysis and adenosine $A_{2A}R$ stimulation downregulates Ntn1expression and inhibits bony destruction at sites of wear particle-induced osteolysis. Moreover, Ntn1-unc5b and A2AR stimulation reciprocally diminish signaling by each other. These results suggest that targeting Ntn1 directly or via stimulation of adenosine $A_{2A}R$ may be a novel approach to prevent osteolysis and joint prosthesis loosening.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Biology and Pathology of Bone and Joint: Bone Remodeling and Metabolism
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Patients suffering from rheumatoid arthritis (RA) are often affected by fracture-healing complications such as increased fracture healing time or non-unions. There is not much information whether this is a result of the disease itself and/or its treatment with glucocorticoids (GC) and other immunomodulatory drugs. Previously, we have shown that immunologically restricted patients lack an adequate adaptation to hypoxia in the fracture hematoma facilitating healing disorders (Hoff et al. 2011 Immunol Res 51(1)). The hypoxic microenvironment during the initial fracture-healing phase is known to be essential for activating the immunological reactions which induce regeneration. The hypoxia-inducible factor (HIF) is one key regulator of cellular adaption to hypoxia that can be stabilized via different factors called in the following HIF-stabilizers. Therefore, we aimed at stabilizing the hypoxic phase by application of HIF-stabilizers to facilitate bone healing.

Methods: A single-center retrospective study was conducted at the Charité University Hospital Berlin focusing on patients with long-bone fractures in order to identify factors which may affect the healing process. Obtained data were analyzed descriptively and statistically. In addition, we established an *in vitro* model simulating the inhibition of osteogenic mesenchymal stem cell (MSC) differentiation via high concentration GC treatment to test the counteracting potential of HIF-stabilizers. Furthermore, we performed an *in vivo*proof of concept study in a mouse osteotomy model (3 weeks, n=8 per group) evaluating the ratio of bone volume (BV) per total volume (TV) in the fracture gap using µCT.

Results: 266 patients were included in the retrospective study, 79 cases (fracture healing disorders) and 178 controls. The descriptive analysis showed higher frequencies of GC (6.3% vs. 1.6%) and NSAID (7.6% vs. 2.7%) administration in patients with fracture healing disorders. Statistical analysis using logistic regression showed a high significance for RA (p=0.028) and a trend for smoking (p=0.075) to negatively affect fracture healing. *In vitro*, we observed a concentration-dependent inhibitory effect of dexamethasone on osteogenesis which could be considerably antagonized by HIF-stabilizers. Both optimal combinations and concentrations of HIF-stabilizers were tested in a mouse osteotomy model. As a result, HIF-stabilizers directly administered into the fracture gap at the time of the osteotomy showed a significant positive effect on healing processes as evidenced after 3 weeks by means of increased bony callus volume (BV/TV) compared to the respective vehicle controls.

Conclusion: The results obtained so far support the hypothesis that RA indeed has a negative impact on the outcome of fracture healing. Our *in vitro* data demonstrate that HIF-stabilizers can be used to at least partially counteract the negative impact of high-dose GC on osseous differentiation. Finally, our *in vivo* data show a significant potential of HIF-stabilizers to facilitate bone healing. Therefore, this approach represents a promising strategy to prevent and overcome bone healing complications in RA patients and perhaps other immunologically restricted patients.

Session Title: Biology and Pathology of Bone and Joint: Bone Remodeling and Metabolism

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Milk consumption during childhood stimulates bone growth but the claimed beneficial effect of milk on bone at adulthood is a matter of debate. Recently extracellular vesicles (EVs) that contain proteins and RNA were discovered in milk but their effect on bone formation has not yet been determined. Our aim was to evaluate the effect of bovine milk-derived EVs (BMEVs) on the differentiation of human mesenchymal stem cells (hMSCs) into osteoblasts, and on bone formation in mice.

Methods: hMSCs in osteogenic medium were treated with BMEVs (200µg/ml protein) and healthy female DBA1/J mice received orally two different particle concentrations of BMEVs $4.7x10^6$/ml (low) or $14.3x10^6$/ml (high) in their drink water during 7 weeks.

Results: Proteomic analysis in BMEVs showed the presence of proteins with a known effect on bone formation. The exposure of hMSCs to BMEVs during 21 days resulted in less mineralization but higher cell proliferation. Interestingly, BMEVs reduced the collagen production per cell, but enhanced the expression of osteoblast genes (Runx2, ALP, osteopontin, RANKL, FGF-2) that are characteristic of immature osteoblasts. A kinetic study up to day 28 showed that BMEVs upregulated many osteogenic genes within the first 4 days of culture. However, the production of type I collagen and its genes (*COL1A1* and *COL1A2)* were markedly reduced at days 21 and 28. At day 28, BMEVs again lead to higher proliferation, but mineralization that was lower at day 21 was significantly increased at day 28. Nonetheless the formation of bone nodules was impaired at day 28 and this was corroborated by a reduction in osteonectin expression. Moreover, BMEVs increased the expression of sclerostin, a marker gene of osteocytes at the same time point. Oral delivery of BMEVs to mice did not alter the tibia trabecular bone area, however the osteocytes numbers increased independent of the dose. In addition, the highest dose of BMEVs reduced the adipose area in bone marrow of the femoral tibia bone and markedly increased the woven bone tissue and the number of osteoclasts by TRAP staining.

Conclusion: Our study showed that BMEVs on hMSCs increased osteoblast differentiation, proliferation and mineralization, probably by the induction of FGF-2 and WISP1. However, the lower type I collagen synthesis, and osteonectin expression could be explained by the presence of miR-29 in BMEVs. The net result of BMEVs exposure is impaired bone nodule formation in vitro and more woven bone formation in mice and this suggest that BMEVs could lead to more brittle bones. Our study add BMEVs to the list of milk components that can affect bone formation and may shed new light on the contradictory claims of milk on bone formation.

Session Title: Biology and Pathology of Bone and Joint: Bone Remodeling and Metabolism

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Rheumatoid arthritis (RA)-specific anti-citrullinated protein/peptide antibodies (ACPAs) appear before disease onset and are associated with bone destruction. We aimed to dissect the role of ACPAs in osteoclast (OC) activation, and to identify key cellular mediators in this process.

Methods:

Polyclonal ACPA were isolated from the synovial fluid (SF) and peripheral blood (PB) of RA patients. Monoclonal ACPAs were isolated from single SF B-cells of RA patients. OCs were developed from blood cell precursors with or without ACPAs. We analyzed expression of citrullinated targets and PAD enzymes by immunohistochemistry and cell supernatants by cytometric bead array. Monoclonal ACPAs were injected into mice and bone structure was analyzed by micro-computer tomography. The effect of an anti-IL-8/CXCL8 neutralizing antibody was tested in the OC cultures and in ACPA treated mice.

Results:

Polyclonal ACPAs enhanced osteoclastogenesis from CD14-dervied macrophages of either healthy donors (fold increase of 1.6±0.4 for osteoclasts number and 2.0±0.6 for bone resorption area as compared to control IgGs) or ACPA-positive RA patients (fold increase of 1.8±0.6 for OC number and 2.3±0.7 for bone resorption as compared to control IgGs). PB derived ACPAs were equally effective with SF ACPAs. Two of the tested monoclonal ACPAs (reacting with the immunodominant cit-epitopes of enolase and vimentin, had similar effects), whereas 2 others monoclonal ACPAs (mainly reacting with cit-fibrinogen peptides) failed to induce osteoclastogenesis. Fab fragments of the active monoclonal ACPAs retained similar effects. Increased osteoclastogenesis was associated with significantly higher levels of IL-8 levels in cultures supernatants of ACPA as compared to control IgGs-treated OCs (fold increase of 2.0±0.5) and completely abolished by neutralizing anti IL-8 antibodies. Transfer of the monoclonal ACPAs into mice induced trabecular bone loss that was completely reversed by the IL-8 antagonist reparixin.

Conclusion:

We provide novel insights into the key role of IL-8 during ACPA-induced OC activation. Our results open the way for preclinical studies to test the therapeutic and preventive effect of IL-8 blocking agents in models of RA and eventually also in ACPA-positive individuals at risk of developing RA.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Biology and Pathology of Bone and Joint: Bone Remodeling and Metabolism
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

The presence of anti-citrullinated proteins antibodies (ACPAs) in RA is associated with a more aggressive disease phenotype and bone destruction. Synovial fibroblasts (SFs) are key players of both synovial inflammation and bone destruction in rheumatoid arthritis (RA). We aimed to invesigate the effect of ACPAs on synovial fibroblasts.

Methods:

SFs were isolated from synovial tissue of RA patients (RA SFs) by enzymatic digestion. ACPA positive and negative IgGs were separated from plasma of RA patients and monoclonal ACPAs were generated from synovial fluid single B-cells. The effect of polyclonal and monoclonal ACPAs and appropriate negative controls was tested in migration scratch assays and adhesion assays by xCELLigence System Real-Time Cell Analyzer (ACEA bioscience). Light microscopy images were analyzed using NIH ImageJ to calculate migration index. Impedance-based signals were monitored every minute for1 hour, every 5 minutes up to 13 hours and every 15 minutes up to 36 hours. Inhibition of phosphoinositide 3-kinase (PI3K), G-protein coupled receptors, focal adhesion kinase (FAK) and peptidylarginine deiminases (PAD) inhibitor were tested in migration scratch assays in the presence or absence of the antibodies.

Results:

Polyclonal ACPAs but not others IgGs than ACPAs induced a 2.6±0.5 (mean±SD) fold increase in RASFs migration ($p<0.05$). ACPAs also induced a significant fold increase in RASFs adhesion of 1.3±0.1 ($p<0.05$). Similar effects were observed with one (D10), but not others two monoclonal ACPAs, with a fold increase of 2.4±0.4 ($p<0.05$) in migration index and 1.2±0.1 ($p<0.05$) in adhesion index.

G-protein coupled receptor blockade completely abolished ACPAs effects on RA SFs migration, while PI3K blockade decreased migration to a residual fold increase of 1.4±0.4 (mean±SD) and FAK blockade had no effect. Irreversible PAD blockade and pre-incubation of antibodies with citrulinated fibrinogen abolished ACPAs effects. No difference in either cytotoxicity or proliferation rate were observed between different treatments.

Conclusion:

ACPAs directly mediate fibroblast migration and adhesion through a novel G protein coupled receptor and PAD-dependent mechanism. Our findings provide novel insights into the link between adaptive immunity and synovial fibroblasts.

Session Time: 9:00AM-11:00AM

Background/Purpose: Bone destruction is one of the main pathological features in ankylosing spondylitis (AS). This research aims to explore the role of nuclear factor kappa-B ligand (RANKL), monocyte-macrophages and RANKL/RANK pathway in AS bone destruction.

Methods: 60 AS patients (age 18-55years, BASDAI>4.0) and 30 healthy volunteers (age 18-50years) were included in the first part of the study. Use ELISA to detect the serum RANKL. The second part, hip joint synovium was used to separate monocyte-macrophages. Specimens were obtained from 10 male AS (age 25-50years) patients who underwent hip joint replacement operation and another 5 male patients (age 30-60years) who had fracture at hip joint and underwent hip joint replacement operation. Digestion and adherent culture was adopted for the primary culture of monocyte-macrophages. Identified the cells with flow cytometry. Detected the expression of protein by Western blot. Immunohistochemical methods were used to test the protein expression in the tissues.

Results: The expression of serum RANKL in the two groups were 103.74±51.09 pg/mL (normal group, n=30) and 228.16±139.15 pg/mL(AS group, n=60). Comparing with normal group, serum RANKL in AS group increased significantly, P <0.05. The correlation test showed that RANKL had no significant correlation with the clinical observation indexes (BASDAI, BASDFI, BASMI, PGA, HAQ) (P >0.05). (Table 1) In vitro, the Western blot results showed that, in AS monocyte-macrophages, the expressions of RANK, TRAF6, NF-kB, JNK, ERK, p38, NFATc1,TRAP, CATK, MMP3 were significantly higher than normal control group, P<0.05.(Table 3) Immunohistochemical results showed that TRAP positive cells in AS synovium was much more than the control group, P <0.05.

Table 1 the correlation between RANKL and BASDAI, BASDFI, BASMI, HYPNALGIA, PGA, HAQ

	RANKL	
	r	*P*
BASDAI	0.085	0.552
BASFI	0.063	0.661
BASMI	-0.083	0.560
HYPNALGIA	-0.165	0.246
PGA	-0.186	0.191
HAQ	0.030	0.835

Table 2 relative intensity of ratio of signaling molecules to b-actin

signaling molecules /b-actin	N	AS
RANK/b-actin	0.0019±0.0002	0.0031±0.0001*
TRAF6/b-actin	0.008±0.0002	0.0185±0.0014*

JNK/b-actin	0.0077±0.0005	0.0132±0.0008*
NF-kB/b-actin	0.6411±0.0442	0.7776±0.0445*

MMP-3/b-actin	0.3988±0.0478	0.643±0.0153*

N: normal group, AS: AS group, * *P<0.05.*

Conclusion: RANKL was highly expressed in active AS patients' serum. Furthermore, experimental results suggested that the mechanism of bone destruction in AS could be: much RANKL combined with RANK, and activated RANKL/RANK pathways, then induced differentiation of monocyte - macrophages into a large number of mature osteoclasts, and eventually caused bone destruction. Serum RNAKL level could indicate the possibility of bone destruction in active AS patients, but could not reflect the progression of AS. Blocking the RANKL/RANK pathway would be an important method for treating bone destruction of AS.

Ticagrelor Regulates Osteoblast and Osteoclast Function and Promotes Bone Formation in Vivo By Increasing Adenosine Levels

Aranzazu Mediero[1], Tuere Wilder[2], Carl Whatling[3] and Bruce Cronstein[4], [1]Medicine, Divison of Translational Medicine, NYU School of Medicine, New York City, NY, [2]Dept of Med, Div of Rheum, NYU School of Medicine, New York, NY, [3]CVMD Innovative Medicine Unit, Translational Sciences, AstraZeneca R&D, Mölndal, Sweden, [4]Medicine, Division of Rheumatology, NYU School of Medicine, NEW YORK, NY

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Biology and Pathology of Bone and Joint: Bone Remodeling and Metabolism

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The antiplatelet drugs Ticagrelor and clopidogrel are $P2Y_{12}$ antagonists but ticagrelor also inhibits cellular adenosine uptake via ENT1 and thereby increases extracellular adenosine levels. Dipyridamole induces its antiplatelet effect indirectly via adenosine, and like ticagrelor, inhibits ENT1. We have demonstrated that dipyridamole stimulates bone regeneration in mice by an A2AR-dependent mechanism. Both adenosine A2AR or A2BR stimulation inhibits osteoclast differentiation. We asked whether the antiplatelet agents ticagrelor and clopidogrel regulated osteoclast differentiation and, if so, $A_{2A}R$ or A2BR stimulation played a role in this effect.

Methods: Osteoclast and osteoblast differentiation were studied in primary murine bone marrow culture as the number of TRAP-positive or Alizarin Red-positive cells, respectively, after challenge with ticagrelor, the active metabolite of clopidrogrel or dipyridamole (1nM-100mM) (n=5 each), in the presence/absence of ZM241385 (A2AR antagonist) or GS6201 (A2BR antagonist) 1mM. Male C57Bl/6 mice were anesthetized, a trephine defect was created in the calvariae, and covered using a collagen scaffold soaked in saline or 10-100mM ticagrelor or clopidogrel (n=5 each). Animals received the appropriate treatment daily until sacrifice 4 weeks after surgery when calvariae were harvested and prepared for microCT and histology.

Results: TRAP staining reveals a dose-dependent reduction in osteoclast differentiation in the presence of ticagrelor (IC50=10μM), clopidogrel (IC50=10μM) and dipyridamole (IC50=1μM), been these concentrations above the clinical exposures.

TRAP staining revealed that ZM241385 blocked the effect of both ticagrelor and dipyridamole, whereas the effect of clopidogrel was reversed by GS6021. Alizarin Red staining revealed a slight but non-significant increase by ticagrelor, clopidogrel and dipyridamole treatment. ZM241385 reversed the effect of both ticagrelor and dipyridamole on osteoblast differentiation but the effects of clopidogrel were reversed by GS6021. microCT showed that blockade of adenosine uptake by treatment with either ticagrelor or clopidogrel markedly enhanced bone regeneration (28±1% and 27±2% respectively, vs. 15±3% in control, $p<0.01$). Bone regeneration was similar to that produced by BMP2 treatment. In ticagrelor- and clopidogrel-treated mice there was a decrease in TRAP-positive osteoclasts that correlated with a decrease in Cathepsin K immunostaining. We observed an increase in Alkaline Phosphatase immunostaining , in ticagrelor or clopidogrel treated bony defects.

Conclusion: Ticagrelor inhibits osteoclast differentiation via blockade of adenosine uptake and resulting increases in extracellular adenosine levels stimulate A2ARs, as we have previously reported for dipyridamole.. Both ticagrelor and the active metabolite of clopidogrel promoted bone regeneration in a murine trephination model. Local treatment with the antiplatelet agents ticagrelor, clopidogrel or dipyridamole may be useful for inhibition of bone destruction or promoting bone growth.

Session Date: Tuesday, November 10, 2015

Session Title: Education Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The Internet can support remote and immediate access to health information. It is the second most consulted information source next to physicians. Google is the preferred search engine. The purpose of this study was to evaluate the quality of currently available websites with content about rheumatoid arthritis.

Methods: We performed an environmental scan of the currently available rheumatoid arthritis education information on the World Wide Web. Three separate search engines were used: Google Advanced, Bing, and Ask.com. The term “rheumatoid arthritis” was used as the search word. The first 100 results were reviewed in each engine and separated in domains (e.g., .gov, .edu, .com, .org). Only patient education websites were included. Two independent investigators collected data regarding type of information provided, design, literacy levels (evaluated using the Flesch Grade Level readability formula), conflicts of interest, and accuracy and currency of information.

Results: We identified 36 websites. All websites provided information about the definition and prevention (disease and flare-ups) of rheumatoid arthritis. Most included material about epidemiology, diagnosis and treatment options but not enough information about prognosis, and complications. Eighty-six percent of the websites had a static design. Reading levels ranged from 6.6 to 16.6 (mean 11.5), which is higher than the governmental recommendation of 6th grade maximum readability level for patient education material. The majority of the included websites did not provide disclosure statements and only 8.3% of the

websites clearly stated to be non-profitable. References were provided by 52.8% of the websites, the rest did not report sources of information. Only 36.1% were updated to 2014.

Conclusion: Current patient information in the Internet does not comprenhensively address all educational needs of patients with rheumatoid arthritis. While websites commonly present general information about the disease and treatment choices, most fail to address prognosis and complications than can occur throughout the course of the disease. In addition, websites commonly fail to report adequate disclosure statements and sources of information and most are unsuitable for low-literacy populations.

#Rheumjc: Development, Implementation and Analysis of an International Twitter-Based Rheumatology Journal Club

Christopher Collins[1], Paul Sufka[2], Jonathan S. Hausmann[3], Arundathi Jayatilleke[4], Jose Campos[5] and Suleman Bhana[6], [1]Rheumatology, Washington Hospital Center, Washington, DC, [2]Rheumatology, HealthPartners, Saint Paul, MN, [3]Rheumatology, Beth Israel Deaconess Medical Center, Boston, MA, [4]Medicine, Division of Rheumatology, Drexel University College of Medicine, Philadelphia, PA, [5]Rheumatology, Puerta de Hierro Majadahonda University Hospital, Madrid, Spain, [6]Crystal Run Healthcare, Middletown, NY

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Education Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Twitter is an increasingly popular platform for discussion and engagement amongst healthcare professionals. Here we describe the development, implementation and analysis of a rheumatology focused journal club on Twitter which utilizes the hashtag #RheumJC.

Methods: A #RheumJC development team was created, consisting of two academic rheumatologists, two private practice rheumatologists, and an adult/peds rheumatology Fellow in Training (FIT). A needs assessment survey was conducted to gauge interest and help define the structure of the proposed journal club, including preferred times and types of articles to be discussed. Prior to journal club sessions, requests were made for temporary open-access privileges to the article as well as invites to principal authors to participate. A total of 4 different journal clubs were conducted between January 29th and May 2nd, 2015, each consisting of two "live" one hour chats, occurring during the evening hours of GMT (European centric) and EST (Americas centric) respectively, as well as a full 24 hrs to allow for asynchronous participation. An analysis of the different sessions was performed to assess participant demographics and participation rates. A qualitative content analysis of the entire 96 hours of transcript (1927 tweets) was conducted with 6 coders assessing 363 tweets each (313 unique and 50 common). Inter-rater agreement was calculated using Krippendorff's alpha. A second survey was conducted after the 4th journal club to assess participant satisfaction and identify additional strengths or barriers.

Results: In total, 133 individuals from 31 different countries participated in at least one #RheumJC session. While the majority of participants were rheumatologists, over 8 different medical fields were represented. There were 13 FIT and other trainees amongst the participants. 38 individuals participated in at least 2 different journal clubs, 16 participated in at least 3, and 8 individuals were present at all four. The mean number of tweets during each of the live journal clubs sessions (n=8) was 197 (166 unique tweets, 31 re-tweets). For 2 of the journal clubs, principal authors of the manuscript were able to participate. A qualitative content analysis (inter-rater agreement alpha =0.801) revealed that the majority of the conversation was relevant with 28% of the tweets addressing the article directly (in the spirit of a "traditional" journal club) and another 62% considered "on-topic" with

tweets referencing personal experiences, opinions, and links to supporting literature. A survey conducted after the 4th journal club revealed that the majority (89%) of those who had participated were either satisfied or very satisfied with the #RheumJC initiative. Of interest, 11% of journal club participants indicated they had joined Twitter solely because of #RheumJC, and another 37% stated that #RheumJC had increased their use of Twitter as a tool for medical education.

Conclusion: #RheumJC is a novel and popular approach to the traditional medical journal club which brings together people from around the globe and across specialties to discuss current medical literature in rheumatology utilizing Twitter as a medium for medical education.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Education Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Video modelling is often used in patient education to improve patient outcomes. We conducted a multi-centered, open-label, parallel, randomized controlled trial that evaluated the efficacy of a multimedia patient education tool (MM-PtET) in patients with knee osteoarthritis (kOA).

Methods: Patients were recruited from 5 centers and through advertisement. Inclusion criteria were: (i) age ≥50, (ii) prior diagnosis of knee OA (unilateral or bilateral) by a physician, (iii) adequate cognitive status, and (iv) ability to communicate in English or Spanish language. Participants completed a baseline questionnaire and then were randomized through an institutional web system to receive either a MM-PtET (including storylines and testimonials) in combination with a written booklet or a written booklet alone (with the same content). Follow-up included a post-intervention, 3 and 6-month questionnaires. Primary outcome measures were: disease knowledge, decisional conflict, and role preferences. Secondary outcomes included: self-efficacy and disease management.

Results: 219 participants were randomized (n=109, MM-PtET + written booklet; n=110 written booklet alone). Mean age was 65±8 years, 76% were female, 82% had adequate health literacy, and 11% spoke Spanish. 173 (83=MM-PtET, 90=booklet) and 189 (98=MM-PtET, 91=booklet) participants returned their questionnaires at 3 and 6 months, respectively. Within groups most outcomes were improved from baseline to 3 and 6 months. At 3 months, participants receiving the MM-PtET + written booklet had lower scores on the uninformed scale of the decision conflict measure compared to those receiving the booklet alone (25.4 vs 32.7, p=0.05). Linear regression showed that Spanish-speakers patients who received the booklet had higher decisional conflict at 6 months compared to baseline (mean difference=18; p=0.04), while those who received MM-PtET had lower conflict (mean difference=-23, p=0.02) and felt less uninformed (p=0.04). Also, having a Bachelor's degree or higher was associated with improved clarity scores after 6 months (p=0.01). Greater improvement in self-efficacy was observed among English speaking patients, receiving the control, and among females, receiving the intervention (p=0.02 and p<0.05, respectively). Generalized estimating equation analysis showed that after adjusting for correlated outcome data and controlling for other variables, Caucasian

(as compared to Hispanic), and higher educated participants (p=0.009 and p=0.01) were more likely to prefer playing an active role on disease management. Also, among patients with inadequate health literacy, those who received the intervention had higher odds of choosing active role than controls (OR=5.1, 95% CI: 1.1 – 22.8, p=0.03).

Conclusion: Patients improve outcomes with any type of educational materials (either DVD or booklet) up to 6 months after being informed. Greater improvements with the use of MM-PtET compared to booklet were seen among Spanish-speakers, females, and those with inadequate health literacy.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Education Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: We conducted a 6-month multi-centered, open-label, parallel, randomized control trial to compare a multimedia-patient education tool (MM-PtET) including storylines and narratives with a written booklet for participants with osteoporosis (OP).

Methods: 225 participants were recruited from 3 outpatient clinics and newspaper advertisement. Inclusion criteria were: (i) diagnosis of osteoporosis/osteopenia, (ii) female gender, (iii) age ≥50 years (iv) at least 3 years post-menopausal, (v) adequate cognitive status, and (vi) ability to communicate in English or Spanish language. Participants were randomized through an institutional web system to either a MM-PtET or a written booklet with same content as MM-PtET. All participants completed questionnaire at baseline (pre and post), 3 and 6 months. Primary outcome measures included: disease knowledge, decisional conflict, and role preferences. Secondary outcomes were: self-efficacy and disease management.

Results: 111 participants were randomly allocated to the MM-PtET intervention and 114 to the control booklet. Mean age of participants was 64±9 years and 82% had adequate health literacy. 183 (85=MM-PtET, 98=booklet) and 189 (90=MM-PtET, 99=booklet) participants returned their questionnaires at 3 and 6 months, respectively. Within groups most outcomes were improved from baseline to 3 and 6 months. At 6 months, more participants in the MM-PtET group switched from active to passive role preference after watching the MM-PtET compared to patients reading the booklet (11% vs 3%, p=0.03). Results from linear regression on the difference between baseline and 6 month scores showed that younger age (p=0.03, p=NS, p=0.04) and receiving booklet among patients with inadequate health literacy levels (p= 0.02, p=0.009, p=0.05, p=0.02) were associated with greater improvements in the total decision conflict scale, uninformed, and clarity subscales, and self-efficacy. In contrast, receiving MM-PtET among patients with adequate health literacy levels led to greater improvements in the uninformed subscale (p=0.03). Greater improvements in the effective disease management scale were associated with younger age (p=0.03). Generalized estimating equation analysis showed that after adjusting for correlated outcome data and controlling for other variables, patients who received the intervention had higher odds of active role preference for disease management if they belonged to the inadequate

health literacy group (p=0.02). Also, the odds of active role preference among participants receiving the intervention are higher than controls but the magnitude decreases with longer disease duration (p=0.004).

Conclusion: Regardless of the delivery method, patients improve outcomes with educational materials up to 6 months after being informed. Participants with either adequate or inadequate health literacy levels improved outcomes with the MM-PtET.

Appropriate Investigations and Costs in Rheumatology: Residents' Attitudes and Knowledge

Victoria YY Xu[1], Neel Shah[2], Christine Soong[3] and Shirley Chow[4], [1]School of Medicine, Queen's University, Kingston, ON, Canada, [2]Harvard Medical School, Harvard University, Cambridge, MA, [3]Division of General Internal Medicine; Centre for Quality Improvement and Patient Safety, University of Toronto, Toronto, ON, Canada, [4]Division of Rheumatology, Sunnybrook Health Sciences Centre, University of Toronto, Toronto, ON, Canada

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Education Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: With the launching of the Choosing Wisely campaign, there has been a growing emphasis in the medical community on addressing unnecessary tests and procedures and their impact on patient care, costs and resources. This study aims to: 1) assess internal medicine and rheumatology residents' attitudes towards appropriate ordering of rheumatology investigations and cost-conscious care; 2) assess residents' knowledge of costs of care in rheumatology; and 3) identify areas of need in the post-graduate rheumatology curriculum with respect to this topic.

Methods: An anonymous survey was distributed to rheumatology trainees at several academic centres and internal medicine residents rotating at one academic hospital between July 1, 2014 and December 31, 2014. Participants were asked to rate statements on a 5-point Likert-scale and estimate costs of common rheumatology investigations. Descriptive statistics were conducted using Microsoft Excel.

Results: The survey was completed by 23 of 49 eligible participants (response rate 46.9%). Fifteen participants (65%) were female. Respondents included 5 internal medicine (post-graduate year 3) residents and 18 rheumatology trainees (post-graduate year 4-5). All participants agreed or strongly agreed that all physicians should be familiar with appropriate use of investigations and costs of care. Twenty-one (91%) participants agreed or strongly agreed that residents should receive training on this topic. Fourteen (61%) felt that teaching on this topic should be mandatory. Fourteen participants (61%) consider pretest and posttest probabilities and test sensitivity/specificity in clinical decision-making, while only eight (35%) consider costs. Only 9% of responders felt confident in appropriately ordering a whole-body bone scan, and fewer than half felt confident in appropriately ordering dual X-ray absorptiometry (DXA) scans. Participants overestimated all the costs except for complete blood count (CBC). The average discrepancy between estimated and true cost was greatest for spine MRI, uric acid level, rheumatoid factor (RF) and erythrocyte sedimentation rate (ESR).

Conclusion: The results reveal areas of need in the post-graduate curriculum with regards to appropriate ordering of rheumatology investigations and costs of care. Future steps include developing a teaching tool outlining this topic for residents.

Engaging Learners in Lupus Education with Pivot (Practice Improvement using Virtual Online Training), a Novel, Digital Case-Based Curriculum

Karen Law[1], Michelle Lin[2], Sheryl McCalla[3] and Maria Dall'Era[4], [1]Emory University School of Medicine, Atlanta, GA, [2]Emergency Medicine, UCSF, San Francisco, CA, [3]American College of Rheumatology, Atlanta, GA, [4]University of California San Francisco School of Medicine, San Francisco, CA

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Education Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Lupus is one of the prototypic rheumatic diseases, yet only a small amount of time in medical school curricula is devoted to lupus-specific education. Moreover, when present, most lupus curricula focus on lists of disease characteristics, overlooking the challenging aspects of the disease, including its often elusive presentation and the social and ethnic factors that contribute to patient outcomes.

To address these concerns, we designed a library of interactive case studies titled "Practice Improvement using Virtual Online Training," or PIVOT. These cases highlight the diagnostic reasoning necessary when evaluating a patient with suspected lupus or lupus-related complications. Unlike traditional curricula, PIVOT engages learners on an interactive diagnostic journey accessible from any mobile or desktop device. Each case has 8 key clues to focus the learner as they work through the case. A point score gives feedback on learner progress. Embedded multimedia to demonstrate patient history and physical exam findings add to the case interactivity and authenticity, and introduce social themes and concepts of health disparities in lupus. Learners select which laboratories to order and interpret the results to arrive at a diagnosis. Each case is followed by a full debrief as well as the diagnostic pathway of expert clinicians as an additional learning opportunity. In this manner, PIVOT reinforces important lupus concepts including diagnosis and health disparities in a fresh, appealing format, while also piloting an innovative method of medical education.

Methods:

Twelve Fourth-year medical students from a single medical school completed PIVOT cases during their elective in rheumatology. Our primary outcome measure was learner satisfaction. Secondary outcomes included general feedback about the PIVOT platform and educational content. A descriptive analysis was performed of the data and free-text responses.

Results:

Student feedback for the PIVOT cases was positive. 100% of learners rated the PIVOT experience ³4 on a 5-point Likert scale.

Table 1: PIVOT platform and content feedback	Disagree	Neutral	Agree
The interactive nature of the cases improved the learning experience	0	7%	93%
Finding the key clues helped to engage me with the cases.	7%	20%	73%
Watching my point score helped to engage me with the cases.	27%	27%	46%
The cases increased my medical knowledge about lupus.	7%	0	93%
The cases increased my awareness of health disparities for patients with lupus.	26%	20%	54%
The cases helped me practice diagnostic reasoning and critical thinking.	0	13%	83%

Survey comments highlighted the most effective teaching points:

- "I liked having to order labs and think about how the exam and labs made certain diagnoses more or less likely"
- "[I learned about] atypical manifestations, subtle history and physical clues... what labs to look for and what else to keep in mind (viral infection, drug induced lupus, etc)"
- "There are significant health disparities in lupus that lead to morbidity that [can be] partially preventable"

Conclusion:

PIVOT, a novel, interactive digital case series, successfully engaged novice learners in lupus education. The case-based curricula richly illustrated both diagnostic reasoning and social considerations that may be overlooked by traditional curricula. Learners found the key clues and interactive lab ordering unique and appealing. These features may be augmented in future cases to further expand PIVOT's utility.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Education Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

At the University of Nebraska College of Medicine (COM), rheumatology is taught in a block to second year medical students (M2s). The educational content was revised significantly in 2014. In addition to standard lectures, the following techniques were employed: faculty led live rheumatology patient encounters, student and faculty led problem and case based learning (PBL/CBL), student and faculty led Augenblick cases (pathognomic rheumatology findings), video game on gout, and independent time in the simulation lab for joint injections.

We desired to obtain student feedback regarding these teaching modalities in order to improve undergraduate rheumatology education moving forward.

Methods:

Upon completion of the rheumatology examination, students were asked to answer a voluntary 30 question evaluation. No evaluation was reviewed until final grades were determined by a grading committee. Students were asked to rate the effectiveness each teaching method using a Likert-scale response, and were given space to provide comments as free text. Free

text comments were reviewed qualitatively for prominent themes.

A chi-square test was done to compare the different teaching methods, and was adjusted for multiple comparisons.

Results:

We received voluntary survey data from 114 of the 124 students participating in the block (92% response). M2 students ranked the rheumatology block the highest among all of those evaluated for the 2014-15 academic year.

Results are summarized in Table 1. Live patient encounters were deemed by students to be significantly more effective than all other modalities ($p<0.001$). With the exclusion of the simulation lab, at least 50% of the students felt the methods implemented were moderately to highly effective. Several themes emerged from the qualitative review of more than 17 pages of written feedback including: "appreciation for efforts incorporating new learning experiences" and universally positive feedback regarding faculty-led patient encounters.

Conclusion:

With a voluntary survey response rate of 92%, COM students were invested in improving learning opportunities in rheumatology. In addition to the standard lecture format, students were receptive and positive toward the novel educational methods employed. Our experience suggests that our recently developed rheumatology curriculum, blending both traditional and novel teaching methods, is highly effective in engaging medical students. Of the modalities employed, faculty-led live patient encounters appear to be particularly appealing to trainees early in rheumatology learning. With ongoing threats to a sustainable rheumatology workforce, it is vital that training curricula engage students early with goals of knowledge acquisition and learner satisfaction.

Abstract Number: 2223

Improving Clinical Decisions for Rheumatoid Arthritis Management Using Online Medical Simulations

Nimish Mehta[1], Keith Johnson[2], Douglas Blevins[3] and Martin Warters[3], [1]Medscape, LLC, New York, NY, [2]Medscape Education, New York, NY, [3]Medscape, LLC, Durham, NC
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Education Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: In many patients with rheumatoid arthritis (RA), the disease is not adequately controlled, and only a minority of patients attain the goal of consistent remission or low disease activity. A study was conducted to determine if online, simulation-based educational interventions could improve clinical decisions made by rheumatologists regarding the management of patients with RA, including first-line and second-line biologic therapies.

Methods: A cohort of practicing rheumatologists from several countries who participated in online, simulation-based education was evaluated. The simulation consisted of two cases presented in a platform that allowed physician learners to choose from numerous lab tests and assessment scales as well as thousands of diagnoses, treatments, and procedures matching the scope and depth of actual practice. The clinical decisions made by the participants were analyzed using an artificial intelligence engine, and instantaneous clinical guidance was provided employing current evidence-based and expert faculty recommendations. Participant decisions were collected after clinical guidance and compared with each user's baseline data using a 2-tailed paired T-test ($P<0.05$ was considered statistically significant) to assess the impact of simulation-based education on the clinical decisions made by participants. Data is reflective of learners who participated in the assessment from 10/29/14 to 4/29/15.

Results:

The assessment sample consisted of 282 rheumatologists who made clinical decisions within the simulation and proceeded to the concluding, debrief section within the study period. As a result of clinical guidance (CG), significant improvements were observed in several areas of management in patients with RA (post-CG vs pre-CG) specifically:

- 33% improvement in the identification of RA flare in a patient who had stopped MTX due to intolerance ($P<.0001$)
- 34% improvement in selection of non-TNF biologic agent upon inadequate response to traditional DMARDs ($P<.0001$). Most of this improvement resulted from increase in tocilizumab monotherapy selection.
- 13% more participants correctly decided to discontinue adalimumab (baseline, $P<.02$)
- 28% increase in the decision to prescribe non-TNF biologic in an adalimumab non-responder ($P<.0001$). Most increase came from selection of tocilizumab, followed by abatacept, and rituximab.

Conclusion: This study demonstrated the success of online, simulation-based education on improving the evidence-based clinical decisions by rheumatologists in selecting appropriate treatment for first-line biologic and switching to second-line biologic agents. Simulation-based instructions that lead to improvement in physician performance in a consequence-free environment can result in more evidence-based clinical decisions for RA and improvement in patient outcomes.

Abstract Number: 2224

Tailored, Online Education on Comparative Effectiveness Studies in Rheumatoid Arthritis: Success in Improving Knowledge and Clinical Decisions

Nimish Mehta, Emilie McCardell and Kathleen Geissel, Medscape, LLC, New York, NY
First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Education Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Analysis of past educational activities on comparative effectiveness studies in RA identified different educational needs for varying segments of rheumatologists – from interpretation of clinical results to application in practice. A study was conducted to measure the effectiveness of using responses to a single-question as a method to segment the physician audience and to provide a tailored learning approach specific to the needs of each group.

Methods: We utilized a unique online, single-question segmentation using branching logic, in order to tailor education that rheumatologists needed most regarding comparative effectiveness studies in RA. Participants were presented with a single question that tested their interpretation of results from AMPLE and ADACTA. Those who answered correctly were directed to an educational activity on applying these results in case scenarios, and those who answered incorrectly were directed to an activity on interpretation of results. Once the participants were directed to a specific activity, online survey instruments using knowledge- and case-based, multiple-choice questions were administered to compare the same participants' responses to 4 identical questions before and after each activity. McNemar's chi-squared test was used to determine statistical significance between responses. Cramer's V was used to calculate the effect sizes of education, based on the strength of association between the pre-assessment and post-assessment responses. The activities launched in December 2014 – January 2015, and data were collected through March, 2015.

Results: In total, 112 rheumatologist responses were analyzed in this study. Tailoring education designed to match individual deficiencies in knowledge and skills of rheumatologists to specific educational activities on comparative effectiveness in RA resulted in robust educational effect (effect sizes ranging from V = 0.038 to 0.134 across 4 activities, $P < .001$). Analysis of the effect of education on specific learning goals showed:

- 52% increase in the decision to add abatacept in a patient with inadequate response to MTX, based on data from AMPLE study ($P < .001$)
- 56% increase in the selection of tocilizumab based on results from ADACTA trial, in a patient who discontinued MTX due to intolerance and progressed to a DAS28 of 6.5 ($P < .001$)
- More than 38% improvement in identifying patient populations and dosage of biologics studied in ADACTA trial ($P < .05$)
- 28% improvement in the interpretation of results of AMPLE trial ($P = .057$)

Conclusion: Large, statistically significant improvements in knowledge and competence of rheumatologists regarding comparative effectiveness studies in RA demonstrated the success of using online branching logic to segment the participants and providing education on topic areas they needed the most. Recognizing that rheumatologists are at various stages of understanding and skills in application of clinical trial data from various landmark studies, this approach may be used to maximize translation of data into clinical decisions.

Abstract Number: 2225

Twitter and Rheumatology: Significant and Incremental Growth in Usage

Ahmed Omar[1], Ismail Sari[1], Jonathan Chan[2], Nigil Haroon[1] and Robert D Inman[3], [1]Rheumatology, Toronto Western Hospital, University of Toronto, Toronto, ON, Canada, [2]Rheumatology, Spondylitis program, Toronto Western Hospital, University of Toronto, Toronto, ON, Canada, [3]Immunlogy and Institute of Medical Science, Toronto Western Hospital, University of Toronto, Toronto, ON, Canada

First publication: September 29, 2015

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Education Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

The continued growth of social media has allowed people to rapidly communicate, share, and develop ideas and information. Twitter is an online social networking service which allows users to submit and to read short 140-character messages called "tweets". Since its creation in 2006, its user base has continued to grow with a currently estimated number of active users of half a billion. In addition, sixty million tweets are estimated to be generated each day.

Used correctly, Twitter can be a valuable portal to educate patients, share research ideas and findings and increase awareness of important health-related issues.

With regards to the subject of Rheumatology, there is lack of knowledge in terms of its online twitter presence and its development over the years.

The aim of this study is to highlight the use of Twitter in relation to Rheumatology. To the best of our knowledge, no previous research has examined this subject.

Methods:

The Symplur® healthcare analytics website was used to retrospectively examine traffic related to chosen Rheumatology-associated hashtags. Symplur® was used to generate statistics for the number of impressions, unique tweets (excluding retweets) and number of participants. Some of the hashtags that were chosen include: #Rheum, #Lupus, #Fibro, #Arthritis, #Osteoporosis, #Spondylitis (AS), #RheumatoidArthritis, and #Vasculitis. #Diabetes, #IBD (Inflammatory Bowel Disease), and #Psoriasis were also chosen as comparators. Statistics were obtained from a 5 year period (2010 to 2014).

Results:

The total number of Rheumatology-related tweets related to the major hashtags grew from only 319 tweets in 2010 to 497,595 tweets in 2014 (Fig. 1a). The #Lupus hashtag showed the most activity, followed by #Fibro (fibromyalgia), #Arthritis and #Rheum.

Between the years 2013 and 2014, there was an average growth in number of total tweets by 37%. When comparing #Diabetes with Rheumatology-related hashtags in 2014, there were a total of 1,037,211 tweets related to #Diabetes *vs* 538,186 tweets related to Rheum hashtags (Fig. 1b).

In terms of number of contributors, in 2014, there were a total of 135,237 participants using Rheumatology-related hashtags. When looking at influence, the top 10 contributors tweeting in the #lupus, #RheumatoidArthritis and #Spondylitis hashtags contributed 12.6 %, 11% and 61.4% of total number of tweets respectively.

Conclusion : Twitter usage in relation to Rheumatology has shown a dramatic growth over the last 5 years and continues to show sustained growth. These novel findings suggest that this social media portal has the potential to be a valuable tool in informing and shaping Rheumatology-related healthcare.

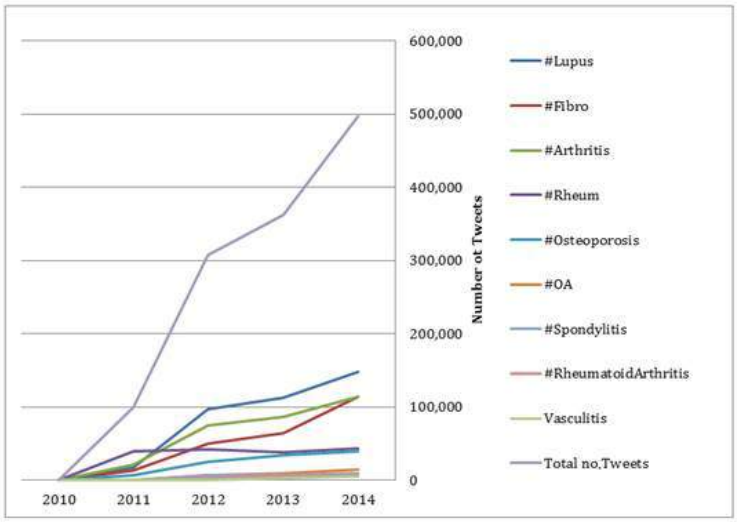

Fig 1a. Total number of tweets over a 5 year period

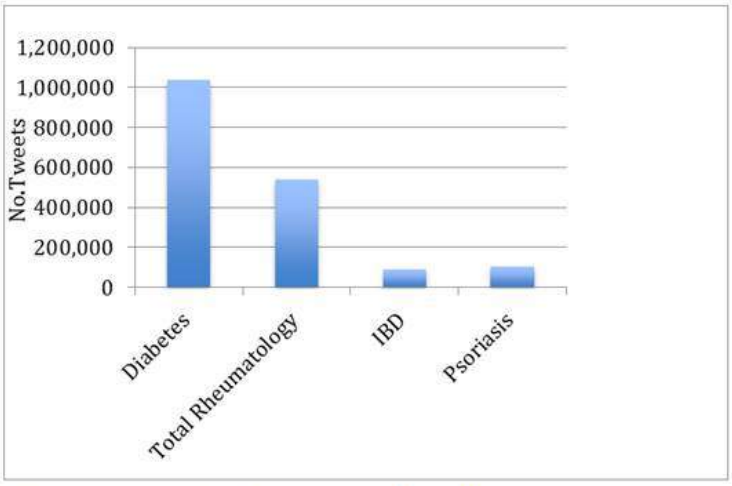

Fig 1b. Total number of tweets in 2014 for Rheumatology vs. Diabetes, IBD and Psoriasis

Enhancing Medicine Trainees' Exposure to Common Musculoskeletal Disorders through a Primary Care Musculoskeletal Clinic

Andrea M. Barker[1], Grant W. Cannon[2], Phillip Lawrence[3], Timothy A. Huhtala[4], Loren Wooldridge[5] and Michael J. Battistone[6], [1]General Internal Medicine, Salt Lake City VA Medical Center and University of Utah, Salt Lake City, UT, [2]Division of Rheumatology, Salt Lake City VA Medical Center and University of Utah, Salt Lake City, UT, [3]Pharmacology, Salt Lake City VA Medical Center and University of Utah, Salt Lake City, UT, [4]Division of General Internal Medicine, Salt Lake City VA and University of Utah, Salt Lake City, UT, [5]Physical Therapy, Salt Lake City Department of Veterans Affairs, Salt Lake City, UT, [6]Rheumatology, Salt Lake City VA Medical Center and University of Utah, Salt Lake City, UT

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Education Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Musculoskeletal (MSK) disorders are common in primary care (PC), however many of these problems are referred to specialty clinics for evaluation and management. High referral rates are partly due to lack of providers' time to fully evaluate the patient during routine clinic appointments, but may also be due to lack of clinicians' experience and training in MSK diseases. To improve patient access to specialty services while aligning with current medical home models, a Primary Care MSK Clinic (PC MSK) was implemented at a Veterans Affairs (VA) Medical Center. The PC MSK Clinic has since become an integral part of our clinical training program, increasing trainees' exposure to MSK disorders.

Methods:

The PC MSK clinic was initiated by a Physician Assistant with orthopedic experience who also works in the general outpatient PC clinic. Soon after implementation, the value of this clinic to the clinical training environment was recognized. A rheumatologist clinician-scholar-educator was invited to attend, and to assist in the cultivation of this resource for rheumatology fellows and other trainees. Most recently, the clinic staffing has been expanded to include an orthopedic Doctor of Physical Therapy. The PC MSK clinic is held one-half day per week within the primary care clinical setting. One rheumatology fellow and 1-2 ambulatory residents are assigned to attend the clinic weekly. Students from medicine, physician assistant, and nurse practitioner programs may also be assigned to this clinic during their clinical rotations.

Results:

A total of 494 consults have been completed since June, 2013; details are presented in the table.

Completed Consults (n, %)	494 (100%)
Academic Year 2013-2014	223 (45%)
Academic Year 2014-2015 (through 5/2013)	271 (55%)
Predicted Academic Year 2014-2015	295
Completed Consults by Provider	494
Faculty	127 (26%)
Fellow	120 (24%)
Rheumatology	112
Geriatrics	8
Residents	247 (50%)
Internal Medicine	181
Physical Medicine & Rehabilitation	28
Med/Peds	8
Emergency Medicine	7
Orthopedics	6
Other	12
Diagnoses	750 (100%)
Shoulder disorders	297 (40%)
Knee disorders	265 (35%)
Hip/Pelvis disorders	61 (8%)
Other	56 (7%)
Osteoarthritis, not specified	38 (5%)
Neurologic/Spine disorders	33 (4%)
Procedures performed (n, % of completed consults)	262 (51%)
Procedures performed by all trainees (n, % of all procedures performed)	185 (71%)
Procedures performed by Rheumatology Fellows (n, % of all procedures performed)	77 (29%)

Conclusion:

The Primary Care MSK Clinic is a feasible and sustainable innovation that provides a unique and efficient clinical experience for medicine trainees. The clinic supplies a high volume of supervised MSK patient encounters that are not typically obtained in traditional rheumatology training experiences or other IM resident rotations. Many of these encounters also involved arthrocentesis and/or joint injections. Additionally, this clinic may serve an important role in improving patient access to appropriate care, and in helping to prioritize specialty referrals.

Resident's Guide to Pediatric Rheumatology Mobile App: Assessing Enablers and Barriers of Use through Qualitative Focus Groups

Evelyn V. Rozenblyum[1], Niraj Mistry[2], Tania Cellucci[3], Maria Athina (Tina) Martimianakis[4] and Ronald Laxer[5], [1]Pediatrics, Hospital for Sick Children, Toronto, ON, Canada, [2]Pediatrics, University of Toronto, Toronto, ON, Canada, [3]Division of Rheumatology, The Hospital for Sick Children, Toronto, ON, Canada, [4]Faculty of Medicine, University of Toronto, Toronto, ON, Canada, [5]University of Toronto, The Hospital for Sick Children, Toronto, ON, Canada

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Education Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

A Resident's Guide to Pediatric Rheumatology (the Guide) is currently used by trainees as an on-the-go learning and teaching resource. Research using the Technology Acceptance Model showed that the concept of developing the Guide into a mobile application (app) was well supported, with the addition of features to facilitate its use, i.e. searchable index, definitions of key terms, clinical photographs and radiology images. Graham's Knowledge-To-Action Framework was used to conduct the needs assessment to underpin the development work.

Objective: (1) To determine perceived enablers and barriers to using the Guide app; **(2)**To explore perceived uses for the Guide app and **(3)**To explore the preferred format, features, and functions of the Guide app.

Methods:

Pediatric residents, rheumatology fellows, and rheumatology staff in both academic and community settings were interviewed in 7 separate focus groups. Focus groups were digitally recorded and transcribed verbatim. Transcripts were analyzed using a combination of deductive and inductive analytical approaches to identify themes.

Results:

medication choices and aid with work-up when no pediatric rheumatologist was available at their center. Residents suggested that they would rather use the app as an on-the-go learning tool and continue with PDF or hard copy on a computer or tablet for more in-depth learning. The guide is used less as a teaching tool than initially thought: fellows and staff used different methods to teach. All groups used the medication section of the Guide regularly.

Users preferred the format of the Guide mobile app to have pictures, easy searchability, mnemonics and clinical pearls, radiographic images, videos endorsed by the section editors, links to references, and treatment algorithms. Tools that ease documentation were not necessary to promote use due to concerns regarding linking to EMR and confidentiality. Games were not a consistently desired feature of the app.

Conclusion:

Creating an easy to use Resident Guide mobile application, with interactive features, concise information, and well-indexed content will yield the most use from the app. Both fellows and staff would be more inclined to use the app as an interactive teaching tool if pictures and cases were available. Results from this needs assessment will be used to convert the sample electronic guide to a functional mobile app prototype.

Brief Educational Intervention Improves Gout Patients' Understanding of Their Disease

Slavica Bobic[1], Mark Tratenberg[1], Julia Ash[1], Amy Wasserman[2] and Kirk Sperber[1], [1]Rheumatology, New York Medical College, Valhalla, NY, [2]New York Medical College, Valhalla, NY

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Education Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To assess gout patients' baseline knowledge of their disease and to measure knowledge improvement after brief educational session.

Methods: In this study, 13 patients with history of gout were given a baseline telephone questionnaire with 11 questions about gout, disease management and medication side effects. Points were given for each correct answer and total score was calculated with a maximum score of 12.5. With each incorrect answer, the patient was educated according to the guideline provided by American College of Rheumatology. Time spent educating each patient was limited to no more than 10 minutes. Data was also collected on duration of disease and patient highest level of school achieved. Two weeks later each patient was called back and the same questionnaire was administered. New post-educational score was calculated using the same methodology. Post-educational activity score was compared with pre-educational activity score. The difference was recorded as a percentage of improvement.

Results: The baseline pre-educational knowledge score ranged from 1 to 11 with the mean score of 6.0. Post-educational score ranged from 4 to 11.5 with the mean score of 8.8. Eighty-five percent of patients improved their knowledge after the educational session. Mean score for patients with high school and/or college improved by 50 percent. Mean score for patients with no formal education improved by 136 percent.

Conclusion: Brief educational intervention can have significant effect on how patients with gout understand their disease and medication side effects. Patient with low educational level benefit from such activity the most. Further study is needed to determine if this improved understanding leads to better clinical outcomes and safety.

New Frontiers: Teaching Quality Improvement to First Year Medical Students in a Rheumatology Safety Net Clinic

Sarah Goglin[1], Mary Margaretten[2], Laura Trupin[3] and Jinoos Yazdany[2], [1]Rheumatology, University of California, San Francisco, San Francisco, CA, [2]University of California, San Francisco, San Francisco, CA, [3]Medicine/Rheumatology, University of California San Francisco, San Francisco, CA

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Education Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The UCSF Action Research Program is a course in Implementation Science started in 2012 for first and second year medical students that has created a platform for faculty to engage with UCSF medical students around critical issues in health care quality and safety. The primary goal of this program is to create a novel experiential learning program integrating a traditional preceptorship with education about health care quality and safety for first year medical students.

Methods: Four UCSF first year medical students were chosen to participate in a year-long experiential learning curriculum in the San Francisco General Hospital (SFGH) rheumatology clinic, under the leadership of two rheumatology faculty members, one rheumatology fellow, and one research analyst. The students attended weekly clinic sessions from September 2014 through June 2015. Faculty provided pre-clinic didactics on quality improvement (QI) or clinical medicine. The students participated in the team huddle at the start of clinic and then focused each week on learning clinical skills or working on their QI project. Faculty saw patients with the students and assisted with QI projects as needed during the clinic session and outside of clinic.

Results: All four of the students completed an individual QI project under the leadership of a faculty mentor and presented their projects at the annual UCSF Quality and Safety Innovations Conference. Projects focused on improving no-show rates, integrating the FRAX tool into the electronic medical record, and creating a health coaching intervention to improve patient-clinician communication and high-risk medication knowledge. Students were well integrated into the clinic and worked collaboratively in interprofessional teams to implement their projects. The primary challenge was the significant time commitment required of faculty members to create a high-quality experience for the students in addition to providing patient care. Student feedback has been overwhelmingly positive, with all four reporting this as one of the highlights of their medical school experience thus far.

Conclusion: We created a novel experiential learning program for first year medical students that integrated a traditional clinical preceptorship with education about health care quality and safety in a rheumatology safety net clinic. Students added value to the clinic and made strides in improving quality in multiple domains. Students and faculty reported high levels of satisfaction with the experience. The primary challenge is to address the need for significant faculty time commitment to ensure a sustainable program that can be carried out in other settings.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Education Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The Veterans Affairs (VA) SimLEARN National Simulation Center, in collaboration with VA Salt Lake City, is developing a continuous professional education (CPE) program in musculoskeletal (MSK) care for clinical educators. The pilot program was presented at SimLEARN in February 2015.

Methods:

The 2-day course focused on evaluation and management of shoulder and knee pain in primary care. Curriculum included didactics, peer-teaching, standardized patients, technologically-enhanced simulation, and interactive sessions addressing clinical performance observation, effective feedback delivery, and principles of adult learning. After competency was observed by OSCE, trainees participated in a comprehensive, five-rotation objective structured teaching experience (OSTE) during which each participant was observed performing roles of simulated patient, evaluator, and learner. Learning was tracked by self-assessment using a 5-point Likert type scale (declarative knowledge) and by pre- and post-course OSCEs.

Results:

The pilot program included seven participants (four physicians, one nurse practitioner, two nurses). Post-course scores representing declarative knowledge and competence were higher than pre-course scores (4.5 vs. 2.8 for self-assessment; 4.5 vs. 0.9 for OSCE). Retrospective pre-course self-assessments were lower than prospective pre-course ratings (2.6 vs. 2.8), suggesting that participants downgraded their pre-course knowledge and skill after experiencing the course.

Conclusion:

The SimLEARN course is an effective model for CPE, demonstrating enhanced declarative knowledge and competency scores, and providing opportunities for reflective practice in education through multi-station OSTE.

Vitamin D Deficiency States Can be Actively Prevented. Results from a Cross-Sectional Study of over 3000 Patients with Rheumatic Diseases

Elena Nikiphorou[1], Pekka Hannonen[1], Paula Väre[1], Arto Kokko[2], Tuomas Rannio[3,4] and Tuulikki Sokka-Isler[4], [1]Jyvaskyla Central Hospital, Jyvaskyla, Finland, [2]Jyvaskyla Central Hospital, Jyväskylä, Finland, [3]Kuopio University Hospital, Kuopio, Finland, [4]Rheumatology, Jyvaskyla Central Hospital, Jyvaskyla, Finland
First publication: September 29, 2015

SESSION INFORMATION
Session Title: Epidemiology and Public Health Poster III (ACR): Gout and Non-Inflammatory Musculoskeletal Conditions
Session Type: ACR Poster Session C

Background/Purpose: Vitamin D (D25) deficiency has been an ongoing matter of concern, especially in countries at northern latitudes. The effects of D25 deficiency in patients with chronic musculoskeletal conditions could be pronounced resulting in greater disability[1].Despite this, D25 deficiency does not always represent a priority treatment in rheumatology clinics.

Methods: Register-based, cross-sectional study of adult patients (n=5857) seen in an outpatient rheumatology clinic. Calcium & D25 supplementation has been advised and prescribed routinely in this clinic for over 20 years at the first clinic review & without measuring D25 levels, especially in patients on steroids. Patients with suspected rheumatic diseases have their demographic, laboratory, clinical & patient-reported outcomes (PROs) e.g. physical status, fatigue recorded on an electronic tool as part of the normal infra-structure of the clinic. D25 is measured & recorded at baseline as part of routine care & as indicated at follow-up visits in Jan2011-Apr2015. Deficiency is defined as D25 level <50 nmol/l, severe deficiency <20; insufficiency 50-75; optimal levels >75; toxic levels >275. Statistical analysis included uni/multivariate regression models adjusting for age/gender; Spearman's correlation testing, significance assumed at 0.01(2-tailed).

Results: D25 was measured in 3203 (55%) patients (mean age 54; 68% female). Diagnoses included:RA (n=1386), unspecified arthralgia/myalgia (n=400), spondyloarthropathy (192) & psoriatic arthritis (n=138). The overall D25 mean (SD) level was 78 (31), median (IQR) 75 (55, 97). 17.8% had D25 deficiency (8.4% less than 40), only 0.7% severe (<20nmol/l). No patient had toxicity.The highest proportion of D25 deficiency was seen in patients with non-specific arthralgia/myalgia, psoriatic arthritis & fibromyalgia (>20%).The lowest mean level (66) at first visit was seen for the sarcoidosis group, highest (91) for SLE/Sjogren. Among 29 patients with darker skin, 48% had D25 deficiency, while only 8.1% among 3174 patients of Northern European origin were deficient. D25 levels were higher in women vs men, mean 79 vs 76 (p=0.044) & non-smokers vs smokers, mean 78 vs 75 (P=.005). D25 levels correlated with longer follow up in the clinic (Sp.Rho 0.101, P<.001). Higher D25 levels correlated with older age (Sp.Rho 0.205,P<.001), lower BMI (Sp.Rho -0.206, P<.001), more physical exercise (Sp.Rho 0.091, P<.001) & lower education (Sp.Rho -0.049, P=.017). None of the PROs correlated significantly with D25 levels. In multivariate analysis, younger age, non-white background, higher BMI & less frequent exercise significantly predicted D25 deficiency.Patients of non-white background were 5.4 times more likely to have D25 deficiency compared to those of white background.

Conclusion: The proportion of patients with D25 deficiency was low, supporting active calcium/D25 supplementation and patient education as an effective strategy for actively preventing D-25 deficiency. Risk groups identified included patients of non-white background, less physical exercise and higher BMI, the latter two possibly representing surrogates of less healthy lifestyle.

SESSION INFORMATION

Session Title: Epidemiology and Public Health Poster III (ACR): Gout and Non-Inflammatory Musculoskeletal Conditions

Session Type: ACR Poster Session C

Background/Purpose: In animal models, cyclo-oxygenase (COX)-2 stimulates osteoclasts through prostaglandin E2 (PGE2). Therefore, non-steroidal anti-inflammatory drugs (NSAIDs) preferentially inhibiting COX-2 (ie-coxibs) should prevent bone resorption. Withdrawal of COX-2 inhibition leads to a rebound effect and excessive osteoclast stimulation which may cause fractures. There are few human studies assessing the risk of fracture with NSAID use. Thus, we examined the risk of osteoporotic fracture with NSAID use, specifically related to the duration and timing of coxib use.

Methods: We conducted a nested case control study using The Health Improvement Network, a population-based electronic medical records database from the UK. We included persons aged 40-89 with hip or knee osteoarthritis (OA). Individuals with malignancy or metabolic bone disease were excluded. NSAID use, including coxibs, was assessed using detailed prescription records.

Incident osteoporotic fracture cases were identified using Readcodes, and the date of fracture was considered the index date. Up to 4 controls were matched to each case by age, gender, year of OA diagnosis and index date.

Fracture risk is expected to depend on the cumulative dose and how recent the drug use was. Hence coxib users were categorized as: (A) Current long term users (>6 months use, and prescription within 3 months of the index date), (B) Current short term users (<6 months use and a prescription within 3 months), (C) Remote long term users (>6 months use and no prescription within 3 months), (D) Remote short term users (<6 months use and no prescription within 3 months), (E) non-selective NSAID users and (F) NSAID non-users. Coxibs included: celecoxib, etorocoxib, lumiracoxib, rofecoxib, and valdecoxib.

Potential confounders included BMI, smoking, alcohol use, history of falls, osteoporosis, other comorbidities and medication use. Conditional logistic regression was conducted to assess the risk associated with each of the coxib exposure categories compared to NSAID non-user.

Results: 4153 cases and 15040 matching controls were identified. Fracture cases had a higher prevalence of osteoporosis, anti-osteoporotic drug use and history of falls. Other baseline demographics were similar between 2 groups (Table). Each of the coxib exposure categories was associated increased risk of fractures. Current coxib use with <6 months of exposure had the highest risk of fracture (Table).

Conclusion: In this large OA population, risk of fracture was most increased with current use of COX-2 inhibitors. While confounding by indication cannot be ruled out, fracture risk was also present with remote use. This topic warrants further research.

Table. Baseline characteristics of fracture cases and matched controls, and odds of fracture with coxib exposure

		Fracture Cases	Controls
Subjects (n)		4153	15040
Age in years, mean ± SD		78.3 ± 7.5	78.0 ± 7.5

Predictors of Imminent Fracture Risk in Women Aged >=65 Years with Osteoporosis

Derek Weycker[1], Richard Barron[2], Alex Kartashov[1], John Edelsberg[1], DB Crittenden[3] and A Grauer[3], [1]Policy Analysis Inc. (PAI), Brookline, MA, [2]Amgen, Inc., Thousand Oaks, CA, [3]Amgen Inc., Thousand Oaks, CA

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Epidemiology and Public Health Poster III (ACR): Gout and Non-Inflammatory Musculoskeletal Conditions

Session Type: ACR Poster Session C

Background/Purpose: Fractures are the major source of morbidity among women with osteoporosis. However, evidence on factors leading to imminent risk for hip or other non-vertebral fracture within the next 12 months among women aged ≥65 years with osteoporosis is limited.

Methods: A retrospective cohort design and data from the Study of Osteoporotic Fractures (SOF)—which includes 20 years of prospectively collected data on osteoporosis care and outcomes—were employed. The study population comprised all women aged ≥ 65 years in the Caucasian cohort with osteoporosis (T-score ≤ -2.5 at total hip). Hip and other non-vertebral fractures were ascertained over a 1-year follow-up period. Potential predictors of fracture were evaluated using multivariate regression models and included anthropometric measures, BMD, cognitive function, comorbidities, drug use, fracture/fall history, lifestyle variables, medical symptoms, physical function/performance, quality of life, and vision status.

Results: The study population included 2,499 women with osteoporosis who contributed 6,811 observations. During the 1-year follow-up, 2.2% had a hip fracture and 6.6% had any non-vertebral fracture (including hip). Independent predictors of hip and/or non-vertebral fracture included impaired cognitive function, total hip T-score, falls history, fracture history, and lower physical performance (Table).

Table. Independent predictors of 1-year hip and non-vertebral fracture in osteoporotic women aged ≥ 65 years from multivariate regression models

	Hazard Ratios* (95% CI)	
Risk Factors	Hip Fracture	Non-Vertebral Fracture**
Age (vs. referent: 65-74)		
≥ 75 to 79	--	0.9 (0.6-1.3)
≥ 80 to 84	--	1.0 (0.7-1.4)
≥ 85	--	1.4 (0.9-1.9)
Total Hip T-Score (vs. referent: > -3.0 to -2.5)		
≤ -3.5	2.3 (1.5-3.7)	1.9 (1.5-2.5)
> -3.5 to -3.0	1.6 (1.0-2.6)	1.6 (1.2-2.0)
No. of Falls in Last 12 Months (vs. referent: 0)		
1	--	1.2 (0.9-1.5)
≥ 2	--	1.7 (1.3-2.2)
History of Fracture (vs. referent: no history)***		
Non-Vertebral Fracture	1.6 (1.0-2.6)	--
Any Fracture	--	1.4 (1.1-1.7)
Walking Speed (m/s) (vs. referent: >1.0)		
≤ 0.70	3.0 (1.5-5.9)	1.5 (1.1-2.1)
0.70 to 1.0	2.6 (1.4-5.0)	1.4 (1.1-1.9)
Short MMSE ≤ 23 (vs. referent: >23)	1.7 (1.2-2.4)	--
Use of Arms for Chair Stands or Poor/Very Poor Tandem Stand (vs. referent: no use of arms)	1.7 (1.1-2.6)	--
Parkinson's or Stroke (vs. referent: without conditions)	--	1.3 (1.0-1.8)
Smoker, Pack Years (continuous measure)	--	1.0 (1.0-1.0)
Bisphosphonate Use (vs. referent: non-users)	0.3 (0.1-0.9)	--
C statistic (95% CI)	0.71 (0.67-0.76)	0.62 (0.59-0.65)

MMSE: Mini-Mental State Examination

*Only hazard ratios for variables retained in the final model (i.e., those with p-values <0.10) are reported; grouped dichotomous variables were retained if any of the grouped variables had a p-value <0.10

**Includes fracture of any non-vertebral site, defined—by SOF in a composite measure—as an incident, non-traumatic fracture of ankle, clavicle, elbow, face, foot, finger, hand, heel, hip, humerus, knee, lower leg, pelvis, rib, toe, upper leg, or wrist

***After age 50 years

Conclusion: Imminent fracture risk within 12 months among osteoporotic women is higher among those with a history of fracture, history of falls, lower BMD, physical dysfunction, and/or cognitive dysfunction. Careful consideration should be given to identifying this population so that those at imminent risk may be targeted for the appropriate therapy.

Abstract Number: 2234

Can the Fracture Risk Assessment Tool (FRAX) Also Predict Falls in Older Women?

Shreyasee Amin[1], Elizabeth J. Atkinson[2], Sara J. Achenbach[2], Jeremy R. Crenshaw[3], Kenton R. Kaufman[3], Sundeep Khosla[4] and L. Joseph Melton III[2], [1]Rheumatology and Health Sciences Research, Mayo Clinic, Rochester, MN, [2]Department of Health Sciences Research, Mayo Clinic, Rochester, MN, [3]Orthopedics, Mayo Clinic, Rochester, MN, [4]Endocrinology, Mayo Clinic, Rochester, MN

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Epidemiology and Public Health Poster III (ACR): Gout and Non-Inflammatory Musculoskeletal Conditions

Session Type: ACR Poster Session C

Background/Purpose: Falls in the elderly can lead to fragility fractures. Fall prevention targeted at those with high risk for falls could help reduce fractures. Although the fracture risk assessment tool, FRAX, does not directly incorporate fall risk, it does include some risk factors for falls. We examined whether FRAX could predict fall risk in older ambulatory women.

Methods: We studied 125 community-dwelling women, age ≥ 65 years, in whom 124 had femoral neck bone mineral density (FN BMD, g/cm^2) and US-FRAX scores (% 10-yr risk for major osteoporotic fractures [FRAX-OP] and hip fractures [FRAX-Hip]) reliably determined at baseline. Falls were tracked longitudinally every two weeks over 1 year by self-reported questionnaire. We examined fall risk for FRAX-OP and FRAX-Hip scores separately. For analyses, we created 4 groups for each FRAX score, using FRAX score cutoffs for osteoporosis [OP] treatment (≥20% for FRAX-OP and ≥3% for FRAX-Hip) as the initial basis for groupings. We then examined whether FRAX scores (by groups and also as a continuous variable) predicted falls using an Andersen-Gill model, adjusted for age and prior fall history.

Results: The median (range) age, FN BMD and FRAX scores of women were 77 (65-92 years), 0.81 (0.54-1.20 g/cm^2), 14.2 (3.3-56.9%, FRAX-OP) and 3.5 (0.1-45.8%, FRAX-Hip), respectively. There were 28 women (23%) with FRAX-OP ≥20% and 67 (53%) with FRAX-Hip ≥3%. There were 47 women (38%) who reported a fall in the year prior to their study visit. Compliance with all fall tracking questionnaires was 97.5%. Over follow-up, 73 women fell, 38 of whom had more than one fall, for a total of 157 falls over 125 person-years of follow-up [p-y] (1.3 falls/p-y). There was a trend for higher fall risk with greater FRAX score group (FRAX-OP, p=0.17; FRAX-Hip, p=0.02) **[Table]**. But the association appeared non-linear when using FRAX as a continuous variable in analyses, with decreasing fall risk in women having the very highest (>25%, FRAX-OP and >10%, FRAX-Hip) scores [data not shown]. Women with some of the highest FRAX scores were more likely to have a parent with hip fracture, increasing the FRAX score, but which may not necessarily have influenced fall risk. They also reported being less active, which may have reduced their likelihood for falling over follow-up.

Conclusion: We found a higher risk of future falls in older women with greater FRAX scores, including at some scores below the recommendations for OP treatment. That said, the non-linear association we observed at the highest FRAX scores suggests that information beyond FRAX would still be necessary to distinguish those at high vs. low fall risk.

FRAX-OP Score [%] (N per Group)	Falls/ P-Y	Hazard Ratio (95% CI)	FRAX-Hip Score [%] (N per Group)	Falls/ P-Y	Hazard Ratio (95% CI)
<10 (N=26)	0.8	referent	<1.5 (N=31)	0.8	referent
10-14.9 (N=41)	1.2	1.9 (0.8, 4.3)	1.5-2.9 (N=26)	0.9	1.3 (0.7, 2.6)
15-19.9 (N=29)	1.5	2.3 (1.1, 4.9)	3.0-5.9 (N=37)	2.0	2.5 (1.3, 4.9)
≥20 (N=28)	1.5	2.6 (1.1, 6.3)	≥6 (N=30)	1.2	1.8 (0.9, 3.9)

Shocking? a Systematic Review of Adrenal Insufficiency in Adults on Oral Steroids

Rebecca M Joseph[1], Louise Hunter[2], David W. Ray[2] and William G Dixon[3], [1]NIHR Manchester Musculoskeletal Biomedical Research Unit, Manchester, United Kingdom, [2]Institute of Human Development, The University of Manchester, Manchester, United Kingdom, [3]Manchester Academic Health Sciences Centre, Arthritis Research UK Centre for Epidemiology, The University of Manchester, Manchester, United Kingdom

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Epidemiology and Public Health Poster III (ACR): Gout and Non-Inflammatory Musculoskeletal Conditions

Session Type: ACR Poster Session C

Background/Purpose: One percent of the adult population are, at any one time, prescribed oral glucocorticoids (GC). GCs are known to be associated with hypothalamic-pituitary-adrenal axis suppression. However, there remains uncertainty regarding: (1) the prevalence of GC-induced adrenal insufficiency (AI); (2) the effects of GC dose and duration; and (3) the time course of adrenal recovery and how GCs should be withdrawn. We undertook a systematic literature review to address these questions.

Methods: Searches were performed in MEDLINE and Web of Science in November 2014. Eligible papers studied adult patients with an indication for long-term GCs, exposure to oral GCs, and adrenal function tests. Screening was performed in duplicate and additional articles identified through citation screening. Three categories each for increasing dose, duration and cumulative dose were assessed.

Results: From 645 screened papers, 42 met the inclusion criteria (14 randomised controlled trials and 28 observational studies). The prevalence of AI ranged from 0-100%. When examined within exposure categories, the prevalence still ranged from 0-100%, with medians of 33-43%. Only exposure <5mg prednisolone equivalent dose/day had reduced AI (range 0-36%, median 15%). There was evidence of persisting adrenal suppression 1-3 years after GC cessation. Only 5 studies reported weaning of GCs and these were too heterogeneous in study design to draw useful conclusions.

Conclusion: Significant variation exists in the reported prevalence of AI after oral GC therapy, irrespective of exposure category. There is evidence, albeit limited, that even low doses can suppress adrenal function, and some patients may have AI after several years of cessation. We suggest clinicians be vigilant for AI with all doses and durations of oral GC therapy. The evidence base supporting current practice, particularly with regards to withdrawal of steroids, is scant. There is imperative need for large-scale prospective studies to guide future practice.

Global Prevalence of Hyperuricemia: A Systematic Review of Population-Based Epidemiological Studies

Emma Smith[1] and Lyn March[2], [1]Department of Rheumatology, Northern Clinical School, Institute of Bone and Joint Research, Kolling Institute, University of Sydney & Department of Rheumatology, Royal North Shore Hospital, St. Leonards, Sydney, Australia, [2]Department of Rheumatology, Northern Clinical School, Institute of Bone and Joint Research, Kolling Institute, University of Sydney & Department of Rheumatology, Royal North Shore Hospital, St Leonards, Sydney, Australia

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Epidemiology and Public Health Poster III (ACR): Gout and Non-Inflammatory Musculoskeletal Conditions

Session Type: ACR Poster Session C

Background/Purpose: Hyperuricemia, or raised serum uric acid (SUA), is the condition closely associated with gout due to the deposition of monosodium urate crystals in peripheral joints and soft tissues. Gout is a chronic musculoskeletal (MSK) disease affecting 1-2% of the world's population and has been identified as one of the major MSK disorders contributing to the rising MSK burden in the Global Burden of Diseases (GBD), Injuries and Risk Factors 2010 & 2013 Studies. Hyperuricemia has also been reported as an independent risk factor for coronary heart disease, the metabolic syndrome, diabetes, stroke and incident mortality. Broader dissemination of hyperuricemia prevalence data should facilitate improvement of gout and other chronic diseases prevention and management strategies.

The purpose of this study is to systematically review published literature and capture country-specific population-based data on the global prevalence of hyperuricemia.

Methods: Using the following terms: 'gout or hyperuri*' combined with the terms: 'prevalen* or epidemiolo*', literature searches were performed for the period Jan 1980 to May 2015 on MEDLINE, EMBASE, CINAHL, CAB Abstracts, WHO Library (WHOLIS) and OpenSIGLE. Inclusion and exclusion criteria were set to identify relevant population-based epidemiological studies for the data extraction. Data were extracted into an Excel spreadsheet, and grouped according to the GBD classified 21 world regions.

Results: Published population-based prevalence data of hyperuricemia were reported in 13 of the 21 GBD regions, and a total of 24 countries. Although hyperuricemia was relatively more prevalent in Asia regions, the lowest (Papua New Guinea 1%) and highest (Marshall Islands 85%) reported prevalence were both in Oceania. The widest range of prevalence was observed in East Asia. It was also noted that over two decades, the prevalence of hyperuricemia in High Income Asia Pacific (Japan) increased by 5 fold. Range of the extracted prevalence data reported by various studies are shown in the table below. The data were for both females & males combined unless specified. For the eight regions marked with "No data", no published population-based epidemiological studies on hyperuricemia were identified during the specified systematic review period.

Prevalence of Hyperuricemia in GBD Regions

GBD Region	Prevalence (%)
Central Asia	
• Mongolia	5 (Females) / 18 (Males)
East Asia	
• China	6-25
• Taiwan	10-52
High Income Asia Pacific	
• Japan	4 (1980s) / 20-26 (2000s)
• South Korea	5
South Asia	No data
Southeast Asia	
• Indonesia	18
• Philippines	25
• Seychelles	25
• Thailand	9-11
Australasia	
• New Zealand	8 (non-Maori) / 17-19 (Maori)
Caribbean	No data
Central Europe	No data
Eastern Europe	
• Russia	17
Western Europe	
• Italy	9-12
• Spain	5-11
• Sweden	10-16
Andean Latin America	No data
Central Latin America	
• Mexico	11
Southern Latin America	No data
Tropical Latin America	
• Brazil	13
North Africa and Middle East	
• Iran	8
• Saudi Arabia	8
• Turkey	12
High Income North America	
• USA	22 (Females) / 21 (Males)

Oceania	
• Marshall Islands	85
• Papua New Guinea	1
• Samoa	33
Central Sub-Saharan Africa	No data
East Sub-Saharan Africa	No data
Southern Sub-Saharan Africa	No data
West Sub-Saharan Africa	
• Nigeria	17

Conclusion: Elevation of serum uric acid (SUA) is evident throughout all regions of the world, where it has been measured, but considerable regional variation exists. Significant increases are evident in regions that have trend data available. The rising burden of gout together with increasing burden of obesity and ageing globally further emphasises the importance and urgent need for the development of prevention and management strategies for hyperuricemia and gout. Population-based epidemiological research and report on hyperuricemia and gout, particularly in regions of the world with no data, should be encouraged.

Disclosure: E. Smith, None; **L. March**, None.

Effects of Coffee Consumption on Serum Uric Acid. a Systematic Review and Meta-Analysis

Jae-Bum Jun[1], Shin-Young Yim[2], Hyun Jung Kim[3], Kyu Yong Park[4], Hyeong Sik Ahn[3], Sun Hee Kim[4] and Eun Ji Park[4], [1]Rheumatology, Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea, [2]Department of Physical Medicine and Rehabilitation, Ajou University School of Medicine, Suwon, South Korea, [3]Department of Preventive Medicine, Korea University College of Medicine, Seoul, South Korea, [4]Department of Physical Medicine and Rehabilitation, Ajou University Hospital, Suwon, South Korea
First publication: September 29, 2015

SESSION INFORMATION
Session Title: Epidemiology and Public Health Poster III (ACR): Gout and Non-Inflammatory Musculoskeletal Conditions
Session Type: ACR Poster Session C

Background/Purpose: Findings on the effect of coffee consumption on serum uric acid has been conflicting. The aim of this systematic review and meta-analysis is to analyze the literature exploring the effect of coffee consumption on serum uric acid.

Methods: We conducted a systematic review to examine the effect of coffee consumption on serum uric acid via meta-analysis. We searched MEDLINE, EMBASE, the Cochrane library, and KoreaMed for all articles published before January 2015. Studies with quantitative data on coffee consumption and serum uric acid level were included. Coffee consumption and serum uric acid level were identified with or without prevalence of gout.

Results: Nine studies were included in the review (published between 1999 and 2014), including a total of 41,217 subjects. Six were from registry and 3 were cross-sectional study. Men showed significantly lower serum uric acid with coffee intake of 1-3 cups/day than coffee intake of <1 cup/day (-0.12 mg/dL [95% CI:-0.17 to 0.08], $I^2 = 41\%$; $p<0.00001$). Women showed significantly lower serum uric acid with coffee intake of 4-6 cups/day than coffee intake of <1 cup/day (-0.11 mg/dL [95% CI:-

0.20 to -0.02]; p=0.02). Meta-analysis showed that the amount of coffee intake of 1 cup/day or more was significant reduction of the prevalence of gout with negative correlation with the amount of daily coffee for both gender.

Conclusion: The review shows that there is lowering effect of coffee on both serum uric acid and the prevalence of gout for both genders. However, women need more coffee intake for lowering serum uric acid than men do. This is the first systematic review on the effect of coffee consumption on serum uric acid, along with gender difference in the amount of coffee for lowering effect of coffee on serum uric acid. There is a large degree of heterogeneity in the results, and the sources of this need to be investigated.

Body Mass Index Modulates the Relationship Between Sugar-Sweetened Beverage Intake and Serum Urate Concentration

Nicola Dalbeth[1], Amanda Phipps-Green[2], Meaghan House[1], Gregory Gamble[1], Anne Horne[1], Lisa K. Stamp[3] and Tony R. Merriman[2,4], [1]Department of Medicine, University of Auckland, Auckland, New Zealand, [2]University of Otago, Dunedin, New Zealand, [3]Medicine, University of Otago, Christchurch, Christchurch, New Zealand, [4]Biochemistry Dept, PO Box 56, University of Otago, Dunedin, New Zealand

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Epidemiology and Public Health Poster III (ACR): Gout and Non-Inflammatory Musculoskeletal Conditions

Session Type: ACR Poster Session C

Background/Purpose: Elevated body mass index (BMI) and intake of sugar-sweetened beverages (SSB) are both modifiable risk factors for hyperuricaemia and gout. BMI can modulate the influence of non-modifiable genetic variants on serum urate. The influence of BMI may also modulate associations between modifiable factors, such as SSB intake, and serum urate. The aim of this study was to determine whether the association between SSB intake and serum urate is moderated by BMI.

Methods: The effects of chronic SSB intake on serum urate were assessed in a cross-sectional study of 12,870 people without gout from the Atherosclerosis Risk in Communities (ARIC), Framingham Heart Study (FHS) and New Zealand datasets. The effects of an acute fructose load on serum urate and fractional excretion of uric acid (FEUA) were examined over 180 minutes in a short-term intervention study. In both analyses, the responses were compared in those with BMI <25mg/kg^2 (low BMI) and ≥25mg/kg^2 (high BMI).

Results: In the cross-sectional study, increased chronic SSB intake was associated with higher serum urate in the entire group (compared with no intake, BMI-adjusted P=0.048 for low SSB intake and P=1.1x10^{-4} for high SSB intake) (Table). There was no association between SSB intake and serum urate within the low BMI group. In contrast, increased SSB intake was associated with higher serum urate in the high BMI group (P=3.9x10^{-4} for low SSB intake and P=5.3x10^{-7} for high SSB intake). The difference in serum urate between the SSB categories was significantly greater in the high BMI group than in the low BMI group ($P_{BMI\ group}$=0.005). The difference in serum urate was higher in the high BMI group for both low SSB intake ($P_{BMI\ group}$=0.002) and high SSB intake ($P_{BMI\ group}$=0.001). In the acute fructose loading study, serum urate was increased in the high BMI group at baseline and throughout the observation period ($P_{BMI\ group}$<0.0001), but there were similar serum urate changes in both BMI groups in response to the fructose load ($P_{interaction}$=0.99). The baseline FEUA was similar between the two BMI groups. However, following the fructose load, FEUA responses in the BMI groups differed ($P_{interaction}$<0.0001), with increased FEUA at 120 minutes and 180 minutes in the low BMI group and reduced FEUA at 60 minutes in the high BMI group.

Conclusion: BMI modulates serum urate responses to chronic sugar-sweetened beverage intake and renal tubular uric acid handling in response to an acute fructose load. In addition to other health benefits, avoidance of sugar-sweetened beverages may be particularly important in those with overweight/obesity to prevent hyperuricaemia and reduce gout risk.

Table. Difference in serum urate for chronic sugar-sweetened beverage intake stratified by BMI group. The difference in serum urate in the overall SSB category is the average difference from sugar-sweetened beverage category 1 to category 2 to category 3 (i.e. 0, to >0 to <2, to ≥2).

Prevalence of Gout and Hyperuricemia and Association with Fat Mass and Fat Free Mass: Results from a Population-Based Study

Tiffany K. Gill[1], Kimberley Ting[2], Graeme R Tucker[1], E. Michael Shanahan[3,4] and **Catherine Hill**[5,6], [1]Medicine, The University of Adelaide, Adelaide, Australia, [2]Rheumatology, The Queen Elizabeth Hospital, Adelaide, Australia, [3]Flinders University, Adelaide, Australia, [4]Repat General Hospital, Flinders University, Adelaide, Australia, [5]The Health Observatory, The University of Adelaide, Adelaide, Australia, [6]Rheumatology Unit, The Queen Elizabeth Hospital, Woodville, Australia
First publication: September 29, 2015

SESSION INFORMATION
Session Title: Epidemiology and Public Health Poster III (ACR): Gout and Non-Inflammatory Musculoskeletal Conditions
Session Type: ACR Poster Session C

Background/Purpose: Gout and hyperuricemia are major co-morbid health issues worldwide, with a known association with metabolic syndrome. Only one previous study based in Vietnam, has investigated the association between body composition and

gout[1]. The aim of this study was to determine the prevalence of self-reported medically diagnosed gout and laboratory determined hyperuricemia and to examine whether fat mass and free fat mass were predictors of gout in a population-based cohort.

Methods: The North West Adelaide Health Study (NWAHS) is a longitudinal cohort study with three stages of data collection. Each stage comprised a self-complete questionnaire, clinic assessment and Computer Assisted Telephone Interview (CATI). In Stage 2 (2004-06), Dual Energy X-ray Absorptiometry (DXA) scans were undertaken on those aged 50 years and over. Additional data included demographics and body mass index (BMI). In Stage 3 (2008-10) participants were asked if a doctor had ever diagnosed them with gout, and a serum uric acid (SUA) measurement was obtained. Participants were defined as having gout if they had self-reported medically diagnosed gout or were taking any gout specific medication (allopurinol, colchicine, probenecid). Hyperuricemia was defined as a SUA >=0.45mmol/l. The association between reporting gout or hyperuricemia in Stage 3 and the measurements of BMI, fat mass, fat mass index, fat free mass and fat free mass index were all examined, using logistic regression analysis.

Results: The prevalence of gout was 9.6% (15.2% and 5.2%, $p<0.001$ for males and females respectively) and hyperuricemia was 6.8% (males vs females, 11.0% vs 3.5%, $p<0.001$). The presence of both gout and hyperuricemia was not independently associated with fat mass index but was associated with all other measures. The association with higher BMI and fat free mass index remained after adjustment for age and sex for gout, and the association with fat mass and fat mass index became significant. The association with fat free mass remained significant for hyperuricemia even after adjustment of age and sex. When adjusted for body composition, fat mass and fat mass index were significantly associated with gout (Table 1).

Conclusion:

This is the first study of body composition and gout in a Western population. The prevalence of gout and hyperuricemia is high. BMI and body composition measurements have been shown to be predictors of gout and hyperuricemia in a community sample and may need to be considered when treating these conditions.

Effectiveness of Allopurinol in Achieving and Sustaining Target Serum Urate: A Study Using Large Intergrated National Health Network

Jasvinder A. Singh[1], Shuo Yang[2], S. Louis Bridges Jr.[3] and Kenneth G. Saag[4], [1]Birmingham VAMC, Birmingham, AL, [2]Clinical Immunology/Rheumatology, University of Alabama at Birmingham, Birmingham, AL, [3]Clinical Immunology and Rheumatology, University of Alabama at Birmingham, Birmingham, AL, [4]University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION

Session Title: Epidemiology and Public Health Poster III (ACR): Gout and Non-Inflammatory Musculoskeletal Conditions

Session Type: ACR Poster Session C

Background/Purpose:

To comprehensively assess patient, comorbidity, physician, system, health care access and disease factors associated with the ability to achieve and maintain target serum urate (sUA) with allopurinol in patients with gout.

Methods:

We used National VA national databases from 2002-2012. Patients were eligible if they had ≥2 outpatient or ≥1 inpatient encounters with an International Classification of Diseases-ninth version (ICD-9) code 274.xx for gout, and met 12-month observability rule. Index allopurinol use was defined as the filling of a new allopurinol prescription with no allopurinol exposure in the previous 121 days. Treatment successes were defined as the achievement of: (1) post-index sUA <6 mg/dl; and (2) post-index sUA <6 mg/dl that was sustained, as defined by achievement of: (1) post-index sUA <6 mg/dl and at least one more follow-up sUA that was <6 mg/dl.

Results:

41,153 unique patients with 47,072 episodes contributed to analyses of achieving target sUA ≤ (success 1) and 17,402 unique patients with 18,323 episodes to achieving and maintaining target sUA (success 2). In multivariable-adjusted models, the following were associated with significantly higher odds of achieving both successes 1 and 2: older age, normal BMI (18.5-25 kg/m2), female sex, black/african-american race, peptic ulcer disease, severe liver disease, hypertension, rheumatologist as the main provider rather than non-rheumatologist, Midwest location for the health care facility, a lower hospital bed size, service-connection conditions of 50% or more, longer distance to the nearest VA facility, lower pre-index sUA, higher allopurinol start and end dose, higher allopurinol adherence, previous use of allopurinol with in 1 year and normal/recommended or fast allopurinol dose escalation. Diabetes with complications and paraplegia, were associated with increased odds of not achieving success 1 and 2. Additionally, increasing BMI and greater baseline sUA showed a clear linear trend toward not achieving success 1 and success 2.

Conclusion:

In this study, we identified several important factors associated with achieving and maintaining sUA <6 mg/dl. This knowledge provides several new potential modifiable targets for improving the ability to lower serum urate with allopurinol pharmacotherapy and sustain a therapeutic target in patients with gout.

Table 1. Multivariable-adjusted association of factors with the ability to achieve and maintain target sUA of < 6mg/dl*

Treating to Target in Gout: The Epidemiology of Serum Urate Measurement Among Patients with Incident Gout in Usual Care Settings in the United States

Marsha Raebel[1], Liza Reifler[1], David Tabano[1], Kristin Goddard[1], Andrew Sterrett[1], T Craig Cheetham[2], Leslie Harrold[3], Daniel Sapp[4], Mark Schmidt[4], Javier Nuevo[5], Robert Morlock[6] and Gregory Nichols[4], [1]Institute for Health Research, Kaiser Permanente Colorado, Denver, CO, [2]Kaiser Permanente Southern California, Pasadena, CA, [3]Dept of Medicine, UMass Medical School, Worcester, MA, [4]Center for Health Research, Kaiser Permanente Northwest, Portland, OR, [5]AstraZeneca, Madrid, Spain, Madrid, Spain, [6]Ardea Bioscience, San Diego, CA

First publication: September 29, 2015

SESSION INFORMATION

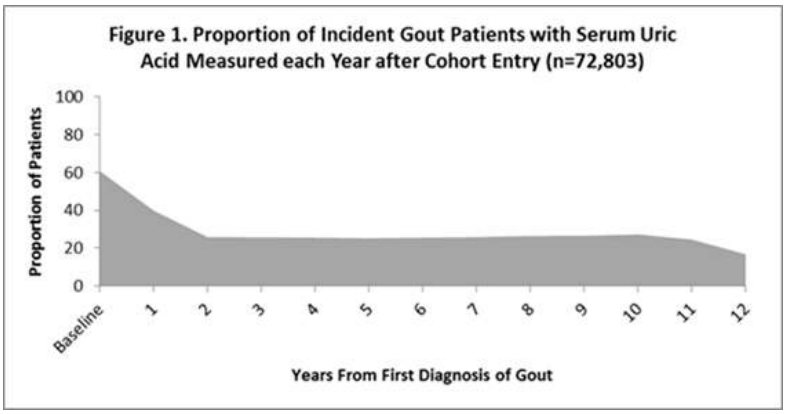
Session Title: Epidemiology and Public Health Poster III (ACR): Gout and Non-Inflammatory Musculoskeletal Conditions

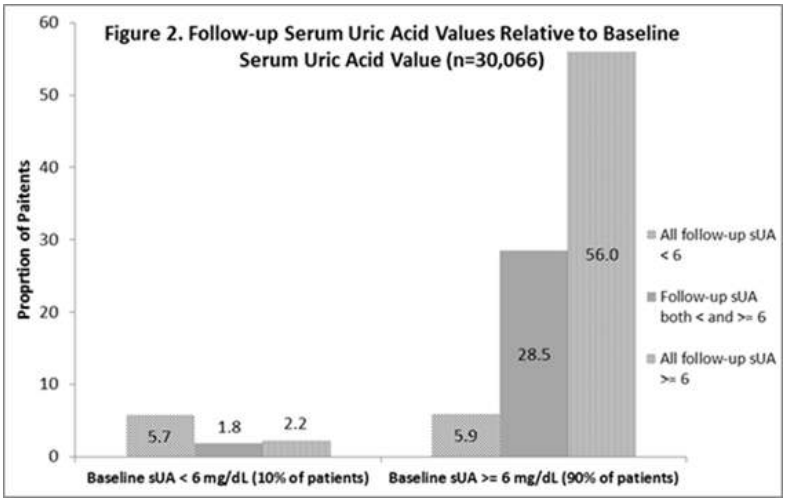
Session Type: ACR Poster Session C

Background/Purpose: American College of Rheumatology (ACR) guidelines recommend lowering serum urate (sUA) to a target value in patients with gout to prevent crystal deposition/promote crystal dissolution. At a minimum, sUA should be reduced to <6 mg/dL; in patients with tophaceous deposits/greater disease severity, the sUA target may be <5. sUA measurement is a necessary step in the treat to target paradigm, but little is known about sUA measurement practices in usual care or attainment of target sUA. The purpose of this work was to characterize sUA measurement and sUA target attainment in patients with incident gout in usual ambulatory care settings in the United States.

Methods: This retrospective cohort study was conducted at 3 geographically, demographically, and socioeconomically diverse sites of an integrated healthcare delivery system. The source population included adults enrolled in the health plan 2001-2010. Patients with >=1 coded gout diagnosis were identified; patients with >=2 years enrollment prior to first diagnosis and with no urate-lowering medication or colchicine dispensings prior to diagnosis were considered incident cases. The participating sites have similarly formatted administrative, pharmacy, lab results, and electronic health records databases that enabled collection of demographic, clinical, medication, and sUA data for each patient from cohort entry through 2013 or until the patient was censored from the cohort, whichever occurred first. Descriptive statistics were used to characterize the cohort and to examine sUA measurement and values at baseline and over time.

Results: The cohort included 72,803 patients, mean (SD) age 60.3 (14.6); 30% female; 15% Hispanic; 57% white, 13% black, 10% Asian; 38% (n=27,780) were prescribed urate-lowering medication after diagnosis. Across mean study follow-up of 5.5 (3.1) years, 87% (n=63,366) had one or more sUA assessments. The proportion of patients with sUA measured each year after diagnosis is shown in Figure 1. The average number of sUA measurements was 3.4 (4.4) per patient, with a mean of 1.5 (1.4) years between measurements. Only 20% (n=12,491) of patients achieved mean sUA <6. As shown in Figure 2, 56% (16,827 of 30,066 with >=2 sUA) of patients never had any sUA <6.





Conclusion: Fully 80% of patients with incident gout in these usual care settings in the United States did not achieve target mean sUA <6 mg/dL. Although most patients had at least one sUA assessment, sUA assessment was infrequent. Given that most patients with incident gout do not reach target sUA, more frequent sUA measurement is urged to enable treating to target.

Compliance with Allopurinol Among Hypertensive Patients with Gout Diagnosis and the Relationship to Onset of End-Stage Renal Disease

Sylvie Perreault[1], Javier Nuevo[2], Scott Baumgartner[3] and **Robert Morlock**[4], [1]University of Montreal, Montreal, QC, Canada, [2]AstraZeneca, Madrid, Spain, Madrid, Spain, [3]Ardea Biosciences, Inc., San Diego, CA, [4]4939 Directors Place, Ardea Biosciences, Inc., San Diego, CA

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Epidemiology and Public Health Poster III (ACR): Gout and Non-Inflammatory Musculoskeletal Conditions
Session Type: ACR Poster Session C

Background/Purpose: The risk of end-stage renal disease (ESRD) in both hypertension and gout has been examined in the clinical literature. However, the impact of allopurinol adherence on primary prevention of ESRD has not been assessed. The objective of this study was to evaluate the impact of better adherence to allopurinol therapy on ESRD onset.

Methods: A cohort of 2752 patients with gout diagnosis was reconstructed using the Québec RAMQ and MED-ECHO administrative databases. Patients were eligible if they were new users of allopurinol, aged between 45 and 85 years, had a diagnosis of hypertension and were treated with an antihypertensive drug between 1997 and 2007. A nested case-control design was used to study the occurrence of ESRD. Every case of ESRD was matched for age, sex and duration of follow-up for up to 15 controls. Adherence level was assessed as a medication possession ratio. Conditional logistic regression models were used to estimate the rate ratio (RR) of ESRD adjusting for covariables.

Results: Patients had a mean age of 68 years, 82% were men, close to 50% had ≥1 cardiovascular disorder, 33% had dyslipidemia, 21% had diabetes, 15% had chronic kidney disease, 21% were thiazides users, 33% were low-dose aspirin users, and 42% were NSAID users. Clinical characteristics among patients adherent to allopurinol were similar to those who were non-adherent. Major risk factor for ESRD onset was chronic kidney disease at stages 1 to 3 (RR: 8.00; CI: 3.16 -22.3) and the severity of hypertension (≥ 3 vs < 3 treatments with antihypertensives) was a trending risk factor as a crude estimate (RR: 1.94; CI: 0.68–5.51). Of 341 patients, cases (n=22) and controls (n=319), high adherence level (≥80%) to allopurinol therapy, compared with lower adherence level (<80%), was associated with a lower rate of ESRD onset (RR: 0.35; confidence interval [CI]: 0.13–0.91).

Conclusion: This population-based study suggests that better adherence to allopurinol may be associated with risk reduction of new-onset ESRD in the hypertensive population. Further research is needed to confirm this risk, as this study was limited by the small number of cases and potential of residual confounding factors.

Economic Burden of Controlled Gout, Uncontrolled Gout, and Gout Exacerbated By Common Comorbidities: Results from the 2012-2013 National Health and Wellness Survey

Robert Morlock[1], Natalia M. Flores[2], Kathy Annunziata[3], Jonathan Chapnick[4] and Javier Nuevo[5], [1]4939 Directors Place, Ardea Biosciences, Inc., San Diego, CA, [2]Kantar Health, Foster City, CA, [3]Kantar Health, Princeton, NJ, [4]Kantar Health, Horsham, PA, [5]AstraZeneca, Madrid, Spain, Madrid, Spain

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Epidemiology and Public Health Poster III (ACR): Gout and Non-Inflammatory Musculoskeletal Conditions
Session Type: ACR Poster Session C

Background/Purpose: Gout is one of the most common forms of inflammatory arthritis and is caused by chronic high serum uric acid (sUA) levels (ie, hyperuricemia), which leads to the deposition of urate crystals in musculoskeletal structures, kidneys, and other connective tissues. Clinical manifestations of gout include painful flares and tophi, which can lead to limited joint function and bone destruction if left untreated, as well as kidney stones and uric acid nephropathy. Recommended treatment goals include maintenance of sUA levels <6 mg/dL. However, sUA often remains elevated because of inadequate therapy or lack of response to treatment. This study aims to understand the relationship between gout control and economic burden and explores the impact of comorbidities on this relationship.

Methods: The data are from the combined 2012 and 2013 US National Health and Wellness Survey (NHWS), a representative, cross-sectional general health survey (2012 NHWS n=71,157; 2013 NHWS n=75,000) of which 3,729 self-reported being diagnosed with gout. Gout was considered "controlled" if patients reported sUA≤6 mg/dL and no flares in the past year. 344 patients were considered controlled, 2,215 uncontrolled (sUA>6 and/or ≥1 flare), and the rest (n=1,170) unknown status. Estimated total costs were calculated by adding direct costs (associated with resource use) and indirect costs (associated with work productivity loss). Those with gout and comorbidities (eg, diabetes) and their relationship with total costs were also examined. Multivariable generalized linear models were used to control for demographic and health characteristics (eg, gender, age, etc.) to assess the unique burden of uncontrolled gout.

Results: Adjusted models indicate that those with controlled gout do not statistically differ from those without gout while those with uncontrolled gout reported approximately $5,000 higher total annualized costs than those without gout ($p<0.01$). Although uncontrolled gout had $2,300 higher total cost than controlled gout, the difference was not significant. A similar pattern was observed for gout control and comorbidities. Those with diabetes and uncontrolled gout reported higher total costs than those without gout or diabetes (mean=$22,186 vs $14,256); there was no statistical difference for those with diabetes and controlled gout vs those without gout or diabetes. Furthermore, those with cardiovascular (CV) disease and uncontrolled gout reported higher total costs than those without gout or CV disease (mean=$25,912 vs $14,313). There was no significant difference between those with CV disease and controlled gout and those without gout or CV disease.

Conclusion: The findings support that uncontrolled gout results in higher total costs than for those without gout. Interestingly, those with controlled gout have a lesser burden closer to those without gout. Total cost for uncontrolled gout may be further exacerbated by comorbidities such as diabetes.

Risk of Incident Atrial Fibrillation in Gout

Seoyoung C. Kim[1], Jun Liu[2] and Daniel H. Solomon[3], [1]Div. of Pharmacoepidemiology and Pharmacoeconomics, Div. of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Boston, MA, [2]Division of Pharmacoepidemiology, Brigham and Women's Hospital, Boston, MA, [3]Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Boston, MA

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Epidemiology and Public Health Poster III (ACR): Gout and Non-Inflammatory Musculoskeletal Conditions

Session Type: ACR Poster Session C

Background/Purpose: Atrial fibrillation (AF) is the most common arrhythmia associated with cardiovascular disease and mortality. There are increasing data supporting the role of inflammation in the development and maintenance of AF. Recent observational studies report an increased risk of sinus tachycardia, AF and left atrial thrombus in patients with hyperuricemia, but little is known whether gout is associated with the risk of AF.

Methods: Using data from a US commercial insurance plan (2004-2013), we conducted a cohort study to evaluate the incidence rate (IR) of AF in patients with gout compared to osteoarthritis (OA). Patients with gout or OA were identified with ≥2 diagnosis codes and ≥1 dispensing for a gout- or OA-related drug. The index date was defined as the date of the first dispensing of a gout or OA-related drug (i.e. NSAIDs, opioids) after ≥365-days continuous enrollment. We excluded patients with a diagnosis of arrhythmia or cardiac surgery, or who used anti-arrhythmics or anticoagulants in the 365-day period prior to the index date. The OA group was then matched to the gout group on age, sex and the index date with a 3:1 ratio. Incident AF was defined as a new AF diagnosis and a dispensing for a new anticoagulant or anti-arrhythmic. Baseline ESR, CRP and serum uric acid levels were available on a subgroup of patients. We calculated the incidence rates (IR) of AF and confidence intervals (CI) in both groups. Multivariable Cox proportional hazards models compared the risk of AF in gout versus OA.

Results: We identified 70,015 patients with gout and 210,045 with OA, matched on age, sex, and the index date. The mean age was 57 years and 81% were men. Among patients with baseline ESR,CRP or uric acid levels available, 35.5% of gout and 23.4% of OA patients had elevated ESR or CRP levels and the mean (SD) uric acid level (in mg/dL) was 7.4 (2.0) in gout and 5.9 (1.4) in OA. Over the mean 2-year follow-up, the IR of AF per 1,000 person-years was 7.19 in gout and 5.87 in OA. The age and sex-adjusted HR of AF was 1.23 (95%CI 1.14-1.32) in gout versus OA. In the multivariable Cox regression adjusted for age, sex, comorbidities, medications and healthcare utilization, the HR of AF in gout was 1.13 (95%CI 1.04-1.23). In the subgroup analyses, the HR of AF in gout was 1.22 (95%CI 0.81-1.84) further adjusted for elevated ESR/CRP and 1.57 (95%CI 1.04-2.36) further adjusted for serum uric acid levels.

Conclusion: In this large population-based cohort study, gout was associated with a modestly increased risk of incident AF versus OA. It may be important to examine the role of gout treatment such as xanthine oxidase inhibitors and colchicine in the primary or secondary prevention of AF in patients with gout.

Table. Risk of incident atrial fibrillation in patients with gout compared to those with OA.

Adjustment	Hazard ratio (95% CI)
Main analysis	
Age, sex	1.23 (1.14-1.32)
Age, sex, comorbidity score and number of prescription drugs	1.19 (1.11-1.28)
Final model [a]	1.13 (1.04-1.23)
Subgroup analysis	
Final model + elevated ESR or CRP level [b]	1.22 (0.81-1.84)
Final model + serum uric acid level [c]	1.57 (1.04-2.36)

[a] The final model includes age, sex, cardiovascular disease, diabetes, other comorbidities, comorbidity index, beta-blockers, calcium channel blockers, diuretics, ACE inhibitors, angiotensin 2 receptor blockers, and other medications, and health care utilization factors.

[b] This analysis was done in a subgroup of patients with baseline ESR or CRP levels (n=15,174).

[c] This analysis was done in a subgroup of patients with baseline uric acid levels (n=20,622).

Periarticular Bone Mineral Density Predicts Structural Progression of Knee Osteoarthritis Independently of Static Alignment

Grace H. Lo[1], Jeffrey B. Driban[2], Lori Lyn Price[3], Charles Eaton[4], Michael T. Strayhorn[5] and Timothy E. McAlindon[6], [1]VA HSR&D Center for Innovations in Quality, Effectiveness and Safety; Medical Care Line and Research Care Line; Department of

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Epidemiology and Public Health Poster III (ACR): Gout and Non-Inflammatory Musculoskeletal Conditions

Session Type: ACR Poster Session C

Background/Purpose: Individuals with a greater medial to lateral tibial periarticular bone mineral density (M:L paBMD) and static malalignment have greater risk for osteoarthritis (OA) progression. As these risk factors are inter-related, we aimed to evaluate whether M:L paBMD is associated with OA progression, independent of static alignment, which would suggest bone as a therapeutic target.

Methods: This was a study nested within two ancillary studies to the Osteoarthritis Initiative (OAI); therefore the visit for dual x-ray absorptiometry (DXA) was the OAI 30 or 36 month visit, for static alignment was mostly the 12 month visit, and for OA progression (longitudinal medial joint space narrowing (mJSN)) between the 24 and 48 month visits. Knee DXAs generated M:L paBMD using proprietary software. Hip-knee-ankle (HKA) angles (static alignment) were measured on long limb films. mJSN (OARSI grade) were assessed using PA semi-flexed radiographs. Knees with 24-month mJSN of 3 were excluded as they were not eligible for mJSN worsening.

Only evaluating one knee per person, usually the right knee unless contraindicated, we generated Pearson's correlations between HKA and M:L paBMD. We also performed logistic regression with predictors of M:L pa BMD quartiles and outcomes of worsening of mJSN between the 24 and 48 month visits (including within OARSI grade worsening). Models were adjusted for HKA quartiles, age, sex, and BMI. The Cochrane Armitage Test assessed for statistical significance of trends. We performed a sensitivity analysis of only neutrally aligned knees, defined as HKA between -2° and 2°.

To further evaluate the influence of M:L paBMD, eliminating the influence of HKA, we used the residual of M:L paBMD regressed on HKA, representing the uncorrelated aspect of M:L paBMD unrelated to static alignment in logistic regression models.

Results: 419 participants were included, with a mean age of 63.8 +9.2 years; BMI of 29.4 +4.8 kg/m^2; 52% male. At the OAI 24 month visit, 60 (14%), 68 (16%), 158 (38%), 122 (29%), and 11 (3%) had Kellgren and Lawrence grades of 0 – 4 respectively. 45% of knees were neutrally aligned.

M:L paBMD and HKA were correlated; R = 0.64 ($p<0.0001$); greater M:L paBMD was associated with greater varus alignment. Those with greater M:L paBMD had greater odds of mJSN progression, even in fully adjusted models (Table). Sensitivity analyses of only neutrally aligned knees were similar. Analyses evaluating M:L paBMD uncorrelated with HKA also supported a relationship with mJSN progression.

Table. Relationship of ML:pa BMD with mJSN progression, crude and adjusted models.					
		Prevalence of mJSN progression	Unadjusted Odds Ratios	Adjusted Odds Ratios[1]	Adjusted Odds Ratios[2]
M:L pa BMD quartiles	Quartile 1 (lowest)	3/102 (2.9%)	Referent	Referent	Referent
	Quartile 2	8/107 (7.5%)	2.7 (0.7 – 10.3)	1.7 (0.4 – 6.8)	1.5 (0.4 – 6.3)
	Quartile 3	15/104 (14.4%)	5.6 (1.6 – 19.8)	3.1 (0.8 – 11.8)	2.8 (0.7 – 10.8)
	Quartile 4 (highest)	30/106 (28.3%)	13.0 (3.8 – 44.3)	5.5 (1.5 – 20.6)	4.8 (1.2 – 18.6)
			p for trend <0.0001	p for trend = 0.0006	p for trend = 0.002
[1]Adjusted for HKA quartiles					
[2]Adjusted for HKA quartiles, age, sex, and BMI					

Conclusion: Higher relative paBMD is associated with greater structural progression, even after adjustment for static alignment, a known correlate of periarticular BMD and predictor of progression. These findings suggest that treatments targeting periarticular bone, not focused solely on static realignment, may ultimately be protective of OA progression.

SESSION INFORMATION

Session Title: Epidemiology and Public Health Poster III (ACR): Gout and Non-Inflammatory Musculoskeletal Conditions

Session Type: ACR Poster Session C

Background/Purpose : CDC guidelines indicate regular physical activity can lead to improved health outcomes. Physically active occupations may contribute toward meeting these guidelines. The impact of this possibility toward the risk of OA has not been tested and is concerning because some jobs are associated with an increased risk of OA (e.g., military, construction, mining). The objective of this study was to evaluate the association between the extent of work-related physical activity and incident knee OA.

Methods : We performed a person-based longitudinal study using Osteoarthritis Initiative (OAI) data. PA semi-flexed knee radiographs were obtained at baseline and annual follow-up visits, centrally assessed for Kellgren-Lawrence (KL) grade (0-4).

Question 10 of the Physical Activity Scale for the Elderly (PASE) at baseline and at each annual OAI visit evaluated the prior 7 days for whether people worked (either paid or volunteer). If a participant did work, they were asked about work-related physical activity level, one of 4 levels (see table) and the number of hours worked. People with no evidence of radiographic knee OA at the baseline visit were included. Those who reported no paid or volunteer work were excluded. We performed logistic regression with the predictor being the work level (1-4), and separately, number of hours worked (<20 hours, 20-39 hours, 40-60 hours and >60 hours), with an outcome of incident person-based ROA (KL $\geq$ 2 in either knee) in the following 12 months. Those who developed ROA were censored from further analysis. We used generalized estimating equations (GEE) to adjust for correlations within person observations over time. We adjusted for age, sex, BMI, injury and the remaining PASE domains. We also tested for interactions between work level and BMI as well as work level and injury.

Results : Of 951 participants (2819 observations), 57.3% were female; baseline mean age was 59.5 (±8.7) years; BMI was 26.8 (±4.5) kg/m^2. Higher work levels were strongly and significantly associated with incident ROA, even after adjustment for BMI and knee injury, and with a significant dose response relationship (Table). However, there was no relationship with number of hours worked. In the fully adjusted model, both knee injury and BMI were also significant risk factors for incident ROA, with a significant interaction between injury and work level.

Conclusion : People who do physically intensive work have a greater odds of incident knee OA compared to those who do sedentary work. In our study, the relationship was with intensity of the work rather than number of hours worked. Strategies are needed to identify at-risk individuals engaged in heavy work, and to mitigate injuries.

Table. Associations of work-related physical activity with incident ROA.

	n = 2819 observations = 951 people	Incidence of ROA	Unadjusted OR	Adjusted OR*
Work level type	**Level 1**= Mainly sitting with slight arm movements (e.g., office worker, watchmaker, bus driver)	17/867 (2.0%)	Referent	Referent
	Level 2 = Sitting or standing with some walking (e.g., cashier, light tool and machinery worker)	30/1233 (2.4%)	1.2 (0.7 – 2.3)	1.2 (0.6 – 2.2)
	Level 3 = Walking, with some handling of materials generally weighing less than 50 pounds (e.g., mailman, waiter/waitress, construction worker)	26/649 (4.0%)	2.1 (1.1 – 3.9)	2.0 (1.1 – 3.8)
	Level 4 = Walking and heavy manual work often requiring handling of materials over 50 pounds (e.g., lumberjack, stonemason, farm laborer)	4/70 (5.7%)	3.0 (1.0 – 9.5)	2.9 (0.9 – 9.5)
			p for trend = 0.007	p for trend = 0.009

*Adjusted for age, sex, injury, BMI and the remaining components of the PASE.

Health Care Practices and Care Consumption in a Population Based Cohort of Symptomatic Knee and/or Hip OA Patients

Anne-Christine Rat[1], Alain Saraux[2], Claudine Gard[3], Francis Guillemin[4] and Bruno Fautrel[5], [1]Rheumatology, Nancy Teaching Hospital, Nancy, France, [2]Rheumatology Department, CHU de la Cavale Blanche, Brest Cedex, France, [3]APHP, Paris, France, [4]University of Lorraine, Nancy, France, [5]GRC08, Sorbonne Universités, UPMC Univ Paris 06, Paris, France, Paris, France
First publication: September 29, 2015

SESSION INFORMATION
Session Title: Epidemiology and Public Health Poster III (ACR): Gout and Non-Inflammatory Musculoskeletal Conditions
Session Type: ACR Poster Session C

Background/Purpose:

Hip and knee OA is frequent and is one of the leading causes of global disability. Population-based data of health care practices and consumption are scarce. The aim of the project was to describe health care consumption of a representative sample of patients with knee or hip symptomatic OA.

Methods:

The KHOALA (Knee and Hip OsteoArthritis Long term Assessment) cohort is a representative population-based multicenter cohort of 878 patients with symptomatic knee and/or hip OA, aged between 40 and 75 years old, established between 2007 and 2009. This study is an analysis of the 3 first years of the cohort follow-up. Patients filled in self-reported questionnaires annually.

Results:

The majority (N=698, 82%) of patients were followed up by their general practitioner and few by a rheumatologist (N=120, 14%). Twenty per cent (N=163) received NSAIDs during the past 3 months at an average of 50 to 56% of the maximal dose over time. Between 30 and 32% (N=268) of patients received grade 1 analgesic and between 20 and 23% (N=195) grade 2. Less than 15% of patients had steroids or hyaluronic injections.

Only 127 patients (15%) have been treated by physiotherapy and 59 (7%) by spa therapy. Almost 10% (N=86) of the patients used a technical aid mainly a walking stick. During the first 3 years of the cohort, between 15 and 19 total knee replacement surgeries and between 9 and 14 total hip replacement surgeries per year have been performed.

More than a third of the patients had blood tests or imaging exams, X rays being the most frequent. During the year before inclusion 120 (14%) patients have been hospitalized while during the follow up between 21 and 25% of patients have been hospitalized per year. Analgesic use was more frequent in women, in patients with a lower level of education, more comorbidities, retired, smoker and not taking alcohol more than 20g a day.

Conclusion:

These results are important data to describe current care practices and health care use in France in a representative population based cohort of patients with knee and/or hip OA.

Chicago, IL, [5]Department of Preventive Medicine, Biostatistics Collaboration Center, Northwestern University Feinberg School of Medicine, Chicago, IL, [6]Rheumatology, University of Arizona, Tucson, AZ
First publication: September 29, 2015

SESSION INFORMATION

Session Title: Epidemiology and Public Health Poster III (ACR): Gout and Non-Inflammatory Musculoskeletal Conditions
Session Type: ACR Poster Session C

Background/Purpose: Knee pain is the presenting symptom in knee osteoarthritis (OA), but the impact of knee pain burden in OA has been understudied. We examined the effect of knee pain on objectively measured moderate/vigorous physical activity among community-dwelling adults with or at high risk for knee OA.

Methods: Physical activity was objectively measured by accelerometer on participants with or at risk for radiographic knee OA in the Osteoarthritis Initiative (OAI) at the 48-month clinic visit, using ActiGraph GT1M uniaxial accelerometers (ActiGraph; Pensacola, FL), and calibrated using activity definitions published by Trioano. Participants were instructed to wear the sensor for seven consecutive days for at least 10 hours per day. Analysis was restricted to those participants with four or more valid days of wear. Knee pain burden was assessed using the Higher Western Ontario McMaster Osteoarthritis Index (WOMAC) knee pain score, and categorized as no pain, and approximate quartiles of the non-zero pain score distribution. Analysis of covariance was used to estimate sex-specific means (± standard error) for time spent engaging in moderate/vigorous physical activity across the five categories of WOMAC pain, with adjustment for age, race, and body mass index (BMI). We considered the effect of WOMAC pain categories on meeting the 2008 Physical Activity Guidelines for Americans, issued by the U.S. Department of Health and Human Services (DHHS) using logistic regression to estimate adjusted odds ratios (aOR) and 95% confidence intervals (95%CI), adjusted for age, sex, race, and BMI.

Results: We included 1,907 participants, 55% female, with a mean age of 65.1(±9.1) years. As shown in Table 1, increasing knee pain burden was associated with decreasing mean average daily bout of moderate/vigorous activity among both men (p=0.0480) and women (p=<0.0001), and decreasing mean average daily minutes of moderate/vigorous activity among both men (p=0.0094) and women (p<0.0001), after adjustment for age, race, and BMI.

Participants with WOMAC pain scores of 2 to 3 had significantly lower odds of meeting the DHHS guidelines (aOR=0.63; 95%CI: 0.43, 0.93), as did participants with scores of 4 to 6 (aOR=0.61; 95%CI: 0.39, 0.96), and those with scores > 6 (aOR=0.32; 95%CI: 0.16, 0.63), as compared to participants reporting no pain. When considering the DHHS guidelines for people with arthritis, point estimates and confidence intervals were similar.

Conclusion: High knee pain burden is associated with less moderate/vigorous physical activity, and may be an impediment to meeting national physical activity guidelines. Targeted interventions to reduce knee pain among adults with or at risk of knee osteoarthritis may increase moderate/vigorous physical activity levels.

		Moderate/Vigorous Physical Activity			
		Average daily bout, minutes		**Average daily minutes**

Risk and Risk Perception of Knee Osteoarthritis in the US: Population-Based Study

Griffin L. Michl[1], Jeffrey N. Katz[2] and **Elena Losina**[3], [1]Orthopaedic and Arthritis Center for Outcomes Research, Brigham and Women's Hospital, Boston, MA, [2]Brigham and Women's Hospital and Harvard Medical School, Boston, MA, [3]Orthopedics, Brigham and Women's Hospital, BU School of Public Health and Harvard Medical School, Boston, MA

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Epidemiology and Public Health Poster III (ACR): Gout and Non-Inflammatory Musculoskeletal Conditions

Session Type: ACR Poster Session C

Background/Purpose: Knee osteoarthritis (OA) is increasingly diagnosed in younger adults, likely due to accumulation of risk factors such as obesity, knee injury, occupational exposure and family history. This shift in the age of the OA population suggests that prevention efforts should focus on younger individuals. However, knowledge of the disease and perceptions of risk among younger people have not been investigated formally.

Methods: We recruited a population-based cohort 25-45 years of age with no history of knee OA using Amazon's Mechanical Turk, an online marketplace used extensively for behavioral research. After collecting demographic and risk factor information, we asked participants to estimate their 10-year and lifetime risk of knee OA. We compared perceived risk with 'actual' risk derived from the OA risk calculator (OARC). OARC is an online tool built on the basis of the validated OA Policy Model. OARC matches user inputs to corresponding model outputs that include 10-year and lifetime risk of diagnosed symptomatic knee OA based on age, sex, race, obesity status, family history of OA, history of knee injury, and occupational risks. Increases in OA risk were quantified using published literature.

Results: 375 people completed the study. Mean age was 32 years; 52% were females; 21% identified as non-white; 56% had a college degree. Study participants resided in all regions of the US: 17% — Northest, 18% — Midwest, 38% — South and 27% — West. 70% reported family history of OA, 20% reported a history of knee injury, and 48% reported occupational exposure. 11% reported having 3+ risk factors for OA, 24% reported two risk factors, and 35% reported one risk factor. Using the OARC, we estimated a mean lifetime OA risk of 25% for this sample and 10-year risk of 4%. Participants estimated their lifetime and 10-year OA risk at 48% and 26%, respectively. 15% estimated their lifetime OA risk within 25% of the lifetime risk determined by the risk calculator. 61% overestimated their lifetime risk by at least 50%, while 16% underestimated their lifetime risk by at least 25%. 46% overestimated their lifetime risk of knee OA at least 2 fold, and 20% overestimated their risk 3 fold. 75% of study participants overestimated their 10 year risk by at least 2 fold and 66% by 3 fold. We found that obesity, female sex, family history of OA, history of knee injury, and occupational exposure were all significantly associated with greater perceived lifetime risk of OA.

Conclusion: Risk factors are prevalent in this relatively young cohort and subjects with risk factors perceived their risk as higher than those without risk factors. However, participants consistently overestimated their lifetime risk and showed even greater overestimation of their 10-year risk, suggesting a lack of knowledge about the timing of OA onset. Family history in particular was associated with overestimation of OA risk. Family members of OA patients may perceive knee OA as inevitable, while its contribution to the risk of knee OA has been shown to be considerably less than contribution of obesity and injury. These data offer insights for awareness and risk interventions among younger persons at risk for knee OA.

The Relationship Between Sex and Incident Knee Osteoarthritis Is Mediated By Shape

Barton L. Wise[1], Jingbo Niu[2], Yuqing Zhang[3], Felix Liu[4], Joyce H. Pang[5], John A. Lynch[6] and Nancy E. Lane[7], [1]Department of

Internal Medicine, UC Davis School of Medicine, Sacramento, CA, [2]Clinical Epidemiology Research and Training Unit, Boston University School of Medicine, Boston, MA, [3]BUSM, Boston, MA, [4]University of California at San Francisco, San Francisco, CA, [5]University of Nevada School of Medicine, Reno, NV, [6]University of California San Francisco, San Francisco, CA, [7]Center for Musculoskeletal Health, Univ of California at Davis, Sacramento, CA
First publication: September 29, 2015

SESSION INFORMATION

Session Title: Epidemiology and Public Health Poster III (ACR): Gout and Non-Inflammatory Musculoskeletal Conditions
Session Type: ACR Poster Session C

Background/Purpose: Incidence of knee osteoarthritis (OA) is higher in women than in men. We have previously shown that knee bone shape differs between men and women. The purpose of the present study was to determine whether knee bone shape is associated with risk of knee OA, and to what extent the difference in the incidence of knee radiographic OA (ROA) between men and women is mediated by bone shape.

Methods: We used data collected from the NIH-funded Osteoarthritis Initiative (OAI), a cohort of persons aged 45-79 at baseline who either had symptomatic knee OA or were at high risk of it. We randomly sampled 304 knees with incident ROA (i.e., development of Kellgren/Lawrence grade ≥2 in central readings by month 48) and 304 knees without incident ROA. We characterized distal femur and proximal tibia shape on baseline radiographs using Active Shape Modeling. Thirteen modes were derived for proximal tibial shape and for distal femoral shape, accounting for 95.5% of the total variance. We examined the relation of sex and each bone shape to the risk of incident ROA using logistic regression. If a specific bone shape was associated with the risk of incident ROA, we then performed a marginal structural model to assess the mediation effect of that bone shape on the relation of sex and risk of incident knee ROA adjusting for baseline covariates.

Results: The mean age was 60.2 years (±8.5 SD) for both cases and controls; the proportion of women was 65.1% in cases and 59.5% in controls. Women had 49% increased odds of incident knee ROA compared with men. Six shape modes were associated with risk of incident knee ROA (tibia: mode 2, 9, 10, and 12; femur: mode 4 and 10). Women had a lower value of tibial mode 2 (mean = -0.23 vs. 0.20) but a higher value of tibial mode 10 (mean = 0.25 vs. -0.21) than men among controls; and higher value of femur mode 4 (mean = 0.30 vs. -0.21) and mode 10 (mean = 0.21 vs. -0.09). The indirect effect of sex on incident OA via tibial mode 2 was negative (OR = 0.96) and the direct effect (not through this mode) was positive (OR = 1.56), suggesting there was inconsistent mediation effect of mode 2. Similar findings were also observed when assessing the mediation effect of tibia mode 10 and femur mode 4 (see Table). See Figure for images of all modes that were found to be significant mediators.

Conclusion: The shapes of the distal femur and proximal tibia that form the knee joint partially and inconsistently mediate the relationship between sex and incident knee OA. Although women had higher risk of incident ROA, their bone shape modestly protects them from even higher risk.

Abstract Number: 2251

Current Tobacco Use and the Rates of Postoperative Complications after Total Knee Arthroplasty

Jasvinder A. Singh, University of Alabama at Birmingham, Birmingham, AL
First publication: September 29, 2015

SESSION INFORMATION
Session Title: Epidemiology and Public Health Poster III (ACR): Gout and Non-Inflammatory Musculoskeletal Conditions
Session Type: ACR Poster Session C

Background/Purpose:

To our knowledge, well-designed studies that have examined the risk of post-arthroplasty implant-related complications after TKA with tobacco use are lacking. Our objective was to assess the effect of current tobacco use on surgical outcomes after primary TKA. We hypothesized that current tobacco use will be associated with an increased risk of infection, revision and wound complications after primary TKA.

Methods:

This observational cohort study included all patients who underwent primary TKA at the Mayo Clinic from 2010 to 2013 and had tobacco use status documented in the Mayo Clinic's nursing database. Current tobacco use status was the predictor of interest. It was defined based on the documentation of cigarette, cigar, pipe or smokeless tobacco use in the nursing database. Current smokers were defined as people who were using cigarettes, cigars, pipes or smokeless tobacco at the time of their surgery. They were compared to current non-smokers and former smokers with regards to post-TKA complications.

Results:

Tobacco use data at the time of TKA were available for 4,227 (95%) TKA patients and not available for 249 (5%) of the patients; mean age (67 vs. 66), BMI (33 vs. 33) and Charlson index (1.5 vs. 1.4) were similar for patients with and without tobacco use data.

There were 228 current tobacco users (5%) and 4,049 non-users (95%) among patients who underwent primary TKA. Compared to the non-users, current tobacco users who underwent primary TKA were more likely to be male, have higher Charlson index and less likely to be older than 80 years ($p<0.01$; reference $\leq$60 years). No significant differences in BMI, ASA class or implant fixation were noted.

Compared to non-smokers, smokers had 2.51 times higher hazard of any revision after primary TKA ($p=0.02$; **Table 1**). Rates of revision for infection, wound complications and any infection showed a trend towards statistical significant with hazard ratios of 2.59 ($p=0.07$) ,1.84 ($p=0.10$) and 1.94 ($p=0.12$), respectively. Rates of deep infection, superficial infection and periprosthetic fracture were higher for current smokers, but were not significantly different between current smokers and non-smokers.

Conclusion:

Current tobacco use was a risk factor for poor postoperative outcomes after total knee arthroplasty, including higher revision rates and the risk of wound complications. Perioperative smoking cessation efforts need to be incorporated into routing post-TKS care to prevent these complications after this elective surgery, aimed at improving patient's quality of life.

Declining Post-Arthroplasty Mortality after Total Knee Arthroplasty in the U.S.: A Time-Trends Study

Jasvinder A. Singh and Rekha Ramachandaran, University of Alabama at Birmingham, Birmingham, AL
First publication: September 29, 2015

SESSION INFORMATION
Session Title: Epidemiology and Public Health Poster III (ACR): Gout and Non-Inflammatory Musculoskeletal Conditions
Session Type: ACR Poster Session C

Background/Purpose:

Total Knee Arthroplasty (TKA) is mostly an elective procedure that is effective in improving pain, function and quality of life in patients with end-stage arthritis. Our objective was to compare mortality after Total Knee Arthroplasty (TKA) over time in a nationally representative sample of patients. We also sought to compare the mortality in patients residing in urban and rural locations to see if the mortality differed by location and over time.

Methods:

We used the U.S. Nationwide Inpatient Sample from 1998-2010 to compare outcomes after total knee arthroplasty (TKA). In-hospital post-arthroplasty mortality related to the index admission was assessed as an outcome. Overall time trends in in-hospital post-TKA mortality were compared using the Cochrane-Armitage test. Rural versus urban residence was determined based on patient's residence at the time of surgery (available 2003-2010). Unadjusted and adjusted logistic regression analyses were performed comparing mortality by rural-urban location between 2003-06 to 2007-10, adjusting for age, race, gender, Charlson score and hospital TKA volume.

Results:

In-hospital post-TKA mortality decreased over time, from 197/100,000 TKA surgeries in 1998 to 97/100,000 TKA surgeries in 2010, a significant 50% reduction over time ($p<0.0001$; Table 1). The reduction was persistent over time. Similar significant time-trends in reduction in in-hospital post-TKA mortality were noted in both patients residing in rural and urban locations ($p<0.0001$ for both; Table 2). No significant rural-urban differences were noted in In-hospital post-TKA mortality in 2003-06 or 2007-10 (Table 3).

Table 1. Time-trend in in-hospital mortality after primary TKA

Year	Total Mortality	#TKA from NIS	Rate per 100,000
1998	497	252266	197
1999	491	263548	186
2000	485	282350	172
2001	501	314402	159
2002	459	351018	131
2003	653	380774	172
2004	582	432379	135
2005	564	498169	113
2006	525	497001	106
2007	455	551259	83
2008	561	616617	91
2009	446	621029	72
2010	481	658340	73

Table 2. Post-TKA in-hospital mortality over time by patient residence, rural vs. urban

Year	Location	Total Mortality	#TKA from NIS	Rate per 100,000
2003	Rural	149	86040	173
2004	Rural	127	99091	129
2005	Rural	166	113396	147
2006	Rural	122	110621	110
2007	Rural	98	121670	80
2008	Rural	96	127085	76
2009	Rural	113	134738	84
2010	Rural	102	152462	67
2003	Urban	501	293772	170
2004	Urban	455	332575	137
2005	Urban	398	384084	103
2006	Urban	399	385777	103
2007	Urban	342	410969	83
2008	Urban	459	473501	97
2009	Urban	323	466017	69
2010	Urban	373	480538	78

Rural-urban residence variable was available only from 2003 onwards; Cochran Armitage test of trend comparing the in hospital mortality rates: Rural: $p<0.0001$; Urban: $p<0.0001$

Table 3. Rural-urban differences in post-TKA in-patient mortality and time-trends

	All combined	Rural		Urban			
	2003-2010	2003-2006	2007-2010	2003-2006	2007-2010	Unadjusted p-value	Adjusted p-value*
In-hospital Mortality, n (%)	874 (0.1)	112 (0.14)	85 (0.08)	366 (0.13)	303 (0.08)	0.45 0.67 0.41	0.82 0.42 0.24

*Adjusted for age, race, gender, Charlson score, hospital TKA volume

For p-values: first p-value denotes rural/urban disparity in 2003 -2006; second the rural/urban disparity in 2007 -2010 and the third denotes the change in the disparity magnitude between 2003 – 2006 and 2007 – 2010.

Conclusion:

Significant decrease in in-hospital post-TKA mortality has occurred from 1998 to 2010 in the U.S. The magnitude of reduction is impressive. Rural and urban residing patients had similar mortality rates and reductions over time.

Abstract Number: 2253

Racial Disparities in Total Shoulder Arthroplasty Utilization and Outcomes Are Persisting

Jasvinder A. Singh and Rekha Ramachandaran, University of Alabama at Birmingham, Birmingham, AL
First publication: September 29, 2015

SESSION INFORMATION
Session Title: Epidemiology and Public Health Poster III (ACR): Gout and Non-Inflammatory Musculoskeletal Conditions
Session Type: ACR Poster Session C

Background/Purpose:

A recent study that used the 1993-2007 U.S. Nationwide Inpatient Sample (NIS) reported that Blacks had lower overall Total Shoulder Arthroplasty (TSA) utilization rates compared to Whites with a risk ratio of 0.6. It is not known, whether the racial disparity in TSA utilization is increasing or decreasing in the U.S. Our objective was to study whether racial disparities in total shoulder arthroplasty (TSA) utilization and outcomes have declined over time in the U.S.

Methods:

We used the U.S. Nationwide Inpatient Sample from 1998-2011. We used chi-squared test to compare characteristics, Cochran-Armitage test to compare utilization rates, and Cochran-Armitage test and logistic regression to compare time-trends in outcomes by race.

Results:

176,141 Whites and 7,694 Blacks underwent TSA from 1998-2011. Compared to Whites, Blacks who underwent TSA were younger (69.1 vs. 64.2 years; $p<0.0001$) and more likely to be female (54.9% vs. 71.0%; $p<0.0001$), have rheumatoid arthritis or avascular necrosis as the underlying diagnosis (1.7% vs. 3.0% and 1.7% vs. 6.1 %; $p<0.0001$ for both) and Deyo-Charlson index of 2 or higher (8.5% vs. 16.7%; $p<0.0001$). Compared to Whites, Blacks had much lower TSA utilization rate/100,000 in 1998 (2.97 vs. 0.83; $p<0.0001$) and in 2011 (12.27 vs. 3.33; $p<0.0001$); disparities increased from 1998 to 2011 ($p<0.0001$). A higher proportion of Blacks than Whites had hospital stay greater than median in 1998-2000, 62% vs. 51.4% ($p=0.02$) and in 2009-2011, 27.3% vs. 34.4% ($p<0.0001$); disparities did not change over time ($p=0.31$). These disparities were borderline significant in adjusted analyses. There were no racial differences in proportion discharged to inpatient medical facility in 1998-2000, 15.2% vs. 15.0% ($p=0.95$) and in 2009-2011, 12.3% vs. 11.1% ($p=0.37$), respectively.

Conclusion:

We found increasing racial disparities in TSA utilization. Some disparities in outcomes exist as well. Patients, surgeons and policy-makes should be aware of these findings and take action to reduce racial disparities.

Socio-Economically Deprived Patients Have a Higher Likelihood for Having Any Type of Rheumatic and Musculoskeletal Diseases and Have Higher Healthcare Costs – Results from a Population-Based Administrative Database Including 1.9 Million Persons (Basque country, Spain)

Polina Putrik[1], Sofia Ramiro[2], Jon Orueta[3], Edurne Alonso Moran[4], Roberto Nuno Solinis[5] and Annelies Boonen[6], [1]Department of Internal Medicine, Division of Rheumatology, Maastricht University Medical Center, Maastricht, Netherlands, [2]Rheumatology, Leiden University Medical Center, Leiden, Netherlands, [3]Centro de Salud de Astrabudua, Osakidetza, Basque Health Service, Erandio, Spain, [4]O+berri, Basque Institute for Healthcare Innovation, Barakaldo, Spain, [5]Universidad Deusto, Bilbao, Spain, [6]Maastricht University Medical Center, Maastricht, Netherlands

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Epidemiology and Public Health Poster III (ACR): Gout and Non-Inflammatory Musculoskeletal Conditions
Session Type: ACR Poster Session C

Background/Purpose:

Rheumatic and musculoskeletal diseases (RMDs) are prevalent and have a strong impact on health care costs. Some evidence in specific diseases indicates that patients with lower socio-economic background are at higher risk to have the disease and incur more healthcare costs. However, knowledge whether these effects of socio-economic status are comparable across all RMDs is lacking. Objective of this study was to compare the impact of socio-economic deprivation on occurrence of different RMDs and associated health care costs.

Methods:

An administrative dataset linking clinical (based on ICD codes), sociodemographics (age, gender and deprivation index) and health care utilization costs information of the entire adult (>=18 y.o.) population of the Basque Country, Spain was used. Deprivation index was based on area employment and education status, and included five categories (1 to 5 (most deprived)). Costs included primary and specialist care, planned and emergency hospital admissions, and ambulatory drug prescriptions. Thirty-six individual diseases were grouped into seven larger diagnostic groups: Rheumatoid Arthritis, Crystal Arthropathies, Osteoarthritis, Soft tissue diseases, Connective Tissue Diseases, and Vasculitis (Table). Logistic and Poisson regression models were computed to explore the relation between the deprivation index and occurrence of the disease (separately and grouped) and health care utilization costs, respectively. All models were adjusted for age and gender.

Results:

In total, data from 1,923,156 individuals were analyzed. Mean age was 49.9 (SD18:4), 49% were males. Soft tissue diseases were the most prevalent (5.5%), third most costly in terms of health care utilization costs after vasculitis and rheumatoid arthritis. Socio-economic deprivation was associated with higher likelihood to have any RMDs except vasculitis and some connective tissue diseases. The strongest socio-economic gradient was seen for occurrence of soft tissue disease (OR 1.82 [95%CI 1.78;1.85], most vs. least deprived). Deprivation was also associated with higher costs across the majority of the conditions, but a somewhat different pattern across diseases was seen, as the strongest gradients were observed in patients with Spondyloarthritis (in particular. with Ankylosing spondylitis) and Vasculitis (Table).

Table. Occurrence of diagnoses and costs by deprivation status across RMDs.				
Disease	**N(%)**	**Mean (SD) total healthcare cost per patient per year (€)**	**OR to have disease (most deprived vs least deprived)**	**IRR total costs (most deprived vs least deprived)**
Rheumatoid arthritis	**4042 (0.21%)**	**3865.93 (6296.16)**	**1.32 [1.19;1.46]**	**1.33 [1.33;1.33]**
Rheumatoid arthritis	3533 (0.18%)	4011.07 (6426.18)	1.30 [1.17;1.45]	1.38 [1.38;1.38]
Undifferentiated (poly)arthritis	536 (0.03%)	2915.41 (5112.51)	1.51 [1.13;2.01]	0.97 [0.96;0.97]

Sjogren's disease	63 (0%)	5224.62 (7098.54)	0.89 [0.37;2.12]	0.91 [0.90;0.92]
Systemic sclerosis	44 (0%)	4989.50 (5586.01)	1.98 [0.71;5.44]	3.54 [3.47;3.60]
Myositis	76 (0%)	3134.68 (3076.92)	0.99 [0.44;2.21]	0.99 [0.97;1.01]
Other connective tissue disease	51 (0%)	4149.71 (4991.57)	1.77 [0.63;4.98]	0.96 [0.95;0.98]
Vasculitis	**300 (0.02%)**	**5235.52 (7924.52)**	**1.10 [0.74;1.63]**	**1.98 [1.96;1.99]**
ANCA associated vasculitis	38 (0%)	5865.84 (6629.81)	1.55 [0.34;6.96]	3.86 [3.70;4.02]
Non-ANCA associated vasculitis	264 (0.01%)	5219.53 (8163.03)	1.08 [0.72;1.62]	1.95 [1.94;1.96]
Osteoporosis	15049 (0.78%)	2945.37 (4630.94)	1.09 [1.03;1.14]	1.34 [1.34;1.34]
Polimyalgia rheumatica	1935 (0.1%)	3828.45 (5508.66)	1.21 [1.04;1.41]	1.16 [1.16;1.16]
Undifferentiated monoarthritis	434 (0.02%)	2614.93 (3578.13)	1.48 [1.07;2.04]	1.18 [1.17;1.19]

Conclusion:

Socio-economic deprivation was consistently associated with higher occurrence and higher costs across most of the RMDs. Among major RMDs, the group of soft tissue diseases (comprising chronic low back and neck pain, fibromyalgia, and soft tissue disease), was the most prevalent and costly for the society, and occured more often in persons with lower socio-economic status.

SESSION INFORMATION

Session Title: Epidemiology and Public Health Poster III (ACR): Gout and Non-Inflammatory Musculoskeletal Conditions

Session Type: ACR Poster Session C

Background/Purpose: Capillaroscopy is a noninvasive and safe method that allows visualization of the capillaries in the finger nailfold, it is useful in the evaluation of Raynaud's phenomenon and collagen diseases, especially scleroderma. There are a variety of studies on the capillaroscopic findings in different collagen diseases, with the SD pattern being the characteristic finding of

scleroderma. However, some microvascular alterations can occur in the healthy population; little is known about the prevalence and distribution of capillaroscopic changes in this group.

Methods: Observational, descriptive and prospective study of healthy subjects selected by inclusion and exclusion criteria. Subjects presenting signs/symptoms or history of any collagen disease, trauma presence in the nailfold due to cosmetic treatment or nail polish, were excluded. Videocapillaroscopy of the nailfold of the nondominant hand's fourth and fifth fingers was conducted on 100 students from the Universidad Espiritu Santo. The capillaroscopy was performed by an experienced rheumatologist in a room with an ambient temperature of 20-23ºC. The fourth and fifth fingers of the nondominant hand were chosen. The capillaries were observed using a 10x magnification capillaroscope (Dino-Lite) and photographs of the last distal row of capillaries were taken. The following capillaroscopic parameters were considered: capillary diameter (ectasia and giant capillaries), crosslinked capillaries, capillary tortuosity, ramified capillaries, avascular zones, hemorrhages, dominant morphology, subpapillar venous plexus visibility, cuticulitis and SD pattern. The images were analyzed by an experienced rheumatologist. Data was analyzed using SPSS. The non-parametric correlations were performed by tau_b Kendall and values were considered statistically significant when p ²0.01 and they had two tails.

Results: 100 patients were analyzed with a mean age of 21.38 years, 50 females (50%) and 50 males (50%), most were of mixed race (87%) and caucasian (13%). Videocapillaroscopy was performed on all participants, 17% of the population didn't present capillaroscopic disorders, 86% had alterations, the most frequent were ectasias (60%), tortuous capillaries (62%) and crosslinked capillaries (59%), the mean capillary size was 42.75µm (women: 41.14µm vs. men: 45.34µm). The population was divided into two groups: smokers and nonsmokers. In the group of smokers (n = 14), the capillary mean was 46.25µm, the most frequent capillaroscopic findings were tortuous capillaries (91%), cross-linked capillaries (72%), ectasias (64%) and ramified capillaries (27%). A correlation between the presence of ramified capillaries and smoking (p <0.05, OR 7.54, 95% CI 1.35-42.11) was found. No giant capillaries nor hemorrhages were found.

Conclusion: This is the first capillaroscopic study with healthy subjects in Ecuador, healthy subjects may present microvascular alterations and this results were similar to previous studies conducted by Hoerth and Coelho Andrade.

Clinical Characteristics, Laboratory Findings and Nailfold Capillaroscopy Microscopy Patterns in a Monocentric Series of 123 Patients with Idiopathic Pernio

Thi Phuong Uyen Doan[1], **Sara Hussein**[1], Martial Koenig[2] and France Joyal[1], [1]Université de Montréal, Montreal, QC, Canada, [2]Internal Medicine, Hôpital Notre-Dame du CHUM, Montréal, QC, Canada

SESSION INFORMATION

Session Title: Epidemiology and Public Health Poster III (ACR): Gout and Non-Inflammatory Musculoskeletal Conditions

Session Type: ACR Poster Session C

Background/Purpose:

Few studies have looked at the characteristics of patients diagnosed with pernio and the significance of the use of capillaroscopy in these patients. The objective of this study is to characterize the clinical features and laboratory findings of pernio, and to determine the nailfold capillaroscopy microscopy (NCM) patterns in patients with the diagnosis of idiopathic pernio.

Methods:

This is a single-center study of patients referred to the vascular medicine unit for evaluation of paroxystical vascular acrosyndrome. Clinical features, laboratory findings and NCM patterns of 123 patients diagnosed as having idiopathic pernio were prospectively recorded from 2005 to 2015. NCM was performed on 8 digits, using a quantitative method: images were recorded using a digital camera and further analyzed to determine capillary diameter and density, and to rule in or rule out microvasculature abnormalities. Twenty healthy patients without any vascular acrosyndrome and 22 patients with primary Raynaud's phenomenon were used to compare NCM features.

Results:

A total of 123 patients were diagnosed as having idiopathic pernio (male/female ratio 1:4.6, median age at diagnosis 42.9 years [39.7;45.6]) and compared to 20 healthy patients (male/female ratio, 1:5.6, median age 32.7 [32.3;43.7]) as well as to 22 patients with Raynaud's phenomenon (male/female ratio, 1:3.4, median age 50.7 [44.2;54.4]).

In the pernio group, the median capillary diameter was 43.4mm [43.4;48.1] as compared to 39.6mm [35.3;41.9] in healthy patients (p=0.0211). There was no other significant difference for NCM features among the three groups. There was no difference when evaluating for disease activity, status of smoking, or recurrence of illness.

Conclusion:

Increased nailfold capillary diameter was observed in patients with pernio when compared to healthy patients regardless of the disease activity, smoking status or recurrence of illness. These findings suggest that capillaroscopy shows microvascular abnormalities suggesting a vasodilation mechanism. As pernio preferentially affects the feet, further studies are needed to specifically assess the NCM pattern on feet and to determine the pathophysiology of this disease.

SESSION INFORMATION

Session Title: Epidemiology and Public Health Poster III (ACR): Gout and Non-Inflammatory Musculoskeletal Conditions

Session Type: ACR Poster Session C

Background/Purpose: Rheumatoid factor (RF) is an autoantibody directed against the Fc component of IgG. It is present in approximately 70-80% of rheumatoid arthritis (RA) patients but also found nonspecifically in chronic inflammatory condition such as sarcoidosis, hepatitis B or C infection, and tuberculosis. It has been suggested that lung may be an important sites generating or sequestering autoantibodies by immune dysregulation. Also, RF-positive patients without inflammatory arthritis showed significantly higher frequency of inflammatory airway abnormality. However, little is known about the influence of RF on

pulmonary function in health screening subjects without any specific medical problem. This study aimed to determine the effect of the presence of RF on pulmonary function in Korean health screening subjects without any history of joint disease and clinically apparent lung diseases.

Methods: Of the 114,944 people who participated in a health checkup program in 2010, 94,438 subjects with normal chest radiography were recruited, whose results of RF and pulmonary function test (PFT) using spirometry were available. Subjects with arthralgia or the past medical history of arthritis including RA, and lung diseases were excluded based on self-reported questionnaire. Association between RF and PFT was assessed by correlation analysis.

Results: Among 94,438 people, RF was positive in 3,326 subjects (3.52%). Their mean age was 41.3 ± 8.3 (range, 21 – 83) and 43.8% were female; these characteristics were not significantly different from those of RF-negative subjects. Ever-smokers (ex- and current smokers) were 39% in RF-positive subjects while 41.2% in RF-negative subjects ($p = 0.009$). Hepatitis B surface antigen (HBsAg) and anti-hepatitis C antibodies (anti-HCV) were more frequently seen in RF-positive subjects (12.1% vs. 3.5%, $p < 0.001$ for HBsAg and 0.5% vs. 0.1%, $p < 0.001$ for anti-HCV). Regarding PFT, RF-positive subjects had lower forced vital capacity (FVC) and forced expiratory volume in on second (FEV_1) compared to RF-negative subjects (3.79 ± 0.83 L vs. 3.87 ± 0.83 L, $p < 0.001$ and 3.17 ± 0.66 vs. 3.25 ± 0.67 L, $p < 0.001$). The proportion of subjects with FVC below 82% and FEV_1 below 84% of the predicted value was significantly higher in RF-positive subjects (50.7% vs. 46.6%, $p < 0.001$ and 54.5% vs.49.4%, $p < 0.001$) but the frequency of airflow limitation ($FEV_1/FVC \leq 70\%$) did not differ between two groups (1.4% vs. 1.5%, $p = 0.47$). FVC and FEV_1 had negative correlations with the RF titers ($r = -0.053$, $p < 0.001$ in FVC and $r = -0.055$, $p < 0.001$ in FEV_1). Multivariate logistic regression analysis showed that RF positivity was an independent predictor for the reduction of FVC (adjusted OR = 1.10, 95% CI 1.01 – 1.20, $p < 0.001$) and FEV1 (adjusted OR = 1.18, 95% CI 1.08 – 1.28, $p < 0.001$).

Conclusion: The results suggest that the presence of RF could impact on pulmonary function in healthy subjects without clinically apparent lung diseases. A follow up study for the serial changes of PFT may reflect the actual influence of the raised RF titers.

Incidence of Obesity, Diabetes and High Blood Pressure Associated with Arthritis: Analysis of the Canadian Longitudinal National Population Health Survey

Orit Schieir[1], Sheilah. Hogg-Johnson[1,2], Richard H Glazier[3,4,5,6] and Elizabeth M. Badley[1,7], [1]Dalla Lana School of Public Health, University of Toronto, Toronto, ON, Canada, [2]Institute for Work and Health, Toronto, ON, Canada, [3]Family and Community Medicine, St. Michael's Hospital, Toronto, ON, Canada, [4]Centre for Research on Inner City Health, St. Michael's Hospital, Toronto, ON, Canada, [5]Institute for Clinical Evaluative Sciences, Toronto, ON, Canada, [6]Family and Community Medicine, University of Toronto, Toronto, ON, Canada, [7]Health Care & Outcomes Research, Toronto Western Res. Institute, Toronto, ON, Canada

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Epidemiology and Public Health Poster III (ACR): Gout and Non-Inflammatory Musculoskeletal Conditions

Session Type: ACR Poster Session C

Background/Purpose: While cross-sectional evidence points to a higher prevalence of cardiovascular (CVD) risk factors in persons with arthritis, longitudinal population based studies are lacking. The objective of the present study was to estimate the incidence of major CVD risk factors (obesity, diabetes and high blood pressure) associated with arthritis in a longitudinal population-based survey.

Methods: The present study was a secondary analysis of the Canadian National Population Health Survey (NPHS), a longitudinal study of 17,276 Canadians followed-up every 2 years from 1994/95 through 2010/11. Survey participants provided updated information on socio-demographic variables, self-reported physician-diagnosed chronic conditions (including arthritis, high blood pressure and diabetes), and lifestyle/health behaviors, including height & weight used to calculate body mass index (BMI) classification of obesity. Cause of death records for diabetes (ICD10 codes:E10-E14) and hypertension (ICD10 codes I10-I15) were confirmed against the Canadian Vital Statistics Database. Adult participants age 18+ and at-risk for each risk factor (i.e. those without a prior history of, or prevalent report of each risk factor at the 1994/95 baseline assessment) were eligible for analysis. Adjusted odds ratios and 95% confidence intervals (CI) conveying the odds of experiencing each risk factor event in a given time period conditional on not having experienced the event before were estimated using separate discrete time survival models. Each model included repeated measures of arthritis updated every 2 years and the following baseline covariates: age sex, race, education, smoking, physical activity, BMI, alcohol consumption, non-CVD comorbidity index, and use of pain medications. All analyses were carried out using appropriate survey weights and bootstrap standard errors to account for the complex survey design.

Results: We identified 2,284, 3,022 and 1,045 incident obesity, high blood pressure and diabetes events during the study follow up period from 1996/97 through 2010/2011. Adjusting for age and sex, arthritis was significantly associated with increased risks of each of the 3 risk factors (obesity OR (95% CI): 1.39 (1.22-1.60), high blood pressure OR (95% CI): 1.30 (1.17-1.45) and diabetes OR (95% CI): 1.25 (1.03-1.52)). In fully adjusted models controlling for all covariates, results were attenuated but remained significant for obesity (OR (95% CI): 1.20 (1.02-1.42)) and high blood pressure (OR (95% CI): 1.19 (1.05-1.34.)) but not for diabetes (OR (95% CI): 0.97 (0.83-1.12)).

Conclusion: Results of this nationally representative Canadian population based study showed that persons with arthritis had increased risks for developing major CVD risk factors. The current findings not only support arthritis as a flag for screening for existing CVD risk factors but suggest that the disease itself, its treatment and/or its consequences (i.e. pain and disability) may be implicated in the onset of obesity and high blood pressure in persons at risk for developing these conditions.

High Prevalence of Hypomagnesemia and Its Relation to BMI, Type 2 Diabetes, and Clinical Disease Measures in a VA Outpatient Rheumatology Clinic Population

Nitika Ghattaura[1], Caleb Murphy[2] and Peter Valen[2,3], [1]Rheumatology, University of Minnesota Medical School, Minneapolis, MN, [2]University of Minnesota Medical School, Minneapolis, MN, [3]Rheumatology, Minneapolis VAMC, Minneapolis, MN
First publication: September 29, 2015

SESSION INFORMATION
Session Title: Epidemiology and Public Health Poster III (ACR): Gout and Non-Inflammatory Musculoskeletal Conditions
Session Type: ACR Poster Session C

Background/Purpose: Magnesium plays an essential role in multiple cellular reactions, and there is increasing interest in its role in inflammation and pain. It has been estimated that nearly half the US population consumes less than the daily requirement of magnesium, likely due in part to decreased magnesium content in processed and refined foods and purified water. There are very few studies of the prevalence of hypomagnesemia in the general population, and no studies in a Rheumatology outpatient clinic population. The purpose of this study was to determine the prevalence of hypomagnesemia in a VA Rheumatology outpatient clinic population, and explore its relationship to BMI, Type II diabetes, clinical disease measures, and potential contributing factors, including PPI use.

Methods: 100 consecutive new referrals to the Minneapolis VAMC Rheumatology clinic and 100 consecutive established inflammatory arthritis patients were included in the study. Serum magnesium (Mg), ESR and CRP were measured, and BMI was

recorded. Data regarding presence of Type 2 diabetes, rheumatoid arthritis (RA), renal function, alcohol, PPI, diuretic and vitamin supplement use was collected. In new patients, self-reported pain scores (VAS) were recorded. DAS28 scores were calculated in the subset of patients with newly diagnosed rheumatoid arthritis. Chi-square and multivariable logistic regression analysis were used for statistical analysis.

Results: 76 of 200 patients (38%) had low serum magnesium levels (< 1.8 mg /dl). There was no significant difference between new vs established patients (41 % vs 35%, p= 0.38). Magnesium levels overall tended to be in the low normal range with an overall mean of 1.8 mg/dl ±0.25. Mean Pain scores were slightly higher in the low magnesium group, but the difference was not significant (4.51 ±3.32 vs 3.76 ±2.87, p= 0.88). Mean values of ESR and CRP were not significantly different in the low vs normal Mg groups. Mean DAS28 scores were slightly higher in the RA patients with low Mg vs normal Mg (5.7±1.5 vs 3.9±1.9), however the number of patients was too small to draw statistical conclusions. Although a larger percentage of patients with low Mg were taking PPIs, the unadjusted effect of PPI use on prevalence of hypomagnesemia was small (OR 1.67, p=0.09). The concomitant use of diuretics did not significantly alter the risk. There was no significant association between reported alcohol or supplement use and hypomagnesemia. There was a weak association of BMI and hypomagnesemia (OR 1.05, p=0.04). The strongest association was with T2DM, which was an independent risk factor for hypomagnesemia (OR 3.77, p=0.001).

Conclusion: We found an alarmingly high prevalence of hypomagnesemia in a cohort of VA Rheumatology clinic outpatients. BMI and PPI use were weakly associated with hypomagnesemia. Hypomagnesemia may be associated with higher disease activity in rheumatoid arthritis. We found a strong association between T2 DM and hypomagnesemia. This study supports the need for future investigation of the prevalence and causes of hypomagnesemia in the rheumatic diseases, and its role in inflammation, pain and disease activity.

SESSION INFORMATION

Session Title: Epidemiology and Public Health Poster III (ACR): Gout and Non-Inflammatory Musculoskeletal Conditions

Session Type: ACR Poster Session C

Background/Purpose: Musculoskeletal pain has been shown to commonly occur at multiple sites. This is likely to have a greater impact on abilities to undertake activities of daily living, work and quality of life in general. While obesity has been shown to impact on the occurrence of musculoskeletal conditions, body composition may also play a role. Few studies have examined the association between body composition and multiple pain sites although a recent study of 133 participants demonstrated that fat mass and fat mass index were associated with pain at a greater number of weight-bearing sites[1]. The aim of this study was to examine the association between pain sites and pain at weight-bearing and non-weight-bearing sites.

Methods: The North West Adelaide Health Study (NWAHS) is a longitudinal cohort study with three stages of data collection. Each stage comprised a self-complete questionnaire, clinic assessment and Computer Assisted Telephone Interview (CATI). In Stage 2 (2004-2006), Dual Energy X-ray Absorptiometry (DXA) scans were undertaken on those aged 50 years and over (n=1066), which enabled the calculation of fat mass index and fat free mass index. Additional data included demographics and body mass index (BMI). As part of the telephone interview, participants were asked if they had ever had back, hip, knee, shoulder and hand pain and/or stiffness on most days for at least a month and whether they had pain or stiffness in the feet on most days. The association with areas of pain and BMI, fat mass (kg), fat mass index, fat free mass (kg) and fat free mass index were examined

using logistic regression analysis.

Results: Among those aged 50 years and over, the prevalence of pain and/or stiffness in the feet was 20.2%, shoulder 27.8%, hip 15.6%, back 40.8%, hand 21.5% and knee 18.0%. The unadjusted and adjusted associations between areas of pain, BMI and body composition measurements are presented in Table 1. There were significant associations for both weightbearing and non-weightbearing joints between BMI and body composition variables even after adjustment for age, sex and the appropriate body composition measure.

Table 1: Unadjusted and adjusted association between areas of musculoskeletal pain, BMI and body composition

	BMI	Fat mass	Fat mass index	Fat free mass	Fat free mass index

[a]Models with fat mass and fat mass index adjusted for fat free mass and fat free mass index respectively

[b]Models with fat free mass and fat free mass index adjusted for fat mass and fat mass index respectively

Conclusion: The prevalence of joint pain is high in community dwelling people aged 50 years and over. BMI and body composition measurements are associated with reports of pain, in both weightbearing and non-weightbearing joints. The association with fat mass and fat mass index in particular may be associated with metabolic effects. However, body composition does need to be considered when treating those with musculoskeletal pain.

A Novel Study Instrument to Identify Household Work Related Musculoskeletal Disorders – Development and Validation

Priyanga Ranasinghe[1], Inoshi Atukorala[2], Sachitra Illangatilaka[3] and Nalika Gunawardena[4], [1]Public Health, Medical Officer, Family Health Bureau, COLOMBO 8, Sri Lanka, [2]Department of Clinical Medicine, Faculty of Medicine, University of Colombo, Consultant Rheumatologist and Senior Lecturer in Medicine, COLOMBO 8, Sri Lanka, [3]Department of Rheumatology and Medical Rehabilitation, Senior Registrar, COLOMBO 8, Sri Lanka, [4]Faculty of Medicine, University of Colombo, Senior Lecturer in Community Medicine, COLOMBO 8, Sri Lanka

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Epidemiology and Public Health Poster III (ACR): Gout and Non-Inflammatory Musculoskeletal Conditions

Session Type: ACR Poster Session C

Background/Purpose:

Household work is significant cause of musculoskeletal pain, particularly in the South Asian setting where household work is labour intensive and manually performed. But, the burden of this problem is unknown with the lack of a valid screening tool cited as a reason for this shortfall. This project develops and validates a novel study instrument to identify household work related musculoskeletal disorders (HWMSD) in the following nine anatomical regions – the neck, shoulder, elbow, wrist/hand, upper back, low back, hip/thigh, knee and ankles/feet.

Methods:

An interviewer -administered tool the Household Work related Musculoskeletal Disorders Questionnaire (HWMQ)) was developed. It assessed the presence/absence of musculoskeletal symptoms and household work-relatedness of these symptoms. This tool was developed by a multidisciplinary panel of experts using the Nordic Musculoskeletal Questionnaire as the base. Identification of the HWMSD was done if all absolute criteria were present for a given region in the presence of 2 or more probable symptom related *and* one or more probable household work related criteria(Table 1). The criterion validity against the diagnosis of a rheumatologist was the gold standard. Subsequently, test-retest reliability and acceptability was assessed in a sample of Sri Lankan housewives.

Results: The study cohort contained 250 full time housewives (median age 40 years, Interquartile range 35-45 years) from

Colombo, Sri Lanka. 77% were engaged in household work for >10 years with a mean of 11.3 hours (±2.8) spent daily on household work. Household work included cooking (96 %), washing clothes by hand (83.6%), sweeping and cleaning (96.4%) carrying water/firewood (72.8%) and childcare (52.8%). Acceptability was high with a response rate of 83.3%. Average time taken to complete the HWMQ was 12min (± 3min). Psychometric properties of the HWMQ were as follows: sensitivity was highest in ankle/feet and lowest in hip/thigh region and specificity was highest in low back assessment and lowest in the knee region (Table 2). Reliability by Cohen's Kappa was above 0.8 for each region.

Conclusion:

The household work related musculoskeletal disorders questionnaire is a valid and reliable instrument to screen the housewives for musculoskeletal disorders related to housework.

Table 1 Absolute and Probable Criteria to Diagnose HWMSD among Housewives

	Absolute criteria	Probable criteria
Symptoms related criteria	• Pain/ache/ discomfort for minimum of 3 consecutive days during last 3 months **(For low back region only)** • No identifiable pattern with menstruation • The pain not related to /associated with pain of sexual intercourse • Burning sensation in abdomen • Pain on passing urine • Constipation	• Pain, ache or discomfort restricts movements • Pain, ache or discomfort has limited household activities performed • Pain, ache or discomfort has worsened intermittently or continuously over time • Pain, ache or discomfort with soreness of 5 or more in the visual analogue scale of (1-10)
Household work related criteria	• The site not subjected to any injury other than household work related injury	• Onset of pain, ache or discomfort after performing household work as a housewife • Pain, ache or discomfort worsen when performing household work • pain, ache or discomfort subsides when having rest from household work

Table 2: Sensitivity and specificity of the HWMQ by region

	Sensitivity (%)(95% CI)	Specificity (%)(95% CI)
Neck	80(75.0-85.0)	99.5 (98.6-100)
Shoulder	97 (94.9-99.1)	98.6 (97.1-100)
Elbow	93.7(90.7-96.7)	98.7 (97.3-100)
Wrist/Hand	89.1 (85.2-93)	99.0 (97.8-100)
Upper back	95.5(92.9-98.1)	98.7 (97.3-100)
Lower back	94.5(91.7-97.3)	99.3 (98.3-100)
Hip/Thigh	80 (75-85)	98.0(96.3-99.7)
Knee	93.6(90.6-96.6)	89.7(85.9-93.5)
Ankle/Feet	97.6(95.7-99.5)	99 (97.8-100)

Construct and Convergent Validity of Four Global Measures of at-Work Productivity Loss in Patients with Rheumatic Diseases

Sarah Leggett[1], Diane Lacaille[2], Carina Mihai[3], Mihai Bojinca[4], Brendan van As[5], Suzanne M. Verstappen[6] and EULAR-PRO worker productivity group, [1]Arthritis Research UK Centre for Epidemiology, Manchester Academic Health Science Centre,The University of Manchester, Manchester, United Kingdom, [2]Arthritis Research Centre, University of British Columbia, Vancouver,

BC, Canada, [3]Internal Medicine and Rheumatology, Ion Cantacuzino Hospital, Bucharest, Romania, [4]Carol Davila University of Medicine and Pharmacy, Internal Medicine and Rheumatology, Cantacuzino Hospital, Bucharest, Romania, [5]Arthritis Research Canada, Richmond, BC, Canada, [6]Arthritis Research UK Centre for Epidemiology, The University of Manchester, Manchester, United Kingdom

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Epidemiology and Public Health Poster III (ACR): Gout and Non-Inflammatory Musculoskeletal Conditions

Session Type: ACR Poster Session C

Background/Purpose:

Several global measures are available to assess at-work productivity loss in rheumatic diseases. Paucity in research exploring the construct validity of such measures contributes to a lack of consensus on which measure is optimum. The purpose of this study was to determine the construct and convergent validity of four global measures of at-work productivity loss, namely the Work Productivity Scale–Rheumatoid Arthritis (WPS-RA), Work Productivity and Activity Impairment Questionnaire (WPAI), Work Ability Index (WAI), and the Quality and Quantity questionnaire (QQ), with multi-item measures of at-work productivity and health specific measures.

Methods:

In this international study, 101 patients with inflammatory arthritis or OA in paid employment were recruited from 3 countries (UK, Canada, and Romania). Demographic, clinical, and occupational data (e.g., occupation; manual vs. non-manual) were collected. The global measures of at-work productivity loss were completed (WPAI; *0=no effect on work – 10=completely prevented from working,* WPS-RA; *0=no interference – 10=complete interference,* WAI; *0=unable to work – 10=work ability at its best,* QQ; *0= practically nothing– 10=normal quantity*), in addition to multi-item measures of at-work productivity loss (the Workplace Activity Limitations Questionnaire; WALS, & the Work Limitations Questionnaire; WLQ-25) and disease specific and health related outcomes. Spearman's correlation coefficients were used to assess the strength of the relationship between the global measures with multi-item and health related measures.

Results:

59% of the study population were female; mean age was 48 years (SD 8.8) and the mean symptom duration was 14 years (SD 10.8). 39% of the population had RA, and 52% had a non-manual occupation. Spearman correlations yielded mostly high (i.e., 0.5-0.7), with some moderate (i.e. 0.3-0.5) convergence between global and multi-item measures (Table 1). Overall, convergence was higher with the WALS (with the WPS-RA having the highest convergence; 0.73) and lower with the WLQ-25 (with the WPAI having the lowest convergence; 0.42), likely because of differences in construct measured by multi-item measures [i.e. degree of limitation (WALS) vs. amount of time limited (WLQ-25)]. Construct validity revealed mostly high, with some moderate, correlations between the global measures and health related questionnaires (Table 1).

Conclusion:

Most of the global measures demonstrated high convergence validity with multi-item measures and construct validity with disease specific measures. The strength of the relationships was variable across instruments, likely due to differences amongst global and multi-item measures (e.g., varying constructs). Overall, the results contribute to the currently sparse validity data supporting the use of global instruments to measure at-work productivity loss.

Table 1. Spearman correlations* of the four global measures with multi-item measures of at-work productivity, disease specific measures and health related measures.

	WALS	WLQ-25 index	HAQ	EQ-5D	VAS pain	VAS well-being	RAID (n=38)	PsAID (n=19)	Lequesne (n=11)	BASDAI (n=30)	BASFI (n=30)
WPAI	0.67	0.42	0.37	-0.45	0.51	0.62	0.55	0.41	0.70	0.50	0.24
WPS-RA	0.73	0.50	0.45	-0.45	0.50	0.56	0.62	0.56	0.58	0.53	0.43
WAI	-0.69	-0.56	-0.50	0.54	-0.50	-0.62	-0.34	-0.57	-0.49	-0.72	-0.57

SESSION INFORMATION

Session Title: Epidemiology and Public Health Poster III (ACR): Gout and Non-Inflammatory Musculoskeletal Conditions

Session Type: ACR Poster Session C

Background/Purpose: The prevalence and burden of chronic low back pain (CLBP) were ill defined in Portugal. The aim of this study was **t**o determine, the prevalence of active CLBP (ACLBP) in the adult Portuguese population; to compare the ACLBP population with the population without ACLBP, and to explore factors associated with ACLBP.

Methods: This study was conducted under the scope of EpiReumaPt, a Portuguese population-based study including 10,661 subjects, representative of the Portuguese population. Trained interviewers undertook structured face-to-face questionnaires in participant's households that included socio-demographic, socio-economic information and medical history, as well as information on functional ability, quality of life and healthcare resources consumption. ACLBP was self-reported and considered if present on the day of the interview and for ³90 days. Prevalence estimates were calculated. Differences in quality of life, functional ability and healthcare resources consumption between subjects with and without ACLBP were evaluated. Factors associated with ACLBP were identified through logistic regression. All analyses were adjusted for possible confounders.

Results: The prevalence of ACLBP was 10.4% (95%CI 9.6%; 11.9%). The mean age was 58.9 (SD 17.2) years old and 68.7% were overweight or obese. ACLBP was significantly more prevalent among women (14.1% vs 6.3% in men).

After adjustment, ACLBP subjects were more likely to have anxiety symptoms (OR=2.66, $p<0.001$), to retire early due to the disease (OR=1.72; $p=0.006$), and to be absent from work due to the disease (OR=1.86; $p<0.001$). The presence of a self-reported rheumatic musculoskeletal disease (RMD), anxiety symptoms, female gender, older age, higher education level and higher number of self-reported comorbidities were significantly associated with the presence of ACLBP, taking potential confounders into account (BMI, NUTS II, present alcohol intake and depressive symptoms). In turn, physical exercise was inversely associated with ACLBP (table 1).

Conclusion: ACLBP is highly prevalent in the Portuguese population and is associated with disability and with a high consumption of healthcare resources. Female gender, older age, anxiety symptoms, educational level, the presence of other RMD and the number of comorbidities were independently associated with the presence of ACLBP. These factors should be taken into account when developing strategies to prevent the occurrence of ACLPB.

SESSION INFORMATION

Session Title: Epidemiology and Public Health Poster III (ACR): Gout and Non-Inflammatory Musculoskeletal Conditions

Session Type: ACR Poster Session C

Background/Purpose:

Rheumatic and musculoskeletal diseases (MSKD) are a prevalent leading cause of disability and consume a large amount of healthcare and social resources. MSKD have been associated with low levels of physical and mental health in other countries. The purpose of this study was to estimate the national prevalence of hand, knee and hip osteoarthritis (OA), low back pain (LBP), rheumatoid arthritis (RA), fibromyalgia (FM), gout, spondyloarthritis (SpA), periarticular disease (PD) systemic lupus erythematosus (SLE), polymyalgia rheumatica (PMR) and osteoporosis (OP)) in the adult Portuguese population; to compare

physical and mental health between participants with and without MSKD.

Methods:

EpiReumaPt is a national health survey conducted from Sep'2011 to Dec'2013, which involved a three-stage approach. First, 10661 adult subjects were randomly selected. Trained interviewers undertook structured face-to-face questionnaires in participant's households that included a screening for MSKD, and the EQ5D and HAQ. Secondly, all participants screened positive for at least one MSKD plus 20% of individuals with no rheumatic complaints were invited to be seen by a rheumatologist at the local Primary Care Center for a structured evaluation. Finally, a team of 3 experienced rheumatologists revised all the clinical data and confirmed the diagnoses according to previously validated criteria. Estimates were computed as weighted proportions, in order to take into account the sampling design.

Results:

Prevalence of MSKD in the adult Portuguese population was as follows with 95% CI (table1): After adjustment, subjects with RMD had significantly lower EQ5D scores (β=-0.09; $p<0.001$) and higher HAQ scores (β=0.12; $p<0.001$) than subjects with no MSKD. Some MSKD were significantly and independently associated with worse EQ5D scores: PMR (β=-0.334), RA (β=-0.132), FM (β=-0.100), LBP (β=-0.07), Knee OA (β=-0.06) and PD (β=-0.04). Proportion of anxiety and depression symptoms among the MSKD Portuguese patients was 16.7% and 8.3%, respectively; the prevalence of anxiety symptoms was significantly higher when compared with subjects without MSKD diseases (OR= 3.4; p=0.003). Moreover, FM (OR=3.12; $p<0.001$), SpA (OR=2.82; p=0.012) and LBP (OR=1.84; p=0.007) were significantly and independently associated with the presence of anxiety symptoms; PMR (OR=18.81; p=0.006), FM (OR=3.73; p=0.001) and LBP (OR=1.55; p=0.030) were significantly and independently associated with the presence of depression symptoms.

	Total prevalence (95% CI) n=3877
LBP (n=1393)	**26.41%** (23.32%; 29.51%)
PD (n=929)	**15.76%** (13.47%; 18.04%)
Knee OA (n=981)	**12.40%** (11.00%; 13.81%)
OP (n=858)	**10.16%** (8.98%; 11.33%)
Hand OA (n=625)	**8.73%** (7.53%; 9.93%)
Hip OA (n=199)	**2.95%** (2.27%; 3.62%)
FM (n=149)	**1.70%** (1.13%; 2.08%)
SpA(n=92)	**1.63%** (1.19%; 2.08%)
Gout (n=92)	**1.28%** (0.96%; 1.60%)
RA (n=61)	**0.73%** (0.52%; 0.95%)
SLE (n=13)	**0.15%** (0.06%; 0.25%)
PMR (n=8)	**0.10%** (0.02%; 0.18%)

Conclusion: MSKDs are highly prevalent in Portugal and are associated with significant impairment of physical and mental health.

Is Rheumatic Disease Really More Severe in Indigenous Populations? a Systematic Review of Clinical Outcomes in Indigenous Populations of Canada,

the United States, Australia and New Zealand

Kelle Hurd[1] and Cheryl Barnabe[2], [1]University of Calgary, Calgary, AB, Canada, [2]Cumming School of Medicine, University of Calgary, Calgary, AB, Canada

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Epidemiology and Public Health Poster III (ACR): Gout and Non-Inflammatory Musculoskeletal Conditions

Session Type: ACR Poster Session C

Background/Purpose: The Indigenous populations of Canada, the United States, Australia and New Zealand have higher disease prevalence for many inflammatory arthritis conditions and connective tissue diseases compared to the non-Indigenous populations in those countries. Phenotypic differences are believed to exist clinically. The objective of our systematic review was to summarize differences in disease characteristics, disease activity and outcomes for Indigenous populations.

Methods: A systematic search (to June 2015) was performed in Medline, EMBASE, the Bibliography of Native North Americans, Circumpolar Health Bibliographic Database, Metis Health Database, Native Health Database, Native Indigenous Studies Portal, Australian Indigenous Health InfoNet, and conference abstracts from rheumatology conferences (2012-2015) in the countries of interest and international conferences. Search terms for Indigenous populations were combined with search terms for inflammatory arthritis conditions (rheumatoid arthritis, spondyloarthropathies, juvenile idiopathic arthritis), connective tissue disorders (systemic lupus erythematosus, scleroderma, myositis, sjogren's), crystal arthritis and osteoarthritis. Studies were included if they reported disease activity measures for the condition of interest, the proportion of patients with recognized classification criteria for the condition of interest, or mortality.

Results: A total of 5,269 titles and abstracts were reviewed, of which 523 underwent full-text review, and 87 were included for extraction of clinical outcomes. Thirty-eight of the studies were published before the year 2000, and only 37% made mention of Indigenous populations collaboration on the studies. Nearly all the studies described outcomes in the North American populations (n=38 American, n=40 Canadian), with only 5 studies from Australia and 4 studies from New Zealand. Forty-four studies described RA characteristics in Indigenous populations, and 14 had a comparator group defined as Caucasian, White, Non-Aboriginal or Non-First Nations. Indigenous populations were younger at disease onset (age range 29-41 years vs 36-55 years). Disease activity measures were not frequently significantly worse in Indigenous patients, although lesser response to treatment was identified in one study. Pain levels were higher in Indigenous patients in all studies reporting this outcome (n=3 studies). No studies examined a mortality rate, but in one study Indigenous patients were younger at death (53 vs 76 years). There were 22 studies identified that described lupus characteristics and outcomes, and 13 had a comparator group. Lupus nephritis was more common in Indigenous populations, with a higher mortality rate.

Conclusion: Our synthesis highlights knowledge gaps that exist and assumptions that have been made with regards to the disease phenotype of Indigenous populations of Canada, the United States, Australia and New Zealand. Contemporary studies performed in collaboration with Indigenous populations are required to more fully understand the consequences of rheumatic disease in these countries.

Rheumatology Work Force Planning in Western Countries – a Systematic Literature Review

Christian Dejaco[1], Angelika Lackner[2], Markus Narath[3] and Martin Sprenger[4], [1]Department of Rheumatology and Immunology, Medical University Graz, Graz, Austria, [2]Avenbruggerplatz 15, Medical University Graz, Graz, Austria, [3]Steiermärkische Krankenanstaltengesellschaft (KAGes), Graz, Austria, [4]Public Health School, Medical University of Graz, Graz, Austria

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Epidemiology and Public Health Poster III (ACR): Gout and Non-Inflammatory Musculoskeletal Conditions

Session Type: ACR Poster Session C

Background/Purpose: To compare models forecasting adult and paediatric rheumatology work force requirement in Western countries

Methods: A systematic literature review (SLR) was conducted by 2 authors (CD, AL) through medical databases (Ovid MEDLINE®, Embase, CINAHL, Cochrane Library), and the homepages (and referenced links) of the departments of health, rheumatology societies and medical associations of the following countries: Austria, Germany, Switzerland, United Kingdom (UK), Ireland, Canada, USA, Australia, New Zealand. Besides, we searched the homepages of EULAR, the European Commission and related organisations. Additional articles were retrieved by reviewing the reference list of full articles, conference abstracts and by contacting the national rheumatology societies of EULAR countries, USA, Australia, New Zealand, Canada and the EU - Joint action on workforce planning and forecasting. We included only English and German articles providing an estimation of (current and/or future) adult and/or paediatric rheumatology manpower (required to serve the respective population), and describing the methods and factors underlying this calculation. Quality appraisal of included articles was not possible because no appropriate instrument is available. Any discordance between the authors (3% of the papers) was resolved by discussion. The protocol of this SLR was registered at the PROSPERO website (CRD42014013948).

Results: The initial search yielded n=5699 articles, a total of 12 articles (9 papers for adult rheumatology, 1 for paediatric and 2 for adult and paediatric rheumatology) met all inclusion criteria. Rheumatology manpower calculations were available for the USA (3 models), Canada (n=3), USA + Canada (n=1), Germany (n=2), Spain (n=1) and the UK (n=2). There was a large variance regarding the estimated number of rheumatologists ranging from 0.7 (UK, 1988) to 3.5 (Spanish projection for 2021) to serve a population of 100,000 people. For paediatric rheumatology, 1 rheumatologist per 100,000 children (Germany) or 0.7-1.0 per 1,000,000 (of the general) population (USA) were suggested. Most models used a demand (n=3) or needs (n=6) based approach whereas in 3 papers, the underlying method was unclear. The following variables were considered by ≥ 1 model: disease prevalence, proportion of patients that should be referred to a rheumatologist, clinical visits/patient/year, population development, workforce provided by one rheumatologist full time equivalent, factors influencing workforce capacity, patient flow/care sharing, effect of medical development.

Conclusion: Different methods have been applied to forecast rheumatology work force requirement in Western countries yielding highly variable results with 0.7 to 3.5 rheumatologists required to serve a population of 100,000 people.

Peripheral Joint MRI for Inflammatory Arthritis and the Choosing Wisely Campaign – Evidence for Wide Variations in Use

Gabriela Schmajuk[1], Chris Tonner[2], Sara G. Murray[3] and Jinoos Yazdany[4], [1]Medicine / Rheumatology, UCSF / San Francisco VA, San Francisco, CA, [2]Rheumatology, University of California, San Francisco, San Francisco, CA, [3]Medicine, University of California, San Francisco, San Francisco, CA, [4]Rheumatology, UCSF, SF, CA

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Epidemiology and Public Health Poster III (ACR): Gout and Non-Inflammatory Musculoskeletal Conditions

Session Type: ACR Poster Session C

Background/Purpose: The Choosing Wisely campaign, which commenced in 2011, focuses on reducing medical services that are

of questionable value or may be harmful. In 2013, the American College of Rheumatology published their own "Top 5" list, which included the recommendation to avoid MRI of the peripheral joints to monitor patients with inflammatory arthritis. We sought to determine the prevalence of MRI of the peripheral joints among patients with inflammatory arthritis before the "Top 5" lists were published to estimate the potential effect of the recommendations on future use of resources.

Methods: We examined use of peripheral joint MRI using data from a nationally representative 5% sample of Medicare fee-for-service claims. Using ICD9 codes we identified patients 65 years or older with at least 2 face-to-face claims for rheumatoid arthritis (714.xx) between Jan 1 and Dec 31, 2009. We used CPT codes to classify patients as having undergone MRI or plain film radiography of the peripheral joints. To assess regional variation, we estimated peripheral joint MRI use per patient by hospital referral region (HRR). We used linear regression to correlate the number of peripheral joint MRI performed in each HRR with the number of physicians or rheumatologists per Medicare beneficiary (supply data from the Dartmouth Atlas).

Results: We included 8,052 patients in our analysis. 81% were women and mean age was 76 years. 7.7% of patients underwent at least 1 peripheral joint MRI compared with 38.6% for peripheral joint plain films. Peripheral joint MRI use varied widely across 304 HRRs (range 0-2.25 per patient; interquartile range 0-0.15). High utilization areas were clustered in the southern and southwestern U.S. (see Figure). Linear regression revealed a non-significant relationship between peripheral joint MRI and HRR supply of physicians (p=0.07) or HRR supply of rheumatologists (p=0.86).

Conclusion: Before the start of the Choosing Wisely campaign, use of peripheral joint MRI for Medicare patients with known or suspected inflammatory arthritis varied widely across geographic regions. Although we cannot judge the appropriateness of each radiographic test performed, marked variation in utilization suggests that studies to assess overuse are warranted. Future analyses should also assess the impact of the Choosing Wisely campaign in reducing the variation in use of peripheral joint MRI.

Figure. Peripheral joint MRIs per rheumatoid arthritis Medicare beneficiary in 2009, by Health Referral Region.

SESSION INFORMATION

Session Title: Epidemiology and Public Health Poster III (ACR): Gout and Non-Inflammatory Musculoskeletal Conditions
Session Type: ACR Poster Session C

Background/Purpose:

Economic considerations and patient preferences are increasingly important when choosing treatments. It is not known to what extent rheumatologists across Europe account for these factors when changing drug therapies in patients with active rheumatoid arthritis (RA).

Objectives:

To evaluate the extent to which rheumatologists across Europe consider costs, cost-effectiveness and patient preferences in addition to efficacy and safety in treatment decisions in RA.

Methods:

In a discrete choice experiment, rheumatologists were asked to choose iteratively between two unlabeled drug treatment options for a hypothetical RA patient with moderate disease activity who failed two synthetic DMARDs. The treatment options were characterized by five attributes further specified by three levels; efficacy (level of improvement and achieved state of disease activity), safety (probability of a serious adverse event), patient preference (level of agreement with proposed treatment), medication costs and cost-effectiveness (incremental cost-effectiveness ratio (ICER)).

Attributes and levels were selected based on literature data and expert consensus. An efficient experimental design was used to construct 14 treatment choices and a mixed logit model was used to estimate the relative importance of attributes.

Results:

559 rheumatologists from 12 European countries contributed to the analysis (50.2% females, mean age 48.3 years). When choosing treatments for RA patients, efficacy was the most important attribute in all participating countries (44%, range 39-52%). Overall, safety also played an important role for treatment decisions (13%) however varied between countries (2-20%). Importance of safety increased with increasing risk of severe adverse events. Patient preference contributed importantly (16%), especially when patients disagreed with the proposed treatment.

Relative importance of economic attributes varied (1) between countries and (2) among individual rheumatologists. In the majority of countries, absolute costs were more relevant for treatment decisions than relative cost-effectiveness. Contributions of attributes to treatment decision (overall and per country) are summarized in table 1.

Table 1: Contribution of selected core treatment attributes to the overall preference for a treatment choice (mean per country, in percent (%) of total explained variance)

Country/N / Treatment Attribute	BE	FR	GE	HU	IT	NL	NO	PT	RO	SE	SP	UK	All countries
	33	40	44	71	59	63	41	39	42	24	63	40	559
Efficacy *Improvement DAS28*	44%	43%	42%	46%	45%	44%	40%	39%	52%	43%	45%	39%	44%
Safety *Probability of a serious AE*	10%	20%	9%	12%	17%	1%	10%	19%	19%	11%	10%	2%	13%
Patient´s Preference	14%	21%	14%	16%	14%	17%	14%	14%	7%	19%	18%	19%	16%
Cost-Effectiveness *ICER, QALY/year*	9%	3%	14%	14%	8%	14%	12%	8%	4%	10%	17%	21%	11%
Medication costs *per year, in local currency*	23%	13%	19%	12%	15%	24%	24%	20%	18%	17%	10%	19%	17%
Model fit, R^2	0.61	0.58	0.66	0.63	0.63	0.46	0.65	0.64	0.63	0.67	0.65	0.63	0.39

BE=Belgium, FR=France, GE=Germany, HU=Hungary, IT=Italy, NL=Netherlands, NO=Norway, PT=Portugal, RO=Romania, SE=Sweden, SP=Spain, N= number of responses per country and overall, DAS28= Disease Activity Score in 28 joints, AE=Adverse Event, ICER=Incremental Cost-Effectiveness Ratio, QALY=Quality Adjusted Life Year

Conclusion:

Drug efficacy clearly remains the most important driver for treatment decisions in all European countries however rheumatologists also take into account economic aspects in their treatment decisions. In most countries, overall costs are still more important than cost-effectiveness considerations. Patient preferences are taken into account, indicating rheumatologists take steps towards patient centered care.

Cardiovascular Disease: The Hidden Risk in Persons with Rheumatoid Arthritis

Karen Soikkeli[1] and Glenn Ehresmann[2], [1]Graduate Nursing (Family Nurse Practitioner Program), Azusa Pacific University, Diamond Bar, CA, [2]Rheumatology, Keck School of Medicine, University of Southern California-Los Angeles County Medical Center, Los Angeles, CA

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Epidemiology and Public Health Poster (ARHP)

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Despite the fact that patients with rheumatoid arthritis (RA) experience a 50-60% increased risk of developing cardiovascular disease (CVD), substantial gaps remain in the knowledge and application of risk prevention measures in RA patients. There is no standardized guideline or protocol for identification and management of the CVD risk in the RA population. The purpose of this study is to develop an algorithm based on current evidence with best practice measures for identification and management of CVD risk in the RA population.

Methods: An extensive review of literature was performed exploring and evaluating CVD impact in the RA population from 2009-2015 to identify current evidence based measures utilized in this population. Retrospective chart review of RA patients at a large community medical center identified the absence of consistent CVD risk screening. The American College of Cardiology/American Heart Association (ACC/AHA) guidelines and the National Cholesterol Education Program (NCEP) Adult

Treatment Panel (ATP) III guidelines were extrapolated to provide the foundation for the development of an algorithm for providers to reflect current best practice to improve patient outcome management.

Results: A review of literature reveals several barriers to the management of CVD risk in RA patients. No standardized guidelines exist relative to the CVD risk management in the RA patient, but European League Against Rheumatism (EULAR) has made recommendations. Existing CVD risk scoring tools often underestimate risk, especially in RA. Computed tomography angiography (CTA) reveals higher plaque burden in asymptomatic RA patients without pre-existing CVD. Lipid knowledge remains incomplete with respect to epidemiology and pathogenesis of RA. Chart review of 35 RA patients at a community medical center revealed that only 40% contained any recorded lipid panel results; in the past year only 11.5% of the reviewed charts contained documentation of lipid panel results. An algorithm was developed to suggest improvements in CVD risk management in the RA population. Increased collaboration between the primary care provider, rheumatologist, and nurse practitioner or physician assistant may enhance overall CVD management (see algorithm *CVD Risk Management in RA Patients*).

Conclusion: There is a paucity of identification and/or management of CVD in this population. An algorithm was developed in order to help providers identify aggressive CVD strategies, including lifestyle instruction as a standard of care in the RA population, thus improving the long term CVD outcomes. Further research is indicated and should be aimed at the development of CVD risk scoring tools specific for the RA patient, with concrete guidelines on the CVD risk in the RA population. Further studies involving the use of imaging and other alternate methods of risk identification are indicated.

Does Arthritis in the Young Adult Life Phase Impact Involvement in Transitional Social Roles?

Arif Jetha[1,2], Kristina Theis[3] and Michael Alden Boring[3], [1]Center for Disability Research, Liberty Mutual Research Institute for Safety, Hopkinton, MA, [2]Institute for Work & Health, Toronto, ON, Canada, [3]Arthritis Program, Centers for Disease Control and Prevention, Atlanta, GA

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Epidemiology and Public Health Poster (ARHP)
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Post-secondary schooling and/or obtaining employment are milestones of a successful transition to adulthood. It is unclear if young adults, ages 18 to 29 years, with arthritis participate in transitional roles similar to their non-arthritis peers. This study compares employment and education participation of young adults with an arthritis diagnosis ("Have you ever been told by a doctor or other health professional that you have some form of arthritis, rheumatoid arthritis, gout, lupus, or fibromyalgia?") to their peers without arthritis.

Methods:

Data from years 2009 to 2013 of the National Health Interview Survey, an ongoing in-home interview survey, nationally representative of the U.S. civilian non-institutionalized population, were analyzed. Our sample was restricted to adults aged 18-29 who were either diagnosed with arthritis (n = 951) or not (n = 28,734). Respondents who were employed or students were grouped together as those participating in transitional social roles. Demographic characteristics, health factors, and health system use were also analyzed. Weighted proportions with 95% confidence intervals (CI) were calculated accounting for complex sample design. Non-overlapping CIs indicated significant differences.

Results:

Young adults with arthritis participated in transitional roles (67.7%, 95%CI = 63.9-71.6) less frequently than their non-arthritis peers (78.5%, 95%CI = 77.7-79.2). While young adults with arthritis were employed in similar proportions (61.7%, 95%CI = 57.5-65.8) to those without arthritis (66.0%, 95%CI = 65.1-66.9), they reported being students about half as often (6.7%, 95%CI = 4.4-9.0 vs. 12.7%, 95%CI = 11.9-13.5). Young adults with arthritis also reported not participating in employment due to disability almost six times as often (11.6%, 95%CI = 9.0-14.1 vs. 2.0, 95%CI = 1.8-2.3) when compared to those without arthritis. Young adults with arthritis were more often female, married, with fair/poor health, obese, and reported more comorbid conditions. Participants with arthritis also reported attending >5 annual doctor visits more often, and less prevalence of health insurance coverage.

Conclusion:

Arthritis in young adulthood is associated with lower participation in transitional social roles and higher disability. Role participation restrictions, especially in education, may have potential long-term career consequences for young people with arthritis and may limit competitivness in a knowledge-based economy that requires specialized skills. Additional research is required to understand how work context factors, psychosocial perceptions, and relationships with close others can influence the transition to adult roles for people with arthritis.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Epidemiology and Public Health Poster (ARHP)
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Fatigue is a prominent problem in persons with rheumatoid arthritis (RA) and often has a detrimental effect on quality of life. Besides variables directly related to disease and disease impact, exercise and physical performance have been found to explain variation in fatigue. However, previous studies have used small samples and the role of aerobic capacity is unclear. The present study assessed the contribution of physical performance in the variation of fatigue in RA, beyond that of previously known factors related to disease and disease impact.

Methods:

This cross-sectional study used data from the Swedish Rheumatology Quality Registers and included 269 persons recruited for a physical activity intervention. They were all diagnosed with RA according to the ACR classification criteria, 82% women, mean age 60 ± 9 years, mean DAS28 2.8 ± 1.2, and mean HAQ 0.5 ± 0.5. The participants completed a questionnaire on fatigue, activity limitation, perceived health, pain, anxiety/depression and physical activity, and were tested for physical performance; lower limb function by Timed-stands Test, grip strength by Grippit, and aerobic capacity by Åstrand's submaximal bicycle test. Fatigue was rated on a visual analogue scale 0-100 with severe fatigue defined as 50-100. Variation in fatigue was analyzed in two logistic regression models including A) variables related to disease and disease impact, and B) variables related to disease, disease impact and physical performance. Multiple imputation was used to account for missing data in explanatory variables. Nagelkerke's R^2 was calculated to assess model fit.

Results:

Severe fatigue was reported by 95 persons (35%). Significant univariate associations ($p < 0.1$) between severe fatigue and disease duration, medication with biological drugs, comorbidities, activity limitation, perceived health, pain, anxiety/depression and grip strength were found and those variables were included in the adjusted models. Model fit statistics indicated that model B explained more of the variance in severe fatigue than did model A. (Nagelkerke's R^2 0.60 and 0.67 respectively, $p < .0001$). Perceived health, pain and anxiety/depression contributed significantly ($p < 0.05$) in both models and lower limb function in model B (Table 1).

Conclusion:

The results indicate that perceived disease impact variables together with lower limb function are predictors of fatigue in persons moderately affected by RA. The role of physical performance should be explored further with multidimensional assessments of fatigue in samples with larger variation in fatigue and in potential explanatory factors.

Table 1. Outcome of logistic regression for severe fatigue with odds ratios (OR) and 95% confidence intervals (CI) using multiple imputation to account for missing data. Model A includes disease-related and perceived disease impact variables and Model B also includes physical performance variables (n = 269).

Model A	OR (95% CI)	p-value	Model B	OR (95% CI)	p-value

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Epidemiology and Public Health Poster (ARHP)
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Widespread pain (WSP) may be present in individuals for numerous reasons, and its presence may affect the degree to which people engage in activities. How the presence of WSP affects the risk of developing knee pain or knee osteoarthritis (OA) is unknown and could enhance the understanding of pain mechanisms in OA. For example, people with WSP may have a lower risk of developing knee OA due to less frequent loading of the knee or they may have an increased risk due to maladaptive movement patterns. The purpose of this study was to determine if WSP is associated with future consistent frequent knee pain (CFKP) or radiographic OA (ROA) two years later.

Methods: Subjects from the Multicenter Osteoarthritis (MOST) study, a NIH-funded longitudinal prospective cohort of older adults with or at risk of knee OA were assessed at the 60-month (baseline) and 84-month (follow up) visits. WSP was defined at baseline as pain on both sides of the body, above and below the waist, and axial pain, using a standard homunculus, with the exception that the knees were not included in defining WSP. Incident CFKP was defined as reporting knee pain on most days during the past month at the 84-month telephone interview and again during the clinic visit that occurred on average one month later among participants who were free of CFKP at 60 months. Incident ROA was defined as presence of Kellgren & Lawrence grade 2 or knee replacement of either knee at follow-up among those who were free of ROA (and knee replacement) at baseline. We assessed the relation of WSP to risk of CFKP and ROA respectively, using multinomial regression adjusting for baseline age, sex, BMI, comorbidities, physical activity and clinic site; the model was also adjusted for depressive symptoms, pain catastrophizing, fatigue and ROA when CFKP was the outcome, and for WOMAC pain severity when ROA was the outcome.

Results:

There were 923 eligible subjects for analysis of incident CFKP (mean age (SD); 67.4 (7.5); BMI 30.0 (5.6) kg/m^2, 56% women, 19% WSP), and 675 for incident ROA (age 65.6 (7.4); BMI 28.9 (4.7) kg/m^2, 60% women, 30% WSP). Baseline presence of WSP was associated with a non-significant 59% increased risk of incident CFKP compared with those without WSP (adjusted OR 1.59, 95% CI 0.94-2.68, p=0.08). Baseline WSP was associated with a non-significant 14% lower risk of incident ROA, (adjusted OR 0.86, 95% CI 0.46-1.63, p=0.65). WSP was associated with a non-significant 65% increased risk of unilateral CFKP vs. no CFKP (adjusted OR 1.65, 95% CI 0.92-2.96, p=0.09) and with a non-significant 35% increased risk of bilateral CFKP vs. no CFKP (adjusted OR 1.35, 95% CI 0.49-3.73, p=0.56). For both incident unilateral and bilateral ROA vs. no ROA, WSP was not statistically significantly associated; unilateral ROA had 1% lower risk (adjusted OR 0.99, 95% CI 0.51-1.92, p=0.97), and bilateral ROA had 77% lower risk (adjusted OR 0.23, 95% CI 0.02-2.53, p=0.23).

Conclusion: WSP was not significantly associated with either incident CFKP or ROA. Development of knee pain and ROA does not appear to be influenced by underlying WSP, suggesting that screening for or managing WSP will not have a meaningful influence on the development of knee pain or ROA.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Epidemiology and Public Health Poster (ARHP)

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Moderate-to-vigorous physical activity (MVPA) is recommended for weight loss; however it is unclear how activity or sedentary changes influence long-term weight loss in obese adults. We examine if changes in MVPA, light intensity physical activity, and sedentary behavior are related to weight loss over a 2 year period in obese adults with knee osteoarthritis (OA) or knee OA risk factors.

Methods: Objectively measured body weight, physical activity, and sedentary time were obtained from 459 obese participants from the Osteoarthritis Initiative at baseline and two years. Weight change was categorized as ≥10, 5.0-9.9, 4.9 to -4.9, -5.0 to-9.9, ≤-10 lbs. The association between 2-year weight change and changes in physical activity (light and MVPA) and sedentary time from accelerometer monitoring were examined by multiple linear regression adjusted for baseline weight, demographic and health factors.

Results: Over 2 years, participants lost 3.48 ± 26.06 lbs., increased sedentary time (9.5 ± 64.5 minutes) and decreased both light and MVPA (-8.6 ± 64.5 minutes, -0.9 ± 14.2 minutes, respectively). Weight loss was associated with increased MVPA gains across five categories of weight change from ≥10lbs. loss (5.2 min), 5-9.9lbs. loss (2.4 min), ±5lbs. (1.4 min), 5-9.9lbs. gain (-0.9 min), and ≥10lbs. gain (-2.7 min) (p for trend < 0.001). Weight loss was also associated with less sedentary gain across five categories of weight change from ≥10lbs. loss (-7.1 min), 5-9.9lbs. loss (7.3 min), ±5lbs. (9.1 min), 5-9.9lbs. gain (9.5 min), and ≥10lbs. gain (25.8 min) (p for trend =0.01). Weight loss had a strong but nonsignificant trend with light activity gain (p for trend = 0.06). All models controlled for baseline weight, demographics and health factors.

Conclusion: Decreases in sedentary time over 2 years and small increases in MVPA and were associated with weight loss among obese adults with or at risk for knee osteoarthritis.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015

Session Title: Epidemiology and Public Health Poster (ARHP)
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Axial spondyloarthritis (axSpA) represents the whole clinical spectrum of ankylosing spondylitis (AS) including those at the non-radiographic (nr) stage of the disease. Although the disease burden associated with radiographic axSpA (classically known as AS) has been extensively studied, the burden associated with nr-axSpA is less well known.Our aim was to assess and compare the burden of radiographic and nr-axSpA.

Methods: This cross-sectional, observational study included consecutive AxSpA patients with varying disease severity, who attended our outpatient clinic between April 2014 and December 2014. During the visits, the following questionnaires were applied by trained health professionals:BASDAI, BASFI, HAQ-S, SF-36, ASQoL,Work Productivity and Activity Impairment (WPAI) and Work Productivity Survey (WPS).

Results:

A total of 381 AxSpA patients (279 AS) were analyzed. Nr-axSpA group, were younger (39.4 vs 43.1, p=0.007), more likely to be female (54% vs 33%, p<0.001), had a shorter disease duration (10.1 vs 16.0 years, p<0.001) and lower CRP (5.9 vs 13.2, p<0.001) and less common use of biologics (41.2% vs 26.5, p=0.008) despite higher BASDAI scores (Table). Broadly similar results were found for the other clinical outcome measures. Of all the axSpA patients, 58% were employed, with non-manual (25%), mixed (19%) and manual works (14%). Only 1.1% of the patients could not work due to arthritis. Patients with nr-axSpA reported more work productivity loss at workplace and at home over the last month, but the difference was significant only for household activities. Subgroup analysis showed that this difference was only found in females.

Conclusion: Patients with AS and nr-AxSpA demonstrate similar degree of disease burden and prodcutivity, with a greater impairment of household work in females. Low rate of inability to work due to arthritis in this population with a relatively high prevalence of anti-TNF use may be a reflection of the effectiveness of such therapies.

Table 1. Clinical variables related to disease burden in study participants. Data are presented as mean ± SD, unless otherwise stated

Variable	AS (n=279)	nr-axSpA (n=102)	P value

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Epidemiology and Public Health Poster (ARHP)
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Widespread pain (WSP) is associated with morbidity, and poor mental and physical functioning, but its etiology is not well understood. It has been hypothesized that painful peripheral pathology may result in WSP. Previous cross-sectional studies have shown an association of knee pain and radiographic knee osteoarthritis (ROA) with WSP. However, the independent relations of knee OA and knee pain, to incident WSP is unknown. We examined the relation of ROA, symptomatic knee OA (SxOA) and consistent frequent knee pain (CFKP) to incident WSP in a large prospective cohort.

Methods: We used data from the Multicenter Osteoarthritis (MOST) Study, a NIH-funded longitudinal prospective cohort of 3026 older adults with or at risk of knee OA. ROA was defined as having radiographic tibiofemoral OA (Kellgren & Lawrence grade ≥2) on the 60-month radiographs. The definition of CFKP was met if a participant reported knee pain on most days during the past month at the 60-month telephone interview and at the clinic visit that occurred on average one month later. SxOA was defined as having both ROA and CFKP at 60 months. We also considered knee replacement as equivalent to ROA and SxOA. WSP was defined as pain above and below the waist, on both sides of the body and axially, using a standard homunculus, excluding knee pain. Incident WSP was defined as presence of WSP at 84 months among those who were free of WSP at 60 months. We assessed the relation of baseline ROA, SxOA, and CFKP, respectively, to incident WSP using logistic regression, adjusting for baseline age, sex, BMI, comorbidities, physical activity, WOMAC pain intensity, study site, depressive symptoms, pain catastrophizing and fatigue.

Results: At baseline, 1309 subjects were eligible for ROA analysis (age mean, SD; 67.3, 7.8; BMI 30.5, 6.0 kg/m^2, 56% women), 1316 for SxOA analysis (age 67.3, 7.8; BMI 30.4, 5.9 kg/m^2, 55% women) and 1383 for CFKP analysis (age 67.4, 7.8; BMI 30.5, 6.0 kg/m^2, 55% women). Baseline presence of unilateral ROA was associated with a non-significant 30% lower risk of incident WSP compared with those without ROA (adjusted OR 0.70, 95% CI 0.46-1.07, p=0.10). Similar results were found for those with bilateral ROA. Similarly, neither baseline unilateral nor bilateral SxOA were associated with risk of incident WSP compared with those without SxOA. Baseline presence of unilateral CFKP was also not significantly associated with incident WSP, while bilateral CFKP approached significance (see table).

Conclusion: Neither ROA, SxOA nor CFKP increased the risk of developing WSP. These results suggest that neither knee joint pathology nor joint pain are major factors in the onset of WSP. Further study is required to clarify what factors contribute to the onset of WSP.

Table: Risk of ROA, SxOA and CFKP to incident widespread pain

	ROA at baseline			SxOA at baseline			CFKP at baseline

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Epidemiology and Public Health Poster (ARHP)
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Early rheumatoid arthritis (ERA) patients attending office visits often report being in a disease flares. We evaluated patient reports of flare in relation to disease activity and self-management behaviors (SM) in a large Canadian ERA observational study (CATCH).

Methods: At each visit, patients provided ratings of flare severity (10 point VAS), duration, symptoms, functional impacts and SM. Joint counts were obtained, and CDAI scores were calculated. A checklist of SM strategies was developed based on international qualitative studies by the OMERACT RA Flare Group.

Results: The 474/1983 (24%) who reported being in flare were mostly female (76%), white (78%) and educated (53%>high school), with a mean (SD) age of 53 (14) yrs and symptom duration of 38 (25) months. Mean (SD) flare severity was 5.4/10 (2.4) and 67% reported duration > 7 days; flaring patients reported significantly more pain, fatigue, stiffness, disability, reduced participation, and difficulty coping (table 1). SM did not differ by sex and included using analgesics (50%) and steroids (13%); reducing (45%) and avoiding (28%) activities; selected behaviors (massage, heat/cold, exercise); 17% called their rheumatologist for help. Use of SM increased with flare severity for all activities except selected behaviors and steroid use (p<.005; Table 2); trends were evident with flare duration and use of analgesics (p=.08), avoiding activities (p=.09) and calling the rheumatologist (p=.001). Recently diagnosed patients (0-12 months) were significantly more likely to report using SM compared to those with RA >12 months (79% vs. 66%; p=.015) mostly using massage, heat and exercise (40% vs 28%, p=.04). As compared to those not on biologics, more patients on biologics reduced or avoided activities (43% vs 60%, p =.016; 25% vs 44%, p = .004). Among those with flare severity ≥ 4 and duration >7d, 80% reported SM including analgesics (57%), reducing activities (46%), behaviors (40%), avoiding activities (34%), or calling MD (19%).

Conclusion: Patient reports of RA flare are associated with higher disease activity; self-management is common, and increases with flare severity and duration. SM includes limiting participation/role activities and using additional medications and behaviors to reduce symptoms and impacts. Self-management appears to be initiated early into flares and highlight their substantial impact on quality of life.

Table 1. Symptoms and impacts of RA patients who did and did not report flares.

	Flare		No Flare		Sig
	N	Value	N	Value

Identification of Long-Term Physical Activity Trajectories in Individuals with Chronic Widespread Pain Who Received Exercise Treatment As Part of a Randomized Controlled Trial

Kathryn Remmes Martin[1], Katie L. Druce[1], Lucia D'Ambruoso[2] and Gary J. Macfarlane[1], [1]Musculoskeletal Research Collaboration (Epidemiology Group), University of Aberdeen, Aberdeen, United Kingdom, [2]Division of Applied Health Sciences, University of Aberdeen, Aberdeen, United Kingdom

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Epidemiology and Public Health Poster (ARHP)

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: For individuals living with chronic widespread pain (CWP), physical activity (PA) can be an effective non-pharmacological therapy for symptom management. PA Interventions may enhance PA levels in the near term, however less is known about longer-term PA maintenance (i.e., ≥2 years) in those with CWP. This study examined PA levels over time and investigated whether subgroups followed distinct PA trajectories that could be useful in developing future stratified interventions.

Methods: Data are from individuals with CWP who took part in a 2x2 factorial randomized controlled trial with data at baseline (-6), treatment end (0), 3, 24 and 60 month post-treatment. Participants' self-report of total PA was generated from a brief two question assessment tool which queried on number of bouts of vigorous-intensity activity ≥20 minutes and on bouts of walking or moderate-intensity activity ≥30 minutes in a usual week. Analyses were conducted on 196 men and women who had either received exercise or combined exercise + cognitive behavioural therapy treatment and who had ≥3 PA data-points. Group-based trajectory modelling was used to identify latent PA trajectory groups between which descriptive statistics were used to identify whether baseline variables (e.g., demographics, chronic pain grade, self-rated health, fatigue, sleep problems, coping strategy use, kinesiophobia) differed (α=0.05).

Results: The best fitting model identified was one with three trajectories: non-maintainers (Group 1: G1), maintainers (G2) and super-maintainers (G3) (Figure 1). Overall, baseline PA levels (mean (SD)) were significantly different between groups (G1: 1.1 (1.2); G2: 4.6 (2.8); G3: 8.6 (2.7), p<0.001) and all other follow up points. While PA levels were higher for all groups (G1: 2.2 (2.2); G2: 6.2 (2.4); G3: 9.9 (1.8)) at treatment end, only G2 and G3 reached ‘adequate' or ‘high' PA levels (total activity score 5-7 or ≥8) and maintained activity over time. Non-maintainers more often reported greater BMI, higher chronic pain grade, poorer self-rated health and SF-36 PCS, as well as greater use of passive coping strategies and reduced use of active coping strategies. Groups did not vary on treatment group, age, gender or baseline employment status, SF-36 MCS, fatigue, sleep, and kinesiophobia.

Conclusion: The majority of individuals with CWP who received an exercise treatment as part of a trial were identified as long-term PA maintainers or super-maintainers. A smaller subset of participants with poorer self-reported health and behavioural response to symptoms were non-maintainers, and as such might benefit the most from intensively targeted interventions to improve long-term PA maintenance for optimal symptom management.

Impacts on Work: Arthritis Vs Chronic Joint Symptoms without Arthritis

Kristina A. Theis and Michael Boring, Arthritis Program, Centers for Disease Control and Prevention, Atlanta, GA
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Epidemiology and Public Health Poster (ARHP)
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: While chronic joint symptoms are characteristic of arthritis, previous studies have shown that many people with chronic joint symptoms do not have doctor-diagnosed arthritis. These people are typically younger, more often male, and report less limitation than those with doctor-diagnosed arthritis. However, differences between the two groups have not been evaluated for the socially and economically important domain of work.

Methods: Data were obtained from ACHES, a random-digit dialed national telephone survey, conducted in 2005-06, of non-institutionalized US adults ages ≥45. We restricted analyses to 45-64 years (working ages). Respondents were classified as ARTH ('yes' to *Have you ever been told by a doctor or other health professional that you have some form of arthritis, rheumatoid arthritis, gout, lupus, or fibromyalgia*?) (n=1,006) OR CJS (joint symptoms in the past 30 days that began >3 months prior but no ARTH) (n=352). Impact on work for pay was measured by 'yes' to: 1) do arthritis or joint symptoms "now affect whether you work for pay or not," 2)"the type of work," or 3)"the amount of work" you do? Only those employed were asked type and amount. We estimated prevalence of each impact for ARTH and CJS separately and compared characteristics using weighted proportions with 95% confidence intervals (CI). All reported proportions represent statistically significant differences based on non-overlapping CIs.

Results: Overall, CJS were younger, employed more (68% vs 54%), disabled less (11% vs 22%), and had less reports of losing ≥1 workday (5% vs 13%) or activity limitations due to symptoms (33% vs 55%) compared with ARTH. Fair/poor health (19% vs 33%), severe joint pain (13% vs 31%), and daily pain (42% vs 59%) were less common among CJS vs ARTH.

Impact on whether one works and type of work were both higher for ARTH vs CJS (36% vs 20% and 43% vs 30%, respectively). Impact on amount of work was not significantly different between groups. Among ARTH greater proportions of females (35% vs 16%), those with some college education (37% vs 18%), and the obese (41% vs 23%) reported impact on whether one works

than CJS counterparts. Also among ARTH greater proportions with **no** activity limitations (55% vs 40%), **no** depression (26% vs 13%), **no** anxiety (21% vs 11%), **no** severe joint pain (23% vs 14%), and **no** bathing/dressing limitations (20% vs 9%) reported impact on whether one works compared with CJS.

Conclusion: Work impacts are high among both ARTH and CJS, despite different group patterns. ARTH work impacts are common even without severe joint pain or physical limitations. Given the economic importance of work, interventions for both groups are warranted, but ARTH identifies a priority population.

The prediction of fatigue in early Rheumatoid arthritis patients

Background/Purpose:

Rheumatoid arthritis-related fatigue is a common problem with a high impact on patients. How fatigue develops over time since early diagnosis of RA is not well known. The aim of this study was i) to describe the pattern of the fatigue over time in patients with early RA under T2T ii) to identify predictive factors /determinants for evolution of fatigue over time stratified for baseline values of fatigue.

Methods: Data from the tREACH study (treatment in the Rotterdam Early Arthritis Cohort) were used. This multi-centered trial compared different initiation treatment strategies in early RA patients. Patients completed VAS and FAS on fatigue, CORS, HADS, RADAI, SF-36 and were clinically assessed by DAS every 6 month. We stratified the patients into no fatigue (FAS values 10-21) and fatigued (FAS values 22-50) and assessed the evolution of fatigue over time and the covariates using a mixed linear model with time lag. Missing covariate data was imputed using a mixed linear model.

Results:

A total of 270 individuals classified as RA using the 2010 criteria, 246 could be stratified according to their baseline fatigue (24 had missing data). The sample resulted in a typical early RA population with a mean age of 53 years (SD 14.3 years) and 68% females, 73% rheumatoid factor and 77% anti-CCP antibodies positive. The percentage of patients with joint damage was 18%.The VAS fatigue was 51.4(SD 25.9) and the FAS 22.2 (SD 7.1). High fatigue at baseline was univariate associated with higher levels of the CORS, high levels of depression and anxiety, a worse physical health (SF-36) and more swollen and tender joints.Over time fatigue decreased slightly with 2-7% on average as shown in figure 1.

Significant determinants for the prediction of fatigue in the univariate and multivariate analysis are presented in table 1.

Conclusion:

About half of the early RA patients reported high levels of fatigue at baseline which for most of them consisted over time. Only better reported physical health (SF36) predicted change of fatigue. Patients with low fatigue at baseline were more likely to develop fatigue over time if they were women, had more tender joints, were more anxious and had a worse Physical SF36 scores.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Epidemiology and Public Health Poster (ARHP)

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Primary Sjögren's Syndrome (pSS) is an autoimmune disease which targets secretory glands and results in dryness. In addition pSS patients frequently experience symptoms of fatigue, pain, low mood and have difficulty performing daily activities and subsequently have poor quality of life. There is currently no curative treatment and medical interventions focus on the symptomatic management of dryness. The aim of this study is to identify independent predictors for each of the SF-36 domains in order to identify targets for future therapy interventions with pSS patients. The goal is to identify potential interventions to be delivered by non-medical health care professionals in order to improve the ability to perform daily activities, facilitate taking on life roles and improve quality of life.

Methods: 149 PSS patients diagnosed according to the American European Consensus Criteria were recruited from 12 sites across England. Participants completed the SF-36 questionnaire and measurements of anxiety and depression (Hospital Anxiety and Depression Scale HADs), functional status (ImprovedHAQ), pain (visual analogue scale (VAS), fatigue (VAS), mental fatigue (VAS), dryness (VAS), cognitive failures (Cognitive Failures Questionnaire) and recorded their age and disease duration. Significant correlates of each of the SF-36 domain were identified and multiple regression analysis performed for each of the domains to determine partial regression coefficients. Model robustness was determined by hierarchical regression analysis testing the sensitivity of the model to the order of inclusion.

Results: With one exception, PSS patients scored significantly worse than the norm-based scores for all domains of the SF-36, including Physical Functioning, Role Physical, Bodily Pain, Vitality, Social Functioning, Role Emotional and Mental Health ($p<0.001$). General Health was the exception and there was no significant difference between the pSS patients and the norm-based scores. All SF-36 domains correlated significantly with anxiety, depression, cognitive failures, mental fatigue, pain, fatigue and dryness ($p<0.001$).

Fatigue and depression were the main predictors of poorer Role Physical and Social Functioning domain scores (all $p\leq0.006$). Fatigue was a predictor of Bodily Pain ($p<0.001$) and pain was an independent predictor of poor Physical Functioning ($p<0.001$). Depression and pain were the main independent predictors of the Vitality domain ($p\leq0.006$) and the General Health domain ($p\leq0.043$). The main predictors of the Role Emotional domain were fatigue, anxiety and depression ($p\leq0.037$) and of the Mental Health domain were disease duration and cognitive failures ($p\leq0.026$).

Conclusion: This study demonstrates that fatigue and depression, followed by anxiety and pain are key predictors of the reduced ability to perform daily activities, take on life roles and quality of life. These factors should be addressed during therapeutic interventions with PSS patients presenting with these symptoms. This in turn could support PSS patients to carry out daily activities, take on social and physical life roles and improve their quality of life.

Abstract Number: 2283

Current and Lifetime Smoking Among US Adults with Arthritis: A Serious Clinical and Public Health Issue

Louise Murphy[1], Miriam G. Cisternas[2] and Teresa J. Brady[1], [1]Arthritis Program, Centers for Disease Control and Prevention, Atlanta, GA, [2]MGC Data Services, Carlsbad, CA
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Epidemiology and Public Health Poster (ARHP)
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Smoking's adverse effects include increased risk of joint replacement failure and decreased medication effectiveness (e.g., methotrexate, TNF blockers). Because little is known about the epidemiology of smoking among US adults with arthritis, we examined prevalence and correlates of smoking.

Methods: We analyzed 2012 and 2013 National Health Interview Survey data for adults ≥ 18 years. Ever smoked was lifetime smoking ≥ 100 cigarettes; current smokers were "ever smokers" who currently smoked every day or some days. We estimated overall and age-specific prevalence of smoking (ever; current) by arthritis status; arthritis was "yes" to "Have you EVER been told by a doctor or other health professional that you have some form of arthritis, rheumatoid arthritis, gout, lupus, or fibromyalgia?". Among people with arthritis, we examined: 1) current smoking prevalence across socio-demographic characteristics, health status, and health behaviors; 2) associations between these characteristics and current smoking using prevalence ratios (PR) and 95% confidence intervals from multivariable logistic regression models.

Results: Ever smoking prevalence was higher among US adults with arthritis (51%) than those without (37%) overall and across all age groups (statistically significant [α=0.05])(Figure). Overall current smoking prevalence was the same for those with and without arthritis (18%); however, among young (18-44 years) and middle age (45-64 years) adults, current smoking prevalence was higher among those with arthritis than those without (statistically significant [α=0.05])(Figure). Among adults with arthritis, current smoking prevalence was at least 25% among those with the following characteristics: high (39%) or moderate (25%) serious psychological distress; unable to work because of disability (34%); young adults (30%); ≥ 2 types of non-arthritis pain (26%); or chronic pulmonary condition diagnosis (25%). In multivariable models, age and education were strongest correlates of current smoking: PRs for current smoking declined with increasing age (18-44=3.0; 45-64=2.3; referent: ≥ 65) and education (< high school=2.9, high school=2.5, and some college=2.1; referent: college degree).

Conclusion: Current smoking is a serious clinical and public health issue among adults with arthritis, especially young adults. By recommending effective and evidence-based tobacco cessation strategies, health care providers may improve treatment effectiveness.

Age and Sex Stratified Normative Data for Shoulder Range of Movement

Tiffany K. Gill[1], E. Michael Shanahan[2,3], Graeme R Tucker[1] and **Catherine Hill**[4,5], [1]Medicine, The University of Adelaide, Adelaide, Australia, [2]Rheumatology, Flinders University, Bedford Park, South Australia, Australia, [3]Repat General Hospital, Flinders University, Adelaide, Australia, [4]Rheumatology Unit, The Queen Elizabeth Hospital, Woodville, Australia, [5]The Health Observatory, The University of Adelaide, Adelaide, Australia

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Epidemiology and Public Health Poster (ARHP)

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Shoulder range of movement is integral to activities of daily living and the impact of pain on shoulder function has a significant effect on quality of life. However, while some studies have examined normative values for shoulder strength, few large studies have determined normative values for shoulder range of movement (ROM) across a wide age range. The aim of this study was to provide normative data for shoulder ROM, using data from a population-based cohort.

Methods: Participants for this study were part of the North West Adelaide Study (NWAHS), a longitudinal cohort study of 4056 randomly selected adults aged 18 years and over (47.7% male) at the time of recruitment. Three stages of data collection have been undertaken. Stage 1 was between 1999-2003, Stage 2, 2004-06 and Stage 3, 2008-10. As part of the Stage 2 assessment, range of flexion and abduction for both the right and left shoulders were measured using an inclinometer and standardised protocols and external rotation was measured by observation. Participants were asked if they had ever had shoulder pain or stiffness, if they had ever been told by a doctor that they had rheumatoid arthritis (RA) and were defined as having diabetes by self-report and/or a fasting plasma glucose level of >= 7.0mmol/l. Those who reported having shoulder pain and/or stiffness and those with RA were excluded from the analysis. Data were weighted by age, sex and probability of selection in the household to correct for disproportionality of response. Age group analyses were undertaken using the following groupings (<40 years, 40-49, 50-59, 60-69, 70-79, 80 years and over).

Results: Overall, there was a significant mean difference ($p<0.05$) between the right and left sides for each movement. Males had higher mean abduction and flexion and lower mean external rotation compared to females (Table 1).

Table 1: Mean shoulder ROM by sex (n=2404)

	Males	Females
	Mean (SD)	Mean (SD)
Flexion		
Right	161.5 (18.7)	158.5 (19.1)
Left	159.9 (18.1)	157.1 (18.2)
Abduction		
Right	151.5 (20.1)	149.7 (20.3)
Left	149.7 (20.3)	147.7 (20.0)
External rotation		
Right	56.8 (17.6)	60.9 (17.9)
Left	55.0 (17.9)	58.5 (17.7)

ROM generally declined with age for each movement with significant correlation between age and ROM ($p<0.05$). People with diabetes also demonstrated a significantly reduced ROM compared to those without ($p<0.05$, Table 2).

Table 2: Mean shoulder ROM for those with and without diabetes (n=2379)

	No diabetes	Diabetes
	Mean (SD)	Mean (SD)
Flexion		
Right	160.8 (18.6)	148.7 (20.9)
Left	159.4 (17.8)	146.7 (20.4)
Abduction		
Right	151.5 (19.5)	136.9 (25.8)
Left	149.6 (19.5)	135.1 (25.1)
External rotation		
Right	59.3 (17.6)	50.0 (17.9)
Left	57.2 (17.7)	47.6 (17.6)

Conclusion: This large population sample provides normative values for shoulder ROM which are important for comparison purposes, in order to determine if a level of impairment exists. Generally it is accepted that normal flexion and abduction range of movement is 180 degrees and external rotation is 90 degrees, however this does not appear to be the case. This needs to be taken into consideration when assessing and treating those with shoulder impairments.

Poor Quality of Sleep Is Associated with Increased Disease Activity and Fatigue in Axial Spondyloarthritis

Lana Frost[1], Jiayi Zhou[2], Lourdes Pena Castillo[2], Sean Hamilton[1], Nayef Al Ghanim[1], Proton Rahman[1] and Jennifer Burt[1], [1]Rheumatology, St. Clare's Mercy Hospital, St. John's, NF, Canada, [2]Computer Science, Memorial University of Newfoundland, St. John's, NF, Canada

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Epidemiology and Public Health Poster (ARHP)
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Sleep disturbance is a common occurrence in musculoskeletal disease including ankylosing spondylitis. The reasons for the sleep disturbance in rheumatic diseases are multifactorial. There are a paucity of studies examining the relationship of sleep disturbance and disease activity in axial SpA patients, with or without TNFi therapy. We set to examine the relationship between sleep quality and disease activity in axial SpA.

Methods: Consecutive patients with axial SpA satisfying the ASAS criteria were asked to fill out a HAQ and BASDAI, prior to seeing a rheumatologist or health care professional. All patients successfully completing both questionnaires at the same visit were included in our study. Demographic information, HLA-B27 status and use of biologic therapy were extracted from the charts. The assessment regarding the quality of sleep was derived from the VAS scale pertaining to a specific question on sleep in the HAQ (question number 4). Quality of sleep then was categorized into three groups based on the VAS score: 0 to 3; 3.1 to 6; and greater than 6.1. The sleep quality was compared to the total BASDAI score and fatigue, as measured by the VAS score from question number 1 from the BASDAI. Spearman's rank correlation coefficient was done between the categorical sleep score and total BASDAI and fatigue.

Results: 92 patients with axial SpA patients were included which comprised of 65 males, and 52 patients on TNFi. 40 patients had a VAS sleep score between 0-3; 25 between 3.1 to 6 and 27 between 6.1 to 10. Then mean BASDAI score respectively in these three groups were: 2.6 (sd 1.4); 4.5 (sd 1.4) and 6.2 (sd 1.7). So high VAS sleep score (poor sleep) was significantly correlated with higher BASDAI; rho 0.74; $p < 0.0001$. Patients on TNFi had a significantly lower mean BASDAI score than patients not on a TNFi, however the relationship between quality of sleep and BASDAI was similar between two groups. We observed a higher correlation between sleep pattern and BASDAI in males as compared to females (rho 0.79 vs 0.67 respectively). Sleep score was also significantly correlated with fatigue with mean scores of 2.1 (sd 1.9); 5.7 (sd 1.9) and 6.6 (sd 2.0) respectively in the three groups, rho 0.76; $p < 0.0001$.

Conclusion: A high VAS sleep score (poor sleep pattern) is associated with higher BASDI score and fatigue, irrespective of treatment with TNFi. Improving sleep hygiene may represent an alternative strategy in lowering disease activity in axial SpA, particularly in male patients.

Correlation of Magnesium Levels and IGF-! Levels in Fibromyalgia Patients

Thomas Romano, Private Practice, Martins Ferry, OH
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: To determine if there is a correlation between RBC Mg levels and IGF-! levels in Fibromyalgia (FM) patients

Methods: 60 FM patients (10 men, 50 women) Mean age 49.5 yrs for men and 42.8 yrs for women were studied. All fulfilled ACR 1990 Criteria for FM. RBC Mg levels and serum Insulin-dependent growth factor levels were measured .

Results: The mean IGF-1 level for FM patients was 159.33 ng/dl which was lower than the expected mean of 235 ng/dl. Mean

RBC Mg level for the FM patients was 4.49 mg/dl which was ststistically significantly lower than the mean for the control group of 12 Osteoarthritis patients and the laboratory standard (5.5 mg/dl for both). A correlation coefficient of 0.48 was calculated with a test statistic of 1.97.

Conclusion: There was a statistically significant positive correlation between IGF-1 levels and RBC Mg levels in the 60 FM patients studied. This has implications for treatment and further diagnostic testing.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Fibromyalgia (FM) is prevalent in patients with chronic inflammatory rheumatic diseases (CIRd), where it hampers diagnosis and activity assessment. No tool for screening FM associated with CIRd has ever been evaluated. The Fibromyalgia Rapid Screening Tool (FiRST) is a brief and simple self-complete questionnaire that has been validated for screening FM in patients with diffuse chronic pain. The purpose of this study was to evaluate how well FiRST performs on screening for FM associated with CIRd.

Methods: This single-center cross-sectional study was conducted between September 2014 and April 2015 on all patients with chronic pain presenting for rheumatoid arthritis (RA), spondyloarthritis (SpA), and connective tissue disease (Sjögren's syndrome (SS), systemic lupus erythematosus (SLE), scleroderma (Scl), myositis). Diagnosis of FM was based on ACR–90 classification criteria (to minimize interfering overlap between rheumatic disease-related pain and FM-related pain) and expert opinion.

Results: The population included 605 patients: 279 RA, 271 SpA (52 psoriatic arthritis, 126 radiographic axial SpA, 64 non-radiographic axial SpA, 29 peripheral SpA), 57 connective tissue disease. In total, 51 patients had FM meeting the ACR–90 criteria, and 93 patients were given a diagnosis of FM by the expert. When tested against the ACR–90 classification criteria, FiRST demonstrated a sensitivity of 74.5%, a specificity of 80.4%, a positive predictive value of 26.6% and a negative predictive value of 97.1%. Specificity was significantly weaker in the connective tissue disease group (RA: 84.4%, SpA: 80.2%, connective tissue disease: 59.6%; $p<0.001$). When tested against expert opinion, FiRST demonstrated a sensitivity of 75.8%, a specificity of 85.1%, a positive predictive value of 48.3% and a negative predictive value of 95%. FiRST underperformed on sensitivity in the SpA group compared to the connective tissue disease group (66% *vs* 94.4%; $p=0.004$). Performances varied according to item in the self-complete questionnaire.

Conclusion: The symptoms of rheumatic disease interfere with the symptoms of fibromyalgia. FiRST nevertheless manages to perform well in this population, showing an excellent negative predictive value.

Effectiveness of Dry Needling and Exercise in Dizziness Caused By Cervical Myofascial Pain Syndrome

Tugba Aydin[1], Bahar Dernek[2], Tulin Senturk[3], Ayse Karan[4] and Cihan Aksoy[5], [1]Physiotherapy and Rehabilitation, Okmeydani Training and Research Hospital, Istanbul, Turkey, [2]Physical Medicine and Rehabilitation, Istanbul Kanuni Sultan Suleyman Education and Research Hospital, Istanbul, Turkey, [3]Department of Otolaryngology, Bagcilar Education and Research Hospital, Istanbul, Turkey, [4]Department of Physical Medicine and Rehabilitation, Istanbul University, Istanbul Faculty of Medicine, Istanbul, Turkey, [5]Department of Physical Medicine and Rehabilitation, Istanbul Medical Faculty, Istanbul Universty, ISTANBUL, Turkey

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

The aim of this study is to compare the effectiveness of dry needling therapy combined with exercise treatment (dry needling+exercise) with exercise treatment alone for alleviating the dizziness caused by cervical myofascial pain syndrome.

Methods: This is a randomized clinical study that included 61 women who complained of cervical pain and dizziness for at least three months, and who had myofascial trigger points on the clavicular side of the sternocleidomastoid muscle and/or trapezius muscle. The patients was randomized into a dry needling+exercise group (n=31) and an exercise-only group (n=30). Both groups were treated for a duration of four weeks. The patients were evaluated before treatment, at the end of one month of treatment, and at the end of four months of treatment. Myofascial pain syndrome was evaluated by cervical pain (measured using the visual analogue scale (VAS)), number of trigger points, manual palpation pain (VAS), algometric measurement, and skin rolling test values. Dizziness was evaluated by the number of dizzy attacks per week, the severity of the dizziness, fall index, and the Dizziness Handicap Inventory (DHI)

Results:

The mean age of participants in this study was 38.4±8.3 years. The severity of dizziness, severity of cervical pain, number of trigger points, severity of manual palpation pain, fall index, and DHI decreased, while algometric measurements and skin rolling test values increased in both groups after treatment. These results were statistically significant in both groups ($p<0.05$). The dry needling+exercise treatment was superior to the exercise treatment alone in decreasing the severity of cervical pain, number of trigger points, number of dizzy attacks per week, and severity of dizziness at the end of the the first and fourth months ($p<0.05$). DHI points and manual palpation trigger point pain had decreased more in the dry needling +exercise group at the end of the first month ($p<0.05$), but by the end of the fourth month there was no statistical difference between the two groups. The two groups saw similar increases in algometric measurements at the end of the first month ($p>0.05$), but dry needling+exercise treatment increased algometric measurements better than exercise treatment alone by the end of the fourth month ($p<0.05$). The fall index was statistically similar in both groups at the end of the first and fourth months ($p>0.05$).

Conclusion: Both dry needling+exercise therapy and exercise therapy alone were effective in treating cervical pain and dizziness caused by cervical myofascial pain syndrome. However, dry needling+exercise treatment was superior to exercise treatment alone in most of parameters.

A Cervical Radiculopathy Can Cause Chest Pain

Robert S. Katz[1], Ben J Small[2] and Alexandra Katz Small[1], [1]Rush University Medical Center, Chicago, IL, [2]MacNeal Hospital, Berwyn, IL

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster II

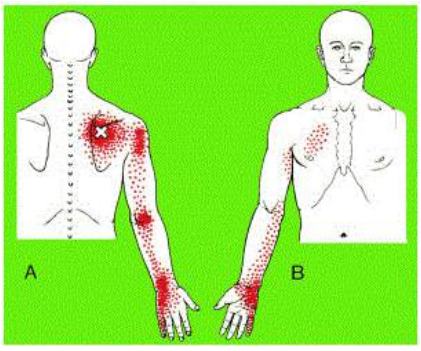
Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Chest pain has multiple etiologies, but cervical radiculopathy is not considered to be one of them. There is innervation of the chest wall from segmental nerves originating from the cervical spine.

Methods: We describe four patients who had left sided chest pain with left arm pain, whose workups demonstrated cervical radiculopathies but no evidence of coronary artery disease.

Results: Four patients, three males and one female, ages 58 to 62, each presented with left chest pain. Each patient had a negative thallium exercise stress test and an echocardiogram. Each of these four patients also described left arm discomfort. The chest and arm discomfort were often felt as a tingling or burning sensation. Each patient had an MRI demonstrating left cervical disc herniation and/or an EMG consistent with a left cervical radiculopathy.



Conclusion: These four patients demonstrate that chest pain accompanied by left arm pain may be a manifestation of a left cervical radiculopathy. Thallium stress tests and echocardiograms were normal in these patients. Each had an MRI, and some also had EMGs, consistent with a cervical radiculopathy.

These cases demonstrate that a cervical radiculopathy should be considered in the differential diagnosis of patients with chest pain especially when accompanied by left arm pain or dysesthesias.

The 2011 Fibromyalgia (FM) Survey Criteria Are a Surrogate Measure of Pain Centralization

Steven E. Harte[1], Daniel J. Clauw[2], Andrew D. Clauw[1], J. Ryan Scott[1], Stephanie Moser[1] and Chad Brummett[2], [1]Department of Anesthesiology, University of Michigan, Ann Arbor, MI, [2]Anesthesiology, University of Michigan, Ann Arbor, MI
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: The 2011 FM Survey Criteria can either be used as a dichotomous measure to diagnose an individual with FM, or in a continuous manner to determine the degree of "fibromyalgianess" an individual is experiencing. Used in this latter manner, studies have suggested that this measure is predictive of decreased responsiveness to opioids in the perioperative period, and decreased improvement in pain following knee and hip arthroplasty. This has led us and others to suggest that this measure is a surrogate measure of the central sensitization an individual is experiencing. However, a critical portion of the central sensitization construct is that an individual experiences pain augmentation or amplification, measured either by quantitative sensory testing (QST) or functional neuroimaging. This study examines the relationship between the FM Survey Criteria and QST findings in a cohort of individuals with osteoarthritis.

Methods: 101 individuals with osteoarthritis (ages 41 – 85, 45 male, 56 female) awaiting joint arthroplasty had a battery of self-report measures including the 2011 FM Survey Criteria. These individuals also underwent an extensive QST battery including mechanical pain threshold and tolerance, temporal summation, and conditioned pain modulation - at both the affected knee, as well as several neutral sites (including thumb and trapezius). The cohort of 101 individuals was then split into three tertiles of FM scores, from 0-3 (n = 37), 4-7 (n = 34), and 8 or greater (n = 30). ANOVA was performed comparing mean QST values in each tertile.

Results: For nearly all static QST variables, there was a stepwise change in the hypothesized direction between QST measures and FM tertiles. Most but not all of these changes reached statistical significance. The three tertiles showed a similar stepwise increase in pain intensity, even though the FM criteria do not assess pain intensity, just distribution.

Conclusion: This is the first study to demonstrate that the 2011 FM Survey Criteria show a strong relationship to QST measures in a cohort of individuals with knee osteoarthritis. This provides further evidence that this simple to administer measure may serve as a surrogate measure of pain centralization in individuals with chronic pain states.

The Factors That Might be Responsible for the Improvement of Fibromyalgia Patients: A Sub-Group That Improved Significantly over Three to Six Months

Robert S. Katz[1] and Lauren Kwan[2], [1]Rush University Medical Center, Chicago, IL, [2]Rheumatology Associates S.C., Chicago, IL
First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: In a rheumatology office practice, patients with fibromyalgia who improved significantly in their symptoms are seen commonly. We evaluated patients whose pain, fatigue, fibrofog, and functional scores were significantly better over a 3-6 month period.

Methods: Patients who had significant improvement on visual analog scales in a rheumatology office practice were further assessed and responded to a questionnaire regarding reasons for improvement.

Results: 19 patients indicated significant improvement in their fibromyalgia symptoms and are included. The mean age of the participants was 42.2 (17 years old -71 years old). 17 of the 19 (89.5%) participants were female and 2 of 19 (10.5%) participants were male. All patients met the 2010 ACR criteria for the diagnosis of fibromyalgia. The mean pain score at the last office visit was 4.8 on a 1-10 visual analog scale. The mean pain score at an office visit 3 months earlier was 7.7 and the mean pain score at an office visit 6 months earlier was 8.4. Patients were asked to list the factors they attributed to their decrease in pain scores of at least 3 points on a 1-10 visual analog scale over the last 6 months. 15 of 19 (78.9%) of patients cited medication as a reason for their improvement. These medications included cyclobenzaprine (9 of 19, 47.4%), amitriptyline (8 of 19, 42.1%), tizanidine (2 of 19, 10.5%), clonazepam (1 of 19, 5.3%), doxepin (1 of 19, 5.3%), hydrocodone (2 of 19, 10.5%), gabapentin (1 of 19, 5.3%), trazodone (1 of 19, 5.3%), chlorzoxazone (1 of 19, 5.3%), and mirtazepine (1 of 19, 5.3%).

The other common reasons cited for improvement included weather changes (5 of 19, 26.3%), increased rest (5 of 19, 26.3%), decreased stress (3 of 19, 15.8%), and improved sleep (3 of 19, 15.8%). Exercise, physical therapy, acupuncture, increased time off work, and increased knowledge about their diagnosis were other reasons occasionally cited as a reason for improvement.

Conclusion: Patients with fibromyalgia who improve significantly generally attribute that improvement to a change in their medication, but other reasons are cited, such as weather and increased rest. Medication, especially muscle relaxants and tricyclics, appears to be an effective strategy for patients with fibromyalgia who improve significantly.

Improvement in Function and Pain Due to Subacromial Bursitis As Related to Dose of Triamcinolone Acetonide or Methylprednisolone Acetate

Spencer Motley[1], Bryan Ramsey[1] and Matthew Carroll[2], [1]Internal Medicine, Keesler Medical Center, Keesler AFB, MS, [2]Rheumatology, Keesler Medical Center, Keesler AFB, MS

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster II

Session Type: ACR Poster Session C

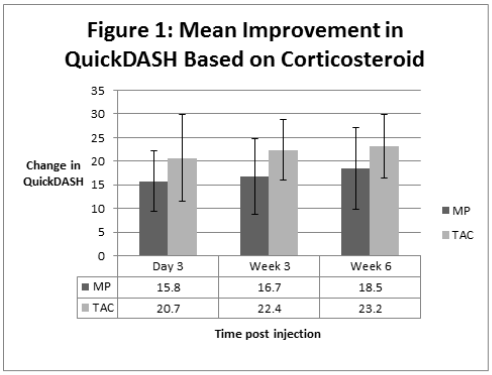
Session Time: 9:00AM-11:00AM

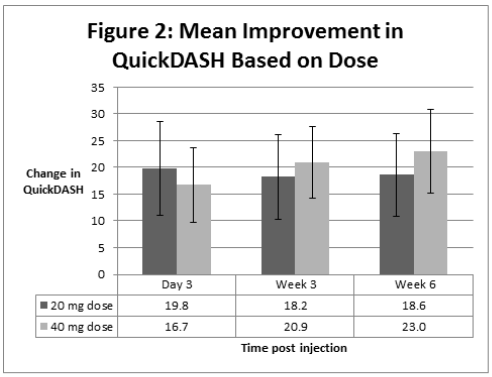
Background/Purpose: Subacromial bursitis is caused by inflammation of the bursa that separates the superior surface of the supraspinatus tendon from the overlying coraco-acromial ligament and acromion. While intra-bursal corticosteroid injection is routinely used to treat pain and help restore function in subacromial bursitis, the optimal corticosteroid dose or preparation is

currently unknown. We hypothesized that there would be no difference between subjects who received triamcinolone acetonide (TAC) or methylprednisolone acetate (MP) but there would be greater improvement with a 40 mg dose as compared to a 20 mg dose.

Methods: This single blinded study randomized subjects with at least 2 weeks of subacromial bursal pain by history and exam to receive intrabursal corticosteroid in one of four groups: TAC 20 mg, TAC 40 mg, MP 20 mg, or MP 40 mg. Concomitant with the corticosteroid injection all subjects also received 2 mL of 1% lidocaine without epinephrine and 2 mL of 0.5% bupivacaine. The Quick Disabilities of Arm, Shoulder, and Hand (or QuickDASH), subject reported pain, and adverse events were recorded at time of injection and then 3 days, 3 weeks, and 6 weeks post-injection. Primary outcome was improvement in the QuickDASH 6 weeks post-injection. Secondary outcomes were improvement in subject reported pain at 6 weeks and occurrence of adverse events. This trial is registered at www.clinicaltrials.gov (NCT02242630).

Results: Forty eight subjects were recruited. Average age was 66.8 ± 10.8 years old. Over 85% of subjects were Caucasian. Twenty left and 28 right subacromial bursa were injected. For the primary outcome, mean improvement in QuickDASH was similar between those who received TAC vs. MP (regardless of dose), shown in Figure 1. Mean improvement in QuickDASH was similar between those who received the 20 mg dose vs. 40 mg dose (regardless of preparation), shown in Figure 2.





No statistically significant differences in subject reported pain based on dose or corticosteroid preparation were noted (data not shown). No statistically significant differences in adverse events were noted between groups, although 3 subjects reported elevations in blood glucose and 2 subjects reported diarrhea.

Conclusion: With our modest sample size we have not identified any statistically significant differences for subjects with subacromial bursitis treated with either corticosteroid preparation or dose. Subject recruitment is ongoing. No significant trends in adverse outcomes were noted.

What Types of Exercises Can Fibromyalgia Patients Perform?

Robert S. Katz[1] and Jessica L. Polyak[2], [1]Rush University Medical Center, Chicago, IL, [2]Rheumatology Associates S.C., Chicago, IL

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Fibromyalgia patients should exercise, but often can't. Though aerobic exercises may help, many patients find them too challenging.

Methods: We administered a questionnaire to fibromyalgia office patients. Types of exercises included aerobic exercise, muscle strengthening, stretching, yoga, and other. All patients met the 2010 ACR criteria for the diagnosis of fibromyalgia.

Results: 91 Fibromyalgia responded to a questionnaire regarding their ability to exercise. The types of exercise of fibromyalgia patients were able to perform, based 1-10 on visual analog scales, were stretching (6.75), yoga (5.82), muscle strengthening (4.92), and aerobic exercise (3.98).

Conclusion: Fibromyalgia patients identify stretching and yoga as two types of exercise they can do. Though previous studies suggest that aerobic exercise is beneficial, the majority of fibromyalgia patients find these to too challenging.

Re-Scoring the 2011 Fibromyalgia Survey Criteria to be a Better Surrogate for Pain Centralization

Stephanie Moser[1], Chad Brummett[2], Alexander Tsodikov[3], David A. Williams[4] and Daniel J. Clauw[2], [1]Department of Anesthesiology, University of Michigan, Ann Arbor, MI, [2]Anesthesiology, University of Michigan, Ann Arbor, MI, [3]Biostatistics, School of Public Health, University of Michigan, Ann Arbor, MI, [4]Anesthseiology, University of Michigan, Ann Arbor, MI

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

The 2011 Fibromyalgia (FM) Survey Criteria is comprised of measures of widespread pain (0-19 body areas) and 6 co-morbid symptoms (scored 0-12). The measure has been termed "fibromyalgianess," which Wolfe and others have shown to be predictive of pain and disability in many rheumatic disorders. We have shown that the continuous measure is predictive of decreased opioid

responsiveness and decreased improvement in pain following arthroplasty, which we feel serves as a marker of pain centralization. We sought to develop a new scoring method for the items that would improve the predictive utility of the measure for centralized pain by re-weighting the existing items to better predict failure to improve pain following arthroplasty. **Methods:**

457 knee or hip arthroplasty patients were included. Changes in pain (WOMAC and Brief Pain Inventory (BPI)) from baseline to 6 months post-surgery and patient global impression of change (PGIC) served as outcomes. A count of 7 body zones (head, spine, trunk, arms, and legs) was compared to the count of 19 original body areas in 6 regression models. Multiple regression models with the criteria items as predictors were then conducted to determine item importance. 10-fold cross validation was used. A new scale score was formed by weighting individual items that consistently best predicted surgical outcomes. Scale scores were evaluated as predictors of surgical outcomes in regression models in the development sample and a model testing sample of 391 other knee or hip arthroplasty patients. Performance was assessed with R-square and AUROC. **Results:**

The count of 7 body zones performed as well or better than the original 19 body areas (Table 1). Thus the scoring using these zones was used in subsequent analyses. In regression models, the body zones, headache, and trouble thinking were consistently strong predictors of outcomes (Fig 1). The new scale score in which headache and trouble thinking were weighted 2X and 3X times, respectively, outperformed the original FM measure (Table 3). **Conclusion:**

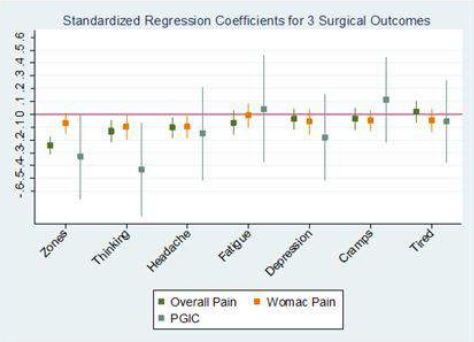
This work provides evidence that the original FM Survey Criteria can be re-scored to be a better predictor of poor response to arthroplasty. Future work is needed to determine the optimal manner to measure critical elements of FM to define a new measure of pain centralization.

Table 1. Regression coefficients and model fit statistics for individual regression models predicting BPI overall pain change, WOMAC change, and PGIC at 6 months from the count of 19 body areas or count of 7 body zones.

	BPI overall pain change		WOMAC pain change		PGIC	
	Standardized Beta	R-squared	Standardized Beta	R-squared	Odds Ratios	ROC
19 body areas	-0.28	0.46	-0.15	0.45	-0.40	0.57
7 body zones	-0.32	0.48	-0.14	0.45	-0.51	0.64

Note: Table presents results from 6 regression models predicting change in BPI overall pain from baseline to 6 months post-surgery, WOMAC pain change from baseline to 6 months post-surgery, and PGIC at 6 months post-surgery from the count of 19 body areas or the count of 7 body zones. A dichotomous variable for PGIC was created such that scores of 2 or 3 were coded as 1 and PGIC scores less than 2 were coded as 0. Linear regression was conducted for models predicting BPI overall pain change and WOMAC pain change. Baseline BPI pain scores and baseline WOMAC pain scores were included in their respective models as covariates. Logistic regression was conducted for the model predicting PGIC. 10-fold cross validation was used. Coefficient estimates and fit statistics are averages across the 10 models.

Figure 2. Standardized regression coefficients for individual regression models predicting BPI overall pain change, WOMAC change, and PGIC at 6 months from the individual ACR score items.



Note: Figure presents results from 3 regression models predicting change in BPI overall pain from baseline to 6 months post-surgery, WOMAC pain change from baseline to 6 months post-surgery, and PGIC at 6 months post-surgery from the 6 ACR criteria components: body zones, fatigue, trouble thinking, tiredness, abdominal cramps, depression, and headaches. A dichotomous variable for PGIC was created such that scores of 2 or 3 were coded as 1 and PGIC scores less than 2 were coded as 0. Linear regression was conducted for models predicting BPI overall pain change and WOMAC pain change. Baseline BPI pain scores and baseline WOMAC pain scores were included in their respective models as covariates. Logistic regression was conducted for the model predicting PGIC. 10-fold cross validation was used. Coefficient estimates are averages across the 10 models. Body zones, trouble thinking, and headache are the consistent

Table 3. Regression coefficients and model fit statistics for individual regression models predicting BPI overall pain change, WOMAC change, and PGIC at 6 months from the old and new scoring methods.

Knees & hips model development sample (n = 457)

	BPI overall pain change		WOMAC pain change		PGIC	
	Standardized Beta	R-squared	Standardized Beta	R-squared	Odds Ratio	ROC
Old scoring	-0.333	0.485	-0.221	0.492	0.866	0.621
New scoring	-0.358	0.504	-0.241	0.501	0.857	0.657

Knees & hips validation sample (n = 391)

	BPI overall pain change		WOMAC pain change		PGIC	
	Standardized Beta	R-squared	Standardized Beta	R-squared	Odds Ratio	ROC
Old scoring	-0.206	0.453	-0.159	0.545	0.769	0.734
New scoring	-0.218	0.459	-0.197	0.559	0.782	0.739

Note: Old scoring method is calculated as the sum of 19 body areas, and 6 symptom severity items. Fatigue, trouble thinking, tiredness are each assessed on a scale of 0 to 3 where 0 is no problems and 3 is severe problems. Abdominal cramps, depression, and headaches are each assessed with a binary scale where 0 is no symptoms and 1 is present symptoms. Possible score ranges from 0 to 31. New scoring method is calculated as the sum of 7 body zones (head, spine, trunk, arms, and legs), fatigue, tiredness, abdominal cramps, trouble thinking multiplied by 2 and headache multiplied by 3. Possible score ranges from 0 to 23. Scores were included in individual regression models predicting BPI overall pain change from baseline to 6 months, WOMAC pain change from baseline to 6 months, and PGIC at 6 months. Baseline BPI pain and WOMAC pain were included in the models predicting their respective change from baseline to 6 months. Scores were first tested in the original model development sample and then tested in a validation sample of 391 knee and hip arthroplasty patients.

Is There Peripheral Large Nerve Involvement in Fibromyalgia? a Systematic EMG / Nerve Conduction Study Evaluation of 55 Consecutive FM Patients

Xavier J. Caro, Robert G. Galbraith and Earl F. Winter, Southern California Fibromyalgia Research and Treatment Center, Northridge, CA

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

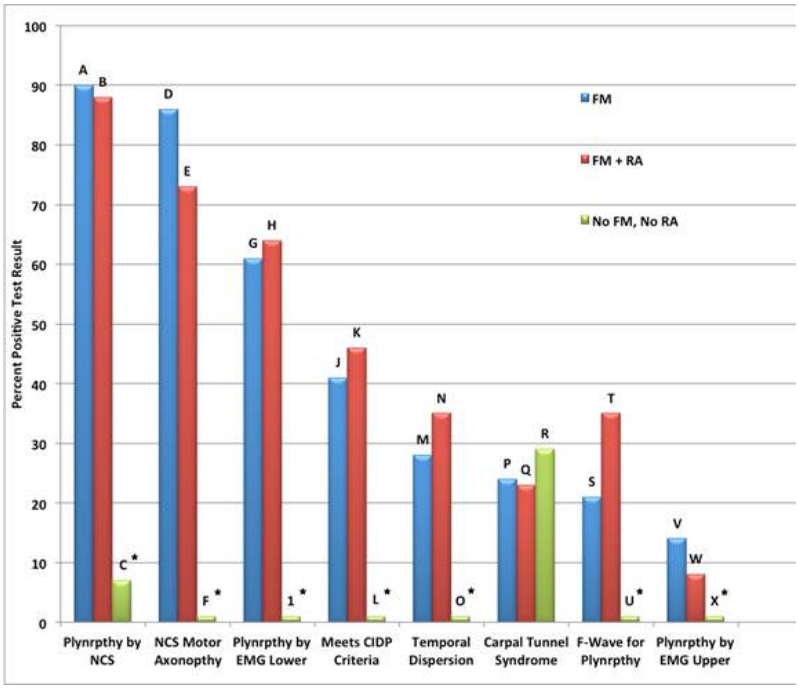
Background/Purpose: Several recent reports have implicated peripheral small fiber neuropathy (SFN) as a significant contributing factor to the pain seen in fibromyalgia (FM). Large fiber neuropathy (LFN) in this disorder has not been extensively described, however. Therefore, we retrospectively examined electromyographic (EMG) and nerve conduction study (NCS) data (collectively, "EDX") on a cohort of FM patients and controls for LFN, and clinically correlated our findings.

Methods: We reviewed clinical and EDX data from 100 consecutive patients, meeting 1990 ACR FM criteria, for study inclusion / exclusion. Subjects with a clinical disorder known to produce LFN (e.g., diabetes, Vitamin B-12 deficiency, familial neuropathy, Sjögren's syndrome, etc.) were excluded. Those with FM + RA were allowed. EDX findings from 30 "FM Only" (27 Caucasian; 23 female; mean age 59, range 21 – 90 yrs.), 25 FM + RA (20 Caucasian; 23 female; mean age 57, range 26 – 84 yrs.), and 14 control subjects with No FM & No RA (mostly incidental evaluation for carpal tunnel syndrome) were compared.

Results: All 55 FM subjects in this cohort had EDX findings of LFN (**Figure)**, with most having a sensorimotor

polyneuropathy (90%), which was demyelinating only, in 22%, axonal only, in 12%, and mixed demyelinating / axonal, in 66%. A sensorimotor polyneuropathy was seen in only 7% of control patients ($P < 0.0001$). NCS features in FM Only included temporal dispersion, prolonged duration, abnormal F-wave, or carpal tunnel syndrome in 28%, 10%, 21%, and 24% respectively. EMG in FM Only showed findings of lower extremity axonal denervation, thought most likely due to a polyneuropathy, in 61%. Clinical correlation in the FM Only group showed a significant association between EMG denervation and proximal muscle weakness ($P < 0.005$). EDX findings meeting published criteria for, at least, "possible" chronic inflammatory demyelinating polyneuropathy (CIDP) were seen in 41% of FM Only subjects, but in no control subjects ($P<0.003$). Calf epidermal nerve fiber density (ENFD) was reduced to ≤ 6.5 fibers / mm in 53% and ≤ 7.0 fibers / mm in 63% of FM Only subjects.

Conclusion: All FM subjects in our cohort had evidence of LFN, suggesting that these lesions participate in FM symptomatology. "FM Only" and FM + RA participants did not demonstrate any major between-group differences in EDX findings. EDX appeared to compliment ENFD determinations in defining the peripheral neuropathology of FM. These EDX findings probably hold important implications for the better understanding and treatment of this painful disorder.



LFN in FM: A vs. C (P value) <0.0001, B vs. C <0.0001, D vs. F <0.0001, E vs. F = 0.0001, G vs. I = 0.02, H vs. I = 0.01, J vs. L = 0.003, K vs. L = 0.002, M vs. O = 0.03, N vs. O = 0.01, S vs. U = 0.08, T vs. U = 0.01. (Fischer's Exact Test, 2 tailed) Other comparisons were NS. * Indicates 1% for illustration purposes; actual value = 0%.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Little is understood about the determinants of symptom expression within individuals with fibromyalgia syndrome (FMS). While FMS sufferers often report environmental influences, including weather events, on their symptom severity, a consistent effect of specific weather conditions on FMS symptoms has yet to be demonstrated. Twitter is a popular internet-based social media platform that enables users to express their thoughts, feelings and details of their daily lives using short text-based messages (tweets) in the public domain. We used computerized content analysis of tweets to investigate the subjective experience of FMS in a large, widely distributed population and any association with coincident environmental factors.

Methods:

We performed an automated search of Twitter between January 2008 and November 2014 using the hashtags #fibromyalgia, #fibro and #spoonie as keywords. Sentiment analysis, a computerized linguistic method that uses natural language processing and text analytics to identify subjective information in written source materials, was performed using a Streamcrab Python library incorporating the Stanford CoreNLP libraries to quantify the affective content of each included tweet. The classification model was trained using two sets of pre-labelled negative and positive tweets, then used to automatically compute negative and positive sentiment scores between 0 and 100 for each tweet. The sum of the two assigned scores for each tweet is 100. A higher negative sentiment score implies a more severe pain experience. Date, time and location data for each individual tweet were used to identify corresponding climate data (temperature, humidity, wind speed, “feels like”, heat index, wind chill, and dew point) via World Weather Online. The association between negative sentiment scores (indicative of greater pain) and environmental variables was measured using Pearson correlation.

Results:

The search returned 140,432 English language tweets for which location data were available. Examples of tweets with their negative and positive sentiment analysis scores are shown in Table 1. There was a low positive correlation between humidity and negative sentiment scores which was significant at the 0.05 level ($r=0.009$, $p=0.001$). There was no significant association between the other environmental variables and negative sentiment scores.

Conclusion: Twitter users who tweet about fibromyalgia are slightly more likely to include content that suggests a higher pain burden as atmospheric humidity increases. Other local weather features, including temperature and wind speed, are not associated with changes in pain sentiment expressed via Twitter. Computerized content analysis is a novel and potentially powerful method for exploring relationships between environmental variables and the subjective experience in rheumatic and other diseases.

Dinamyx Neuromodulation in Fibromyalgia

CAMILLO GIACOMELLI, Antonino Santagati, Arianna Consensi, Alessandra Rossi and Laura Bazzichi, Division of Reumatology, Univeristy of Pisa, Pisa, Italy

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Fibromyalgia (FM) is one of the most common diseases manifested by pain, tenderness and fatigue. FM is still a disorder of unknown etiology that is generally diagnosed according to the ACR criteria. According to Cochrane Reviews, **current therapy** is clearly and largely **not satisfactory (1).** Transcutaneous electrical nerve stimulation (TENS) is a non-invasive technique that is used throughout the world to manage painful conditions, although there continues to be uncertainty about efficacy and effectiveness (2). The purpose of TENS is to selectively activate low threshold peripheral afferents as this has been shown to inhibit ongoing transmission of nociceptive input in the spinal cord, leading to pain relief. A variety of TENS-like devices, that differ in design to a standard TENS device, are available to the general public without prescription although there is very little research on mechanisms, efficacy, and effectiveness. Non-invasive Interactive Neuromodulation (INM) is a relatively new TENS-like device and is sold under the trade name Dynamix®. Often pain relief lasts long after the treatment is over which hints at a neuropeptide/cytokine cascade effect and a CNS response. Manufacturers claim that non-invasive INM relieves pain and promotes healing of various injuries. The aim of our study will be evaluate the safety and efficacy of Dynamix application in FM patient.

Methods:

At the division of Rheumatology of University of Pisa, we enrolled 20 Female affected by Fibromyalgia, with a stable therapeutic regimen for at least 3 month, and we treated with Dinamix (A-circle) for 1 times at week for 6 times. Each patients completed FIQ, SF-36, FACIT-Fatigue scale, FAS Evaluation. Prior the treatment, at the end of the treatment and after 4 weeks after the end of the study. The INM treatment was applied on all the efferent nerve of the column and on the exit of trigeminal nerve (the treatment was named column basis). A tender point count with tender point index evaluation was performed by a Rheumatologist.

Results: No patient showed an adverse event during the treatment and at the follow up. We found a statistically significant reduction in FIQ, pain evaluated by VAS and SF-36 item, FAS score (both Self-Assessment Pain Scale and total FAS index), Tende Point index ($p<0.05$). Moreover we found a slight improvement of neck rotation. We don't found a significant reduction in Tender Poins number. The same results was found at follow up visit, after 4 week from the end of the treatment.

Conclusion:

The INM is a non-invasive technique that require a specific skills to obtain satisfactory results, however, the ease of use and speed of application make it a potentially useful technique in pain management. Moreover the INM is well tolerated by the patients. This is a preliminary work that underline the beneficial effects of this treatment in FM patients. The limit of the study was the absence of the control group, for example a placebo group.

Abstract Number: 2298

Misdiagnosis of Fibromyalgia (FM) As Axial Spondylarthritis (SpA): Lessons from Analysis of 26 Cases

Dongfeng Liang, Jianglin Zhang and Feng Huang, Rheumatology, Chinese PLA General Hospital, Beijing, China
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Both patients with fibromyalgia (FM) and with axial spondyloarthritis (SpA) are suffering from pain. The patients with axial SpA are mainly manifested as inflammatory back pain, while widespread pain is found in the patients with FM. However for those FM patients, the commonly-seen sleep disturbance due to anxiety/depression usually amplifies the sensation of back pain during the night time, which is likely to be recognized as inflammatory back pain; thus some FM patients had been misdiagnosed as axial SpA. This study intends to further understand the modified American College of Rheumatology (ACR) 2010 diagnostic criteria for FM, increase diagnostic accuracy of axial SpA and reduce misdiagnosis of FM as axial SpA.

Methods: Clinical data of 26 patients with primary FM were collected, who had previously misdiagnosed as axial SpA by other tertiary hospitals in China. The re-diagnosis of those 26 FM patients was established based on the modified ACR 2010 criteria. Each patient was assessed by Widespread Pain Index (WPI) and Symptom Severity (SS) scale adopted by the modified ACR 2010 criteria, as well as parameters including serous C-reactive protein, erythrocyte sedimentation rate (ESR), HLA-B27 and sacroiliac joint images.

Results: Among the subjects, 8 males (30.77%) and 18 females (69.23%) complained widespread pain, most notably in the spine. None of peripheral arthritis, enthesitis, dactylitis, and limited spine motion was found. WPI median (P25-P75) was 5.0 (4.0-8.0). SS score was 9.269 ±1.589. Serous C-reactive protein (normal range: 0 - 0.8 mg/dl) was 0 in 5 cases, less than 0.348 mg/dl in 15 cases and between 0.37-0.74 mg/dl in 6 cases. ESR median (P25-P75) was 5.0 (3.0-9.0) mm/1h. HLA-B27 positivity was detected in 73.08% cases. 4 patients (15.38%, all females) were found with osteitis condensans ilii by CT and MRI, 5 patients with normal sacroiliac CT scan, 6 with normal sacroiliac MRI result, and the rest 11 with normal sacroiliac CT and MRI.

Conclusion: The modified ACR 2010 criteria for FM has adopted the criteria of WPI and SS scale replacing the tender point count and enhanced the diagnostic weight of anxiety/depression. However, in medical practice in China, it isn't uncommon to see the misdiagnosis of FM as axial SpA, which was caused by two reasons: (i) over-relying on the tender point counts indicated in ACR 1990 criteria for FM and (ii) failure to take inflammations as the priority factor of diagnosis of axial SpA. In order to increase diagnostic accuracy of FM and axial SpA, it is necessary to (i) fully investigate and evaluate somatization of anxiety/depression, instead of using tender point counts as the exclusive criterion of FM; and (ii) emphasize inflammations in diagnosis of axial SpA, i.e., at least one of the following factors should be identified: peripheral arthritis, enthesitis, dactylitis, definite sacroiliitis on imaging and elevated inflammatory biomarkers such as serous C-reactive protein and/or ESR.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Although polymorphisms of the catechol-O-methyl transferase (COMT) gene have been implicated in altered pain sensitivity, results concerning the association between COMT gene polymorphisms and FM are equivocal. The present, large-scale case-control study assessed the associations between COMT single-nucleotide polymorphisms (SNP) and FM risk and symptom severity.

Methods: In total, 409 FM patients and 423 controls were enrolled. Alleles and genotypes at five positions [rs6269 (A>G), rs4633 (C>T), rs4818 (C>G), rs4680 (C>G) and rs165599 (A>G)] in the COMT gene were genotyped from peripheral blood DNA. Associations between COMT SNPs, FM susceptibility and FM patient clinical measures were assessed.

Results: Alleles and genotypes of the rs4818 COMT gene polymorphism were significantly associated with increased susceptibility to FM. The rs4818 GG genotype was more strongly associated with susceptibility to FM compared to the CC genotype (OR = 1.681). Although allele and genotype frequencies did not differ among groups, the rs4633 CT genotype was protective against FM following adjustment for age and sex (OR = 0.745). However, no association was observed between clinical measures and individual COMT SNPs. In haplotype analysis, there was a significant association between ACG haplotype and FM susceptibility (OR = 2.960) and the number of tender points (P = 0.046).

Conclusion: This large-scale study suggests that polymorphisms of the COMT gene may be associated with FM risk and pain sensitivity in Korean FM patients. However, our results differed to those of previous studies using Caucasian or Latin-American populations, suggesting ethnic variation in COMT gene polymorphisms in FM.

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Fibromyalgia (FM) is a chronic pain syndrome characterized by lowered pain thresholds and other FM-related symptoms such as fatigue, anxiety and depression. Recent studies have focused on genetic factors that influence pain sensitivity and development of FM. There are emerging evidences that transient receptor potential vanilloid (TRPV) channels have been contributed to pain hypersensitivity. However, whether polymorphisms of TRPV are associated with FM is unknown. The aim of present study was to evaluate association between polymorphisms of TRPV2 and TRPV3 gene and FM susceptibility, and FM symptoms in a Korean population.

Methods: A total of 409 patients with FM and 423 controls were enrolled from 10 medical centers which participated in the Korean nationwide fibromyalgia survey. The alleles and genotypes at 3 positions [rs3813768(C>G), rs8121(C>T) and rs1129235(C>A)] in the TRPV 2 gene and 2 positions [rs7216486 (G>A) and rs395357(C>T)] in the TRPV 3 gene were genotyped from peripheral blood DNA. The associations of TPPV 2 and TRPV3 genes polymorphisms with FM susceptibility and clinical symptoms of FM were assessed.

Results: The frequencies of alleles and genotypes of individual TRPV2 and TRPV3 genes were not significantly associated with susceptibility of FM. However, the GTA haplotype of TRPV2 gene showed protective against fibromyalgia susceptibility after age- and sex adjusted analysis (OR 0.637; 95% CI; 0.418-0.969; P=0.035). Furthermore, SNP rs395357 of TRPV3 was associated with scores of Brief Fatigue Inventory (BFI) (P=0.017) in FM patients. Although haplotypes of TRPV3 did not show different distribution between FM patients and healthy controls, haplotypes of TRPV3 was associated with BFI and the Short Form-36 Health Status Questionnaire (SF-36) physical health summary scores (P=0.036, respectively)

Conclusion: This large-scale study is the first to evaluate association of TRPV gene polymorphisms with fibromyalgia susceptibility and symptom severity of FM. Our results suggested that certain TRPV2 haplotype have a protective role against FM, and also some genotype and haplotype of TRPV3 contribute to fibromyalgia symptoms. Further researches needed to be confirmed.

Facing Fibromyalgia; How Patients Describe Their Symptoms Based on a Retrospective Evaluation of a Patient Survey and Vitality Assessment in Clinical Trials

Andrew Clair[1], Lynne Pauer[2] and Elizabeth Masters[1], [1]Pfizer Inc., New York, NY, [2]Pfizer Inc, New London, CT

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Fibromyalgia (FM) is a common chronic widespread pain disorder with comorbid symptoms of fatigue, sleep disturbance, cognitive dysfunction and depression. It is believed to be a central pain processing disorder. **Results** of a recent patient survey conducted in the United States showed that those diagnosed with FM are misunderstood regarding condition severity, debilitating pain experienced and the impact it has on their lives. These factors may lead to damaged relationships, lost productivity and a general inability to perform daily tasks. In this assessment, we evaluated pain descriptors provided by FM survey respondents as well as baseline SF-36 vitality scores from 4 clinical trials to better understand the patient experience with FM pain and FM health status burden.

Methods: The Functioning with Fibro Survey was carried out in August 2013 and included 1,223 Americans ≥18 years old with fibromyalgia. Participants had received an FM diagnosis from a healthcare provider and provided survey responses through an online data collection tool. Separately, SF-36 vitality scale baseline data from 4 placebo-controlled Phase 3 FM clinical studies was assessed (range: 0-100; higher = better functioning). Subjects across the 4 clinical studies had FM diagnoses (1990 ACR criteria) with mean baseline pain scores ≥4 (0-10; higher = worse pain), and scores ≥40 mm on a Visual Analog Scale (range: 0-100; higher = worse pain).

Results: Survey results demonstrated that fibromyalgia pain is experienced differently across FM patients. In response to the survey question, "If you had to describe to a friend how your fibromyalgia pain feels, which of the following situations comes closest to what you would say?", the following was observed: radiating pain all over: 30%; getting run over by a truck: 28%; constant flu-like ache: 23%; stabbed by a knife: 10%; strenuous workout: 10%

Baseline mean SF-36 vitality scores ranged from 18.4 to 27.6 across the 4 clinical trials. For comparison, normative data for the US general population for women between ages 45–54 in 1998, was 60.6 (mean); standard deviation 21.3 (Hoffman et al. *Int J Clin Pract*. 2008:115-126).

Conclusion: Fibromyalgia patients often experience debilitating pain which may impact multiple areas of their lives. In a patient-rated survey of over 1,200 FM sufferers, pain was characterized in different ways but all were descriptive of debilitating pain. SF-36 vitality scores at baseline from 4 FM studies confirmed significant vitality impairment. These scores reflected lower vitality than what has been reported for many other health conditions widely accepted as impairing, including COPD, congestive heart failure, diabetes, clinical depression, RA, OA, SLE, primary Sjogren's Syndrome and Myofascial Pain Syndrome (Hoffman et al). Decreases in vitality scores are significantly associated with increased odds of negative outcomes, including inability to work due to health, job loss, increased hospitalization, and short and long-term mortality (Bjorner et al. *Curr Med Res Opinion.* 2007:731-739). These data underscore the important health burden in people with FM.

The Impact of Prior Fibromyalgia Treatment on the Response to Pregabalin in Fibromyalgia Clinical Trials

Lynne Pauer[1], Andrew Clair[2], Pritha Bhadra Brown[2], Marie Ortiz[2] and Joseph Scavone[1], [1]Pfizer Inc, Groton, CT, [2]Pfizer Inc., New York, NY

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Fibromyalgia (FM) is a chronic, widespread pain disorder for which Lyrica is an approved treatment. Antidepressants, gabapentin, muscle relaxants, and opioids are frequently used to treat FM. The impact of prior use of these treatments on the response to pregabalin treatment in FM has not been assessed. Previous work showed that FM patients respond to treatment with pregabalin with significant improvements in pain scores irrespective of prior opioid use (Argoff et al. *Clin J Pain.* 2015).

Methods:

A pooled analysis of 4 Phase 3 placebo-controlled clinical trials of pregabalin (300-600 mg/day) of 13-15 week duration in FM patients was conducted to assess the effect of prior treatment with antidepressants (including SSRIs, SNRIs, and TCAs), gabapentin, or muscle relaxants on the response to treatment with pregabalin. Patients were divided into those who had used one of these treatments prior to the trial and those who had not. Patients could have taken prior FM treatments in more than 1 category. Changes in least squares (LS) mean pain scores (assessed by NRS-Pain, a 0-10 numeric rating scale administered daily, controlled for baseline pain score) in the pregabalin and placebo groups were assessed. Last observation carried forward (LOCF) methodology was used to impute missing data.

Results:

There were 2668 patients in the analysis set, including 717 patients with prior antidepressant use, 380 with prior muscle relaxant use, and 113 with prior gabapentin use. Pregabalin improved the LS mean difference in pain score compared with placebo in patients both with and without prior use of these medications. Treatment differences (placebo adjusted) for subjects with prior use of these medications were as follows: gabapentin: -0.78 (95% confidence interval -1.56, 0.01), p=0.0522; antidepressants: -1.00 (CI -1.33, -0.67), p<.0001; and muscle relaxants: -0.96 (CI -1.46, -0.46), p=0.0002. Treatment differences (placebo adjusted) for subjects who did not previously use these medications were as follows: no prior gabapentin: -0.54 (CI -0.71, -0.37), p<.0001; no prior antidepressant: -0.40 (CI -0.59, -0.21), p<.0001; and no prior muscle relaxant: -0.49 (CI -0.67, -0.31), p<.0001. These results were statistically significant in each case apart from prior gabapentin (treatment difference -0.78, p=0.0522), likely due to the smaller size (N=113; pregabalin N=74, placebo N=39) of this cohort. Similar results compared with the overall antidepressant result were observed for SSRIs, SNRIs, and TCAs separately, based on summary statistics. In general, patients with prior FM treatment had slightly higher baseline pain scores.

Conclusion:

FM patients responded to treatment with pregabalin with improvements in pain scores relative to placebo, irrespective of prior treatment with gabapentin, muscle relaxants, or antidepressants. These results were statistically significant apart from the smallest population studied (gabapentin, N=113), which had a similar magnitude of effect. Similar conclusions were reached in previous work regarding opioids (Argoff et al). These data could inform treatment decisions for FM patients currently taking these medications.

Session Date: Tuesday, November 10, 2015

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

The Fibromyalgia Impact Questionnaire – Revised (FIQR) [1] has been in wide use since Bennett et al revised the original FIQ[2]. While the instrument was originally validated and analyzed from questionnaires completed in person on computers, there has been no similar study of the FIQR completed in an online questionnaire. This presentation hopes to address this research gap.

Methods:

Potential participants included persons aged 21-89 with self-report of a provider diagnosis of fibromyalgia. Participants responded to an email from a fibromyalgia support and advocacy non-profit that described the study purpose and led them to a confidential link to an online survey with a unique identifier. The survey consisted of two standardized questionnaires: FIQR and the Five Facet Mindfulness Questionnaire. The sample was further profiled with a 16-item investigator-designed questionnaire that collected clinical and demographic information. Data were collected between November 2012 and January 2013. This study was approved by the Institutional Review Board of Oregon Health and Science University, Portland, Oregon. The statistical analysis from the 2009 manuscript was repeated in order to have similar comparisons. This included item analysis and questionnaire properties using basic statistics, reliability item analysis, and Cronbach alpha. Significance of specific means was analyzed using Tukey honestly significantly differences (HSD) for unequal sample size.

Results: A total of 4,986 respondents represented all 50 states in the United States and 30 countries. FIQ-R scores demonstrated moderate to severe fibromyalgia with the majority of subjects (59%) scoring ≤ 60. The mean total score was 63.4 ± 17.8 indicating that our population had a slightly higher FIQR score than originally reported. The average age was 52.2 ± 10.6. Most (74%) were symptomatic with FM for over 10 years. 53% reported not working outside the home due to their FM, despite being highly educated (47% college graduates and post graduate degrees). Individual items were compared as well as subscores. All subscores were higher than the original paper but within the standard deviations. The correlations between individual items and subscales were comparable to the original study.

Conclusion: The characteristics of the FIQR when administered online are similar to the original paper. However, our sample indicates that the population averages for the FIQR Function, Impact, and Symptom subscales as well as the Total score were all higher than originally reported.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Carpal Tunnel Syndrome (CTS) is produced by the entrapment of the median nerve (MN) in the carpal tunnel. It is characterized by pain and paresthesia in the territory of MN. It is associated with diabetes mellitus, hypothyroidism, autoimmune diseases, dyslipidemia, and etc. Tinnel and Phalen maneuvers are positive in most of the patients, with a sensitivity of 70 % and 85 %, respectively. CTS diagnosis is clinical; electromyography (EMG) with conduction velocity is considered the most objective test for the diagnosis, with sensitivity of 86 % and specificity of 95 %, ultrasound has shown an increased cross-sectional area of MN compared with healthy controls. **Purpose:** Correlate the clinical manifestations of patients with CTS with increased cross-sectional area of the MN and the neurophysiological findings.

Methods: analytical, longitudinal, prospective, study in which patients from the Rheumatology service of the Hospital Docente Padre Billini (HDPB) with clinical diagnosis of CTS were selected from August to November 2014. Ultrasound of the Carpal Tunnel was done by two rheumatologists with training in musculoskeletal ultrasound (MSU), half of the sample was evaluated by each, the result was considered pathological if they both agreed. An ultrasound SIEMENS model Acuson X150 with 13 MHz transducer was used in the study. Ultrasound images of longitudinal and transverse carpal tunnel cuts were taken and MN circumference was measured in cross section, considering a normal circumference of the MN of 10mm2. Other variables taken in consideration: sex, age, co morbidities and positive maneuvers. The diagnosis was confirmed by EMG; those patients with no EMG were excluded. The descriptive analysis was done with frequencies and percentages for categorical variables and measures of central tendency and dispersion for the number using SPSS Statistics (v20.x86). The study was approved by the ethics committee.

Results: Of a sample of 62 patients, 52 were included in the study. 51 (98.1%) were females, with a median of age of 55.2 years; 13.5% of the patients were diabetic; 13.5% had hypothyroidism; 9.6% autoimmune disease; 5.8% suffered dislipaemias; and the remaining 57.7% had no co morbidities. On physical examination, Tinel and Phalen maneuvers were positive with percentages of 90.4% and 75% respectively. As for the MN diameter, 51 patients (98.1%) had an enlarged MN circumference (>10mm^2), 90.4% bilateral. With a median 15.3mm^2 for the right MN and 13.9mm^2 for the left MN all the patients had EMG study compatible with the syndrome.

Conclusion: The ultrasonographic results of patients with CTS in the rheumatology service of the HDPB showed that the cross-sectional diameter of the MN is increased in a high percentage of the patients, and this findings are related with clinical and EMG diagnostics. We conclude that ultrasound is a very useful diagnostic tool as reported in the literature.

Relationship Between Anxiety, Depression, Sleep, Fibromyalgia and BMI in Patients with Rheumatic Disease

Shazia Bég[1] and Ali Ahmad[2], [1]Rheumatology, University of Central Florida, Orlando, FL, [2]University of Central Florida, Orlando, FL

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with rheumatic diseases often have comorbidities that complicate their psychological well-being and affect prognosis. In this study, we looked at 216 patients with rheumatoid arthritis (RA), systemic lupus erythematous (SLE), psoriatic arthritis (PsA), or Sjogren's syndrome (SS) to determine (a) the prevalence of anxiety, depression, sleep disturbance, fibromyalgia (FMS), BMI greater than 23, and gastroesophageal disease (GERD) in each patient population (b) the relationship between FMS, BMI, disease activity measure known as RAPID3.

Methods: Study participants were 216 rheumatology patients seen at the UCF Pegasus Health clinic from November 2011 to May 2014 with one or more of the following diseases: rheumatoid arthritis (n=116), Sjogren's syndrome (n=20), SLE (n=27), or psoriatic arthritis (n=22). 28 were male and 88 were female. Variables that were collected included RAPID3 scores, patient demographics (age, sex), BMI, presence of GERD, and presence of FMS. Each patient was randomly assigned, unique and unidentifiable study number.

Results: Significant differences in the prevalence of anxiety and fibromyalgia were found in the study populations, with anxiety being more prevalent in Sjogren's syndrome, and fibromyalgia being more prevalent in patients with >1 diagnosis. The presence of fibromyalgia was significantly correlated with RAPID3 score in all patients except those with PsA. Significant correlations between BMI and RAPID3 score were found for patients with rheumatoid arthritis and for patients with Sjogren's syndrome who demonstrated the most pronounced relationship.

Table 1: Incidence of selected comorbidities at baseline in patients with rheumatoid arthritis, systemic lupus erythematous, psoriatic arthritis, Sjogren's syndrome, and >1 diagnosis.

	RA	SS	PsA	SLE	>1 Diagnosis	p-value
Depression	40.2%	71.4%	33.3%	30.4%	51.9%	.088
Anxiety	47.3%	78.6%	38.1%	30.4%	55.6%	.049
Sleep disturbance	78.6%	85.7%	71.4%	60.9%	77.8%	.364
Overweight or obese	71.3%	90%	90.5%	74.1%	83.9%	.245
Fibromyalgia	12.1%	20%	9.1%	18.5%	41.9%	.003
GERD	12.9%	10%	9.1%	14.8%	29%	.183

Table 2: Relationship between the presence of fibromyalgia and RAPID3 score at baseline in patients with rheumatic disease

	Correlation	p-value
All patients	.328	.000
RA	.245	.010
SLE	.763	.000
SS	.646	.013
PsA	.167	.482
>1 diagnosis	.514	.006

Table 3: Relationship between BMI and RAPID3 score at baseline in patients with rheumatic disease[a]		
	Correlation	p-value
All patients	.263	.001
RA	.246	.015
SLE	.345	.176
SS	.760	.007
PsA	.289	.261
>1 diagnosis	.420	.105
[a]Patients with fibromyalgia were excluded to as they were a confounding factor.		

Conclusion: Our study confirmed the increased prevalence of anxiety in patients with Sjogren's syndrome. Evaluation and treatment for comorbid psychiatric conditions may be pertinent in these patients. Fibromyalgia was confirmed to be related to disease activity scores. Clinically, this may incorrectly be perceived as worsening of rheumatic disease. In RA and SS patients, BMI was significantly correlated with RAPID3 scores. Studies confirm that obesity in RA patients reduces rates of remission and response to treatment.

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Fibromyalgia (FM) is a prevalent syndrome in patients with inflammatory rheumatic disease. The purpose of this study was to evaluate and compare the prevalence of FM in various inflammatory rheumatic diseases.

Methods: This single-center cross-sectional study was conducted between September 2014 and April 2015. We screened for clinical signs of fibromyalgia in all patients presenting for rheumatoid arthritis (RA), spondyloarthritis (SpA), and connective tissue disease (Sjögren's syndrome (SS), systemic lupus erythematosus (SLE), scleroderma (Scl), myositis). Diagnosis of FM was based on ACR–90 classification criteria (to minimize interfering overlap between rheumatic disease-related pain and FM-related pain) and expert opinion.

Results: In total, 691 patients were included in the study: 325 RA, 298 SpA (59 psoriatic arthritis, 137 radiographic axial SpA, 64 non-radiographic axial SpA, 38 peripheral SpA), 28 SLE, 27 SS, 14 Scl, and 6 myositis. The population counted 451 women (65.3%) and 240 men (34.7%). Mean all-population age was 55.8 ± 15.5 years. Median disease duration was 11 years [IQR 5–20]. In the total population, 55 patients (8%) met the ACR–90 criteria, and 97 patients (14%) were given a diagnosis of FM by the expert doctor. Prevalence of FM meeting ACR–90 criteria was 4.9% in RA, 11.1% in SpA, and 11.3% in connective tissue disease, and was significantly higher in the SpA group than in the RA group (p=0.05). The expert settled on a diagnosis of FM for 7.7% of patients with RA, 17.5% of patients with SpA, and 28.2% of patients with connective tissue disease. The expert

diagnosed significantly more FM in SpA (p=0.003) and connective tissue disease (p=0.001) than in RA.

Conclusion: Concomitant fibromyalgia is prevalent in inflammatory rheumatic disease, especially in spondyloarthritis and connective tissue disease. The expert doctor makes the diagnosis of fibromyalgia more often than ACR–90 criteria.

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The importance of nonrestorative sleep in the pathophysiology of fibromyalgia (FM) suggests that treatments that improve sleep quality would address global symptoms. TNX-102 SL[1]a proprietary eutectic sublingual (SL) tablet formulation of low dose cyclobenzaprine HCl (2.8 mg) tablet designed for rapid absorption and long-term bedtime use. TNX-102 SL was assessed for its safety and efficacy in a phase 2b study of FM (the BESTFIT study).

Methods: A total of 205 FM patients who satisfied the ACR 2010 FM criteria were enrolled at 17 sites in a 12-week, double-blind, placebo-controlled trial in which participants were randomized 1:1 to receive TNX-102 SL (N=103) or placebo (N=102). Outcome measures included daily diary assessments of pain and sleep (0-10 NRS), the Fibromyalgia Impact Questionnaire-Revised (FIQ-R), Patient Global Impression of Change (PGIC), and the PROMIS Sleep Disturbance scale (PROMIS).

Results: Subjects treated with TNX-102 SL improved in all measures of sleep quality, as well as pain, FIQ-R and PGIC ratings over the 12 weeks. The PROMIS sleep disturbance scale reached statistical significance by week 4, p = 0.021, and had sustained benefit through week 12, p = 0.005 (-8.96 on TNX-102 SL v -5.13 on placebo). Daily sleep diary (change from baseline to endpoint) reached statistical significance at week 1, regained significance at week 6, p = 0.015, and was sustained through week 12; p < 0.001 (-1.85 v -0.88). The sleep quality item on the FIQ-R reached significance at week 2, p=0.012, and was sustained through week 12; p <0.001 (-2.9 v 1.2). The improvements in sleep quality preceded other FM changes. The responder analysis of daily diary pain (with =>30% improvement from baseline defined as response) was significant at week 12 p = 0.033 (34.0% response rate v 20.6%) and reached initial statistical significance at week 9, p = 0.042 (logistic regression). Improvement in sleep by PROMIS correlated with improvement in pain by 30% responder analysis (r=0.3, p=<0.001). PGIC favorable response was significant at week 12 (30.1% vs. 16.7%, p = 0.025 by logistic regression). PGIC correlated with improvement in PROMIS sleep (r=0.6, p=<0.001) and sleep diary (r=0.5, p=<0.001). FIQ-R total score became significant at week 8, p = 0.041, and was sustained through week 12, p = 0.014 (-15.6 v -8.5). FIQ-R correlated with improvement in PROMIS sleep (r=0.5, p=<0.001) and with sleep diary (r=0.6, p=<0.001).

Systemic adverse events (AEs) were infrequent. Weight gain was negligible. Local administration site reactions (transient tongue or sublingual numbness) occurred in 42% of treated patients.

Conclusion: Bedtime TNX-102 SL improved sleep quality by multiple measures of FM which is consistent with the antagonistic activity of cyclobenzaprine at 5HT2A, alpha-1 adrenergic and H-1 receptors. The improvement in sleep quality temporally preceded improvements in pain, PGIC and FIQ-R, with which sleep quality improvements were correlated. Together, these data suggest TNX-102 SL targets non-restorative sleep and provides a novel approach to treating FM.

[1]TNX-102 SL is an Investigational New Drug and has not been approved for any indication.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Fibromyalgia (FM) is characterized by symptoms that include widespread pain and sleep disruption. Clinical studies that rely on patient self-reported outcome measures such as pain scales may be analyzed by responder analysis (comparisons of proportions of treated patients achieving a predefined clinically meaningful improvement threshold) and by group mean changes. In a Phase 2b trial of TNX-102 SL[1], a proprietary eutectic sublingual (SL) tablet formulation of low-dose cyclobenzaprine HCl (2.8 mg) in FM patients (BESTFIT), we compared these approaches to the evaluation of changes in pain and FM symptoms.

Methods: 205 FM patients who satisfied the ACR 2010 FM criteria from 17 US investigational sites were randomized in a double-blinded fashion to placebo (n=102) or TNX-102 SL (n=103) for 12 weeks. Topline results from BESTFIT are presented elsewhere. For this analysis, we compared changes in pain score, patient global impression of change (PGIC), and Fibromyalgia Impact Questionnaire-Revised (FIQ-R), analyzed by both responder analyses and group mean change from baseline techniques.

Results: For the daily pain diary, the responder analysis (=>30% improvement from baseline) resulted in 34.0% on TNX-102 SL compared to 20.6% on placebo, p=0.033. The same daily pain data when analyzed as mean change from baseline, TNX-102 SL had improvement of -1.50 units vs. -1.0 units on placebo, p=0.086. Using the FIQ-R pain item as the pain measure resulted in a response rate of 38.8% on TNX-102 SL vs. 23.5% on placebo, p=0.025, while the mean change was -1.8 on TNX-102 SL vs -0.7 on placebo, p=0.004. PGIC is a 7 point Likert scale and defining response “very much improved” or “much improved”, the

response rate was 30.1% on TNX-102 SL vs. 16.7% on placebo, p=0.025, and the mean change was 3.1 on TNX-102 SL vs 3.6 on placebo, p=0.025. The FIQ-R was evaluated as 21 discrete items, three defined domains (symptoms, overall impact and function) and a total score. The FIQ-R total score and symptom domain were statistically different between treatment groups by both responder and mean analyses. The function domain separated on the responder analysis but was not significant (p=0.059) on mean change. Systemic adverse events (AEs) were infrequent. Local administration site reactions (transient tongue or sublingual numbness) occurred in 42% of treated patients.

Conclusion: Results from this Phase 2b trial support the finding that responder analyses for analgesia[2]and other patient-reported outcomes may reveal significant and meaningful effects that are missed by group mean changes. In the particular case of the BESTFIT study of TNX-102 SL, the pain questionnaire was not specific to central or regional pain and TNX-102 SL targets non-restorative sleep with secondary improvement in pain. An ongoing confirmatory study is utilizing pain and other responder analyses as the primary and secondary endpoints which are more appropriate and sensitive measures for the evaluation of TNX-102 SL for FM.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Fibromyalgia (FM) is characterized by chronic widespread pain and sleep disturbance. Treatments that improve sleep quality in FM patients may improve fibromyalgia by a mechanism distinct from centrally acting analgesics. TNX-102 SL[1]is a proprietary eutectic sublingual (SL) tablet formulation of low-dose cyclobenzaprine HCl (2.8 mg) designed for rapid absorption and long-term bedtime use. This double-blind, randomized, placebo-controlled multicenter study (BESTFIT) evaluated the safety and efficacy of TNX-102 SL in FM.

Methods: A total of 205 patients who met ACR 2010 FM criteria were enrolled at 17 sites in a 12-week, double-blind, placebo-controlled trial. Patients were randomized 1:1 to receive TNX-102 SL (N=103) or placebo (N=102). Outcome measures included daily pain and sleep diaries (0-10 NRS averaged over each week), Fibromyalgia Impact Questionnaire (FIQ-R), Patient

Global Impression of Change (PGIC), and PROMIS Sleep Disturbance scale (PROMIS). Data were analyzed by mean change from baseline using Mixed Effects Model Repeated Measures (MMRM) unless otherwise noted.

Results: Patients treated with TNX-102 SL showed improvement in multiple domains of FM. Responder analysis of week 12 daily diary pain (with =>30% improvement from baseline defined as response) was statistically significant with a 34.0% pain response rate compared to 20.6% for placebo; p = 0.033. This same pain diary data showed a decrease in pain by -1.5 compared to -1.0 for placebo; p = 0.086. Pain scores reported during clinic visits (7 day recall NRS) showed significant improvement (p = 0.033) as did the pain item on the FIQ-R (7 day recall), p = 0.004.

TNX-102 SL improved the FIQ-R total score by -15.6 compared to -8.5 for placebo, p = 0.014. PGIC response rate(responses of 1 or 2 on a 7 point Likert Scale) was improved vs. placebo (30.1% vs. 16.7%, p = 0.025 by logistic regression). All measures of sleep quality improved, including PROMIS sleep disturbance with an -9.0 improvement on TNX-102 SL compared to -5.1 on placebo, p = 0.005. Sleep as measured by daily diary (change from baseline) was improved by -1.9 compared to -0.9 on placebo; p = <0.001, and the sleep quality item on the FIQ-R improved by -2.9 compared to -1.1 on placebo; p <0.001.

Systemic adverse events (AEs) were infrequent, no item was reported in >5% of TNX-102 SL- treated patients and were similar to the placebo-treated patients. Local administration site reactions (transient tongue or sublingual numbness) were commonly reported, occurring in approximately 42% of treated patients. Only 3 patients withdrew from participation in the study due to local adverse events. 86% of TNX-102 SL treated patients completed versus 83% on placebo.

Conclusion: Bedtime TNX-102 SL improved sleep quality by several measures and also improved multiple other symptoms and domains of FM. Nonrestorative sleep has been linked to central sensitization, which is characterized by changes in central pain processing. Together these findings suggest that sleep quality is a target of therapy in FM and TNX-102 SL improvement in sleep quality was well tolerated was associated with broad symptomatic improvement.

[1]TNX-102 SL is an Investigational New Drug and has not been approved for any indication.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Fibromyalgia syndrome (FMS) is characterized by widespread pain, fatigue, memory problems. The syndrome is present in about %2-8 of general population. However, knowledge about this topic in specific populations is limited. Our aim was to evaluate FMS in patients undergoing peritoneal dialysis, and association between clinical and laboratory parameters.

Methods: Twenty-six patients (7 females and 19 males with mean age of 53±15,9 years) receiving peritoneal dialysis were enrolled in this study. The control group compromised 25 healthy adults (16 females and 9 males with mean age of 41±12,8 years). Diagnosis of fibromyalgia was performed according to the 1990 American College of Rheumatology (ACR) and 2011 modification of the ACR preliminary diagnostic criteria. Age, sex, causes of renal failure, dialysis duration, the level of parathyroid hormone, renal function tests and electrolites were recorded. Mann-Whitney U and chi-square test were performed as statistical analysis and $p<0.05$ was accepted as statistically significant.

Results: The etiology of renal failure was diabetes mellitus in 3 patients (11,5%), hypertension in 10 (38,5%), glomerulonephritis in 4 (15,4%), idiopathic in 5 (19,2%), polycystic kidney disease in 1 (3,8%), nephrolithiasis in 2 (7,7%), and pyelonephritis in 1 (3,8%). The mean dialysis duration was 50,42±35,19 months. One (3,84%) patients receiving peritoneal dialysis and one of 25 control subjects were diagnosed with fibromyalgia, respectively. The mean age was 53±15,9 years in dialysis group, and 41±12,8 years in control group. All of FMS was female. There was significant difference for renal function tests and electrolites between both groups ($p<0,001$). Ionized calcium and phosphorus were higher in the FMS group than in the control group ($p=0.056$, $p=0.596$, respectively). There was no association between FMS and secondary hyperparathyroidism. The level of plasma parathyroid hormone in FMS patients was significantly lower than other patients.

Conclusion: There was similar prevalence for fibromyalgia between patients on peritoneal dialysis and healty group. It may be associated with actively participate in treatment, less stress factors, and better preservation of renal functions.

Safety of Pregabalin for Treatment of Fibromyalgia Is Comparable Between Subjects with Moderate or Severe Baseline Widespread Pain

Andrew Clair[1] and Birol Emir[2], [1]Pfizer Inc, New York, NY, [2]Primary Care Business Unit, Pfizer Global Research and Development, New York, NY

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Fibromyalgia, Soft Tissue Disorders, Regional and Specific Clinical Pain Syndromes Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Pregabalin has demonstrated efficacy and safety for the treatment of pain associated with fibromyalgia (FM) and is approved by the US Food and Drug Administration for this indication. Although pregabalin has been shown to be well tolerated in subjects with moderate or severe baseline pain, no studies have assessed whether its safety and tolerability differs by baseline pain severity. In this analysis, we evaluated data from subjects from 5 pooled clinical trials using pregabalin for FM-related pain to determine whether safety profiles were different in subjects with moderate versus severe baseline pain severity.

Methods: Safety data were pooled from 5, Phase III, placebo-controlled, clinical trials using pregabalin (8–15 weeks; 300 or 450 mg/day) for treatment of FM-related pain (study numbers 1008105, A0081056, A0081077, A0081100, A0081208). Subjects had FM diagnoses (1990 ACR criteria), were aged ≥18 years, had mean baseline pain scores ≥4, and had scores ≥40 mm on the Visual Analog Scale of Short-form McGill Pain Questionnaire. Descriptive statistics were used to classify adverse event (AE) profiles after 12 weeks of treatment categorized by baseline moderate (pain scores ≥4-<7) or severe (≥7-10) pain severity.

Results: Overall, the incidences of treatment-emergent AEs, treatment-related AEs, serious AEs (SAEs), and discontinuations were comparable between subjects with baseline moderate and severe pain who received the same treatment (**Table 1**).

Table 1. Safety and tolerability of pregabalin across all five clinical trials.				
Number (%) of Subjects with AEs[a]	Pregabalin (300 or 450 mg/day)		Placebo	
	Moderate (n = 785)	Severe (n = 820)	Moderate (n = 504)	Severe (n = 425)
Subjects with treatment-emergent AEs	694 (88.4)	725 (88.4)	371 (73.6)	312 (73.4)
Subjects with treatment-related AEs	588 (74.9)	613 (74.8)	234 (46.4)	192 (45.2)
Subjects with SAEs	7 (0.9)	20 (2.4)	5 (1.0)	6 (1.4)
Subjects with severe intensity treatment-emergent AEs	87 (11.1)	117 (14.3)	36 (7.1)	34 (8.0)
Subjects who permanently discontinued due to treatment-emergent AEs	134 (17.1)	130 (15.9)	44 (8.7)	35 (8.2)
Subjects with dose reduction or temporary discontinuation due to treatment-emergent AEs	52 (6.6)	47 (5.7)	19 (3.8)	11 (2.6)
[a]AEs defined by Medical Dictionary of Regulatory Activities (MedDRA) Preferred Terms.				

The incidences of the most common treatment-emergent AEs were also comparable between subjects within the same treatment group who had moderate and severe baseline pain severity (**Table 2**).

Table 2. Most common treatment-emergent AEs (≥5% incidence in any treatment group) across five pregabalin clinical trials.				
Number (%) of Subjects with AEs[a]	Pregabalin (300 or 450 mg/day)		Placebo	
	Moderate (n = 785)	Severe (n = 820)	Moderate (n = 504)	Severe (n = 425)
Constipation	66 (8.4)	57 (7.0)	27 (5.4)	8 (1.9)
Diarrhea	29 (3.7)	37 (4.5)	24 (4.8)	29 (6.8)
Dizziness	282 (35.9)	302 (36.8)	53 (10.5)	34 (8.0)
Dry mouth	59 (7.5)	54 (6.6)	8 (1.6)	6 (1.4)
Fatigue	54 (6.9)	61 (7.4)	19 (3.8)	18 (4.2)
Headache	85 (10.8)	104 (12.7)	56 (11.1)	47 (11.1)
Nasopharyngitis	51 (6.5)	57 (7.0)	51 (10.1)	27 (6.4)
Nausea	56 (7.1)	52 (6.3)	35 (6.9)	36 (8.5)
Edema peripheral	46 (5.9)	42 (5.1)	9 (1.8)	6 (1.4)
Somnolence	189 (24.1)	185 (22.6)	47 (9.3)	29 (6.8)
Vision blurred	48 (6.1)	49 (6.0)	5 (1.0)	5 (1.2)
Weight increased	96 (12.2)	94 (11.5)	16 (3.2)	10 (2.4)
[a]AEs defined by Medical Dictionary of Regulatory Activities (MedDRA) Preferred Terms.				

Conclusion: No notable differences in the safety or tolerability of pregabalin were observed between subjects with moderate and severe baseline pain severity. The treatment-emergent AEs and their incidence rates were consistent with the known safety profile of pregabalin.

Patient Preferences for Total Knee Replacement Surgery: Two Year Follow-up

Ernest Vina[1], Di Ran[2], Erin Ashbeck[2], Said Ibrahim[3], Michael J. Hannon[4], Jin Zhou[5] and C. Kent Kwoh[1], [1]Rheumatology,

University of Arizona, Tucson, AZ, [2]Arthritis Center, University of Arizona, Tucson, AZ, [3]Medicine, University of Pennsylvania, Philadelphia, PA, [4]Medicine, University of Pittsburgh, Pittsburgh, PA, [5]Epidemiology & Biostatistics, University of Arizona, Tucson, AZ

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Health Services Research Poster III: Patient Reported Outcomes, Patient Education and Preferences

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Patients' preferences for total knee replacement (TKR) may determine actual receipt of TKR and may also change over time. Yet, no study has longitudinally evaluated the treatment preferences regarding joint replacement of patients with knee osteoarthritis (OA). Our objectives were to evaluate the consistency of patients' preferences for TKR with receipt of TKR surgery, and to assess patient characteristics that may influence change in willingness to undergo TKR over 2 years.

Methods:

Structured interviews were conducted to determine the socio-demographic data, clinical characteristics, and treatment preferences (i.e. willingness to undergo TKR) of patients with knee OA. Willingness was measured using a Likert scale ranging from -2 (definitely not willing) to +2 (definitely willing). Consultation with an orthopedic surgeon and receipt of TKR surgery were ascertained by medical record reviews and structured interviews at 6 months and at 2 years. Logistic regression models were conducted to assess the association between willingness and consultation with an orthopedic surgeon (or receipt of TKR), adjusted for age, sex, race, education, recruitment site, income, insurance, social support, and baseline WOMAC score. Mixed models for repeated measures were used to estimate the effects of age, sex, race, social support, change in WOMAC subscale scores, and orthopedic surgical consult on change in willingness over 2 years.

Results:

At baseline, 589 were willing, and 215 were unsure or not willing to undergo TKR surgery. Willing participants, compared to those who were unwilling, were more often White (69.4% vs. 48.4%), with more than a high school education (60.8% vs. 47.0%), employed (39.1% vs. 26.5%), and had a lower WOMAC total score (46.05 ± 16.12 vs. 50.37 ± 15.42). At 2-year follow-up, baseline willingness was not associated with having seen an orthopedic surgeon (adjusted OR 0.89, 95% CI [0.62, 1.29]) after adjustment for sociodemographic and clinical variables. The odds of having TKR was twice as high among those who were willing to have the procedure at baseline, compared to all others, but this was not a statistically significant difference (adjusted OR 2.04, 95% CI [0.92, 4.53]).

There was a general decline in willingness to undergo TKR over the follow-up period. Among those who were willing to undergo TKR at baseline, only 66.5% were still willing 2 years later. This decline in willingness was less among those who had a greater increase (> median) in WOMAC disability scores (adjusted Δ -0.34, 95% CI [-0.47, -0.20]) than those who had minimal change (≤ median) in their WOMAC disability scores (adjusted Δ -0.51, 95% CI [-0.64, -0.37]) (p=0.08). The decline in willingness was also less among those who had seen an orthopedic surgeon (adjusted Δ -0.32, 95% CI [-0.46, -0.17]) than those who did not during the study period (adjusted Δ -0.51, 95% CI [-0.63, -0.38]) (p=0.05). Other patient characteristics did not influence changes in willingness.

Conclusion:

Patients' preferences for TKR were not consistent with utilization of TKR surgery over two years of follow-up. Willingness to undergo TKR declined over time, but this decrease was mitigated by worsening OA-related disability and by consultation with an orthopedic surgeon.

Session Title: Health Services Research Poster III: Patient Reported Outcomes, Patient Education and Preferences

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Sarilumab is a human monoclonal antibody (mAb) directed against the soluble IL-6 receptor (sIL-6R), administered subcutaneously (SC) every 2 weeks (q2w). In the phase 3 RCT MOBILITY study (NCT01061736), sarilumab 150 mg and 200 mg SC q2w+MTX demonstrated efficacy in patients (pts) with moderate-to-severe RA[1] and was generally well tolerated. Patients treated with sarilumab also experienced significantly greater improvements in HRQoL, fatigue and sleep compared with placebo.[2] Understanding the clinical importance of group differences can be enhanced by assessing treatment benefit based on the proportion of patients who report improvements meeting or exceeding minimum clinically important differences (MCID). These analyses compared the percentages of patients who reported MCIDs at week 24 across treatment groups.

Methods: The intent-to-treat population included 1,197 patients randomized 1:1:1 to placebo+MTX, sarilumab 150 mg q2w+MTX, or sarilumab 200 mg q2w+MTX. PROs included Patient Global Assessments (PtGA), Pain by VAS, HAQ-DI, SF-36v2 and FACIT-Fatigue. Patients were classified as responders if their change scores were ≥ MCID for that PRO. A binary logistic model with responder classification as the response and treatment group, prior use of biologic agents and region as fixed effects was used to estimate differences from placebo in response rates (RR) and numbers needed to treat (NNT).

Results: RRs in sarilumab were significantly better than placebo for all PROs with exception of SF-36 Mental Component Summary and Mental Health domain scores with sarilumab 150 mg and Role Emotional domain in both active treatment groups. Compared to placebo, there were an additional 15%-21% of responders by PtGA, 14%-17% by Pain-VAS, 10%-13% by Fatigue, 12% by HAQ-DI, 18%-21% by PCS and 17% by MCS (150 mg only). There were 9% - 21% more responders by 7 of the 8 SF-36v2 domains (200 mg). NNTs ranged from 4.7 (PCS; 200 mg) to 9.7 (FACIT-Fatigue; 150 mg) similarly favoring sarilumab vs placebo.

Conclusion: More patients receiving sarilumab+MTX reported changes in PROs ≥MCID, resulting in small NNTs, indicating a significantly greater likelihood of clinically meaningful improvement with active treatment than placebo+MTX.

Figure 1 Difference from placebo in the percentage of patients reporting minimally clinically important difference or better after 24 weeks of treatment with sarilumab or placebo

Minimal Important Difference in HAQ: A Validation from Health Economic Perspectives in Patient with Rheumatoid Arthritis Using Real-World Data

Chenglong Han[1], Nan Li[2] and Steven Peterson[3], [1]Outcomes Research, Janssen Global Services, LLC, Malvern, PA, [2]Janssen Global Services, LLC, Spring House, PA, [3]Janssen Global Services, LLC, Malvern, PA
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Health Services Research Poster III: Patient Reported Outcomes, Patient Education and Preferences
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: A change of 0.25 in HAQ score has been considered as clinically meaningful. This study is to evaluate the clinical meaningfulness of the HAQ change from health economic perspectives in patients with rheumatoid arthritis using real-world data.

Methods: This is a retrospective cross-sectional study using data in ADELPHI Disease-Specific Program collected in 2014 (EU5 and US). Patients with clinically diagnosed rheumatoid arthritis (N=1032) were enrolled and completed self-reported outcomes measures including physical function by Health Assessment Questionnaire-disability index (HAQ-DI), employment status, work productivity by Work Productivity and Activity Impairment Questionnaire-General Health (WPAI-GH) and general health status by EQ visual analogue scale (EQ VAS). Clinical characteristics include disease activity defined by DAS28. Correlations between HAQ-DI score and other outcomes were analyzed using univariate or multiple regression analysis.

Results: The majority of patients were female (72.1%) with average age of 55 years old and disease duration of about 9 years. The mean (SD) HAQ-DI score was 0.76 (0.69) with 42.2% having a HAQ-DI score ≥ 1, indicating moderate to severe physical disability. 58% of patients were currently unemployed. Patients with a HAQ-DI score of >1.0, 77% were unemployed with a EQ VAS of 54.2, while patients with normal HAQ score of ≤ 0.5, 40% were unemployed with a EQ VAS of 75.6. HAQ-DI score was significantly correlated with the unemployed in multivariate logistic regression model ($p<0.001$), and correlated with time lost from work ($p<0.001$) and general health status by EQ VAS ($p<0.001$) by multivariate linear regression model. After adjustment for demographic characteristics including age, gender, and disease duration, an 0.25 increase in HAQ-DI score was associated with a 30% increase in likelihood for unemployed status (OR=1.30, 95% CI=1.22, 1.39).

Conclusion: Physical function measured by HAQ-DI is a valid measure to predict employment status and general health status in patients with rheumatoid arthritis.

Session Title: Health Services Research Poster III: Patient Reported Outcomes, Patient Education and Preferences
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: We conducted a multi-centered, open-label, parallel, randomized controlled trial to evaluate the efficacy of a multimedia-patient education tool (MM-PtET) for patients with rheumatoid arthritis (RA) in improving outcomes immediately after the intervention and at 3 and 6 months.

Methods: Patients were recruited from 5 centers and through advertisement. Inclusion criteria were: (i) age ≥18 years (ii) diagnosis of RA by a rheumatologist (iii) disease duration ≤10 years (iii) adequate cognitive status and, (iv) ability to communicate in English or Spanish language. The efficacy of the MM-PtET was evaluated longitudinally using questionnaires on disease knowledge, decisional conflict and role preferences, self-efficacy and disease management before and after viewing the assigned materials, at 3 and 6 months. Linear regression and generalized estimating equation were used in order to determine the effective impact of correlative factors on the efficacy of the MM-PtET, including age, sex, race, education level, language in which the questionnaire was answered, health literacy and disease duration.

Results: 221 participants were randomized (111=MM-PtET, 110=written booklet). Mean age was 51±13 years, mean disease duration was 5±3 years, 85% were female 24% had inadequate health literacy levels and 46% answered the questionnaire in Spanish. 116 (64=MM-PtET, 52=booklet) and 158 (76=MM-PtET, 82=booklet) participants returned their questionnaires at 3 and 6 months, respectively. Within groups most outcomes were improved from baseline to 3 and 6 months. At 6 months, participants assigned to the intervention group had statistically significantly higher disease management scores compared to the control group (mean 81.1 vs 76.6, p=0.03). Greater improvement in knowledge scores from baseline to 6 months were observed in those participants who received the intervention (p=0.03) and those with inadequate health literacy (p=0.006). Meanwhile, among Whites, the intervention was associated with greater improvements in the decisional conflict scale and uninformed subscale (p=0.004 and p=0.02, respectively); and among males, receiving the intervention group led to improvement in the clarity subscale (p=0.02). Among younger individuals, booklet was associated with improvement in self-efficacy but among older ones, it was MM-PtET (p=0.003). Shorter disease duration, on the other hand, was associated with better disease management (p=0.009). Higher level of education (High School or above) was associated with active role played in health decision-making (p<0.003) after adjusting for correlated outcome data and controlling for other variables.

Conclusion: Our MM-PtET was more effective in improving disease management compared to reading written materials in RA patients at 6 months. The multimedia tool was associated with greater health outcomes improvement among older patients, Whites, and males. Independent factors associated with improvement include disease duration (shorter) and level of education (at least High School diploma).

An Ethnographic Observational Study of the Biologic Initiation Conversation Between Rheumatologists and Biologic Naïve Rheumatoid Arthritis Patients

Nicholas Kottak[1], Melissa Rosenberg[2], Dennis Parenti[3] and **Shelly Kafka**[3], [1]Ethnographic Solutions, Washington, DC, [2]Janssen Pharmaceuticals Inc, Horsham, PA, [3]Janssen Scientific Affairs, LLC, Horsham, PA

First publication: September 29, 2015

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Health Services Research Poster III: Patient Reported Outcomes, Patient Education and Preferences
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: To better understand how rheumatologists communicate the need to initiate biologic treatment and explain the risks and benefits, Janssen Pharmaceuticals initiated an ethnographic market research study. This initiative assessed shared decision making approaches and how modes of administration were presented to RA patients (pts).

Methods: Study participants included rheumatologists and their RA pts who were naïve to biologics. Rheumatologists and pts consented to be videotaped during their visits with one another and to be interviewed by a trained ethnographer before and after these medical visits. The study included 16 experienced rheumatologists (>2 yrs in practice and >100 RA pts/month) and 50 RA pts. Eleven rheumatologists had in-office infusion services and 5 did not. Rheumatologists selected pts who were inadequately controlled on DMARD therapy and for whom biologic therapy was being considered. One day of fieldwork by the ethnographer was conducted with each rheumatologist. The 50 videotaped physician-patient conversations were analyzed to determine content, timing and structure of the biologic initiation conversations.

Results: The mean duration of the patient visit was approximately 15 minutes, on average, with 5.7 minutes devoted to a discussion of biologic initiation. The specific discussion of mode of administration options (IV, SC, or oral) lasted approximately 30 seconds and the discussion on brands lasted <1.5 minutes. In 37% (13/48) of the patient visits, the option of IV administration was not discussed. When IV therapy was discussed, the frequency of IV administration was mentioned only half of the time (17/35). Rheumatologists often provided little description of SC or IV therapy and how they differ. When pts knew or learned more about IV therapy, they were more receptive to it. The post-visit interview also showed that many pts were confused or overwhelmed after their conversation with their HCP, including not truly understanding the benefits of initiating a biologic. When rheumatologists presented pts with a choice of biologic products, pts struggled to recall the various products mentioned and to understand their key differences.

Conclusion: These ethnographic data revealed that there was limited discussion regarding biologic treatment options, which presents challenges to a shared decision making process. Key aspects of biologic therapy options (modes of administration, dosing frequency, how products differ) were omitted or given cursory explanation. In post-visit interviews, pts also struggled to recall and understand key elements of the discussion, including their different treatment options. There are opportunities for rheumatologists and RA pts to partner more extensively on biologic therapy decisions. Educational tools may not only help rheumatologists explain complex information about biologic therapy options more efficiently, but the tools may give pts more confidence when choosing and starting a biologic therapy.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Health Services Research Poster III: Patient Reported Outcomes, Patient Education and Preferences
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Accurate rheumatoid arthritis (RA) disease activity assessment is required for treatment consistent with

Treat-to-Target (T2T) recommendations. Rheumatologists currently use a variety of patient-generated, physician-generated, and laboratory data to assess RA disease activity (DA). Discordance among different clinical measures, and more recently between clinical measures and a multi-biomarker test, has been documented. This study investigates discordance among DA measures in multiple clinical practice RA populations.

Methods: The Rheumatoid Arthritis Practice Performance (RAPP) Project is a voluntary collaboration of U.S. clinician rheumatologists whose goal is to provide T2T care and optimal RA disease outcomes. Of the 168 participants in the RAPP Project, 86 have enrolled their entire RA population (ICD-9 code 714.0) in a HIPAA-compliant disease population registry and are tracking DA measures in the registry. With isolated exceptions, their preferred measures include one or more of the following: RAPID3, a 0-10 Provider Global Assessment (PGA), Clinical Disease Activity Index (CDAI), and a multi-biomarker (MB) test. Table 1 reports the number of registries tracking each of these measures and the distributions of controlled, low, moderate, and high DA for each measure using the most recent assessment for each patient. Table 2 reports discordance rates between different date-matched DA results from those registries entering more than one measure, again using the most recent assessment for each patient.

Results:

Table 1. DA Distributions for Different Measures in 86 RAPP Practice Registries

	RAPID3	PGA	CDAI	MB
Registries tracking (N)	15	39	15	86
Controlled and Low DA (median %)	52%	74%	55%	22%
Moderate DA (median %)	22%	21%	27%	39%
High DA (median %)	26%	5%	19%	39%

Table 2. Discordance among Paired DA Measures

	MB vs CDAI	MB vs PGA	MB vs RAPID3
Registries included (N)	5	12	10
Measure pairs (N)	746	2162	1845
Discordance (median %)	44%	41%	33%
Discordance range	41-49%	18-59%	24-42%

	CDAI vs PGA	CDAI vs RAPID3	PGA vs RAPID3
Registries included (N)	4	5	10
Measure pairs (N)	1759	2239	3570
Discordance (median %)	17%	26%	32%
Discordance range	15-18%	15-41%	20-71%

Conclusion: 1. Different measures provide differing DA distributions within RA populations and discordant results for many individual patients. 2. Treatment decisions will likely differ based on which measures are used. 3. Factors contributing to discordance among measures at the population and patient levels appear to include patients' and providers' variable subjective perceptions, variability of joint examinations, and sub-clinical inflammation detected only by MB testing.

Inflammatory Arthritis Patient Perspectives on Strategies to Support Medication Adherence: A Qualitative Study Using a Novel Group Exercise

Sharan K. Rai[1], Pavandeep Mehat[2], Anne Townsend[3], Carlo Marra[4], Harpreet Chhina[5], Rhonda Shuckett[6] and Mary A. De Vera[2], [1]Experimental Medicine, University of British Columbia, Vancouver, BC, Canada, [2]Faculty of Pharmaceutical Sciences, University of British Columbia, Vancouver, BC, Canada, [3]Medical School, University of Exeter, Exeter, United Kingdom, [4]School of Pharmacy, Memorial University, St. John's, NF, Canada, [5]Orthopedic Surgery, BC Children's Hospital, Vancouver, BC, Canada, [6]Rheumatology, University of British Columbia, Vancouver, BC, Canada
First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Health Services Research Poster III: Patient Reported Outcomes, Patient Education and Preferences
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Disappointing and inconsistent findings of adherence intervention research in inflammatory arthritis (IA) highlight the need for further work in designing interventions that promote and support treatment adherence. Patient-centered approaches to developing medication adherence interventions have shown promise in other chronic diseases, and may be particularly relevant in IA where they have scarcely been applied. We aimed to explore IA patients' perspectives on strategies to support medication adherence.

Methods: Individuals were eligible for the study if they: (1) had a rheumatologist-confirmed diagnosis of IA, (2) were taking a DMARD(s), and (3) could communicate in English. A novelty of our study, an experienced facilitator led participants through a group exercise where participants were asked to design a hypothetical tool(s)/aid(s) supporting medication use. Participants developed their tools individually using provided activity sheets and coloured cards corresponding to features of their tools, including (1) **what** (is your tool?), (2) **how** (does your tool work?), and (3) **who** (is there anybody who uses your tool with you?). They were then invited to share their tools with the group, and the facilitator used open-ended questions to promote discussion. In our qualitative analysis, we applied an iterative, thematic approach informed by aspects of grounded theory and using the constant comparison method. Three study team members independently read and annotated the transcripts, and after discussion agreed on an initial coding framework. Categories emerging from the focus groups were identified and collected under major thematic headings.

Results: Six focus groups were held with 4-6 participants each. Qualitative analyses resulted in the identification of three predominant emerging themes: (1) educational resources; (2) lifestyle modifications and adaptations; and (3) the journey of medication use. Educational resources encompassed communication with a healthcare provider (e.g., rheumatologist, pharmacist), patient group classes, pamphlets and written resources, eHealth/mHealth, and learning about medication side-effects. Lifestyle modifications and adaptations were comprised of physical reminders/prompts for medication use (e.g., blister packs, pill boxes), electronic alerts/reminders (e.g., smartphone apps), establishing a routine (e.g., taking medication with breakfast), and managing multiple medications. The journey of medication use encompassed the sequential process of patients learning about and gaining confidence in prescribed medications, and the subsequent integration of these medications into their daily life ("Once I know the med, once I'm confident in the med, it's working, then I phase it into my lifestyle").

Conclusion: To our knowledge, this is the first study to use a novel group exercise to explore patients' perspectives on strategies to support medication use in IA. Both educational resources and lifestyle modifications/adaptations were paramount to medication use among IA patients. These findings have important implications for the development of patient-centered medications adherence interventions.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Health Services Research Poster III: Patient Reported Outcomes, Patient Education and Preferences

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Mobile medical Applications (mApps) with integrated patient-reported outcome instruments (PROs) allow patients (pts) with rheumatoid arthritis (RA) self-monitoring and might strengthen self-management. Use of mApps might simplify PROs' information transfer between pts and physicians. Within the MiDEAR (Mobile medically supervised patient management in rheumatoid arthritis patients using DocuMed.rh and RheumaLive (RL-) App)) project we studied pts' mobile data entry of PROs using the mApp RL on an iPhone in comparison to paper-pencil versions to evaluate media bias ahead of routine clinical application.

Methods: As the project's concept relies on 'bring your own device' 271 consecutive RA out-pts were screened for App compatible devices. 156 owned App compatible devices and were thus eligible. 60 pts agreed to complete established (electronic (e)) PROs (Funktionsfragebogen Hannover FFbH/calculated HAQ; RA disease activity index (RADAI)) by using the RL-App installed on an iPhone 3 GS (installed iOS 6.1.3) owned by the clinic and as paper-pencil versions. Pts answered their questions and saved their data themselves. The quality and validity of data obtained using RL-App and the capability of disabled pts to handle it were tested; pts' experiences, App/internet use and sociodemographic respectively clinical data were assessed. Ethic approval and signed informed consents were obtained.

Results: Pts were predominantly female (78.3%), mean age was 50.1±13.1 years (yrs), mean disease duration 10.5±9.1 yrs. 50% had a high education level. 91.7% reported substantial experience with a smartphone, 68.3% with a TabletPC. 56.7% used iOS and 53.3% Android on their App compatible devices. 90.0% already used Apps. Mean confidence in Apps in general was rated 3.2±1.5 (1-6 Likert scale).

Scores obtained by pts direct data entry on the smartphone did not differ significantly from the scores obtained by the paper-pencil questionnaires, see Table1. Even when pts were splitted by FFbH groups (≤50;51-70;>70) paper-pencil and e scores did not differ significantly and correlated well.

Three pts did not complete both PRO versions. In one patient the paper-pencil version of the FFbH/HAQ could not be calculated due to too many missing values. Five pts reported problems with the data entry on the touchscreen, no other major difficulties using the RL-App for the ePROs occurred.

Score	Smartphone	Paper-pencil based	Spearman Rho#	P*
FFbH (n=56)	94.4 (17.0-100.0)	94.4 (14.0-100.0)	0.976	p>0.05
HAQ (n=56)	0.5 (0.36-2.7)	0.5 (0.36-2.8)	0.976	p>0.05
RADAI (n=57)	1.9 (0.0-7.5)	2.1 (0.0-7.8)	0.948	p>0.05

Table 1 Median scores ranges; #bivariate correlation; *Wilcoxon Rank test

Conclusion: RA pts are able to complete ePROs in a mApp on a smartphone. Thus, monitoring disease activity, disability and treatments' efficacy continuously apart from the physician visit by a mApp seems feasible. Regular and broader use of mApps offers new opportunities for tight disease control concepts. Before the mApp with PROs is used in routine care its acceptance from patients' and physicians' perspectives needs further evaluation.

The Use of Doppler Ultrasound in Patients with Rheumatoid Arthritis Improves Patient Understanding of Disease and Adherence to Treatment and Alters Clinical Practice

Fred Joshua[1], Christine Bailey[2], Mona Marabani[3], Evange Romas[4], Raymond White[3] and Peter Wong[5], [1]Combined Rheumatology Practice and Macquarie University, Sydney, Australia, [2]AbbVie, Sydney, Australia, [3]Private Rheumatology Practice, Sydney, Australia, [4]Department of Medicine, University of Melbourne, Melbourne, Australia, [5]Mid-North Coast Arthritis Clinic and University of New South Wales Rural Clinical School, Coffs Harbour, Australia

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Health Services Research Poster III: Patient Reported Outcomes, Patient Education and Preferences

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Doppler ultrasound (DUS) can detect subclinical joint inflammation and can be used to predict disease relapse or flare in patients with RA. The objectives of the present study were to assess 1) the current use of DUS, 2) if DUS and visual aids with explanation improved patient understanding of disease, and 3) whether exposure to DUS alters rheumatologists' clinical practice.

Methods:

Australian rheumatologists were invited to take part in the DEDUCE Medical Practice Activity that enrolled 4−6 RA patients from each practice aged ≥18 years in DAS28 remission. Rheumatologists and patients completed a pre-activity survey assessing experience of DUS prior to DUS evaluation using the US7 score. Rheumatologists discussed results with patients using specifically developed visual aids. Patients and rheumatologists then completed post-activity questionnaires followed by a final survey six months later. Summary statistics were used as appropriate.

Results:

Eighty patients recruited by 21 rheumatologists completed pre-activity questionnaires. Patients who had previously undergone DUS found it improved their understanding of RA (18/19, 95%) and likelihood of medication adherence (16/19, 84%). Fifteen of the 21 rheumatologists had previously used DUS. Ten (67%) used DUS in patients in clinical remission and low disease activity (LDA) while 12/15 (80%) and 9/15 (60%) agreed it aided patient communication and medication adherence, respectively. The most common reasons for not using DUS were cost, inconvenience, and concern regarding usefulness and practicality.

Sixty six patients completed post-activity questionnaires. Of the 58 patients who had post-DUS discussions with their rheumatologist, 51 (88%) reported these improved understanding of their disease and 55 (95%) believed that it will encourage them to take medications as prescribed. Fifty of the 61 (82%) patients whose discussions utilised the visual aids found them useful. Overall, 56/66 (85%) of patients agreed DUS was useful in assessing disease activity.

Immediately post-activity, 20/21 (95%) of rheumatologists felt they would use DUS to guide therapeutic decisions and 16/21 (76%) found the visual aids useful for patient communication. Thirteen of 21 (62%) thought DUS would aid patient medication adherence.

Six months post-activity, all but one physician (95%) intended to continue to use DUS in their clinical practice. 15/21 (71%) of the rheumatologists had incorporated DUS into routine clinical practice, mainly for patients in LDA. Nineteen rheumatologists

(91%) believed DUS aided patient understanding and 17 (81%) believed it assisted communication with patients.

Conclusion: Almost all rheumatologists and patients who experienced DUS felt that it was a useful clinical tool. Communication of results using visual aids enabled patients to better understand their disease and increased the likelihood of medication adherence. Importantly, at 6 months the vast majority of participating rheumatologists had incorporated DUS into routine clinical practice.

Session Date: Tuesday, November 10, 2015

Session Title: Health Services Research Poster III: Patient Reported Outcomes, Patient Education and Preferences

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Activity of rheumatoid arthritis (RA) can be assessed by several outcome measures : joint counts, inflammatory syndrom but also auto-questionnaires such as global patient assessment. The importance of Patient Reported Outcomes (PROs) has been recently put forward. The purpose was to determine whether patient self-assessment can reflect RA disease activity.

Methods: Data from patients included in the early arthritis ESPOIR cohort and fulfilling ACR/EULAR 2010 RA criteria at month 12 were used. The following PROs (Visual Analog Scales for fatigue, pain, patient assessment of disease activity; HAQ; SF36; EMIR-court and RAPID3) and their association with disease activity assessed by DAS28-3 variables, were measured.

DAS28-3 variables (including tender joint count, swollen joint count and erythrocyte sedimentation rate) was preferred to DAS28-4 variables in order to limit the input of subjective and patient-derived appreciation when defining the level of disease activity.

We compared the influence of disease characteristics on each PRO by Student t tests. The association between PROs and disease activity was assessed in several ways: part of explained variance, correlation and performance of each PRO in differentiating low versus higher disease activity states.

Results: 677 patients (83.2%) of the 813 patients of the ESPOIR cohort, were analyzed as they responded to the ACR/EULAR 2010 criteria of RA at month 12.Their mean age was 48.6±12.3 years with 77.4% of female, with a mean duration of disease of 3.41±1.74 months, 60.5% were rheumatoid factor or anti-citrullinated protein positives, 16.4% had anxiodepressive disorder and 15.1% had radiological lesions according to ACR/EULAR criteria. Disease activity assessed by DAS28-3 avriables was, at inclusion, 5.0±1.2, with a decrease during the follow-up.

Whatever the status of disease activity, patients with the lowest disease activity always had significantly less impaired

PROs. All analyzed PROs showed moderate correlations with RA disease activity. The PRO showing the best association with

DAS28-3v in determining RA disease activity states, was RAPID3 (Pearson correlation coefficient between 0.45-0.55, explained variance between 30-45%, sensitivity between 69-100% and specificity between 55-78%).

PROs with the highest association with disease activity were global PROs (RAPID3, EMIR-court) followed by those assessing physical function.

Conclusion: Association between PROs and RA disease activity as measured by DAS28-3 variables remains moderate. RAPID3, a global PRO, showed the best association with disease activity compared to the other analyzed PROs.

Patient Priorities in Rheumatoid Arthritis (RA) Research: An Exploration of Patient Perspectives from Those Enrolled in an Ontario RA Cohort

Laura Fullerton[1], Angela Cesta[2], Catherine Hoffstetter[3] and Claire Bombardier[2,4,5], [1]Support, Systems and Outcomes, University Health Network, Toronto, ON, Canada, [2]Toronto General Hospital Research Institute, University Health Network, Toronto, ON, Canada, [3]Patient partner, Toronto, ON, Canada, [4]Division of Rheumatology and Institute of Health Policy, Management, and Evaluation, University of Toronto, Toronto, ON, Canada, [5]Division of Rheumatology, Mount Sinai Hospital, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Health Services Research Poster III: Patient Reported Outcomes, Patient Education and Preferences

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Patient experiences with rheumatoid arthritis (RA) symptoms, treatments, and rheumatology care are critically important for the assessment of treatment-effectiveness and quality of care for RA. Despite recommendations for more patient-centered research, measures to evaluate the effectiveness of RA therapies often fail to reflect patient priorities.[1] The Ontario Best Practices Research Initiative (OBRI) is a clinical registry focused on improving the quality of care and health outcomes of patients with RA through long-term data collection on therapies, clinical practices, and health-care utilization. In OBRI, patient self-reported data is collected using structured interviews and validated questionnaires. The objectives of this study were to explore patient priorities in RA research, identify gaps in OBRI data collection, and explore options for improved data collection and communication with patients.

Methods:

RA patients enrolled in the OBRI clinical registry were invited to participate in 1 of 3 patient sessions in 2014 to provide feedback on how OBRI data collection could be improved to better capture patient needs/priorities. In small groups facilitated by a moderator, patients were asked to identify gaps in OBRI data collection, share experiences with RA and rheumatology care, and discuss priorities for RA research. In total, 48 RA patients participated in a facilitated discussion. After each session, patients completed a questionnaire on their use of social media.

Results:

Four overarching research priorities were identified: 1) A need for qualitative research focused on patient experiences with RA including: journeys to diagnosis, symptoms, treatment side effects, and challenges/concerns; 2) A need for qualitative research into patient satisfaction with rheumatology care including: rheumatologist accessibility, communication, and disease management;

3) A need for OBRI research questions addressing patient social support networks, strategies for coping with flares, diet and exercise, and the use of alternative therapies; and 4) A need for more information from rheumatologists on medication risks and side effects. Of those who completed the social media questionnaire, 100% reported regular use of email and 81% reported regular use of social networking sites, however only 54% reported a preference for research-related communication through email compared with regular postage.

Conclusion:

RA patients expressed that some of their most important disease-related experiences are not captured by structured questionnaires, suggesting a need for mixed-methods research to capture both qualitative and quantitative patient-reported outcomes. This study identifies patient research priorities and opportunities for improved care and communication.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Health Services Research Poster III: Patient Reported Outcomes, Patient Education and Preferences

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic, debilitating condition for which there is no cure. The RA NarRAtive is a global initiative to identify patient perceptions regarding barriers to treatment and self-management.

Methods: The RA NarRAtive initiative is composed of a global advisory panel of 27 rheumatologists and patient advocacy group leaders. An online, patient-based survey, designed by the working group, was fielded across 13 countries between September 2014 and January 2015. The results are presented from all respondents who consented to the online survey.

Results: Patients from across the spectrum of disease activity (3,649) were represented, with 37% (1,346) self-reporting moderate/severe symptoms, while 12% (436) self-reported low disease activity, 4% (156) remission, and 28% (1,005) RA under control. Only 34% (1,251) described their current overall health as good/excellent. The median time since diagnosis was 7 years (range <1 to >10 years). The most frequently-cited concerns were disease progression (67% [2,437]), and impact of RA on quality of life (QoL; 62% [2,266]). Almost 50% reported stopping participation in certain activities and 29% discontinued work due to RA. Almost half of respondents seeing a healthcare provider (HCP) to manage their RA (48% [1,616/3,378]) acknowledged that dialogue/discussion with the HCP would help to manage their RA more successfully. However, over half of all respondents (62% [2,278/3,649]) felt uncomfortable raising concerns or fears with their HCP. Overall, 76% (2,764/3,649) of respondents received medication for their RA. Of those taking prescribed medication (2,139), 38% (808) were not taking this medication exactly as prescribed, although non-compliance rates varied substantially from 18–64% depending on country. The most frequently-cited reasons for non-compliance were treatment side-effects (16% [344]) and inconvenience (15% [320]).

Aspects of current, prescribed RA treatment that patients would most like to change included: number/frequency of medications (35% [742]); side-effects (34% [728]); access/cost (30% [632]); availability of monotherapy (25% [533]); alternative to subcutaneous mode of action (18% [377]); inconvenience/limitations (16% [344]); and mode of administration (12% [260]). Although 78% (1,674/2,139) of respondents were satisfied with their prescribed RA treatment, 70% (1,507) expressed a wish for fewer medications, and 56% (1,200) desired more choice. These patients defined treatment success according to: reduction of pain and/or swelling (81% [1,733]); improvements in QoL (77% [1,637]); control of disease progression (46% [992]); and treatment meeting goals/reducing medication (40% [852]).

Conclusion: These findings highlight that, while many patients are satisfied with their RA medication, non-compliance persists and there are many who would like to change certain aspects of their prescribed treatment. Furthermore, patient-HCP dialogue is important in the successful management of RA, which is clear as patients define successful treatment in terms of significant improvements in their overall symptoms and improvements in QoL.

Quantitative Clues to Recognize and Document Comorbid Fibromyalgia in Routine Care of Patients with Other Rheumatic Diagnoses on a 10 Cm Distress Visual Analog Scale Found on 1-Page Physician Rheumetric Checklist

Kathryn A. Gibson[1], Katherine J. Bryant[2] and Theodore Pincus[3], [1]Liverpool Hospital, Liverpool, Australia, [2]University of New South Wales, Sydney, Australia, [3]Rheumatology, Rush University Medical Center, Chicago, IL

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Health Services Research Poster III: Patient Reported Outcomes, Patient Education and Preferences

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: A physician global estimate (DOCGL) is commonly used to assess patients with rheumatic diseases. Fibromyalgia (FM) has been reported as a comorbidity in 10-35% of patients with rheumatoid arthritis (RA), osteoarthritis (OA), and other rheumatic diseases, and may complicate assessment and management in these patients. Formal criteria for fibromyalgia have been described and are included in many research studies. However, these formal criteria generally are not assessed in busy clinical settings, in which FM generally is diagnosed according to “gestalt,” narrative, non-quantitative descriptions. Quantitative standard data on a 1-page physician RheuMetric checklist, which is completed in 20-30 seconds, include a standard 0-10 visual analog scale (VAS) for DOCGL, and 3 further 0-10 VAS for the levels of inflammation or reversible findings (DOCINF), damage or irreversible findings (DOCDAM), and patient distress, e.g. fibromyalgia, depression (DOCDIS). We analyzed RheuMetric VAS for possible value to estimate FM in routine care.

Methods: A RheuMetric checklist is completed by one rheumatologist in all patients in routine care. Mean scores for DOCGL (0-10) and for the DOCINF (0-10), DOCDAM (0-10), and DOCDIS (0-10) subscales were compared in patients with rheumatoid arthritis (RA), other inflammatory arthritides (ankylosing spondylitis, psoriatic arthritis, inflammatory arthritis), and osteoarthritis (OA), who had or did not have a clinical diagnosis of secondary comorbid FM. Statistical significance was analyzed using 2-tailed t-tests.

Results: A total of 82 RA patients - 75 with no FM and 7 with FM, 51 with other inflammatory arthritides - 42 with no and 9 with FM, and 64 OA patients - 49 with no FM and 15 with FM, were studied (Table). Mean DOCGL scores for patients in each group

who had or did not have comorbid FM were similar: RA 2.71 vs 2.75 p=0.43; other inflammatory 3.67 vs 2.76 p=0.81; OA 3.43 vs 3.41 p=0.97 (Table). Mean DOCINF and DOCDAM estimates also did not differ significantly between patients with and with no FM in the 3 groups. Mean estimates for DOCDIS differed significantly in each of the 3 diagnostic groups in patients who had or did not have comorbid FM: RA 5.90 vs 2.38 p<0.0001; other inflammatory 5.56 vs 2.63 p=0.004; OA 5.25 vs 2.92 p=0.0008 (Table).

Conclusion: In this study, DOCDIS estimates to quantitate the degree of distress were significantly higher in patients with primary RA, OA or other inflammatory arthritides who also had comorbid FM than in those with no FM. DOCGL, DOCINF, or DOCDAM did not distinguish significantly patients who had or did not have comorbid FM. The DOCDIS scale may help clinicians to recognize and document secondary comorbid FM, without a need to administer other FM specific questionnaires, to help guide diagnosis and optimal patient care.

Table: Mean scores for physician RheuMetric scales for overall global estimate, inflammation, damage, and distress in 3 patient groups: rheumatoid arthritis, other inflammatory arthritis (Other Inflam), and osteoarthritis who do or do not have secondary fibromyalgia

	N	Overall Global Estimate	Inflammation	Damage	Distress
Rheumatoid arthritis with no comorbid fibromyalgia	75	2.75	1.79	2.74	2.38
Rheumatoid arthritis with comorbid fibromyalgia	7	2.71	2.08	1.00	5.90
p value		0.43	0.68	0.06	<0.001
Other Inflam with no comorbid fibromyalgia	42	2.76	2.28	1.75	2.63
Other Inflam with comorbid fibromyalgia	9	3.67	2.22	1.94	5.56
p value		0.81	0.93	0.81	0.004
Osteoarthritis with no comorbid fibromyalgia	49	3.41	0.45	4.50	2.92
Osteoarthritis with comorbid fibromyalgia	15	3.43	0.21	3.82	5.25
p value		0.97	0.40	0.15	0.0008

Patient Preferences Regarding Route of Biologic Administration in an Inflammatory Arthritis Cohort

Alysia Kwiatkowski[1], Lucas Grisanti[2], Joseph Grisanti[3] and James Hatem[4], [1]Internal Medicine, Albany Medical Center, Albany,

NY, [2]Department of Biology, College of Wooster, Wooster, OH, [3]Buffalo Rheumatology and Medicine, Orchard Park, NY, [4]BioStatistics, Buffalo Rheumatology and Medicine, Orchard Park, NY

Session Date: Tuesday, November 10, 2015

Session Title: Health Services Research Poster III: Patient Reported Outcomes, Patient Education and Preferences

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Multiple biologic treatment modalities are available for managing systemic inflammatory disease states. Patient preference regarding routes of administration is frequently unclear and has not been well studied. Existing literature demonstrates that patient involvement and shared decision-making lead to greater levels of compliance and patient satisfaction (1). Additionally, correlation with demographic variables may assist the physician in tailoring individualized patient care. The goal of this study was to assess openness to and preferences for subcutaneous (SQ) versus intravenous (IV) routes of medication administration for biologic disease modifying medications in inflammatory rheumatologic disease states.

Methods:

Patients from a suburban outpatient rheumatology practice with a diagnosis of RA, PsA or AS were asked to complete a survey. Responses were reported anonymously and health care providers were blinded to results**.** Consecutive patients during a 3-month period were queried about their openness to and preferences for the use of a self administered SQ and/or IV biologic disease modifier. Data was analyzed using a two sided t-test and ANOVA. Subset analyses of gender, age and disease state were also explored.

Results:

A total of 236 subjects completed the survey and were considered for analysis (females: 73.7%; mean age: 60 years). Survey participants included 172 subjects with RA, 48 subjects with PsA and 24 subjects with AS; 107 (46.7%) were naïve to the use of a biologic DMARD. Openness to SQ and/or IV routes in subjects naïve to biologic disease modifiers can be seen in Table 1.

Overall, patients preferred IV to SQ route (34.2% vs. 25.3%, p=0.039) and 31.1% had no preference. Biologically naive patients preferred IV to SQ (34.0% vs. 18.9%, p=0.013), and 32.1% had no preference. Patients over the age of 60 preferred IV to SQ (41.4% vs. 12.5%, p=0.026), while those less than age 40 preferred SQ to IV (50% vs. 27.7%, p=0.008). Females preferred IV to SQ while males did not have a preference. PsA patients preferred SQ to IV (45.2% vs. 9.7%, p = 0.001) while RA patients preferred IV to SQ (36.2% vs. 23.2%, p=0.007).

Conclusion:

The results of the survey reveal that the majority of patients with inflammatory arthritis are open to the use of biologic agents. Surprisingly, in office infusion was preferred overall to subcutaneous injection. Differences exist between age groups, gender, disease and current biologic use. When considered, these variables can aid the clinician in tailoring care and may also have broader implications on future pharmacologic manufacturing.

Documentation of Clinical Improvement in Patient with Polymyalgia Rheumatica According to MDHAQ/RAPID3 (Multidimensional Health Assessment Questionnaire/Routine Assessment of Patient Index Data): Longitudinal Analysis from Routine Care

Isabel Castrejón[1], Annie Huang[1], Sarah L. Everakes[2], Ailda Nika[1], Winston Sequeira[1] and Theodore Pincus[1], [1]Rheumatology, Rush University Medical Center, Chicago, IL, [2]Internal Medicine, Rush University Medical Center, Chicago, IL
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Health Services Research Poster III: Patient Reported Outcomes, Patient Education and Preferences
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: RAPID3 is an index found on the MDHAQ, which is effective in rheumatoid arthritis (RA) clinical trials and clinical care (1). MDHAQ/RAPID3 also is informative in osteoarthritis (OA), ankylosing spondylitis (AS), gout, systemic lupus erythematosus (SLE) (2), and vasculitis (3). A reported clinical composite index for polymyalgia rheumatica (PMR) includes 3 patient reported measures, which are found on MDHAQ/RAPID3 (4). We analyzed whether MDHAQ/RAPID3 would be of value to document clinical improvement in clinical status over time in patients with PMR.

Methods: All patients with all diagnoses seen at an academic rheumatology center complete an MDHAQ/RAPID3 at all visits in the waiting area, before seeing the rheumatologist. The MDHAQ includes 0-10 scores for physical function (FN), pain (PN), patient global estimate (PATGL), compiled into a 0-30 RAPID3. The MDHAQ also scores fatigue, morning stiffness, and a RADAI self-report of painful joints which queries 16 joint groups bilaterally, including shoulders and hips, as well as demographic data. Prospectively-collected MDHAQ/RAPID3 data, as well as laboratory and medication data, of PMR patients seen between 2010 and 2014 were collected retrospectively from the medical record, including MDHAQ/RAPID3 scores, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), and prednisone dosage. Data from a baseline visit and most recent visit over a mean interval of 15.5 months were compared for MDHAQ/RAPID3 scores, laboratory tests and medications. Statistical significance was analyzed using paired t-tests and chi-square tests.

Results: 34 patients with PMR seen in routine care were included in the study: 59% were females, 71% Caucasian, and mean age

was 71.6 years. The mean duration from a baseline visit to most recent visit was 15.5 months (range 1 to 43 months). At initial presentation, mean RAPID3 was 12.2/30, physical function 2.2/10, pain 5.3/10, and PATGL 4.7/10, fatigue 3.9/10, and morning stiffness 63.1 minutes; 64.7% of the patients had painful hips, 79.4% had painful shoulders; 73.5% had abnormal ESR; 70.6% had abnormal CRP (Table). Significant improvement was seen between baseline and last visit in mean levels of RAPID3 and all other MDHAQ measures, except fatigue ($p<0.05$), as well as ESR and CRP (Table). The mean dose of prednisone was decreased from 12.2 at first visit to 4.3 mg at most recent visit.

Conclusion: In patients with PMR, improvement was seen according to MDHAQ/RAPID3 scores in a similar range to ESR and CRP, documenting effective response to prednisone. MDHAQ can be useful to document and monitor status of patients with PMR in busy clinical settings.

The Correlation of Childhood Health Assessment Questionnaire with Disease Activity in Juvenile Idiopathic Arthritis

Watchareewan Sontichai[1,2] and Soamarat Vilaiyuk[1], [1]Division of Pediatric Rheumatology, Department of Pediatrics, Faculty of Medicine Ramathibodi Hospital, Mahidol University, Bangkok, Thailand, [2]Department of Pediatrics, Faculty of Medicine, Chiang Mai University, Chiang Mai, Thailand

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Health Services Research Poster III: Patient Reported Outcomes, Patient Education and Preferences
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Juvenile idiopathic arthritis (JIA) is a common childhood arthritis, which is classified into 7 subtypes. Each subtype has different clinical manifestations, treatment, and disease course. The Childhood Health Assessment Questionnaire (CHAQ) is widely used for functional ability assessment. Many studies investigated the correlation between CHAQ and JIA outcomes but the correlation between CHAQ and disease activity in each JIA subtype is still obscured. Therefore, this study aims to determine the correlation between CHAQ and disease activity in each JIA subtype during active and inactive disease.

Methods: All JIA patients in pediatric rheumatology clinic at Ramathibodi hospital between January 2011 and December 2013 were included in this study. Demographic data, disease activity variables, and CHAQ were reviewed from medical records for 6 visits in each patient. Disease activity variables included active joint count, limited joint count, erythrocyte sedimentation rate, patient's global assessment (PtGA), and physician's global assessment (PGA). Juvenile Arthritis Disease Activity Score-27 (JADAS-27) was also performed by physician. The correlation between CHAQ and disease activity variables in each JIA subtype during the active and inactive disease was analyzed by Spearman's correlation.

Results: 139 JIA patients [31% enthesitis-related arthritis (ERA), 28% systemic JIA (SJIA), 17% oligoarthritis, 15% rheumatoid factor (RF) negative polyarthritis, 6% RF positive polyarthritis, and 3% undifferentiated arthritis] were enrolled into this study. Data of 812 visits were reviewed, 606 visits were in active disease while 206 visits were in inactive disease. The median of disease duration was 2.8 years. RF negative polyarthritis patients had highest CHAQ score (0.39 ± 0.66) while oligoarthritis patients had lowest score (0.20 ± 0.32). During active disease, CHAQ had moderate to strong correlation with JADAS-27, PGA, and PtGA in all JIA subtypes (p<0.05), whereas CHAQ had low correlation with disease activity variables during inactive disease. In SJIA patients, CHAQ had strong correlation with active joint count (r=0.70), whereas CHAQ in other subtypes had only moderate correlation. CHAQ also highly correlated with joint tenderness in polyarthritis (r=0.70 in RF positive group and r=0.64 in RF negative group).

Conclusion: Polyarthritis patients had the worst functional impairment, while oligoarthritis patients had the least functional impairment. CHAQ had good correlation with disease activity during active disease, whereas CHAQ had poor correlation during inactive disease in all JIA subtypes. Therefore, CHAQ is useful to assess disease activity in JIA patients only during active disease.

Describe Treatments As 'new' or 'old' at Your Peril: Influences on Patient Decision Making

Mark Harrison[1,2], Carlo Marra[3] and Nick Bansback[4,5], [1]Faculty of Pharmaceutical Sciences, Vancouver, BC, Canada, [2]Centre for Health Evaluation and Outcomes Sciences, St Paul's Hospital, Vancouver, BC, Canada, [3]School of Pharmacy, Memorial University, St John's, NF, Canada, [4]St. Paul's Hospital, Centre for Health Evaluation and Outcome Sciences, Vancouver, BC, Canada, [5]School of Population and Public Health, University of British Columbia, Vancouver, BC, Canada

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Health Services Research Poster III: Patient Reported Outcomes, Patient Education and Preferences
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Using an example of a new drug for rheumatoid arthritis which offers comparable effectiveness and side-

effect point estimates to older drugs, we explore preferences for treatments labelled 'new'. We then examine the persistence of preferences once ambiguity in the evidence base due to it being new is introduced.

Methods: We randomized a representative sample of the Canadian general population to one of three discrete choice experiment (DCE) designs which sought choices between hypothetical treatments for rheumatoid arthritis based on different levels of 7 attributes: route and frequency of administration, chance of benefit, serious and minor side-effects and life expectancy, and uncertainty in benefit and side-effect estimates. The DCEs differed in whether the treatment was 1) described as new (recently available) or older (available 5 or 10 years), 2) whether a qualitative description describing the confidence in the evidence was included instead, or 3) both the length of time available and confidence in evidence was provided. We collected characteristics of respondents including the self-reported Innovativeness scale, Subjective Numeracy Scale, and Health Risk Attitude Scale.

Results: 2837 people responded to the survey. Overall, all 6 consistent attributes (route and frequency of administration, chance of benefit, serious and minor side-effects and life expectancy) influenced preferences for treatment. An overall significant preference for less ambiguity (more confidence) in benefit and side-effect estimates was observed, but there was no preference for a treatment labelled 'new' or 'old'. However, in a subgroup analysis, early adopters (n=173) had a significant preference for 'newer' treatments relative to old treatments (B=0.157, p=0.045), preferences comparable in magnitude to preferences for reducing the risk of (rare) serious side-effects in this group. While early adopters valued reducing ambiguity in the evidence base consistently with later adopters, when the newness of the drug was combined with ambiguity in the evidence base, preferences for 'new' treatments diminished. There was evidence of a dose-response relationship across innovator categories.

Conclusion: Preferences for innovation in health care appear to exist for some potential groups of patients. However, when presented with the implications of new treatments, namely increased ambiguity in the evidence base, these preferences diminished. When communicating with patients, physicians should either avoid describing whether treatments are 'new', or be mindful to qualify the implications of a 'new' treatment in terms of ambiguity in estimates of risks and benefits.

Session Title: Health Services Research Poster III: Patient Reported Outcomes, Patient Education and Preferences

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The Systemic Lupus Erythematosus Quality of Life Questionnaire (L-QoL) is a disease-specific measure of needs-based quality of life developed in the United Kingdom (1).

Aim: To assess the validity and reliability of the L-QoL in a Turkish population.

Methods: The L-QoL was translated into Turkish using the dual-panel process. Patients with SLE were recruited from 4 different rheumatology clinics. L-QoL administered twice with 3-4 weeks of interval to assess the test-retest reliability (intraclass correlation coefficient). Face validity was assessed via cognitive debriefing interviews with SLE patients. The convergent and divergent validities were assesed for determine the construct properties of the questionnaire. The relation of the L-QoL with subsets of Nottingham Health Profile (NHP) (energy level, pain, emotional reactions, sleep, social isolation, physical mobility) and Health Assessment Questionnaire (HAQ) were assessed for convergent validity. The relation of the L-QoL with non functional parameters such as age, disease duration, perceived general health and SLEDAI were assessed for divergent validity. Spearman's correlation coeficient (rho) was used to assessed the relation between quantitative parameters. $P<0.05$ was accepted as significant.

Results: Fifty-five SLE patients (53 female, 2 male) with 43.55 (SD:14.33) mean of age were recruited into the study. Test–retest reliability was very good (0.87), indicating low random measurement error for the scale. The measure was well accepted and the items considered understandable and relevant which showed the face validity of Turkish version of the questionnaire. The L-QoL has good correlation with subsets of NHP and HAQ were suggesting the measure assess related but distinct constructs (convergent). Its poor and not significant correlation with non functional parameters (divergent) showed its discriminative properties (Table).

Convergent validity of L-QoL	**Spearman's (rho)**	**Significance (p)**
NHP-energy level	0.52	<0.0001
NHP-pain	0.64	<0.0001
NHP-emotional reactions	0.72	<0.0001
NHP-sleep	0.65	<0.0001
NHP-social isolation	0.60	<0.0001
NHP-physical mobility	0.53	<0.0001
HAQ	0.62	<0.0001
Divergent validity of L-QoL	**Spearman's (rho)**	**Significance (p)**
Age	0.19	0.1640
Disease duration	0.18	0.1930
Perceived general health	0.32	0.0460
SLEDAI	0.29	0.1000

Conclusion: The Turkish version of L-QoL has good reliability and validity properties. It is practical and useful scale to assess the quality of life in SLE patients in Turkish population

Agreement Between Patient's and Physician's Reported Bath Ankylosing Spondylitis Disease Activity Index in Patients with Axial Spondyloarthritis

Liana Ghukasyan[1], Adrien Etcheto[2], Anna Moltó[3] and Maxime Dougados[3], [1]Rheumatology B Department, Paris-Descartes University, Cochin Hospital, Paris, France, [2]Rheumatology B, Rheumatology B Department, Paris-Descartes University, Cochin Hospital, Paris, France, [3]Paris Descartes University, Rheumatology Department, Cochin Hospital, AP-HP. SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Health Services Research Poster III: Patient Reported Outcomes, Patient Education and Preferences
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose *:* The Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) is the more frequently used index for evaluating disease activity in Spondyloarthritis (SpA) in clinical practice. However patients frequently have questions concerning its wording or need assistance to fill it out. Despite BASDAI is a patient reported outcome, physicians often ask the questions to the patients themselves and give their own explanations. Moreover, in patients with axial SpA a short version of the BASDAI including only questions 1,2,5 and 6 has been proposed (referred here to axial-BASDAI).

These remarks prompted us to conduct this study aiming to assess the agreement between doctor's and patient's BASDAI and axial-BASDAI in the clinical evaluation of patients with SpA in daily practice.

Methods:

Study design: this was a cross-sectional study including patients with axial SpA according to the rheumatologist. Patients filled out the BASDAI questionnaire in the waiting room. Thereafter, unaware of the results provided by the patients, the rheumatologist collected another BASDAI by reading out loud the questions to the patient and giving explanations if needed.

Statistical analyses: agreement between patient and physician BASDAI and axial-BASDAI were compared by the intraclass coefficient of correlation (ICC) and its 95% confidence interval (CI) for continuous variables and by the kappa statistics (95%CI) when evaluating the percentage of patients with high disease activity (e.g. BASDAI > 4).

Results:

Of the 50 enrolled patients (mean age: 44± 10 years; disease duration: 15 ± 10 years) 32 (64%) were male, 40 (81,6%) were B27 positive and 34 (69,4%) had a radiographic sacroiliitis.

The agreement between patient's versus physician's BASDAI and axial BASDAI were excellent [ICC 0.91 [95% CI, 0.84-0.95]] and ICC 0.94 [95% CI, 0.90-0.97]] respectively. Regarding each question of the BASDAI (see table) the lowest agreement was found for Q4 (i.e. referring to enthesitis) with an ICC[95%CI] = 0.51 [0.28 – 0.69].

The agreement between patient and physician assessment of high disease activity (e.g. BASDAI > 40 yes/no) was better when considering the axial BASDAI in comparison with the total BASDAI (see table).

Table 1

	Patient	Doctors	ICC
BASDAI 1			
Mean (sd)	4.91 (2.40)	4.95 (2.38)	0.94[0.89-0.96]
BASDAI 2			
Mean (sd)	3.74 (2.34)	3.78 (2.55)	0.91[0.85-0.95]
BASDAI 3			
Mean (sd)	2.22 (2.02)	2.30 (2.29)	0.78[0.64-0.87]
BASDAI 4			
Mean (sd)	2.91 (2.31)	1.85 (2.26)	0.51[0.28-0.69]
BASDAI 5+6/2			
Mean (sd)	3.11 (2.30)	2.59 (2.08)	0.84 [0.73 - 0.91]
BASDAI total			
Mean (sd)	3.38 (1.73)	3.09 (1.75)	0.91[0.84-0.95]
“Axial” BASDAI			
Mean (sd)	39.22 (20.10)	37.75 (19.85)	0.94 [0.90 - 0.97]
BASDAI total>40			
	17/50 (34%)	13/50 (26%)	0.53[0.27-0.78]
“Axial” BASDAI>40			
	21/50 (42%)	20/50 (40%)	0.88[0.74 - 1.00]

Conclusion:

Despite an excellent agreement between the physician's and patient's total BASDAI scores, these data suggest that:

a)The fourth question of the BASDAI (e.g. relative to enthesitis) is the less concordant.

b)The physician's reported total BASDAI resulted in lower number of patients considered as active patients.

c) Such results should prompt the scientific community to revise such outcome or at least to provide clear recommendations on the optimal way to collect it.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Health Services Research Poster III: Patient Reported Outcomes, Patient Education and Preferences

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The ASAS Health Index (HI) was developed to assess the impact of spondyloarthritis (SpA) on the patients' overall function and health. Utilities are a special type of health-assessment measures that reflect a ‘preference' for the different health states that patients with SpA can experience. Utilities range from 0 (death) to 1 (perfect health). While the patient's preference is increasingly recognized as resource for utilities, preferences from the general population remain the corner stone in healthcare decisions. Therefore, the aim of this study was to develop a conversion tariff for the ASAS HI to derive utility of health states of patients with SpA from the perspective of the general population. As it is known that preferences can be culturally dependent, we also derived country specific utilities.

Methods: An online survey was performed in a random sample of subject from the general population in the UK, France, Germany, the Netherlands, Spain and Italy. Subject completed first the ASAS HI. Next, two lead Time Trade Off (LTTO) experiments were performed to anchor the health states defined by the ASAS HI on a 0 to 1 utility scale. The lowest value was based on the health state ‘severe SpA' and the highest value on their ‘own ASAS-HI health state'. ‘Severe SpA' was defined by impairments in 8 items of the ASAS HI, selected previously by patients as having most impact on their health. In addition, subjects completed a Best-Worst Scaling (BWS) experiment comprising 17 choice tasks to assess the relative contribution of each item of the ASAS HI to overall health. Finally, the relative importance score of each item of the ASAS HI as derived by BWS, was used to rescale the ‘value of health' between the anchors of worst and best health defined in the LTTO.

Results: In total, a representative sample of 3,039 persons from the general population (age 46.5 years (SD 15.2), 1556 women (52.2%)) contributed to the analysis (about 500/country). As analyses showed comparable results among countries, we here present the overall results. Table 1 shows the results of the contribution of each item in the ASAS HI to the utility conversion formula. It can be seen that an individual who has no health problems related to SpA would experience a utility as 0.92. On the other hand, subjects of the general population indicate that the utility of a patient with SpA that scored problems on all 17 items of the ASAS HI would be as low as -0.37: a health state worse than death. A patient with SpA with pain, problems in sleeping, and problems with standing would be considered by society to have a utility of 0.59. Further analyses showed these results were largely comparable across countries.

Conclusion: From now onwards, a European transformation formulae is available to convert scores on the ASAS HI in a utility of the societal perspective. This makes it possible to use disease specific utilities in cost-utility analyses in patients with SpA.

Table 1: Contribution of presence of a problem for each item of the ASAS Health Index to the utility formula

Item	Contribution in Utility formula
Intercept (ASAS HI =0)	0.92
Pain	-0.13
Sleeping	-0.12
Exhausted	-0.10
Overcome difficulties	-0.10
Concentration	-0.09
Standing	-0.08
Financial changes	-0.08
Motivation to do physical effort	-0.07
Frustrated	-0.07
Walking outdoors	-0.07
Toileting	-0.07
Travelling	-0.06
Sexual relationship	-0.06
Running	-0.05
Driving	-0.05
Contact with people	-0.05
Washing hair	-0.03

Curtis**[1], [1]University of Alabama at Birmingham, Birmingham, AL, [2]Immunology/Rheumatology, University of Alabama at Birmingham, Birmingham, AL, [3]CreakyJoints, New York, NY, [4]Creaky Joints/Global Healthy Living Foundation, Upper Nyack, NY

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Health Services Research Poster III: Patient Reported Outcomes, Patient Education and Preferences

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: While healthcare provider priorities often coalesce around clinical concerns, little has been done to explore which concerns are the most pressing educational concerns among the rheumatic disease patient community. This study conducted a cross-sectional analysis elicited by rheumatic disease patients using nominal groups to identify the set of topics most relevant to patients regarding their disease and care. Items were rank-ordered according to importance and used to identify the educational concerns with which rheumatic disease patients most identify.

Methods: Participants were recruited from within the membership registry of the rheumatology patient community, CreakyJoints, to participate in one of four nominal groups held in June 2015. Each of the four groups generated a set of educational topics or questions ('items'), and then rank-ordered them within each focus group. We manually reviewed all items to aggregate them into common topic groups, de-duplicating redundant items, and categorizing the topic groups in to themes according to their highest patient-ranked order.

Results: Among the 31 participants distributed across 4 nominal groups, mean (SD) age was 52.5 (9.8) years with 94% being women. Participant diseases included rheumatoid arthritis (74%), osteoarthritis (29%), osteoporosis (29%), fibromyalgia (23%), lupus (16%), ankylosing spondylitis (13%), and psoriatic arthritis (10%). Overall, 98 educational topics were suggested by the four groups, de-duplicated to 44 unique topic groups, which then were grouped into 14 representative themes. Themes consisted of 2-15 topic groups with each topic group encompassing 1-8 individual items. "Lifestyle changes and patient environment modifications" was the most valued theme, receiving 14% of votes. Medication data (drug dosing, interactions, performance, etc.), physician selection, and knowledge of disease/disease progression were also strongly emphasized with voting rank scores of 12%, 11%, and 10%, respectively. Themes of least interest included friend/family/community support, financial concerns (including insurance), and social interactions, which held vote percentages of 3%, 2%, and 1%, respectively.

Conclusion: Patients with rheumatic diseases are concerned about a variety of topics, which include lifestyle changes/patient environment modifications, medication data, and physician choice. Patient-centered research should maximally respond to addressing questions of importance to patients, and this survey is a first step in identifying and prioritizing the topics that matter most to patients.

Table 1: Top-ranked rheumatic disease educational concern themes with topic group and item examples.

Theme	Topic Group Example	Item Example
Lifestyle Changes & Patient Environment Modifications	Dietary Choices	What would be good food alternatives for reducing flares?
Medication Data (Dosing, Effects, Limitations)	Drug Effects	Drugs take a couple of months to work; don't expect an immediate fix.
Physician Selection	Finding the Right Specialist	Make sure to have a proper diagnosis by a rheumatologist.
Knowledge of Disease & Disease Progression	Disease Progression	What do you look for that indicates the condition is getting worse?
Reliable Resources	Individual Research Resources	It is important to educate yourself and do your own research.
Asking for Help & Extent of Limitations	Asking for Help	Don't be afraid to ask for help when you are having a flare.
Coping	Emotional	How do you deal with the mental and emotional problems that come with the condition?
Personalized Disease needs Personalized Treatment	Individualized Treatment Options	What are all medications/treatments available to you for your case in particular?
Alternative Treatments	Alternative Treatments	What alternative therapies that might be helpful (i.e. acupuncture and biofeedback)?
Self-Efficacy and Voicing Concerns	Self-Efficacy	Be your own advocate in your disease; trust your instincts and speak up.

Session Date: Tuesday, November 10, 2015

Session Title: Health Services Research Poster III: Patient Reported Outcomes, Patient Education and Preferences

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Patient passports have been used in chronic diseases to promote active involvement of patients in their care. In RA, patient monitoring of their disease activity could facilitate the treat to target approach by providing early warning signs when disease is not controlled. The Arthritis Health Journal (AHJ) is a patient-centered online tool that helps patients track symptoms, monitor disease activity and develop action plans. We performed a proof of concept study to assess its use in people with RA.

Methods: Participants, recruited from arthritis clinics, consumer newsletters and advertisements, were randomly assigned (1:1) to the immediate; or the delayed group, which received the intervention after 6 months. Participants were provided with online access to the AHJ and asked to use it for 6 mos (no frequency specified). The tool consists of 6 sections: 1) symptom and exercise log; 2) disease activity assessment; 3) mood assessment; 4) medical information; 5) goals and action plans; 6) health reports. On-line questionnaires every 3 months evaluated frequency of use, satisfaction, self-management, consumer effectiveness, and health status. Semi-structured interviews were conducted on a purposive sample selected to represent a range of experiences with the AHJ.

Results: 94 participants were recruited (45 immediate/49 delayed groups); mostly women (88.3%), Caucasian (78%), with post-secondary or higher education (88.3%), and a mean (SD) age of 52.9 (11.0) yrs and RA duration of 12.5 (10.6) yrs. The AHJ was used less frequently than expected, likely because participants were not instructed about how often to use it. Disease activity and mood assessment were the most frequently used sections [median (25Q; 75Q) frequency of use over 3 mos: 1.5 (0; 3) and 1.5 (0; 4), resp., with 35% not using the disease activity section over 3 mos and 29% using it > 3 times. User satisfaction was mod to high across sections (median varying from 6.0 to 7.3 on 1-10 scale), with highest satisfaction with the disease activity section. In preliminary analyses of 6-month data, no significant differences were observed in consumer effectiveness attributes or in health status. Perceived benefits of the AHJ mentioned in interviews included enhanced self-awareness, ability to see relationships between symptoms and trends over time in symptoms and disease activity, which was felt to facilitate medical-decision making during medical visits. Barriers to use included lack of perceived need when disease was stable, well-controlled or longstanding (stating they would have used it at disease onset), internal factors (e.g. fatigue, unwillingness to focus on disease, denial), external factors (lack of time due to life events). Those who found AHJ beneficial tended to use it more frequently.

Conclusion: Our proof of concept study shows that people were satisfied with the AHJ, but many did not use it frequently for a variety of reasons. No difference between groups were detected in consumer attributes or health status in preliminary analyses; however, the 6-month timeline might be short to expect such difference. A number of benefits were identified, esp. in people who used it frequently.

Session Date: Tuesday, November 10, 2015

Session Title: Health Services Research Poster III: Patient Reported Outcomes, Patient Education and Preferences

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Fatigue is an important problem for many patients with rheumatic diseases. Fatigue is associated with disease severity, psychological distress, and a poorer quality of life in rheumatoid arthritis (RA) (1), but the extent to which the level of fatigue may contribute to disease activity is controversial. A fatigue 0-10 visual analog scale (VAS) is included on a multidimensional health assessment questionnaire (MDHAQ). We analyzed possible associations between fatigue and global estimates of disease activity according to the patient (PATGL) and the physician (DOCGL) in patients with different rheumatic diseases seen in routine care.

Methods: All patients seen in one academic clinical setting complete a 2-page MDHAQ in 5-10 minutes in the waiting area, prior to seeing the rheumatologist in the infrastructure of usual care. The MDHAQ includes physical function (FN) in 10 activities of daily living, three 0-10 visual analog scale (VAS) for pain (PN), PATGL, and fatigue (FT), and demographic data. Four activity categories were defined for PATGL and DOCGL: <1 for 'inactive disease', 1-3 for 'low', 3-6 for 'moderate', and >6 for 'high'. Median values for fatigue and interquartile range (IQR) were compared in the 4 PATGL and DOCGL categories in 4 diagnostic groups: rheumatoid arthritis (RA), osteoarthritis (OA), systemic lupus erythematosus (SLE), and fibromyalgia (FM), using one-way analysis of variance; Kruskall-Wallis tests of significance were performed.

Results: The study included 612 consecutive patients, 173 with RA, 199 with OA, 146 with SLE and 94 with FM. Median fatigue scores were significantly higher in FM (7, IQR=5-8) $p<0.001$, but similar in RA (4, IQR=1-7), OA (5, IQR=2-7.5), and SLE (5, IQR=1.5-7.5). Fatigue scores were significantly higher according to disease activity categories in RA, OA and SLE patients for both PATGL and DOCGL, suggesting associations with diseases that are characterized by inflammatory or structural abnormalities (Table). By contrast, only PATGL, but not DOCGL, was associated significantly with fatigue, but a linear trend, as seen in RA, OA, and SLE, was not observed in patients with FM.

Conclusion: Fatigue scores are associated with severity of disease activity in conditions with inflammatory or structural abnormalities, such as RA, OA, and SLE, but do not appear to be similarly associated in myofascial pain syndromes. Fatigue may be due to different mechanisms in different rheumatic diseases. Fatigue is a relevant and important symptom, which may be assessed in the infrastructure of routine care as quantitative data on an MDHAQ, with no extra work for the doctor and minimal interference with clinic patient flow.

Literature Review of Patient Reported Outcome and Health Related Quality of Life Measures for Biologic Therapies in the Management of Psoriatic Arthritis and Ankylosing Spondylitis

Steffen Jugl[1], Sultana Syeda[2] and Gunda Praveen[2], [1]BF I&D GPA, Health Economics and Outcomes Research, Novartis Pharma AG, Basel, Switzerland, [2]Novartis Healthcare Pvt. Ltd., Hyderabad, India, Hyderabad, India

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Health Services Research Poster III: Patient Reported Outcomes, Patient Education and Preferences

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriatic arthritis (PsA) and ankylosing spondylitis (AS) are chronic progressive conditions with substantial humanistic burden on patients and care givers. A variety of instruments, both generic and disease specific have been used in PsA and AS clinical studies. These Patient Reported Outcome (PRO) instruments allow to compare and measure impact on patient's quality of life and thus play an essential role in evaluating humanistic burden. Objective of this project was to review generic and disease specific PRO measures used in clinical studies for biologics in the management of PsA and AS.

Methods: A literature search review of literature in English language from 1996-2015 was conducted. Embase, MEDLINE®, Tuft's Cost-effectiveness Analysis registry, National Health Services Economic Evaluation Databases were searched. Inclusion criteria for review and data extraction were at least one biologic DMARD intervention, at least one utility, quality of life or patient reported outcome measure mentioned. Clinical as well as non-RCTs, observational or retrospective trials were eligible for inclusion.

Results: The literature search retrieved 3,175 articles, whereof 124 were included. Maximum articles were obtained for AS (N=73), followed by PsA (N=46). In addition five articles were included that captured both conditions. Across studies, a wide variation was observed in baseline characteristics such as age (Years, PsA: 35.5–65.0; AS: 24.4–61.0), disease duration (Years, AS: 0.7–30.2; PsA: 1.7–22.2) and gender distribution (Females, AS: 0–70%, PsA: 25–88%). The Short Form health survey 36 (SF-36) was the most commonly used generic health related quality of life (HRQoL) measure (N=27 for PsA, N=55 for AS), followed by Euro QoL 5d (EQ-5d) (N=10 PsA, N=14 AS). Variation was seen with respect to the utilization and reporting of disease specific instruments. Health Assessment Questionnaire (HAQ)/HAQ-Disability Index (N=36) was the most common in PsA while Ankylosing Spondylitis QoL (ASQoL) (N=21) was common in AS. Other common instruments reported were measured by Visual Analogue Scale (total pain, nocturnal pain, fatigue, physician global assessment etc.). Measures like Fatigue-VAS (0-10), Stiffness severity (0-100), Nottingham Health Profile (NHP)-fatigue, NHP-pain were reported the least.

Conclusion: A large variety of generic and disease specific PROs are utilized increasingly in the recent years in PsA and AS studies to measure HRQoL. This also shows the complexity and the multidimensional impact of these conditions on HRQoL. As there is no gold standard established, new tools may be needed to measure this impact holistically and reduce complexity of various measures across trials.

Depression, Bad Sleep Quality, and Functional Deficit Are Independently Associated with Persistent Fatigue in Arthritic Patients with Low Disease Activity Under Biological Dmards

Vitalie Nizeica[1], Myriam Normand[2], Delphine Denarie[1], Béatrice Pallot Prades[1], Philippe Collet[1], Adamah Amouzougan[1], Hervé Locrelle[1,2], Thierry Thomas[1,2] and Hubert Marotte[1,2], [1]Rheumatology Department, University Hospital of Saint-Etienne, Saint-Etienne, France, [2]INSERM U1059/LBTO, Université de Lyon - Université Jean Monnet, Saint-Etienne, France

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Health Services Research Poster III: Patient Reported Outcomes, Patient Education and Preferences

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: In rheumatoid arthritis (RA) or axial spondyloarthritis (axSpA) patients, fatigue has been mainly related to disease activity. Current management of rheumatic inflammatory diseases aims for low disease activity as the desirable target. However, many arthritic patients with such a therapeutic response still report severe fatigue with negative consequences on their quality of life. The main objective of our study was to investigate the potential mechanisms of this fatigue by exploring factors associated with fatigue in low-activity RA and axSpA patients.

Methods: Arthritic patients with low disease activity (DAS28<3.2 for RA or BASDAI<4/10 and ASDAS<2.1 for axSpA) were enrolled in a monocentric observational and cross-sectional study. All patients were treated with a bDMARD associated or not with conventional synthetic (cs)DMARD. All patients were successively enrolled in this study. Demographic, clinical and biological patient characteristics were recorded. Fatigue was assessed by a validated self-questionnaire FACIT-F and by VAS for fatigue. Anxiety and depression were estimated by HAD scores. Physical activity was assessed by a validated score IPAQ-SF. Sleep quality was assessed using the PSQI score. Function disability was evaluated with HAQ. Function disability was evaluated with HAQ.

Results: One hundred patients were included in the study with 55 RA (86% female) and 45 axSpA (68% men), with a mean

disease duration of 11.9 ± 7.9 years. Furthermore, higher levels of physical activity together with lower functional disabilities were observed in axSpA patients compared to RA patients (Table 1). Notably, fatigue level was similar in RA and axSpA patients.

After the univariate statistical analysis, 7 parameters were statistically correlated with FACIT-F in our whole population: age, gender, sleep quality (PSQI and number of nighttime awakenings), anxiety (HAD anxiety), depression (HAD depression), and functional disability (HAQ). Four parameters remained positively associated with fatigue in the multiple linear regression: age, sleep quality (PSQI), depression (HAD depression), and functional disability (HAQ). Similar results were obtained when adding arthritic disease type (either RA or axSpA) in the multivariate analysis. Further analyses using ANCOVA test identified higher association between handicap and fatigue in axSpA patients than in RA patients. Fatigue level increased with higher handicap ($p<0.001$) and this trend was stronger in axSpA patients ($p<0.05$). Fatigue also increased with higher depression ($p<0.001$), with higher age ($p<0.05$), and sleep quality ($p<0.05$), but the strength of these associations was similar in both RA and axSpA patients.

Conclusion: Our study suggests the importance of advance care of depression, sleep quality, and functional deficit in patients with low-activity RA or axSpA in order to improve their state of fatigue and consequently to increase their quality of life.

"It Was like No One Is Listening to Me"[illegible]: A Qualitative Study of the Lived Experiences of Patients with Rheumatoid Arthritis in the Setting of Patient-Physician Discordance in Assessments of Disease Activity

John M. Davis III[1], Zoran Kvrgic[2], Melissa M. Plagge[1], Jennifer L. Ridgeway[3] and Gladys B. Asiedu[3], [1]Division of Rheumatology, Mayo Clinic, Rochester, MN, [2]Rheumatology, Mayo Clinic, Rochester, MN, [3]Center for the Science of Health Care Delivery, Mayo Clinic, Rochester, MN

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Health Services Research Poster III: Patient Reported Outcomes, Patient Education and Preferences

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Discordance between patients with rheumatoid arthritis (RA) and their rheumatologists in their global assessments of disease activity affects around 33% of clinical encounters. The objective of this study was to understand the perspective of patients with measured discordance on issues like disease assessments and patient-provider communication.

Methods: We conducted individual interviews with 20 patients (six males and 20 females) with RA (ACR/EULAR 2010 criteria) who had patient-physician discordance as defined by a ≥25-mm absolute difference in global assessments of disease activity at the most recent rheumatology appointment within 4 weeks (median patient global assessment = 56 mm; median provider global assessment =15 mm). The interviews were audio recorded, transcribed verbatim, and checked for accuracy. Interviews were analyzed using content analysis by coding the texts, identifying themes and patterns and then grouping them into meaningful clusters. To aid interpretation of the qualitative data, the Clinical Disease Activity Index (CDAI) was collected from the most recent clinical evaluation, and participants also completed the pain visual analog scale (VAS) and the Patient Health Questionnaire-9 (PHQ-9).

Results: The average age was 63 years (range 38-85). The medians (IQRs) for CDAI, pain VAS, and PHQ-9 were 10.2 (8.3 to 22.4), 61.5 (42.8 to 77.8), and 3.5 (2 to 7.8), respectively. Qualitative data analysis yielded six key themes (Table). Many patients described being misunderstood by others, including medical and non-medical communities, and distinguished their experiences

from those with other, perhaps more objectively defined diseases. Not all patients reported feeling like their providers assessments differed from their own, but those who perceived discordance attributed it to providers' failure to listen, lack of empathy, or rushed behaviors. Many reported consternation with completing pain, disability and global activity ratings, and few reported discussions of these with providers. Other patients did not necessarily understand the meaning of disease assessments (e.g., blood tests, x-rays). Patients also described the psychosocial burden of RA on daily life, noting unmet psychosocial needs and confusion about whether these issues should be addressed with their providers.

Conclusion: The findings of this study reveal several key themes for rheumatologists to take into account in their daily approach to patients with RA. The results should inform future studies aiming to enhance patient-physician communication and to develop management approaches targeting optimal health outcomes for patients with RA, including those that acknowledge the impact that RA has on daily living, which may not be currently perceived as important to disease assessments in clinic.

Theme	Illustrative Patient Quote	Key Patient Descriptors
Being misunderstood by others	"You know, people with cancer are treated differently. People understand they have cancer; they're going through chemo or radiation. But people with RA, I think they're classified as being…I don't know…like it's all in their head? And it's not, because there is medical proof showing that I have a disease, so I'm not making this up."	Female, age 46, CDAI=43.3, PHQ-9=23, pain VAS= 80
Limitations of provider assessments	"It just seems very vague. I mean, you have a line, and you put on there what level are you at and you know the worst possible, I don't know what that looks like. I know that I'm not. Not at all. Because I feel it every day and it frustrates me every day. So you know, it's like OK, what's a five? That's what I do, I think well, I kind of put a number scale on there in my mind… I wake up in the morning and my neck hurts, my feet hurt…I mean I would always say that usually I'm somewhere between like a four and a six. That's where I would put myself on the scale… the nurse or whoever you are speaking to, because they see people who are really terrible, and then I might walk in and I look absolutely fine, and they look at me and they're like, oh, you look great, but you know you don't…it's difficult to see pain when somebody doesn't express it. Um, and do you know right now, I'm sitting here with back pain."	Female, age 38, CDAI=11.7, PHQ-9=1, pain VAS=52
Discrepancy with provider examination findings	"Well, he talks to me somewhat, but then he examines me, and that's part of why I'm here. He doesn't see that there's that much damage being done, so he doesn't…I don't that think he relates to how much it hurts…I mean, not caring…he doesn't act like oooh, you're stupid or whatever he just…I don't know, I just feel like he doesn't. And again, as far as the RA goes, maybe it isn't that bad and it's other things that are hurting."	Female, age 66, CDAI=10, PHQ-9=4, pain VA=85
Inadequate active listening	"…it was like nobody is listening to me. I can tell you what's happening to me but your… and then there was like oh I think you have rotator cuff, and so I went through all these tests and it comes back go, I guess it is your arthritis. I'm like. I know that is what I tried to tell you… I actually asked somebody else if she was new because I felt like she was just overwhelmed. I could just sense the overwhelm-ness of her. "	Female, age 64, CDAI 6.4, PHQ-9 1, pain 22
Psychosocial burden of disease	"I can either go out now and screw my employment history up completely or I can keep pissing away my savings… after 30 years I'm getting a divorce because she's tired of paying for all of the bills even though I made boohoo money and put all kinds of money into investments. Now she's tired of paying all of the bills."	Male, age 50, CDAI=10.4, PHQ-9=2, Pain VAS=71
Unmet psychosocial needs	"I just rate it how I feel. And I think a huge part of that is the stress. And, you know, fatigue, depression, so that to me rates of how you are feeling, not only physically but mentally, emotionally. So there should be your pain, physical, emotionally, you know. And that way they can say, OK, I see that, you know, you're having an extremely hard time with this emotionally, physically you're OK, your pain is tolerable. And then talk from there."	Female, age 46, CDAI 43.3, PHQ-9 23, pain 80

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Health Services Research Poster III: Patient Reported Outcomes, Patient Education and Preferences

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: AbbVie provides a Patient Support Program (PSP) to adalimumab (ADA)–treated patients to assist them with issues pertaining to medication costs, nurse support, injection training, pen disposal, and medication reminders.[1] Whether

these resources impact costs associated with healthcare utilization has not been assessed. We aimed to quantify the relationship between participation in any component of the PSP and resource costs (medical and total).

Methods: Longitudinal, patient-level data on the utilization of AbbVie's PSP were linked with Source Healthcare Analytics administrative claims data for patients initiating ADA treatment from 01/2008 to 06/2014. The sample included patients aged ≥18 years with a diagnosis of Crohn's disease, ulcerative colitis, rheumatoid arthritis, psoriasis, psoriatic arthritis, or ankylosing spondylitis who were anti-tumor necrosis factor naïve prior to initiation of ADA. Patients who enrolled in the PSP (PSP cohort) were matched to those who did not enroll (non-PSP cohort) based on age, sex, year of ADA initiation, comorbidities, diagnosis, and initiation at a specialty pharmacy. For the PSP cohort, the index date was the date of enrollment into the PSP program and their time to enrollment following initiation was used to assign index dates for the non-PSP cohort. All patients were required to have evidence of medical and pharmacy coverage for 6 months before/after their first ADA claim and for 12 months after the index date. Medical costs associated with emergency department, inpatient, physician, and outpatient visits (all-cause and disease-related) and total costs (medical costs plus drug costs) were compared at 12 months following the index date using t-tests and generalized linear models adjusting for key baseline variables. Patients with costs exceeding 5 times the standard deviation of the mean were excluded as outliers (52 for PSP, 64 for non-PSP).

Results: A total of 1,199 PSP patients and 1,187 non-PSP patients were included. Baseline characteristics were similar between cohorts. During the follow-up period, unadjusted analyses showed PSP patients had significantly lower 12-month medical costs than non-PSP patients by 23% ($18,322 vs $23,679; *P*=.003). Disease-related medical costs were 22% lower for PSP patients compared to non-PSP patients ($8,001 vs $10,201; *P*=.045). Total costs were 10% lower for PSP patients than non-PSP patients ($35,741 vs $39,713; *P*=.03). Adjusted analyses yielded similar findings.

Conclusion: AbbVie's free-to-patient PSP was associated with lowering medical costs (all-cause and disease-related) and total healthcare costs.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Metabolic and Crystal Arthropathies Poster II

Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: 1) assess the current quality of care in gout patients and 2) compare the current management with previous audit data.

Methods: a second audit of clinical management of gout was conducted in 2014, including centers audited in 2006. The current Gout Evaluation and MAnagement-II audir included patients whose first visit was prior to the release of the ACR guidelines. In both audits, the degree of agreement was assessed according to the EULAR 2006 recommendations. The selection of patient's files for review was performed by a stratified 2-stage sampling. The number of centers per stratum was proportional to the population ≥50 years according to national statistics. In a second stage, a random sample from all patients in each participant unit with a diagnosis code of gout (ICD, R9), and who had been attended in 2006 and 2012 respectively was centrally selected. The sample size was estimated at 1,000 patients in 50 units for GEMA and then 500 patients from 40 units for GEMA-II according to previous results and expected outcomes. The main co-principal variables for GEMA-II were >50% improvement from GEMA in the rate of gold-standard diagnosis (based on crystal observation) and >50% improvement in the rate of patients at target serum urate levels (< 6 mg/dl in the last visit). In addition, an aprioristic evaluation of whether gold standard diagnosis was to be obtained in >50% of patients and target serum urate in > 50% of patients was asked from principal investigators prior to the inclusion of patient data.

Results: data from 511 randomly selected clinical records from 38 units were included. Out of the 38 units, 93% reported having a polarized microscopy facility at the office. sUA at final visit was available in 479/511 (93.7%). Samples from the two audits (GEMA and GEMA-II) did not differ in age, sex distribution or time from onset to first visit. Crystal-based diagnosis was performed in 209/803 (26.0%) and 162/511 (31.7%) in the GEMA and GEMA-II studies, not reaching endpoint. By contrast, the pre-defined improvement >50% for the rate of patients achieving target serum urate (< 6 mg/dl) was achieved (Table) for the overall population, independently of the aprioristic perception of the rate of control of target sUA. A post-hoc analysis including only patients on urate-lowering medications, the improvement in the rate of patients achieving sA target was 49.31%, very close to the >50% improvement (Table).

(Table, left columms= all patients; right columms= patients on urate-lowering medications).

sUA (mg/dl)	*< 6 mg*	*≥6 mg*		*< 6 mg*	*≥6 mg*
GEMA (N=701)	286 (40.8)	415 (59.2)	**GEMA (N= 642)**	274 (42.7)	368 (57.3)
GEMA-II (N=479)	294 (61.4)	185 (38.6)	**GEMA-II (N= 450)**	285 (63.3)	165 (37.7)

Conclusion: Overall the improvement in the rate of patients achieving target serum urate over a 6-year period exceeded 50%. The rate of gold-standard diagnosis improved, but did not reach the expected outcome. Although still under further analysis, these preliminary data show for the first time that substantial improvement has been achieved in treat to target serum urate levels strategy for gout in the Rheumatology community.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015

Session Title: Metabolic and Crystal Arthropathies Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

The interplay of use of dietary supplement, diet modification and ULT adherence in gout management is not known. Therefore, we aimed to begin to assess the ULT adherence and choice of non-pharmacological interventions by patients with gout, using a cross-sectional online survey.

Methods:

People visiting the Gout and Uric Acid Education Society's website (http://gouteducation.org) were invited to participate in a brief anonymous Internet survey on a voluntary basis between 08/11/2014 to 04/14/2015. We collected each individual's report of their age, gender, race, physician-diagnosed gout, receipt of physician prescription of urate-lowering medication (ULT; allopurinol or febuxostat; responses were yes/no), number of days the patient forgot to take ULT in the last month, the use of cherry extract vs. diet modification vs. ULT medication as what individuals thought might be the best life-long strategy for gout and patients' likelihood of making a lifelong change to their diet (0=not at all likely to 10=extremely likely scale) for better gout management.

Results:

Of the 524 survey participants reporting a physician diagnosis of gout, 499 respondents were included in the final analysis (**Table 1)**. Mean age of survey responders was 56.3 years (standard deviation, 12.6), 50% were 41-60 years old, 74% were males, and 74% were White and 9% Asians.

57% participants responded that they were prescribed a ULT for gout, allopurinol or febuxostat. Gender, age or race were not significantly associated with the likelihood of receiving a ULT prescription. Of those who were prescribed ULT, 251/285 (88.1%) were taking ULT, 20/285 (7%) quit taking ULT, 2/285 (0.4%) were taking ULT only when they had a gout flare and 13/285 (4.5%) did not respond to this question. 197/251 (78.5%) had ULT adherence >80% and 54/251(21.5%) had ULT adherence ≤80%. In univariate and multivariable-adjusted analyses (**Table 1**), gender, race and age were not significant predictors of ULT adherence.

56% of respondents said that they preferred ULT as a lifelong treatment for gout, 24% preferred cherry extract, 16% preferred diet modification and 4% preferred none of the treatments. In multivariable-adjusted analyses, men had significantly lower odds of preferring ULT as the lifelong treatment choice for gout vs. other therapies (**p=0.03; Table 1**).

54% of participants were highly motivated to make a lifelong dietary modification to improve their gout (likelihood score of 9-10; 72.7% had score of >5). In adjusted analyses, age was significantly associated with high level of willingness to modify diet (**p=0.023; Table 1**).

Table 1. Multivariate-adjusted odds of the choice of ULT as gout treatment (ULT vs. others), adherence to ULT >80% and likelihood of lifelong diet change as treatment for gout by gender, race and age

White/Caucasian	Ref	Ref	Ref	Ref

[a]p-value <0.05

---, no odds ratio calculable since no patients in this category

* Reference category is ULT was not prescribed

** Reference category is preference for non-pharmacological treatment options (cherry extract or gout-specific diet modification) for gout

*** Reference category is urate-lowering medication adherence of ≤80% in the last month

**** Reference category is the likelihood of diet change with a score ≤8 (range 0-10)

Conclusion:

Only 57% of gout patients reported having been prescribed ULT by their healthcare providers. 40% gout patients responding to the survey said that they preferred non- pharmacological interventions. Further study would be of interest to ascertain what they expected from those interventions.

Session Title: Metabolic and Crystal Arthropathies Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: ACR guidelines exist for the management of gout including the use of uric acid-lowering therapy. ACR guidelines recommend routine monitoring of uric acid levels and dose titration to achieve a uric acid goal of <6.0 mg/dL as well as regular drug safety monitoring in patients receiving uric acid lowering therapy. This study assesses the adherence of rural VA primary care providers with these ACR clinical guideline recommendations.

Methods: Patient records were examined from rural primary care provider panels. To be included in the analysis, patients were required to have been seen by their primary care provider within a one year observation period from November 1, 2013 until Oct 31, 2014 and to have been prescribed allopurinol or febuxostat. The following information was obtained for each patient: the number of uric acid determinations, the uric acid blood values, and the clinical actions that were taken if uric acid was above 6.0 mg/dL, or if the AST and ALT serum values were ≥ 2 times the upper limit of normal (74 U/L for AST and 154 U/L for ALT). If uric acid level was not at goal, or elevated AST or ALT noted, the patients' medical record was reviewed. Clinical action was considered to be appropriate for a uric acid ≥ 6.0 mg/dL if 1) an upward dose titration was documented in clinic notes or pharmacy records, 2) uric acid-lowering therapy was initiated, or 3) compliance counseling was documented in cases of suspected non-compliance. In the case of AST or ALT values ≥ 2 times the upper limit of normal, a clinical action was considered appropriate if a dose decrease or discontinuation of allopurinol or febuxostat was documented.

Results: There were 17,458 patients that had at least one primary care provider visit within the one year observation period and 772 (4.4%) of these patients had been prescribed either allopurinol or febuxostat. Of these 772 patients receiving allopurinol or febuxostat, 392 (51%) had at least one uric acid level documented during the observation period, and 738 (96%) patients had AST and/or ALT determinations. Among the 392 patients that had a uric acid level checked, 130 (33%) had a uric acid level ≥6 mg/dL. In this group of 130 patients with hyperuricemia (≥6 mg/dL), 73 (56%) had an appropriate clinical action taken. Among the 738 patients with AST and/or ALT lab determinations, 6 patients (0.8%) had an elevated AST and 1 had an elevated ALT level ≥ 2 times the upper limit of normal, and no dose adjustments or discontinuations of uric acid-lowering therapy were documented in clinical notes or pharmacy records.

Conclusion: Among rural V.A. primary care provider panel patients prescribed uric acid- lowering therapy only 51% of patients had a uric acid level checked within a year while 96% had routine AST and ALT monitoring. When the uric acid was above the goal of 6.0 mg/dL, defined appropriate action was documented in 56% of patients. There were 0.8% of patients with elevations of AST and 0.1% ALT ≥ 2 times the upper limit of normal, all of which lacked a documented adjustment of uric acid-lowering

therapy. These findings suggest the need for better education for rural VA primary care providers in the management of uric acid-lowering therapy in gout patients.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Metabolic and Crystal Arthropathies Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with gout experience both inflammation and increased risk of cardiovascular disease (CVD). Studies suggest that colchicine reduces myocardial infarction (MI) risk, but whether colchicine reduces incident coronary artery disease (iCAD), vs. acute plaque disruption/inflammation, is unknown. We assessed colchicine's impact on iCAD in gout patients.

Methods: Patients with gout or hyperuricemia (2000-2009) were identified by ICD-9 code. We then included only subjects with 1) microscopic diagnosis of urate crystals; 2) 6/12 ACR gout classification criteria, 3) rheumatologist gout diagnosis; or 4) 4-5 ACR criteria plus a PCP gout diagnosis. Patients with a diagnosis of CAD at index date were excluded. Pharmacy records distinguished colchicine users (1 period of prescription for >30 days) vs non-users. Chart review identified iCAD, defined as first positive cardiac stress test or cardiac catheterization, PCI (stent or angioplasty) or CABG. Incident MI was also recorded.

Results: Of 7,819 patients with an ICD-9 diagnosis of gout/hyperuricemia, 446 colchicine users and 278 non-users met inclusion criteria (2,118 vs. 1,367 years of follow-up for colchicine vs control group). Baseline characteristics were generally similar across groups (Table 1). We found no increased iCAD prevalence among colchicine users vs non-users (Table 2). Inclusion of incident MI as a criterion for iCAD did not result in any significant difference between the groups. When expressed as incidence rate (events per patient-years), iCAD again did not vary between groups. The individual components of the outcome were also similar between the two groups (not shown). In multivariate models, after controlling for potential variables, colchicine use still did not impact the risk of iCAD.

Conclusion: Our data suggest that chronic colchicine use does not impact the rate of iCAD in gout patients. In conjunction with prior studies suggesting a reduction in acute cardiovascular events among colchicine users, our data suggest that colchicine is likely to act by preventing acute events (e.g., plaque rupture, or vascular occlusion post-plaque rupture), rather than by reducing iCAD.

Supported by an investigator-initiated grant from Takeda, Inc.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Metabolic and Crystal Arthropathies Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Although anti-inflammatory drugs such as nonsteroidal anti-inflammatory drugs and colchicine are the recommended treatment options for pain and inflammation management in patients (pts) with acute gouty arthritis (GA) flares, alternative treatments are necessitated in pts with frequently flaring GA owing to contraindications, intolerance, and ineffectiveness. Safety of canakinumab (CAN), a selective, human anti-interleukin-1β antibody, vs triamcinolone acetonide (TA) over the initial 24 weeks has been reported.[1]Here we present the long-term safety of CAN over 36 months.

Methods: Pts who completed 2 phase III, multicenter, double-blind, randomized (subcutaneous [s.c.] CAN 150 mg and

intramuscular [i.m.] triamcinolone acetonide [TA] 40 mg) trials were enrolled in 2 similar design extension (E1) studies. Those completing E1 were enrolled in E2, a single arm study that was followed by an extension, E3. All in E2 and E3 received s.c. CAN 150 mg "on demand" upon a new flare. Long-term safety was assessed in terms of exposure-adjusted incidence rates per 100 patient-years (pyr) of adverse events (AEs) and serious AEs (SAEs) and efficacy was assessed by flare rate per year and high sensitivity C-reactive protein (hs-CRP) levels for a cumulative follow-up of 36 months.

Results: Of the 456 randomized in core studies, 272 pts entered the open label treatment with CAN during the extension phase E2 with re-treatment upon flare. Of those, 136 entered and 122 completed the open label treatment with CAN in E3. Overall, the exposure-adjusted incidence of AEs in CAN group was lower (264.6/100 pyr) than in TA group (308.8/100 pyr). Retreatment with CAN did not increase the incidence of AEs. Overall, the incidence of exposure-adjusted SAEs in CAN and TA groups was 17.3 and 17.7 per 100 pyr, respectively. The overall incidence of SAEs did not change in pts retreated with CAN (15.2 vs 15.1 per 100 pyr). Overall, 4 deaths—none related to study drug—were reported (2 pts in each group) due to intracranial hemorrhage [1; not retreated with CAN] and pneumonia [1; retreated with CAN] in CAN group and sudden cardiovascular death (1) and pneumococcal sepsis [1; never received CAN] in TA group. Mean flare rates/year were lower in CAN group (1.1) vs TA Group (2.5). CAN treated pts maintained clinical efficacy (pain intensity and physician's global assessment (PGA) of response to treatment) upon "on demand" retreatment over 3 years. Median hs-CRP levels remained below the upper limit of normal in pts retreated with CAN "on demand" for new GA flares from 7 days after the initial dose until end of study. Thirty % (n=12) of pts initiating or modifying urate-lowering therapies during E3 (n=40) reached target serum uric acid levels (<6 mg/mL).

Conclusion: Over 3 years, a mean "on demand" dosing of CAN was 2.68 per pt. Efficacy of CAN was demonstrated via stable pain intensity levels and PGA response scores in difficult-to-treat pts with GA. These results support the long-term safety of CAN treatment in those with frequently flaring GA pts. CAN safety profile was consistent with that observed in previous studies.

Session Title: Metabolic and Crystal Arthropathies Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with gouty arthritis (GA) experience frequent flares with pain and inflammation. The limited

available treatment options and typical comorbidities warrant effective alternative treatments[1]. A liquid formulation of canakinumab (CAN), presented as pre-filled syringe (CAN-PFS) has been developed to improve upon the lyophilized form (CAN-LYO). Efficacy and safety profile of CAN-PFS vs triamcinolone acetonide (TA) over 12 weeks in GA patients was reported earlier. Here we present the cumulative, safety, and efficacy results over 48 weeks.

Methods: Patients with GA who completed the 12-week core study[1] were enrolled in this 36-week, open-label extension (E1) study. All patients entering E1 received CAN-PFS 150 mg s.c. on demand upon new GA flare irrespective of the assigned treatment during randomization (CAN-PFS, CAN-LYO or TA 40 mg). The primary objective was to confirm the long-term safety of CAN-PFS vs TA. Secondary objectives included evaluation of CAN-PFS vs TA and CAN-LYO vs CAN-PFS for the time to first new flare over 48 weeks. Long-term safety outcomes and safety upon retreatment were assessed as the exposure-adjusted incidence rate of adverse events (AEs) and serious AEs (SAEs).

Results: Of the 397 patients randomized in the core study, 232 (58.4%) entered E1, of whom, 198 (50%) completed E1. Baseline characteristics were comparable between the treatment groups. The exposure-adjusted incidence of AEs was lower for both CAN-PFS [254.9/100 patient-years (pyr)] and CAN-LYO (224.8/100 pyr) groups vs TA (362.7/100 pyr) group over the 48 weeks. The exposure-adjusted incidence of SAEs was 14.7/100, 16.1/100, and 15.5/100 pyr in patients randomized to CAN-PFS, CAN-LYO, and TA groups, respectively. Infections and infestations were the most frequently reported SAEs in the CAN-PFS (3.4/100 pyr), CAN-LYO (3.2/100 pyr), and TA (0/100 pyr) groups. Over the 48 weeks, one death (cardiac failure), not suspected to be related to study drug, was reported in a patient randomized to CAN-PFS who was not re-treated during this period. CAN-PFS significantly delayed time to first new flare vs TA, with a relative risk reduction of 55% (hazards ratio [HR], 0.45; 95% confidence interval [CI], 0.32 to 0.64; $p<0.0001$) over 48 weeks. The mean number of new GA flares per patient was lower for both CAN-LYO (0.50) and CAN-PFS (0.76) groups than the TA group (0.96). Patients in the CAN-PFS group showed a 56% reduction in the number of new flares than the TA group (flare rate ratio, 0.44; 95% CI, 0.32 to 0.61; $p<0.0001$).

Conclusion:

These results provide evidence for the long-term safety and efficacy of CAN-PFS in patients with frequent GA flares, compared with TA. The safety profiles were consistent with those observed in the core study, and the efficacy of CAN-PFS was maintained upon retreatment.

Session Title: Metabolic and Crystal Arthropathies Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: This study investigated the effect of rebamipide on activation of NLRP3 inflammasome and reactive oxygen species (ROS) in monosodium urate (MSU) crystal-induced interleukin-1b (IL-1b) production.

Methods: Human monocyte cell line THP-1 cells and human umbilical venous endothelial cells (HUVECs) were used for assessing inflammatory response to MSU crystals. NADP/NADPH activity assay was used for an alternative marker for ROS generation. Quantitative Real-time polymerase chain reaction (qRT-PCR) and western blotting was performed to evaluate levels of IL-1b, caspase-1, NLRP3, ASC, nuclear factor-kB (NF-kB), IkB, intercellular adhesion molecule 1 (ICAM-1), or vascular cell adhesion molecule 1 (VCAM-1). Experimental pharmaceuticals included rebamipide, colchicine, dexamethasone, and ascorbic acid.

Results: MSU crystals treatment to THP-1 cells induced NADP/NADPH ratio and IL-1b expression, which was potently inhibited by addition of rebamipide. Rebamipide also significantly attenuated enhanced mRNA expression of caspase-1 by MSU crystals ($p = 0.0033$), in addition to colchicine and ascorbic acid ($p = 0.0323$ and $p = 0.0266$, respectively). Western blotting demonstrated that MSU crystals stimulated only caspase-1, but not NLRP3 and ASC activation. Similarly, MSU crystals activated NF-kB pathway, which in turn was blocked by rebamipide. Increased expression of VCAM-1 and ICAM-1 by stimulation of MSU crystals to HUVECs was markedly inhibited by rebamipide, in addition to dexamethasone.

Conclusion: This study demonstrated that rebamipide inhibits IL-1b activation through suppression of ROS-mediated NF-kB and caspase-1 activation in MSU crystal-induced inflammation.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Metabolic and Crystal Arthropathies Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Allopurinol is a first line urate lowering therapy in the management of gout. The observation that allopurinol hypersensitivity was associated with allopurinol dose, renal impairment and diuretics led to the suggestion that lower doses should be used in patients with renal impairment. It is well documented that many patients receiving creatinine clearance (CrCL)-based allopurinol doses fail to achieve target plasma urate. Allopurinol doses above 300mg daily are used rarely despite increasing evidence that doses higher than those based on CrCL may be safe and effective. With the introduction of new urate lowering therapies the ability to predict the dose at which a particular patient may achieve target urate may influence a clinician's decision on first line therapy.

The aims of this study were to explore factors that predict allopurinol response in patients with gout, to determine the probability of achieving the recommended plasma urate of ≤0.36mmol/L using CrCL-based doses and to predict the maintenance doses required to achieve the target plasma urate.

Methods : Data were sourced from five studies. A population analysis was conducted using NONMEM® v.7.2. Covariates included renal function, body size, sex, ethnicity, concomitant drugs, and renal transporter genotype. The final PKPD model was implemented in MATLAB (2014a). Stochastic simulations were performed under two scenarios; 1) using doses recommended by CrCL-based dosing recommendations, and 2) using daily doses sufficient to achieve target plasma urate concentrations in >75% of simulates. The model was evaluated against previously published data.

Results: A total of 1135 oxypurinol and 1178 urate plasma concentrations from 134 patients were available. A one compartment PK model with first order absorption and elimination was the best fit to the oxypurinol data. A simple direct effects (Emax) model provided an adequate description of the steady-state plasma urate data. Renal function, diuretic use, and body size were found to be significant covariates. Dose requirements were found to increase approximately 2-fold over a 3-fold range of weights and were 1.25-2 times higher in those taking diuretics. Renal function had only a relatively minor impact on allopurinol dosing. Table 1 shows the probability of achieving urate with CrCL based dose for a 70kg patient not taking diuretics and the dose predicted to achieve target urate. The model performed well when evaluated against external urate data.

Conclusion: This population PKPD model for allopurinol supports the contention that patients receiving CrCL-based allopurinol doses frequently fail to achieve target urate. The model provides a means of predicting allopurinol maintenance dose requirements for individual patients but needs to be validated against prospective data.

Table 1: Model predictions for percentage of patients achieving target urate on CrCL based doses and dose required to achieve target

CrCL ml/min	Hande allopurinol dose	% patients likely to achieve target urate based on model	CrCL	Predicted dose to achieve target urate in a 70kg patient no diuretics
0	100mg every 3 days	0		
10	100mg every 2 days	1		
20	100mg/d	12	>15-30	350mg/d
40	150mg/d	29		
60	200mg/d	44	>50-70	350mg/d
80	250mg/d	56		
100	300mg/d	64	>90	400mg/d

The Efficacy and Tolerability of Febuxostat in Hyperuricemic Patients with Severe Renal Impairment

Ji Seon Oh and Seungwon Choi, Division of Rheumatology, Department of Internal Medicine, University of Ulsan College of

Medicine, Ulsan University Hospital, Ulsan, South Korea
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Metabolic and Crystal Arthropathies Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Febuxostat has shown to be effective and safe in the treatment of hyperuricemia in patients with mild-to-moderate renal impairment without dose adjustment. However, there are insufficient data for the use of febuxostat in patients with severe renal impairment or hemodialysis. We investigated the efficacy and tolerability of febuxostat in patients with hyperuricemia and severe renal impairment (chronic kidney disease, stage 4 or 5).

Methods: We retrospectively reviewed clinical and laboratory data from a tertiary hospital from 2012 to 2015. We included 57 patients with severe renal impairment (estimated glomerular filtration rate [eGFR] < 30 mL/min/1.73m^2) who had been treated with febuxostat. Data regarding serum uric acid and serum creatinine level before and after the start of febuxostat treatment, and clinical information including adverse events were obtained from medical records. The paired t-test was used to determine statistical significance of the effect of febuxostat on serum uric acid levels.

Results: Among 57 patients, there were 46 men (81%) and 11 women (19%). Mean age was 57.8±13.7 years (range, 28-79). Before the start of febuxostat treatment, mean serum uric acid level was 9.2±1.9 mg/dL (range, 5.6-16.4), and mean creatinine level was 4.2±2.4 mg/dL (mean eGFR 18.6±7.6 mL/min/1.73m^2; range, 3.0-29.7). Mean daily doses of febuxostat and median duration of follow-up under treatment were 54±23 mg (range, 40-160) and 15 months (range, 2-38 months), respectively. Twenty-one patients (36.8%) were on dialysis. Under treatment with febuxostat, serum uric acid levels were significanly reduced at 3 months: Mean reduction of serum uric acid levels was 5.64±3.09 mg/dL ($p<0.001$) in patients on dialysis and 3.81±2.24 ($p<0.001$) in patients not on dialysis; Eighteen of 20 patients (90%) on dialysis and 26 of 36 patients (72.2%) not on dialysis achieved a target serum uric acid level ≤6.0mg/dL. In one patient, febuxostat was stopped because of skin itching and generalized edema. In most patients (98%), febuxostat was well tolerated without withdrawals due to side effects.

Conclusion: This study showed that febuxostat was efficacious and was well tolerated in hyperuricemic patients with severe renal impairment undergoing or not undergoing dialysis.

Session Title: Metabolic and Crystal Arthropathies Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Although allopurinol is the first urate lowering therapy (ULT), its limited dosage in gouty patients with stage 4 or 5 chronic kidney disease (CKD 4/5) prevents to achieve serum urate level (sUA) target (< 6.0 mg/dL). Febuxostat is a nonpurine xanthine oxidase inhibitor with predominant hepatic metabolism and can be used without dosage adjustment in gouty patients with CKD. However, its safety and efficacy in advanced CKD have been reported in only one study and no data are available yet in patients with kidney transplantation (1).

Methods: In this retrospective multicenter study, clinical records of all gouty patients with estimated glomerular filtration rate (eGFR) ≤ 30 ml/min/1.73 m2 (MDRD formula) at febuxostat initiation and at least after 3 months follow-up period were selected. Items to be collected (demographic data, co-morbidities, renal disease, gout history and former treatments, increasing serum urate drugs, laboratory data and any adverse effects (AEs) were approved by all participant centers. Variables to be analyzed were: sUA level at initiation and last available sUA levels; variation of eGFR; percentage of patients who achieved sUA levels < 6.0 mg/dL and 5.0 mg/dL; flares under ULT and all AEs with specific attention to cardiovascular (CV) events.

Results: Fifty-five gouty patients (mean age 70.7 ± 11.1, 47 men) from 7 French rheumatology departments were included. 26 patients (47.3%) suffered from vascular CKD and 13 patients (23.6%) had received renal transplant. Mean duration of gout was 7 years. 15 patients (27.2%) had tophi and 23 (41.8%) gout arthropathies. Diuretics were used in 47 patients (85.5%). Cardiac dysfunction was present in 9 patients (16.4%). 54 patients had hypertension, 15 (27.3%) diabetes mellitus, 40 (72.3%) dyslipidemia, 19 (34.5%) CV diseases, 20 (36.3%) had past history of vascular events (stroke, myocardial infarction). Mean sUA level and eGFR at febuxostat initiation were 8.8 ± 2.7 mg/dL and 21.3 ± 6.5 ml/min (6-30 ml/min), respectively. Febuxostat initiation dosage was 80 mg daily for 36 patients (65.5%), 80 mg every 2 days for 12 patients (21.8%) and 120 mg daily for 3 patients (5.5%). At last visit (mean follow-up 72 weeks (12-260)) mean sUA level was 4.8 ± 2.2 mg/dL; 39 patients (65.5%) achieved sUA target < 6.0 mg/dL and 34 (61.8%) had sUA ≤ 50 mg/L. Renal function improved (defined by > 10% increase of eGFR from baseline) in 13 patients (23.6%) (mean eGFR change: + 8.4 ml/min), was unchanged in 16 (29.1%) and worsened (defined by > 10 decrease of eGFR from baseline) in 21 (38.2%) (mean sGFR change: -6.3 ml/min). 33 patients experienced flares under febuxostat treatment. AE was observed in one patient who had suffered from limb edema. No CV event was reported during febuxostat exposure.

Conclusion: Febuxostat appears efficient in gouty patients with stage 4/5 CKD or renal transplants. However, safety data is not yet validated with respect to renal function. Further studies with larger samples are warranted for assessing this issue.

A Study to Evaluate the Pharmacodynamics, Pharmacokinetics and Safety of Arhalofenate in Combination with Febuxostat When Treating Hyperuricemia Associated with Gout

Alexandra Steinberg, Yun-Jung Choi, Robert Martin, Charles McWherter and **Pol Boudes**, Cymabay Therapeutics, Newark, CA
First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Metabolic and Crystal Arthropathies Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Arhalofenate is a novel Urate-Lowering Anti-Flare Therapy (ULAFT) for the treatment of gout. It lowers serum uric acid (sUA) by blocking URAT1, a tubular UA transporter, and reduces gout flares by blocking the local release of IL-1β. The study evaluated the serum uric acid (sUA) lowering effect of arhalofenate when combined with febuxostat, the potential for drug-drug interaction and safety.

Methods: This was a single-center, open label Phase 2 (NCT02252835) with two cohorts of volunteer gout subjects (n = 16 each). Subjects were treatment naïve or willing to discontinue urate lowering therapy. Dosing was once daily oral including flare prophylaxis with colchicine. One cohort received arhalofenate 600 mg for 2 weeks followed by sequential one-week co-administration of febuxostat 80 mg and 40 mg. During the final 2 weeks, febuxostat 40 mg alone was continued. The second cohort received arhalofenate 800 mg for 2 weeks, followed by sequential one-week co-administration of febuxostat 40 mg and 80 mg. During the final 2 weeks, febuxostat 80 mg alone was continued. sUA and oxypurines (xanthine, hypoxanthine, guanine) were assessed at multiple time-points. Arhalofenate (800 mg) and febuxostat (80 mg) pharmaco-kinetics were determined in the second cohort.

Results:

Thirty-two subjects were enrolled. Baseline mean sUA were 9.4 and 9.2 mg/dL, respectively. The largest decrease in sUA (63%) was seen in the arhalofenate 800 mg plus febuxostat 80 mg combination. With this treatment, 100% of subjects achieved a goal of < 6 mg/dL, 93% < 5 mg/dL and 79% < 4 mg/dL.

The mean ± SD arhalofenate acid $AUC_{(0\ \tau)}$ was 2,960 ± 730 and 3,190 ± 871 μg·h/mL in the absence and presence of febuxostat, respectively. The ratio of $AUC_{(0\ \tau)}$geometric means of the combination to arhalofenate alone was 108% (90% CI 89-131%).

The mean ± SD febuxostat $AUC_{(0\ \tau)}$ was 11,100 ± 2,940 and 9,590 ± 2,270 ng·h/mL in the absence and presence of arhalofenate, respectively. The ratio of $AUC_{(0\ \tau)}$geometric means of the combination to febuxostat alone was 87% (90% CI 74-103%).

As expected from its mechanism of action, febuxostat alone dramatically increased the plasma levels of oxypurines. These levels were unchanged, or even slightly increased, by the co-administration of arhalofenate.

Arhalofenate, either alone or in combination, was well tolerated and appeared safe. No subjects had >1.5X elevation in serum creatinine or any value above normal.

Conclusion: The combination of arhalofenate with febuxostat was well tolerated, appeared safe and was more efficacious in decreasing sUA than both drugs alone. Arhalofenate decreased the AUC of febuxostat when compared with febuxostat alone, however this was not clinically relevant as this was not associated with a decrease of oxypurines levels. Arhalofenate in combination with febuxostat is now in phase 3 to reduce sUA and prevent gout flares.

Session Date: Tuesday, November 10, 2015

Session Title: Metabolic and Crystal Arthropathies Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: In the randomized, double-blind, placebo-controlled, Phase III CRYSTAL trial, more patients taking lesinurad 200 mg (LESU200) or 400 mg (LESU400), in combination with febuxostat (FBX) 80 mg, achieved serum uric acid (sUA) <5.0mg/dL at 6 months versus FBX + placebo (PBO). Patients completing 12 months on study could enroll in an extension study (NCT01808144). The objective was to examine efficacy and safety in patients taking lesinurad combination therapy for up to 2 years.

Methods: Patients on PBO+FBX in the core study were randomized to LESU200+FBX (200CROSS) or LESU400+FBX (400CROSS). Patients randomized to LESU200+FBX and LESU400+FBX in the core study were continued on their therapy (200CONT, 400CONT). Primary endpoint was the proportion of patients experiencing complete resolution (CR) of ≥1 target tophus (measurable tophus on hands/wrists and/or feet/ankles 5–20mm in longest diameter, using Vernier calipers) during core and extension studies by extension Month 12. The sum of areas for all target tophi, proportion of patients achieving sUA <5.0mg/dL, and proportion of patients experiencing gout flares requiring treatment (GFRT) were secondary endpoints.

Results: Of 235 patients completing the core study, 196 enrolled in the extension: 200CONT (n=64), 200CROSS (n=33), 400CONT (n=65), and 400CROSS (n=34). For those continuing core treatment (200CONT, 400CONT), 59.6% and 66.7% of patients had CR of ≥1 target tophus (Figure), with 68.3% and 72.4% reductions in the sum of areas for all target tophi, respectively, after 2 years. GFRT during extension occurred in 32.8% and 13.8% of patients, with few patients having GFRT during the second year (Figure). Target sUA levels <5.0mg/dL at Extension Month 12 were achieved in 77.1% and 88.5% of patients. For crossover groups (200CROSS, 400CROSS respectively), 43.5% and 50.0% of patients had CR of ≥1 target tophus, with 64.1% and 44.1% reductions in target tophi area after 1 year of combination therapy. GFRT rates during extension were 37.5% and 38.2%, with 79.2% and 71.4% of patients achieving target sUA <5.0 mg/dL. Treatment-emergent adverse events (TEAEs) with extended exposure to lesinurad were generally comparable between groups. The most common TEAEs for the CONT groups were serum creatinine increase (10.9%) and bronchitis (7.0%); for the CROSS groups, nasopharyngitis (13.4%) and headache (7.5%) were most common, with serum creatinine increase occurring in 6.0% of patients.

Conclusion: Patients continuing on lesinurad + FBX therapy over 2 years continued to be at sUA target, with no attenuation of sUA effect. Patients exhibited continued increase in complete resolution of tophi, additional tophi area reduction, and reduction of GFRT over the second year on study. AEs in the extension study were consistent with those observed in the core study.

Lesinurad and Febuxostat Combination Therapy: Analysis of Treatment Based on Patient Baseline Renal Function

Session Title: Metabolic and Crystal Arthropathies Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: A randomized, double-blind, placebo-controlled, Phase III clinical trial showed that lesinurad, a selective uric acid reabsorption inhibitor (SURI), in combination with febuxostat 80 mg (FBX) significantly increased the proportion of patients with tophaceous gout who achieved the serum uric acid (sUA) target of <5.0 mg/dL at 6 months compared to FBX alone. Lesinurad was generally well tolerated, with the 200 mg dose having a safety profile comparable to FBX alone, with the exception of a higher incidence in predominately reversible serum creatinine (sCr) elevations. As renal impairment and hyperuricemia frequently coexist, we aimed to analyze treatment with respect to patient baseline renal function.

Methods: Patient data was obtained from the CRYSTAL study (NCT01510769) where patients with estimated creatinine clearance (eCrCl; Cockcroft-Gault formula using ideal body weight) <30 mL/min were excluded. In current analyses, patients were analyzed by renal baseline function using eCrCl groups of <60, <90, and ≥90 mL/min; statistical analyses were unadjusted for multiplicity.

Results: In total, 324 patients were randomized and included in these analyses. Demographic characteristics, including age, gender, race, weight, and BMI, were broadly similar between patient groups stratified by baseline renal function. The proportion of patients achieving sUA target levels of <5.0 mg/dL was greater in the lesinurad 200 mg + FBX group compared with FBX alone at 12 months in those with eCrCL <90 and ≥90 mL/min (P<0.05 for both) (Table). For lesinurad 400 mg + FBX, the proportion of patients achieving <5.0 mg/dL was greater than FBX alone at Month 6 (P<0.05 for <60; P<0.001 for <90 and ≥90) and Month 12 (P<0.05 for <90 and ≥90).No consistent differences in treatment-emergent AE rates were observed based on baseline renal function (Table). sCr elevations occurred at increased rates in the lesinurad groups (particularly the 400 mg dose) versus FBX + placebo, without evident differences according to baseline renal function.

Conclusion: The results of this Phase III study subanalysis indicate that lesinurad in combination with febuxostat is efficacious in all renal function groups. Safety findings were consistent between treatment groups across all renal function categories.

Table: Efficacy and safety endpoints in CRYSTAL: stratification by baseline eCrCl <60, <90, and ≥90 mL/min

Session Title: Metabolic and Crystal Arthropathies Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Previous studies have shown that long-term urate-lowering therapy (ULT) is required for improvements in gout flare frequency and tophi reduction, and that lower serum uric acid (sUA) levels may result in greater benefit. However, optimal sUA levels to jointly achieve these outcomes within a year using single or combination oral therapies are uncertain, as they come mostly from observational studies. Lesinurad in combination with a xanthine oxidase inhibitor (XOI) is highly effective in reducing and sustaining sUA below target levels in Phase III studies. The current analysis explored the relation between extent of reduction in sUA level and efficacy and safety endpoints in these Phase III studies.

Methods: Patient data were combined from 3 Phase III clinical studies on the efficacy and safety of lesinurad, a selective uric acid reabsorption inhibitor (SURI), in combination with an XOI (allopurinol: CLEAR 1 [NCT01510158], CLEAR 2 [NCT01493531]), or febuxostat: CRYSTAL [NCT01510769]). For the analyses, patients irrespective of treatment assignment were categorized by their on-study median sUA level, which used all scheduled post-baseline sUAs for each individual. Efficacy endpoints included clinical outcomes for ULT: tophus size reduction and proportions of patients experiencing gout flares requiring treatment (GFRT). Safety endpoints included treatment-emergent adverse events (TEAEs).

Results: In total, 1537 patients were eligible for efficacy analysis, including 474 patients with ≥1 target tophi at baseline. Patients with the lowest on-study median sUA levels achieved the greatest reduction in tophus area at Month 12 and were least likely to have GFRT during the last quarter of the study (Figure). GFRTs occurred in 11/90 (12.2%) of patients in the <3 mg/dL sUA subgroup and in 137/689 (19.9%) of patients in the ≥5 mg/dL subgroup (Figure). TEAEs occurred in 82/104 (78.8%) of patients in the <3 mg/dL sUA subgroup and in 671/886 (75.7%) of patients in the ≥5 mg/dL subgroup.

Conclusion: Based on a pooled analysis of 3 Phase III clinical studies, patients with lower median on-study sUA experienced greater reductions in tophus area, as well as a lower likelihood of having a gout flare requiring treatment. A similar safety profile was noted irrespective of the median sUA levels.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Metabolic and Crystal Arthropathies Poster II
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: There is a remarkable, increasing disease burden of gout and its associated cardiovascular-metabolic comorbidities (e.g., hypertension in 74% of cases in the US), underscoring an urgent need for holistic strategies to effectively address these conditions together. The DASH diet, which emphasizes fruits, vegetables, low-fat dairy foods, and reduced saturated and total fat, substantially reduces blood pressure and is also recommended in dietary guidelines to prevent cardiovascular disease (CVD). This approach could also lower SUA levels by its anti-hypertension effects and favorable urate-lowering components, such as low-fat dairy foods. Thus, the DASH diet holds the remarkable promise of "killing two birds with one stone" in the prevention of gout by improving both SUA outcomes and its associated CVD complications. We investigated the SUA response to the DASH diet as compared to a control diet over a 6 month period.

Methods: The DASH trial population consisted of adults with stage 1 hypertension (not on any antihypertensive agents) who received either the DASH diet, a fruit/vegetable-rich diet, or a control diet (reflective of the average American diet) over the span of 8 weeks (NEJM 1997). Sodium intake and body weight were maintained at constant levels to isolate the diet's effect. We

measured SUA levels at baseline and 8 weeks among 327 participants with complete datasets and analyzed the SUA level response. Since our central objective was to examine the potential utility of the DASH diet in the prevention of gout, our analyses had an a priori focus on high risk sub-groups for gout at baseline (i.e., those with hyperuricemia, those who were overweight/obese, and men).

Results: The mean age was 44 years and the mean BMI was 28.1 kg/m^2. Most participants (53%) were men. The overall dropout rate was <4%, and the overall rate of adherence to the diets was > 93% during the 8-week study period. The mean baseline SUA level was 5.70 mg/dL, and the DASH diet reduced SUA levels by 0.24 mg/dL more than the control diet (p = 0.01). Among the 75 subjects with hyperuricemia (men: SUA > 7mg/dL, women: SUA > 6mg/dL), the DASH diet reduced SUA levels by 0.59 mg/dL more than the control diet (p=0.005) and 0.46 mg/dL more than the fruit/vegetable group (p=0.028). Additional benefits included significant improvements in systolic and diastolic blood pressure (**Table**). For example, among 75 subjects with hyperuricemia and hypertension, the DASH diet reduced systolic and diastolic pressure by 5.0 and 3.3 mm Hg more, respectively, than the control diet (P=0.008 and P=0.012 for each).

Conclusion: Our findings suggest that the DASH diet can reduce SUA and blood pressure in high risk groups for gout. This diet offers an additional nutritional approach to preventing (and potentially treating) hyperuricemia and gout, as well as hypertension (a comorbidity present in 74% of gout patients).

Table. Comparison of Mean Changes in SUA and BP in High Risk Subgroups and All Subjects

Category	SUA Change in DASH Group Minus Change in Control Group	SBP Change in DASH Group Minus Change in Control Group	DBP Change in DASH Group Minus Change in Control Group	SUA Change in Fruit/Vegetable Group Minus Change in Control Group
Hyperuricemia (n=75)	– 0.59 (–0.99 to – 0.19)	– 5.0 (–8.6 to –1.3)	– 3.3 (–5.9 to –0.7)	– 0.13 (–0.51 to 0.25)
Overweight/Obese (n= 246)	– 0.26 (–0.47 to – 0.05)	– 5.7 (–7.8 to –3.7)	-2.9 (–4.3 to –1.4)	–0.19 (–0.39 to –0.00)
Men (n=174)	– 0.35 (–0.66 to – 0.04)	– 4.9 (–7.4 to –2.4)	– 2.7 (–4.4 to –0.9)	– 0.20 (–0.48 to – 0.08)
All Subjects (n=327)	– 0.24 (–0.43 to – 0.06)	– 5.9 (–7.7 to –4.0)	– 2.6 (–3.8 to –1.3)	– 0.20 (–0.37 to – 0.03)

SUA = serum uric acid; BP = blood pressure; SBP = systolic blood pressure; DBP = diastolic blood pressure

Session Date: Tuesday, November 10, 2015

Session Title: Metabolic and Crystal Arthropathies Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Xanthine oxidase inhibitors (XOI) reduce both urate levels and oxidative stress in the vasculature, both of which are cardiovascular disease (CVD) risk factors. However, the impact of an individual XOI agent on major cardiovascular events (MCE) may vary based on the agent's efficacy, dosing constraints and mitigating polychronic disease.

Methods:

Gout patients (ICD-9-CM 274.xx), aged >18, with a baseline (12 months) diagnosis of stage 3/4 chronic kidney disease (CKD) and CVD (coronary artery disease (CAD), cerebrovascular disease (CBV) and peripheral vascular disease (PVD)) or heart failure were selected from the MarketScan® databases (January 2009-June 2013) upon initiating urate lowering therapy (ULT) with either allopurinol (ALO) or febuxostat (FBX). Patients were followed until disenrollment, discontinuation of the qualifying ULT or use of the alternate study agent. MCE included myocardial infarction, stroke, transient ischemic attack, non-traumatic, lower extremity (LE) amputation or coronary, cerebrovascular or LE revascularization. MCE incidence was measured per 1000 person-years (PY). Cox proportional hazards models assessed MCE risk as a function of age, gender, region, payer, CKD stage, exposure to other anti-gout medications (NSAID, colchicine, steroids, probenecid), recent CVD hospitalization and a history of CAD, CBV, PVD, heart failure (HF), diabetes or hyperlipidemia.

Results:

A total of 2,426 patients (2056 ALO, 370 FBX) met eligibility criteria (63% male; mean age 73±11). Two thirds of patients had a history of CAD, 18% CBV and 23% PVD. There were no significant differences in CVD type by cohort. Half of patients also had HF and 73% had stage 3 CKD at the time of initiation. A total of 162 MCE occurred during follow-up in 3.8% and 7.2% of FBX and ALO cohorts respectively. A total of 80 patients (3.3%) had a CAD specific MCE, 51 (2.1%) a PVD specific event and 38 (1.6%) a CBV specific event. The MCE rate per 1000 PY (95% CI) in the FBX cohort was 51.8 (28-87) as compared to 99.3 (84-117) in the ALO cohort.

Cox model results suggest significantly increased MCE risk (any MCE) among patients with baseline PVD (HR 2.7; 95% CI 1.9 – 3.7, $p<0.0001$) and baseline CVD/HF hospitalization (HR 1.7; 95% CI 1.2 – 2.5, $p=0.0023$). Model results suggest significantly decreased MCE risk amongst patients initiating on FBX (HR 0.5; 95% CI 0.3 – 0.9, $p=0.02$), with baseline history of another circulatory disorder (HR 0.5; 95% CI 0.3 – 0.85, $p=0.007$) and those receiving other baseline anti-gout medications (HR 0.7; 95% CI 0.5 – 0.998, $p=0.049$). The hazard ratio (95% CI) associated with membership in the FBX cohort on PVD specific outcomes was 0.2 (0.05 – 0.8, $p=0.026$), on CAD specific MCE was 0.6 (0.3 – 1.3, $p=0.20$) and on CBV specific MCE was 0.9 (0.4 – 2.4, $p=0.88$).

Conclusion:

Patients with moderate to severe CKD and CVD/HF initiating on FBX had a significantly lower rate of MCE than patients initiating on ALO. This may be due to the direct effects of lower sUA or the effect of reduced oxidative stress and other pleiotropic effects on the endothelium. It is unclear if this is due to channeling, greater clinical effectiveness on the part of FBX or to ALP under-dosing in renally impaired patients.

Session Date: Tuesday, November 10, 2015

Session Title: Metabolic and Crystal Arthropathies Poster II

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: There is evidence suggesting that high levels of uric acid represent an independent cardiovascular risk factor and that the use of xanthine oxidase inhibitors (XOI) may reduce the risk of major adverse cardiovascular events (MACE) (1). To date, this evidence is based mainly on observational studies (2), which are frequently subject to selection and confounding bias. Our objective in this systematic review and meta-analysis is to compare the incidence of MACE and mortality in patients enrolled in randomized controlled trials (RCTs) comparing XOI with placebo or no treatment.

Methods: A systematic review of the literature searching for RCTs was held on September 9, 2014 using PubMed, EMBASE, Cochrane Library, Web of Science, and Lilacs databases (from their inception), and hand search. The study was conducted and reported in accordance with the recommendations of the PRISMA statement (3), and the protocol was registered in PROSPERO (CRD42015016073). All RCTs comparing XOIs with placebo (or no treatment) lasting four weeks or more were eligible, independent of the presence of comorbidities or outcomes of interest in each particular study. Studies including individuals under the age of 18, as well as treatment or follow-up lasting less than 4 weeks, were excluded from the meta-analysis. The primary outcomes were the incidence of MACE (cardiovascular death, non-fatal myocardial infarction, unstable angina requiring urgent revascularization, or non-fatal stroke) and mortality; total cardiovascular events (TCE), serious adverse events (SAE), and skin rash served as secondary outcomes. Statistical analysis was made using the REVMAN 5.2 software, and associations were analyzed using the Peto or Mantel-Haenszel odds ratios (OR), depending on the frequency of events. A subgroup analysis was performed including only studies in which subjects were at high-risk for cardiovascular events.

Results: In Total, 61 RCTs including approximately 5500 individuals were considered eligible for the meta-analysis. The use of XOI was not significantly associated with the risk of MACE (OR=1.24, 95% CI 0.54 to 2.85, P = 0.61), death (0.93, 0.49 to 1.75, P = 0.82), total cardiovascular events (0.85, 0.61 to 1.18, P=0.33), and SAE (0.98, 0.74 to 1.30, P=0.90). The risk of skin rash was higher in the XOI group (1.89, 1.16 to 3.08, P = 0.01). In a subgroup analysis performed in studies including mainly individuals with high cardiovascular risk profile, there was no significant difference in the risk for MACE (1.05, 0.44 to 2.50, P=0.92), TCE (0.79, 0.57 to 1.11, P=0.18), and death (0.88, 0.46 to 1.67, P=0.70).

Conclusion: A meta-analytical pooling of the results of several RCTs performed in different clinical contexts failed to demonstrate that the use of XOIs is associated with reduced risk of major cardiovascular events, death, any adverse cardiovascular event, and serious adverse events. A small but statistically significant increase in the risk of skin rash was observed in the XOI group.

Atorvastatin-Induced Autoimmune Myopathy: An Emerging Dominant Entity in Patients with Autoimmune Myopathy Presenting with a Pure Polymyositis Phenotype

Océane Landon-Cardinal[1], Yves Troyanov[2], Marvin J. Fritzler[3], José Ferreira[1], Ira Targoff[4], Eric Rich[2], Michelle Goulet[1], Jean-Richard Goulet[1], Josiane Bourré-Tessier[2], Yves Robitaille[1], Alexandra Albert[5] and Jean-Luc Senécal[2], [1]Université de Montréal, Montréal, QC, Canada, [2]Université de Montréal, Montreal, QC, Canada, [3]Division of Rheumatology, University of Calgary, Calgary, AB, Canada, [4]University of Oklahoma, Oklahoma City, OK, [5]Université Laval, Québec, QC, Canada

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Muscle Biology, Myositis and Myopathies Poster II: Autoantibodies and Treatments in Inflammatory Myopathies
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: The classification of autoimmune myopathies (AIM) is evolving. Pure dermatomyositis (DM) and overlap myositis are dominant AIM subsets, while pure polymyositis (pPM) is uncommon and confused with myositis mimickers. Our objective was to evaluate the disease spectrum in patients presenting with a pPM phenotype and to evaluate clinical features, autoantibodies (aAbs) and membrane attack complex (MAC) in muscle biopsies of patients with treatment-responsive, statin-exposed necrotizing AIM.

Methods: Our study included all patients from the CHUM AIM Cohort with a pPM phenotype (i.e absence of DM rash, overlap features and overlap aAbs), a documented response to immunosuppression and a follow-up of at least three years. We selected statin-exposed necrotizing AIM, thus excluding patients with significant inflammatory infiltrates on muscle biopsy or no previous statin-exposure.

Results: Of 17 consecutive patients with pPM, 14 patients had a necrotizing AIM, of whom 12 were previously exposed to atorvastatin (mean duration: 38.8 months). These 12 patients were therefore suspected of atorvastatin-induced AIM (atorAIM) and selected for study. None had overlap aAbs, anti-SRP or cancer. Anti-HMGCR aAbs were present in sera of these 12 patients using addressable laser bead immunoassay.

Three clinical stages of myopathy were recognized: stage 1 (serum CK elevation, normal muscle strength, normal EMG), stage 2 (CK elevation, normal strength, abnormal EMG) and stage 3 (CK elevation, proximal weakness, abnormal EMG). At diagnosis, 10/12 patients (83%) had stage 3 myopathy (mean CK elevation: 7,247 U/L). However the presenting feature was stage 1 myopathy in 6 patients (50%) (mean CK elevation: 1,540 U/L), all of whom later progressed to stage 3 myopathy (mean delay: 37 months) despite atorvastatin discontinuation.

MAC deposition was observed in all tested muscle biopsies (n=13). Three patterns were seen: isolated sarcolemmal deposition on non-necrotic fibers, isolated granular deposition on endomysial capillaries and a mixed pattern.

Oral corticosteroids alone were unable to normalize CKs and induce remission (n=9). Ten patients (83%) received intravenous immune globulin (IVIG) as part of an induction regimen. Of 10 patients with evaluable maintenance therapy (≥ 1-year remission on stable maintenance therapy), IVIG was needed in 5 patients (50%), either with MTX monotherapy (n=3) or with combination immunosuppression (n=2). In the remaining 5 patients, MTX monotherapy (n=3) and combination therapy (n=2) maintained remission without IVIg.

Conclusion: atorAIM emerged as the dominant entity in patients with a pPM phenotype and treatment-responsive myopathy. Isolated CK elevation, i.e. stage 1 myopathy, was the initial mode of presentation of atorAIM. Thus, the new onset of isolated CK elevation on atorvastatin and persistent CK elevation on statin discontinuation should raise early suspicion for atorAIM. Three patterns of MAC deposition were seen and, while non pathognomonic, were pathological clues to atorAIM. AtorAIM was uniformly corticosteroid resistant but responsive to IVIG as induction and maintenance therapy.

Session Title: Muscle Biology, Myositis and Myopathies Poster II: Autoantibodies and Treatments in Inflammatory Myopathies

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Interstitial lung disease (ILD) secondary to connective tissue disease (CTD) is most commonly seen in systemic sclerosis followed by polymyositis and dermatomyositis. Anti-synthetase syndrome is a myositis associated with ILD and antibodies directed against tRNA synthetases. To date, there is no standard of treatment for ILD secondary to CTD, but retrospective data suggest that tacrolimus may be an effective therapeutic option. We conducted a retrospective study to assess the effectiveness of tacrolimus in patients with ILD secondary to CTD.

Methods:

A chart review was performed of adult patients with ILD secondary to CTD who received tacrolimus between December 1, 1996 and December 31, 2014 at a single center academic hospital. A diagnosis of ILD was made based on pulmonary function tests, lung biopsy, high-resolution CT of the chest, and chest radiograph. The primary endpoint was improvement or stability in pulmonary function at six months based on FEV1 (forced expiratory volume in 1 second) and diffusing capacity for carbon monoxide (DLCO). Secondary endpoints included imaging results and clinical measurements at six and 12 months.

Results:

Fifteen cases of ILD secondary to CTD treated with tacrolimus were identified. All patients had a diagnosis of polymyositis, of which two also had systemic lupus erythematosus and Sjogren's syndrome. The mean age was 53 years, 86% were females, and 46% were previous smokers. Clinical characteristics are reported in Table 1. Baseline and six month mean creatinine kinase levels (IU/L) were 794 and 97 respectively. At six months, FEV1 improved in 50% of patients who had available data and in 43% of those with anti-synthetase antibodies (Table 2). Two anti-synthetase positive patients who had DLCO measured at six months showed improvement. FK506 levels were not significantly different between responders and non-responders.

Conclusion:

Tacrolimus appears to be a well-tolerated and effective therapy for stabilizing ILD in patients with CTD, particularly anti-synthetase syndrome. Our small sample size limits the ability to determine whether these findings are statistically significant. Additionally, several patients were on concomitant mycophenolate mofetil. To date, no controlled studies have been conducted to evaluate the effectiveness of tacrolimus in the treatment of ILD secondary to CTD. Our findings warrant larger prospective randomized controlled trials to evaluate and compare the outcomes of tacrolimus therapy as adjunctive or monotherapy for ILD secondary to CTD.

Session Title: Muscle Biology, Myositis and Myopathies Poster II: Autoantibodies and Treatments in Inflammatory Myopathies

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

The aim of the study was to assess the effects of abatacept, a T cell blocking agent, on disease activity and on muscle biopsy features of adult patients with dermatomyositis (DM) or polymyositis (PM).

Methods:

Patients with DM or PM with persisting signs of active disease after treatment with glucocorticoids and ≥ one immune modulating drug for ≥ 3 months were enrolled in this randomized treatment delayed-start design trial to receive either active treatment with intravenous (10 mg/kg) infusions of abatacept or delayed start for 3 months. The primary endpoint was the number of responders, defined as improved according to the International Myositis Assessment and Clinical Studies (IMACS) Group definition of improvement (DOI), after treatment for 6 months. Secondary endpoints were the number of responders in the active treatment arm compared to the delayed onset arm at 3 months, and the efficacy after 6 months treatment on the individual components of the IMACS core set measures for the disease activity, and health-related quality of life assessed by SF-36. In 6 patients muscle biopsies were taken before and after 6 months of treatment and investigated by immunohistochemistry for inflammatory cell markers including CD3, and Foxp3 (regulatory T cells) and for cytokines. Each tissue section was evaluated coded and the degree of inflammation was evaluated by digital image analysis.

Results:

Among 20 randomized patients (9 DM, 11 PM; 13 female, 7 male), 17 were included in the analyses and 8 (47%) achieved the DOI after 6 months of active treatment. No differences between DM and PM or female and male patients were seen.

At 3 months after study start, 5 (50%) patients were responders after active treatment whereas only one (14%) patient in the delayed onset arm was defined as responder. After active treatment for 6 months (n=17), significant improvement was seen in muscle strength, assessed by the manual muscle test (MMT)-8, from (median) 70 to 73 (p=0.0082), in gastrointestinal disease activity from 3 to 0 (p=0.0156), and in muscle disease activity from 18 to 10 (p=0.0133). SF-36 physical was significantly improved from median 31 at start to 36 at end of treatment (p=0.0054). Eight adverse events were regarded as related to the drug (infections, flank pain and dizziness), of which 4 were mild and 4 were moderate. There were 3 serious AE, none of which was related to the drug. These included hospitalization due to fracture, worsening in muscle weakness and pre-existing basal cell cancer. The 6 patients with repeated muscle biopsies had a significant improvement in MMT-8 (p=0.03). There was a significant increase in positively stained area for Foxp3 whereas other markers were unchanged.

Conclusion:

In this pilot study, treatment of PM and DM patients with abatacept resulted in improved muscle performance and health-related quality of life in half of the patients. In patients with repeat muscle biopsies an increased frequency of Foxp3+ cells was recorded suggesting an effect of treatment on cells in muscle tissue.

Session Title: Muscle Biology, Myositis and Myopathies Poster II: Autoantibodies and Treatments in Inflammatory Myopathies
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Rituximab (RIX) has successfully been used for the treatment of severe Jo-1 antibody-associated antisynthetase syndrome (Jo-1 ASS). The aim of this retrospective study was to evaluate the effect of RIX in severe Jo-1 ASS and to determine predictive factors for response.

Methods: 61 patients with Jo-1 ASS were identified in two centres between 2006 and 2014; 18 of these received RIX. 17 patients in a dosage of 2x1g i.v. (day 0 and 14) and 1 patient 4 weekly infusions of 375 mg/m^2 body surface. Treatment cycles were repeated every six months. One patient was lost to follow-up, but the remaining 17 RIX-patients, and 30 out of 43 patients who were treated with conventional immunosuppressive drugs, were followed for a mean of 35 and 84 months, respectively. Anti-Ro52 antibodies in serum were measured with a semiquantitative immunoblotting assay (EUROLINE, Euroimmun, Germany) and the test was validated with standard immunoprecipitation technique.

Results: Polymyositis (in 95%) and interstitial lung disease (ILD, in 67%) were the dominant clinical manifestations. Detection of anti-Ro52 antibodies (in 43%) in serum was significantly associated with acute onset ILD ($p=0.016$) with O_2 dependency, and patients with high concentrations of anti-Ro52 (in 20%) had the highest risk ($p=0.0005$). 16 out of 18 patients (89%) showed a fast and almost complete response to RIX. CK serum concentrations (mean CK was 663 U/l before treatment) dropped to normal values in all patients. Results in pulmonary functional tests improved significantly ($p<0.05$). Prednisolone-equivalent doses per day decreased from a mean of 30.4 mg/d to 6.0 mg/d. Patients received 4.6 cycles of RIX on average (range: 1–13). There were five relapses in four patients. Three of them occurred when intervals between RIX treatment cycles were extended longer than 6 months. In all these patients treatment with RIX was repeated and again had a good effect. Among those patients who were highly positive for anti-Ro52, good response to RIX was seen in 7 out of 7 cases (100%), but no response to either cyclophosphamide (n=4), cyclosporine A (n=3), azathioprine (n=9), methotrexate (n=5) or leflunomide (n=2) was observed in the patients highly positive for anti-Ro52-antibodies who did not receive RIX. One patient treated with RIX and long term medium dose prednisone died of pneumonia after the second treatment cycle. No other severe adverse events occurred during RIX therapy.

Conclusion: RIX seems to be highly effective in the treatment of severe forms of Jo-1 ASS. The presence of high anti-Ro52 antibody concentrations in these patients predicts severe acute onset ILD, non-response to immunosuppressive drugs, but good and lasting response to RIX.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Muscle Biology, Myositis and Myopathies Poster II: Autoantibodies and Treatments in Inflammatory Myopathies

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Adrenocorticotropic hormone (ACTH) gel (repository corticotropin injection) is a long-acting full sequence ACTH that may include other pro-opiomelanocortin peptides thought to have anti-inflammatory and immunomodulatory effects through melanocortin receptors. Its approval by FDA for polymyositis (PM) and dermatomyositis (DM) in 1952 was based on few case reports. We sought to evaluate the efficacy, safety, tolerability and steroid-sparing effect of ACTH gel in refractory adult PM and DM patients in a 6 month prospective, open-label uncontrolled pilot trial.

Methods: 12 adult patients (5 PM; 7 DM) were enrolled at 2 centers. ACTH gel was given as 80 U twice weekly by self-injection. One DM patient withdrew consent before study drug. The primary outcome was the proportion of patients meeting definition of improvement (DOI), defined by IMACS as improvement of ≥ 20% in 3 of 6 core set measures (CSM) with no more than 2 worsening by ≥25% [(which cannot include the manual muscle testing (MMT)]. CSM include MD global, patient global, MMT, health assessment questionnaire (HAQ), muscle enzymes and extra-muscular global assessment. Secondary endpoints included steroid-sparing effect, safety, tolerability and recently proposed myositis response criteria.

Results: Eleven patients (5 PM; 6 DM) were analyzed. Median age was 51 (IQR 37.9, 58.7), with 91% females and 46% Caucasians. All patients "failed" prednisone and a median (IQR) of 2 (2-3) additional immunosuppressive agents. Although the trial is ongoing, 8 patients completed 6 months on the drug and 3 have completed 1, 2 and 4 months in the trial, respectively. One patient stopping drug due to heart block at 2 months is considered a treatment failure. 91% (10/11) of subjects met the primary outcome by a median (IQR) of 3 (2-4) months, but the response was not sustained in 2 patients (on drug). Sustained improvement (DOI at subsequent visits) was seen in 8 (73%) patients. Median relative % improvement in MD global was 73%, 38% in patient global, 14% in MMT, 78% in extra muscular global, 13% in HAQ, 7% in muscle enzymes (Figure 1). Regarding the new myositis response criteria, 9 patients achieved minimal, 6 moderate and 4 major improvement with a median (IQR) total improvement score of 40 (25-65) on scale of 0-100. ACTH gel was safe, well-tolerated, and steroid-sparing with a drop in the median (IQR) prednisone dose from 15 mg (7.5-30) at baseline to 1.25 mg (0-4) at last visit (p=0.001). There were 4 serious adverse events in 3 patients: 2 with herpes zoster related to drug and 1 with musculoskeletal chest pain and 1 with heart block, both unrelated to study drug.

<>**Conclusion:** ACTH gel improved most enrolled myositis patients and was steroid sparing, safe and well tolerated. Viral infections require monitoring. A randomized controlled trial should be considered to further assess its efficacy in myositis.

Figure 1: Median relative percent change in core set measures on treatment with ACTH gel.

Anti-3-Hydroxy-3-Methylglutaryl-Coenzyme a Reductase Positive Myopathy Patients without Statin Exposure May Have a Progressive Disease That Worsens Despite Aggressive Immunosuppressive Therapy

Session Title: Muscle Biology, Myositis and Myopathies Poster II: Autoantibodies and Treatments in Inflammatory Myopathies

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: While the majority of myopathy patients with antibodies recognizing H 3-hydroxy-3-methylglutaryl-coenzyme A reductase (HMGCR) have had a statin exposure, approximately one third have not. In a previous study, we reported on the evolution of antibody titers, muscle strength, and creatine kinase (CK) levels of 17 anti-HMGCR+ subjects with and without statin exposure followed longitudinally between May 2002 and July 2011. We found that (a) antibody titers correlated with CK and muscle weakness and (b) only statin-exposed patients clearly improved with immunosuppressive therapy. Here, we extend that study to these and additional anti-HMGCR+ patients followed for an additional 4 years.

Methods: Anti-HMGCR titers, CK levels, muscle strength and immunosuppressive treatment for each visit were assessed for 117 anti-HMGCR patients of the Johns Hopkins Myositis Cohort. Twenty-six patients were followed longitudinally with more than 4 visits, of which 7 were statin-unexposed.

Results: We confirmed our previous finding that statin-exposed patients experience improved strength, decreased CK levels, and decreased antibody titers with immunosuppressive therapy. Here, we demonstrate for the first time that statin-unexposed patients, despite a decrease in both anti-HMGCR titers and CK levels with immunosuppressive therapy, still have a steady decline in proximal muscle strength (deltoid, $p<0.001$ and hips, $p=0.001$) over time.

Conclusion: Unlike statin-exposed anti-HMGCR+ patients, who improve with immunosuppressive therapy, we found that statin-unexposed anti-HMGCR+ patients had a progressive decline in muscle strength despite aggressive treatement. Interestingly, the decline in muscle strength occurred even though CK levels and antibody titers decreased over time. These observations suggest that statin-exposed and statin-unexposed anti-HMGCR patients may have different underlying pathophysiological processes. Statin-exposed patients seem to have a predominantly autoimmune disease that responds to therapy. In contrast, we hypothesize that statin-unexposed patients have both an autoimmune process and an underlying myodegenerative process. The autoimmune component can be at least partially treated with immunosuppressive therapy, explaining their decreasing CK levels and antibody titers. However, we suspect that an underlying myodegenerative process does not respond to immunosuppression and causes progressive weakness. Future studies will be aimed at determining whether statin-unexposed anti-HMGCR+ patients do, indeed, have an underlying myodegenerative process, such as a muscular dystrophy.

Session Date: Tuesday, November 10, 2015
Session Title: Muscle Biology, Myositis and Myopathies Poster II: Autoantibodies and Treatments in Inflammatory Myopathies
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Intravenous immunoglobulin (IVIg) therapy is recommended for patients suffering from inflammatory myopathies refractory to corticosteroids and immunosuppressive drugs. It is also recommended for patients with myositis who are unable to continue immunosuppression due to adverse reactions (ADRs) or for whom such immunosuppressive therapy is contraindicated. However, long-term IVIg therapy is associated with a risk of systemic adverse reactions, and is also associated with the need of intravenous access, surveillance and hospitalizations. Therefore, employing an alternative route of administration, subcutaneous immunoglobulin (SCIg) was made available. For the majority of patients, IVIg and SCIg are equally efficacious; however, they are not equally exchangeable.

Methods:

A retrospective analysis studied compliance, tolerance and effectiveness (using muscle testing, muscle disability scale and enzyme CK) of a 16,5% SCIg therapy in inflammatory myopathies. Between August 2011 and February 2015, 19 patients were enrolled: 10 with polymyositis (PM), 2 with dermatomyositis (DM) and 7 with inclusion body myositis (IBM).

Results:

Patients on SCIg therapy were followed on average 16.9 months (range: 1 to 42 months). Reasons to switch to the subcutaneous route were: patients being more independent (14/19), therapeutic failure (3/19), end dose effect (1/19), and poor venous access (1/19). Ten of 19 patients previously received IVIg. Average dose of SCIg was 1.7 [±0.4] g/kg/month. General regimen of SCIg treatment included two weekly administrations totalling 130.0 [±73.0] mL/week. Maximally 25 mL/site were infused at 4 sites each. All patients were followed by home delivery companies. Any deviations from the physician-defined protocol were recorded. Regarding treatment efficacy, data on muscle testing and/or functional scale were available for 9 of 12 PM/DM patients. All of these patients significantly improved (p>0,05), and 3 of them had normalized testing (88/88 on muscular testing). In IBM patients, no significant improvement was expected but 4 patients stabilized under SCIg therapy, and 2 patients with initial dysphagia recovered. Ten of 19 patients experienced adverse reactions during the follow-up period. Local reactions (skin rash, swelling, redness, induration, pain or reflux at injection site) and systemic reactions (headache, chills, hot flushes, high blood pressure, dizziness and tiredness) were reported. These ADRs resolved after decreasing the infusion rate, dose adapting or using premedication.

Conclusion:

In all patients, the use of SCIg was feasible and well-tolerated during long-term therapy. Furthermore, relevant improvement in muscle strength was observed in 8 of 14 patients. SCIg therapy allowed for reducing the daily corticoisteroid use in 3 patients and stopping the immunosuppressant therapy in 2 patients. These observations suggest that SCIg could be used as an alternative route to IVIg in auto-immune diseases.

Session Date: Tuesday, November 10, 2015

Session Title: Muscle Biology, Myositis and Myopathies Poster II: Autoantibodies and Treatments in Inflammatory Myopathies

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-MDA5 autoantibody associated syndrome is a novel entity within the spectrum of autoimmune myositis. It has been described as a clinical mimic of the anti-synthetase syndrome, but is associated with a characteristic cutaneous phenotype and, unlike anti-synthetase syndrome, has been associated with rapidly progressive interstitial lung disease (RPILD). This clinical picture has been primarily reported in Asians and has a poor prognosis, especially in the presence of elevated ferritin. However, in North American cohorts these associations are not as clear due to a paucity of data.

The primary goal of our study was to define clinical, biochemical and radiological features predictive of anti-MDA5-associated RPILD that would justify empirical treatment, pending confirmation of anti-MDA5 autoantibody status.

Methods: We retrospectively analyzed the clinical features of 7 patients (pts) who presented with features suggestive of anti-MDA5-associated RPILD and who were subsequently confirmed (or strongly suspected in one case) to have anti-MDA5 autoantibody, using a novel line immunoassay (Euroline, Euroimmun, Lubeck, Germany) in 3 pts.

Results: Six of the 7 pts were men; five were Caucasian. Six pts presented with dyspnea, and RPILD developed in all 7 pts. Anti-MDA5-associated cutaneous signs appeared within one month of respiratory symptoms in 6 (86%) pts, but were recognized at initial presentation in 2 pts. These included palmar or lateral finger papules (n=4), skin ulcerations (n=2), and mechanic's hands (n=4). Gottron papules and sign were sometimes psoriasiform. Shawl and V-signs were not seen, whereas periungueal erythema was always present.

Profound weight loss over 1 to 2 months (mean 21.9 lbs, range 14-37 lbs) and articular symptoms occurred in all pts. One pt had Raynaud phenomenon. Four pts were clinically amyopathic; only 1 pt had CK levels >500 U/L. Hepatic enzymes were elevated in 6 (86%) pts. The ANA test was negative for nuclear and cytoplasmic staining on HEp-2 substrate. Imaging at initial presentation showed ground glass opacities with consolidation in 6 (86%) pts, isolated ground glass opacities in 1 pt, and reticulations in 4 pts, in a bibasilar peripheral distribution in 6 pts.

Four (57%) pts died. Time from hospitalization to death ranged from 6 to 41 days. Time from initial symptoms to death ranged from 6 weeks to 4 months. Survivors received mycophenolate mofetil with or without tacrolimus, concomitantly with corticosteroids. Hyperferritinemia (>1000 mcg/L, n=4 pts) upon admission was associated with a fatal outcome (n=4 deaths).

Conclusion: In an inpatient setting, anti-MDA5-associated ILD can be a rapidly progressive condition with a high mortality. Cutaneous findings are subtle and may follow the respiratory symptoms. Dyspnea, cutaneous findings, profound weight loss, articular symptoms, normal or low CKs with elevated AST/ALT, and absence of nuclear and cytoplasmic fluorescence on ANA testing should alert the clinician to the possibility of anti-MDA5-associated RPILD. Hyperferritinemia is associated with a poor outcome. Early institution of immunosuppressive therapy may prove lifesaving.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Muscle Biology, Myositis and Myopathies Poster II: Autoantibodies and Treatments in Inflammatory Myopathies

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-CADM-140/ Melanoma Differentiation-Associated Gene 5 (MDA5) antibody is found specifically in patients with dermatomyositis (DM). This autoantibody is associated with clinically amyopathic DM (CADM) and rapidly progressive interstitial lung disease especially in eastern Asian population. However, the association of malignancy and anti-CADM-140/ MDA5 antibody had not been examined in detail. Aim of this study is to determine the association between cancer-associated myositis (CAM) and anti-CADM-140/ MDA5 antibody in Japanese patients.

Methods: Sixty-two patients with classic DM or CADM who were seen at our University from 2011 to 2014 were retrospectively evaluated for the associations between anti-CADM-140/ MDA5 antibody and the occurrence of malignancy. CAM was defined as a patient having a cancer within 5 years of DM diagnosis. Anti-CADM-140/ MDA5 antibody were examined by protein immunoprecipitation assay and enzyme-linked immunosorbent assay. Comparisons between two groups were made using the chi-square test.

Results: Of 62 patients, 44 patients were diagnosed as having classic DM (male/female: 15/29, a mean age ± SD: 56.8 ± 13.5) and 18 were diagnosed as having CADM (male/female: 3/15, a mean age ± SD: 54.3 ± 9.6). Sera from 3 patients with classic DM and all 18 patients with CADM were found to contain anti-CADM-140/ MDA5 antibody (6.8%; 3/44 vs. 100%; 18/18, P< 0.0001). CAM was seen in 25.0% (11/44) of classic DM as compared to 5.6 % (1/18) of CADM (P = 0.15). Malignancies in classic DM included lung (3 patients), colon (2 patients) and bladder, lymphoma, breast, oropharynx, external auditory canal and unknown (1 patient each) while CADM included colon (1 patient). CAM was found in only one patient with anti-CADM-140/ MDA5 antibody positive, whereas 11 patients with anti-CADM-140/ MDA5 antibody negative (4.8% 1/21 vs. 26.8% 11/41, P= 0.046).

Conclusion: Anti-CADM-140/ MDA5 antibody was significantly found with a high frequency in patients with CADM as compared to those with classic DM. Malignancy was significantly less found in DM patients with anti-CADM-140/ MDA5 antibody compared with those without this antibody. These results suggest that DM patients with anti-CADM-140/ MDA5 antibody might have a low risk of malignancy.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Muscle Biology, Myositis and Myopathies Poster II: Autoantibodies and Treatments in Inflammatory Myopathies

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The treatment of idiopathic inflammatory myopathies (IIM) is challenging, complicated by its rarity and heterogeneity. Currently few studies have suggested the efficacy of RTX in refractory idiopathic inflammatory myopathies (IIM). The interpretation of their findings is hampered by the lack of a uniform and restrict criteria of refractory myositis. Herein, we established rigorous definition of refractory. The objective of this study was to evaluate efficacy and predictors of clinical improvement of RTX treated-refractory IIM.

Methods: This prospective single-center study included 25 consecutive adult patients with refractory IIM [7 anti-synthetase syndrome, 12 dermatomyositis (DM), 6 polymyositis (PM) - Bohan & Peter, 1975] from 2011 to 2015. Refractory myositis was defined by an inadequate response to prednisone ≥ 0.5mg/kg/day for ≥ three months and at least two other immunosuppressive or immunomodulatory drugs (azathioprine, methotrexate, cyclosporine, leflunomide, mycophenolate mofetil and/or human intravenous immunoglobulin, in their full-dose, for a minimum period of three months). These patients received two infusions of RTX (1g each, two weeks apart). After RTX initiation only one immunosuppressive was maintained and prednisone dose was tapered gradually. In six months evaluation, clinical improvement was defined as a 20% in at least three of the following six core set measures of disease activity: physician's and patient's global assessment of disease activity, manual muscle testing (MMT8), physical function (HAQ), muscle enzymes,

Results: The mean age of patients was 40.2±11.2 years, with 57.7% Caucasian, 88.5% female gender and mean disease duration of 6.4±3.2 years. Forty percent had antisynthetase (of these, 28% anti-Jo-1), 12% anti-Mi-2 and 12% other subtypes. The majority of the patients (74%) achieved clinical response. Comparison of study entry and six months after RTX revealed a reduction in mean glucocorticoid dose (26.1±16.9mg/day vs. 17.2±16.3mg/day *P*=0.008) and improvements of physician's [5.0 (4.0-6.0) vs. 4.0 (2.0-5.0), *P*=0.01) and patient's global assessment [5.0 (3.0-7.0) vs. 5.0 (2.0-5.0) , *P*=0.045) , MMT8 [70.0 (58.0-74.0) vs. 76.0 (64.0-78.0), *P*=0.006), HAQ [1.1 (0.9-1.9) vs. 0.9 (0.3-1.5), *P*=0.02), creatine kinase [481(98-1261)U/L vs. 236 (84-487)U/L, *P*=0.042], aldolase [5.3 (4.4-14.1)U/L vs. 4.1 (3.2-6.1)U/L, *P*=0.002). Further analysis of responders vs. non-responders at baseline identified that autoantibodies were more frequently detected in responder patients (75.0% *vs*. 12.5%, *P*=0.004).

Conclusion: Our study provided evidence of short-term RTX treatment efficacy for refractory IIM. We also confirmed and extended previous observations in overall IIM that myositis autoantibodies is also predictor of RTX treatment response for refractory IIM.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Muscle Biology, Myositis and Myopathies Poster II: Autoantibodies and Treatments in Inflammatory Myopathies
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Dermatomyositis (DM) patients with anti-melanoma differentiation-associated gene 5 (MDA5) antibodies are at increased risk of developing interstitial lung disease (ILD). The natural history of ILD among this subset of DM patients is poorly characterized among non-Asian populations. Skin disease studies in anti-MDA5 DM are largely cross-sectional in nature. We sought to characterize the temporal trends in ILD severity, cutaneous ulceration and calcinosis in anti-MDA5 DM patients.

Methods: We retrospectively reviewed the charts of 25 anti-MDA5 DM patients seen between July 2004 and September 2014.

Results: Of the 25 anti-MDA5 DM patients seen, 23 patients were assessed for evidence of ILD (Table 1). 17 patients (74%) had evidence of ILD corroborated by both pulmonary function tests (diffusion capacity (DLCO) less than 75% predicted or forced vital capacity (FVC) less than 80% predicted) and high-resolution chest computed tomography scans. The median time to ILD development was 5 months, (range 0-71 months), with 89% of patients developing ILD within 9 months from symptom onset.

In the 12 patients with longitudinal data, we found a small, but statistically significant increase in DLCO over time (Figure 1), 0.30% per month (95% CI 0.02-0.58%, p=.036). All 12 patients with ILD received immunosuppressive therapy.

We found a significant inverse relationship between DLCO and ulcer burden (p=0.006, Figure 2). The median times to onset of cutaneous ulceration, ulcer healing and calcinosis were 6, 22 and 30 months, respectively. Use of phosphodiesterase type 5 inhibitors, such as sildenafil, was associated with ulcer healing in 3 patients with recalcitrant cutaneous ulceration.

The proportionate mortality was significantly greater in anti-MDA5 DM patients (5/25=20%) vs non-MDA5 DM patients (7/148=4.7%) (p=.016).

Conclusion: In this cohort, 17 of 25 (74%) of anti-MDA5 DM patients developed ILD, most (89%) within 9 months of symptom onset. The ILD severity as measured by DLCO may improve over time with treatment. Among anti-MDA5 DM patients with ILD, the severity of their skin ulceration appears to correlate with ILD severity. The classic mucocutaneous feature of anti-MDA5 DM, cutaneous ulceration, appears during the onset of ILD but usually resolves and is replaced by calcinosis.

Session Title: Muscle Biology, Myositis and Myopathies Poster II: Autoantibodies and Treatments in Inflammatory Myopathies

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Clinically amyopathic dermatomyositis (CADM) patients have the classic rash (es) of DM but no objective proximal muscle weakness. Asian studies report a unique clinical phenotype in anti-MDA5 (+) CADM which has not been well described in the U.S. Our goal was to determine the clinical features associated with the anti-MDA5 autoantibody (autoAb) in CADM as compared to classic DM in U.S. patients.

Methods: CADM patients were selected consecutively from patients prospectively enrolled in a computerized university Myositis Center database between January 1985 and July 2013. CADM was defined by a typical DM rash without objective muscle weakness for at least 6 months after rash onset and no or minimal abnormalities of serum muscle enzymes [< 3 x ULN], electromyography or muscle biopsy. Classic DM was defined as probable or definite by the criteria of Bohan and Peter and 1:1 matched (gender and age +/- 5 years) to CADM patients. Clinical features were extracted from the database and supplemented with electronic medical record review when necessary.

Results: We identified 61 CADM patients (female 64%; mean age 44.8) and 61 matching classic DM controls (female 62%; mean age 48.2). Anti-MDA5 frequency was similar in both cohorts (13.1% [8/61] vs. 13.1% [8/61]). Anti-MDA5 positivity was associated with a higher likelihood of vasculitic rash and digital tip ulceration and with a trend towards more abnormal capillary microscopy and a lower frequency of Raynaud phenomenon compared to anti-MDA5 negative patients. The frequency of Gottron sign or papules, heliotrope rash and mechanic hands were similar in both groups. However, puffy fingers and dysphagia frequency were significantly higher in the anti-MDA5+ patients. Anti-MDA5 positivity was significantly associated with interstitial lung disease (ILD) ($p=0.043$), rapidly progressive ILD (RPILD) ($p<0.001$), and poor survival ($p=0.007$). Multivariate analysis suggested that anti-MDA5 positivity was predictive of poor survival even after controlling for diagnosis, age at diagnosis, gender, ethnicity, smoking, and ILD ($p=0.001$). ILD frequency was similar in CADM and classic DM (31.1% vs. 26.2%) as was RPILD (8.2% vs. 5%). CADM patients were more likely to have heliotrope rash and dysphagia as compared to classic DM patients. The remaining clinical features were similar for both CADM and classic DM cohorts (Table 1).

Conclusion: Anti-MDA5 positivity has a similar frequency in CADM and classic DM patients in the U.S. Anti-MDA5 autoAb is associated with a unique clinical phenotype consisting of ILD, RPILD, and a vasculitic rash with digital tip ulceration. CADM patients had more dysphagia and heliotrope rash as compared to classic DM, apart from obvious disease-defining features of muscle weakness and muscle enzyme.

Table 1. Clinical features of anti-MDA5 positive and CADM patients as compared to anti-MDA5 negative and classic DM patients, respectively.

Clinical features	MDA5 + (N = 16)	MDA5 – (N = 106)	p value	CADM (N = 61)	Classic DM (N = 61)	p value
ILD	50%	25.5%	0.04	31%	26%	0.46
RPILD	87.5%	3.7%	<0.001	8%	5%	0.55

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Muscle Biology, Myositis and Myopathies Poster II: Autoantibodies and Treatments in Inflammatory Myopathies

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Interstitial lung disease (ILD) is the most common cause of mortality in polymyosytis (PM) and dermatomyositis (DM). It is well known that the DM patients with anti- melanoma differentiation-associated gene 5 (MDA5) antibody (Ab) frequently develop acute progressive ILD and fatal outcome within the first year from the onset. Although survival rate of anti-MDA5-positive patients tends to be sustained after 6 months from the treatment, the characteristics of ILD-recurrent cases are still unclear. Here, we intended to investigate the characteristics of recurrent ILD among anti-MDA5-positive DM-ILD patients.

Methods: Clinical data and serum samples were collected from adult Japanese anti-MDA5-positive DM-ILD patients who visited our department from January 2006 to May 2015. 14 of 20 patients were alive after more than one year from the onset and treated with high dose glucocorticoids (GC) and intravenous cyclophosphamide (IVCY) therapy as the initial treatment. The patients who showed the recurrent symptoms after at least 6 months since the last IVCY therapy were defined as recurrence group. Anti-MDA5 was screened using the immunoprecipitation assay with [^{35}S] methionine-labelled HeLa cells.

Results: 14 patients treated with high dose GC and IVCY therapy as initial treatment survived after more than 6 months. Among these patients, 4 (29%) showed the recurrence. Among them, 3 (75%) were exacerbation of ILD and 1 (25%) was arthritis. The average duration from the last IVCY therapy to recurrence was 42.5±7.9 months. The lymphocyte counts before the initial treatment were significantly lower in recurrence group than in no-recurrence group (556±187 vs 992±118, $P<0.05$). Moreover, the total dose of IVCY until recurrence was significantly lower in recurrence group (7758±1137 vs 10364±758mg, $P<0.05$). There were no significant differences in age, sex, duration of diseases, and minimal dose of GC. 3 of 5 (60%) who were treated without calcineurin inhibitors (CNI) showed the exacerbation of ILD, whereas none of 11 who were treated with CNI ($P<0.05$).

Conclusion: Our study clarified the clinical features of recurrence among anti-MDA5-positive DM-ILD patients. The enough dose of IVCY after the induction of remission combining with CNI as well as high dose GC should be strongly recommended to prevent the recurrence of ILD in anti-MDA5-positive DM-ILD patients.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Muscle Biology, Myositis and Myopathies Poster II: Autoantibodies and Treatments in Inflammatory Myopathies
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: arthritis, myositis and interstitial lung disease (ILD) are reported in up to 90% of patients affected by antisynthetase syndrome (ASSD) and thus represent the most common manifestations of this rare condition. Arthritis presentation ranges from symmetrical polyarthritis to oligoarticular/asymmetrical arthritis. IgM-rheumatoid factor (RF) and anti-cyclic citrullinated peptide antibodies (ACPA) may be positive, and joint erosions mat be observed at plain radiographs of hands and feet. On this basis, in ASSD differential diagnosis with rheumatoid arthritis (RA) may be challenging. Arthritis may occur at disease onset, with or without myositis and/or ILD, or during the follow-up. The aim of this multicenter, international, retrospective study was to assess whether in ASSD the timing and the cluster of onset with other typical disease manifestations may influence arthritis characteristics

Methods: anti Jo-1 positive patients presenting with arthritis (joints swelling and tenderness required) were included in the study. Clinical, radiology and laboratory characteristics of arthritis and the occurrence of myositis and ILD, were retrospectively reviewed. Patients were divided in 3 groups: Group 1) isolated arthritis at disease onset, Group 2) arthritis associated with myositis and/or ILD at disease onset, Group 3) arthritis occurrence after disease onset

Results: the starting cohort included 252 anti Jo-1 positive ASSD. Arthritis was identified in 186 (74%) cases and it was mainly polyarticular and symmetrical (120, 65%). The remaining patients (64, 36%) had an oligoarticular/asymmetrical arthritis. RF-IgM was positive in 54/154 patients tested (30%). ACPA were positive in 19/139 patients tested (14%). Hands and feet plain radiographs were available in 179 patients, in 39 cases (22%) with evidence of erosions. Anti Ro antibodies were positive in 102/180 patients tested (57%). Patients' characteristics and statistical significances between groups are shown in table 1. Symmetrical polyarthritis was the main pattern of presentation in all groups. Ig-M RF positive and joint erosions were less common in patients without arthritis at disease onset (Group 3) than in those presenting with isolated arthritis (Group 1). ACPA and joint erosions were more common in Group 1 than in Group 2

Conclusion: in anti Jo-1 positive ASSD, the timing and the cluster of appearance influence arthritis features. According to our findings, heterogeneity within the clinical spectrum of arthritis is one of the main characteristics of anti Jo-1 positive ASSD. Typical RA features are more common at disease onset and in patients presenting with isolated arthritis

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Muscle Biology, Myositis and Myopathies Poster II: Autoantibodies and Treatments in Inflammatory Myopathies

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Dermatomyositis (DM) and polymyositis (PM) are forms of IIM that involve skeletal muscle as well as many other organs. As in other systemic rheumatic diseases the IIM are characterized by the production of various autoantibodies that are of diagnostic and prognostic help because they are frequently associated with specific clinical subgroups. To determine the frequency of anti-nuclear antibodies (ANA), myositis specific autoantibodies (MSA) and myositis associated autoantibodies (MAA) in Latin-American patients with IIM from various centers of Mexico, Central and South America.

Methods: 155 serum samples from unselected patients with IIM were included in the study: 109 from México, 20 from Peru, 16 from Dominican Republic and 10 from Argentina. DM and PM were diagnosed according to the Bohan and Peter criteria**.** ANA were detected by IIF on HEp-2 cells (Antibodies Inc., Davis, CA, USA), MSA and MAA were tested by a line immunoassay method (Euroline Myositis Antigens Profile 3) (Euroimmun, Luebeck, Germany). In addition, anti-HMGCR was detected with an addressable laser bead immunoassay (ALBIA: Luminex)

Results: Of the 155 IIM patients, 106 (68%) had DM, 37 (24%) PM and 12 (8%) JDM. Mean age 42.4 (6-79 years), 117 (75%) were female and 38 (25%) were male. The frequency of ANA was 51%, being more frequent in Mexico (54%) than in Argentina (50%), Dominican Republic (44%), and Peru (40%); not statistically significant ($p = 0.20$; Chi square test for trend). The most frequent patterns were speckled (82%) and cytoplasmic (10%). The highest dilution (1:1,280) was present in 42% of the patients. The frequency of MSA was Mi-2 (21%), HMGCR (6%), Jo-1 (2.5%), PL-12 (2.5%), SRP (2.5%), PL-7 (1.2%), EJ (1.2%), and OJ (1.2%). Anti-Jo-1 was not present in the sera from Peru and Dominican Republic. The frequency of MAA was Ro-52/TRIM21 (18%), PM-Scl75 (3.8%), Ku (3.8%) and PM-Scl100 (1.5%); however, anti-Ro52/TRIM21 was not detected in sera from Peru and Dominican Republic.

Conclusion: This is the first study of ANA, MSA and MAA from eight centers in the PANLAR myositis study group. We observed a general prevalence of 51% of ANA by IIF, but more frequent in Mexico (54%). In relation to MSA and MAA, anti-Mi-2 was the more frequent (21%), a finding that is in contrast to studies in other geographic areas in which anti-synthetase antibodies tend to be more common. In general, we found some differences in the presence of these two groups of antibodies in the Latin-American countries included in this study.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Muscle Biology, Myositis and Myopathies Poster II: Autoantibodies and Treatments in Inflammatory Myopathies

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Pulmonary arterial hypertension (PAH) may be a disease manifestation of patients with anti-PM-Scl antibody (PM-Scl). In the 2014 ACR annual meeting we reported significantly higher prevalence of precapillary PAH proven by right heart catheterization (RHC) in our patients with PM-Scl compared to historical general population. This study aimed to further characterize PAH in our cohort of patients with PM-Scl.

Methods: All patients screened for PM-Scl between October 1999 and April 2014 were evaluated through our electronic medical record. PAH had to be established by RHC and patients were further subdivided into 'PAH with interstitial lung disease (ILD)' and 'PAH without ILD'. The patients were defined to have 'PAH with ILD' if RHC confirmed pre-capillary PAH and forced vital capacity (FVC) was < 60% of predicted. High resolution CT scans (HRCT) were reviewed by a thoracic radiologist with expertise in ILD (RY), and scored to estimate severity of ILD according to the criteria defined by Ooi et al (Acta Radiologica 2003;44:258-264). Radiographic diagnoses on HRCT [cellular non-specific interstitial pneumonia (NSIP), fibrotic NSIP, usual interstitial pneumonia (UIP), and organizing pneumonia (OP)] were determined. Also, the correlation between HRCT score and mean pulmonary artery pressure (mPAP) was analyzed.

Prevalence of PAH in the general population and in patients with SSc were identified by a systematic literature review. A meta-analysis was performed to formulate prevalence of pre-capillary PAH in SSc patients both with and without ILD. Estimates of prevalence were compared using exact binomial tests.

Results: Of the 42 patients with PM-Scl, 3 patients (7.1%) had PAH with ILD and 2 patients (4.8%) had PAH without ILD. Among the 3 patients with PAH with ILD, 2 had cellular NSIP and 1 had UIP. Due to the small sample size it was difficult to establish any significant linear correlation between mPAP and HRCT score. Systematic literature review identified 5 studies looking at prevalence of PAH in the general population, 3 evaluating PAH with ILD in SSc and 7 assessing PAH without ILD in SSc. Based on these studies the mean prevalence of PAH in the general population was 8.6/million and the maximum estimated prevalence of PAH in the general population was 13.8/million. These numbers were statistically lower than the prevalence of pre-capillary PAH in our cohort ($P<0.001$) and that of PAH without ILD ($P<0.001$). Meta-analysis revealed the estimated prevalence of pre-capillary PAH in patients with SSc was 6.3% (95%CI 4.6-8.6%), that of PAH with ILD in patients with SSc was 2.1% (95%CI 1.3-3.5%), and that of PAH without ILD in patients with SSc was 6.4% (95%CI 4.6-9.0%). In comparison to our cohort with PM-Scl no statistically significant difference was noted but there was a trend towards a higher prevalence of PAH with ILD in our cohort compared to that in SSc patients (7.1% vs 2.1%, $P=0.058$).

Conclusion: Prevalence of PAH in patients with PM-Scl may be higher than that in the general population but may be comparable to the prevalence of PAH in SSc. Prevalence of PAH with ILD may be higher in patients with PM-Scl compared to that in SSc patients. In this small study, it was difficult to ascertain any correlation between ILD severity and mPAP.

Interstitial Lung Disease in Patients with Anti-PM-Scl Antibody

Hiromichi Tamaki[1], Ruchi Yadav[2], James Bena[3] and Soumya Chatterjee[4], [1]Department of Rheumatic and Immunologic Diseases, Cleveland Clinic Foundation, Cleveland, OH, [2]Diagnostic Radiology, Cleveland Clinic, Cleveland, OH, [3]Department of Quantitative Health Sciences, Cleveland Clinic Foundation, Cleveland, OH, [4]Cleveland Clinic Foundation, Cleveland, OH
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Muscle Biology, Myositis and Myopathies Poster II: Autoantibodies and Treatments in Inflammatory Myopathies
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with anti-PM-Scl antibody (PM-Scl) can present with several different phenotypes: polymyositis (PM), dermtomyositis (DM), systemic sclerosis (SSc), scleromyositis, or sclero-dermatomyositis. Interstitial Lung Disease (ILD) is a disease manifestation of SSc and PM/DM. However, characteristics of ILD in patients with PM-Scl have not been characterized in the published literature.

Methods: All patients screened for PM-Scl between October 1999 and April 2014 were evaluated through our electronic medical record (EMR) and patients with positive PM-Scl were identified. Data on demographics, rheumatologic diagnoses (PM, DM, SSc, PM-SSc, DM-SSc), and high resolution computed tomography (HRCT) defined interstitial lung disease (ILD) were extracted from their EMR. Available HRCT images were reviewed by a thoracic radiologist with expertise in ILD (RY). Radiographic diagnoses on thoracic HRCT scan [cellular non-specific interstitial pneumonia (NSIP), fibrotic NSIP, usual interstitial pneumonia (UIP), and organizing pneumonia (OP)] were determined. The degree of parenchymal inflammation and fibrosis were scored using the criteria defined by Ooi (Acta Radiologica. 2003;44:258-264) Comparisons between initial and follow-up scans were performed using Wilcoxon signed rank tests.

Results: PM-Scl was detected in 42 patients. Of these, ILD was described on HRCT scan in 27 patients (64.2%). HRCT images were available for review in 23 patients; 17 (73.9%) were female. The rheumatologic diagnoses of these patients include diffuse cutaneous SSc (dcSSc) (n=1), limited cutaneous SSc (lcSSc) (n=4), PM (n=6), DM (n=3), overlap of dcSSc and DM (n=1), overlap of lcSSc and PM (n=2), overlap of lcSSc and DM (n=4) and other diagnoses (n=2). HRCT diagnoses of these 23 patients include fibrotic NSIP (n=13), cellular NSIP (n=6), organizing pneumonia (OP) (n=2), UIP (n=1), and bronchiolitis (n=1). Fifteen patients had follow-up HRCT images available after a mean interval of 46.5 months. The initial HRCT scans indicated fibrotic NSIP (n=8), cellular NSIP (n=5) and OP (n=2). Of the 5 patients with initial cellular NSIP, 3 patients continued as cellular NSIP and 2 progressed into fibrotic NSIP. Two patients with initial OP developed fibrotic NSIP on follow up HRCT scan. The mean total HRCT score on the initial scan was 6 and the mean HRCT score on the follow up scan was 6.6 (P=0.14). The mean inflammation score on the initial scan was 4.9 and that of fibrosis score was 1.1. On the follow up HRCT scan the inflammation score was 4.4 (P=0.41) and the fibrosis score was 2.2 (P=0.063). All patients received immunosuppressive therapy including glucocorticoids (n=15), azathioprine (n=10), mycophenolate mofetil (n=4), methotrexate (n=3), tacrolimus (n=2), rituximab (n=2), leflunomide (n=2), cyclophosphamide (n=1) and intravenous immunoglobulin (n=4).

Conclusion: NSIP was the predominant HRCT-based subtype of ILD in our cohort of patients with PM-Scl. All patients received immunosuppressive therapy. The total lung score did not change significantly over a mean follow-up period of 46.5 months but fibrosis score showed an upward trend over the study period.

Abstract Number: 2376

Clinical Features in Dermatomyositis Patients with Novel Autoantibody to Small Ubiquitin-like Modifier Activating Enzymes (Anti-SAE Antibody) and Relationship to Interstitial Lung Disease: A Systematic Review of 29 Cases

Sirada Panupattanapong[1], Jessica Sun[2] and Kevin Baszis[1], [1]Pediatrics, Division of Rheumatology, Washington University School of Medicine, St. Louis Children's Hospital, St. Louis, MO, [2]Pediatric, Division of Rheumatology, Washington University School of Medicine, St. Louis Children's Hospital, St. Louis, MO

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Muscle Biology, Myositis and Myopathies Poster II: Autoantibodies and Treatments in Inflammatory Myopathies

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Anti-SAE antibody is a novel myositis-specific antibody first described in 2007. SAE is an enzyme that facilitates sumoylation, leading to the formation of stable conjugates of target proteins including transcription factors. Anti-SAE is observed exclusively in dermatomyositis patients and has not been seen in other types of myositis or healthy controls.

We conducted a systematic review of case series to summarize the clinical features of this group of patients. As interstitial lung disease is a major cause of mortality in dermatomyositis, we conducted a univariate analysis to identify association of clinical features with interstitial lung disease.

Methods:

A systematic electronic search of PubMed and EMBASE was conducted, with no language restriction, from database inception through April 2015, for articles containing clinical data of patients with anti-SAE antibodies. Statistic analysis was done using Excel and SPSS version 22.0. Characterization of the features was analyzed using descriptive statistics and Fisher's exact test.

Results:

Five publications met our inclusion criteria. From 874 reported dermatomyositis cases, anti-SAE was detected in 29 cases (3.3%). There was no sex preponderance (male 41.6% and female 58.3%). The mean age of onset was 59 ± 16.3 years, except for one case of juvenile dermatomyositis, which presented at 5 years of age. The majority of patients with anti-SAE (70%) initially presented with hallmark cutaneous findings; 84% of these patients eventually developed myositis. The most common cutaneous findings were Gottron papules (81.8%), heliotrope rash (68.9%), periungual lesions (66.6%), and Gottron signs (lesions on elbows and knees, 65.5%). 56% of patients had systemic symptoms, including fever, weight loss and elevated inflammatory markers. Arthritis (13.7%), Raynaud's phenomenon (12.5%), and mechanic's hands (5.5%) are uncommon features. None developed calcinosis. Concurrent malignancy presented in 20.7% of cases (2 colon, 1 rectal and 1 ovarian cancer). 44.4% of patients had dysphagia, and 25% of them had more severe disease requiring enteral feeding. Degree of interstitial lung disease was mild and was reported in 31% of patients. In comparison between individuals with and without interstitial lung disease, periungual lesions, shawl sign and V-sign were associated with presence of interstitial lung disease (p 0.008, p 0.004, and p 0.048 respectively).

Conclusion:

The most prominent presenting features of dermatomyositis patients with anti-SAE are systemic symptoms and cutaneous findings, the majority of which eventually develop muscle involvement. Interstitial lung disease and dysphagia are fairly common. Further study from larger databases is warranted to accurately evaluate the distinct clinical features, prognosis and response to treatment of patients with this antibody.

Table 1: Clinical features and association to interstitial lung disease

Clinical features	Total (%)	ILD (%) n=9	Non-ILD (%) n =20	p-value
Arthritis	4/29 (13.7%)	0	21.0%	0.65
Calcinosis	0	0	0	-
Cancer	6/29 (20.7%)	22.2%	20.0%	0.89
Dysphagia	12/27 (44.4%)	44.4%	44.4%	1.0
Elevated CK	20/25 (80%)	75.0%	82.3%	0.672
Mechanic's hands	1/18 (5.5%)	12.5%	0	0.193
Gottron papules	18/22 (81.8%)	75%	85.7%	0.537
Gottron signs	19/29 (65.5%)	44.4%	75%	0.114
Heliotrope rash	20/29 (68.9%)	77.7%	65.0%	0.159
Muscle weakness	26/27 (96.3%)	87.5%	100%	0.112
Periungual lesions	16/24 (66.6%)	100%	52.9%	0.008
Raynaud's phenomenon	2/16 (12.5%)	0	20%	0.152

Session Title: Muscle Biology, Myositis and Myopathies Poster II: Autoantibodies and Treatments in Inflammatory Myopathies

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Statins are among the most frequently prescribed medications for the treatment of dyslipidemia. Amongst users, between 9-20% of

patients will develop a self- limited myopathy in which musculoskeletal symptoms may range from myalgia to rhabdomyolysis (0.4/10 000 patient years)(1-4). In the last decade, there has been considerable interest focusing on an association between statin exposure, anti-3-hydroxy-3-methylglutaryl-coenzyme A reductase (HMGCR) antibodies and autoimmune necrotizing myopathy. Systemic sclerosis is a highly heterogenous disease characterized, among other things, by autoantibodies and inflammatory myositis. The objective of this study was to investigate the frequency of anti- HMGCR antibodies in SSc and associations with inflammatory myositis and statin exposure.

Methods:

This was a cross-sectional, multicenter study of 306 subjects from the Canadian Scleroderma Research Group cohort who had complete data on statin exposure and history of inflammatory myositis (recorded by a study physician at baseline) and anti-HMGCR antibodies assayed by an addressable laser bead immunoassay (ALBIA, Luminex, Austin, TX (cutoff 200 units, high positive cutoff 500 units). Descriptive statistics were used to summarize the baseline characteristics of the subjects. Fisher's exact test for categorical variables and Mann Whitney U test for continuous variables were used to compute p values. All statistical analyses were performed with SAS v.9.2 (SAS Institute, USA).

Results:

Fifty-one (17%) subjects had anti-HMGCR antibodies, of which only 4 (1.3%) had high positive titers (Table 1). Subjects with high positive anti-HMGCR antibodies titers tended to be older (mean 60.3+14.9 versus 56.1+12.5 years) compared to negative subjects. They tended to have shorter disease duration (8.6+5.6 versus 11.2+9.0 years) and more diffuse skin involvement (75% versus 58%), pulmonary hypertension (67% versus 10%, p=0.03) and interstitial lung disease (75% versus 35%) compared to negative subjects. They also tended to have more severe heart disease when measured on the Medsger Disease Severity Scale (2.0+1.6 vs 0.5+0.9, p=0.005).

Of particular interest, though, none of the subjects with high positive anti-HMGCR antibodies titers had a history of inflammatory myositis, compared to 9% of those with negative titers. In addition, none of those with high positive titers had past or current exposure to statins compared to 11% of those with negative titers.

Conclusion:

High titer anti-HMGCR antibodies are rare in SSc (1.3%) but are not associated with inflammatory myositis or statin exposure. Larger studies will be required to confirm these preliminary observations. Nevertheless, we conclude that anti-HMGCR antibodies are unlikely to play a major role in inflammatory myositis in SSc and that high titers can be present in subjects without exposure to statins.

Mycophenolate Mofetil As a Steroid Sparing Agent in Polymyositis and Dermatomyositis: a Systematic Review of the Literature

Janet Roberts and Stephanie O. Keeling, Medicine, University of Alberta, Edmonton, AB, Canada
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Muscle Biology, Myositis and Myopathies Poster II: Autoantibodies and Treatments in Inflammatory Myopathies
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Idiopathic inflammatory myopathies (IM's) including polymyositis (PM) and dermatomyositis (DM) are rare systemic autoimmune diseases causing chronic muscle inflammation with significant morbidity and mortality. Corticosteroids are the primary treatment; however, given the chronic nature of these conditions and the inherent risk of long term steroid use, additional immunosuppressive agents are often required. Myocophenolate mofetil (MMF) may be beneficial in the treatment of IM's with a relatively favorable side effect profile. We systematically reviewed the literature to evaluate the benefits of MMF in the treatment of PM and DM.

Methods:

A systematic review of four databases (Embase, Pubmed, Web of Science and Scopus) using keywords pertaining to IM's, DM, PM, immunosuppression and MMF was conducted. All studies up to June 2014 including patients over the age of 18 with PM or DM defined by Bohan and Peter and treated with MMF were included. Two reviewers independently reviewed the title screen

and data was extracted using a standardized form. Primary outcomes included changes in corticosteroid dose, muscle enzymes, strength, skin manifestations, and interstitial lung disease outcomes (ILD) (computed tomography (CT) scan and pulmonary function tests (PFTs)).

Results:

One hundred and ninety (190) full articles were reviewed after the title screen of 458 articles. Eighteen articles met inclusion criteria including 5 case reports, 11 case series and 2 open label trials. A total of 110 patients (PM 16; DM 46) were treated with MMF. Ninety three percent of patients were on concomitant corticosteroids (n=102), with 89% (n=91) decreasing their steroid dose after initiation of MMF. Of those with baseline elevation in muscle enzymes, 77% (n=30) showed a decrease post treatment. In 10 patients, the change in CK was not specified. In those patients with skin manifestations (n=32), 88% (n=28) showed improved skin manifestations. In the 51% (n=56) of ILD patients, improvements were noted in PFTs, perceived dyspnea and CT scan findings, including improvement in ground glass opacities and pneumonitis. Side effects (21%) were generally mild, most common being gastrointestinal upset. Only 7% (n=8) required cessation of treatment due to side effects.

Conclusion:

MMF is a potential alternative first line steroid-sparing agent in those with IM's. High quality trials are needed to further evaluate the efficacy and safety of MMF in this patient population. Lack of consensus on diagnostic approaches and outcome measures in IM research limits the ability to compare individual patients and studies. The development of core set measures by the International Myositis Assessment and Clinical Studies Groups (IMACS) will allow collaboration between multiple disciplines and centers to increase the quality and number of trials in this area.

Table 1. Change in IM outcomes with Mycophenolate Mofetil According to Study

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Muscle Biology, Myositis and Myopathies Poster II: Autoantibodies and Treatments in Inflammatory Myopathies
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: arthritis, myositis and interstitial lung disease (ILD) constitute the classic clinical triad of antisynthetase syndrome (ASSD). Even if reported in up to 90% of cases, concomitant onset of these manifestations uncommon. A recent study has shown that 60% of anti Jo-1 positive ASSD presenting without the complete triad may develop other manifestations in a very wide range of time. At baseline, the only predictor of subsequent disease pattern evolution is the onset with just one of the classic triad findings, whereas the occurrence of other ASSD typical but less frequently observed manifestations, such as Raynaud's phenomenon (RP), fever or mechanic's hands (MH), does not add further information. The aim of this multicenter, international, retrospective study is to assess whether the appearance of RP, fever or MH (defined as *accompanying features*) during the follow-up may predict the subsequent occurrence of the baseline absent classic triad manifestations

Methods: anti Jo-1 positive patients presenting with no more than 2 classic triad findings (for a practical purpose defined as *incomplete ASSD*) were included in the analysis. Clinical characteristics and different clusters of disease manifestations were retrospectively collected and analyzed

Results: we identified 170 patients (126 females, 44 males) with incomplete ASSD. The median age at disease onset was 53 years (IQR 42-64), median follow-up 88 months (IQR 48-155). Ninety-nine patients (58%) developed new classic triad manifestations and 41 (24%) new accompanying features, especially in those patients in whom isolated arthritis was the first manifestation (p=0.0049). In these 41 patients, the subsequent ex-novo appearance of classic triad features was statistically

increased (p=0.0170) and it was always concomitant or subsequent to the development of accompanying features. Furthermore, these patients had more frequently all triad manifestations (p=0.0004). The clinical characteristics of patients and statistical significances are reported in table 1 and 2

Conclusion: in anti Jo-1 positive patients with incomplete ASSD the occurrence of RP, fever or MH during the follow-up may suggest the subsequent occurrence of new classic triad manifestations

Session Title: Muscle Biology, Myositis and Myopathies Poster II: Autoantibodies and Treatments in Inflammatory Myopathies

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Jo-1 positive myositis patients tend to have more severe muscle and lung involvement than PM-Scl positive patients

Background/Purpose: Jo-1 and PM-Scl positive myositis patients share many clinical features, however the differences between these two subtypes is unknown. The purpose of this study was to determine the unique phenotypes of these two subgroups.

Methods: From 5/1/2002 to 4/15/2015, 1700 patients with suspected myositis were enrolled in a longitudinal cohort study at our center. Patients were included in our analysis if they met Bohan and Peter (B&P) criteria for definite/probable polymyositis (PM)

or dermatomyositis (DM) and were positive for Jo-1 antibody or PM-Scl antibody. Only patients who had confirmed autoantibody testing at a CLIA certified lab were included. Retrospective chart review was conducted from the time of first clinic visit until 4/15/2015 or last clinical encounter. To determine the severity of disease phenotype maximum creatine kinase (CK) and aldolase, the lowest DLCO and forced vital capacity (FVC) was used to assess the severity of lung function. Muscle strength at first visit was scored on a modified 10-point scale adapted from the manual muscle strength testing scale recommended by the International Myositis Assessment and Clinical Studies Group. Right and left sided measurements were combined (range of 0-20). The presence of edema or fatty replacement on MRI of the thighs was categorized as a dichotomous variable. Pulmonary hypertension was defined by either echocardiography or cardiac catheterization and ILD on imaging findings. Differences in baseline characteristics of patients with Jo-1 vs. PM-Scl antibodies were assessed by Fisher's exact and student's t tests.

Results: A total of 91 patients were identified in our single-center database who met the B&P criteria for PM or DM and were positive for either Jo-1 or PM-Scl autoantibodies. Of the 91 patients, 60/91 (65.9%) were Jo-1 positive and 31/91 (34.1%) were PM-Scl positive. The mean follow-up time was 50.8 months for both groups. The mean age at diagnosis of the Jo-1 positive group was 45.8 ± 12.9 years vs. 47.1 ±14.3 years in the PM-Scl group. At initial visit to our center, muscle strength did not differ between the two groups. The mean maximum CK was 2197 ± 2589 IU in Jo-1 positive patients vs. 610 ± 893 IU in PM-Scl positive patients (p=0.002). ILD was found more commonly in Jo-1 positive patients (84.8% vs. 46.7%, p=<0.0001), as well as muscle edema on MRI of the thighs (79.1% vs. 25%, p=0.001). Raynaud's phenomenon and deltoid atrophy were more commonly found in PM-Scl patients and both associations were statistically significant.

Conclusion: Jo-1 positive myositis patients tended to have more severe muscle involvement with higher CK levels, more muscle edema on MRI, and more ILD when compared to PM-Scl positive patients.

Table 1. Clinical characteristics of Jo-1 positive vs. PM-Scl positive myositis patients

	Jo-1 positive (n=60)	PM-Scl positive (n=31)	p-value
Age (mean ± SD)	45.8 ± 12.9	47.1 ± 14.3	0.65
Female gender	47 (78.3%)	21 (67.7%)	0.20
White Race	40 (66.7%)	28 (90.3%)	0.10
Arm abduction (0-20)	16.3 ± 4.9	17.6 ± 4.0	0.23
Hip flexor (0-20)	16.5 ± 5.3	17.9 ± 3.3	0.13
Maximum CK (mean ± SD)	2197 ± 2588	610 ± 893	0.002
Maximum aldolase	39.6 ± 54.0	15.2 ± 13.9	0.02
MRI thighs (edema)	34 (79.1%)	3 (25%)	0.001
MRI thighs (fatty replacement)	19 (44.2%)	5 (41.7%)	0.57
Deltoid atrophy	1 (1.7%)	5 (16.1%)	0.02
Raynaud's phenomenon	27 (45%)	21 (67.8%)	0.03
Calcinosis	5 (8.3%)	6 (19.5%)	0.12
Dysphagia	22 (36.7%)	15 (48.4%)	0.20
Mechanic's hands	36 (60%)	16 (51.6%)	0.29
Interstitial lung disease	50 (84.8%)	14 (46.7%)	<0.0001
Pulmonary hypertension	11 (21.2%)	2 (7.4%)	0.10
Lowest FVC	61.5 ± 17.4	69.7 ±17.7	0.11
Lowest DLCO	55.1 ± 19.8	62.5 ± 21.9	0.21
Death	3 (5%)	1 (3.2%)	0.60

Postural Stability in Adolescents with Ehlers-Danlos Syndrome (Hypermobility

Type) Following an Exercise Intervention

Jason Long[1], **Stephanie Sabo**[2], Cailee Caldwell[2] and Bailey Petersen[3], [1]Orthopaedic Surgery, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Occupational and Physical Therapy, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [3]Kinesiology, Penn State University, State College, PA
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Orthopedics, Low Back Pain and Rehabilitation Poster (ARHP): Rehabilitation Sciences
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Ehlers-Danlos Syndrome (EDS) comprises a group of disorders marked by abnormal collagen function. In EDS Hypermobility Type (EDS-HT), major diagnostic findings involve joint hypermobility and chronic pain. Physical therapy has been recognized for its benefits to patients with joint hypermobility. Evidence suggests that mechanical interventions may improve pain, strength and stability [1,4]. Pilot findings suggest that an intensive exercise intervention (IEI) may lead to improved joint control, loading, and symmetry [3,4]. The purpose of this study was to assess postural stability (PS) in patients before and after participation in the IEI.

Methods:

Seventeen adolescents with EDS-HT made an initial visit immediately prior to starting the IEI, and a second visit within five days of completing the IEI (a 10-day program focused in neuromuscular re-education, flexibility, strengthening, joint stabilization, and endurance). During each visit, participants underwent PS testing under Eyes Open (EO) and Eyes Closed (EC) conditions. For each trial, ground reaction force data were processed to obtain center of pressure (COP) information. Measures of interest included linear and nonlinear metrics in the A/P and M/L directions. **Results:**

Findings indicated reduced M/L position variability between the EO Pre and EO Post conditions (Fig 1). Significant increases in nonlinear postural control metrics were also observed in the M/L direction, indicating changes in the structure of the M/L position variability (Fig 2). These findings suggest improved ability to stabilize in the M/L direction, with patterns of balance demonstrating increased complexity. This may point to an increase in patients' postural adaptability.

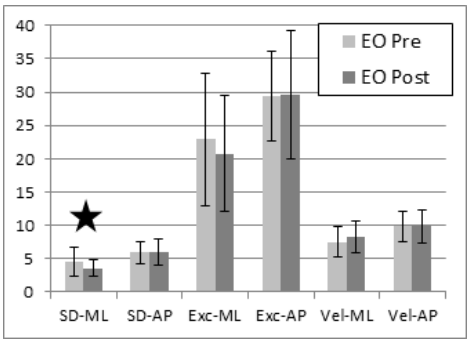

Figure 1: Linear measures of COP excursion (*SD* standard deviation, *Exc* excursion, *Vel* velocity). Star indicates significant difference ($p<0.05$).

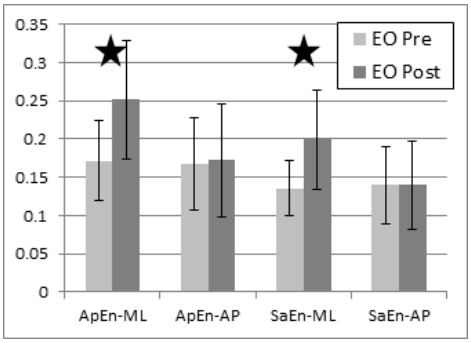

Figure 2: Approximate entropy (*ApEn*) and sample entropy (*SaEn*). Star indicates significant difference ($p<0.01$).

Conclusion:

Significant improvements in PS were observed in adolescents with EDS-HT following the IEI. Further study is warranted to learn how these changes are affected by patients' baseline characteristics (e.g. pain level, fitness level, etc.) Additional stratification by age and gender may also be useful in delineating the most appropriate intervention strategy for subsets of this population.

Session Date: Tuesday, November 10, 2015

Session Title: Orthopedics, Low Back Pain and Rehabilitation Poster (ARHP): Rehabilitation Sciences

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Health-enhancing physical activity (HEPA), i.e. at least 150 weekly minutes of moderate-intensity and at least twice-weekly muscle-strengthening activities, is recommended for every adult. Long-term studies on HEPA promotion in rheumatoid arthritis (RA) are scarce. Our aim was to describe HEPA levels and explore aspects of adherence and response during the second year of an outsourced two-year intervention in people with RA.

Methods: Two-hundred and twenty individuals not reaching maintained (>6 months) HEPA were included at baseline and 177 of them (81% women, mean age 60 years, mean time from disease onset 12 years) remained at the end of year two of this uncontrolled cohort study[1]. Adherence, without support from health care, to circuit training at public gyms and moderately intense daily physical activity was prompted and recorded by weekly short text messages. Bi-weekly physiotherapist-led support group meetings to facilitate behavior change during the first intervention year were replaced during year two with optional peer-support groups. Response variables included current (past week) and maintained (past six months) HEPA, socio-demographics, disease-related and psychosocial factors collected by questionnaires and performance tests of aerobic capacity and muscle function. Perceptions on the HEPA program were assessed with a study-specific questionnaire. Each participant with unchanged/improved values in general health perception (100 mm VAS) and at least two of three performance tests (aerobic capacity, grip srength and timed standing) year was considered a responder to the HEPA program.

Results: Current and maintained HEPA decreased from 82% to 75% (p=0.0141) and from 41% to 27% (p<0.0001), respectively, during the second year. Fifty-four participants were defined as total responders during the second year, while 105 were non-responders. The mean number of reported circuit-training sessions was 41 (SD 35.3) among total responders and 35 (SD 33.4) among non-responders (p=0.2708), the mean number of days with total HEPA were 194 (SD 80.8) and 171 (SD 76.9) respectively (p=0.0828) and the mean registered support group meetings 12 (SD 6.1) and 10 (SD 6.1) respectively (p=0.0943). Strategies for maintenance and relapse prevention learned during the first intervention year were reportedly used by 35% of the participants. Circuit training, daily physical activity and short text message reminders were perceived (scale 1-5) as valuable (=4), while the value of peer support groups was rated somewhat lower (=3).

Conclusion: Although maintained HEPA decreased from the end of the first intervention year, about one fourth of the originally sedentary individuals with RA still sustained their new behavior after two years. It remains unclear whether improvements in health and functioning relates to the HEPA program and its different components.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Orthopedics, Low Back Pain and Rehabilitation Poster (ARHP): Rehabilitation Sciences
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Physical activity participation can reduce pain, improve mobility and enhance quality of life in people with arthritis.[1] Despite these benefits, it was reported in the 2011 Canadian Community Health Survey that less than half of Canadians with arthritis are physically active.[2] While emerging evidence supports the use of some wearable physical activity monitoring tools to support an active lifestyle among patients with chronic diseases, little is known about how to integrate wearable tools to support self-management.[3] We aimed to examine the barriers and facilitators to using these wearable tools from the perspectives of arthritis patients.

Methods: Patient focus groups were conducted within a larger project that aimed to examine the context of using wearable physical activity monitoring tools to support arthritis self-management. To be eligible, patients had 1) a diagnosis of osteoarthritis (OA) and/or any type of inflammatory arthritis (IA), 2) any level of experience with wearable physical activity monitoring tools, and 3) were English-speaking. Participants were recruited via notices in hospitals and clinics of rheumatologists and rehabilitation professionals, and via online ads. An iterative, thematic analysis approach using constant comparative methods was applied to the data.

Results: In 2014 - 2015, 40 patients (31 women; 9 men) took part in 9 focus groups in-person or by teleconference. Of the 37 participants who provided information, 29 had used a wearable physical activity monitoring tool in the past. 17 (46%) had OA, 13 (35%) had IA, and 7 (19%) had OA and IA. Focus groups ranged from 3-6 participants, and the median age was 59 years (range: 23 –78). Preliminary findings revealed key barriers to patients' use of online physical activity monitors, which included: 1) an unfamiliarity with the tools, 2) a concern that the tool may be too expensive, and 3) doubts that use of the tool would be sustainable. If use was to be sustained, participants identified the importance of a tool that was user-friendly and provided information that was meaningful to their individual circumstance. Key facilitators were identified as: 1) an existing level of motivation to try out ways to be more active; 2) ease of use of the tool; 3) ongoing support from health professionals to use the tool optimally.

Conclusion: Participants identified the accessibility of wearable physical activity monitoring tools and the prospect of their long-term use as hurdles for using wearables activity monitors. The patients' perspective has also highlighted the importance of tool design and health professional support in facilitating ongoing use of these tools. These findings provide an important first step to informing future implementation strategies for patients to use wearable physical activity monitoring tools in supporting self-management.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Orthopedics, Low Back Pain and Rehabilitation Poster (ARHP): Rehabilitation Sciences

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The aim of this study was to compare the therapeutic effects of kinesio taping (KT),traditional physical therapy and dry needling therapy in patients with myofascial pain syndrome (MPS) at trapezius region, with regard to pain, and disability.

Methods : Sixty-eight female patients with MPS were enrolled into the study. Demographic and clinical characteristics including age, sex, duration of disease were recorded. The patients were randomized into three treatment groups receiving either a single dry needling injection to trigger points in the trapezius muscle (n=21), local physical therapy (hot pack and ultrasound) for 10 sessions (n=18) or kinesio taping performed to trapezius muscle, three times by intervals of 3 day (n=19). Visual analog scale (VAS) was used to assess pain intensity Neck Pain and Disability Index (NDI) was performed to evaluate functional disability, before treatment, at the end of therapies and four weeks after the therapies. All groups were educated for home exercise programme to perform trapezius stretching exercises.

Results : Sixty-eight female patients with a mean age of 32.1 ±10.7 years; mean disease duration of 13.1± 10.2 months were included in the study. There were no differences between the groups regarding demographic variables on entry to the study ($p>0.05$). Pain and NDI scores were improved significantly in all groups at the end of therapies and four weeks after, and these improvements were statistically similar between the groups at ANOVA analysis with Bonferroni adjustments (Table 1, $p>0.05$).

Conclusion : We imply that single dose dry needling injection, three times of kinesio taping by 3 day intervals and 10 sessions of physical therapy have favorable effects on pain and functional status in the early period (up to one month) in MPS. Although the improvements in pain and functional disability were similar between the groups, we suggest that KT may be an alternative non-invasive and time consuming method for patients suffering from MPS syndrome in the early period.

Table 1: The scores of pain intensity and neck disability index at baseline, at the end therapies and four weeks after the therapies (*improvement differences between groups,ANOVA).

	Dry needling n=21	**Kinesio taping** n=19	**Physical therapy** n=18	**P**
VAS-pain Baseline At the end of therapy 4 weeks after therapy	5.71±1.87 3.12±2.7 2.61±2.31	5.15±1.51 1.89±1.28 1.71±1.61	5.33±1.9 1.8±1.51 1.75±1.38	*>0.05
Neck Disability index Baseline At the end of therapy 4 weeks after therapy	52.4±12.9 24.8±19.7 21.33±17.2	46.4±15.1 21.4±12.8 17.8±14.8	48.38±13.2 18.05±10.7 16.11±13.6	*>0.05

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Orthopedics, Low Back Pain and Rehabilitation Poster (ARHP): Rehabilitation Sciences
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

For patients with osteoarthritis (OA) physical therapy is recommended first line treatment and performed in primary care while patients with rheumatoid arthritis (RA) may be treated in primary care at disease onset and during stable phases of the disease. This requires updated skills and evidence based knowledge of the physical therapists (PTs) in arthritis treatment. The aim of this study was to explore physical therapy arthritis practice in primary care and to study the application of evidence based care given to patients with OA or RA.

Methods:

All PTs working in primary care in one health care region in Sweden (n=70) were e-mailed a questionnaire (the Canadian Physiotherapists Arthritis Care Survey[1]) to assess the frequency of current practice, feeling of confidence, educational needs and adherence to national guidelines in managing patients with OA or RA. The questionnaire was translated and culturally adapted into Swedish according to international recommendations. Interventions supported by national guidelines were compared with reports of treatment modalities in the questionnaire. Mann-Whitney U test, Chi-square test or Fishers Exact test, were used where appropriate, to analyze differences between groups (PT management of patients with OA vs. RA).

Results:

Sixty-four PTs responded (91%), reporting a higher feeling of confidence in assessment, treatment and education for patients with OA than for RA ($p<0.001$). The total numbers of roles assumed by the PTs were higher in management of OA compared to RA ($p<0.001$). PTs who assumed a large numbers of roles also reported a higher feeling of confident in assessing OA ($p=0.036$). PTs who assumed a lower numbers of roles also reported a lower feeling of confidence in RA treatment ($p=0.045$). The recommendations in the guidelines were reported to be followed by almost all PTs in managing patients with RA and for eight out of eleven treatment modalities for patients with OA. Most PTs did provide joint mobilization and education of proper footwear for patients with OA even though Swedish national guidelines did not recommend this as treatment until further research has proven its effectiveness.

Conclusion:

PTs reported a lower feeling of confidence and to have assumed a lower numbers of roles in managing patients with RA than OA. There was a good adherence to the national guidelines for almost all listed treatment modalities. However, experienced evidence care and national guidelines did not totally agree. The results indicate a need for education in arthritis care, especially in RA.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Orthopedics, Low Back Pain and Rehabilitation Poster (ARHP): Rehabilitation Sciences
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Wearable physical activity monitoring tools can be used for goal-setting and progress-monitoring in rehabilitation programs for patients with arthritis. Little is known about the views of health professionals regarding the use or potential of these tools in clinical application. As part of a larger project about the barriers and facilitators to using physical activity trackers in clinical practice, this qualitative study aimed to examine the perspective of healthcare professionals on the prospect of using commercially available wearable trackers in their practice.

Methods: We conducted focus groups and one-on-one interviews to explore the views of health professionals towards physical activity trackers. Eligible participants were physiotherapists or occupational therapists with at least 40% of their caseload dedicated to arthritis. English-speaking therapists with any level of experience with online tools were considered eligible. Transcripts of the interviews and focus groups were coded and analyzed in a qualitative, theme-based examination of the views that healthcare professionals held toward these devices.

Results:

Across 5 focus groups and 3 interviews conducted in 2014-15, the sample of 25 health professionals recruited were mainly female (92%). Of the 18 participants who provided more demographic information, 94% were physiotherapists, 94% were living and working in an urban or suburban environment, with 60% of participants working full-time, and 67% working in outpatient clinics. The participant age range was between 28 and 61, with the median age of participants being 47, and the range of years in practice was between 5 and 39, with a median of 22 years. Approximately one third of participants had experience in using physical activity trackers.

The majority of healthcare professionals participating in the study regarded these devices as potentially useful tools because of the objective data they provide and their ability to facilitate the setting of and adherence to goals throughout rehabilitation. Some of the participants, however, thought that they would be of limited use due to: 1) the lesser computer literacy of older patients, who were the majority of patients with osteoarthritis; 2) their potential to be just another novelty; 3) the inaccessibility for people with

health-related challenges such as hand pain and deformity due to arthritis, or vision problems; 4) the cost of these devices for patients.

Conclusion: Therapists report activity trackers show promise for improving physical activity habits, however, some therapists are skeptical regarding the benefit for and accessibility to specific patients, particularly older adults with osteoarthritis.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Osteoarthritis - Clinical Aspects Poster II: Biomarkers, Biomechanics and Health Services Research

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Meniscal damage and extrusion are both strongly associated with the progression of knee OA. Concerns have recently been raised that arthroscopic partial meniscectomy (APM) may accelerate OA development. It is currently unclear whether performing APM or leaving a meniscal tear *in situ* affect meniscus position differently. Thus we determined the effect of APM on medial meniscal body extrusion in patients with OA and meniscal tear.

Methods: Post-hoc analysis using data from the MeTeOR trial (ClinicalTrials.gov number, NCT00597012), a multi-center randomized controlled trial that involved patients aged 45 or older with knee symptoms and meniscal tear as well as osteoarthritic changes detected on MRI (cartilage lesions) or radiography. Patients were randomized to either APM coupled with postoperative physical therapy (PT) or a standardized PT regime. Cross-over from PT to APM due to treatment failure was allowed. One orthopedic surgeon, who was blinded to treatment allocation, actual treatment received, and patient characteristics, but who had knowledge of the time sequence, performed paired meniscal measures on the baseline and 18-month mid-coronal 1.5T knee MR images. The observer measured medial meniscal body extrusion to the closest 0.1 mm using Sante DICOM Editor software. Intra-observer reliability (intra-class correlation coefficient) was 0.85 (95% CI: 0.73-0.92). We defined our primary outcome as the absolute change in mm of the position of the external medial meniscal body margin from baseline to the 18-month exam. We used the intention-to-treat (ITT) principle for the primary analysis, and we also performed a secondary as-treated analysis, i.e., taking into account the cross over after randomization (including those who crossed over from PT to APM into the APM group).

Results: The MeTeOR trial patients have mean (SD) age 59 (7.9) years at baseline and 56% were women. In this analysis we included the first 223 patients who had both baseline and 18-month follow-up knee MRIs available and readable. Of these, 108 patients were randomized to APM and 115 to standardized PT. The mean medial meniscus body extrusion at the baseline exam was similar; mean (SD) 3.2 (1.4) mm in the APM arm vs. 3.4 (1.5) mm in the physical therapy arm (p=0.34). We found no statistically significant difference in the change of extrusion of the medial meniscal body in the ITT analysis; mean (SD) change +0.47 mm (1.6) in the APM arm vs +0.40 (1.6) mm in the PT arm (p=0.72). In the PT arm, 42 patients (36.5%) crossed over to

surgery during the 18 months of follow-up, and 4 patients (3.7%) randomized to APM never had the surgery. We did not find statistically significant differences in the corresponding as-treated analysis, mean (SD) change +0.36 mm (1.5) in those having APM (n=146) vs +0.58 (1.8) mm in those patients having PT only (n=77) (p=0.32).

Conclusion: We observed on average small changes in medial meniscal body extrusion over 18 months in MeTeOR trial participants. APM of a meniscal tear in patients with knee OA does not lead to increased meniscal body extrusion as compared to non-operative management.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Osteoarthritis - Clinical Aspects Poster II: Biomarkers, Biomechanics and Health Services Research

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Alterations in hip morphology, such as femoroacetabular impingement, have been associated with incident hip OA and total hip replacement (THR), but associations of these morphologic variations with hip symptoms are less clear, and have not been studied in a community-based sample including participants with and without OA.

Methods: This preliminary analysis was performed as part of our ongoing work to determine the prevalence of morphologic features at the hip at the baseline visit for the Johnston County OA project, a large community-based cohort. At the time of this analysis, 2612 hips had been read, 120 were excluded based on excessive tilt/rotation, and 2492 hips (from 1252 individuals) were included. The outcome of hip symptoms was assessed in 3 ways: 1) response to the question "On MOST days do you have pain, aching or stiffness in your right|left hip?" (graded none, mild, moderate, or severe); 2) pain on internal rotation during clinical exam (graded none, mild, or moderate/severe); 3) self-reported groin pain (present or absent). Validated software (Oxmorf) was used to assess 27 aspects of hip morphology, and differences in means among categories of the symptom variables were assessed using GEE to account for within-person correlation (but no adjustment for any covariates in these preliminary analyses). P values <=0.05 for any difference between groups were considered significant.

Results: Of the included individuals, 37% were men, 36% were African American, with a mean age of 63.8 ± 9.8 years and BMI 28.8 ± 5.9 kg/m^2. Kellgren-Lawrence grade was 0 or 1 in 72% of hips. Reliability for all measures was acceptable (intra- [ICC 0.7-1.00] and inter-reader ICC 0.5-1.00). We focused on 10 continuous measures of hip morphology (Table). None of these was statistically significantly associated with hip pain, aching, or stiffness on most days (p>0.2 for all). However, several of the morphologic indicators (increased acetabular depth/width ratio, AP alpha angle, extrusion index, femoral shaft angle, and Gosvig ratio, as well as decreased minimum joint space width [JSW] and proximal femoral angle) were significantly associated with pain on internal rotation (Table). All but extrusion index, femoral shaft angle, and proximal femoral angle were also associated with groin pain.

Conclusion: Indicators of femoral morphology, including measures of acetabular dimension, acetabular coverage (extrusion

index), femoral angles, and indicators of cam-type lesions (AP alpha angle and Gosvig ratio), were associated with pain on internal rotation and with groin pain, but not with self-reported pain, aching and stiffness. These preliminary findings are supportive of an association between femoral morphology such as that seen in FAI and symptoms at the hip in the general population. Further study in a larger number of hips will assess differences by race, gender, and other key covariates.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Osteoarthritis - Clinical Aspects Poster II: Biomarkers, Biomechanics and Health Services Research
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Pronated foot posture is prevalent in older adults with knee cartilage damage and younger adults with knee pain. Yet, there is disagreement about the role of the pronated foot in knee OA. Many footwear interventions for older adults encourage a highly pronated foot posture in an effort to redistribute provocative loads away from the medial tibiofemoral (TF) compartment. Conversely, interventions for younger adults often seek to correct the pronated foot in order to minimize painful loading of adjacent knee compartments. In adults that have or at risk of knee OA, we assessed the relation of pronated foot posture to 2-year risk of worsening knee pain during walking and stairs, and worsening medial TF, lateral TF, and patellofemoral (PF) cartilage damage.

Methods: The Multicenter Osteoarthritis Study (MOST) includes adults aged 50-79 years that have or are at risk of knee OA. At the 60 month exam, foot posture was measured by a single reader (ICC= 0.69) as Resting Calcaneal Stance Position (RCSP) from photos acquired in bipedal standing. RCSP is a validated measure, with higher values indicating a more pronated foot. From 1.0 T MRIs at 60 and 84 months, readers scored 1 knee per subject for cartilage damage in each sub-region of the medial TF, lateral TF, and PF compartments using WORMS (weighted kappa > 0.63). Worsening damage was any increase in WORMS score. Worsening knee pain during walking and stairs was defined over the same period as any increase in Likert score on corresponding questions of the WOMAC index. After forming case-based quintiles of increasing RCSP, we combined quintiles 1-4 and used logistic regression to estimate the odds of worsening knee pain or compartment-specific cartilage damage in knees with the most pronated feet (quintile 5) as compared to all others (quintiles 1-4). Adjustments were made for age, sex, and BMI. GEE accounted for non-independent knees in a person, or sub-regions in a compartment.

Results: 2021 (mean age 67.6 ± 7.7 years, BMI 30.8 ± 6.1 kg/m^2, 61.0% female) and 2412 participants contributed 2 knees each to the analysis of worsening knee pain during walking and stairs, respectively, and 1 knee each to the analysis of worsening

medial TF (1185 knees), lateral TF (1145 knees), and PF (1145 knees) cartilage damage. Mean RCSP was 5.1 ± 4.7°. Odds of worsening knee pain during walking and stairs were 23% lower (OR= 0.77, p= 0.03) and 26% lower (OR= 0.74, p< 0.01), respectively, among knees with the most highly pronated foot posture (RSCP 8.2° to 27.0°). There was no association between pronated foot posture and risk of worsening knee cartilage damage (see table).

Conclusion: In adults that have or are at-risk of knee OA, a highly pronated foot posture is protective against worsening knee pain during walking and stair climbing, but does not protect against worsening knee cartilage damage.

Table. Relative odds of worsening knee pain during walking and stairs, and worsening medial tibiofemoral (TF), lateral TF, and patellofemoral (PF) cartilage damage in knees with the most pronated Resting Calcaneal Stance Position (RCSP) compared to all others.

Session Date: Tuesday, November 10, 2015

Session Title: Osteoarthritis - Clinical Aspects Poster II: Biomarkers, Biomechanics and Health Services Research

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Biomechanical treatments for medial knee osteoarthritis (OA) often target the knee adduction moment (KAM). Foot-mediated biomechanical interventions for knee OA may operate through altering foot kinematics and foot center of pressure (COP). Flexible footwear has recently been shown to effectively reduce the KAM, but specific mechanisms underlying this reduction are not clear. We hypothesize that the use of flexible footwear allows increased foot pronation and medial shift in foot COP that are associated with reduction in the KAM.

Methods: Participants with symptomatic medial compartment knee OA (KL 2 and 3) were evaluated at baseline using simultaneous barefoot COP analyses and 3-D gait analyses including detailed foot kinematic modeling. All participants were provided flexible shoes (Dr. Comfort Flex-OA, Mequon, WI) and instructed to wear them at least 6 hours/day, 6 days/week. Gait and COP analyses were repeated after 12 weeks of wearing the shoes. Gait testing consisted of five trials each while barefoot, in subjects “own shoe”, and in the flexible shoe. During barefoot trials, plantar pressure distribution was acquired simultaneously by mounting a pressure platform onto a force plate and leveling the stacked assembly with the walkway. COP was quantified by determining the Medial to Lateral Pressure Index (MLPI) and normalizing to foot width, with smaller values representing more medialized COP. The primary outcomes were the peak KAM and COP during the first half of stance and foot kinematic variables. Paired samples t-tests were used to evaluate changes in kinematics and foot COP. Pearson correlations were used to evaluate the association between foot kinematics, shift in COP and percent reduction in KAM.

Results: 28 participants were evaluated (mean age 59±7 years, 21 women). At 12 weeks, the KAM in the flexible shoe was reduced compared with their own shoes at baseline (2.17± 0.82 vs 2.32±0.81%BW*Ht, p=0.030). The foot COP medialized compared with baseline (4.61±4.28 vs 5.88±4.39%FW, p=0.034). No significant correlation was found between medialization of foot COP and reduction in KAM (p=0.430). No significant changes occurred in measures of foot kinematics including rearfoot eversion (p=0.975), foot supination (p=0.372) and medial arch (p=0.841). However, lower maximal rearfoot eversion at 12 weeks correlated with both the medialization of foot COP (r=0.438, p=0.02) as well as the percent reduction in KAM with the mobility shoe at 12 weeks compared to own shoes at baseline (r=0.438, p=0.02).

Conclusion: Walking with flexible shoes for 12 weeks significantly reduces loading at the medial tibiofemoral joint in participants with knee OA and shifts the foot COP medially during walking. Interestingly, though, there was no association between the medialization in foot COP and reduction in knee loading, suggesting that both phenomena could be explained by an unidentified mechanism. Also, there were no significant differences found in foot kinematics over 12 weeks, yet less rearfoot eversion during walking at 12 weeks was associated with the extent of COP medialization and reduction in medial knee loading.

Hip Osteoarthritis as the cause for Knee Osteoarthritis in the Multicenter Osteoarthritis Study

Background/Purpose:

While the hip and knee are linked biomechanically, there have been no studies of the risk of knee OA in persons with hip OA. Unilateral hip OA has been shown to increase dynamic load and bone mineral density in the contralateral knee, thus theoretically putting the contralateral knee at risk for OA development. However, weak hip abductor muscles which can be seen in hip OA can lead to an increased knee adduction moment on the ipsilateral leg, possibly increasing risk for knee OA ipsilaterally. We examined the risk of knee OA in those with hip OA in the Multicenter Osteoarthritis Study (MOST). We secondarily tested whether hip OA increased the risk of ipsilateral or contralateral knee OA.

Methods:

MOST is a NIH funded longitudinal cohort study of risk factors for knee OA. For radiographic hip OA assessment, we used long limb films which included hip imaging obtained at baseline. For knee OA assessment, PA and lateral weight bearing films were obtained at each examination up to 84 months and read for tibio-femoral and patella-femoral OA. The exposure groups were subjects with or without radiographic hip OA at baseline, and we excluded persons with any radiographic knee OA at baseline. The outcome was incident radiographic knee OA at any of the follow-up exams (30, 60, or 84 months).

For the 1st analysis, we assessed the risk of radiographic knee OA in subjects with or without radiographic hip OA. The risks of incident radiographic knee OA were compared among the exposure groups after excluding any subjects with hip replacements during follow-up. The analysis was adjusted for knee OA risk factors including age, sex, BMI, knee injury/surgery, leg length inequality.

For the 2nd analysis, we assessed the risk of contralateral and ipsilateral knee OA in subjects with unilateral radiographic hip OA in a matched within-person analysis. We examined the risk of incident radiographic knee OA (ipsilateral vs contralateral to the affected hip).

Results:

For the 1st analysis, of the 989 subjects eligible, the risk of incident radiographic knee OA in subjects with any radiographic hip OA was greater than risk of incident radiographic knee OA in subjects without radiographic hip OA (see table). For the 2nd analysis, there was a trend for incident radiographic knee OA for the contralateral side, but this did not meet statistical significance (see table).

Conclusion:

Subjects with radiographic hip OA had an increased risk of incident radiographic knee OA. While our findings were limited by small numbers, we did not find a special association of hip OA with either contralateral or ipsilateral knee OA, suggesting that in persons with hip OA, both knees are at increased risk of OA.

Vibration Perception Threshold and Hip Osteoarthritis in Multicenter Ostoearthritis Study

Background/Purpose:

It is hypothesized that reduced sense of position in space leading to increased impact force and unbalanced foot strike during gait contributes to osteoarthritis (OA). In previous work from the Multicenter Osteoarthritis Study (MOST), we reported that high VPTs were associated with knee OA especially in men and women aged 65 or greater. However, the association of VPT and hip OA has not been studied for a large population. It is unclear whether sensory deficits which are mostly distal can lead to hip OA. We examined the association of vibratory sense with radiographic hip OA in participants of MOST.

Methods:

MOST is a NIH funded longitudinal study that recruited participants at risk for knee OA. We carried out a cross sectional assessment of vibration perception threshold (VPT) and hip OA at the 60 month exam. Using a protocol from knee OA studies, we measured VPT at 3 anatomical bony sites: 1st MTP, tibial tuberosity, and radial styloid. VPT measures the voltage threshold at which a subject senses vibration, thus a higher VPT threshold represents a greater sensory deficit. Long limb radiographs obtained at the same visit were read for radiographic hip OA (RHOA) using criteria devised at UCSF that incorporated features of modified Croft criteria. Symptomatic hip OA (SHOA) was defined as hips with pain and RHOA. Persons with total knee replacements, total hip replacements and diabetes were excluded from this analysis.

Because large differences in VPT exist between genders and age, men and women were evaluated separately and divided into age subgroups: <65 years and ≥65 years. The unaffected hips of persons with unilateral RHOA may be intermediate in VPT between hips with OA and normal hips without any radiographic knee OA, so a limb-based analysis was performed with three hip groups: 1) RHOA; 2) contralateral "normal" hip of unilateral RHOA; and 3) control hip (no RHOA in either hip). Statistical analysis entailed using linear regression with GEE to compare VPT between groups adjusted for age, BMI, radiographic knee OA, and accounting for the correlation between hips.

Results:

VPT was assessed in 612 men and 930 women. Of the 612 men, 72 hips were excluded from analysis (missing RHOA status due to poor quality radiographs). Of the 930 women, 99 hips were excluded. For both men and women for all age groups, VPTs were not higher for those with RHOA or SHOA compared to controls (results only shown for men age < 65 years). VPTs at the radial styloid on the non-OA side for those with unilateral RHOA and SHOA were significantly lower than controls for men age < 65 years.

Conclusion:

In MOST, RHOA was not associated with any meaningful alteration in VPT.

Radiographic hip OA for men (age < 65 years)*					
		Mean VPT (95% CI)	P value (compared to control)	Mean VPT (95% CI) adjusted for BMI and age	P value (compared to control)

Session Title: Osteoarthritis - Clinical Aspects Poster II: Biomarkers, Biomechanics and Health Services Research

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Bone marrow lesions (BML) and synovitis are MRI features that have been associated with symptoms and disease progression in patients with osteoarthritis. The Hip Inflammation MRI Scoring System (HIMRISS) has been developed to specifically score these active lesions in hip OA. We aimed to conduct validation according to the OMERACT framework of a novel web-based overlay integrated to facilitate sectoral scoring of these lesions in patients receiving intra-articular hyaluronate.

Methods: We conducted MRI at baseline in patients receiving intra-articular hyaluronate for symptomatic hip OA. A circular overlay integrated with a web-based DICOM viewer was designed for use with DICOM MR images of the hip for evaluation according to the HIMRISS method. Using a mouse, the overlay can be positioned over the largest diameter of the femoral head and resized to ensure alignment with the subchondral bone. BML are assessed on coronal fluid-sensitive MR scans using an overlay comprising a circle divided into octants. The presence/absence of BML in each of the octants is scored dichotomously directly on the image display in 5 consecutive coronal slices, simply by mouse-clicking on any octants containing BML, thereby dispensing with scoring sheets. The overlay is also used to score BML in the acetabulum, assessed in 3 sectors. Synovitis is scored in 2 locations according to a grading scheme (0-2) that reflects thickness of synovitis-effusion.

Intra-class correlation coefficients (ICC) were used to assess reliability between 4 readers without any formal calibration. Correlation analysis, univariate and multivariate analyses, adjusted for age, sex, symptom duration, BMI, and baseline WOMAC pain, were used to assess the predictive capacity of baseline BML and synovitis scores for change in WOMAC pain from baseline to 12 weeks.

Results: The cohort included 60 patients, 28 (46.7%) males, mean (SD) age of 63.0 (11.2) years, mean (SD) disease duration of 31.4 (43.4) months, baseline mean (SD) WOMAC pain of 49.7 (16.3), mean (SD) change in WOMAC of -17.9 (19.2), mean (SD) femoral BML of 10.6 (13.9) (0-65 is maximum possible range), mean (SD) acetabular BML of 7.0(5.5) (0-35 is maximum possible range), mean (SD) effusion of 13.3 (8.1) (0-30 is maximum possible range).

Inter-observer ICC [95% CI] was 0.83[0.78-0.87] for femoral BML, 0.64 [0.52-0.74] for acetabular BML, 0.78 [0.65-0.86] for synovitis-effusion, and 0.86 [0.81-0.89] for total HIMRISS score. Significant correlation was evident between baseline femoral BML score and change in WOMAC pain (r =0.44, p=0.001). In univariate analysis, baseline femoral BML (β=0.58, p=0.0009) was significantly associated with change in WOMAC pain, an association which remained present in multivariate analysis (β=0.51, p=0.01). 21/55 subjects (38.2%) had a 50% reduction in WOMAC pain and 39/55 (70.9%) a 20% reduction in WOMAC pain. Baseline femoral BML predicted a WOMAC 20% response (OR [95%CI]: 0.95 [0.91-0.99], p=0.018) in multivariate logistic regression.

Conclusion: The web-based adaptation of HIMRISS facilitates reliable scoring of active lesions in hip OA and is relevant to patient symptoms and response to treatment.

Session Date: Tuesday, November 10, 2015

Session Title: Osteoarthritis - Clinical Aspects Poster II: Biomarkers, Biomechanics and Health Services Research

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

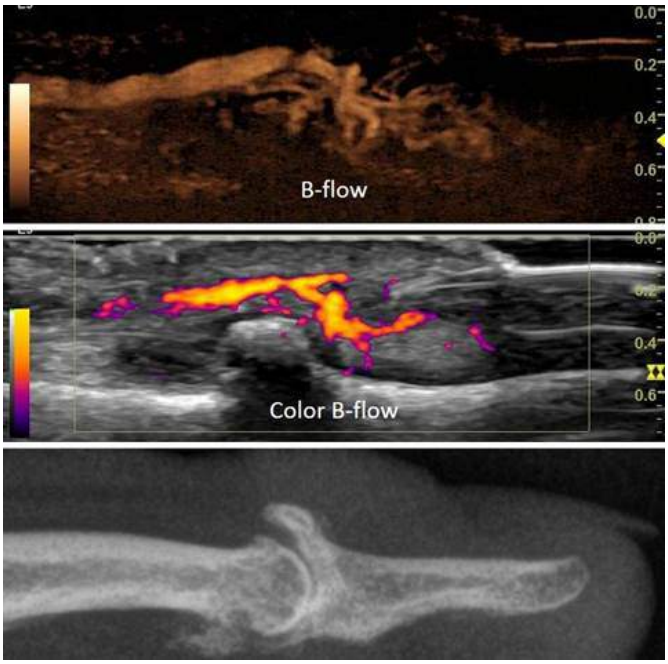
Background/Purpose: Development of disease modifying medication for osteoarthritis (OA) is desirable, but the target tissue of such treatment remains unclear. We have previously shown that proliferative and hyperemic synovial tissue is rare in joints affected by erosive osteoarthritis (EOA), if power Doppler ultrasound (US) is used as the detecting instrument. Doppler ultrasound gives indirect information about blood flow by assessing amplitude or velocity of a frequency shift. In contrast, B-flow ultrasound directly visualizes blood flow, and can visualize synovial hyperemia in a precise (flow only in the vascular lumen) and sensitive (small vessels) fashion. No previous studies have used B-flow ultrasound to assess synovial hyperemia.

The aim of this study was to assess synovial proliferation and synovial hyperemia in proximal interphalangeal and distal interphalangeal joints of patients with a radiologic diagnosis of OA or EOA using high-frequency B-mode gray scale US and B-flow US.

Methods: Joints affected by OA or EOA based on bilateral hand radiographs in 3 planes were then examined sonographically. For enrollment, the assessment of the MSK radiologist was counted. Gray scale US, native B-flow US and color B-flow still images and 3-second video clips were obtained by a rheumatologist with 20 years of experience in MSK US, certified in rheumatologic US (RT). All US and B-flow scans were performed on a GE Logiq E9 built 2014 machine, with an 18 MHz small footprint probe using a B-flow software package. Vascular factory settings were optimized for low flow in fingers. Distension of the hyperechoic, fibrous joint capsule was scored for GS synovitis from 0-3 (absent, mild, moderate, severe), analogous to scoring for RA. Intra-articular synovial blood flow was scored from 0-3 (no flow, individual signals, involving less, and equal to/ more than half the area of detected synovitis). Total scores for EOA patients were compared with OA patients.

Results: 559 still images and video clips were obtained. 84 joints of 20 consecutive OA and EOA patients were examined: DIP n=55; IP/PIP n=29. EOA patients, n=11 (55%); OA, n=9, (45%) as determined prior to US by the reading radiologist. Age range was 51-88 years; mean age 68. Female, n=16; male, n=4.

Resulting scores: Gray scale (score=n) 0=45; 1=31; 2=4; 3=2. B-flow (score=n) 0=81; 1=4; 2=1; 3=0. Mean GS score EOA=56.6; OA=53. Scores for intra-articular B-flow were too low to compare.



Conclusion: B-flow US was well suited to detect blood flow in small digital vessels. While physiologic flow in soft tissues adjacent to joints was seen in all images and video clips, intra-articular, synovial blood flow was rarely observed in OA or EOA patients. Synovial proliferation, if present, was mild and appeared to be due to mechanical distension of the joint capsule by osteophytes. No significant difference in mean GS synovitis score was observed between OA and EOA patients.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Osteoarthritis - Clinical Aspects Poster II: Biomarkers, Biomechanics and Health Services Research
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Knee Osteoarthritis (OA) is the most common musculoskeletal condition affecting quality of life and was one of the leading causes of the years lived with disability in the global burden of disease 2010 study by the World Health Organisation. Knee OA can result in pain and stiffness leading to impairment in routine daily activities. The aim of this study was to examine the demographic, structural and non-structural factors predicting and associated with change in knee pain, stiffness and physical function in a midlife cohort, with a low prevalence of radiographic OA, over 8 years.

Methods:

220 participants [mean age 47 (28-63); 57% female] were studied at baseline and eight years. Approximately half were the adult offspring of subjects who had a knee replacement performed for knee OA and the remaining were randomly selected controls. Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) was used to assess pain, stiffness and physical function at both baseline and follow up visits. Pain, stiffness and physical function scores were combined to get a complete WOMAC Index (WI) score representing overall morbidity. Cartilage volume/defects, bone marrow lesions (BMLs), meniscal tears/extrusion and effusion were assessed on MRI and joint space narrowing and osteophytes on radiographs. BMI was classified as normal=18.5-24.9, overweight=25-29.9 and obese=≥30.

Results:

At the baseline visit, higher BMI **(prevalence ratio (PR) for WI= +1.5 (+1.1 , +2.2), p= 0.02)**, history of knee injury **(PR for WI= +1.9 (+1.1, +3.2), p=0.01)** and patellar BMLs **(PR for WI= +1.5 (+1.1,+1.9), p=<0.01)** showed an independent cross-sectional association with the complete WI as well as each individual sub-scale. Total tibiofemoral BMLs **(PR=+1.82 (+1.2, +2.7), p=<0.01)** showed an independent association with knee stiffness only.

Baseline patellar cartilage defects **(β for WI= +6.4 (+1.0,+12.0), p=0.02)** and total (medial + lateral) body meniscal tears **(β for WI= +16.1 (+4.0. +28.0), p=0.01)** independently predicted change in WI as well as each sub-scale over 8 years. Total knee meniscal tears **(β= +1.1 (+0.2, +1.9), p=0.01)** independently predicted change in stiffness only.

Change in total knee meniscal tears **(β for WI= +6.1 (+0.2, +12.0), p=0.045)** and extrusion **(β for WI= +7.6 (+0.9, +14.3), p=0.026)** showed an independent deleterious association with change in WI and each individual sub-scale over 8 years. In unadjusted analysis change in both medial and lateral radiographic OA scores were associated with change in WI but in the fully

adjusted model, only change in lateral radiographic OA **(β for WI= +7.9 (+2.8, +13.0), p=<0.01)** was independently associated with WI and each sub-scale. Change in meniscal tears and extrusion explained most of the changes in the medial compartment on radiographs.

Conclusion:

In this midlife cohort higher BMI, history of knee injury and BMLs are associated with prevalent disability. Patellar cartilage defects and meniscal tears predicted worsening morbidity over 8 years. Change in meniscal tears/extrusion and lateral compartment radiographic OA were independently associated with worsening pain, stiffness and physical function.

Session Date: Tuesday, November 10, 2015

Session Title: Osteoarthritis - Clinical Aspects Poster II: Biomarkers, Biomechanics and Health Services Research

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Although osteoarthritis(OA) is predominantly considered as a disease of cartilage, articular cartilage is an aneural tissue, and there is a consensus that the association between knee radiographic OA and knee pain is modest. To investigate the prevalence of asymptomatic subjects with advanced knee OA, we examined databases obtained from 2 Korean community residents.

Methods:

Subjects included were from Hallym Aging Study(HAS) or from the Korean National Health and Nutrition Examination Survey(KNHANES, year 2010-2012). Participants in each study were asked knee-specific questions regarding the presence of knee pain. Radiographic evaluations consisted of weight-bearing anteroposterior, semi-flexed knee radiographs. Each knee was evaluated for the presence of osteophytes, joint space narrowing, subchondral sclerosis, and cysts, and was graded for overall evidence of radiographic OA using the K-L grade. Advanced knee OA was defined as K-L grade 4(large osteophytes, severe joint space narrowing, and/or bony sclerosis). Clinical factors associated with the presence of knee pain were evaluated with multivaritate logistic regression analysis.

Results:

Included were 504 subjects from HAS and 8679 from KNHANES. Advanced knee OA was identified in 47(9.3%) and 685(7.8%) in HAS and KNHANES, respectively. The mean age of these 732 subjects were 72.5 years and 16.5% were male. Two hundred twenty five subjects(30.7%) did not report any pain despite having K-L grade 4 OA. Female, non-smoker, the presence of osteoporosis, and lower education were significantly associated with knee pain. After multivariate association, female and

osteoporosis was significantly associated with the presence of knee pain. Advanced OA Subjects without knee pain had functional status evaluated with WOMAC and chair stand not different from that of non-OA subjects.

Conclusion:

Our community study showed that 30% of subjects with K-L grade 4 OA was asymptomatic and had functional status similar with non-OA subjects. The guidance of therapeutic decision merely based on imaging study as well as treatment option focusing solely on cartilage engineering should be viewed with caution.

Detection of Changes in the Serum and Synovial Fluid Levels of Resistin during Flare Ups and Remissions in Primary Knee Osteoarthritis

Hassan Bassiouni, Rheumatology, Al-Azhar University, Cairo, Egypt
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Osteoarthritis - Clinical Aspects Poster II: Biomarkers, Biomechanics and Health Services Research
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Resistin is a secreted factor that is elevated following traumatic joint injury, causing matrix degradation and it releases inflammatory cytokines from articular cartilage in vitro. This study was designed to plot changes in the levels of serum and synovial fluid (SF) resistin during flare-ups and remissions in patients with primary Osteoarthritis (OA) of the knees.

Methods: The level of resistin was measured in paired serum and SF samples from 60 patients with Primary OA of the knees during flare-ups when KOFUS $\geq$ 7, and then re-measured after remissions were attained, and from 15 controls without radiographic knee OA [Kellgren & Lawrence (K&L) =0] . Resistin levels were measured by enzyme-linked immunosorbent assay (ELISA).

Results: Serum resistin levels were higher in patients compared to controls (9.66±5.21 versus 3.31±1.04) ($P < 0.001$). In patients, serum resistin collectively was higher than in SF (9.66±5.21versus 2.45±1.04 ng/ml) ($P < 0.001$). In flare-ups serum resistin was higher than in remissions (9.66±5.21versus 5.68±3.22) ($P< 0.001$). SF resistin was higher in flare-ups than in remissions (2.45±1.04 versus1.35±0.72) ($P < 0.001$).

Conclusion: This study suggests an important involvement of resistin in OA patients considering their high serum levels compared to controls and furthermore, the up regulation of resistin during flare-ups in both serum and SF may suggest an involvement of resistin in the inflammatory component of OA.This may pave the way for using resistin as a marker of disease activity in OA.

Session Date: Tuesday, November 10, 2015

Session Title: Osteoarthritis - Clinical Aspects Poster II: Biomarkers, Biomechanics and Health Services Research

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Our current understanding of osteoarthritis (OA) comes mainly from late stage disease and this is partly due to when patients present with symptoms. It is therefore essential to find biomarkers indicative of OA development. One promising biomarker is circulating microRNAs, which were discovered to exist in an acellular form within the plasma and serum (1). Previous work has suggested that the level of microRNA Let7e is a potential predictor of severe hip and knee OA, with a negative correlation between expression and number of joint replacements (2). We found that microRNAs that are predicted to regulate BMP/TGFβ signalling pathways (miR24-3p and miR342-3p), are robustly expressed in the cartilage suggesting a role in the regulation of cartilage remodelling. Our current study was aimed at investigating the levels of cartilage associate candidate microRNAs in plasma of established OA.

Methods: RNA was extracted from the plasma of both end stage OA patients (mean age 69.6 years) at the point of joint replacement surgery and age/sex matched healthy controls (mean age 69.5 years) using the miRNeasy kit (Qiagen). Synovial fluid from OA patients and rheumatoid arthritis patients was extracted using the Qiagen kit. cDNA was synthesised with miScript RT kit (Qiagen). qPCR was carried out using miScript SYBR green (Qiagen) and miRNA specific primers (Qiagen). C.elegans miR-39 (Qiagen) was used as a spike in control for normalisation of RNA input.

Results: The circulating levels of miR24-3p ($p < 0.01$), miR342-3p ($p < 0.05$), miR-140 ($p < 0.05$) and Let7e ($p < 0.05$) were significantly decreased in OA patients (n=9) compared to healthy individuals (n=9). Evaluation of the synovial fluid showed that the levels of miR24-3p and miR342-3p were also decreased ($p < 0.01$) in OA (n=9) compared to rheumatoid arthritis patients (n=4) suggesting a direct involvement in OA joint remodelling. Synovial fluid levels of miR-140 and Let7e were unchanged.

Conclusion: The 4 microRNAs, differentially expressed in the OA plasma, offer a potential signature that could be used as a convenient, easily accessible OA biomarker. This circulating signature is also partially reflected in the synovial fluid where miR24-3p and miR-342-3p are distinctively changed. Further studies are underway to evaluate the predictive potential of this signature in early OA.

Session Title: Osteoarthritis - Clinical Aspects Poster II: Biomarkers, Biomechanics and Health Services Research
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Fibulin3 is highly expressed in osteoarthritic cartilage and inhibits angiogenesis and chondrocyte differentiation. It has been demonstrated to interact with the tissue inhibitor of metalloprotease (TIMP)-3, which is a matrix bound inhibitor of matrix metalloproteinases (MMPs) and stimulates the expression of TIMP-1 and TIMP-3, but inhibits the expression and activities of MMP-2, MMP-3, and MMP-9. In the present study, the association between three Fibulin3 peptides identified by proteomics and the incidence of radiographic and clinical knee osteoarthritis (OA) in middle-aged overweight and obese women, free of radiographic and symptomatic knee OA at baseline was tested.

Methods: Women between 50 and 60 years, with a BMI ≥ 27 kg/m^2, free of knee OA were recruited through their general practitioner. At baseline, physical examination including serum collection was performed and radiographs and questionnaires on knee complaints were obtained. Using binary logistic regression, the association between baseline concentration of Fibulin (Fib)3-1, Fib3-2 and Fib3-3 and incidence of clinical and radiographic knee OA after 30 months of follow-up was tested, adjusting for age, BMI, and other potential covariates that were identified in multivariable regression analyses.

Results: Baseline serum samples and follow-up measurements were available for 242 women. Mean age was 55.9 ± 3.2 years, mean BMI was 31.6 ± 3.6 kg/m^2 and 70% was postmenopausal. All subjects were free of clinical and radiographic knee OA at baseline, but 24% had a unilateral K&L score of 1 and 33% bilaterally. Mild symptoms were present in 24% and 17% of the subjects, uni- and bilaterally respectively. Baseline concentrations of all Fib3 fragments were log-transformed for a normal distribution and z-transformed for uniformity reasons. Correlation coefficients for the baseline concentrations of the three Fib3 fragments ranged from 0.13 to 0.58. Neither of the concentrations of the three Fib3 fragments were associated with incidence of medial or lateral joint space narrowing ≥ 1.0 mm. or incidence of K&L grade 2. All three Fib3 fragments were associated with incidence of the clinical and radiographic ACR-criteria and Fib3-1 and Fib3-3 also with chronic pain at follow-up. When adjusted for the other Fib3 peptide concentrations, only Fib3-1 was significantly associated to the incidence of the ACR criteria (OR 2.5 [1.0-6.2]) and chronic pain at follow-up (OR 2.6 [1.1-5.9]).

Conclusion: Baseline Fibulin3 concentrations are associated to the incidence of clinical knee OA among middle-aged overweight and obese women. Therewith, they meet the criteria of a prognostic biomarker according to the BIPED biomarker classification for OA. Further validation of the Fibulin3 fragments seems warranted in order to better distinguish subgroups of individuals at increased risk for knee OA development.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Osteoarthritis - Clinical Aspects Poster II: Biomarkers, Biomechanics and Health Services Research
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: We recently reported an association between gout and osteoarthritis (OA) presence and severity, and a possible association between hyperuricemia and OA severity (Howard et al, JCR 2014). Others have reported that synovial fluid uric acid levels among non-gout patients correlate with OA severity (DeNoble et al, PNAS 2011). To date however, the possibility that serum UA (sUA) levels may be associated with OA progression has not been assessed. We therefore asked whether higher levels of sUA were associated with OA progression, determined as joint space narrowing (JSN), in a natural history cohort of non-obese symptomatic knee OA (SKOA) patients.

Methods: The NYU SKOA cohort consists of subjects followed for clinical, imaging and laboratory parameters for 24 months. Only patients with BMI<32 are included. From 144 completers we selected the first 80 subjects enrolled, and measured a single-point sUA level by ELISA (in duplicate) using previously banked and frozen serum. At entry and 24 months, patients underwent standardized weight-bearing fixed-flexion posteroanterior knee radiographs using the SynaFlexer™ methodology. Diseased compartment joint space width (dcJSW) and Kellgren-Lawrence (KL) grades in the signal (more painful) knee were determined by a musculoskeletal radiologist blinded to patient information (LR). Our primary outcome was extent of progression of JSN (decline in JSW in mm) over 24 months, as a function of sUA.

Results: Mean baseline KL score for all 80 subjects was 2.2, and mean baseline dcJSW was 3.5 ±1.3mm. Patients were 62% female, with a mean age of 61±10 years and mean BMI of 26.7±3.6kg/m^2. Most sUAs were <7.0 mg/dL, consistent with a non-obese, predominantly female population. Consistent with prior reports, sUA levels correlated with age (p=0.02) and BMI (p=0.04). We observed no significant associations between sUA and baseline JSW or KL score. In contrast, we observed a modest but statistically significant correlation between sUA and JSN across all patients (R=0.22;p=0.048). Additionally, when dichotomized by JSN (≥0.5 or <0.5mm/24mo), progressors demonstrated significantly higher sUA levels vs non-progressors (2.35 vs 2.92mg/dl, p=0.004). Conversely, patients with above-median sUA levels experienced more JSN compared with those below the median, though these differences did not achieve significance (0.41 vs 0.63 mm, p=0.30). When analyzed according to baseline severity (either KL grade or dcJSW quartiles) we observed non-significant trends of increasing JSN with increasing sUA in all but the KL3 and third quartile of dcJSW groups.

Conclusion: Our data suggest that increasing sUA concentrations may be associated with increased rates of JSN among non-obese patients with SKOA. If confirmed in other populations, these data would warrant investigation into the mechanisms/directions of the association, and possibly into the question of whether urate lowering in patients with early OA may be a strategy to reduce and/or prevent progression.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Osteoarthritis - Clinical Aspects Poster II: Biomarkers, Biomechanics and Health Services Research

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The osteoarthritis (OA) population is heterogeneous and it is therefore difficult to target all patients with the same intervention. Thus there is a clinical need for diagnostic tools, which can aid in identification of patients of different phenotypes. Urinary CTX-II is a biomarker of cartilage degradation, which previously have been associated with disease severity. Serum C3M is a biomarker of type II collagen remodeling, which is released from the synovial membrane when induced with pro-inflammatory cytokines. We hypothesize that patients with low cartilage degradation (low CTX-II), but a high synovial turnover (high C3M) have a synovial-driven OA, whereas patients with a high level of cartilage degradation and a low level of synovial turnover have a cartilage-driven phenotype, and that these phenotypes are markedly different. The aim of the study was to compare these two phenotypes on clinical parameters and thereby test above hypothesis.

Methods: CTX-II and C3M were measured in the urine/serum of knee OA patients (n=497) from the placebo arms of the two phase III RCTs (NCT00486434 and NCT00704847). Baseline pain questionnaires (WOMAC), as well as radiography and MRI of both knees (target (T), non-target (NT)) were recorded for each patient. Biomarker cut-offs were determined at the 75%-quartile limit. The synovial phenotype (n=89) was defined as having C3M levels above 7.3ng/mL and CTX-II levels below or equal to 345pmol/mL (creatinine corrected). The cartilage phenotype (n=99) was defined as the inverse. Difference between clinical measures and biomarkers in the two patient groups were analyzed by Mann-Whitney.

Results: There were no difference in age and BMI, nor gender distribution, in the two phenotype groups. Joint space width were significantly lower in both knees the cartilage phenotype (NT, p=0.0083; T p=0.042). The sum of Kellgren-Lawrence score was significant higher in the cartilage phenotype (p=0.0001). This corresponded to a significantly higher cartilage volume in the synovial phenotype (NT, p=0.0026; T, p=0.046). Interestingly, WOMAC pain was significantly higher in the cartilage-driven phenotype as compared to the synovial phenotype (NT, p=0.045; T, p=0.014).

Conclusion: We found the two phenotypes, defined by two biomarkers reflecting synovial and cartilage turnover, respectively, where significantly different when comparing standard clinical measures. This may indicate that non-invasive biomarkers may aid in the identification of patient phenotypes and thereby, in the future, aid in guiding treatment of patients.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Osteoarthritis - Clinical Aspects Poster II: Biomarkers, Biomechanics and Health Services Research
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: CPPD crystals are frequently deposited in the fibrocartilage of the meniscus and detected radiographically as linear calcification, termed chondrocalcinosis (CC). Several studies have found an association between CC and the severity of OA. However, CC has not been associated with worsening of OA, and its role in the pathogenesis of OA is not well understood. In this study, we explored whether CC was associated with synovitis on MRI or pain in patients with knee OA by examining data from the Osteoarthritis Initiative (OAI).

Methods: The study rationale and inclusion criteria for the OAI (men and women ages 45–79 with symptoms of and/or knee radiographic OA or risk factors for developing knee OA) have been described previously (http://oai.epi-ucsf.org/datarelease/). We included subjects who were 60 years and older and had Kellgren-Lawrence (KL) grade 0, 1, or 2 on baseline radiograph. We conducted a matched cohort study by selecting subjects with CC on baseline knee radiograph and age, gender, and KL grade-matched controls with no CC. We assessed each subject for synovitis by MRI Osteoarthritis Knee Score (MOAKS) on 4-year MRI. MOAKS synovitis score includes the Hoffa synovitis and effusion synovitis score. If the person had the same KL grade in both knees, we assessed one knee (left knee) per person. Wilcoxon two sample test was performed to compare MOAKS synovitis scores. Then we conducted a cohort study to assess the association between baseline CC and the Intermittent and Constant Osteoarthritis Pain (ICOAP) score at 4 years. ICOAP is a questionnaire to assess intermittent and constant pain for the past 7-day period with score ranging from 0 to 100. Linear regression was performed and the data were adjusted for age, gender, BMI, and KL grade. The correlation between two knees in a subject was controlled using generalized estimating equation.

Results: We assessed MRI of 191 knees (97 CC, 94 control) from the OAI data base. There was no difference in Hoffa synovitis score (0.9 [0.8,1.0] vs 0.9 [0.8,1.0], p=0.81) and effusion synovitis score (3.7 [3.2,4.2] vs 3.8 [3.3,4.3], p=0.60) at 4 years between the CC group and the control group. We also compared subjects within each KL grade and found there was no association with synovitis. However, there was an association between CC and ICOAP score. Knees with CC (n=138) had significantly higher intermittent pain score at 4 years compared to knees without CC (n=1760) (Table 1).

Conclusion: Knees with CC did not have higher MOAKS synovitis scores on MRI compared to knees without CC but CC was associated with significantly higher ICOAP intermittent pain scores. These results suggest that CC is associated with increased intermittent knee pain but that this pain may not be explained by an increase in synovitis.

Session Date: Tuesday, November 10, 2015

Session Title: Osteoarthritis - Clinical Aspects Poster II: Biomarkers, Biomechanics and Health Services Research

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

The objective of the study was to determine whether clinically assessed baseline quadriceps weakness predicts cartilage loss on

MRI after 3 years.

Methods:

Subjects 40-79 years old with knee pain were recruited as a random population sample. Stratified sampling technique was used to achieve equal representation of age and gender. A physician examiner assessed quadriceps strength with the subject in the sitting position, using a standardized procedure, previously shown to be reliable. Quadriceps strength was graded from 0 to 2 (0: poor resistance, 1: moderate resistance, 2: full resistance). Subjects were then classified as having either normal strength (grade 2) or quadriceps weakness (grades 0 and 1). Radiographs were graded using Kellgren-Lawrence (KL) 0-4 scale with KL ≥2 considered radiographic osteoarthritis (ROA). MRI of the knees was obtained on a 1.5T magnet at baseline and at 3-year follow up. MRI cartilage was graded on a scale from 0 to 4 and bone marrow lesions (BML) were graded from 0 to 3 by an experienced musculoskeletal radiologist, blinded to time sequence and clinical information. Progression of OA was defined as worsening of cartilage damage by ≥1 MRI grade in at least 2 joint surfaces or ≥2 MRI grades in 1 joint surface. Logistic regression analysis was performed to evaluate the association of quadriceps weakness with whole knee cartilage loss (primary outcome) and with compartment-specific cartilage loss in the medial and lateral tibiofemoral (TF) and patellofemoral (PF) compartments (secondary outcomes). Crude OR, adjusted OR and 95% confidence intervals (CI) were calculated. Adjustments were included for age, sex, BMI, malalignment (varus or valgus), baseline MRI cartilage score (using the maximum cartilage score for the entire joint), baseline presence of BML and follow-up time.

Results:

Of 255 subjects, 163 were seen at a mean follow-up of 3.3 years. Of these, 24.1% had no OA (normal MRI and radiograph), 36.5% had pre-ROA (normal radiograph, abnormal MRI) and 39.4% had ROA (abnormal MRI and radiograph) at baseline. Mean (SD) age was 57.7 (10.1) years, BMI 26.1 (4.2), WOMAC pain score 19.6 (16.8) and 54% were female. Baseline quadriceps weakness was seen in 17.5% of females and 5.3% of males. Quadriceps weakness was a significant predictor of whole knee cartilage loss (OR 3.38, 95% CI 1.01-11.30). In sex-specific analyses, cartilage loss was significantly increased in females with quadriceps weakness (OR 4.91, 95% CI 1.11-21.79), not in males (OR 0.63, 95% CI 0.04-10.09). In compartment-specific analyses, quadriceps weakness was significantly associated with cartilage loss in the medial TF compartment (OR 7.12, 95% CI 1.39, 36.45), while no significant associations were seen in the lateral TF (OR 1.40, 95% CI 0.16-12.02) and PF compartments (OR 2.28, 95% CI 0.35-14.90).

Conclusion:

In this population-based cohort with knee pain, quadriceps weakness at baseline assessed by clinical examination, predicted whole knee cartilage loss in females, not males and predicted cartilage loss in the medial TF compartment after 3 years. A simple clinical test can assist clinicians to predict the risk of progression of early and advanced knee OA.

Implications of a Positive Patellar Bulge Sign of Knee Joint Effusion in Patients with Osteoarthritis: Association with MRI Signs of Inflammation and with Increased Rate of 5-Year Total Knee Arthroplasty. Data from the Osteoarthritis Initiative

Benjamin Smith[1], David McDougall[2], Robert G Lambert[3], Walter Maksymowych[4] and Jacob Jaremko[3], [1]Radiology & Diagnostic Imaging, University of Alberta, Edmonton, AB, Canada, [2]Radiology, University of Alberta, Edmonton, AB, Canada, [3]Radiology, Radiology, University of Alberta, Edmonton, AB, Canada, [4]Medicine, University of Alberta, Edmonton, AB, Canada
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Osteoarthritis - Clinical Aspects Poster II: Biomarkers, Biomechanics and Health Services Research
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Most of our understanding of the clinical significance of a knee joint effusion is derived from trauma in young patients, with surprisingly little assessment of the meaning of an effusion in osteoarthritis (OA). It is unclear whether clinical examination of the knee for effusion is of any practical use or correlation to outcome. We sought to determine the specificity and sensitivity of clinical evaluation of knee joint effusion in OA for presence of an effusion on MRI, and the relationship of a clinical effusion to patient status and clinical outcome.

Methods:

We performed a case-control study of 80 patients with OA, with a 5 year follow-up, and validation in the Osteoarthritis Initiative dataset. This cohort study included knees from 40 subjects from the OAI dataset that had a knee corticosteroid injection within 1 year after baseline evaluation, and 40 that did not, matched by age, sex, and Kellgren-Lawrence (K-L) grade of radiographic OA.

Baseline MRI, clinical examination (patella tap and patella bulge test), Kellgren-Lawrence grading, and WOMAC scores were obtained. The MRI were evaluated for effusions by two semi-quantitative scoring systems (MOAKS and KIMRISS). The incidence of corticosteroid injection and WOMAC scores at 12 months, and of total knee replacement (TKR) within 5 years, as well as 5-year radiographic progression using K-L grade, were recorded. Pearson correlation coefficients, one-way analysis of variance (ANOVA) and multivariate logistic regression were used as appropriate to assess for significant associations.

Results:

Subjects averaged 62.3 years old (range: 45-78), 78% were women, and BMI averaged 30.3±4.6, with moderate to severe OA (K-L grade 2.8±1.0 (mean±standard deviation).

The clinical bulge test was 100% specific but only 29% sensitive for knee joint effusion as detected by MRI. The patella tap sign was only 4.8% sensitive, and not analyzed further. Bulge-positive knees were associated with higher baseline WOMAC disability (26.9 vs 18.2, p=0.02) and pain scores (5.4 vs 3.7, p=0.03) compared to bulge-negative knees. Bulge-positive knees were significantly more likely to have corticosteroid injection within 12 months (78% vs 58%, p=0.007).

An analysis of the whole OAI dataset revealed a 3-fold increase in 5 year TKR for bulge-positive patients (9% vs 3%, p<0.0001, n=9302), with bulge-positivity significantly predicting TKR using multivariate logistic regression (odds ratio 2.0 [95% CI 1.4-2.9], p<0.0001, n=4324).

Conclusion:

The patellar bulge test is a relatively insensitive but highly specific clinical marker for joint effusion in OA. A positive patellar bulge test at presentation is associated with greater pain, disability, a higher rate of corticosteroid injections and a 2- to 3-fold increase in TKR within 5 years.

Knee Sounds May Predict Osteoarthritis Severity, Symptoms and Function: Pilot Investigation Toward a Novel Dynamic Imaging System

Victoria Manning[1], Costas Yiallourides[2], Mads Brevadt[1], Alastair Moore[2], Edouard Auvinet[1], Patrick Naylor[2] and Justin Cobb[1], [1]Musculoskeletal Lab, Imperial College London, London, United Kingdom, [2]Communications and Signal Processing Group, Imperial College London, London, United Kingdom

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Osteoarthritis - Clinical Aspects Poster II: Biomarkers, Biomechanics and Health Services Research

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Knee sounds (KS) may provide a low-cost, risk-free means of identifying presence and severity of knee osteoarthritis (KOA). Unlike static imaging, KS during dynamic activity may correlate with symptoms and function. This study aimed to explore the association between KS, KOA severity, symptoms and function.

Methods:

Adults with clinical KOA (1986 ACR) were recruited from a UK orthopedic clinic by the attending surgeon (JC). Adults (at Imperial College London) reporting no previous knee pain >2 weeks were recruited. Knees were classified as: 1) OA, 2) healthy, 3) OA healthy (contralateral KOA). Exclusion criteria were: aged <18 years, previous surgery, unable to provide consent.

Severity of OAwas assessed (single rater) using the Kellgren-Lawrence (KL) radiographic scoring method. Knee symptoms and function were assessed via self-reported Knee Injury and Osteoarthritis Outcome Scores (KOOS). KS were acquired (rate 44-48kHz) during treadmill walking (4km/h) using a contact microphone (Basik Pro, Schertler, 20Hz to 20kHz) attached to the patella, supported by a digital preamplifier (RME Babyface; PreSonus DigiMax LT).

KS features were extracted from recordings using spectro-temporal and cepstral analysis, and correlations (r) with KL and KOOS explored. Features correlating over $|r|>0.6$ were used to train binary regression decision trees to identify KS feature-combinations predictive of KOOS. Pearson's and Bland and Altman's 95% limits of agreement (LOA) were used to assess association between predicted and true values.

Results:

Twenty-eight participants were recruited; 14 knees were excluded due to previous surgery, 42 knees were included (Table 1). OA healthy knees were excluded from KOOS. Twenty knee x-rays were available dating 10±7 (all ≤ 27) weeks pre-assessment.

Of 8,141 extracted KS features, 267 exceeded $|r|>0.6$ with KL and KOOS (Figure 1). Predicted KOOS were strongly correlated with true KOOS, except quality of life (QOL) (Figure 2); mean (95% LOA) = pain -0.8 (47.2 to -48.8); symptoms 0.2 (34.6 to -34.1), activities of daily living 0.7 (40.2 to -38.8); QOL 2.1 (67.1 to -63.0).

Conclusion:

These preliminary findings indicate that KS are predictive of OA symptoms and function, and possibly severity. Whilst encouraging, further investigation is required among a larger cohort.

The 2011 Fibromyalgia (FM) Criteria Are Helpful in Identifying Central Sensitization in Knee Osteoarthritis

Steven E. Harte[1], Andrew D. Clauw[1], J. Ryan Scott[1], Daniel J. Clauw[2] and Chad Brummett[2], [1]Department of Anesthesiology, University of Michigan, Ann Arbor, MI, [2]Anesthesiology, University of Michigan, Ann Arbor, MI

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Osteoarthritis - Clinical Aspects Poster II: Biomarkers, Biomechanics and Health Services Research

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Both animal and human studies have suggested that both peripheral and central sensitization may occur in nociceptive pain states such as OA. This distinction is important since although peripheral sensitization is due to ongoing peripheral nociceptive input and would respond to more aggressive use of peripherally-directed therapies, if central sensitization or centralized pain is identified, this may indicate that treatments aimed at the central nervous system may be more helpful. Using quantitative sensory testing (QST), the presence of peripheral sensitization is suggested when there is tenderness (i.e. mechanical hyperalgesia/allodynia) localized to the knee, whereas if both the knee and a distant site are tender this is suggestive of central sensitization. Although both peripheral and central sensitization are typically identified using sophisticated pain research tools such as quantitative sensory testing (QST) or functional brain imaging, recent studies have suggested that the 2011 Survey Criteria for FM, used as a continuous rather than dichotomous variable, may be helpful in identifying individuals who have centralized pain. We hypothesized that if this was the case, individuals with knee OA with higher FM scores should have a stronger relationship between the mechanical pain threshold at the knee and that at a distant "neutral" site such as the thumb.

Methods: As part of a larger study of analgesic outcomes following total knee arthroplasty, a subset of 63 individuals (ages 42 – 81, 24 males, 39 females) scheduled to undergo arthroplasty had a mechanical pain threshold assessed at both their painful knee and dominant thumb, and also completed the 2011 FM criteria. We then performed a tertile split of the cohort using FM scores, with the lowest tertile of 22 individuals having FM scores of 0-3, the middle tertile of 23 individuals having scores of 4-7, and the highest tertile of 18 individuals having scores of 8 or greater.

Results: Using non-parametric correlations (Spearman's rho), we found that in the lowest FM tertile, there was no significant relationship between the mechanical threshold at the knee, and that measured at the thumb (r_s = .305, p = .167). The middle FM tertile showed a stronger but still statistically insignificant correlation (r_s = .352, p = .099). However, individuals with KOA in the highest FM tertile displayed a highly significant correlation between the threshold at the knee, and that measured at the thumb (r_s = .651, p =.003).

Conclusion: These data lend further evidence that the 2011 FM Survey Criteria, when used us a continuous rather than dichotomous measure, serve as a surrogate measure for the presence of central sensitization in KOA. Together with previously published studies from this same cohort suggesting that this measure is also strongly predictive of both opioid and surgery non-responsiveness, this suggests that this measure may provide useful in both research and clinical practice in identifying individual who might benefit from more centrally-directed therapies such as centrally acting analgesics, or non-pharmacological therapies.

Comparison of Knee Osteoarthritis Treatment in the Non-Obese Versus Obese Populations Across Different Medical Specialties

Kelly Forrester[1], Farah Taufiq[1] and Jonathan Samuels[2,3], [1]NYU Langone Medical Center, New York, NY, [2]Rheumatology, NYU - Hospital for Joint Diseases, New York, NY, [3]Rheumatology, NYU Langone Medical Center, New York, NY
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Osteoarthritis - Clinical Aspects Poster II: Biomarkers, Biomechanics and Health Services Research
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Knee osteoarthritis (KOA) in the obese population is underdiagnosed and routinely undertreated, as providers often attribute pain to excess weight without considering articular pathology. The literature does not speculate if obese and non-obese patients are offered the same treatment options for their KOA. Using a retrospective chart review, we compared approaches to KOA treatment across BMI subgroups as well as between physician specialties: rheumatology, orthopedics, sports medicine, physiatry, and internal medicine.

Methods: We searched the NYU electronic medical record between January 1 and December 31, 2013 for patients seen for KOA by selected physicians in the 5 specialties. From the resulting list of 4,486 patients, we reviewed the first 1,500 charts and selected for clinical and radiographic KOA while excluding patients with bilateral knee replacements, trauma within 6 weeks, or concurrent rheumatoid arthritis, psoriatic arthritis, gout, pseudogout, or bursitis. From this cohort we found 702 who met criteria (191 patients seen by rheumatology, 162 by orthopedics, 198 by sports medicine, 132 by physiatry, and 20 by internal medicine). We recorded BMIs, comorbidities, KOA characteristics, and KOA management including acetaminophen, NSAIDs/COX-2 inhibitors, physical therapy referrals, and intra-articular injections of steroids or hyaluronic acid (HA). We analyzed differences in overall KOA treatment of non-obese vs. obese patients (BMI <30 vs ≥ 30 kg/m^2), and between the 5 physician specialties regardless of patient BMI.

Results: The resulting cohort of 702 patients had an overall mean BMI of 29.1 (±7). The mean age was 60.5 (±14) with 75% females. Surprisingly, we did not find any significant differences in KOA treatment of non-obese (BMI<30) vs obese patients when aggregating scores across physician specialties; this held true when comparing the non-obese with the morbidly obese (BMI>35). Our data do suggest that rheumatologists recommend acetominophen for KOA far more often than do the combined cohort of orthopedists, physiatrists and sports medicine physicians (37% vs 3%, $p<0.001$); internists (at 43%) are even greater proponents of acetaminophen. We did not identify any significant difference between specialties in the percentage of KOA patients prescribed NSAIDs or COX-2 inhibitors, referrals to physical therapy, or the use of corticosteroid injections. With regards to HA, rheumatologists in our cohort inject less than orthopedists (17% vs 26%, $p=0.06$), sports medicine physicians (17% vs 30%, $p=0.004$), and physiatrists (17% vs 29%, $p=0.02$). We also found no reportable difference in specialty-specific KOA treatment between the BMI sub-groups.

Conclusion: In treating KOA, rheumatologists and internists are more likely to prescribe acetaminophen for KOA while orthopedists, sports medicine physicians, and physiatrists are more like to inject HA. Despite preconceived bias, we did not identify significant differences in the KOA treatment of non-obese vs obese patients, in aggregate or within any of the subspecialties. Nevertheless, identification of divergent treatment patterns between specialties warrants discussion to optimize algorithms across musculoskeletal care.

Session Date: Tuesday, November 10, 2015

Session Title: Osteoarthritis - Clinical Aspects Poster II: Biomarkers, Biomechanics and Health Services Research

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The burden of osteoarthritis (OA) is substantial and expected to increase because people are getting older and heavier. Health care providers need to monitor and improve the quality of health services for people with OA. The purpose of this study was to evaluate the state of quality of care for OA by summarizing studies that have assessed the care provided to patients.

Methods: A systematic review of community-based observational studies that assessed the quality of care for patients living in the community with OA, by comparing actual clinical practice to a quality indicator (QI) was performed. Four databases were searched from January 2000 to November 2014. Two reviewers independently determined study eligibility, assessed risk of bias and extracted study data. The outcome was adherence to the QIs (pass rate), calculated as all instances in which recommended care was received or delivered divided by the number of times participants were eligible. No pooling of overall pass rates was performed, but when at least 50% of the studies had comparable individual QIs, the data were pooled with proportion meta-analyses.

Results: Nine studies from North America and Western Europe comprising 4037 patients were included. The Assessing Care Of Vulnerable Elders (ACOVE) indicators and RAND's Quality Assessment Tools system and were the most commonly used QI sets. The number of individual indicators in the sets used varied from 3 to 17, and data were collected from medical records in five studies, and by patient reports in four studies. The median overall pass rate across studies was 38% (ranging from 22% to 65%). Six individual indicators were similar across at least five studies, and were consequently pooled (table).

Quality Indicator	Pooled Passrate (95% CI)
Referral to orthopedic surgeon if no response to other therapy	73.5 (52.4-87.5)
Paracetamol or acetaminophen first drug used	45.9 (39.6-52.4)
Assessed for pain and/or function	45.8 (30.0-62.5)
Offered education and/or self-management	32.3 (17.8-51.3)
Referral or recommendation to exercise	30.4 (23.4-38.5)
Informed about potential risks if NSAIDs prescribed	21.4 (10.6-38.5)

Conclusion: On average, one-third of OA patients received first line non-pharmacological approaches, which was significantly lower than the nearly three-quarters referred to orthopedic surgery. This pattern seems to be consistent across North America and Western Europe, and indicates a substantial need for improvement in community-based OA care.

Factors Associated with Physical Therapy Use in Osteoarthritis of the Knee:

Results from a Population-Based Study

Sicong Huang[1], Eric C. Sayre[2] and Jolanda Cibere[1,2], [1]Department of Medicine, University of British Columbia, Vancouver, BC, Canada, [2]Arthritis Research Canada, Richmond, BC, Canada

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Osteoarthritis - Clinical Aspects Poster II: Biomarkers, Biomechanics and Health Services Research
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoarthritis (OA) is the most common form of arthritis. Physical therapy (PT) has previously been demonstrated to benefit patients with osteoarthritis, especially with early referral. However, few studies have investigated factors affecting PT use and none have involved a Canadian population, where the mixed private and public payer system could affect usage rates. The objective of this study is to identify factors associated with PT use in a population-based cohort with OA-associated knee pain.

Methods: 255 subjects were recruited as a random population sample (MoDEKO study) in Greater Vancouver, Canada. Inclusion criteria were: 1) age 40–79 years, 2) pain, aching, or discomfort in/around the knee on most days of the month at any time in the past, and 3) any pain, aching, or discomfort in/around the knee in the past 12 months. Exclusions were: 1) inflammatory arthritis or fibromyalgia, 2) knee arthroplasty, 3) knee injury or surgery within the past 6 months, 4) referred pain from hips or back, and 5) inability to undergo MRI. PT use during the past 12 months (dependent variable) was ascertained by self-report. Independent variables included predisposing characteristics including age, sex, ethnicity, level of education (≤/> grade 12), and median household income using the 2006 Canadian Census data based on postal codes, as well as need characteristics including body mass index (BMI), self-reported knee swelling in the past 12 months, physician diagnosis of OA, radiographic severity (Kellgren–Lawrence grading (KL) ≥2/KL <2), and pain severity on flat walking, as assessed by the Western Ontario and McMaster Universities (WOMAC) Osteoarthritis Index. Univariate logistic regression analysis was performed. Variables with $p<0.20$ were included in a multivariable logistic model to assess the association with PT use.

Results: 29 of 255 (weighted 12%) subjects reported PT use. Mean age was 57, mean BMI 26.5, mean household median income $61,560, and mean WOMAC pain 17. 56% were female, 76% Caucasian, 77% attended post-secondary education, 39% were diagnosed with OA by a physician, 38% had KL ≥2, 51% reported knee swelling. In multivariable logistic regression analysis, female gender (OR 3.19, 95% CI 1.29-7.89) and self-reported knee swelling (OR 3.51, 95% CI 1.42-8.68) were significantly associated with PT use, while household income (as a factor of $10,000, OR 1.15, 95% CI 0.97-1.37), physician diagnosis of OA (OR 1.19, 95% CI 0.53-2.71), WOMAC pain on flat walking (as a factor of 10, OR 1.11, 95% CI 0.93-1.32) were included in the multivariable model, but were not statistically significant.

Conclusion: In this population-based study of subjects with knee pain, women and those with self-reported knee swelling were three times more likely to be current PT users. Interestingly, disease severity, physician diagnosis of OA, and household income were not significantly associated with current PT usage. Further longitudinal research will be important to identify other factors affecting PT use in order to target individuals at risk of underuse and/or overuse.

Session Title: Osteoarthritis - Clinical Aspects Poster II: Biomarkers, Biomechanics and Health Services Research

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To define a minimum Standard Set of outcome measures and case-mix factors for monitoring, comparing, and improving healthcare for patients with clinically diagnosed hip or knee osteoarthritis (OA) with a focus on defining the outcomes that matter most to patients.

Methods: An international Working Group (WG) of patients, arthroplasty register experts, orthopedic surgeons, primary care physicians, rheumatologists, and physical therapists representing 10 countries was assembled to review existing literature and practices for assessing outcomes of pharmacological and non-pharmacological OA therapies including surgery. A series of 8 teleconferences, incorporating a modified Delphi process, were held to reach consensus.

Results: The WG reached consensus on a concise set of outcomes measures to evaluate patients' joint pain, physical functioning, health-related quality of life, work status, mortality, reoperations, readmissions, and overall satisfaction with treatment result. To support analysis of these outcome measures, pertinent baseline characteristics and risk factor metrics were defined (see Table 1). Annual outcome measurement is recommended for all patients.

Conclusion: We have defined a Standard Set of outcome measures for monitoring the care of people with clinically diagnosed hip and knee OA that is appropriate for use across in all treatment and care settings. We believe this Standard Set provides meaningful, comparable, and easy to interpret measures ready to implement in clinics and/or registries globally. We view this as an initial step that, when combined with cost data, will facilitate value-based healthcare improvements in the treatment of hip and knee OA.

Outcome Domains	Risk Factor Domains
Patient reported • Hip and/or knee function (HOOS-PS or KOOS-PS) • Pain in the hips, knees or lower back (Numeric or visual analog rating scale) • Quality of life (EQ-5D-3L or VR-12/SF-12) • Satisfaction with treatment • Work status Surgical outcomes • All cause 30-day mortality • All cause 30-day readmissions • Reoperation Disease progression • Care utilization • Treatment progression	Demographics • Age • Gender • Education level Baseline clinical status • Joint specific history • Joint specific surgical history Case-mix factors • Living status • BMI • Smoking status • Co-morbid conditions

Abstract Number: 2411

Patient Preference for Using Technology to Track and Self-Manage Osteoarthritis

Laura Khurana, **Ellen Durand**, Sarah Gary, Tony Otero, Chris Hall and Susan Dallabrida, ERT, Boston, MA

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Osteoarthritis - Clinical Aspects Poster II: Biomarkers, Biomechanics and Health Services Research

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Active and consistent self-management is essential for patients suffering from chronic diseases to improve their health. Electronic clinical (eClinical) technology may improve how patients track and manage disease. The aim of this study was to establish how subjects with osteoarthritis (OA) currently use technology to monitor and manage their health and their interest in using eClinical technology in clinical care.

Methods: Subjects aged 37-90 with OA (n=104) were surveyed as part of a mode equivalence study. Subjects were diverse in age, sex, ethnicity, and technology use. Subjects answered questions regarding how they use technology to manage disease and general health.

Results: 50% of subjects have access to a home computer, and 53% have home internet. Subjects that use the internet most commonly use a computer (71%), smartphone (22%), or tablet (7%). 48% reported using the internet daily. 39% of subjects reported that they regularly monitor or keep track of their disease. Of those subjects that do monitor their OA, 94% use paper and 6% use a computer or online forum. Subjects reported that if they need more information about managing their OA they ask their physicians (88%), use the internet (42%), and ask friends/family (35%). 48% of subjects reported searching online for information about OA and/or treatments on at least a monthly basis. With respect to OA, subjects were most likely to research information on their current treatments (83%) and the impact of diet on their disease (64%), followed by new drugs (44%), disease complications (43%), and the impact of exercise on OA (35%). With respect to their general health, subjects were most likely to search online for recommendations about diet (68%), and least likely to research how much water they should drink (12%). When asked about a potential smartphone application that provides educational messages about OA, subjects wanted messages to include information on the effects of foods/beverages on medications they are currently taking (69%), nutritional value of foods they currently eat (66%), and heathy alternatives to those foods (66%).

Conclusion: This study characterized how subjects with osteoarthritis use technology to track and research their disease. Nearly half of subjects use the internet to get information about managing their OA on a monthly basis or more. Subjects prefer to research their current treatments and the impact of diet on disease, and would like similar information provided via smartphone app. Understanding the type of information that patients track regarding their health may help identify areas for more effective intervention, and assist in the development of tools to improve patient engagement.

Abstract Number: 2412

Assessment and Comparison of Responsiveness of Four Patient Reported Outcome Measures to Assess Physical Function in Patients with Knee Osteoarthritis: WOMAC-PF Subscale Responds Best

Elien A.M. Mahler[1], Nienke Cuperus[2], Johannes W J Bijlsma[3], Thea Vliet Vlieland[4], Frank H.J. van den Hoogen[5], Alfons den Broeder[5] and Cornelia H.M. van den Ende[1], [1]Department of Rheumatology, Sint Maartenskliniek, Nijmegen, Netherlands, [2]Rheumatology Department, Sint Maartenskliniek, Nijmegen, Netherlands, [3]Rheumatology and Clinical Immunology, ARC Amsterdam; UMC Utrecht, Utrecht, Netherlands, [4]Rheumatology, Department of Rheumatology, Leiden University Medical Center, Leiden, Netherlands, [5]Rheumatology, Sint Maartenskliniek, Nijmegen, Netherlands
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Osteoarthritis - Clinical Aspects Poster II: Biomarkers, Biomechanics and Health Services Research
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Although physical function is one of the core outcome domains in knee osteoarthritis (OA), the ability of a measurement instrument to detect changes over time in the construct (physical function) being measured, i.e. the responsiveness, has never been tested as currently recommended by the Consensus-based Standards for the selection of health status Measurement Instruments (COSMIN)[1]. The aim of the current study was to compare the responsiveness of physical function between four commonly used disease-specific patient related outcome measures in patients with knee OA following currently recommended standards.

Methods:

Patients with knee OA fulfilling the clinical ACR criteria and receiving conservative treatment following a stepped care approach were invited to complete a set of questionnaires at baseline and three months. Questionnaires included four commonly used measures of physical function ie Knee Injury and Osteoarthritis Outcome Function Short Form (KOOS-PS), the Lequesne Algofunctional index (LAI), Lower Extremity Functional Scale (LEFS), and Western Ontario and McMaster University Osteoarthritis Index Physical Function subscale (WOMAC-PF). Responsiveness of physical function was investigated according to the COSMIN standard by testing 15 a priori defined hypotheses formulated by an expert group regarding expected correlations between changes in physical function with changes in other (un)related measures (pain, fatigue, self-efficacy, coping, anxiety, depression and mental health) or expected differences in correlation. Responsiveness was considered positive if > 75% of the hypotheses could be confirmed.

Results:

Of the 161 included patients, the majority was female (61%), with a mean age of 59 years and a body mass index of 29.7 kg/m^2. We could confirm 12 out of 15 predefined hypotheses (80%) about expected correlations using the physical function subscale of the WOMAC. For the KOOS-PS, LAI and LEFS respectively 11 (73%), 10 (67%) and 11 (73%) hypotheses could be confirmed.

Conclusion:

This is the first study that evaluated and compared the responsiveness of physical function measured with KOOS-PS, LAI, LEFS and WOMAC-PF according to the latest COSMIN standards[1]. Our results suggest that the WOMAC-PF is potentially better able to detect changes over time in physical function than the LAI, LEFS and KOOS-PS in a population of patients with knee OA receiving conservative treatment. We therefore recommend the WOMAC-PF subscale should be the measure of first choice in in clinical trials evaluating the effectiveness of an intervention in knee OA patients.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Osteoarthritis - Clinical Aspects Poster II: Biomarkers, Biomechanics and Health Services Research

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoarthritis (OA) is associated with functional limitations, including difficulty walking. However, comorbid disease is common in people with OA and may also be associated with functional limitations; this includes chronic conditions such as obesity, stroke, angina, heart failure, diabetic neuropathy, and intermittent claudication. Previous studies have demonstrated that walking disability is associated with cardiovascular (CV) events and all-cause mortality. Our aim was to examine the extent to which knee and hip OA contribute to walking disability.

Methods: A population cohort aged ≥55 years was recruited from one urban and one rural community from 1996-98. Age, sex, height and weight, joint complaints, functional limitations and self-reported medical comorbidities known to be associated with walking disability were collected by questionnaire. Subjects with inflammatory arthritis, rheumatic disease, amputation and/or reported use of a wheelchair were excluded. OA was defined as (1) swelling, pain, or stiffness in any joint lasting 6 weeks in the past 3 months; and (2) indication on the homunculus that a knee and/or hip was “troublesome”. Walking disability was defined as self-reported difficulty standing or walking in the last 3 months. Participants were classified into 4 mutually exclusive joint groups based on the presence/absence of knee and hip OA. Using logistic regression, we assessed the independent correlates of walking disability. Covariates of interest were: combined knee and hip OA, knee OA only, hip OA only, neurological disease, CV disease, diabetes and peripheral vascular disease.

Results: 20,644 participants were included: mean age 68.2±8.5 years, 58.5% female, 51.8% rural-dwelling and mean body mass index (BMI) of 25.9±4.5 kg/m^2. Self-reported walking disability was present in 5,667 (27.5%) subjects. In bivariate analysis, presence of walking disability was associated with increased age, female sex, higher BMI and all covariates of interest ($p<0.01$). In the final regression analysis, walking disability was significantly associated with older age (odds ration [OR] 1.04, 1.04 – 1.05, $p<0.01$), sex (OR 0.83, 0.77 – 0.89, $p<0.01$), BMI (OR 1.07, 1.07 – 1.08, $p<0.01$), presence of CV disease (OR 2.12, 1.88 – 2.36, $p<0.01$), diabetes (OR 1.48, 1.28 – 1.71, $p<0.01$), peripheral vascular disease (OR 6.98, 3.46 – 14.06, $p<0.01$) and neurological diseases (OR 3.67, 2.58 – 5.20, $p<0.01$). Controlling for all of these factors, knee and hip OA remained significantly associated with walking disability: knee and hip OA (OR 17.50, 15.33 – 19.97, $p<0.01$), knee OA only (OR 6.66, 6.03 – 7.37, $p<0.01$) and hip OA only (OR 7.13, 6.15 – 8.27, $p<0.01$).

Conclusion: In a large population cohort aged ≥55 years, the greatest independent contributor to walking disability was the presence of symptomatic knee and hip OA. Given the previously documented relationship between walking disability and mortality, addressing OA-associated functional limitations is important in the management of other common chronic conditions.

Session Title: Osteoarthritis - Clinical Aspects Poster II: Biomarkers, Biomechanics and Health Services Research

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Exercise or physical activity are complex interventions whose effectiveness depends on more than one component. We aimed to determine the benefits and harms of high- *vs* low-intensity exercise or physical activity programs in patients with hip or knee OA.

Methods: We searched CENTRAL, MEDLINE and EMBASE to June 2014, CINAHL, PEDro, Scopus and WHO International Clinical Registry to October 2012. We included RCTs of patients with knee or hip OA that compared high- *vs*low-intensity physical activity or exercise programs. High-intensity programs training referred to an increase in the overall amount of training time or in the amount of work or in effort/energy expenditure. Two authors independently assessed study eligibility and extracted data. The quality of the body of evidence was assessed using the GRADE approach

Results: 6 studies (N=656) were included: 5 studies recruited patients with knee OA (N=620) and 1 with hip or knee OA (N=36). In patients with knee OA, pain symptoms and physical function were more improved with high- than low-intensity exercise programs, immediately at the end of the exercise programs (from 8 to 24 weeks). Low-quality evidence indicated reduced pain on a 20-point WOMAC pain scale (mean difference [MD] -0.84, 95% confidence interval [95% CI] -1.63 to -0.04; 4% absolute reduction; NNTB 11, 95% CI 14 to 22) and improved physical function on the 68-point WOMAC disability subscale. We found no statistical difference on major outcomes at mid- or long-term follow-up. Subgroup analysis of 4 studies showed a statistical significant difference with increased exercise time on pain (MD -1.37, 95% CI -2.47 to -0.28; 7% absolute reduction; NNTB 11, 95% CI 9 to 14, very low level of evidence) and physical function (MD -4.10, 95% CI -8.12 to -0.07; 6% absolute reduction; NNTB 10, 95% CI 8 to 13; very low level of evidence). Only one study systematically monitored adverse effects. We are uncertain whether high intensity increase the number of adverse effects (Peto odds ratio 1.72, 95% CI 0.51 to 5.81; 2% absolute reduction, very low level of evidence). We found the overall quality of evidence as low to very low. Most of the studies had an unclear or high risk of bias for several domains and imprecision. Five of the six studies were at high risk for performance, detection and attrition bias.

Conclusion: We found no clear clinical benefits of high intensity *vs* low intense exercise programs for pain, function and quality of life in patients with knee or hip OA. We found no important clinical benefits depending on the type of intensity of exercise programs. Very low quality of evidence shows no difference in the rate of adverse effects. The evidence was downgraded from high to low or very low because of the risk of bias, inconsistency and imprecision. The small number of studies comparing high- *vs* low-intensity exercise programs in OA underscores the need for more studies investigating the dose-response relationship in exercise programs. In particular, further studies are needed to establish the minimal effective intensity of exercise programs needed for clinical effect and the highest intensity patients can tolerate.

Use of Plasma Exchange for Children Hospitalized with ANCA-Associated Vasculitis in the United States

Karen James[1], Rui Xiao[2], Peter A. Merkel[3] and Pamela F. Weiss[1], [1]Rheumatology, Children's Hospital of Philadelphia, Philadelphia, PA, [2]Department of Biostatistics and Epidemiology, University of Pennsylvania, Philadelphia, PA, [3]Division of Rheumatology, University of Pennsylvania, Philadelphia, PA

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters (ACR): Imaging and Novel Clinical Interventions

Session Type: ACR Poster Session C

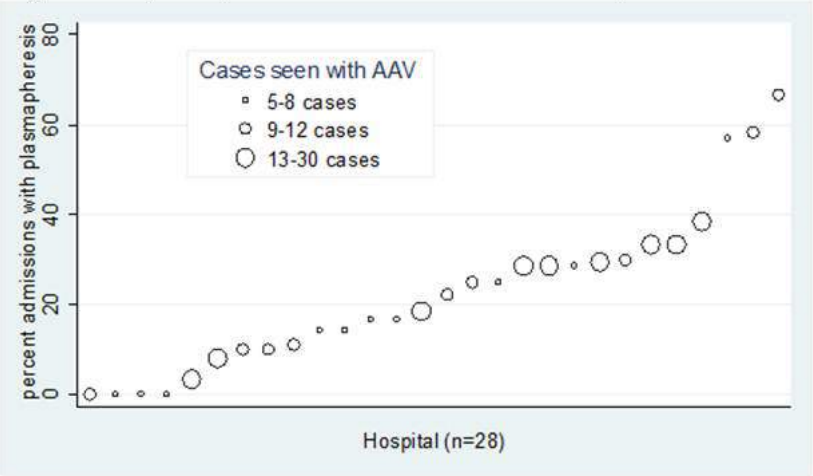
Background/Purpose: ANCA-associated vasculitis (AAV) is a group of rare systemic vasculitidies with significant morbidity and mortality. Plasma exchange (PLEX) has been shown to decrease risk for end-stage renal disease in adults with severe AAV, however there are no data in children. We aimed to characterize the use of PLEX in children with AAV hospitalized in the United States.

Methods: We conducted a retrospective cohort study of children hospitalized with AAV from 2004-2014 utilizing the Pediatric Health Information System database which contains inpatient administrative and billing data from 47 hospitals in the United States. The cohort included patients with the ICD-9-CM code 446.4 as one of the discharge diagnoses and ≥1 charge for glucocorticoids. Cyclophosphamide and rituximab exposure was determined using pharmacy billing data. Receipt of PLEX was determined using ICD-9-CM and clinical transaction classification codes. Demographics and clinical variables were summarized using count & percentage or median & interquartile range as appropriate. We built a multivariate mixed effects regression model accounting for clustering by hospital using a backwards selection model starting with preset variables (age, sex, rituximab, cyclophosphamide, mechanical ventilation, dialysis, year, & hospital case load of AAV) to determine factors associated with use of PLEX.

Results: During the study period there were 1290 admissions for 393 children with AAV at 43 hospitals. Median age at first admission was 14.6 (IQR 12.2,16.1); 60.6% were female. 236 (60%) children required readmission with a median of 2 readmissions (IQR 1, 3). The median length of stay for first admission was 9 days (IQR 4,15). The first readmission was a median of 55 days (IQR 12, 165) after initial discharge, with a median duration of 3 (IQR 2,6) days. During the first admission, 60 (15.5%) children needed dialysis, and 67 (17.1%) required mechanical ventilation. 222 (56.8%) children received cyclophosphamide, 83 (21.2%) received rituximab, 40 (10.2%) received both. Eighty-four children (21.5%) received PLEX, of whom 80 (95%) received concomitant cyclophosphamide and/or rituximab. The median proportion of children who received PLEX at each hospital with ≥5 cases of AAV was 0.20 (range 0-0.67) (Figure). There was a significant increase in the use of PLEX for new patients over the years of study (p=0.04). In multivariate regression, male sex, cyclophosphamide, rituximab, and dialysis were associated with increased odds of receipt of PLEX.

Conclusion: PLEX use for treatment of AAV in children is increasing over time, however its use varies significantly between hospitals. Use of rituximab, cyclophosphamide, and dialysis are associated with receipt of PLEX, confirming its use is reserved for children with more severe manifestations. Future studies are needed to assess the impact of PLEX on outcomes for children with AAV.

Figure. Use of plasmapheresis for children with AAV at US hospitals



Legend. Proportions of children with AAV at each hospital who received plasmapheresis during their first admission are shown. Only hospitals with at least 5 cases of AAV and who contributed data for at least 10 of the 11 years of the study are included. Size of the circle indicates the case load of patients with AAV seen at that hospital during the study period, each size category representing a tertile of case loads

SESSION INFORMATION

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters (ACR): Imaging and Novel Clinical Interventions

Session Type: ACR Poster Session C

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor for the treatment of adult patients with rheumatoid arthritis (RA). We report the pharmacokinetics (PK), safety and taste acceptability of tofacitinib following multiple oral doses in children 6 to <18 years of age with active juvenile idiopathic arthritis (JIA).

Methods: Data were obtained from an ongoing open-label, non-randomized, multi-center, Phase I study (NCT01513902) where children with JIA were given 5 mg adult equivalent (based on body weight) of tofacitinib (tablet or solution) twice daily (BID) for 5 days. There were 3 cohorts (COH) based on subject age, COH 1: 12 to <18 years, COH 2: 6 to <12 years, and COH 3: 2 to

<6 years, with a target enrollment per group of at least 8 children with JIA for a total number of at least 24 evaluable subjects completing the PK period. Patients were enrolled in a step-wise approach beginning with the older age cohort first. Subsequent younger age cohorts were enrolled following confirmation of safety and PK from the previous cohorts. PK parameters of tofacitinib were calculated using non-compartmental analysis of plasma concentration (conc)-time data.

Results: Results from the first 16 subjects from COH 1 and COH 2 were included in this analysis. Overall, subjects' age ranged from 8 to 17 years; all were white race except for one. There were 5 females and 3 males in COH 1 and in COH 2. Baseline disease characteristics were similar across both COH, except CRP; where the mean value was slightly higher in COH 2 than COH 1 (5.7 versus 3.8 mg/L). All exposure metrics including area under the conc-time curves (AUC_{tau}), maximum (C_{max}), minimum (C_{min}), predose (C_{trough}) conc were lower in COH 2 relative to those in COH 1. Apparent volume of distribution (V_z/F) was approximately 32% lower in COH 2 (71 L) relative to COH 1 (104.9 L). Average terminal half-life ($t_{½}$) was 25.5% shorter in the younger patients (1.949 hours in COH 2, to 2.616 hours in COH 1). Mean CL/F of tofacitinib in children with JIA in this study were 52.7% and 38.4% higher in COH 1 and COH 2 subjects, respectively, compared with adult patients with RA receiving tofacitinib 5 mg BID equivalent (based on allometry) dose of tofacitinib (18.4 L/h). PK parameters were similar between males and females. Tofacitinib, administered over 5 days as multiple dose tablets or solution formulation, was well tolerated and taste was found acceptable in children with active JIA. No serious adverse events or new safety signals were identified.

Conclusion: PK results from this study established dosing regimens for children aged 6 years and older to be used in the upcoming efficacy and safety studies of tofacitinib in patients with JIA. Tofacitinib was well tolerated in this study in children with JIA. Overall, subjects found the taste of the tofacitinib solution formulation to be acceptable.

SESSION INFORMATION
Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters (ACR): Imaging and Novel Clinical

Interventions

Session Type: ACR Poster Session C

Background/Purpose:

Enthesitis-related arthritis (ERA) is a juvenile idiopathic arthritis (JIA) category affecting entheses and joints. The REMINDER study to analyse the efficacy of etanercept (ETA) in active and refractory ERA pts, was used to analyse the stability of remission on and off medication (Horneff et al. Arthritis Rheumatol. 2015 Apr 17).

Methods:

In this 2-part, 48-week, randomised, placebo-controlled, double-blind withdrawal study, first, all pts received open-label ETA for 24 weeks. At week 24, pts with at least a JIA-ACR30 response entered a 24-week randomised (1:1 placebo (PLC) or ETA), double-blind withdrawal period. Remission was defined as JADAS10≤1.0. In addition, absence of tender enthesis (TE), active uveitis and spinal involvement (judged by BASDAI) were analysed.

Results:

41 pts (mean age 13.4 y, disease duration 2.8 y, active joint count 5.3, JADAS10 15.8) received open-label ETA (0.8 mg/kg bw., max.50 mg/week) for 24 weeks. 2 pts discontinued prematurely, one for intolerance and one due to a protocol violation. JIA-ACR30/50/70/90/100 response rates at week 24 were 93%/93%/80%/56% and 54%. Remission (JADAS) was reached by 14.6/35/51.3/59.0% at week 4/12/16/24. Until Week 48, 9 JIA-ACR30 flares occurred on PLC, 3 on ETA (odds ratio 6.0, p = 0.02). Until week 48, 6 of 11 (55%) pts had stable JADAS remission while continuing on ETA and 3 of 12 (25%) on PLC (OR 3.6 [0.6-21, p=0.15). An additional patient randomized to ETA achieved remission at week 28 and stayed in remission until week 48. Two pts of the ETA cohort had a disease reactivation at week 28 and week 32, which did not qualify for an ACR30 flare. They continued on double blind ETA and regained remission thereafter. The mean TE count decreased from 1.8 [range 0-7] to 0.8, 0.4, 0.2 and 0.5 and the rate of pts with no TE increased from 34% to 79/76/84/84% at week 4/8/12/24. 13/17 (76%) pts on ETA with no TE at week 24 remained without TE until week 48. 9 pts (69%) of the PLC cohort continued without a TE from week 24 to 48. The mean BASDAI score decreased from 2.6 (range 0-7.3) to 0.8/0.7/0.5/0.4 and the number of pts with a BASDAI of 0 increased from 7.8% to 31.5/34.2/36.8/50% at week 4/8/16/24. 7/10 pts on ETA with BASDAI of 0 at week 24 remained with a BASDAI of 0 until week 48. All 7 pts randomized to placebo, who had a BASDAI of 0 maintained a BASDAI of 0 until week 48 or until reset on ETA. A single uveitis event was reported in a patient randomized to ETA at week 48.

Conclusion: In this placebo-controlled randomized trial ETA proved to be effective with a high rate of pts reaching JADAS remission. Remission continued off treatment in a quarter of pts only while more pts remain in stable remission who continued treatment with ETA.

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters (ACR): Imaging and Novel Clinical Interventions

Session Type: ACR Poster Session C

Background/Purpose: We aimed to compare the clinical features and treatments of children with Enthesitis-related arthritis (ERA) from 5 pediatric rheumatology centers in order to determine whether pediatric ERA manifests differently and/or is treated differently based on geographical location.

Methods: We performed a retrospective multicenter cohort study that included subjects from 5 pediatric rheumatology centers who were diagnosed with ERA from 1989-2012. Baseline visit for patients was defined as the first rheumatology appointment at which the patient had enthesitis, arthritis, or symptomatic uveitis. To be included in the study, patients had to fulfill the ILAR criteria for ERA within the first 6 months from baseline visit. Patient data collected included the following: demographics, clinical features, patient reported outcomes, and medications prescribed at diagnosis and over the following 12 months. Differences across sites were compared using the Kruskal-Wallis or chi-squared test, as appropriate.

Results: 296 children with ERA were included in the study. Patients were predominantly male (69%) and Caucasian (83%). Median age at diagnosis was 12 years (IQR: 10-14) and 53% were HLA-B27 positive. The prevalence of arthritis and uveitis criteria did not differ significantly across sites. The prevalence of the remaining criteria, however, was significantly different across sites (all $p<0.001$): enthesitis (range: 40-88%); sacroiliac tenderness or inflammatory lumbosacral pain (range: 10-55%); HLA-B27 positivity (range: 30-84%); onset of arthritis in a male over 6 years (range: 47-77%); and history of HLA-B27 associated disease in a first-degree relative (range: 8-37%). The table shows medication use stratified by site and clinical features. Overall use of DMARDs and biologics differed significantly among sites ($p<0.001$ and $p<0.001$, respectively). Use of biologics for arthritis (+/- enthesitis) and sacroiliitis (+/- peripheral arthritis or enthesitis) also differed significantly among sites ($p<0.001$ and $p<0.001$, respectively).

Conclusion: Comparison of children with ERA from 5 pediatric rheumatology centers reveals significant variability in the presenting features and initial treatment strategies. The variation in presenting features may reflect either true differences by geographic location or differences between sites in assessment of particular features. Biologic use was significantly different among sites for children with arthritis and sacroiliitis. These differences highlight the need for standardized assessments for ERA as well as comparative effectiveness studies of the different treatment options.

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters (ACR): Imaging and Novel Clinical Interventions

Session Type: ACR Poster Session C

Background/Purpose: Treatment with Etanercept (ETA) was followed prospectively. The purpose of this interim analysis is to evaluate efficacy/ safety of ETA in routine care settings.

Methods: Documentation of pts characteristics, previous/concomitant therapy, disease activity and adverse events. The efficacy was assessed by PedACR criteria and JADAS10 (remission and minimal disease activity, MDA). A control cohort not treated with biologics was established.

Results:

Until 31.12.2014, 2000 JIA pts (67.2% fem.) started ETA. The mean/median age at baseline was 9.4/8.2, disease duration 4.5/3.3 years. The RF-Polyarthritis was the most frequent JIA category (633pts), followed by extended Oligo (396), ERA (330), RF+Poly (171), PsA (149), systemic JIA (143), persistent Oligo (111) and unclass. JIA (67). Pretreatments were performed with steroids 55.5%, methotrexate 88.2%, sulfasalazine 16.6%, azathioprine 11.6%, antimalarials 10.4, and other DMARDs (n=379) as well as 62 therapies with other biologicals (n=35 adalimumab). The initial concomitant treatment was carried out using NSAIDs 81.1%, steroids 40.9%, methotrexate 70.4% and other DMARDs (n=313). A JIA-ACR30/50/70/90 response was reached by 81%/75%/61%/40% after 12 months. A JADAS remission (JADAS10≤1) at month 12/24/36/48/60 was reached by 28%/33%/33%/26%/33% and a JADAS-MDA by 49%/51%/46%/42%/45%. Response rates according to the JIA categories are given in the table.

1225 adverse events were reported (29.1/100 PY), 158 (3.8/100 PY) were serious. Infections were the most frequent AE (350), 29 were SAE. Opportunistic infections including TB did not occur. Rates of adverse events of special interest are shown in table 2. In 1055 patients (53%) the therapy was discontinued. Reasons reported were (>1 possible) remission 409 (20%), ineffectiveness 391 (17%), patient request 342 (17%), intolerance, 124 (6%) and 174 (9%) other. 5 patients died, none during or in connection with the treatment with ETA.

Conclusion: JIA patients achieved high ACR response rates upon treatment with ETA, a JADAS-MDA was frequently reached as well. A JADAS remission was achieved only in part. Overall tolerability was good. Only a small portion discontinued therapy because of intolerance or side effects.

Azathioprine for Glucocorticoid Resistant Non-Renal Henoch-Schönlein Purpura

Paul Tuttle IV[1], Peri Pepmueller[2] and Terry Moore[3], [1]IM-Rheumatology, Saint Louis University, St. Louis, MO, [2]Rheumatology, Saint Louis University, St. Louis, MO, [3]Division of Rheumatology and Pediatric Rheumatology, Saint Louis University School of Medicine, St Louis, MO

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters (ACR): Imaging and Novel Clinical Interventions

Session Type: ACR Poster Session C

Background/Purpose:

Henoch-Schönlein purpura is the most common small vessel vasculitis in childhood and has a classic presentation of palpable purpura. The disease is typically benign and self limited although some patients have gastrointestinal or renal complications requiring more aggressive therapy. Rarely, a subset of patients have persistent or recurrent musculoskeletal, gastrointestinal, and/or cutaneous symptoms without renal involvement despite use of supportive therapy, nonsteroidal anti-inflammatories, and glucocorticoids. There is a paucity of literature regarding therapy of such patients. Some patients respond well to further immunosuppression. We report a case series of three such patients.

Methods:

A retrospective chart review of patients with a diagnosis of Henoch-Schönlein purpura followed in the pediatric rheumatology clinic at Saint Louis University from 1997-2014. All patients met classification criteria for Henoch-Schönlein Purpura with the course of disease, treatment regime, and number of relapses were recorded. Patients referred to rheumatology in our institution generally had musculoskeletal, cutaneous manifestations, and /or mild gastrointestinal or renal involvement. Patients with renal or severe gastrointestinal disease are traditionally followed by those specialists.

Results:

From 1997-2014, 204 patients were seen at Cardinal Glennon Children's Medical Center in all clinics with a diagnosis of Henoch-Schönlein purpura. Twenty four patients meeting classification criteria were referred to the pediatric rheumatology clinic with musculoskeletal, gastrointestinal, and/or cutaneous manifestations. Of those 24 patients, 18 had non-renal disease and 6 had coexisting renal disease. Of those patients with non-renal disease, 15 had resolution of disease with supportive therapy, nonsteroidal anti-inflammatories, and/or one course of corticosteroids. Three patients with non-renal disease failed to control their disease with supportive measures, nonsteroidal anti-inflammatories, and/or glucocorticoids, even after 6-14 months with repeat courses of glucocorticoids at 0.5-1.0 mg/kg/day. These patients were started on azathioprine for 12-19 months which allowed successful prednisone tapering and amelioration of symptoms. Two of the three patients had cutaneous and gastrointestinal symptoms without musculoskeletal disease with remission preserved off all medications with the use of azathioprine at 1 mg/kg/day and 1.4 mg/kg/day. The third patient with cutaneous, musculoskeletal, and gastrointestinal disease was successfully tapered off his prednisone and is currently in remission on azathioprine alone at 2 mg/kg/day over the last 12 months.

Conclusion:

Azathioprine can be used successfully to treat glucocorticoid resistant non-renal Henoch-Schönlein purpura. To our knowledge this is the first published report documenting this therapy.

SESSION INFORMATION

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters (ACR): Imaging and Novel Clinical Interventions

Session Type: ACR Poster Session C

Background/Purpose: Adalimumab (ADA) has become a valuable option for treatment of juvenile idiopathic arthritis (JIA), which significantly improves the outcome of patients. The aim of the German BIKER registry is surveillance of biologics. The purpose of this interim analysis is to evaluate the efficacy and safety under practical conditions.

Methods: Treatment with ADA was followed prospectively by documentation of pts' characteristics, pervious/concomitant therapy, disease activity parameters and adverse events. The efficacy was assessed by PedACR criteria and JADAS10. A control cohort not treated with biologics was established in parallel.

Results: 568 JIA pts (67.2% fem.) started ADA. The mean/median age at baseline was 12.6/13.3, disease duration 5.8/4.9 years. The RF-Polyarthritis was the most frequent JIA category (200pts), followed by extended Oligo (143), ERA (74), persistent Oligo (47), RF+Poly (45), PsA (35), systemic JIA (15), and unclass. JIA (9). Pretreatments were performed with steroids 59.3%, methotrexate 91%, sulfasalazine 12.1%, azathioprine 9.9%, leflonomide (7.2%), antimalarials 5.6%, and other DMARDs (n=47) as well as 347 therapies with other biologicals (313 with Etanercept). The initial concomitant treatment was carried out using NSAIDs 57.7%, steroids 31.3%, methotrexate 59.0% and other DMARDs (n=69). A JIAACR30/50/70/90 response was reached by 69%/66%/51%/35% after 12 months. A JADAS remission (JADAS10≤1) at month 3/6/12/18/24 was reached by 29%/34%/29%/37%</36% and a JADAS-MDA by 53%/59%/54%/56%/59%. Response rates according to the JIA categories are given in table 1.

416 adverse events were reported (57.2/100 PY), 32 (4.4/100 PY) were serious. Infections were the most frequent AE (n=133), 6 were SAE. Opportunistic infections including TB did not occur. 142 patients had had a history of uveitis before baseline. There were 30 uveitis flares. A single patient had a first uveitis upon ADA. Rates of adverse events of special interest are shown in table 2. In 168 patients (29.6%) the therapy was discontinued. Reasons reported were (several same time) remission 39 (6.9%), inefficacy 99 (17.4%), patient request 77 (13.6%), intolerance 34 (5.9%) and 21 (3.7%) other. No patients died.

Conclusion: JIA patients achieved high ACR response rates upon treatment with ADA, a JADAS-MDA was frequently reached as well. A JADAS remission was achieved only in part. Overall tolerability was good. Only a small portion discontinues therapy because of intolerance or side effects.

SESSION INFORMATION

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters (ACR): Imaging and Novel Clinical Interventions

Session Type: ACR Poster Session C

Background/Purpose: Systemic juvenile idiopathic arthritis (SJIA) is a debilitating form of arthritis associated with systemic symptoms such as anemia, rash, leukocytosis, elevated erythrocyte sedimentation rate and acute-phase reactants. High and spiking fevers are also features of the disease. Canakinumab (CAN) leads to improvement for patients (pts) with SJIA exhibiting articular and systemic features at treatment onset.[1] However, little is known about the long-term safety and efficacy in CAN-naïve pts, including those who may not exhibit systemic fever. Here we present the long-term efficacy and safety profile of CAN in SJIA pts with and without fever at CAN initiation.

Methods: Pts aged 2-20 years with SJIA with and without SJIA associated fever at enrollment received open-label CAN 4mg/kg s.c. every 4 weeks. Efficacy was assessed every 3 months by adapted JIA ACR response criteria (aACR/JIA); juvenile arthritis disease activity score [JADAS]; clinical inactive disease; clinical remission on medication [CRM, 6 months continuous clinical inactive disease]. Safety was assessed monthly.

Results: Of 123 pts, 70 (57%) with and 52 (42%) without SJIA associated fever, were available for analysis with a median study duration of 96 weeks. At Week 4, 73% and 81% of pts with and without fever at study entry, respectively had ≥ aACR/JIA30,

increasing to 89% and 92% at Wk12. At Week 2, 23.9% and 24.5% of pts with and without fever at study entry, respectively, had inactive disease which increased to 61.5% and 59.5%, respectively, at Week 32 and thereafter. CRM was achieved in 42.3% of pts in the overall group with 26.8% maintaining it for 12 consecutive months. Median JADAS27-CRP and JADAS10-CRP scores were 6.0 (suggesting moderate disease activity) at Day 15 and 1.5 (indicating low disease activity) at the last assessment, respectively. The disease activity status at baseline and end of study for JADAS10-CRP and JADAS27-CRP are presented in Table. Adverse events (AEs) were reported in 63 (90%) and 45 (86.5%) pts with and without fever, respectively. Serious AEs were reported in 24 (34.3%) and 16 (30.8%) pts with and without fever, respectively. Overall, 8 events of MAS (pts with fever, n=6; pts without fever, n=2) were reported in both the groups. No deaths were reported during the study. No new safety signals were observed in the subgroup.

Table . Disease activity states based on JADAS27-CRP and JADAS10-CRP

	Disease state, %	SJIA patients, N=123			
		Fever at baseline			
		Yes (n=70)		No (n=52)	
		Baseline n=68	Last assessment n=70	Baseline n=52	Last assessment n=51
JADAS10-CRP	ID	0	50	0	47.1
	LDA	0	12.9	0	9.8
	MDA	10.3	5.7	9.6	19.6
	HDA	89.7	31.4	90.4	23.5
JADAS27-CRP	ID	0	50	0	47.1
	LDA	0	12.9	0	9.8
	MDA	8.8	2.9	7.7	15.7
	HDA	91.2	34.3	92.3	27.5
Cut-off values for inactive disease (ID), low disease activity (LDA) , moderate disease activity (MDA), and high disease activity (HDA), respectively for JADAS10: ≤1, >1– ≤3.8, >3.8 – ≤10.5, and >10.5; and JADAS27: ≤1, >1 – ≤ 3.8, >3.8 – ≤8.5, and >8.5					

Conclusion: Canakinumab provides similar long-term efficacy in SJIA pts, irrespective of presence of systemic fever at treatment onset. The safety profile was acceptable and similar to the pivotal program in SJIA pts with fever at enrollment.

SESSION INFORMATION

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters (ACR): Imaging and Novel Clinical Interventions

Session Type: ACR Poster Session C

Background/Purpose:

A Phase 3b, open-label, multicenter study (CLIPPER; NCT00962741) demonstrated the efficacy of etanercept (ETN) in subjects with the extended oligoarticular (eo), enthesitis-related (ERA), and psoriatic (PsA) subtypes of juvenile idiopathic arthritis (JIA). The objective of the extension study (CLIPPER2; NCT01421069) was to assess the safety and clinical benefit of ETN in pediatric subjects with these JIA subtypes in the long term (8 years).

Methods:

127 subjects with eoJIA (2–17 yrs), ERA (12–17 yrs), or PsA (12–17 yrs) who had ≥1 dose of ETN (0.8 mg/kg QW [max. 50 mg]) and who participated for ~24 months in CLIPPER were eligible for CLIPPER2. Efficacy endpoints included the proportions of subjects achieving JIA ACR 30/50/70/90/100 and Wallace/JADAS inactive disease responses and standard measures of disease activity. Safety, including malignancy and other treatment-emergent adverse events (TEAEs) and serious TEAEs, was assessed from baseline of CLIPPER to month 48.

Results:

109/127 (86%) subjects (eoJIA n=55, ERA n=31, PsA n=23) entered CLIPPER2. Improvements from baseline in disease activity (table 1) and proportions of subjects achieving JIA ACR 30/50/70/90/100 and inactive disease responses (figure) at months 24 were largely maintained at months 48. Safety results are summarized in table 2. All 23 serious TEAEs occurred at a rate of ≤2 events each. Most frequently reported TEAEs were (number of events [N], events per patient yr [EPPY]): headache (27, 0.061), arthralgia (15, 0.034), pyrexia (14, 0.032), diarrhea (12, 0.027), and leukopenia (10, 0.023). Most commonly reported treatment-emergent (TE) infections were (N, EPPY): upper respiratory tract infection (115, 0.260), pharyngitis (73, 0.165), gastroenteritis (29, 0.066), and bronchitis (24, 0.054). TEAEs and TE infections were less frequent in months 36–48 (N, (EPPY)): 48 (0.596), 54 (0.670) than in months 0–12: 193 (1.738), 248 (2.233). One case of malignancy (Hodgkin's disease) was reported in an eoJIA subject who was treated with ETN for 27 months and methotrexate ~8 years prior to onset. No cases of active tuberculosis, demyelinating disorders, or deaths were reported.

Conclusion:

Open-label ETN treatment up to 48 months was well-tolerated and effective in treating subjects with JIA subtypes. AEs were fewer in months 36–48 versus months 0–12.

Macrophage Activation Syndrome in Systemic Juvenile Idiopathic Arthritis Patients Treated with Canakinumab: Results from Phase 3 Trial Program

Alexei A. Grom[1], Hermine I. Brunner[1], Nicolino Ruperto[2], Alberto Martini[2], Daniel Lovell[1,3], Virginia Pascual[4], Karine Lheritier[5], Karolynn Leon[6], Ken Abrams[6] and Norman Ilowite[7], [1]PRCSG, Cincinnati, OH, [2]PRINTO-Istituto Gaslini, Genova, Italy, [3]Rheumatology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [4]Baylor Institute for Immunology Research, Dallas, TX, [5]Novartis Pharma AG, Basel, Switzerland, [6]Novartis Pharmaceuticals Corporation, East Hanover, NJ, [7]Pediatrics, Albert Einstein College of Medicine, Bronx, NY

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters (ACR): Imaging and Novel Clinical Interventions

Session Type: ACR Poster Session C

Background/Purpose: Macrophage activation syndrome (MAS), a potentially fatal complication of systemic juvenile idiopathic arthritis (SJIA), was reported as an adverse event in both canakinumab and placebo group patients in Phase III trials.[1] This prompted the formation of an independent expert MAS Adjudication Committee (MASAC), to develop a methodology to identify and adjudicate potential MAS events. Here, we report frequency of MAS as adjudicated by the MASAC, in canakinumab-naïve SJIA patients[2] from the Phase III, trial program.

Methods: Potential MAS events were identified by periodic searches of the canakinumab SJIA clinical study safety and lab databases for MASAC-specified screening AE terms and lab criteria. MAS events were then adjudicated blinded to treatment by the MASAC as either probable, possible, or unlikely MAS, or insufficient information loosely based on the diagnostic criteria by Ravelli et al.[3]

Results: MASAC identified 72 potential cases for adjudication. Twenty one events in 19 patients were adjudicated as Probable MAS and 10 events in 9 patients as Possible MAS. Of the 21 Probable MAS events, 19 occurred in the canakinumab and 2 in the placebo group. The time period between the first injection of canakinumab and the onset of MAS ranged between 3 to 1359 days (median, 531 days). The rate for MASAC adjudicated Probable MAS was 2.8/100 patient-years and 7.7/100 patient-years for the canakinumab and placebo groups (Table), respectively with no statistically significant difference between groups (diff=-4.9, 95% CI, -15.6, 5.9). Three patients (canakinumab, n=2; placebo, n=1) died due to complications of MAS and full recovery was reported in the remaining patients.

Table. Exposure adjusted incidence rate of events adjudicated as Probable MAS

	Canakinumab*	Placebo	Difference canakinumab – placebo (95% confidence interval)
Number *Probable MAS* adjudicated events	19	2	
Patient- years exposure	668.61	26	
Rate of *Probable MAS* adjudicated events/ 100 PTY	2.8	7.7	-4.9 (-15.6, 5.9)

*Clinical program included studies: Phase II; Phase III Trial 1; Phase III Trial 2; Phase III Trial 2

extension; MAS = macrophage activation syndrome; MASAC = MAS Adjudication Committee

Conclusion: Canakinumab does not appear to have an effect on the frequency of macrophage activation syndrome or modify its clinical features.

Abstract Number: 2425

Safety of Tocilizumab in Young Adults with Juvenile Idiopathic Arthritis (JIA)

Jens Klotsche[1], Martina Niewerth[2], Johannes Peter Haas[3], Angela Zink[4], Gerd Horneff[5] and Kirsten Minden[6], [1]Programme Area Epidemiology, German Rheumatism Research Center, a Leibniz institute, Berlin, Germany, [2]Epidemiology, German Rheumatism Research Centre, Berlin, Germany, [3]German Centre for Rheumatology in Children and Young People, Garmisch-Partenkirchen, Germany, [4]Epidemiologie, Deutsches Rheuma-Forschungszentrum, Berlin, Germany, [5]Asklepios Clinic Sankt Augustin, Sankt Augustin, Germany, [6]Children's University Hospital Charite/German Rheumatism Research Centre Berlin, Berlin, Germany

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters (ACR): Imaging and Novel Clinical Interventions

Session Type: ACR Poster Session C

Background/Purpose: Tocilizumab was recently approved for the treatment of systemic JIA (sJIA) and polyarticular JIA (pJIA). Published data on the tolerability of tocilizumab in patients with JIA are rare. The aim of the study was to investigate the safety of tocilizumab in routine care in young adults with JIA.

Methods: Patients with JIA were enrolled in the national JIA biologic register BiKeR and were prospectively followed into adulthood in the follow-up register JuMBO. All adverse events (AE) were recorded by physicians over the observation period and were categorized on the basis of MedDRA. An event was attributed to tocilizumab when the treatment was either ongoing or terminated in less than 3 months prior to the event. Rates of AE and serious AE (SAE) were calculated per 100 years of tocilizumab exposure (EY).

Results: A total of 929 JIA patients were included in the JuMBO register by the end of January 2015. The tolerability of tocilizumab could be studied in 87 patients (143 EY) who were ever exposed to tocilizumab (14 sJIA, 63 pJIA). Tocilicumab was the first-line biologic disease modifying antirheumatic drugs (DMARD) in 4 (5%) patients, the other 83 patients were treated with tocilizumab after treatment failures with other biologics (second-line bDMARD in 26%, third-line in 47%). In the majority of cases (78%) tocilicumab was first prescribed in young adulthood. At the last available JuMBO visit, 63 patients (8 sJIA, 49 pJIA) were on current treatment with tocilizumab. At treatment start with tocilizumab, patients had a mean disease duration of 13 years, a mean age of 23 years and had been treated in mean by 4.5 other DMARDs before tocilizumab. A total of 81 AE (56.6 events/100 EY) were recorded and 19 (13.3 events/100 EY) AE were rated as serious. Among the SAE, 10 surgical and medical procedures (7.0 events/ 100EY), 4 infections (2.8 events/ 100EY, herpes zoster, genital herpes, norovirus infection, pneumonia) and 2 gastrointestinal disorders (1.4 events/ 100EY) were reported.

Conclusion: Tocilizumab is often started at first time in JIA patients in young adulthood and after treatment failure with other biologic DMARDs. Thus, the JuMBO register supplements the findings about drug safety from the BiKeR register. The obtained safety data are similar to those of tocilizumab in children and of other biologics used in young adults with JIA. However, the number of observed years of drug exposure is still very limited.

SESSION INFORMATION

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters (ACR): Imaging and Novel Clinical Interventions

Session Type: ACR Poster Session C

Background/Purpose: Pediatric uveitis can be vision-threatening. Treatment typically consists of ocular steroids, methotrexate, and anti-tumor necrosis factor (TNF) agents. Optimal duration of treatment and risk of relapse after medication taper is not well studied in children. Our aim is to describe the course of medication taper and discontinuation in a pediatric uveitis cohort.

Methods: There were 107 children with uveitis - JIA-associated uveitis (JIAU), idiopathic uveitis, HLA-B27 (+) uveitis, and other etiologies. Demographic and clinical data were collected. We compared children who attained remission after medication discontinuation to those who relapsed, using Wilcoxon rank-sum tests, Fisher's exact tests and Kaplan-Meier estimates.

Results: There were 28 (26%) children in whom we attempted to taper medication. Of these, 15 had JIAU, and 13 had other forms of uveitis (U). They were primarily female (82%), Caucasian (54%), and had anterior location (63%), bilateral involvement (73%), and ocular complications (72%), most commonly synechiae (57%), cataracts (54%) and macular edema (32%).

Medications were discontinued in only 6 (21%) children (4 with U, and 2 with JIAU). Of these, 5 were on methotrexate and 1 on infliximab. Median time from start of taper to discontinuation was 7 months (0-18 months). Children remained relapse-free for a median of 8 months (0 – 2.1 years).

Of 21 children who failed medication taper, 17 relapsed during taper, 2 are completing taper, 2 restarted methotrexate while on anti-TNF therapy, and 1 was lost to follow up. Comparing children with a recurrence of uveitis to those who achieved remission, those who flared were younger at uveitis diagnosis (4.1 vs. 10.3 years, $p = 0.033$). There was clinical trend of relapse in Caucasians compared to African Americans, (11/13 (85%) vs. 1/4, (25%) $p = 0.053$), those treated for a shorter duration (1.4 [0.9 – 2.3] vs. 1.8 [1.7-7.2] years), $p = 0.166$) and those with JIAU (12/17 (71%) vs. 5/17 (29%), $p = 0.162$). There were no significant differences in gender, etiology, laterality, complications, anterior chamber cells, visual acuity, or duration of uveitis before taper.

Kaplan-Meier product-limit survival estimates showed that approximately 30% failed taper within 4 months, 40% within 9 months, 50% within 10 months, and 60% within 1 year.

Conclusion: Only 21% of children achieved drug-free remission, and 60% relapsed within a year of medication taper. Older age at diagnosis may be associated with success of drug taper. Our results suggest potential differences in likelihood of remission associated with race, duration of treatment, and uveitis diagnosis. Further study of factors associated with optimal treatment of pediatric uveitis leading to disease remission are warranted.

Table 1. Comparison of Children with Uveitis who Relapsed During Medication Taper			
	No Relapse N = 6	**Relapse N = 17**	**p -value**

Long-Term Efficacy and Safety of Mycophenolate Mofetil in Childhood Primary Central Nervous System Vasculitis

Alice Brambilla[1], Alessandra Cosi[2], Anna Rosati[2], Renzo Guerrini[2], Rolando Cimaz[1] and **Gabriele Simonini**[1], [1]Pediatric Rheumatology, Pediatric Rheumatology Unit, Anna Meyer Children's Hospital-University of Florence, Firenze, Italy, [2]Neurology Unit, Neurology Unit, Anna Meyer Children's Hospital-University of Florence, Firenze, Italy
First publication: September 29, 2015

SESSION INFORMATION

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters (ACR): Imaging and Novel Clinical Interventions

Session Type: ACR Poster Session C

Background/Purpose:

Childhood primary central nervous system vasculitis (cPANCS) is an inflammatory brain disease targeting either small (angiography-negative) or medium-large (angiography-positive) central nervous system vessels. Vascular inflammation is reversible with proper immunosuppressant treatment, preventing disabling neurologic impairment. **Objective.** To report efficacy and sustained remission in 4 children affected by cPANCS treated with MMF.

Methods: Between December 2011 and August 2014, 4 patients (median age 77 months, range 9-165) were referred to our centre due to stroke symptoms associated to focal areas of acute ischemia at brain neuroimaging. Screening for thromboembolic and metabolic diseases was negative in all patients as well as complete cardiologic evaluation. Antiplatelet and anticoagulant treatments lead to transient clinical and radiological improvement. After a median period of 7 months (range 2-11) they showed clinical and/or radiologic relapse, with documented progression of vascular involvement at magnetic resonance angiography (MRA) or cerebral angiogram. Laboratory work up for infectious diseases, inflammatory and autoimmune conditions excluded secondary causes of central nervous system vasculitis, thus prompting the diagnosis of cPANCS. Methyl-prednisolone (30mg/kg for 3-5 days) was then started, followed by administration of oral Prednisone (1-2 mg/kg/day) and induction therapy with MMF (1000 mg/m^2 divided BID). Brain MRI controls have been performed every 3-6 months according clinical history and neurological evaluation

Results: Median period of MMF treatment was 19 months (range 6-27). Steroid tapering was started after 6 weeks from the beginning and complete discontinuation was achieved within 7-8 months in 3 out of 4 patients. One patient is still on steroid tapering. Periodic clinical examination, blood tests and MRA were performed with evidence of clinical and radiological improvement or, at least, stable findings. In all children, no relapse of cerebral vasculitis occurred during the follow-up period (median 19.8 months, range 5-29). No major side effects and/or drug-related adverse events were documented during the study period of treatment.

Conclusion: Despite the restricted number of enrolled patients, we report efficacy, good tolerance along with persistent improvement and remission in children affected by cPANCS treated with MMF for up to 27 months

SESSION INFORMATION

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters (ACR): Imaging and Novel Clinical Interventions

Session Type: ACR Poster Session C

Background/Purpose: The diagnosis of polyarticular JIA (pJIA) is made in childhood but the disease and the diagnosis are carried into adulthood. Adults with pJIA have heterogeneous clinical manifestations, many of which differ from rheumatoid arthritis. These adults warrant a tailored approach for optimal management of pJIA. The objective of this study was to assess adalimumab (ADA) effectiveness and safety in pts with pJIA who turned 18 years (yrs) of age anytime during Study DE038.

Methods: This was a multicenter, phase 3, randomized, double-blind (DB), stratified study in children (4 to 17 yrs at baseline) with pJIA treated with or without MTX prior to the study entry. Pts in the MTX arm were treated concomitantly with MTX during the entire study duration. Pts in the non-MTX arm were either naïve to or withdrawn from MTX at least 2 weeks (wks) prior to study drug administration. The study consisted of 16 wk open label lead-in, a 32 wk DB phase and an open label (OL) extension phase. This post-hoc analysis assessed outcomes during the OLE for pts who turned 18 yrs anytime during the course of study in comparison to pts who remained under 18 yrs during their study participation. Twenty sevenjoint juvenile arthritis disease activity score (JADAS27), based on C-reactive protein (CRP) response was measured upto 312 wks of the OLE. Adverse events (AEs) were also monitored and compared between the two age groups throughout the study duration.

Results: 171 pts with pJIA between 4-17 yrs of age at the time of study entry were enrolled. Among them, 51(30%) turned 18 yrs of age during the course of their participation in the study and were compared to the remaining 120 pts that remained <18 yrs throughout the study participation. There were (42; <18 yrs) vs (46; ≥18 yrs) pts who received at least 4 yrs of ADA. The mean age at the time of study enrollment was 14.6 yrs vs 9.8 yrs in pts ≥18 yrs and <18 yrs respectively. The majority of pts were white (90.2% vs 92.5%) and female (74.5%; ≥18 yrs) vs 80.8%; <18 yrs). The subgroup of 51 pts that turned 18 yrs had a mean age of 19.8 ± 1.5 yrs at the time of their last dose of ADA in the study. The JADAS27(CRP) response was measured from baseline up to 312 wks and demonstrated maintainance of efficacy ($p<0.05$)from week 72 onwards, irrespective of age (Figure). The overall rate of AEs was lower in pts ≥18 yrs than pts <18 yrs (432 [95% CI, 407.6 - 458.6] vs 701 [95% CI, 672.1 - 731.0] events/100 pt-y) respectively.

Conclusion: The efficacy results based on the JASDAS27(CRP)responses demonstrated maintenance of efficacy over time for both age groups. Safety data showed the overall rate of AEs was lower in pts ≥18 yrs than pts <18 yrs. No new safety signals were observed; thus the safety profile of ADA remained unchanged. The findings from this study support a favorable benefit-risk profile of for the ADA treatment in adult pts (≥18 yrs of age) with moderately to severely active pJIA.

Figure: JADAS27 (CRP) response over time for pJIA patients <18 yrs and ≥18 yrs of age in the OL-extension phase

Varicella Vaccination in Patients with Pediatric Rheumatic Diseases Receiving Immunosuppression: Proposal of a Pre-Vaccination Checklist to Ensure Safety

Fabian Speth[1], Johannes Peter Haas[1], Susanne Loeber[1] and **Claas Hinze**[2], [1]German Center for Pediatric and Adolescent Rheumatology, Garmisch-Partenkirchen, Germany, [2]Department of Pediatric Rheumatology and Immunology, University Hospital Münster, Münster, Germany

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters (ACR): Imaging and Novel Clinical Interventions

Session Type: ACR Poster Session C

Background/Purpose:

Varicella zoster virus (VZV) infection is a serious preventable infection in patients (pts) receiving immunosuppression (IS). The purpose of this study was to determine the safety and efficacy of administering the VV to pts with PRD on IS after passing a pre-vaccination checklist of immunologic criteria.

Methods:

In this single center study, after screening >2800 pts, 21 VZV-susceptible pts with clinically inactive PRDs, including different categories of juvenile idiopathic arthritis and connective tissue diseases between the ages of 2–18 years on low-intensity IS (LIIS) (methotrexate [MTX] ≤15mg/m2/week and/or prednisolone <10mg/day) or high-intensity IS (HIIS) (MTX>15mg/m2/week, leflunomide, mycophenolate mofetil [MMF], etanercept, tocilizumab, anakinra, abatacept, or a combination thereof) were included in this study. Prior to vaccination, pts were screened according to an immunologic checklist with predefined cut-offs, i.e. for pts on LIIS: WBC>3000/µl, ALC>1200/µl, IgG>500mg/dl, IgM>0, Tetanus toxin-IgG >0,10IU/ml, and, in addition, for pts on HIIS: CD4 >200/µl [if>5 yrs] or CD4 >500/µl [if 1-5 yrs] and positive T cell reactivity to mitogen or antigen, e.g. via TB-EliSpot positive control. Pts meeting these safety criteria received either a 1st and/or 2nd dose of VV. VZV-IgG levels were measured before applying VV and after each dose. VZV cellular mediated immunity (CMI) was measured after VV. Potential side effects and PRD flares were monitored.

Results:

Out of 9 pts receiving LIIS and 12 pts receiving HIIS none failed the immunologic checklist. Eight pts (2 LIIS, 6 HIIS) had already received their 1 dose of VV prior to this study and received a booster dose of VV only. Thirteen pts (7 LIIS, 6 HIIS) received their 1st dose of VV within the study and 7 of these 13 pts received a 2nd dose of VV. 11/13 pts demonstrated protective VZV-IgG levels of >150 IU/ml after the 1st dose of VV, and 5/7 pts of those receiving a 2nd dose of VV achieved levels of >500 IU/ml. Two pts (one on MMF one on leflunomide and abatacept) did not achieve protective VZV-IgG levels, despite otherwise adequate humoral and cellular immunity. Of those 8 pts receiving a booster dose only, all exceeded VZV-IgG levels of >500 IU/ml by far.

There was no difference in either the mean absolute or relative increase (Δ) in VZV-IgG between pts on LIIS vs. HIIS (after 1st dose of VZV Δ341 IU/ml vs. Δ378 IU/ml and 4.7-fold vs. 4.2-fold, respectively; after 2nd dose Δ745 IU/ml vs. Δ1001 IU/ml and 6.9-fold vs. 6.4-fold, respectively). Data on VZV-CMI and long-term VZV-IgG levels are pending at the time of abstract submission. There was no evidence of VV-induced varicella or other complications. None of the pts developed a PRD flare and no change in the IS regimen was required in any pt during a minimum follow-up of 4 wks. 7 pts had transient arthralgias of unclear association with VV administration.

Conclusion:

After meeting easy-to-obtain immunologic criteria, the VV could safely be applied to a diverse cohort of pts with clinically inactive PRD on IS with good immunologic response in the majority of pts.

Immunological Risk Factors after Rituximab Therapy in Patients with Pediatric Rheumatic Diseases – a Prospective Single-Center Study

Fabian Speth[1], Johannes Peter Haas[1] and **Claas Hinze**[2], [1]German Center for Pediatric and Adolescent Rheumatology, Garmisch-Partenkirchen, Germany, [2]Department of Pediatric Rheumatology and Immunology, University Hospital Münster, Münster, Germany

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters (ACR): Imaging and Novel Clinical Interventions

Session Type: ACR Poster Session C

Background/Purpose:

Rituximab (RTX) is used in refractory pediatric rheumatic diseases (PRD). Data regarding the effects of RTX on the immune system in children and safety in PRD is scarce. The purpose was to prospectively evaluate indicators of humoral immunity before and until 2 yrs after RTX administration.

Methods: Twenty patients (pts) with PRD (4 SLE, 3 MCTD, 3 JIA, 2 eosinophilic fasciitis, 2 juvenile dermatomyositis, 2 Sjögren-syndrome, 2 GPA (Wegener), 1 MPA, 1 PM/Scl-overlap) after excluding common variable immunodeficiency received at least 1 standard dose RTX cycle (some pts up to 3 cycles). Additional treatment consisted of prednisolone (10), hydroxychloroquin (10), mycophenolate mofetil (9), methotrexate (6), leflunomide (4), abatacept (2), everolimus (2), cyclosporin (1) and antiinflammatory doses of i.v. immunoglobulin (IVIG) (3). Lymphocyte subpopulations, IgA, IgG, IgM and IgE levels, IgG subclasses, isoagglutinins, antigen-specific IgG levels to tetanus toxin, H. influenzae type B (Hib), pneumococcus and measles, spleen size, presence of Howell-Jolly bodies (functional hyposplenism) and throat culture were obtained 6, 12 and 24 months (mos) after RTX. IgG and antigen-specific IgG levels in pts receiving IVIG were not included in the analysis. The continuous variables at time points 6, 12 and 24 mos were compared by paired T test to time point 0 mo (prior to RTX).

Results:

All pts achieved complete B cell depletion. B cells repopulated in all pts with a median of 8.5 mos. IgG and IgM levels were (mean [standard deviation] mg/dl at 0, 6, 12, 24 months) IgG 1428 [723], 1255 [653], 1075 [452], 1243 [617]; IgM 119 [61], 71 [52], 54 [39], 52 [46]. Significant reductions were observed for IgG (6/12 mos), IgM (6/12/24 mos), IgA (6/12 mos) and IgE (6/12/24 mos). Overall, 7/17 (41%) of patients received IVIG substitution based on predefined IgG and/or IgM threshold levels. One pt developed low IgG2/3, IgA and IgM levels, and 2 pts developed low IgG4 levels, at 24 mos after RTX. Tetanus toxoid IgG decreased significantly at 12 mos but not below a protective threshold in any pt. There was a non-significant decrease in pneumococcal antibodies at 12 and 24 mos. Individually, Hib-IgG and pneumococcal antibodies fell below protective thresholds

in some pts. Measles IgG levels decreased significantly at 12 and 24 mos but not below a protective threshold. There was a non-significant decrease in spleen size at 6 months. Transient Howell-Jolly bodies were observed in 8 pts, and antibiotic prophylaxis was begun. Throat culture showed colonization with C. albicans in 12, S. aureus in 3, Hib in 2, both P. aeruginosa and S. marcescens in 1, E. coli in 1 and Enterobacter in 1 pt. One pt developed fever, neutropenia, received i.v. antibiotics and recovered fully.

Conclusion:

Acquired humoral immunodeficiency occasionally occurs after RTX treatment in PRD, especially after repeated treatment cycles. Preventive strategies, including IVIG substitution and/or antibiotic prophylaxis informed by immunologic studies maybe useful in preventing serious invasive infections. We suggest at least 2 yrs of surveillance for acquired humoral immunodeficiency, incl. IgA, IgG, IgM, IgG subclasses and immunization titers after RTX treatment in PRD.

SESSION INFORMATION

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters (ACR): Imaging and Novel Clinical Interventions

Session Type: ACR Poster Session C

Background/Purpose: The long-term safety of anti-tumor necrosis factor (TNF) drugs is particularly important in pediatric patients (pts) who may require prolonged treatment of their inflammatory disease. The purpose of the study is to evaluate long-term rates of serious adverse events (AE) and anti-TNF AEs of special interest in adalimumab (ADA) clinical trials in pediatric pts with polyarticular or polyarticular course juvenile idiopathic arthritis (pJIA) or enthesitis-related arthritis (ERA)

Methods: Safety data from pts treated with ADA, either dosed 24 mg/m^2 BSA every other week (eow) or 20 mg eow (<30 kg) to 40 mg eow (≥30 kg), in 4 clinical trials in pJIA and ERA were analyzed. Three studies in pJIA enrolled pts aged 2–17 years (yrs) treated with ADA for up to approximately 7 yrs. One study enrolled pts with ERA aged 6–17 yrs to be treated with ADA for up to 144 wks (interim results through 52 weeks were included in this analysis). AEs of special interest included malignancy, serious infections, tuberculosis (TB) and other opportunistic infections, and death. Events per 100 patient-years (PY) were calculated using AEs reported after first ADA dose through 70 days after last dose.

Results: ADA was administered to 274 pts, representing 705.0 PY of exposure. Infections, the most common AE, occurred in ≥10% of pts. Serious infection was the most frequently reported SAE (table). No cases of active or latent TB were reported. No malignancies, opportunistic infections, or deaths were reported. 7.3% of pts (20/274) discontinued study due to AE (range, 5.1% in age <5 yr to 9.6% in ages 5 - <12 yrs). Other than uveitis, liver events, and injection site-related AEs, no differences in AE rates were observed between age groups. (Table)

Conclusion: These data provide support for the long-term safety of ADA in pediatric pts aged 2–17 yrs with pJIA or aged ≥6 to <18 with ERA and demonstrate a safety profile consistent with ADA in adult pts and known information about the anti-TNF class.

Rates (E, E/100PY)	**Age <5 yr N=39**	**Age 5 - <12 yr N=104**	**Age 12 - <18 yr N=131**	**Total N=274**

The Preventive Effect of Methotrexate on Uveitis Onset in JIA Depends on Uveitis Risk Factors

Mikhail Kostik[1], Ekaterina Gaidar[1], Margarita Dubko[1], Ludmila Snegireva[2], Vera Masalova[2], Irina Chikova[1], Eugenia Isupova[3], Tatiana Nikitina[4], Elena Serogodskaya[1], Olga Kalashnikova[1], Angelo Ravelli[5] and Vyacheslav Chasnyk[3], [1]State Pediatric Medical University, Saint-Petersburg, Russia, [2]Hospital Pediatrics, State Pediatric Medical University, Saint-Petersburg, Russia, [3]Hospital Pediatry, State Pediatric Medical University, Saint-Petersburg, Russia, [4]State Pediatric Medical University, St. Petersburg, Russia, [5]Pediatria-II, IRCCS G. Gaslini and University of Genova, Genova, Italy

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters (ACR): Imaging and Novel Clinical Interventions

Session Type: ACR Poster Session C

Background/Purpose:

Uveitis is the most common extra-articular manifestation of juvenile idiopathic arthritis (JIA), often entirely asymptomatic but could be sight-threatening. The main predictors of uveitis in JIA are oligoarticular (OA) subtype, ANA-positivity and younger age at the JIA onset. Methotrexate (MTX) has been able to decrease the incidence of uveitis in JIA up to 2 times [1].

Objectives: To evaluate the possibility of MTX to prevent the onset of uveitis in different JIA subgroups according to the main uveitis risk factors.

Methods:

The clinical charts of all consecutive patients who had received a stable management for at least 2 years with or without MTX were reviewed. Patients who were given systemic medications other than MTX (except NSAID) were excluded. Patients with systemic arthritis, rheumatoid factor-positive arthritis, or enthesitis-related arthritis were also excluded. In each patient, the al least 2-year follow-up period after first visit was examined to establish whether uveitis had occurred. MTX was administered in the subcutaneous injections in the dosage 15 mg/m^2/week.

Results:

A total of 281 patients with a median disease duration of 3.8 year were included. One hundred and ninety one patients (68%) were treated with MTX compare to 33.9% in previous study [1]. During the at least 2-year follow-up, 64 patients (22.8%) developed uveitis, a median of 1.6 year after the disease onset. The frequency of uveitis was lower in MTX-treated than in MTX-untreated patients (11.5% vs 46.7%, respectively, OR=6.7 (95%CI:3.7-12.3), p= 0.0000001). In previous study the frequency of uveitis was 10.5 in MTX-treated vs 20.2 in MTX-untreated patients [1]. Survival analysis confirmed that patients treated with MTX had a lower probability of developing uveitis (HR=4.35, p=0.000001). The results of preventive effect of MTX in different JIA subgroups, according to the main uveitis risk factors are shown in the table 1.

Table 1. The ability of MTX to prevent uveitis in different subgroup.

Group	MTX, Y/N	Rate (%)	OR (95% CI)	p†	HR*	p§
Boys	N	9/26 (34.6)	7.3 (2.0-26.6)	0.001*	6.7	0.0007
	Y	4/59 (6.8)				
Girls	N	19/132 (14.4)	5.9 (3.0-11.9)	0.000001	3.6	0.000001
	Y	32/64 (50.0)				
Oligoarticular course	N	37/81 (45.7)	5.7 (2.9-11.3)	0.000001	4.0	0.000001
	Y	16/125 (12.8)				
Polyarticular course	N	4/9 (44.4)	6.7 (1.5-31.2)	0.007	3.7	0.02
	Y	7/66 (10.6)

	Y	2/90 (2.2)				

† χ2-test, §Log-Rank test, * Cox regression models

Conclusion:

Conclusions:MTX therapy may differently prevent the onset of uveitis in children with JIA depends on uveitis risk factors. Further randomized controlled trial required to confirmation our results.

Anti Interferon-Gamma (IFNg) Monoclonal Antibody Treatment in a Child with NLRC4-Related Disease and Severe Hemophagocytic Lymphohistiocytosis (HLH)

Claudia Bracaglia[1], Giusi Prencipe[1], Antonio Gatto[2], Manuela Pardeo[1], Geneviève Lapeyre[3], Luigi Raganelli[1], Emiliano Marasco[2], Antonella Insalaco[2], Walter Ferlin[3], Robert Nelson[3], Cristina de Min[3] and Fabrizio De Benedetti[1], [1]Department of Pediatric Medicine, Division of Rheumatology, Ospedale Pediatrico Bambino Gesù, IRCCS, Rome, Italy, [2]Pediatric Medicine, Division of Rheumatology, Ospedale Pediatrico Bambino Gesù, IRCCS, Rome, Italy, [3]NovImmune S.A., Geneva, Switzerland
First publication: September 29, 2015

SESSION INFORMATION

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters (ACR): Imaging and Novel Clinical Interventions

Session Type: ACR Poster Session C

Background/Purpose: Animal and humans data suggest that IFNγ plays a pathogenic role in HLH. A pilot trial in primary HLH with NI-0501, an anti-IFNγ monoclonal antibody, is ongoing. Mutations in *NLRC4*have recently been reported to cause recurrent macrophage activation syndrome and increased production of IL-18, that is known to induce IFNγ.

Methods: We report safety and efficacy of NI-0501 in a patient, carrying an *NLRC4*mutation with severe recalcitrant HLH.

Results: The patient presented at 20 days of age with fever, hepatosplenomegaly, pancytopenia, hypofibrinogenemia, hypertriglyceridemia, hyperferritinemia and sCD25 increase, meeting 6 HLH-criteria. Liver and subsequent multiorgan failure required ICU admission. Genes causing primary-HLH (*PRF1, UNC13D, STXBP2, STX11, RAB27A, XIAP*) and functional tests (perforin expression, degranulation assay and NK cytotoxic activity) were negative. Subsequent analysis of *NLRC4* showed a *de novo* missense mutation (T337N) located in the same codon as that reported by Canna et al (1). Elevated serum IL-18 (>30.000 pg/ml) was documented, confirming the biologic and pathogenic relevance of the *NLRC4* mutation. High-dose glucocorticoids and cyclosporine-A led to partial improvement. Development of sepsis (*C.albicans and K.pneumoniae*) triggered HLH reactivation. Etoposide and/or ATG were not considered because of the presence of active infections. Measurable IFNγ levels (6 pg/ml) and high levels of CXCL9 (5670 pg/ml) and CXCL10 (4400 pg/ml) were found. NI-0501 (compassionate use) was started on background dexamethasone (13.6 mg/m2) and cyclosporine-A. NI-0501 was administered every 3 and subsequently every 7 days according to pharmacokinetics. No infusion reaction was observed. Progressive improvement allowed rapid glucocorticoid tapering. After 6 months of treatment, the child is in excellent condition; all HLH parameters have normalized. Serum IL-18 levels remain elevated (32.000 pg/ml). High circulating levels (in the range of nanogram/ml) of IFNγ complexed with NI-0501, reflecting high IFNγ production, are detectable, and fully neutralized, as shown by undetectable levels of IFNγ-inducible chemokines (Table 1). He is receiving cyclosporine-A (6 mg/kg) and prednisone (0.3 mg/kg equivalent to 0.9 mg/m^2 dexamethasone).

Conclusion: In a patient, carrying a pathogenic *NLRC4*mutation with severe recalcitrant HLH, neutralization of IFNγ allowed control of all HLH features, while enabling glucocorticoid tapering. No safety concern emerged.

Promis Tools for Measurement of Patient-Reported Outcomes in Children with Juvenile Arthritis

Timothy Brandon[1], Brandon Becker[1], Katherine Bevans[1] and **Pamela F. Weiss**[2], [1]Pediatrics, Children's Hospital of Philadelphia, Philadelphia, PA, [2]Rheumatology, Children's Hospital of Philadelphia, Philadelphia, PA

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters (ACR): Imaging and Novel Clinical Interventions

Session Type: ACR Poster Session C

Background/Purpose: Child/parent perspectives on their own/their child's health are highly pertinent to disease management. PROMIS is a collection of patient-reported outcome measures that were developed to be non-disease specific. For each PROMIS domain there are "item banks" (13-29 questions) and associated "short forms" (8-10 questions) that generate a score representing the level of that trait in comparison to a sample of US children (inclusive of children with common chronic diseases). This study examines the applicability of PROMIS tools to children with juvenile idiopathic arthritis (JIA) and their parents.

Methods: A convenience sample of patients with JIA aged 8-17 years (all JIA categories) and parent proxies (5-17 years) were recruited from a single center and completed 1 to 4 PROMIS item banks. In all, 8 PROMIS items banks were administered: anger, anxiety, depression, fatigue, pain interference, mobility, upper extremity, and peer relationships. We used item response theory scoring to generate T-scores for each item bank and 8-item short form. Responsiveness of the item banks and short forms over disease activity states defined by the Juvenile Disease Activity Score (JADAS-3) was evaluated using ANOVA tests for equal variances. Standard error plots were generated for each full bank and corresponding short form. The association between child and proxy dyad responses was assessed using Spearman pairwise correlation coefficients.

Results: 229 patients (67.3% female, median age=13yrs) and 224 parents (70.5% female, median age=12yrs) completed at least one PROMIS form, resulting in 71-78 responses per item bank. Fatigue, mobility, and pain interference full item banks and short forms showed significant responsiveness to JIA disease activity (Figure; all $p<0.05$) for both patient and parent proxy report. Peer relationships, anxiety, depression, and anger had significant responsiveness (all $p<0.05$) over the disease activity levels for parent proxy but not patient report. The upper extremity instrument did not show significant responsiveness for either patient or parent proxy report. Patient and proxy PROMIS short forms exhibited comparable standard error across the range of T-scores to that seen in the full item banks. The pairwise correlations between patient and proxy dyads for the item bank scores were: **anger (r=0.38), anxiety (r=0.36), depression (r= 0.45), fatigue (r=0.65), pain interference (r=0.70), mobility (r=0.55), upper extremity (r=0.49), and peer relationships (r=0.32).**

Conclusion: Our results demonstrate that the 8-item PROMIS pediatric short forms are feasible to complete, responsive to JIA disease activity, and have comparable error to the full item banks for child and proxy report. The moderate associations between patient and proxy report are consistent with prior reports and suggest that administration of both forms should be considered.

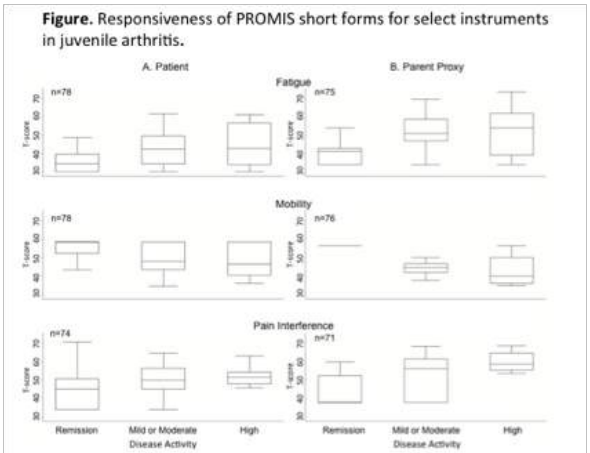

Figure. Responsiveness of PROMIS short forms for select instruments in juvenile arthritis.

Legend. Scores represent T-scores across three levels of juvenile arthritis disease activity as defined by JADAS3 for patients (A) and parent proxies (B). Mean T-score in sample of US children (inclusive of children with common chronic diseases)= 50.

Pregnancy Outcomes in Adult Juvenile Idiopathic Arthritis Patients Treated with Biologic Agents

Katerina Jarosova[1], Katerina Andelova[2], Karel Hejduk[3], Michal Uher[3] and Jiri Vencovsky[4], [1]Institute of Rheumatology, Prague, Czech Republic, [2]clinical, Institute for the Care for Mother and Child, Prague, Czech Republic, [3]Institute of Biostatistics and Analyses, Masaryk University, Brno, Czech Republic, [4]Institute of Rheumatology and Department of Rheumatology, Charles University, Prague, Czech Republic

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters (ACR): Imaging and Novel Clinical Interventions

Session Type: ACR Poster Session C

Background/Purpose:

Biologic drugs are effective therapeutic option in patients with juvenile idiopathic arthritis (JIA). However, data regarding the use during pregnancy and breastfeeding in adult women with JIA are rare. The purpose of this report is to summarize the pregnancy outcomes in adult female patients with JIA treated with TNF inhibitors (TNFi) and with other biologic agents.

Methods:

Pregnant patients with JIA have been prospectively followed since 2003 to 2015. The length of pregnancy, complications, preterm delivery, birth defects and disease exacerbations after delivery were entered into the database. Patients were treated with TNFi or with rituximab, abatacept and tocilizumab in recommended doses for rheumatoid arthritis. Data on disease activity, safety and doses of used medication were extracted from the Czech national registry of patients treated with biologics (ATTRA).

Results:

JIA patients were diagnosed with RF positive polyarthritis (9), RF negative polyarthritis (10), extended oligoarthritis (7), psoriatic arthritis (1) and arthritis with enthesitis (1). Twenty five live births in 28 pregnancies were observed. The age of

mothers at the onset of pregnancy was 28,1 (range 20 -40) years. Nine patients discontinued biologicals shortly before the pregnancy was confirmed. In 19 cases patients were exposed to biological drugs after conception; infliximab in 4 cases, etanercept in 9, adalimumab in 3, certolizumab in 2 and abatacept in 1. Biologic drugs were administered for 6-8 weeks during pregnancy in 17 cases. One patient who discontinued etanercept was returned on the drug at week 26 because of severe JIA relapse and the drug was administered until the delivery. One patient received etanercept throughout of pregnancy in halved dose due to a persistent activity. Two pregnancies were not planned and both patients were exposed to methotrexate in the first 6 weeks in addition to exposure to rituximab 4 and 8 months before conception.

One patient treated with infliximab had spontaneous abortion at week 7. Repeated pregnancy in this patient with the exposure to infliximab for 4 weeks was successful. Another spontaneous abortion was seen in patient exposed to adalimumab at week 6. There was one still birth terminated at week 11 in a patient on etanercept stopped at week 6 of gestation. All the other pregnancies were uneventful with just one case of hypertension. Gestation was terminated by Caesarean section in six cases (1x hypertension, 2x limited hip movement, 1x non-functional placenta, 1x JIA activity and 1x foetus defective position). There was no preterm delivery.

Birth weight was between 2470- 4000 grams. One child was born with mastocytosis.

Conclusion:

Our data from 28 pregnancies suggest that the use of biologics in the early phases of gravidity in JIA patients is safe and does not affect the gestation duration or the delivery or lead to increased frequency of birth defects.

Views and Prescribing Habits of Pneumocystis Prophylaxis in the Pediatric Rheumatology Community

Matthew Basiaga[1], Alexis Ogdie-Beatty[2] and for the CARRA Investigators, [1]Pediatric Rheumatology, The Children's Hospital of Philadelphia, Philadelphia, PA, [2]Medicine/Rheumatology, University of Pennsylvania, Philadelphia, PA

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters (ACR): Imaging and Novel Clinical Interventions

Session Type: ACR Poster Session C

Background/Purpose: Pneumocystis pneumonia (PCP) is a potentially devastating opportunistic infection. The incidence of PCP and the risk of adverse events secondary to prophylactic medication in children with rheumatic disease are unknown. As a result, healthcare providers must make the decision about providing prophylaxis on a case by case basis without formal guidelines. The objective of this study was to describe current prescribing habits of PCP prophylaxis among pediatric rheumatologists. We hypothesized that significant variation exists in the prescribing of PCP prophylaxis.

Methods: We performed a cross sectional survey of pediatric rheumatologists in the Childhood Arthritis & Rheumatology Alliance (CARRA). CARRA is an alliance of pediatric rheumatologists in the United States and Canada. A questionnaire was administered using REDCAP, a secure web based research platform. The anonymous survey ascertained basic demographic and PCP prophylaxis prescribing habits. After approval by the IRB and CARRA, the questionnaire was piloted and then distributed via an email in May 2015. A reminder email was sent 2 weeks later to members who had not responded to the questionnaire. Descriptive analysis was performed using STATA v 13.1 (Stat Corp; College Station TX).

Results: The questionnaire was sent to 280 pediatric rheumatologists and 76 (27%) responded; results are shown in Table. Most respondents practice at an academic medical center (N=74, 97%) and 66 (87%) of pediatric rheumatologists prescribe PCP prophylaxis. Only nine (12%) report institutional prescribing guidelines. The most common indications listed for prescribing prophylaxis were for use of cyclophosphamide (42%) or a diagnosis of Granulomatosis with Polyangiitis (38%). Trimethoprim-sulfamethoxazole was the most common first line prophylactic agent prescribed (N=68, 91%). Indications for initiation of PCP prophylaxis are diverse. Thirty-three (43%) respondents indicated prescribing in the setting of a specific medication, thirty-seven (49%) for a specific combination of medications, twenty-six (34%) a specific laboratory threshold and thirty-one (41%) for a specific disease.

Conclusion: We found significant variation in prescribing habits of PCP prophylaxis between pediatric rheumatologists in the United States and Canada. While most providers prescribe prophylaxis, we found that 13% do not. Common reasons given why prophylaxis was not prescribed include a perceived low risk of infection and that they have never seen a PCP infection before in practice. Future studies aimed at identifying the incidence of PCP in children with rheumatic disease and the incidence of adverse events associated with the prophylactic agents are needed to inform the development of evidence based guidelines for PCP prophylaxis prescribing.

Table. Characteristics of Pediatric Rheumatology Respondents and Responses (n=76)

Characteristic	N (%)
Years in Practice	
Currently in training - 5 years	30 (39%)
6 – 10 years	11 (14%)
11 – 20 years	15 (20%)
21 – 30 years	15 (20%)
30 + years	5 (6%)
Average number of patients seen per week	
0–15	24 (32%)
16-30	36 (48%)
31-45	9 (12%)
46-60	5 (7%)
60+	1 (1%)
What prompts you to start PCP prophylaxis?	
Specific medication monotherapy	33 (43%)
Specific medication combination	37 (49%)
Laboratory value threshold	26 (34%)
Specific disease	31 (41%)
Which specific monotherapy prompts you to prescribe PCP prophylaxis?	
Chronic Glucocorticoids > 20 mg daily	1 (1%)
Chronic Glucocorticoids ≥ 2 mg/kg daily	4 (5%)
Methotrexate	1 (1%)
Rituximab	7 (9%)
Mycophenolate Mofetil	1 (1%)
Cyclophosphamide	31 (41%)
Which specific medication combination prompts you to prescribe PCP prophylaxis?	
TNF Inhibitor and Methotrexate	1 (1%)
TNF Inhibitor and Glucocorticoids	2 (3%)
TNF Inhibitor and Azathioprine	2 (3%)
TNF Inhibitor and Calcineurin Inhibitor	2 (3%)
Glucocorticoids and:	
Rituximab	12 (16%)
Cyclophosphamide	33 (43%)
Calcineurin Inhibitor	5 (7%)
Methotrexate	4 (5%)
Azathioprine	4 (5%)
Mycophenolate Mofetil	7 (9%)
Anti-IL1 Therapy	2 (3%)
Anti-IL6 Therapy	3 (4%)
Which laboratory threshold prompts you to prescribe PCP prophylaxis?	
Absolute Neutrophil Count < 1000 / μL	4 (5%)
Absolute Lymphocyte Count < 1000 / μL	15 (20%)
CD4 Count < 200 / μL	11 (14%)
Which specific disease prompts you to prescribe PCP prophylaxis?	
Juvenile Dermatomyositis	6 (8%)
Systemic Lupus Erythematosus	7 (9%)
Juvenile Idiopathic Arthritis	1 (1%)
Granulomatosis with Polyangiitis	27 (36%)
Other Vasculitis	8 (11%)
When do you stop PCP prophylaxis	
Discontinuation of medication that prompted initiation	49 (65%)
Improvement in clinical condition	2 (3%)
Improvement in laboratory value that prompted initiation	15 (20%)

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters (ACR): Imaging and Novel Clinical Interventions

Session Type: ACR Poster Session C

Background/Purpose: Tocilizumab (TOC) has become a valuable option for treatment of systemic juvenile idiopathic arthritis (sJIA), which significantly improved the outcome of patients. The aim of the German BIKER registry is surveillance of biologics. The purpose of this interim analysis is to evaluate the efficacy and safety under practical conditions in childhood.

Methods: Documentation of pts' characteristics, pervious/concomitant therapy, disease activity parameters and adverse events. Treatment with TOC was followed prospectively. Efficacy was assessed by PedACR criteria and JADAS10 remission and minimal disease activity (MDA). Safety was compared to a cohort of pts treated with sJIA methotrexate only and a cohort with poly JIA treated with TOC.

Results: 56 JIA pts (54% female) started TOC. The mean/median age at baseline was 9.3/9.7, disease duration 4.9/4.1 years. 44 previous biologic therapies were performed 3 pts (Anakinra 14, Canakinumab 1,Etanercept 25, Adalimumab 3, Abatacept 1). 26 pts were biologics naïve. The initial concomitant treatment in consisted of NSAIDs 63.3%, steroids 70%, methotrexate 63.3%, other DMARDs (n=6).

Clinical response rates are given in table 1. Reported adverse events were compared to a cohort of 79 pts with polyarticular JIA and 58 sJIA pts receiving MTX onlym, both recruited and followed in parallel. 122 adverse events (AE, 83.3/100 PY) were reported, 12 (9.0/100 PY) were serious. Infections were the most frequent AE (48), 3 were serious. Opportunistic infections including TB did not occur. There were 4 events of macrophage activation syndrome in sJIA pts with TOC, none in polyJIA and 1 in sJIA controls. All resolved. Rates of other adverse events of special interest are shown in table 2. Therapy was discontinued in 32 (57%) sJIA pts due to remission (15/27%), inefficacy (7/13%), patient request (5/9%), intolerance (4/7%) and other (1/2%). No patients died.

Conclusion: sJIA pts achieved high ACR response rates upon treatment with TOC. JADAS-MDA was frequently reached. JADAS remission was achieved in about half of pts. While more serious adverse events were reported in sJIA than in controls, overall tolerability was good. Only a small portion discontinues therapy because of intolerance or side effects while remission is the leading cause of discontinuation of treatment.

Table 1: Treatment response until month 12

	Baseline	Month 3	Month 6	Month 12
Pts with active joints (n/%)	34/64.2%	7/22.3%	10/27.8%	9/30%
Pts with organomegaly (n/%)	5/10.2%	1/3.3%	0	0
Pts with serositis (n/%)	3/6.1%	0	0	0
Pts with fever (n/%)	2/4.1%	0	0	1/3.4%
JADAS 10 (mean/median)	8.7/9.4	4.9/4.5	2.2/0.7	3.5/1.0

SESSION INFORMATION

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters (ACR): Imaging and Novel Clinical Interventions

Session Type: ACR Poster Session C

Background/Purpose:

Arthritis of the temporomandibular joint (TMJ) in patients with Juvenile Idiopathic Arthritis (JIA) is increasingly recognized. In the last decade, studies report that the frequency of TMJ involvement in JIA patients is between 45-100% depending on the population examined and the diagnostic tool used. The gold standard to diagnose TMJ arthritis is use of Gadolinium-enhanced MRI. Clinical symptoms have been shown to be unreliable for diagnosis of TMJ arthritis, however their usefulness in monitoring during the disease course needs to be determined. This study was undertaken by the Clinical Recommendation group of euroTMjoint, an international network established in 2010 to enhance mutidisciplinary, multicenter TMJ research in JIA. This study describes the reliability and reproducibility of a clinical tool that can be implemented in any practitioner.

Methods:

A clinical tool was developed based on the results of a Delphi study and expert panel. The examined tool items were: TMJ pain reported by patient; TMJ tenderness on palpation; mandibular deviation at maximal mouth opening; maximal mouth opening capacity; vertical incisal overlap; frontal facial asymmetry; facial profile. 33 patients with JIA were examined eight times, twice by four independent examiners; 2 pediatric rheumatologists and 2 orthodontists with experience in clinical examination. An independent experienced orthodontist instructed all examiners on the use of the recommendation tool. The examiners were blinded to each other's results.

Results:

The time to perform the examination differed significantly between investigators irrespective of their professional background (median 89-179 sec, $p<0.0001$), however all examiners were able to perform the exam within the 3 minutes limit. The intra- and inter-agreement was lower for questions, such as absence or present of pain, than objective measurements. Comparing pediatric rheumatologists with the more experienced orthodontists revealed a high reproducibility for the measurement items maximal mouth opening and vertical incisal overlap (Spearman rho respectively 0.81 and 0.55), indicating these items can be used by inexperienced examiners after instructions. Frontal facial asymmetry showed the least reproducibility among the items (kappa 0,23).

Conclusion:

Clinical signs and symptoms of TMJ arthritis remain controversial for diagnostic purposes; however this study does show a fair to moderate agreement for all items and a moderate to almost perfect agreement for the measured items. This study shows the possible applicability of this tool in the rheumatology clinic during the course of the disease.

Methotrexate Failure in Pediatric Uveitis

Courtney McCracken[1], Steven Yeh[2], Kirsten Jenkins[3], Daneka Stryker[4], Steven Tommasello[5], Curtis Travers[1], Scott R. Lambert[2], Carolyn Drews-Botsch[6] and Sheila T. Angeles-Han[1,2,3], [1]Pediatrics, Emory University School of Medicine, Atlanta, GA, [2]Ophthalmology, Emory University School of Medicine, Atlanta, GA, [3]Children's Healthcare of Atlanta, Atlanta, GA, [4]Pediatrics, Emory University School of Medicine and Children's Healthcare of Atlanta, Atlanta, GA, [5]University of Alabama, Birmingham, AL, [6]Epidemiology, Emory University School of Public Health, Atlanta, GA

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters (ACR): Imaging and Novel Clinical Interventions

Session Type: ACR Poster Session C

Background/Purpose: Pediatric uveitis can lead to ocular complications and vision loss. Treatment consists of steroid drops, methotrexate (MTX), and anti-tumor necrosis factor (TNF) drugs. Only 50-75% of children respond to methotrexate. Our aim was to describe the use and timing of MTX and anti-TNF drugs in pediatric uveitis.

Methods: We reviewed medical records of 104 children with pediatric uveitis. We collected demographic and clinical data, and timing of initial MTX use and subsequent anti-TNF use following uveitis diagnosis. MTX failure was defined as the addition of anti-TNF agents for the treatment of uveitis. Time to MTX failure was described using survival analysis modeling strategies.

Results: There were 59 children with JIA-associated uveitis (JIAU) and 45 with other forms of uveitis (U). Of these, 85 (82%) were treated with MTX. The majority were female (69%), Caucasian (61%) or African American (29%). Most had anterior disease (76%), bilateral involvement (71%), and ocular complications (65%), commonly synechiae (45%), cataracts (40%), and macular edema (24%). More than half (51% JIAU; 60% U) were treated with MTX within 6 months of diagnosis. For children with JIAU, MTX was initiated either prior to uveitis diagnosis (27%) or within 6 months (33%).

Forty one (48%) required the addition of anti-TNF agents for uveitis at a median of 16 months following MTX use, and 2.2 years following uveitis diagnosis. The majority (60%) initially received infliximab, and 20% required a second anti-TNF drug. Kaplan-Meier estimates suggest that 13% need anti-TNF agents within 6 months of MTX treatment; 16% by 1 year; 36% by 2 years and 59% by 5 years. Data suggests that one year after MTX therapy, fewer females than males required anti-TNF agents (8/59 (14%) vs. 6/22 (27%) $p<0.1$) [Figure1], and more Hispanic children were treated with anti-TNF agents compared to non-Hispanics (4/11 (36%) vs. 10/68 (15%) $p<0.1$) [Figure2]. Timing of initial MTX use following uveitis diagnosis, type of uveitis, race, ANA positivity, complications, and age at uveitis diagnosis did not predict timing of MTX failure.

Conclusion: Most children with uveitis require therapy beyond corticosteroid treatment. Up to 82% are treated with MTX within 6 months of diagnosis, and almost 50% require an anti-TNF agent within 2.5 years of diagnosis. One in five children are treated with a second anti-TNF drug. Male gender and Hispanic ethnicity may be associated with severe uveitis requiring biologic therapy. Further elucidation of the factors associated with severe uveitis may help with optimal early treatment of disease.

Tucker[7] and ReACCh-Out Investigators, [1]Rheumatology, Division of Rheumatology, BC Children's Hospital, Vancouver, BC, Canada, [2]Statistics and Actuarial Science, Simon Fraser University, Burnaby, BC, Canada, [3]Children's Hospital of Western Ontario, London, ON, Canada, [4]Pediatric Rheumatology, University of Saskatchewan, Saskatoon, SK, Canada, [5]University of Ottawa, Ottawa, ON, Canada, [6]Alberta Children's Hospital Research Institute/University of Calgary, Calgary, AB, Canada, [7]Rheumatology, BC Children's Hospital, Vancouver, BC, Canada

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters (ACR): Imaging and Novel Clinical Interventions

Session Type: ACR Poster Session C

Background/Purpose: To define distinct disease course groups among children with Juvenile Idiopathic Arthritis (JIA) based on observed changes in quality of life, pain, medication requirements, medication side-effects and active joint counts (AJC) during the first 5 years of the disease. These variables were prioritized by patients, parents and clinicians in a previous study.

Methods: We used data from the Research in Arthritis in Canadian Children emphasizing Outcomes (ReACCh-Out) prospective inception cohort. We included 618 children newly diagnosed with JIA between 2005 and 2010 with information for at least 6 of 8 study visits within the first 5 years after diagnosis. Health-related quality of life and pain were measured with 10 cm visual analogue scales. Each current medication was given a weight and weights were added to obtain a medication requirements score. Medication side effects were reported using the Juvenile Arthritis Quality of Life Questionnaire and were weighted according to how frequently they were experienced by the child to obtain a side-effects score. AJC were reported by the attending pediatric

rheumatologist. We grouped patients by course using multivariable cluster analysis and K-means clustering. Silhouette coefficients, R-Square statistics and clinical judgment were used to select the ideal number of clusters. The frequency of each disease course was described by JIA category.

Results: Four clusters provided the best discrimination: 1) Mild (43.0% of children)-almost normal quality of life throughout the disease course with initial mild pain and low AJC requiring minimal treatment, followed by normalization; 2) Moderate (33.7%)-moderate initial impact on quality of life and mild to moderate pain and AJC, followed by normalization; 3) Severe Controlled (11.6%)-moderate initial impact on quality of life and moderate pain levels with high AJC requiring aggressive treatment, followed by normalization; 4) Severe Persisting (11.6%)-persisting mayor impact on quality of life and moderate pain with moderate decreasing AJC, but ongoing treatment needs and side-effects. Children with oligoarthritis most often followed a Mild course. Almost half the children with RF negative polyarthritis, systemic and psoriatic JIA followed a Moderate course. Children with RF positive polyarthritis most often followed a Severe Controlled course. The Severe Persisting course was observed in all JIA categories but it was infrequent in systemic JIA and oligoarthritis.

Table: Proportion of children in each JIA category stratified by disease course cluster

JIA Category	Mild	Moderate	Severe Controlled	Severe Persisting
Oligoarthritis (n=228)	68.4	24.6	0.9	6.1
RF-negative polyarthritis (n=130)	21.5	46.9	17.7	13.8
Enthesitis-related (n=81)	37.0	29.6	14.8	18.5
Systemic (n=47)	23.4	48.9	25.5	2.1
Psoriatic (n=38)	36.8	47.4	2.6	13.2
RF-positive polyarthritis (n=26)	3.8	23.1	61.5	11.5
Undifferentiated (n=68)	38.2	29.4	8.8	23.5

Conclusion: Using patient-relevant variables the course of JIA can be described by four disease course groups with two of them reflecting a severe disease course, one that responded to treatment despite severe initial presentation and one with persisting impact on quality of life and pain despite moderate decreasing AJC. JIA category alone does not predict disease course.

Serum 14-3-3η Is Present in JIA and Is Not Associated with RF+ Polyarthritis

Alan M. Rosenberg[1], Walter Maksymowych[2], Yuan Gui[3] and Anthony Marotta[3], [1]Department of Pediatrics, University of Saskatchewan, Saskatoon, SK, Canada, [2]Department of Medicine, University of Alberta, Edmonton, AB, Canada, [3]Augurex Life Sciences Corp., Vancouver, BC, Canada

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters (ACR): Imaging and Novel Clinical Interventions

Session Type: ACR Poster Session C

Background/Purpose: Juvenile Idiopathic Arthritis (JIA) is a collective term used to denote clinically discrete subtypes, which include: Enthesitis-related arthritis, Oligoarthritis, Polyarthritis, Psoriatic arthritis, Systemic arthritis and unclassified arthritis. Polyarthritis is further categorized according to rheumatoid factor (RF) status. The International League of Associations for Rheumatology (ILAR) has devised classification criteria of JIA with specific exclusion criteria and its diagnosis is reliant upon clinical symptoms. While laboratory tests like CBC, CRP, ESR, RF, ANA, and anti-CCP add prognostic value, they have limited utility for diagnosis. Thus, markers that can assist in sub-typing JIA at presentation are imperative as this can influence patient management strategy. 14-3-3η is a joint derived, rheumatoid arthritis (RA) specific marker that informs radiographic damage. The

purpose of this study was to examine the expression of 14-3-3η in the sub-types of JIA, and to assess whether a relationship existed between 14-3-3η and RF+ polyarthritis.

Methods: 14-3-3η serum levels were measured in 60 JIA patients as shown in Table 1. One-way ANOVA analysis was used to determine if group differences existed. 14-3-3η positivity was defined using the adult RA diagnostic cut-off of ≥0.19 ng/ml. The Fisher's Exact test was employed to assess the relationship between RF and 14-3-3η positivity in polyarthritis patients.

Results: ANOVA analysis revealed differences in 14-3-3η serum levels between the groups. Patients with RF positive polyarticular disease had significantly higher serum 14-3-3η levels than the other groups. 14-3-3η positivity analysis revealed that 30% of the oligoarthritis, 53% of RF negative polyarticular, 50% of psoriatic and 57% of patients with systemic arthritis were positive for 14-3-3η. Although there were only four patients in the enthesitis group, none of them were 14-3-3η positive. Fisher's Exact testing returned no significant association between RF and 14-3-3η positive status (p-value = 0.35) indicating that the two markers may uniquely inform patient profiles within subtypes of JIA, especially since 53% of RF negative polyarticular JIA patients had positive 14-3-3η tests.

	Enthesitis	Oligo	Poly, RF-	Poly, RF+	Psoriatic	Systemic
# of Pts	4	21	19	7	2	7
Median (QR)	0.06 (0.02-0.09)	0.10 (0.02-0.23)	0.19 (0.02-0.33)	1.83 (0.09-10.59)	0.20 (0.01-0.38)	0.20 (0.01-1.54)
Mean (SD)	0.06 (0.04)	0.23 (0.35)	0.29 (0.38)	4.69 (6.51)	0.20 (0.26)	0.55 (0.69)
% Positivity (n)	0% (0)	30% (7)	53% (10)	71% (5)	50% (1)	57% (4)
ANOVA	p=0.0008					

Conclusion: 14-3-3η is a joint-derived mechanistic marker that up-regulates factors that are involved in joint damage pathogenesis. While RF+ polyarthritis patients had higher 14-3-3η levels, in JIA, 14-3-3η expression has no significant association with RF positivity and may provide insights into biochemical processes that uniquely inform JIA sub-typing.

The Family Journey to Diagnosis with Systemic Juvenile Idiopathic Arthritis As Evidenced through Changing Social Media Presence

Renee F Modica[1], Kathleen G Lomax[2], Pamela Batzel[3], Leah Shapardanis[3], Kimberly A Compton[3] and Melissa E Elder[4], [1]UF Health Shands Children's Hospital, Gainesville, FL, [2]Medical Affairs, Immunology and Dermatology, Novartis Pharmaceuticals Corporation, East Hanover, NJ, [3]TREATO, Princeton, NJ, [4]Pediatrics, Univ of Florida, Gainesville, FL

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters (ACR): Imaging and Novel Clinical Interventions

Session Type: ACR Poster Session C

Background/Purpose:

Patients with systemic juvenile idiopathic arthritis (SJIA) frequently encounter delays from symptom onset to SJIA diagnosis (dx), partly due to the broad differential of fever of unknown origin, lack of provider recognition, and its rarity. Given this typical

diagnostic delay, families often seek multiple medical opinions and post to social media about their frustration. This linguistic analysis observed the changing language and social media posting behavior of parents during the time period to SJIA dx.

Methods: US-hosted English-language public social media sites were manually reviewed by linguists to identify posts consistent with an SJIA dx, divided into pre- and post-dx periods, with a linguistic analysis.

Results:

4221 posts with a date range of 7/10/01-1/7/15 on 108 sites were reviewed from 1/11-3/12/15. 283 posts (all unique authors) consistent with pre-dx SJIA patients (pts), and 722 posts (381 unique authors) involving post-SJIA dx pts were found. Parents of pre-dx pts looked to social media for answers and to share status updates, focusing on 3 site types: natural therapy forums (39%), Facebook (27%), and disease-specific forums (17%). Posts in the early pre-dx phase were characterized by language showing confidence in the healthcare provider (HCP) and trust in parental instincts, with frequent expressive language. As time passed without a dx, posts showed parents beginning to doubt their intuition and faith in the HCP's ability to dx their child. Later posts also had more objective narratives of symptoms observed with less of a child-centered emotional focus and reduced-to-absent expressive language as parents became caregivers. At later pre-dx stages, caregivers continued to post most often to alternative/natural parenting forums (22%) and Facebook (18%). Once dx of SJIA became clear, caregivers moved to disease specific websites–although they still used Facebook. At the time of dx, caregivers used dry straightforward language in their "announcement" posts. After dx, caregivers posted about renegotiating HCP relationships and usually did not explicitly solicit advice but asked for other parents' experiences, analogies and anecdotes. With initiation of treatment, posts began to show a slow return of expressive language and understanding of their "new normal."

Conclusion:

Caregiver presence on social media sites provides key indicators about the stages in the diagnostic journey for SJIA pts. Analysis of posts reveals the often delayed diagnosis of SJIA, its complex course and impact on relationships of pts and caregivers with their HCP. Caregivers use different language, references and websites pre-dx than post-dx and demonstrate gaps in caregiver/HCP communication. Importantly, post-dx parent language in social media posting did not return to the original linguistic parent frame prior to disease onset. This diagnostic process changes the parents – not just the child, as evidenced by social media posts. Furthermore, the parents' role changes from parent to caregiver, and this role fluctuates throughout the disease course and treatment. They do continue to actively develop understanding of SJIA and treatment options through social media.

Pediatric Tele-Rheumatology: A Pilot Project to Assess Accuracy of Physical Examination Findings and Diagnostic Concordance at a Distance

Michael Henrickson[1], Jody Raugh[2], Kelsey Hofacer[3] and Adam Furnier[4], [1]Division of Rheumatology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Occupational and Physical Therapy, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [3]Center for Telehealth, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [4]Quality Improvement Systems, Cincinnati Children's Hospital Medical Center, Cincinnati, OH

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters (ACR): Imaging and Novel Clinical Interventions

Session Type: ACR Poster Session C

Background/Purpose: Telemedicine (TM) offers a strategic means of extending limited clinical pediatric rheumatology (PR)

workforce capacity to improve access to care for patients in remote locations. Tele-rheumatology (TR) often depends on a remote site provider to convey physical examination (PE) findings. While adult TR has diagnostic accuracy of 97% compared to in-person consultations, there are no published data for pediatric TR PE or diagnostic accuracy. This cross-sectional observational study assessed the accuracy of PE findings in 10 new PR TR consultations. Pragmatically, we envision a service delivery model involving initially inexperienced musculoskeletal examiners at remote locations. Hence, our aim was to determine the reproducibility of PE findings and diagnostic agreement. The primary outcome was comparison of the physician TR and remote examiner PE findings, and diagnostic concordance.

Methods: The physician conducted the interview within our hospital at a dedicated TM suite, then guided and documented the remote provider's PE. This examiner, a developmental pediatrics physical therapist, was physically located with the patient at our institution's PR clinic. We deliberately sought an examiner naïve to PR musculoskeletal examination. Knowing PE skills improve with repetition, we restricted the study to 10 patients to limit this effect. Patient selection focused on ensuring a variety of presenting complaints and ages. The initial 30% knew they had TR consultation scheduled; the remainder was unaware. We sought parental TM satisfaction after each session via on-line survey and/or in-person interviews. We used a Likert scale to determine the impact revised PE findings had on clinical decision-making.

Results: We identified 26 PE errors in this cohort of broad age range (14 months to 16 years). The table summarizes concordance. PE errors mainly involved biomechanical disorders with or without generalized hypermobility (7, 2) and musculoskeletal abnormalities (5). Weighted averages for diagnostic concordance varied: overall (37%), biomechanical disorders (31%), inflammatory diseases (83%) and pain amplification (0%). The practical impact on decision-making (20% none, 30% minimal, 50% moderate, 0% marked) affected 8 patients: physiotherapy orders (5), and one patient each for lab/x-ray, medication options, and additional consultation. Completed surveys (50%) indicated 100% agreed or strongly agreed with using TR again, with overall satisfaction of 100%.

Concordance for PE Findings and Diagnosis

	PE Findings Identified		Diagnostic Concordance (%)
	MD only	Both Examiners (PT & MD)	
Acrocyanosis		1	100
Complex regional pain syndrome	1	0	0
Hypermobile type Ehlers Danlos syndrome	2	4	67
Oligoarticular JIA (TMJs, peripheral joints)		2	100
Other biomechanical disorders (iliotibial band, ligament laxity, patellofemoral instability)	7	0	0
Other physical findings			
General (escutcheon)	1	0	0
Musculoskeletal (flexion contracture, joint crepitus or tenderness, malocclusion, and muscle atrophy)	5	0	0
Periodic fever syndrome		2	100
Reactive arthropathy	1	1	50

Conclusion: Pediatric TR requires a remote site examiner trained in musculoskeletal PE with an emphasis on biomechanical abnormalities which are prevalent in PR. Concerns about reliably identifying juvenile arthritis do not appear to be a major risk of TR, although errors did occur in detecting all involved joints. Pediatric TR can provide access to clinical care with high levels of satisfaction.

Accelerometer-Assessed Daily Physical Activity in Relation to Pain Cognitions and Quality of Life in Juvenile Idiopathic Arthritis

Mette Noergaard[1], Johanne Lomholt[2], Mikael Thastum[2], Morten Herlin[3], Marinka Twilt[4] and Troels Herlin[4], [1]Department of Physiotherapy, Aarhus University Hospital, Aarhus, Denmark, [2]Psychology and Social Sciences, Aarhus University, Aarhus, Denmark, [3]Pediatrics, Aarhus University Hospital, Aarhus, Denmark, [4]Pediatric Rheumatology Clinic, Department of Pediatrics, Aarhus University Hospital, Aarhus, Denmark

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters (ACR): Imaging and Novel Clinical Interventions

Session Type: ACR Poster Session C

Background/Purpose:

Juvenile Idiopathic Arthritis (JIA) has been associated with decreased physical activity (PA). However, accurate, objective measurements of PA related to potential factors limiting PA in children with JIA have been lacking. Joint pain is a primary symptom of JIA and pain has been shown to be a significant predictor of impaired physical and psychosocial function, affecting the quality of life in these patients. Therefore, it could be anticipated that pain would explain the decreased PA in JIA. The use of pain-coping strategies and pain-specific health beliefs in children with JIA has previously been found to be associated with both clinical and experimental pain reports. Beliefs about a stressor such as pain are thought to influence an individual's coping responses. We have previously reported that pain-related beliefs were significantly associated with pain in children with JIA even after controlling for disease-related variables and pain coping.

The aim was to relate accelerometer-assessed PA (PA-Acc) to disease activity, pain intensity, the use of pain coping strategies, pain-related health beliefs and health-related quality of life (HRQoL) measures in children with JIA.

Methods:

PA was assessed using the hip-worn GT1M Actigraph accelerometer during wakening hours for one week, providing at least 3 separate days of each 8 hours of valid recording accelerometry in JIA patients using 10 sec. count-time periods (epochs). Demographic, disease and pain measurements, pain coping strategies assessed with the Pain Coping Questionnaire (PCQ), pain-specific beliefs assessed with the Survey of Pain Attitudes for Children (SOPA-C), and HRQoL assessed with the Pediatric Quality of Life Inventory (PedsQL), arthritis module, were simultaneously obtained.

Results:

Accelerometer data of 61 JIA patients (60.7%) were available for analysis. Accelerometer values of mean counts per minute (c/min), minutes with moderate and high PA (>1000 c/min) and high PA (>2500 c/min) were significantly lower in patients compared to normative values. Disease activity, expressed as JADAS-27, was negatively correlated to accelerometer counts. However, PA-Acc was neither correlated to pain intensity, pain coping strategies, nor to HRQoL. Accelerometer counts were significantly correlated to the pain-specific belief that one is in control of pain ('Control'), but not to other pain-specific beliefs. In a hierarchical regression analysis 'Control' did not explain a significant unique part of the variance when controlling for JADAS-27, whereas JADAS-27 significantly explained 27% of the variance in moderate and high intensity PA when controlling for the health belief 'Control'.

Conclusion:

Accelerometer-assessed PA-levels of JIA-children were significantly lower than those of normative controls and were negatively correlated to JADAS-27. Levels of PA-Acc were not correlated to pain intensity, pain coping strategies, or HRQoL , but significantly correlated to the pain-specific belief that one is in control of pain ('Control').

SESSION INFORMATION

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters (ACR): Imaging and Novel Clinical Interventions

Session Type: ACR Poster Session C

Background/Purpose:

Juvenile Idiopathic Arthritis (JIA) is a common chronic childhood illness that can negatively impact health-related quality of life (HRQL). In younger years, children manage JIA with support from parents and health care providers. However, early childhood engagement as shared care partners can optimize disease management, assist with symptom control, including pain, and hence improve HRQL. This becomes imperative as children move into the adolescent period and are expected to a larger role in the co-management of their JIA. There is evidence to suggest that psycho-educational treatments can improve health outcomes in JIA; however, the uptake of these interventions into routine care has been slow. The vast majority of children and their parents do not receive comprehensive JIA education, disease management and coping skills training. While self-management programs for adolescents and adults with JIA do exist, to our knowledge there are no such programs for children. The aim of this current research study is to develop and assess the usability of a bilingual (English and French) interactive, iPad-based psycho-educational game for 8 to 11 year old children with JIA. The game aims to help children and parents learn disease management and coping skills using gamification mechanics to reduce pain and pain-related activity limitations and improve HRQL.

Methods:

The core game concepts were developed in collaboration with subject matter experts, patient partners, and project investigators. Usability testing of the game is being conducted in 2-3 iterative cycles with patients (8-11 years old) and parents. Participants interact with the game in a step-wise manner and errors and efficiencies of gameplay are observed and documented. Participants also provide feedback through a semi-structured interview. Data are analyzed using content analyses.

Results:

Stakeholders collaborated to create the core game concept, which entails players battling physical (i.e., pain, stiffness, and fatigue) symptoms and psychological (e.g., worry, sadness) symptoms associated with JIA. Players use appropriate treatment strategies to battle their symptoms throughout an 8-week period of game play. Usability testing has been completed for 5 English-speaking children (average age = 10.4 years; 3 male, 2 female) and 4 parents. Children and parents have responded positively to the game. Suggestions have been minor (e.g., changing specific graphics, adding more animation) and there have been no changes to core game mechanics. Minor errors are related to navigation (e.g., failure to locate functions or follow recommended screen flow) and presentation (e.g., failure to locate and properly act upon desired information).

Conclusion:

Children with JIA may benefit from educational games to teach self-management strategies in order to improve HRQL. A core game concept was developed and overall reception to the game has been positive. Based upon user suggestions, changes to the prototype will be implemented and tested using further iterative cycles. The game will be translated into French. The feasibility and overall effectiveness of the game will be evaluated using a pilot randomized control trial.

Synovial Fluid Proteins Differentiate Patients with Oligoarticular Juvenile Idiopathic Arthritis Who Are Destined to Extend from Those Who Will Remain Persistent in Course

SESSION INFORMATION

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters (ACR): Imaging and Novel Clinical Interventions

Session Type: ACR Poster Session C

Background/Purpose: Children with oligoarticular juvenile idiopathic arthritis (JIA) who have an extended course (recruitment of 5 or more joints after 6 months of disease) have a worse prognosis than those who have a persistent oligoarticular course (4 or fewer joints involved for the duration of disease). We want to predict those patients whose arthritis will ultimately extend early in the disease course, before the course has declared itself. Our goal is to identify protein biomarkers which will discriminate between patients whose involvement will remain persistently oligoarticular and those who are destined to have an extended oligoarticular course. **Methods:** As part of a separate ongoing IRB approved protocol, remnant synovial fluid was obtained from patients undergoing medically indicated arthrocenteses. Using our clinical database, JIA samples were separated into two groups: oligoarticular JIA with persistent course (PR), oligoarticular JIA with extended course (E). All samples were from steroid-na•ve joints and samples from E were obtained prior to time of extension. Using synovial fluid samples from 4 PR and 4 E patients, protein arrays were completed using RayBiotech Membrane-based Antibody Arrays. Expression of 89 cytokines, chemokines, and other inflammatory proteins were measured by calculating intensity using ImageJ. Key significant proteins were then confirmed using R&D Systems Quantikine Colorimetric Sandwich ELISAs. **Results:** Based on the analysis of the protein arrays, 20 proteins had significantly different expression levels (Table 1). Of these 20, 3 proteins were overexpressed in PR samples, while 17 were overexpressed in E samples. To confirm these results, ELISAs (Fig. 1) were performed on IL-5, a cytokine that acts as a growth and differentiation factor for B cells, Angiogenin, a potent stimulator of new blood vessels, IL-6, an interleukin with both pro- and

anti-inflammatory roles, and VEGF, a signal protein that stimulates angiogenesis. Both IL-5 and Angiogenin were significantly overexpressed on protein arrays in PR samples when compared to E samples (p-values <0.05). VEGF and IL-6 were significantly overexpressed in E samples when compared to PR samples (p-values <0.001). **Conclusion:** Samples of synovial fluid from differing courses of JIA, PR and E, taken before the ultimate course is clinically apparent, have significantly different protein levels of important chemokines and cytokines. These differences can be exploited to predict which patients may extend, allowing earlier therapeutic intervention to prevent long term disability.

SESSION INFORMATION

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters (ACR): Imaging and Novel Clinical Interventions

Session Type: ACR Poster Session C

Background/Purpose: A considerable proportion of children with polyarticular juvenile idiopathic arthritis (polyJIA) continue to experience active disease into adulthood. There is no validated disease activity measure for these adults; when children transfer to adult services they are often reclassified as having rheumatoid arthritis (RA) and assessed using the Disease Activity Score 28 (DAS28). DAS28 is validated in adults with RA to assess disease severity and in the UK a score of >5.1 defines qualification for biological drugs. However, in contrast to the Juvenile Arthritis Disease Activity Score (JADAS), the DAS28 does not include joints that are frequently affected in polyJIA. In this study, we compared the DAS28 with JADAS-10 and questioned whether DAS28 is appropriate to use in adults with polyJIA.

Methods: Tender and swollen joint counts out of 28, active joint count of all joints up to a maximum of 10, patient/parent global assessment and physician global assessment visual analogue scales were collected prospectively from paediatric, adolescent and young adult rheumatology clinics in patients aged 10 and above with polyJIA (classified by International League of Associations for Rheumatology). Erythrocyte sedimentation rate (ESR) values were taken within 30 days before or after the assessment (when unavailable, values were taken within 3 months before or after, providing the patient remained stable between the ESR test and assessment). When unavailable within these time periods, patients were excluded from analysis. DAS28 and JADAS-10 were calculated and compared using Spearman's rank correlation coefficient. A DAS28 of >5.1 constitutes high disease activity in adults with RA while a JADAS-10 of >10.5 is considered to reflect high disease activity in children with polyJIA.

Results: Forty-nine patients were analysed (range 10-27 years, median 15 years, M:F ratio 1:3.5). Thirteen out of 49 patients were classified as high disease activity by JADAS-10, while only 1 out of 49 was defined as high disease activity by DAS28. Good correlation was seen between DAS28 and JADAS-10 (Spearman r=0.6939, p<0.0001) with no considerable difference between children (range 10-15 years, median 13 years, n=25, Spearman r=0.8269, p<0.0001) and adults (range 16-27 years, median 17 years, n=24, Spearman r=0.7345, p<0.0001).

Conclusion: Discrepancy in high disease activity thresholds between DAS28 and JADAS may have implications when determining which patients qualify for biological drugs, although the absolute values correlate well. Hence the JADAS may remain the more appropriate disease activity marker to use in adults with polyJIA.

SESSION INFORMATION

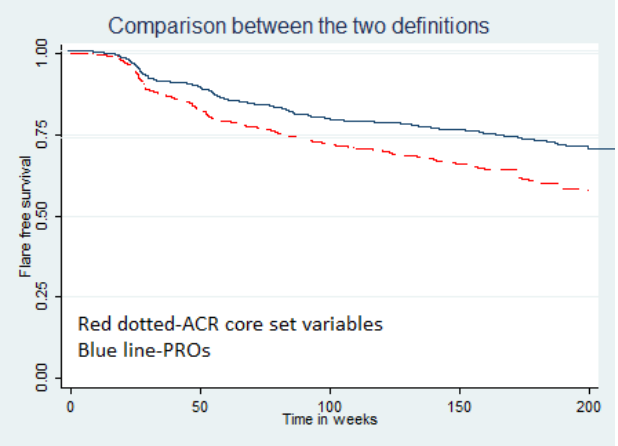
Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters (ACR): Imaging and Novel Clinical Interventions

Session Type: ACR Poster Session C

Background/Purpose: A valid flare definition is needed in clinical practice to identify a clinically relevant worsening which will guide us make treatment decisions. While the ACR core variables are primarily physician based criteria, patient reported variables could have a significant role in helping patients identify worsening early and seek medical attention sooner .Our aims were to 1) Examine the feasibility of using Patient Reported Outcomes (PROs) and ACR core set variables to define flare in children with JIA and 2) Examine the concordance between the two definitions

Methods: We studied children in the Research in Arthritis in Canadian Children emphasizing outcomes (ReACCh-Out) prospective cohort. Data were collected during routine clinical practice for newly diagnosed patients at 16 pediatric rheumatology centres enrolled between 2005 and 2010. ACR core set variables and patient reported variables were collected at 0, 6, 12, 18, 24, 36, 48 and 60 months after enrolment. The PROs included Pain visual analogue scale, functional status measured by the Childhood Health Assessment Questionnaire (CHAQ) and duration of morning stiffness. Flare was defined as: 1) PROs flare: at least 30% worsening in 2/3 PROs with minimum duration for stiffness of 30 minutes; 2) ACR Core Set flare: worsening of at least 3/6 ACR core variables by at least 30% without concomitant improvement of more than one variable by ≥ 30%. Flare status was assessed for each patient visit after the subject attained clinically inactive disease. Concordance between the two flare definitions was assessed with the Kappa statistic. The risk of first flare was estimated by Kaplan-Meier survival analysis.

Results: A total of 1146 patients were included in the study with a median follow up of 24 months after inactive disease. Of the total 6177 study visits, 2358 visits occurred after patients had attained inactive disease. Imputation was required for missing data in 42 % of visits for ACR core variables and 35 % for PROs. After imputation the definition for flare was fulfilled in 478 (20.2%) visits using ACR core variables and in 366 (15.5%) visits using PRO variables. In 231 visits flare was identified by both definitions. The overall concordance was 83.8% with kappa value of 0.45 suggesting moderate agreement (p =0.00001). Applying minimum cut-offs for ACR core variables, as done in randomized trials of polyarticular course JIA, only 278 visits would fulfill the criteria. The Kaplan Meier curves are presented in the figure.



Conclusion: A flare definition based on PROs had moderate concordance with the one based on ACR core set variables. It tended to underestimate the risk of flare. The feasibility of using both the definitions to define flare in this routine practice-based cohort was limited by missing data requiring imputation and by study visits scheduled at set intervals.

Does Antinuclear Antibodies Predict Remission in JIA ?

Mia Glerup[1], Troels Herlin[2] and Marinka Twilt[3], [1]Pediatrics, Aarhus University Hospital, Skejby, Aarhus, Denmark, [2]Department of Pediatrics, Århus University Hospital Skejby, Århus, Denmark, [3]Rheumatology, Alberta Children's Hospital, Calgary, AB, Canada

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters (ACR): Imaging and Novel Clinical Interventions

Session Type: ACR Poster Session C

Background/Purpose:

In the recent years the classification of Juvenile Idiopathic Arthritis (JIA) according to the ILAR criteria has been questioned as some categories still include heterogeneous conditions. One of the questions posed is if patients with a positive Antinuclear Antibody (ANA) should be a separate category. Previous studies have shown contradicting evidence to support the separation of patients based on ANA status.

The aim of this study was to evaluate disease outcome defined as remission based on ANA status. Secondary aims of the study included the clinical and disease activity features of ANA positive patients in comparison to the ANA negative patients at disease onset and last follow-up.

Methods: A retrospective cohort study; all patients diagnosed with JIA according to the revised ILAR criteria attending our Pediatric Rheumatology Center from January 2000 until May 2014 were included.

A minimum follow-up of 1 year was required. ANA positivity was defined as at least 2 positive results with a titer ≥ 1:160. ANA was measured by indirect immunofluorescence assays on HEp-2 cells. Demographic and clinical features were collected. Remission at last follow-up was defined by Wallace criteria for remission on (>6 months) and off (>12 months) medication. Descriptive analysis (Chi-square) was performed (SPSS).

Results:

A total of 625 patients met the inclusion criteria. Of these patients 229 (37%) were ANA positive. ANA positivity was correlated to a female predominance and young age at diagnosis ($p<0.05$). Joint count at diagnosis and at last follow-up showed no difference between both groups. At least half of the patients in both groups were treated with MTX. Treatment with TNF alpha blocking agents was seen more frequently in patients with a positive ANA.

Nine % of the total patient cohort had uveitis and 50% of these patients were treated with anti-TNF-alpha.

Disease outcome; remission on or off medication, showed no differences between both groups and it was irrespective of uveitis. Sub-analysing the ANA positive oligoarticular-persistent, extended and polyarticular RF-neg patients (n=200) showed a significant difference for remission on and off medication; oligoarticular-persistent patients more frequently were in remission off medication, while oligoarticular-extended and polyarticular RF-neg were more frequent in remission on medication. The latter groups also received more MTX and anti-TNF alpha treatment.

	ANA negative	ANA positive
JIA	396 (63%)	229 (37%)
Systemic JIA	48 (92%)	4 (8%)
Oligoarticular persistent	122 (57%)	93 (43%)
Oligoarticular extended	51 (50%)	50 (50%)
Polyarticular RF-neg	68 (54%)	57 (46%)
Polyarticular RF-pos	13 (62%)	8 (38%)
Psoriatic JIA	34 (83%)	7 (17%)
ERA	31 (82%)	7 (18%)
Undifferentiated JIA	29 (94%)	3 (6%)
Gender*	226 male, 169 female	50 male, 179 female
Age at diagnosis* (years)	9.2	6.4
Disease duration* (years)	5	6.4
Uveitis*	13(3%)	42 (18%)
Joint count at diagnosis	2.9	3.1
Methotrexate treatment	203 (51%)	134 (59%)
Anti-TNF alpha treatment*	86 (22%)	71 (31%)
Last follow-up		
Joint count last follow-up	< 0.1	< 0.1
Remission on medication < 6months	26 (7%)	13 (6%)
Remission on medication > 6 months	99 (25%)	61 (27%)
Remission of medication < 12 months	33 (8%)	19 (8%)
Remission of medication > 12 months	219 (55%)	115 (50%)
Active disease	22 (1%)	21 (9%)

*Statistically significant (P<0.05)

Conclusion:

Our findings show that ANA positive patients do not differ from ANA negative patients when comparing remission rate. This was independent of uveitis. However in the ANA positive group a different remission rate and medication use is seen for the different subtypes. Although ANA positive oligoarticular-extended and polyarticular RF-neg patients reach remission on medication, oligoarticular-persistent patients have a higher remission rate off medication.

Examination of the Clinical Significance of 14-3-3 Eta in Juvenile Idiopathic Arthritis

Lance Feller[1], **Austin M. Dalrymple**[2], Paul Tuttle IV[3], Reema H. Syed[3], Peri Pepmueller[1] and Terry Moore[4], [1]Rheumatology, Saint Louis University, St. Louis, MO, [2]Pediatric Rheumatology, St. Louis University, St. Louis, MO, [3]IM-Rheumatology, Saint Louis University, St. Louis, MO, [4]Division of Rheumatology and Pediatric Rheumatology, Saint Louis University School of Medicine, St Louis, MO

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters (ACR): Imaging and Novel Clinical Interventions

Session Type: ACR Poster Session C

Background/Purpose:

14-3-3 proteins are chaperonins found in all eukaryotic cells. There are multiple isoforms which are thought to be involved in intracellular signaling and transcription regulation. Recent work has implicated the η (eta) isoform as having diagnostic potential in inflammatory arthritis. Its utility and significance in juvenile idiopathic arthritis (JIA) has not been established, but our prior investigation revealed 14-3-3η positivity in some JIA patients. In this study we investigated the utility of measuring 14-3-3η in children with juvenile idiopathic arthritis.

Methods:

Measurements of 14-3-3η were obtained during evaluations of new patients with joint pain and in routine follow-up of JIA patients presenting between July 2013 and April of 2015. Rheumatoid factor (RF) and anti-cyclic citrullinated peptide antibodies (anti-CCP Ab) were measured. A chart review was later conducted to evaluate the clinical significance 14-3-3η. Joint imaging was evaluated for erosive changes.

Results:

23 JIA patients were evaluated. 10 had polyarticular disease, 3 had oligoarticular extended, 3 had seronegative spondyloarthritis (SNSA), 2 had oligoarticular, 2 were undifferentiated, 2 had enthesitis-related arthritis (ERA), and 1 had systemic-onset.

7 of 23 were 14-3-3η positive (5 had polyarticular disease, 1 with ERA, & 1 with oligoarticular). All 5 patients with polyarticular disease also were RF positive and 3 were both RF & anti-CCP Ab positive. The ERA patient was seronegative, and the oligoarticular patient was positive only for RF.

9 of the 23 had erosive disease, 4 of which were polyarticular with a positive 14-3-3η. Of those 1 was RF positive, and the remaining 3 patients were positive for RF and anti-CCP Ab. Neither the 14-3-3η positive patient with ERA nor the one with oligoarticular disease had erosions.

Conclusion:

14-3-3η can be found in polyarticular JIA and correlates with a positive RF and to a lesser extent a positive anti-CCP Ab. The majority of polyarticular JIA patients with erosions were 14-3-3η positive. We hope to expand this small study to include a larger sample and evaluate for any further relationships.

Scoring Medication Requirements and Side-Effects in Juvenile Idiopathic Arthritis: Perspectives of Patients, Parents and Clinicians

Lori B. Tucker[1], Natalie Shiff[2], Susanne Benseler[3], Roberta Berard[4], Roman Jurencak[5], Thomas Loughin[6], Jaime Guzman[7] and Andrew Henrey[6], [1]Rheumatology, BC Children's Hospital, Vancouver, BC, Canada, [2]Pediatric Rheumatology, University of Saskatchewan, Saskatoon, SK, Canada, [3]Pediatrics, University of Calgary, Toronto, ON, Canada, [4]Children's Hospital of Western Ontario, London, ON, Canada, [5]University of Ottawa, Ottawa, ON, Canada, [6]Statistics and Actuarial Science, Simon Fraser University, Burnaby, BC, Canada, [7]Rheumatology, Division of Rheumatology, BC Children's Hospital, Vancouver, BC, Canada
First publication: September 29, 2015

SESSION INFORMATION

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters (ACR): Imaging and Novel Clinical Interventions

Session Type: ACR Poster Session C

Background/Purpose: Medication requirements (MedReq) and medication side effects (MedSE) were found to be top priorities by patients, parents and clinicians in describing the course of the disease in children with juvenile idiopathic arthritis (JIA) in a previous study. There are no validated scales to measure these constructs in JIA. The aim of this study was to get input from patients, parents and clinicians to develop MedReq and MedSE scales in JIA.

Methods: We developed MedReq and MedSE scales, based on data available in the Research in Arthritis in Canadian Children-Outcomes cohort, and convened focus groups of youth with JIA (n=3), parents of children with JIA (n=3), and pediatric rheumatology clinicians (2 pediatric rheumatologists, 1 nurse) to evaluate the draft scales (Table). The draft MedReq scale was an ordered 11-level scale from 0=no medications to 10= Biologic, DMARD and systemic corticosteroids, with or without other medications. The MedSE scale was an 11-level scale from 0=no side effects to 10= Side-effect resulting in death or disability. Each of the proposed 11 levels for each scale was printed onto a Q card and participants were asked to rank the cards, without knowledge of the proposed order. Participants then viewed the rankings, and discussed reasons for their rankings. They could change their ranking if wanted and open discussions about JIA medications and medication side effects followed. Notes were recorded by a research assistant at each group, and data was summarized.

Results: Overall there was excellent agreement on ranking of the extreme levels of the scales (0,10) with substantial differences in the 6-9 ranks in the MedReq scale and the 3-6 ranks in the MedSE scale. MedReq scale values were changed to rank joint injection with a lower value than daily NSAID therapy. Patients own experience with side effects of prednisone and methotrexate influenced their ranking on the MedReq scale. Participants also pointed out that medication frequency has an impact on the perceived “intensity” of treatment. The MedSE scale based on the number and frequency of side-effects was said not to reflect the “real importance” of a side effect. Participants felt that future MedSE data collection must include measures of severity and impact of the side effects on daily living; information that was not available in the current data set. Additional descriptors were proposed for prednisone side-effects and inconveniences of injections.

Conclusion: Parents and patients were highly engaged and provided unique insights to the research team beyond the task they were asked to complete. The draft MedReq scale was overall well received but required weighting adjustments. Patients, parents and clinicians believe a MedSE scale should focus on the global severity and impact of experienced side-effects on daily living rather than number and frequency of side-effects.

TABLE: Proposed MedReq and MedSE items and ranking

MedReq Items	Item score	MedSE Items
No treatment at this visit	0	No side effects
Anti-inflammatory med only	1	One side effect occurring rarely
Intra-articular corticosteroid only	2	One side effect occurring some of the time
Anti-inflammatory med and intra-articular corticosteroid	3	Two side effects occurring rarely
DMARD only	4	Two side effects occurring some of the time
DMARD with anti-inflammatory and intra-articular corticosteroid	5	One side effect occurring 50% or more of the time
Multiple DMARDs	6	Two side effects occurring 50% or more of the

Multiple DMARDs	6	time
Multiple DMARDS with anti-inflammatory med and intra-articular corticosteroid	7	Three side effects occurring 50% or more of the time
DMARD and systemic corticosteroid	8	More than 3 side effects present more than 50% of the time
Biologic and DMARD	9	Side effect requiring in-hospital treatment
Biologic, DMARD, systemic corticosteroid, with or without other medications	10	Side effect resulting in death or disability

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters (ACR): Imaging and Novel Clinical Interventions

Session Type: ACR Poster Session C

Background/Purpose: The Juvenile Arthritis Disease Activity Score (JADAS) is increasingly accepted for defining a treat-to-target strategy in patients (pts) with juvenile idiopathic arthritis (JIA)[1] The purpose of this study is to use JADAS to evaluate clinical disease activity/control, with or without functional control, in pts with polyarticular or polyarticular-course JIA (pJIA), following the initiation of adalimumab (ADA) ± concurrent methotrexate (MTX) treatment. To assess the feasibility of JADAS definition of remission (REM) and minimal disease activity (MDA) as part of a treat-to-target strategy.

Methods: Data for this post hoc analysis originated from M10-444, an open-label study in pJIA pts 2 to <4 yrs old or ≥4 yrs weighing <15 kg with moderately to severely active pJIA, in the US and EU (in the EU pts had to previously fail, have an insufficient response, or intolerance to MTX). Pts received subcutaneous ADA (24 mg/m^2 body surface area, up to 20 mg/dose), every other week (wk), for ≥24 wks, or until pts reached 4 yrs and weight ≥15 kg (in the EU, pts could continue for up to 1 additional yr). Disease activity was determined by JADAS based on C-reactive protein (CRP, normalization from 0-10), for 10 or 27 joints (JADAS10/27); functional impairment was determined by the Disability Index- Childhood Health Assessment questionnaire (DI-CHAQ). At wks 12 and 24, the proportion of pts achieving physician-assessed REM (JADAS≤2) or MDA (JADAS≤3.8), and the proportion of pts who achieved both MDA/REM and DI-CHAQ<0.5, was determined using observed cases.

Results: Out of 32 pts, 25 (78%) had received prior MTX and 27/32 (84%) received concomitant MTX during the study. At baseline, pts had a mean JADAS10 of 18.8, JADAS27 of 19.0, and DI-CHAQ of 1.2. After 12 wks on open-label ADA, improvements were observed in clinical and functional outcomes. At wks 12 and 24, the mean JADAS10 was 6.2 and 5.3; mean JADAS27 was 6.4 and 5.6; mean DI-CHAQ was 0.7 and 0.7, respectively. No pts were in REM/MDA at baseline; however after 12 and 24 wks, a sizeable proportion achieved disease control (table). After 12 and 24 wks of ADA treatment, the proportions of pts achieving both, disease control and DI-CHAQ<0.5 also increased from baseline.

Conclusion: Addition of open-label ADA treatment resulted in clinically important improvements in clinical and functional outcomes in pts with pJIA. JADAS 10 and -27 gave comparable results. JADAS REM and MDA are achievable targets with ADA

treatment.

Table: Numbers of patients who achieved disease control with/without DI-CHAQ<0.5, n/N (%)

Evidence-Based Decision Support for Pediatric Rheumatology Reduces Diagnostic Errors, with the Potential to Reduce Capacity Shortage

Balu Athreya[1], Mary Beth Son[2], Jonathan S. Hausmann[3], Elizabeth Ang[4], David Zurakowski[5], Michael Segal[6] and **Robert Sundel**[7], [1]duPont Hospital for Children/Thomas Jefferson University, Wilmington, DE, [2]Division of Immunology, Children's Hospital Boston, Boston, MA, [3]Rheumatology, Children's Hospital Boston, Boston, MA, [4]Paediatrics, University Children's Medical Institute, NUH, Singapore, Singapore, [5]Departments of Anesthesia and Surgery, Boston Children's Hospital, Boston, MA, [6]SimulConsult, Chestnut Hill, MA, [7]Immunology, Childrens Hospital, Boston, MA

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters (ACR): Imaging and Novel Clinical Interventions

Session Type: ACR Poster Session C

Background/Purpose: This projects seeks to respond to the critical shortage of pediatric rheumatologists encapsulating the diagnostic information of the field in an advanced diagnostic decision support software (**DDSS**) tool. We present here an assessment of the benefits of such rheumatology assistance in the evaluation of actual case vignettes.

Methods: The evaluation used the SimulConsult DDSS tool, based on Bayesian pattern matching with temporal onset of each finding in each disease. The software covered 5,405 diseases, taking into account the incidence, treatability, relative frequency, age of onset and age of disappearance for each finding in each disease. The output includes a rank-ordered differential diagnosis and a display of clinical and lab findings ranked by pertinence (measured by the ability of a finding to modify the differential

diagnosis) and cost-effectiveness in distinguishing among diagnoses. Rheumatology information was entered by junior clinician curators primarily from textbook material and edited by senior clinicians. A checklist of 46 common rheumatologic findings was developed to assist in both curation of information and entry of findings in clinical use.

Results: Twenty-six testers were asked to evaluate 8 case vignettes of real patients with laboratory-established diagnoses (6 had pediatric rheumatologic diagnoses; 2 had other conditions with some rheumatologic findings). Of the 26 testers, 13 were "junior" clinicians in the final year of residency or first post-residency year. The remaining 13 had been practicing for at least 10 years ("senior"). Ten of the 26 testers were pediatric rheumatologists, 9 were pediatric emergency medicine physicians and 7 were general pediatricians. Clinician testers generated a differential diagnosis before and after using diagnostic decision support software. Overall, testers demonstrated a significant reduction in diagnostic errors following introduction of the software, from 28% unaided to 15% using decision support ($p<0.001$). Error reduction was significantly larger for emergency medicine physicians compared to generalists and rheumatologist ($p=0.013$). This error reduction occurred despite the fact that testers employed an "open book" approach to generating their initial lists of potential diagnoses, spending an average of 8.6 minutes using sources of medical information generally available on the internet before using the diagnostic software.

Conclusion: Use of DDSS can reduce diagnostic error, cutting a greater amount of error for generalists, but a greater percentage of error for rheumatologists. Junior rheumatologists equipped with decision support were able to rival the diagnostic accuracy of senior colleagues at baseline, an improvement that could further extend the availability of pediatric rheumatology consultations. These findings suggest that decision support can reduce diagnostic errors and improve use of relevant information by practitioners, potentially helping to address the shortage of experts in pediatric rheumatology and similarly underserved specialties.

Target and Targetoid Reactions at Bacillus Calmettee-Guérin Inoculation Site Revealed By Dermatoscopy Correlate with Systemic Involvements in Patients with Kawasaki Disease

Kuo Ho-Chang and Kawasaki Disease Center, Pediatrics, Kaohsiung Chang Gung Memorial Hospital, Kaohsiung, Taiwan
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters (ARHP): Pediatrics
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

For the past decades, the rash at the Bacillus Calmettee-Guérin (BCG) inoculation sites has been recognized as a useful diagnostic clue in Kawasaki disease (KD). However, the detailed characterization of the BCG reaction and its correlation with systemic involvements in KD has not been evaluated. We sought to characterize the BCG reaction in KD and correlate the grade of BCG reaction with the systemic involvements in patients with KD.

Methods: History taking, laboratory examination, physical examination, and dermatoscopic examination were performed in 10 patients diagnosed with KD

Results:

We identified four dermoscopic patterns: atypical targets (targetoid) pattern in 3 patients; typical target pattern in 2 patients; faint

homogenous erythema in 3 patients; a more or less evident white patch, in the central area in 2 patients. Elevated blood level of liver enzymes is associated with the presence of typical target and atypical target pattern in patients.

Conclusion:

The dermoscopic patterns may help dermatologists and pediatrician to consolidate the diagnosis of Kawasaki disease. The target or targetoid pattern observed under dermoscope is a useful biomarker for systemic involvements in patients with KD.

Disclosure: K. Ho-Chang, None;

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters (ARHP): Pediatrics

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Due to the shortage of subspecialty physicians there is an increasing need of adding mid-level practitioners to specialty practices (Solomon, Bitton, et.al., 2014). However there is little guidance as to best practices and standards for training a nurse practitioner (NP) or physician assistant (PA) in specialty practice. In this study we investigated the scope of practice and training for NPs in pediatric rheumatology in the United States by a nationwide survey.

Methods:

The Pediatric Nurse ListServe in the United States has an over 100 NP members and currently no known PA's. We developed an 18 question survey focused on the education, background, training and practice of Nurse Practitioners in Pediatric Rheumatology Practices. Survey monkey was utilized and sent to both the Pediatric Rheumatology and Pediatric Rheumatology Nursing List Serves. Questions included state of employment, years working a nurse prior to and as a nurse practitioner, length of training with the Rheumatologist staffing patients, focused education in the specialty, scope of practice, length of appointments, volume of clinics per week, billing practices and research engagement. The survey was sent out as an e-mail blast with two follow up reminders to practitioners.

Results:

33 NP's from 17 States in the United States responded. Response rates were evenly distributed across the country. 67.7% had a background in acute care settings as RN's with anywhere from less than 2 to over 20 years of experience prior to becoming a NP. 57% had prior experience as an NP in primary care or other specialty setting. Training with a Rheumatologist ranged from <6 months=31.0%, 6 month=31.0% and 1 year=27.6% and 10% 1-2 years. Subsequent to this, 93.7% reported seeing patients in follow up independently with an MD available, while 28.1% see the patients together with an MD; 53.1% report seeing new patients with an MD, 36.5% with a MD available. Most common diagnosis being followed: Juvenile Idiopathic Arthritis 97%, uveitis 90.9%, systemic lupus 84.8%, dermatomyositis 84.8% and linear/morphea scleroderma 81.8%. Respondents reported a broad range of acuity. 93.9% followed patients on infusion therapy. 60.6% participated in research trials although 90.6% had no protected research time. Rheumatology education of the respondents was obtained as follows: 87% within their own department, 51.5% through attending ACR/ARHP PRYSM, 54.5% by attending the ACR/ARHP Annual Meeting, 33.3% by

taking the ARHP Advanced Rheumatology Course, and 9.1% through the Rheumatology Nurses Society. 78.8% of the respondents were billing under their own name. The average job profile was 5 days a week with 43.7% averaging 3-5 half day clinics and 37.5% averaging 6-8 half day. 72.4% of the respondents had 30 minute follow up visits.

Conclusion:

Nurse Practitioner's entering pediatric sub specialty practice have a wide range of clinical background frequently with limited experience as a NP. The scope of practice and job profile appears to be broad with an average work load ranging from 3 to 8 half day clinics. There does not appear to be consistency between programs regarding length of training and educational plan. A formalized clinical training for NP's going into specialty practices is needed.

Anti SRP+Ve Myositis in Childhood. Presentation and Physiotherapy Treatment of This Rare Childhood Myositis

Susan Maillard and Clarissa Pilkington, Paediatric Rheumatology, Great Ormond Street Hospital NHS Foundation Trust for Children, London, United Kingdom

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters (ARHP): Pediatrics

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Previously it was understood that all Myositis in childhood was Juvenile Dermatomyositis. More recently Myositis specific antibodies have been discovered and these appear to be linked to specific clinical phenotypes. One of these called anti SRP+ve has been linked to a very severe form of Myositis and this review of 3 patients presents the clinical description and treatment, focusing on the physiotherapy, of these patients.

Methods: It is believed that anti SRP+ve antibodies are only present in 5% of children with Myositis**.** In the cohort of patients within the paediatric rheumatology service only 3/250 patients were found to be anti SRP+ve. The clinical case notes were reviewed and the results are presented here. The main focus of this review is during the initial presentation and treatment with specific focus upon the physiotherapy, and does not address long term outcome.

Results: Despite the rare nature of this Myositis and the relatively new recognition of this condition there have been 3 patients diagnosis within the last 1year. All 3 patients have been female aged 11-14 at time of onset. Their initial onset was rapid onset of extremely severe muscle weakness but with minimal skin involvement. CMAS score at onset ranged between 0 - 6 and MMT 8 16 – 23 and they all presented with multiple joint restrictions due to inflamed joints and muscle tightness. They have all had such severe swallowing difficulties that they were naso-gastrically fed for many weeks. The medical treatment consisted of multiple immunosuppressant agents including high dose steroids, IVIG, Methotrexate, Cyclophosphomide and Rituximab. Intensive physiotherapy was required for all and this ensured the maximum recovery of the muscle strength, muscle patterning and functional improvement. The physiotherapy was started from the initial presentation and was provided twice a day. The initial focus was on regaining range of movement and active-assisted muscle strengthening. The exercises were progressed as they were able to anti-gravity work and then into resisted work. The recovery for all 3 was very slow initially and required an extended hospital admission of many months. Two of the patients were discharged with an MMT8 of 76/80 and were able to manage full time school, walking independently and managing all activities of daily living, but did require a wheel chair for longer distances. The 3rd remains in hospital at this point but is improving significantly.

Conclusion: Anti SRP+ve Myositis in children is a very rare and severe disease presenting with profound muscle weakness and

requires both intensive physiotherapy and high dose immune-suppressants. Though long-term outcome is not known rehabilitation to restore independent function is possible.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters (ARHP): Pediatrics

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: This study sought to assess the physical function and psychological well- being of teens with juvenile idiopathic arthritis (JIA) as well as to assess social media as an effective option for peer support among teens with JIA.

Methods: Eighteen teens (age range 13-18) with medically managed JIA were recruited to participate in the study. The study team measured functional ability, functional capacity, and psychosocial wellbeing via standardized assessments. A randomly selected subgroup of the cohort were given the opportunity to wear an activity monitor, with the intent of exploring the effects of technology in promoting self-management behaviors (increased activity levels or increased awareness of activity level). All participants were invited to join a moderated online social media forum to qualitatively assess psychosocial well-being, as well as to explore social media as a potential option for peer support among teens with JIA.

Results: Study results indicate that despite the presence of a chronic condition and occasional physical limitations, there are not significant differences in functional ability or psychosocial well-being amongst teens with JIA when compared to current literature describing healthy peers. The qualitative responses from the online forum indicated difficulty with managing medications and a desire to participate in the same activities as peers, despite having pain.

Conclusion: The qualitative responses, along with the overall poor compliance with the activity monitors and online forum, may indicate that teens with JIA require continued assistance from medical professionals and caregivers to take steps towards self-management of their condition.

Psychostimulant-Induced Vasculopathy: A Retrospective Study in a Pediatric

Rheumatology Clinic

Freda Singletary[1], Nirupma Sharma[1] and Rita Jerath[2], [1]Pediatrics, Georgia Regents University-Children's Hospital of Georgia, Augusta, GA, [2]Dept of Pediatrics, Childrens Med Ctr Med Schl GA, Augusta, GA
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters (ARHP): Pediatrics
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Attention-deficit/hyperactivity disorder (ADHD) is the most common neurobehavioral disorder of childhood. The first line treatment is psychostimulant medications namely, methylphenidate, amphetamines, or their derivatives. The more common side effects of psychostimulants noted in children or adolescents are insomnia, decreased appetite, weight loss, and headaches. In recent years other side effects of these medications have been noted. Our aim was to study patients who have been prescribed psychostimulants and experienced vascular changes in the spectrum of symptoms that included color change, pain, numbness to hands and feet, or similar peripheral vascular symptoms that will be globally termed peripheral vasculopathies. These symptoms are also seen in other autoimmune disorders therefore a secondary analysis of association with ANA positivity was also explored.

Methods: A retrospective chart review was completed that was derived from patients seen in Children's Hospital of Georgia's Pediatric Rheumatology clinic that were referred with complaints of peripheral vasculopathies. We searched for concurrent diagnosis of ADD/ADHD, and the use of various psychostimulants. Data was analyzed using contingency tables to derive p-values from Fisher's Exact Test, Pearson's Chi-Square, and Likelihood Ratios.

Results: Initial data collection was compiled using ICD-9 codes related to peripheral vasculopathy symptoms and psychostimulant medication usage in patients seen in the Pediatric Rheumatology Clinic over 15 months. Patient charts were then reviewed for 1) type of psychostimulants 2) length of use, 3) description of symptoms, 4) Positive ANA, 5) other Rheumatologic diagnoses, and 6) family history. Collectively 145 patients were identified in the initial data pool. Patients were excluded if they were less than 5 years old, did not have a diagnosis of a perhipheral vasculopathy, not taking psychostimulants , or had a previous rheumatologic disease. After all exclusions a total of 47 patients were used in data analysis. Chi-Square values ranged from 9.98 to 16.76 producing p-values less than 0.05. The null hypothesis in the test was taking psychostimulants and having symptoms of peripheral vasculopathy were independent of each other. Thus the null hypothesis was rejected concluding that the use of psychostimulants and presence of peripheral vasculopathy symptoms are related.

Conclusion: Our retrospective analysis demonstrated that there is a strong association between the use of psychostimulants and peripheral vasculopathy symptoms. The sample size in this analysis is larger than previously published literature thus reinforcing concern for vasculopathy as a significant side effect of psychostimulants. A larger controlled prospective study is needed to further establish the exact statistical co-relation. In conclusion, the diagnosis of ADHD and prescribing of psychostimulant medications is on a rise. Our study demonstrates the need of making prescribing physicians aware of this significant side effect so they may educate the families and also elucidate occurrence of new vascular symptoms from this patient population.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters (ARHP): Pediatrics

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: To identify potential disease-related, personal and environmental factors associated with leisure in children and adolescents with juvenile idiopathic arthritis (JIA) according to the International Classification of Functioning, Disability and Health for Children and Youth framework.

Methods: One hundred and seven children and adolescents (8-17 years) diagnosed with JIA followed at the Montreal Children's Hospital, McGill University Health Center completed the Children's Assessment of Participation and Enjoyment (CAPE). The CAPE measures involvement in leisure (recreation, active physical, social, skill-based, self-improvement). The disease characteristics related to JIA were abstracted from the child's medical file (JIA sub-type, active joint count, age of diagnosis), pain perception and functional status were obtained through self-report. Participants with JIA and their parents completed a series of questionnaires to gather information on the child's mastery motivation, self-concept, activity preference, and perceived social support. Parents completed questionnaires on socio-demographic data, as well as on family function and environmental barriers. Hierarchical regression analysis was used to explore factors associated with leisure in children and adolescents with JIA.

Results: Personal (age, sex, preferences for activities, motivation for gross motor tasks) and environmental (cultural background, maternal education, median household neighborhood income) factors were important in explaining leisure participation for different types of activities. Overall, included variables explained between 10.8% (self-improvement) and 29.7% (active physical) of the adjusted total variance.

Conclusion: Leisure participation in JIA is a complex phenomenon that may be explained by a multitude of factors related to the child, the family and the environment. Identification of these variables may help rehabilitation professionals ascertain those with JIA who are at greater risk for decreased participation in leisure, as well as tailor safe and effective treatment strategies to meet the child's and family's needs.

B10 Cells May be Involved in Controlling Disease Activity in Polyarticular Juvenile Idiopathic Arthritis Patients

Qianzi Zhao[1] and Lawrence K. Jung[2], [1]Rheumatology, Children's National Medical Center, Washington, DC, [2]Pediatric Rheumatology, Children's National Medical Center, Washington, DC
First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Pediatric Rheumatology - Pathogenesis and Genetics Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

In addition to antibodies production, B cells have been shown to have down-regulatory function on immune response in both mouse and human. The down-regulatory function of B cells is partially dependent on their production of Interleukin-10 (IL-10), an anti-inflammatory cytokine. IL10-producing B cells (B10 cells) are not restricted to a defined population. $CD24^{hi}CD38^{hi}$ transitional B cells and $CD24^{hi}CD27^{+}$ memory B cells have been reported to contain the majority of B10 cells in different studies. B10 cells have been demonstrated to ameliorate collagen-induced arthritis in mice. In human, very little is known about the role of B10 cells in juvenile idiopathic arthritis (JIA). In this study, we aimed to analyze the percentage and phenotypes of B10 cells in active and inactive polyarticular JIA (poly-JIA) patients and controls.

Methods:

Ten poly-JIA patients (7 active and 3 inactive) and 10 children with joint pain but without arthritis were included in this study. Inactive disease was defined as an active joint count of 0, absence of uveitis and a Physician Global Assessment <10 mm with normal erythrocyte sediment rate (ESR). B10 cells were generated from peripheral blood mononuclear cells stimulated with CpG and CD40L for 48 hours, and phorbol 12-myristate 13-acetate+ionomycin+brefeldin A (PIB) for the last 6 hours. Intracellular B cell IL-10 and surface markers were assessed by flow cytometry.

Results:

The percentage of B10 cell was significantly higher in inactive poly-JIA patients than in active patients and controls (12.83±0.50 vs. 5.05±1.31, P=0.006; 12.83±0.50 vs. 4.62±0.73, P<0.0001), while there was no significant difference of B10 % between active patients and controls (P=0.762)(Figure A and B). Although there was no significant difference of the percentages of $CD24^{hi}CD27^{+}CD19^{+}$ B cells among the three groups (8.22±1.78 in active poly-JIA, 10.94±1.05 in inactive poly-JIA, and 10.60±1.96 in healthy control, P=0.623), the percentage of $\mathbf{IL10^{+}}CD24^{hi}CD27^{+}CD19^{+}$ B cells was significantly higher in inactive patients than in active patients (1.82±0.25 vs. 0.71±0.17, P=0.007), and was similar in active patients compared to controls (0.71±0.17 vs. 0.86±0.24, P=0.658)(Figure C). The percentages of $CD24^{hi}CD38^{hi}CD19^{+}$ B cells and $\mathbf{IL10^{+}}CD24^{hi}CD38^{hi}CD19^{+}$ B cells between active and inactive patients had not reached statistical difference, but the percentage of $IL10^{+}CD24^{hi}CD38^{hi}CD19^{+}$B cells in inactive patients was significantly higher than in controls (2.48±0.55 vs. 1.14±0.17, P=0.008)(Figure D). There was no correlation between B10 percentage and ESR within active poly-JIA patients.

Conclusion:

B10 cells are increased in patients whose disease is inactive, which suggests a role of them in controlling disease activity in poly-JIA pathogenesis. More samples and follow-up are needed to confirm these results.

Identification of Target Antigens for Anti-Endothelial Cell Antibodies in Patients

with Pediatric Rheumatic Diseases Using Proteomics

Rie Karasawa[1], Mayumi Tamaki[1], Yanmin Chen[2], Kaiyu Jiang[2], Kazuo Yudoh[1] and James Jarvis[2], [1]Institute of Medical Science, St. Marianna University School of Medicine, Kawasaki, Japan, [2]Pediatrics, The University at Buffalo, Buffalo, NY

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Pediatric Rheumatology - Pathogenesis and Genetics Poster
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Juvenile dermatomyositis (JDM), the most common inflammatory myopathy of childhood, is a rare systemic autoimmune vasculopathy. Juvenile idiopathic arthritis (JIA), the most common pediatric rheumatic disease, is a heterogeneous group of inflammatory diseases. The etiology of these diseases is unknown, and we lack disease and disease activity--specific biomarkers. Anti-endothelial cell antibodies (AECA) are autoantibodies against antigens on endothelial cell surface and are detected frequently in rheumatic diseases such as vasculitis. We tried to detect target proteins of AECA comprehensively by proteomics in patients with pediatric rheumatic diseases such as JIA and JDM. Furthermore we investigated relationship to these diseases in AECA from individual identified target antigens.

Methods: We separated proteins extracted from human aortic endothelial cells (HAEC) by one-dimensional electrophoresis (1DE) and two-dimensional electrophoresis (2DE) and transferred them onto membranes. By western blotting (WB) using sera from patients with pediatric rheumatic diseases and healthy donors, we detected antigens that were positive only in pediatric rheumatic disease sera but not in healthy donor sera. We next identified the detected proteins by peptide mass finger-printing.

Results: By using 1DE, 70-kDa and 88-kDa target protein of AECA were detected only in active patients without treatment. 48-kDa and 75-kDa target protein of AECA were detected only in active patients with treatment. 110-kDa target protein of AECA was detected only in active patients. These target proteins of AECA were not detected in inactive patients and healthy donors. Eighteen candidate protein spots as pediatric rheumatic diseases-specific proteins were detected in 2DE-WB. From these spots, we successfully identified 738 proteins which we functionally characterized: (1) 37% were ATP-related proteins such as proteins of the tricarboxylic acid (TCA) cycle (e.g., phosphoserine aminotransferase and methylmalonyl-CoA mutase; (2)19% were muscle-related proteins, including tropomyosin beta chain and PDZ and LIM domain protein 7; (3)13% were calcium regulated protein and/or calcium binding proteins (e.g., annexin A1 and calreticulin); (4)10% were redox related proteins (e.g., procollagen-lysine, 2-oxoglutarate 5-dioxygenase 2, and procollagen-lysine,2-oxoglutarate 5-dioxygenase 2). Furthermore 50% of the identified antigens represented membrane proteins.

Conclusion: Antibodies directed toward the proteome of HAEC are present in the sera of patients with pediatric rheumatic diseases. These antibodies recognize a broad range of cellular targets, including those associated with skeletal muscle function and inflammatory processes.

Altered Expression of IL-10 Family Cytokines in Chronic Recurrent Multifocal Osteomyelitis Result in Enhanced Inflammasome Activation

Sigrun Hofmann[1], Angela Rösen-Wolff[1], Hermann Girschick[2], Henner Morbach[3] and **Christian Hedrich**[4], [1]Children's Hospital Dresden, Dresden, Germany, [2]Children's Hospital, Berlin, Germany, [3]Children's Hospital Würzburg, Würzburg, Germany, [4]Pediatric Rheumatology and Immunology, Children's Hospital Dresden, Dresden, Germany

Session Date: Tuesday, November 10, 2015

Session Title: Pediatric Rheumatology - Pathogenesis and Genetics Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Chronic recurrent multifocal osteomyelitis (CRMO) is the most severe presentation of the autoinflammatory bone disorder chronic nonbacterial osteomyelitis (CNO). The pathophysiology of CNO remains to be determined. We recently demonstrated reduced activation of mitogen-activated protein kinases ERK1 and 2 in monocytes from CRMO patients responsible for impaired activation of the transcription factor signaling protein (Sp-)1. This resulted in failure to express the immuno-modulatory cytokine IL-10. The *IL10* gene, together with its homologues *IL19* and *IL20*, is organized in the 145 kb spanning *IL10* cytokine cluster on chromosome 1q32. In most cells, including monocytes, IL-10 cytokine family members are co-regulated in response to certain stimuli. IL-10 and IL-19 mainly have immune-modulating functions, while IL-20 acts as a pro-inflammatory cytokine contributing to inflammatory bone-loss. The NLRP3 inflammasome is a multi-protein complex forming in response to innate stimuli, subsequently mediating the cleavage and release of IL-1β. Enhanced inflammasome activation in IL-10 deficient mice was linked with bone-loss. Convincing evidence of this mechanism playing a role in CNO, however, is lacking. The aim of our study was to determine i) IL-10 cytokine family expression patterns in CRMO monocytes, ii) molecular mechanisms underlying impaired cytokine expression, and iii) potential effects on inflammasome-dependent cytokine secretion.

Methods: *Ex vivo* isolated monocytes from CRMO patients were cultured in the absence or presence of LPS. Expression patterns of cytokines were monitored on the transcriptional (mRNA) and protein level. Effects of impaired Sp-1 activation on cytokine expression were investigated through forced expression, chemical inhibition, or knock-down of Sp-1.

Results: We saw reduced expression of anti-inflammatory cytokines IL-10 and IL-19 and unaffected expression of IL-20 in CRMO monocytes when compared to controls. We for the first time demonstrate Sp-1 recruitment to the *IL19* promoter, governing IL-19 expression in monocytes. Impaired expression of IL-10 and IL-19 in CRMO monocytes was caused by reduced binding of Sp-1 to regulatory regions. Expression of IL-20 was independent of Sp-1. Reduced IL-10 and IL-19 secretion from CRMO monocytes mediated increased activity of the NLRP3 inflammasome, as assessed by IL-1β secretion. Addition of recombinant IL-10 or IL-19 reversed these findings.

Conclusion: Impaired activation of Sp-1 in monocytes from CRMO patients contributes to reduced expression of IL-10 and IL-19, resulting in an imbalance between pro- (IL-20) and anti-inflammatory IL-10 cytokine family members. Subsequently enhanced NLRP3 inflammasome activation results in IL-1β secretion which may in turn contribute to inflammatory bone-loss. A complete understanding of the molecular pathophysiology of CNO will aid in developing new disease biomarkers and therapeutic targets.

Session Date: Tuesday, November 10, 2015

Session Title: Pediatric Rheumatology - Pathogenesis and Genetics Poster
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Low-density lipoprotein receptor–related protein 1 (LRP1), a transmembrane protein, mediates endocytosis of an array of extracellular ligands. LRP1 has intracellular and extracellular domains. With inflammation the extracellular domain can shed into the circulation as soluble LRP1 (sLRP1). Increased sLRP1 has been reported in adult rheumatoid arthritis but not in childhood arthritis. This study aimed to determine, in children with juvenile idiopathic arthritis (JIA), levels of sLRP1 and correlations with age, clinical indicators of disease activity, and inflammatory biomarkers.

Methods: 111 newly diagnosed, treatment naïve children with JIA from 11 Canadian pediatric rheumatology centers were studied. Plasma was assayed for sLRP1 by ELISA and for 47 inflammation-related biomarkers by bead-based, multiplex immunoassays. Pearson correlations identified relationships between sLRP1 levels and indicators of disease activity and logarithmic transformed multiplex biomarker levels. Differences in mean sLRP1 levels in relation to presence/absence of morning stiffness were analyzed by t-tests. Comparison of sLRP1 means across JIA categories was assessed by ANOVA.

Results: Mean sLRP1 levels were highest in rheumatoid factor negative (RF-) polyarticular, oligoarticular, and psoriatic JIA and lowest in systemic JIA (Table).

JIA Subtype (n)	Mean sLRP1 + 1 SD (ng/ml)
RF– Polyarticular (41)	166.92 + 402.74
Psoriatic (9)	136.34 + 161.16
Oligoarticular (27)	120.51 + 156.97
RF+ Polyarticular (8)	67.69 + 132.77
Undifferentiated (4)	43.94 + 38.76
Enthesitis Related (8)	33.40 + 29.72
Systemic (14)	30.01 +14.48

ANOVA did not show significant mean sLRP1 differences among JIA subtypes. Groups of children stratified as < age 4 years and < age 5 years had higher levels of sLRP1 than older children (p=0.019 and 0.028 respectively). sLRP1 levels did not correlate with active joint count, presence of morning stiffness, ESR, or CRP. In oligoarticular and RF- polyarticular JIA levels of sLRP1 were positively correlated with the same 32 biomarkers encompassing a wide array of pro- and anti-inflammatory cytokines, chemokines, matrix metalloproteinases, and growth factors (p=0.026 to <0.001). An additional 2 correlations with biomarkers were found in RF- polyarticular JIA. In contrast, sLRP1 levels correlated with only a small number of the 47 biomarkers in other JIA subtypes (9 in psoriatic , 4 in RF+ polyarticular, 2 in enthesitis related arthritis, and none in systemic).

Conclusion: In this first report of sLRP1 in JIA we found correlations of sLRP1 with young age and, in oligoarticular and RF- polyarticular subtypes, with inflammation-related biomarkers. Findings suggest that oligoarticular and RF- polyarticular JIA are linked pathobiologically with respect to sLRP1 and the profile of biomarkers with which it is associated. Plasma sLRP1 could be a valuable biomarker reflective of inflammatory-mediated processes related to JIA subtype and onset age.

Session Title: Pediatric Rheumatology - Pathogenesis and Genetics Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Juvenile idiopathic arthritis (JIA) is the most common chronic childhood arthropathy. Most children with JIA phenotypically differ from adults with rheumatoid arthritis (RA) although some children resemble RA by demonstrating rheumatoid factor (RF) and anti-cyclic citrullinated peptide antibodies (CCP). Our objective was to characterize the association between anti-citrullinated protein antibodies (ACPA) and several clinical/epidemiological features in children with CCP-positive and CCP-negative JIA.

Methods: Cases were 157 children with JIA. (73 CCP-/RF-; 12 CCP-/RF+; 9 CCP+/RF-; 63 CCP+/RF+), mostly female (80%), with a mean onset age of 8.6 years. Oral health and smoking exposure history were available on 107 cases. Stored serum/plasma samples were evaluated for reactivity to 30 citrullinated peptide/protein antigens and 7 native controls using a multiplex antigen array. Significance analysis of microarrays (SAM) was used to analyze a multiplex of specific ACPAs among JIA cases to identify differences in ACPA profiles associated with variables. False-discovery corrected significance values <5% were considered statistically significant.

Results: All ACPA evaluated were significantly different between CCP-/RF-, CCP-/RF+, CP+/RF-, and CCP+/RF+ subjects with JIA (q value <0.1%). Figure 1 is a heatmap demonstrating increased levels of several antigen-specific ACPAs in seropositive JIA patients. Among CCP+ children, those who reported having no dental caries had significantly less ACPAs compared to those who reported having dental caries (Figure 2). Several other variables were also associated with significant differences in ACPA positivity among children with CCP+ JIA (Table 1).

Conclusion: Children with JIA positive for both CCP and RF demonstrate significantly increased antibody response to a variety of citrullinated antigens compared to children who are CCP and RF negative, as well as those who are positive for either CCP or RF alone. This suggests that CCP and RF-positive JIA is phenotypically similar to adult seropositive RA. Presence of dental caries may be associated with increased ACPA subtypes in children with CCP-positive JIA.

Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

An Interferon (IFN) Regulated Gene Signature (IRS) was previously reported in patients with two complex autoimmune diseases, juvenile systemic lupus (JSLE)[1] and juvenile dermatomyositis (JDM).[2] Recently, three Mendelian conditions including CANDLE syndrome[3], STimulator of IFN Genes or STING-associated Vasculopathy with onset during Infancy (SAVI)[4], and Aicardi Goutieres syndrome (AGS)[5] have demonstrated a prominent IRS. Previous evaluations[6] found clinical phenotypic overlap such as basal ganglia calcifications (CANDLE, AGS), lipodystrophy (CANDLE, JDM), and myositis (JDM, CANDLE, SLE) raising interest in a shared role of IFN in disease-pathogenesis. This study aims to assess cytokine profile differences between IFN conditions, healthy controls and the IL-1 mediated monogenic disease, NOMID, to better understand pathogenesis and identify potential disease-specific biomarkers.

Methods:

Plasma/serum cytokine levels of 6 cytokines identified by literature review and preliminary analysis[6] were measured in 5 IFN conditions (3 Mendelian and 2 complex), the IL-1 mediated disease, NOMID, and healthy controls using a multiplex bead -based assay (Luminex/Austin, TX). Analysis of variance (ANOVA) followed by Dunnett's tests were performed to identify significant differences between each IFN condition and: 1) healthy controls and 2) NOMID (IL-1 mediated disease control). ANOVA, followed by Student-Newman-Keuls post-hoc tests, were used to assess for significant differences among the 5 IFN conditions. Statistical analysis done with Stata 12 (College Station, TX).

Results:

		IFN-mediated				*non-IFN*	
	(n)	IP10	MCP1	MIP1-alpha	RANTES	IL13	IL15
IFN conditions	CANDLE (12)	*4.16***	2.33***	0.99	4.24	1.38**	0.22
	SAVI (4)	*3.82***	2.13	0.94	4.34	1.08	0.15
	AGS (16)	2.95	2.18	*1.08**	*4.07**	1.23	0.57*
	JDM (20)	3.14*	2.25**	1.00	4.29	1.27	0.32
	SLE (16)	3.11	2.20	***1.17****	4.34	1.29	0.59*
	NOMID Control (15)	2.90	2.25	0.88	4.27	1.13	0.68
	Healthy Control (11)	2.72	1.98	0.83	4.25	1.04	0.02

*: p≤0.05 ** : p≤0.01 *** : p≤0.001

Table 1. Mean Cytokine Values (log 10 scale) by cytokine (columns) and condition (rows).
Values significantly different from healthy controls are marked by an asterisk. Number of astericks indicate level of p value. Values in italics are significantly different versus healthy controls and NOMID controls, except RANTES in AGS which is only significantly different versus NOMID controls. MIP1-alpha for SLE is bolded due to differential p values versus NOMID (0.02, **) and healthy controls (0.01, ***).

All significant values are higher in an IFN condition than NOMID or healthy controls, except RANTES which is lower in AGS versus NOMID. Most significantly elevated are IP-10 in CANDLE and SAVI, and MIP1-alpha in SLE compared to healthy controls and NOMID. Among the 5 IFN conditions, IP-10 is significantly higher in CANDLE and SAVI versus AGS, JDM, and SLE. RANTES is significantly lower in AGS versus the 4 other IFN conditions.

Conclusion:

The IFN inducible chemokine, IP-10/CXCL10, is significantly elevated in CANDLE and SAVI, even compared to AGS, JDM, SLE, and NOMID suggesting IFN-driven systemic inflammation in CANDLE and SAVI. The monocyte migration factor MCP-1/CCL2 is similarly induced in IFN diseases and the IL-1 disease, NOMID, consistent with its role in routine immunological

surveillance observed in a variety of inflammatory conditions. Significant and specific elevation of MIP1-alpha may play a role in granulocyte recruitment and activation in SLE. Distinct cytokine profiles in IFN and IL-1 mediated diseases may help in understanding organ-specific inflammatory pathogenesis and development of disease-specific biomarkers.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Pediatric Rheumatology - Pathogenesis and Genetics Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Epigenetic regulation of gene expression is increasingly under scrutiny to understand the pathogenesis of multifactorial human diseases, such as juvenile idiopathic arthritis (JIA). Indeed, the low concordance rate between monozygotic twins (20-40%) underscores that, while this autoimmune disease has a genetic component, environmental triggers are fundamental in the disease pathogenesis. Epigenetic mechanisms are believed to integrate such non-genetic factors, and may underlie the dysregulation of the immune system.

Methods: We interrogated the DNA methylome of JIA patients before and after anti-TNF therapy withdrawal with the Infinium HumanMethylation450 BeadChip. Patients were stratified by clinical activity 8 months after withdrawal.

Results: Individual CpG sites were clustered in coherent modules without any a priori knowledge of their function. Strikingly, modules statistically associated with clinical activity were enriched in CpG sites belonging to genes that mediate T cell activation. Conversely, modules linked to age or gender controlled fundamental, non-immune functions of the cell, such as metabolism. Of note, the DNA methylome was stable, showing little variation before and after therapy discontinuation. When a similar analysis was performed on matched transcriptomic data, we found that the correlation of mRNA abundances with clinical activity was much lower than that observed for DNA methylation.

Conclusion: Our work (i) demonstrates that medically relevant information is encoded in epigenetic traits; (ii) reveals biological functions tied to clinical activity; and (iii) establishes the superiority of epigenetic markers over gene expression-based markers.

Interaction Between Senescent T Cells and Fibrocyte-like Cells through CD31, TNFα, and IL-17 Create a Tissue Destructive Environment in the Synovium in Juvenile Idiopathic Arthritis

Session Title: Pediatric Rheumatology - Pathogenesis and Genetics Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: T cells are considered effectors of immunopathology in JIA. In previous work, we reported dominance of senescent CD8T cells in synovial fluid of children with oligoarticular (oligo-) and polyarticular (poly-) JIA disease. Here, we examined for additional effector cells and how they shape the inflammatory microenvironment of the synovium.

Methods: Healthy children, children with oligo- and poly-JIA, and their legal guardians provided informed assent/consent. Blood samples were obtained, and where medically indicated, synovial fluids were collected from JIA patients. Cell populations were examined by flow cytometry. Cell cultures and bioassays of cell activation were performed using previously established protocols. Cytokine profiles of plasma, synovial fluids, and culture supernatants were determined by the Luminex system.

Results: The local and systemic cytokine signatures of JIA were dominated by five molecules including TNFα and IL-17. The corresponding cellular signatures included senescent $CD31^+$ CD8T cells, and $CD31^+$ double negative (DN) T cells that lack both CD4 and CD8. In synovial fluid, large numbers of fibrocyte-like cells (FLC) expressing procollagen, proline-4-hydroxylase, IL-17 receptor A, and the CD31 ligand CD38, also abound. Ligation of CD31 either with specific antibody or recombinant CD38, independent of the TCR, on synovial CD8T and DNT cells was sufficient to induce production of TNFα and IL-17. CD31 ligation alone was also sufficient to transactivate the *IL-17* gene promoter, and the *IL-17* gene transcription factor RORγT. Incubation of FLC with TNFα, IL-17, or both led to the induction of vascular endothelial growth factor, a known propagator of tissue inflammation, and three species of matrix metalloproteinases known to directly elicit cell/tissue damage. These T cell and FLC responses were abrogated by steroids, infliximab, tocolizumab, and a novel experimental small molecule inhibitor.

Conclusion: Collectively, our data indicate CD8T/DNT-FLC communication circuit via CD31 and IL-17. CD31-driven, TCR-independent induction of TNFα and IL-17 clearly demonstrate dysregulation of T cell effector function. Activation of FLC by T cell-derived TNFα and IL-17 amplifies synovial inflammatory processes. Further understanding of the control of this T cell-FLC circuit will pave way to innovative strategies to dampen immunopathology of JIA.

Session Title: Pediatric Rheumatology - Pathogenesis and Genetics Poster
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Microchimerism with HLA mismatched maternal cells can be readily demonstrated in normal individuals and is now established as a normal biological phenomenon. Pediatric SLE patients have decreased levels of blood maternal microchimerism, suggesting a loss of T-cell tolerance to maternal antigens. Because maternal MHC molecules are the most likely targets of the T-cell hyperactivity, we reasoned that pediatric lupus patients may also have B cell reactivity to maternal MHC.

Methods:

To test for loss of B-cell tolerance to maternal MHC, we measured IgG specific for HLA Class II antigens in plasma samples from children who have never been pregnant: 81 with SLE (49 (60%) with active disease, SLEDAI >4), 20 patients (24%) with nephritis. Control groups consisted of 16 systemic sclerosis (SSc), 20 juvenile idiopathic arthritis (JIA), and 78 healthy children. OneLambda, Inc. LABScreen microbeads coated with purified Class II HLA antigens were used to detect specific IgG. Data acquisition and analysis was performed using LABScan™ Statistical analysis was performed using SPSS version 16.0, Mann Whitney was used to determine median difference between groups, Correlations were tested by Spearman and associations by Likelihood ratios or Fisher Exact Test, ROC curves were constructed to test for the specificity of HLAab for lupus diagnosis and active lupus.

Results: All Subjects: The median values of 90% of specific HLAab were high in patients with SLE compared to controls. HLAab levels in JIA and SSc were similar to controls. Among the SLE patients, 27 out of 77 HLA antigens were increased in patients with active disease compared to those without active disease. Of these, a significant association was found with disease activity in 15 HLAab (see Table 1). ROC curves demonstrated specificity for active SLE in 4 HLAab, with AUC >.700: DQA1*0301-DQB1*0302 (AUC .758, 95% CI 0.66-.86, p<0.001), DQA1*0301-DQB1*0303, (AUC 0.76, 95% CI 0.66-.87, p<0.001), DQA1*0501-DQB1*0201 (AUC 0.73, 95% CI 0.61-.84, P=0.001, and DPB1*1401=DPA1*0201 (AUC 0.72, 95% CI 0.6-.84], P=0.001. Ten HLAab demonstrated a significant median difference between those with and without nephritis, and seven of those showed significant associations (Table 1).

Conclusion:

Children with SLE have high values and a considerable number of anti-HLA class II autoantibodies which seem to be specific, related with disease activity and to a lesser extent with nephritis. If confirmed, HLAab could represent useful biomarkers for disease activity.

Session Title: Pediatric Rheumatology - Pathogenesis and Genetics Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: In adult dermatomyositis, clonal populations of T lymphocytes with shared variable (V) gene usage have been identified, suggesting aberrant T cell responses to a common antigen. A $CD4^+$T cell subset, regulatory T (Treg) cells, has recently been identified as important mediators of muscle tissue repair. A diverse Treg repertoire is thought to be important in

maintaining Treg function and may contribute to the Treg response to muscle damage. Little is known about the T cell repertoire in juvenile dermatomyositis (JDM); further, the Treg repertoire in human inflammatory myopathies has not been evaluated. Therefore, we employed next generation sequencing to characterize the Treg and effector T (Teff) cell repertoires in JDM.

Methods: Peripheral blood (PB) was obtained from JDM patients (n=6) at disease onset and healthy children (n=3). Treg ($CD4^+CD25^+CD127^{lo}$) and Teff ($CD4^+CD25^-$) cells were isolated from PB mononuclear cells by fluorescence-activated cell sorting. The T cell receptor (TCR) β chain was amplified by multiplex PCR with genomic DNA serving as the template (ImmunoSEQ™). Illumina HiSeq platform was used for sequencing. Wilcoxon sign ranked tests were used to compare the clonality index and normalized Shannon entropy in patients and controls. 2-way ANOVA with Bonferroni correction was used to compare TCRVβ family usage in patients versus controls.

Results: Three males and 3 females with JDM, average age 7.0 years (range: 3.3-9.4 years), were studied. The average disease duration was 7 months, and the average MMT8 score was 69.6. Five of the patients were evaluated before the initiation of any immunosuppressive therapy. Treg and Teff repertoire clonality and diversity were similar in JDM patients and controls. In JDM Treg and Teff subsets, TCRVβ families 7, 19, and 28 were used more and TCRVβ families 2, 3, 5, 6 were used less than in controls ($p<0.0001$ for both Treg and Teff cells). In particular, TCRVβ7 skewing was most striking, and this Vβ family was used more than twice as often in JDM PB Treg and Teff cells compared to controls.

Conclusion: Skewed TCRVβ family usage was observed in JDM patients at disease onset. Increased usage of TCRVβ7 was observed in JDM PB Treg and Teff cells, and this Vβ family has been linked with other autoimmune conditions including type I diabetes and anti-phospholipid syndrome. Our early pilot results suggest that T cell repertoire abnormalities may contribute to disease pathogenesis in JDM. Further studies are planned to evaluate the T cell repertoire in JDM muscle and skin biopsies, as well as longitudinally over the course of disease.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Pediatric Rheumatology - Pathogenesis and Genetics Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Autoinflammatory disorders (AIDs) represent an expanding group of complex diseases characterized by periodic or chronic systemic inflammations. Mutations in more than 15 genes have been associated with autoinflammatory recessive or dominant syndromes (1). Next Generation Sequencing (NGS) has emerged in the last year as new diagnostic tool in this field. to share data obtained by the application of NGS in a cohort of patients affected by an autoinflammatory disease of undefined origin evaluated at our center.

Methods: In this study we enrolled 158 patients evaluated at our center from 2010 to 2014. We developed NGS approache already known to be involved in AID (Panel 1: MVK, MEFV, NRLP12, NRLP3, NOD2, TNFRSF1A and PSTPIP1 and Panel 2: IL1RN, LPIN2, IL36RN, PSMB8). Targeted resequencing was performed using customized panel and analyzed with the MiSeq®

sequencing platform (Illumina, San Diego, CA). All variants identified have been confirmed by Sanger sequencing.

Results: 48,73% of the patients present variants in genes of Panel 1. 32,46% have variants in NLRP3 gene: the most frequent variants are Q705K (56%) and V200M (32%). About 26% have variants in NOD2, the most frequent variant is R702W (25%). 30% have variants in NLRP12, the most frequent variant is F402L (65%), in two cases is homozygous. 23,37% have variants in MEFV, the most frequent variant is E148Q (22%). 4% have variants in MVK, V377I (100%). 10,38% have variants in TNFRSF1A, the most frequent variant is R121Q (75%). 9% have variants in PSTPIP1. 69% of the patients present variant in only one gene; 28,57% present variants in two different genes and two patients in three genes. We performed 15 familial study to unravel the segregation of some variants.

Conclusion: NGS leads to the identification of many genetic variants that could be associated with disease susceptibility. The major challenge is in the interpretation of the clinical relevance of identified variants (2). Some patients show variants in multiple analyzed genes: it can be assumed that different variants in different genes may cooperate to determine a pathological phenotype. This will necessitate large-scale population studies, in vitro functional assay and careful correlation of genetic information with phenotypic data (3). Crucial is, therefore, close collaboration with clinicians.

Session Title: Pediatric Rheumatology - Pathogenesis and Genetics Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose : Juvenile dermatomyositis (JDM) is a rare autoimmune disorder characterized by muscle weakness, skin rashes and other systemic features. The immunopathogenesis of JDM is unknown, but recent biomarker studies revealed that up-regulation of several type I interferon (IFN)-related mediators might play a role in the development of JDM. In this study, we focused our attention on the inflammatory cytokine interferon-γ (IFN-γ), the only member of type II class of interferons. We analysed muscle biopsy samples of JDM-affected children to characterize IFN-γ expression levels and to identify possible correlations with clinical features.

Methods : We identified a retrospective cohort of patients diagnosed with JDM at our Center between 2001 and 2014 and for whom a muscle biopsy was performed during diagnostic work-up. Expression levels of IFN-γ, chemokine (C-X-C motif) ligand 9 (CXCL-9), chemokine (C-X-C motif) ligand 10 (CXCL-10), chemokine (C-X-C motif) ligand 11 (CXCL-11), class II major histocompatibility complex, transactivator (CIITA) were analysed by real-time PCR on muscle biopsy samples from patients with JMD (n = 18) and compared with samples from Duchenne muscular dystrophy (DMD) patients (n = 29) by Mann Withney test.

Results : Median age at diagnosis of JDM patients was 5.4 years (interquartile range, IQR: 4.2-9.1), with a median disease duration at diagnosis of 2.1 months (IQR: 1.2-6.9). For each patient we recorded clinical features at diagnosis, physician's global assessment of the patient's overall disease activity on a 100-mm visual analog scale (VAS), serum levels of muscle enzymes (CK, ALT, AST, LDH), erythrocyte sedimentation rate, C-reactive protein level, and antinuclear antibodies status. Six patients were already treated with systemic glucocorticoids before time of biopsy sampling, whereas all DMD patients were untreated. Levels of IFN-γ, CXCL-9, CXCL-10, CXCL-11 and CIITA expression were significantly higher in JDM biopsy samples compared with those of DMD patients ($p = 0.0004$, $p = 0.0004$, $p < 0.0001$, $p < 0.0001$, $p = 0.0017$, respectively). In JDM patients we found that IFN- γ mRNA levels significantly correlated with CXCL-9 and CIITA mRNA levels; on the contrary, we do not observed correlations between IFN-γ mRNA levels and clinical scores. JDM patients treated before biopsy were excluded from final statistics since the molecular analysis resulted strongly influenced by glucocorticoid therapy.

Conclusion: The increased muscle expression of IFN-γ and IFN-γ correlated genes in muscle biopsy samples of JDM patients suggests a potential pathogenic role of IFN-γ in JDM.

Highly Elevated S100A8/A9 and S100A12 Levels May Distinguish Systemic Juvenile Idiopathic Arthritis Patients with New Onset Disease and Subclinical Macrophage Activation Syndrome

Jessica Turnier[1], Ndate Fall[2], Alexei A. Grom[3], Sherry Thornton[2] and Hermine I. Brunner[4], [1]Pediatric Rheumatology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Division of Rheumatology, Cincinnati Children's Hospital, Cincinnati, OH, [3]PRCSG, Cincinnati, OH, [4]Cincinnati Children's Hospital Medical Center, Cincinnati, OH

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Pediatric Rheumatology - Pathogenesis and Genetics Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Systemic juvenile idiopathic arthritis remains a clinical diagnosis without a specific diagnostic test. Previous studies have demonstrated that extremely high levels of S100 proteins may distinguish patients with systemic juvenile idiopathic arthritis (sJIA) from patients with other inflammatory diseases or additional subtypes of juvenile idiopathic arthritis. A great degree of heterogeneity exists within the serum levels of S100 proteins amongst sJIA patients. The purpose of this study was to explore the degree of variability within S100 protein levels in sJIA patients and to correlate S100 protein levels with clinical presentation.

Methods:

A total of 189 serum samples were collected from patients with different subtypes of juvenile idiopathic arthritis, including sJIA (n=22), persistent oligoarthritis (n=28), extended oligoarthritis (n=28), rheumatoid factor positive polyarthritis (n=27), rheumatoid factor negative polyarthritis (n=28), enthesitis-related arthritis (n=29) and psoriatic arthritis (n=27). In addition, patients with sJIA were further divided into active sJIA (n=11) and clinically inactive disease (n=11). Control samples (n=90) were obtained from healthy children aged 2-18 years old. Serum samples were analyzed for protein levels of S100A8/A9 and S100A12 using commercial ELISAs (BÜHLMANN MRP8/14 and CircuLex S100A12/EN-RAGE). Clinical characteristics of the sJIA patients were examined for differences in symptoms, exam findings, lab values and treatment at the time of sample collection.

Results:

Patients with active sJIA had the highest levels of S100 proteins when compared to other subtypes of juvenile idiopathic arthritis. Patients with clinically inactive sJIA had S100 protein levels comparable to controls. A bimodal distribution was noted in both the S100A8/A9 and S100A12 levels in patients with active sJIA. Systemic juvenile idiopathic arthritis patients in the subgroup with higher levels of S100 proteins were determined to have new onset disease as well as subclinical features of macrophage activation syndrome (low hemoglobin, elevated ferritin, hepatosplenomegaly, relatively low platelets in the setting of elevated CRP). The fold difference between protein levels in new onset sJIA versus active sJIA was 29 for the S100A8/A9 levels and 31 for the S100A12 levels.

Conclusion:

Higher levels of S100A8/A9 and S100A12 proteins correlate with disease activity in systemic juvenile idiopathic arthritis as previously described. Marked heterogeneity exists in S100 protein levels amongst active sJIA patients. Active sJIA patients in the subgroup with significantly higher levels of S100 proteins could represent a unique disease subtype.

Psycho-Socio-Economic Burdens of Childhood Onset Rheumatic Diseases on Families

Sook Fun Hoh[1], Manasita Tanya[2], Justin Hung Tiong Tan[2], Lena Das[2,3] and Thaschawee Arkachaisri[2], [1]Nursing, KK Women's and Children's Hospital, Singapore, Singapore, [2]Rheumatology and Immunology, KK Women's and Children's Hospital, Singapore, Singapore, [3]Dept of Rheumatology, Cincinnati Children`s Hospital Medical Center, Cincinnati, OH
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Psychology/Social Sciences (ARHP)
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Rheumatic diseases (RD) in children, being complex and chronic in nature, do not only pose physical insult to the affected child, but also psychological and socioeconomic impacts to the families. Data on impact to the families are scarce. We aim to assess the financial and psychosocial impacts on family confronting with such conditions in our cohort of children with RD in Singapore.

Methods:

Patients with chronic RD were recruited. The Impact on Family (IOF) scale was completed by the caregivers. The weighted IOF score was calculated from the total of 24 items in 4 dimensions; financial burden (FB), familial/social impact (FS), personal strain (PS) and mastery (MT) with possible scores 0-4 for each domain, the higher, the more impact. In financial aid recipients, FB was collected before and after the financial helps. Nonparametric tests were used for comparative analysis. Correlation studies were performed to address the association of family factors to IOF.

Results:

139 children were recruited (55% female, median age 14.2, 7.8-20.6 years).Majority were Chinese (74%), followed by Malays (16%). The prominent diagnosis were JIA (50%) and SLE (26%). 1/3 were on biologics. 76 families (62%) earned < 5000 S$/month and 30% received financial assistance.

The internal consistency of the total IOF and subscales indicated high reliability (shown in Figure 1), except MT which posed Cronbach's alpha of 0.67.

Our RD patients' IOF scores were of milder degree (FB, FS, PS) compared to those with childhood cancers in a previous local study. FB negatively correlated to household income (rho = -0.51) but it was markedly alleviated after receiving financial aid (3.38 vs. 2.75, p< 0.001). Despite lowest income/high FB, Malay/Indian parents seemed to cope with diseases better. The highest FS, PS and total IOF were seen in CNS vasculitis (explained by debility and dependent status), while SLE affected FB the most. Lupus nephritis and sacroiliitis in JIA did not render higher family impact. Neither were age, disease duration, biologics treatment, caregiver education nor the presence of siblings associated with higher IOF.

Table 1. Patient and Family Characteristics

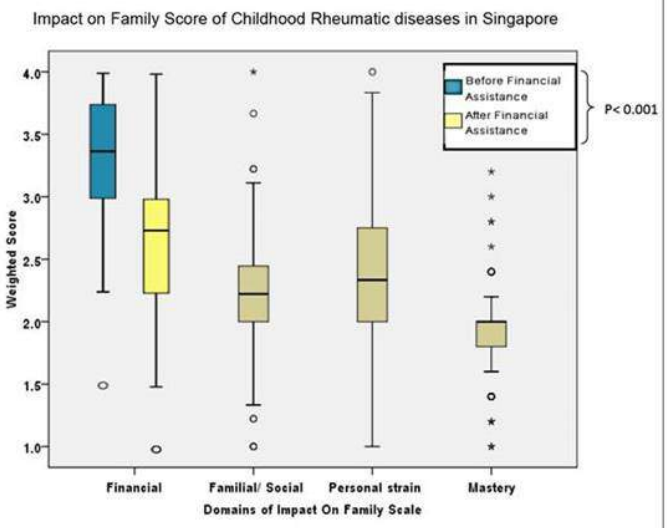
Figure 1. Impact on Family Scale and Its' Internal Consistency (Cronbach's Alpha) in Children with Chronic Illness in Singapore

IOF scale (number of items)	Weighted Impact on Family Score*			Cronbach's Alpha	
	Rheumatic Diseases (n= 139)		Cancer (n= 79)	Rheumatic Diseases (n= 139)	Cancer (n= 79)
	Median (IQR)	mean (SD)	mean (SD)		
Financial burden (4)	2.75 (2.25-3.00)	2.73(0.65)	3.41	0.83	0.69
Familial/Social Impact (9)	2.22 (2.0-2.44)	2.24 (0.50)	3.8	0.84	0.88
Personal Strain (6)	2.33 (2.0-2.83)	2.37 (0.60)	2.89	0.85	0.79
Mastery (5)	2 (1.6-2.2)	1.93 (0.42)	1.45	0.67	0.61
Total score (24)	9.19 (8.16-10.11)	9.21 (1.56)	10.74	0.88	0.64

* Calculated from the total score in each dimensions divided by the number of items. Each subscale ranges from 0 to 4 and the total IOF is 16



Conclusion:

Pediatric rheumatic diseases in Singapore affect various aspects of the family at a considerable degree. Although household income inversely correlates with FB, none of other strong associations was demonstrated between family factors and IOF scores. As we are seeking methods to minimize impact of chronic diseases on families, IOF scale seems to be a useful tool in assessing disease burdens which, overall, will help improving disease outcome and ascertain effective healthcare supporting system.

Session Title: Psychology/Social Sciences (ARHP)
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Despite the common appearance changes in patients with systemic sclerosis (SSc), and the potential adverse psychosocial impact of such changes, research in this area is limited. This may be, in part, because there are few validated measures evaluating the psychosocial impact of disease-related appearance changes in SSc. Thus, the goal of the present study was two-fold: 1) to evaluate the psychometric properties of the Social Appearance Anxiety Scale (SAAS), a measure that assesses fear of situations in which one's appearance will be evaluated, in a sample of SSc patients, and 2) to determine if scores from the SAAS can be meaningfully compared across limited and diffuse SSc subtypes.

Methods: The sample included SSc patients ($N = 600$; 59% limited, 41% diffuse) enrolled in the Scleroderma Patient-centered Intervention Network Cohort. Confirmatory factor analysis (CFA) was used to examine the structural validity of the measure; a one-factor model was hypothesized. Once the model with adequate fit was identified, multiple-group CFA was used to evaluate measurement invariance of the SAAS across limited and diffuse SSc patients. Internal consistency reliability was examined using Cronbach's coefficient alpha. Convergent validity was examined via Pearson product-moment correlations with the SAAS and a measure of depression, body image dissatisfaction, and two measures of social anxiety.

Results: Based on descriptive fit indices, a one-factor model showed good fit with the data using CFA (Comparative Fit Index [CFI] = 0.91, Standardized Root Mean Residual [SRMR] = 0.04, Root Mean Square Error of Approximation [RMSEA] = 0.12). The multiple-group CFA evaluated configural invariance (i.e., baseline model fitting a one-factor solution for limited and diffuse subtypes), metric invariance (i.e., factor loadings constrained to equivalence across subtypes), and factor variance invariance (i.e., factor loadings and variances constrained to equivalence across subtypes) based on descriptive fit indices (CFI, SRMR, and RMSEA), change in CFI, and the Satorra-Bentler X^2 difference test. Results from the multiple-group CFA provided support for the factor variance invariance model, suggesting a one-factor structure with equivalent response patterns and variances across limited and diffuse subtypes. Internal consistency was good for both limited ($\alpha = 0.96$) and diffuse ($\alpha = 0.97$) groups. Convergent validity was demonstrated via moderate to strong correlations with measures of depression ($r = 0.52$, $p < .01$), body image dissatisfaction ($r = 0.68$, $p < .01$), and social anxiety (2 measures; $r = 0.58$ to 0.67, $p < .01$) in the total sample.

Conclusion: Overall, results indicate that the one-factor SAAS can be used to assess fear of appearance evaluation among patients with SSc. In addition, scores on the SAAS can be meaningfully compared across limited and diffuse subtypes.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Psychology/Social Sciences (ARHP)

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Chronic pain conditions are related poor overall health, economic burden, and mental disorders including suicidal ideation (SI), suicide attempts (SA), and completed suicides. Fibromyalgia is one of chronic pain syndrome that is a highly prevalent condition in United States. We performed a systematic review and meta-analysis of available articles that assess association between fibromyalgia and suicidal ideation or suicidal attempt.

Methods: We comprehensively searched the databases of MEDLINE and EMBASE from their dates of inception to June 2015. The inclusion criteria were published articles that reported prevalence or association of fibromyalgia and suicidal ideation or suicidal attempt. The primary outcome was the odds ratio (OR) or risk ratio (RR) of SI or SA compared between patients with and without fibromyalgia. The secondary outcome was prevalence of SI or SA in the fibromyalgia group.

Results: From 53 full-text articles, 8 studies with a total of 202 participants were included in the meta-analysis. Compared with non-fibromyalgia group, patients with fibromyalgia had significantly higher chance of SI or SA (OR=2.15, 95% CI: 1.006 to 3.30). In addition, pooled prevalence of SI or SA was high (Pooled prevalence= 0.11, 95% CI: 0.02 to 3.30).

Conclusion: We have shown that SI and SA are prevalent among patients with fibromyalgia and there is a significant association between these two conditions. These findings underscore the importance of assessment of SI and SA among the individuals presenting who have fibromyalgia.

Patient-Reported Cognitive Impairment, Pain, and Depressive Symptoms in

Patients with Systemic Lupus Erythematosus and Comorbid Depression

Kelly Beck[1], Xing Gao[2], Yu Cheng[3] and Carol M. Greco[4], [1]School of Health and Rehabilitation Sciences, University of Pittsburgh, Pittsburgh, PA, [2]Biostatistics, University of Pittsburgh, Pittsburgh, PA, [3]Biostatistics and Psychiatry, University of Pittsburgh, Pittsburgh, PA, [4]University of Pittsburgh, Pittsburgh, PA

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Psychology/Social Sciences (ARHP)
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with systemic lupus erythematosus (SLE) frequently report cognitive impairment as well as depressive symptoms and significant pain. However, depression criteria and SLE symptoms may overlap (e.g., difficulty concentrating, low energy), and may both be exacerbated by pain. The purpose of this study is to evaluate the associations of patient-reported pain and cognitive symptoms in SLE patients with co-morbid depressive symptoms. Exploration of the relationships between these variables can better inform clinicians regarding treatment of individuals with SLE and depression.

Methods: Ninety patients with SLE (1997 Criteria) diagnosed with major depressive disorder or subsyndromal depression completed a baseline assessment for the NIH-NIAMS funded study, Reducing Depressive Symptoms in SLE (R01 AR 57338). Depressive symptoms were measured by the Center for Epidemiologic Studies Depression (CESD) scale. Self-reported ratings of pain and cognitive symptoms were collected with the PROMIS®Pain Interference short form and Cognitive Symptoms Inventory (CSI), respectively. Associations of baseline CESD total score and subscales, CSI and subscales, and Pain were evaluated cross-sectionally using Pearson's r.

Results: Participants' average age was 49 (+/- 12) years, 92% were females, and 23% were African American or other minority race. 48% had household income of < $50,000. The mean CESD score was 29.8 (SD=6). Baseline scores on the three variables of interest all met assumptions for normality and homoscedasticity. CESD total score was significantly associated with both total CSI (r = .38, p<.001) and pain (r = .38, p<.001). Specifically, the CESD somatic subscale had the strongest relationship with the attention/concentration subscale on the CSI (r = .4, p<.001). Similarly, the CESD somatic subscale was the only subscale that significantly correlated with pain (r = .36, p<.001), as the depression, positive affect, and interpersonal subscales were not significantly correlated with pain scores. Total cognitive symptoms score had a moderate positive correlation with pain scores, (r = .52, p<.001). Specifically, all of the CSI subscales were significantly correlated with PROMIS pain scores: attention/concentration (r = .49, p<.001); pattern recognition/activity management (r = .44, p<.001); immediate memory (r = .41, p<.001); and executive functioning (r = .37, p<.001).

Conclusion: In SLE patients with co-morbid depression, somatic features of depression (e.g., restless sleep, appetite disturbance) were most strongly associated with cognitive symptoms and pain, in contrast to sadness and interpersonal features of depression. Interestingly, correlation analyses indicated that the strongest relationship lies between pain and cognitive symptoms, specifically attention and concentration. The importance of pain, perceived cognitive disruption, and depressive symptoms should not be underestimated in evaluating and treating SLE.

What Older Adults with Restricting Back Pain Worry about: Deteriorating Function, Reliance on Others, Distrust of Medications

Una E. Makris[1,2], Liana Fraenkel[3], David W Serrano[4], Jae H Yun[4], Thomas M. Gill[5] and MC Reid[6], [1]Rheumatology, Dallas

VA Medical Ctr, Dallas, TX, [2]Rheumatology, UT Southwestern Medical Center, Dallas, TX, [3]Rheumatology, Yale University School of Medicine, Veterans Affairs Connecticut Healthcare System, New Haven, CT, [4]Internal Medicine, UT Southwestern Medical Center, Dallas, TX, [5]Geriatrics, Yale School of Medicine, New Haven, CT, [6]Geriatrics, Weill Cornell Medical College, New York City, NY
First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Psychology/Social Sciences (ARHP)
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Although back pain is the most common type of pain disorder reported by older adults, its impact on the daily life of older adults remains poorly understood, particularly among racial/ethnic minorities. In this qualitative study, we explored older adults' beliefs and attitudes regarding restricting back pain (defined as back pain severe enough to restrict activity).

Methods: We conducted in-depth, one-on-one interviews and focus groups with older adults (ages ≥65 years) who reported restricting back pain within the past 3 months. We recruited participants from 3 different sources (interviews and focus groups in Connecticut and focus groups in New York City) to ensure a racially diverse sample; recruitment efforts ended once thematic saturation was achieved. A semi-structured discussion guide was used to prompt participants to discuss their beliefs, attitudes, and experiences regarding restricting back pain. Audio recordings were transcribed and analyzed (using NVivo) in an iterative process to develop and analyze thematic categories. All transcripts were independently coded (blinded to population) by four reviewers using iterative thematic analysis. Discrepancies in coding were resolved through group discussion until consensus was reached.

Results: We conducted 23 one-on-one interviews and 16 focus groups (n=70 participants), for a total of 93 participants. The majority of participants were female (68%). The median age was 83; over one-half lived alone, and 46% belonged to a minority group. We identified 3 themes related to worry and fear about restricting back pain (Table 1): (1) worry and preoccupation with deteriorating function [and need for mobility aids], (2) concerns about loss of independence and reliance on others, (3) fear of medication. Themes did not vary by race/ethnicity or by gender.

Conclusion: This study suggests that older adults with restricting back pain worry about future physical deterioration, reliance on mobility aids, and dependence on others (related to the back pain). Older adults described a common distrust of medications. A better understanding of the attitudes and beliefs, including worries and fears, of older adults with restricting back pain, will inform the development of non-pharmacological, multimodal interventions. Additionally, these data will enable clinicians and researchers to gain insight about potential barriers and facilitators to engaging in or adhering to restricting back pain management.

Table 1: Illustrative Quotes of Themes

1. Worry and preoccupation with deteriorating function including reliance on mobility aids	--I have finally succumbed to a walker and to a cane. I never…I didn't want to but I had to. --Fear appears. Is this going to get worse to the point that I can't be mobile at all?
2. Participant fear about loss of independence and reliance on others	--It makes me stop and ask somebody else to do something for me…that's very aggravating. --It has ruined my life.… I don't go anywhere alone anymore...
3. Distrust of medication	--They always want to give me medicine. I don't want medicine! Because I don't think it helps any…I don't want another medication. --First of all it makes me groggy and all I want to do is sleep and I don't want to get hooked on it so I don't want to take [the medicine].

Session Time: 9:00AM-11:00AM

Does Affect Predict Willingness to Take Medication?

Background/Purpose: Affect is known to have a significant impact on judgment and decision making. The data supporting this finding, however, are based on subjects' reactions to written materials. Our objective was to examine whether the valence and intensity of a patient's affective reactions to audible information influences their willingness to take medication.

Methods: We measured affect in real time as subjects with a chronic inflammatory rheumatic disease listened to a description of a hypothetical new medication. Subjects used a joystick to indicate moment-by-moment their reaction to what they were hearing (+10= Very good, -10= Very bad, and middle position= 0 being neutral). Patterns of affect reactions were classified using a cluster analysis approach applied to time series data. After hearing the presentation, subjects rated their willingness to take the medication on a 7-point Likert rating scale. We used a multivariate linear regression model to examine the association between affect patterns and willingness, adjusting for age, numeracy, use of immunosuppressant, and patient global assessment. An

interaction between affect pattern and ethnicity was included in the model to assess whether ethnicity modified the association of affect and willingness.

Results: The mean (SD) age of the study sample (N= 382) was 55 (14) years, 75% were female, 58.4% identified themselves as being Non-Hispanic White, 23.3% as Non-Hispanic Black, and 18.3% as Hispanic. Affect reactions were classified into 4 patterns: feel consistently ‘good' (n= 58), feel consistently close to ‘neutral' (n= 33), ‘extreme' positive reaction to benefits and negative reaction to adverse events (AEs) (n= 109), and ‘average' (or expected) reaction to benefits and AEs (n= 182). Based on differences of adjusted least squares means, the patients with good patterns reported greater willingness than neutral, extreme, or average patterns (t= 2.69, p= 0.007, t= 2.98, p= 0.003, t= 2.37, p= 0.018, respectively). Black patients reported less willingness than Hispanics or Whites (t= -2.76, p= 0.006, t= -3.34, p=0.001, respectively). The interaction results revealed that Blacks were significantly less willing than Hispanics or Whites within the extreme group only (t= -2.66, p= 0.008, t= -3.36, p=0.001, respectively). Mean willingness by affect pattern and ethnicity is presented in the Figure below.

Conclusion: Patients who feel consistently good are most willing to take the new medication compared to groups with other affect reaction patterns. Black patients, particularly those with an ‘extreme' reaction pattern, are less willing. These data are consistent with recent findings demonstrating that both positive and negative affect intensity predict reluctance to accept risk, and may help explain the increased risk aversion previously documented in Black patients with rheumatic disease.

The Association between Social Network, Disease Activity, and Pain in Rheumatoid Arthritis

Background/Purpose: Current research suggests that high social network status is related to lower levels of reported pain in rheumatoid arthritis patients (RA). The nature of this relationship is not well known but may be related to disease activity. This study aims to examine the relationship between social network, reported pain, and disease activity.

Methods: Data collected from a single-center, prospective observational RA cohort study, including joint examinations, blood draws, and patient reported outcome measures, were analyzed cross-sectionally. Subjects completed the Berkman-Syme Social Network Index (SNI), an ordinal scale ranging from 0 to 4 where 0 indicates no social network and 4 indicates high social network. Disease activity scores were calculated using the DAS28-CRP3. Reported pain data were obtained from the pain scale in the Multidimensional Health Assessment Questionnaire (MDHAQ); a continuous scale ranging from 0 to 100 where 0 indicates no pain and 100 indicates severe pain. A multivariable linear regression model was performed using a stepwise selection approach to examine the association between social network, reported pain, and disease activity. The variables initially entered into the model included age, gender, social network, disease activity, disease duration, and seropositivity. Disease duration and seropositivity were not significant, and thus were excluded from the final model.

Results: 1053 subjects with a mean age of 57.5 (SD13.6) years and a mean disease duration of 13.8 (SD11.9) years were analyzed. In this cohort, 83% were female and 69.7% were seropositive. On average, DAS28-CRP3 score was 3.2 (SD1.5), SNI was 2.4 (SD1.0), and MDHAQ pain score was 32.0 (SD26.2). Using a univariate analysis it was found that age, disease duration, seropositivity, disease activity, and SNI were associated with reported pain. In the final multivariable linear regression model, SNI was significantly inversely associated with reported pain (β coefficient -1.8, p=0.02), after controlling for disease activity.

Conclusion: High social network status was associated with lower reported pain, in this cohort of RA patients, even after controlling for disease activity. It is unclear if high social network status has psychosocial benefits that lead to reduced pain, or if low pain promotes patients' social participation causing a high social network status. Future studies are needed to further examine the relationship between social support and reported pain, and if this association is present longitudinally.

The association of social support and disease activity with pain in RA		
	β coefficient	p-value
Social Network Index (SNI)	**-1.82**	**0.02**
Age	-0.09	0.15
Gender	3.43	0.11
DAS28-CRP3	6.14	<.0001

The Impact of Emotional Trade-Off Difficulty on Choice

Raluca Cozmuta[1], Sonal Bhalla[2] and Liana Fraenkel[3], [1]Rheumatology, Yale University School of Medicine, New Haven, CT, [2]Yale University School of Medicine, New Haven, CT, [3]Medicine, Yale University School of Medicine, New Haven, CT

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Psychology/Social Sciences (ARHP)

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients' preferences for competing treatment options can be measured using stated preference methods which require subjects to make trade-off between specific attributes. Responses can then be used to calculate the importance of specific attributes on patients' choices. Previous marketing research has found that the extent of negative emotions elicited by specific trade-offs is related to choice. Given the known literature that choice difficulty increases the likelihood of opting out or deferring, the objective of this study was to examine whether emotional trade off difficulty impacts choices after accounting for the importance of each attribute.

Methods: Women between the ages of 20 and 49 years, admitted to the hospital or infusion center, completed a discrete choice experiment (DCE) to examine preferences for a hypothetical medication for a standardized patient with joint pain, migraines and fatigue. The DCE included 4 attributes each having 3 levels: route (oral, sc, iv), benefit (35%, 45%, 75% benefit), risk of TB (1 in 1,000, 10,000, and 100,000) and cost (easy, moderately hard, or hard to afford). Subjects then rated how threatening, stressful and risky they found choices involving each attribute (measured on 7-point scales). Emotional trade off difficulty was defined as the average of these 3 items. We used multiple linear regression models to examine whether emotional trade off difficulty is associated with preference to opt out of treatment after controlling for the importance of each attribute (which sum to 100), as well as numeracy (the only characteristic found to be associated with preference in bivariate analyses).

Results: Subjects' (N=271) mean (SD) age was 34 (8) years; 94 (35%) were non-Hispanic White, 95 (35%) non-Hispanic Black, and 82 (30%) were Hispanic; 27% of all subjects had a college degree, and 45% rated their health as being fair or poor. The mean (SD) importances were; route = 16.3 (10.4), benefit = 31.3 (15.1), risk of TB = 17.6 (10.1), and cost = 34.8 (15.3). The mean (SD) emotional trade-off difficulty ratings were: route = 3.2 (1.6), benefit = 3.6 (1.5), and 4.2 (1.8) for both risk of TB and cost. The strength of preference (SE) to opt out of treatment was 24.6% (2.2) for an IV drug (with moderate benefit, risk and cost), 27.5% (2.3) for a low benefit pill (with moderate risk and cost); 28.3% (2.3) for a high TB risk pill (with moderate benefit and moderate cost), and 36.5% (2.5) for an expensive pill (with moderate benefit and moderate risk of TB). The association of emotional trade-off difficulty for each of these choices is presented in the Table.

Conclusion: Negative emotions associated with making tradeoffs predict treatment preferences even after taking into account the importance weights of each attribute. Moreover, patients experiencing greater emotional trade off difficulty are more likely to opt out of treatment.

Table. Emotional Tradeoff Difficulty and Preference to Opt Out of Treatment.

Treatment Option	Variable	t Value	Pr > |t|
IV Drug	Emotional trade-off difficulty associated with route	2.49	0.013
	Importance of route on decision making	1.76	0.079
	Numeracy	1.26	0.207
Low Benefit Pill	Emotional trade-off difficulty associated with benefit	2.86	0.004
	Importance of benefit on decision making	-0.84	0.403
	Numeracy	0.56	0.573
High Risk of TB	Emotional trade-off difficulty associated with risk of TB	2.78	0.006
	Importance of risk of TB on decision making	4.19	<.0001
	Numeracy	1.33	0.184
Expensive Drug	Emotional trade-off difficulty associated with cost	3.31	0.001
	Importance of cost on decision making	1.28	0.203
	Numeracy	2.00	0.046

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Psychology/Social Sciences (ARHP)

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Several studies showed that unemployment and work disability are high in patients with Psoriatic Arthritis (PsA). Te purpose of this study is to evaluate work status in a cohort of patients with PsA and to identify variables associated to work disability.

Methods: A cross-sectional study was conducted including patients ≥ 18 years old with PsA according to classification criteria for Psoriatic Arthritis (CASPAR). Demographic data, disease duration, clinical features, articular and extra articular

manifestations, comorbidities and current treatment were collected. Disease activity was assessed by the 66 swollen and 68 tender joint counts, DAS28, DAPSA, BASDAI and RAPID3. Quality of life was assessed using DLQI and PsAQoL questionnaires. Functional capacity was assessed by HAQ and BASFI. Skin involvement was evaluated using PASI. Presence of dactylitis and enthesitis (MASES) were evaluated. Statistical analysis: T test, Mann Whitney, Chi^2 and Fisher exact test. Multiple logistic regression analysis to explore factors associated to work disability.

Results: 87 patients with PsA were evaluated. Median age was 52 years (IQR 40.2-61.7). 28 patients (32.2%) were unemployed and 18 of them (20.6%) were unemployed due to PsA, 10 were retired. Unemployed patients had a lower age at disease onset (33.9 ± 12.28 vs 38.87 ± 11.91, p=0.042), higher disease activity (BASDAI 5.7 ± 2.9 vs 4.06 ± 2.8, p=0.03, RAPID3 13.99 ± 7.4, vs 10.5 ± 6.27 p=0.03, DAPSA 20.5 ± 10.7 vs 16.5 ± 5.16 p=0.04, DAS28 4.2 ± 1.3 vs 3.44 ± 1.4, p=0.032), worse functional status (HAQ 1.18 ± 0.8 vs 0.68 ± 0.6, p=0.006) and worse quality of life (PsAQoL 12.1 ± 3.7 vs 6.56 ± 6, p<0.001). In the multivariate analysis, lower age [OR 0.9 (CI 95% 0.8-0.9), p=0.004] and worse functional status [HAQ OR 7.1 (IC 95% 1.9-25.7), p=0.003] were independently associated with WD.

Conclusion: In our cohort the prevalence of work disability attributed to PsA was 20.6%, and it was associated to lower age and worse functional capacity.

Session Time: 9:00AM-11:00AM

Background/Purpose: The American College of Rheumatology published its Top 5 List of Things Physicians and Patients Should Question as part of the American Board of Internal Medicine's Choosing Wisely campaign. First on the list was “Don't test ANA subserologies without a positive ANA and clinical suspicion of immune-mediated disease. We instituted a system to promote more cost effective subserology ordering.

Methods: We identified 101 of 1100 providers who were over utilizers (more than 2 subserologies ordered when ANA negative in a 26 month period). These providers received an email informing them of their ordering practice with explanation of ANA reflex testing, and a link to an online education module. Providers were surveyed pre and post intervention on their preferred quality improvement method. We prospectively examined for 1 year subsequent instances of unnecessary subserology ordering defined as anti-dsDNA, anti-SM/RNP, and SCL70 ordered when simultaneous ANA was negative. This was compared with the prior 26 months. If SLE was suspected, the ANA would reflex if positive to anti-ds DNA, anti-cardiolipin ab, and anti-Smith/RNP ab. For Sjogren's, the positive ANA would reflex to the SSA/SSB ab. 29/101 providers completed the non-required online education. Generalized estimating equations models were used to obtain estimates of odds ratios (OR) with their 95% confidence intervals (CI). A cluster effect by provider was included in the model to take into account the correlation within each

provider. Finally, a cost analysis based on the Medicare fee schedule was performed. This analysis assumed that when reflex testing was ordered, unnecessary subserologies were avoided.

Results: Unnecessary subserology ordering across all system providers decreased significantly after the intervention (OR 0.625, CI 0.425, 0.918, P-value 0.0167). Over the 26 month pre_intervention period, the mean percentage of unnecessary subserology ordering episodes was 44.5% when the ANA was negative. In the other 55.6%, the SSA/SSB or anti Jo1 antibodies were ordered which can be appropriate when the ANA is negative. In the 10 month post intervention period, the number of unnecessary instances decreased to 35.1% of the total. Surveyed providers preferred reflex testing and education over other practice improvement strategies. Of the 101 providers who over utilized subserologies, 26 started using ANA reflex testing. Cost analysis showed that ANA reflex testing potentially saved $8,462.50 by reducing unnecessary subserology utilization.

Conclusion: The introduction of optional ANA reflex testing with optional online education led to significant decreases in unnecessary subserology ordering when the ANA was negative across the entire integrated health system. Although, the calculated potential cost savings was not large, we only examined the instance of simultaneous ANA and subserology ordering when the ANA was negative, and not the entire spectrum of ordering practices. ANA reflex testing potentially saves providers time and patients inconvenience for 2nd phlebotomies. We expect that ANA reflex testing will be adopted by additional providers and are developing a scleroderma reflex test.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Quality Measures and Quality of Care Poster Session

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: American Academy of Ophthalmology (AAO) 2011 guidelines recommend that patients receiving hydroxychloroquine (HCQ) or chloroquine (CQ) undergo regular screening for retinal toxicity with 1 of 3 objective tests (spectral domain macula ocular CT (SD-mOCT), fundus autofluorescence (FAF), or multi-focal electroretinogram (mf-ERG)), which are sensitive for early retinal damage. In this study, we examined adherence to AAO guidelines for retinal toxicity screening in patients seen in ophthalmology clinics within a single health system who were users of HCQ or CQ.

Methods: We performed a system-wide electronic medical record (EMR) query to identify all patients seen in ophthalmology clinic between June 2012 – June 2014 who had mention of HCQ or CQ in the clinical note associated with the encounter (n=523). A chart review was performed on a random sample of these patients (n=294) to identify active users of HCQ or CQ or patients undergoing a baseline ophthalmology exam prior to starting these medications (denominator population) and to confirm

performance of SD-mOCT, mfERG and/or FAF (numerator). We also examined use of 10-2 Acute Visual Fields (AVF), the previous standard of care for antimalarial toxicity screening. Finally, we determined whether the newly recommended tests could be reliably identified through automated EMR queries since this would increase the efficiency of future quality improvement efforts.

Results: 208 patients in our sample were active users of HCQ/CQ or receiving a baseline ophthalmology exam prior to starting HCQ/CQ at the time of their ophthalmology encounter (denominator). 57.2% (n=119) had the recommended screening test performed over the study period (119 had SD-mOCT, 22 had FAF, and 7 had mf-ERG). An additional 4.3% (n=9) received only AVF screening. The automated EMR query accurately and reliably identified all 119 patients who had received the recommended objective screening. Chart review was used to determine the reasons why 42.8% (89) patients did not undergo the recommended screening tests (Table).

Table: Reasons for Not Undergoing Objective Screening for Antimalarial Retinal Toxicity

Reason for Not Undergoing Objective Screening	**Frequency**
No mention of any objective screening procedure in ophthalmology note	43.8% (n=39)
Appropriate objective screening procedure ordered but not performed	33.7% (n=30)
Documented in ophthalmology note that the patient is also followed by an outside ophthalmologist	11.2% (n=10)
Appropriate objective screening procedure mentioned but neither ordered nor performed	7.8% (n=7)
Testing was deferred because the patient planned on using HCQ/CQ for a short period of time	3.4% (n=3)

Conclusion: We found that only 57.2% of patients who were active users of HCQ or CQ underwent objective screening tests recommended by the AAO 2011 guidelines, suggesting a significant gap in quality of care. Structured query retrieval of this information was highly reliable, which will increase the efficiency of identifying care gaps for patients using these medications in future quality improvement projects.

Use of Lean Six Sigma Methodology to Improve Time to Scheduling for New Patient Referrals to Rheumatology

Nicole Orzechowski[1], Mary Bolg[2], Rachael Bergeron[1], Christopher Dorman[2], Lauren Sanderson[2], Miranda Stark[2], Stacey Wilk[2] and Tammy Gray[3], [1]Rheumatology, Dartmouth Hitchcock Medical Center, Lebanon, NH, [2]Dartmouth Hitchcock Medical Center, Lebanon, NH, [3]White River Junction Family Practice, White River Junction, VT

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Quality Measures and Quality of Care Poster Session
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Patient satisfaction is an important driver of patient-centered care. The Section of Rheumatology was taking on average 5 days to contact and schedule new patients for consultation, with only 30-50% of patients rating the scheduling experience as excellent. Our practice was tasked by an organizational goal of Dartmouth-Hitchcock to reduce new referral scheduling time to 48-hours. The purpose of this quality improvement initiative was to develop a process to reduce referral scheduling time with a downstream impact of improving patient satisfaction.

Methods: An interdisciplinary team consisting of on-site clinicians, allied-health staff and practice managers, in addition to scheduling staff in our own practice and at referral practices met three times over a period of 6 weeks. Each meeting lasted between 4 and 7 hours. To understand the current workflow to allow for process improvement, we used the Lean Six Sigma DMAIC methodology (Define, Measure, Analyze, Improve, Control). Data was collected at baseline and at follow-up, including number of external referrals by month, number of days to triage referral, contact patient, and close referral, number of days from referral to appointment date, percent of 3rd calls that result in a scheduled appointment, and patient satisfaction on question regarding ease of scheduling.

Results: New referral scheduling dropped to less than two business days and the percent of patients rating the scheduling experience as excellent rose to 82% after process changes. Baseline process evaluation allowed us to identify considerable areas of waste including: a section-specific referral form; secretaries calling new patients up to three times prior to closing a referral when 3rd calls never resulted in an appointment being scheduled; a physician triage system resulting in batching of referrals and delays in scheduling; and secretaries hand-writing demographic information on a pre-appointment checklist. Our methodology led to the implementation of three process changes: non-urgent referrals were scheduled with the first available provider to eliminate scheduling delay due to the triage process; an electronic smartphrase eliminated the need for handwritten information and was embedded into the electronic referral containing a prior pre-appointment checklist; elimination of requiring all clinical documentation to be on hand prior to appointment scheduling but incorporated a secretarial electronic checklist to ensure all documents arrived prior to the patient's scheduled appointment.

Conclusion: Using quality improvement methodologies allowed the Section to initiate low-cost modifications to existing workflows to reduce overall scheduling times and improve patient satisfaction.

Quality of Evidence of the American College of Rheumatology (ACR) Clinical Practice Guidlines

Mushabab Alghamdi[1] and Mohammed Al Mansour[2], [1]Internal Medicine, University of Bisha, Bisha, Saudi Arabia, [2]Rheumatology, King Fahad Medical City, Riyadh, Saudi Arabia
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Quality Measures and Quality of Care Poster Session
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

The American College of Rheumatology (ACR) regularly establishes and publishes guidelines for the management of various rheumatic diseases. These guidelines assist physicians in providing appropriate care to patients afflicted with rheumatic diseases. The objective of this study is to evaluate the quality of evidence supporting recommendations in the American College of Rheumatology (ACR) clinical practice guidelines.

Methods: Current guidelines for management of rheumatic diseases posted on the ACR website (http://www.rheumatology.org/) were evaluated using the methods reported by the American College of cardiology as follows: 1) for level of evidence A, data were derived from multiple RCTs or ameta-analysis, 2) for level B evidence, data were derivedfrom a single RCT or nonrandomized study, and 3) for level C evidence, data were derived from consensus, expert opinion, or case series.

Results:

At the time of our review, there were 7 guidelines posted on the ACR website, 5 of which were eligible for data analysis. Two guidelines were excluded (not followed the same quality of evidence format). The summary of the distribution is reported as the median of the percentage of all the eligible guidelines. The 5 analyzed guidelines contained a total of 191 recommendations, 56 were supported by Level A evidence (Median, 27.6(%); Inter-quartile range [IQR],15.4%-52.5%); 44 were supported by Level B evidence (Median, 18.9%; IQR,8.3%-33.8%); 91 were supported by Level C evidence (Median,45.2(%); IQR,33.2%-58.6%). (Table 1)

Table 1. Summary of All Current ACR Recommendations Level of Evidence, Number of recommendations (n), Percentage (%), Median (%) and Inter Quartile Range. 47.6% of the recommendation in the available website recommendation are supported by Level C evidence.

Level of evidence	Number	Percentage (%)	Median (%)	IQR
A	**56**	**29.3**	**27.6**	**15.4%-52.5%**
B	**44**	**23.0**	**18.9**	**8.3%-33.8%**
C	**91**	**47.6**	**45.2**	**33.2%-58.6%**

Conclusion: The ACR recommendations are supported mainly by level C evidence. These findings highlight the areas which have a paucity of high quality evidence and are not supported by either Level A or B evidence. The study highlights the limitations of current clinical rheumatological diseases research that can provide high quality of evidence. Support of high quality evidence research is crucially needed.

Rheumatoid Arthritis Quality Measures – Automated Display of Care Gaps and Capture of Physician Decision Making at the Clinic Visit

Eric Newman[1], Tarun Sharma[2], **Alicia Meadows**[2], Jason Brown[3], Michael Rowe[4] and Shelly Vezendy[5], [1]Department of Rheumatology, Geisinger Health System, Danville, PA, [2]Rheumatology, Geisinger Health System, Danville, PA, [3]Henry Hood Center for Clinical Research, Geisinger Health System, Danville, PA, [4]Institute for Advanced Application, Geisinger Health System, Danville, PA, [5]Division of Medicine, Geisinger Health System, Danville, PA

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Quality Measures and Quality of Care Poster Session

Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid Arthritis (RA) quality measures evaluate performance, and thus do not by themselves result in improvement. The ideal system to improve quality would provide real time actionable data by embedding the measures in the clinical workflow.

Methods: We designed a quality measurement system that 1) integrates with the electronic health record (EHR); 2) provides real-time recognition and closure of care gaps; and 3) allows easy recording of justifiable exceptions. Quality measures included RA on DMARD (Disease Modifying Anti-Rheumatic Drug), RA with MDHAQ (functional assessment), RA with CDAI (disease activity measure), RA at low disease activity, TB testing (if on biologic), flu and pneumococcal vaccination, and biologic de-escalation candidate. Color coding the measure status allowed easy recognition of an actionable item (green = measure met, red = not met/opportunity, gray = not applicable).

Using software integrated with the EHR, the RA quality measures were programmed to appear in a specific "tasks" tab. The tasks tab was user specific. The nurse tasks tab showed 1) the vaccination and TB testing measures, and 2) a decision tool where the nurse could select her decision (e.g. flu shot ordered). The rheumatologist tasks tab showed 1) all of the quality measures, 2) the nurse decision (in real time), and 3) a decision tool for RA on DMARD and biologic de-escalation. An opportunity was defined as an RA patient NOT on DMARD, or a biologic de-escalation candidate (low disease activity for at least a year). The rheumatologist used a drop-down list to easily document medical decision making for any opportunities. To reduce redundant work, each decision had an automatic "turn off" interval so that the decision tool did not appear at every visit.

Results: The tasks tabs were designed and programmed. The measures were validated against the EHR. Using PDSA (Plan Do Study Act) improvement methodology, the quality measurement system was implemented and the first cycle of data obtained regarding adoption of use and decisions made. Over the course of PDSA cycle 1 (4 weeks), 18 rheumatologists used the decision tool for 62% of the opportunities (54% for RA on DMARD, 66% for Biologic De-escalation). For RA patients NOT on DMARD, use of the tool resulted in 35% of the decisions to discuss a DMARD or add a DMARD. For biologic de-escalation candidates, use of the tool resulted in 34% of the decisions to de-escalate biologic therapy.

Conclusion: We designed, tested, and implemented a quality measurement system that integrates with the EHR, provides real time recognition of care gaps and cost reduction opportunities across a broad array of quality measures, and records provider decisions. The system was well-adopted, and early data suggests that it has facilitated improving the percent of RA patients on DMARD, as well as biologic de-escalation in well-controlled RA patients. Repeated PDSA cycles are planned to further increase tool adoption. As we gain additional data, we will explore the system's effect on improving the quality measures, and use the decision tool data to better understand modifiable barriers to improving these measures.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015

Session Title: Quality Measures and Quality of Care Poster Session
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Population management (PM) offers a promising approach to providing Treat-to-Target (T2T) care for rheumatoid arthritis (RA). PM depends on providing standardized, on-time disease activity (DA) assessments and coordinated care across the entire disease population, as well as for individual patients within this context. This study investigates the adoption of PM registries in rheumatology practices, the use of standardized DA measures (referred to as *signal measures*) as chosen by participating rheumatologists, and the barriers some practices are encountering as they strive to implement PM.

Methods: The Rheumatoid Arthritis Practice Performance (RAPP) Project is a voluntary collaboration of U.S. clinician rheumatologists (current N = 168) who manage more than 80,000 RA patients in total. Participating physicians are enrolling their RA patients (ICD-9 code 714.0) into a HIPAA-compliant disease population registry from practice billing records or during clinical visits. They are then collecting signal measures and current medications on these patients over time. With isolated exceptions, their preferred signal measures include one or more of the following: RAPID3, a 0-10 Provider Global Assessment (PGA), Clinical Disease Activity Index (CDAI), and a multi-biomarker (MB) test. The registry enables real-time Population Reports that track assessment timeliness (consistent with T2T recommendations) and monitor the DA distribution within each physician's enrolled RA population. Lists of overdue patients are also generated from the registry. The RAPP Project's coordinators regularly assess physicians' progress toward PM and the barriers they encounter.

Results: To this point, 86 RAPP Project physicians have fully enrolled their RA population in a population registry. Signal measure results reported by these physicians include:

Measure	Practices Reporting (Number)	Percentages of Patients Reported (Range)	Patients with Measures in All Registries (Number)
RAPID3	15	10-93%	4176
PGA	39	2-93%	8679
CDAI	15	2-93%	4151
MB Test	86	3-100%	38412

Despite strong intentions, many practices encounter barriers to implementing a population registry and PM workflows, including: 1) temporary practice or personal crises, such as partners leaving or illnesses; 2) physicians and staff lacking the time, resources, and skills to implement the necessary practice changes; and 3) administrative objections, especially in larger group practices.

Conclusion: 1. Increasing numbers of physicians and staff have been able to implement a simple yet robust population registry in their busy practice environments. 2. They are collecting one or more signal measures across their population. 3. They are using their registry data to create PM workflows and improve "on-time" DA assessment. 4. Both practice-based and health system barriers present challenges to implementing PM in many practices.

Impact of Protocolized Tight Control and Biological Dose Optimization in Daily Clinical Practice: Results of a Pilot Implementation Study

Nienke Lesuis[1], George Bruyn[2], Paul Baudoin[2], Lieke Nieboer[3] and Alfons den Broeder[1], [1]Rheumatology, Sint Maartenskliniek,

Nijmegen, Netherlands, [2]Rheumatology, MC Zuiderzee, Lelystad, Netherlands, [3]rheumatology, Sint Maartenskliniek, Nijmegen, Netherlands

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Quality Measures and Quality of Care Poster Session
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

It is possible to optimize and reduce the individual dose of biological Disease Modifying Anti-Rheumatic Drugs (bDMARDs) in patients with rheumatic diseases, in combination with tight control strategies, while maintaining adequate disease control.[1] Nevertheless, most rheumatologists in daily clinical practice do not apply these strategies. As the potential benefit for both patients (side-effects) and society (costs) is large, we aimed to implement dose optimization strategies in real clinical practice.

Methods:

This pilot implementation study was conducted at the rheumatology department of a general hospital in the Netherlands between May and October 2014. Both rheumatologists working in this center were eligible for participation. The implementation strategy comprised three steps: 1) education, feedback, and the development of guidelines on bDMARD dose optimization and tight control based treatment of rheumatoid arthritis (RA), psoriatic arthritis (PsA) and axial spondyloarthropathy (SpA), 2) individualized treatment advices of all patients using bDMARDs (written in the electronic health record of individual patients) followed by 3) monitoring and feedback after three and six months. To determine the effectiveness of this strategy, the percentage of patients with measured disease activity was assessed, i.e., the Disease Activity Score in 28 joints (DAS28), or the *Bath Ankylosing Spondylitis Disease Activity Index* (BASDAI). In addition, mean DAS28 and BASDAI scores and the percentage of patients using a reduced dose of their bDMARD were calculated. All outcomes were assessed at baseline (directly after step 1) and three and six months thereafter.

Results:

Both rheumatologists participated in this study and were present during the implementation of steps 1 through 3. At baseline, 275 patients (mean age 56 years ± 16 years; 56% female) were using a bDMARD, the most commonly prescribed bDMARDs were adalimumab (41%), etanercept (23%) and tocilizumab (13%). The majority of patients were diagnosed with RA (63%), SpA (17%), and PsA (15%). Disease activity measures and dose reduction data are listed in table 1.

Table 1 Outcomes on DAS28, BASDAI and bDMARD use

Outcome	Baseline	T = 3	T = 6
DAS28 performed* (%)	40	63	70
BASDAI performed$^{\Xi}$ (%)	20	38	40
Mean DAS28*	2.1 ± 0.9	2.4 ± 1.1	2.3 ± 0.9
Mean BASDAI$^{\Xi}$	3.6 ± 2.8	5.0 ± 1.0	3.8 ± 1.3
Using a reduced bDMARD dose† (%)	11	37	63

*Outcome only assessed in RA patients. $^{\Xi}$Outcome only assessed in SpA patients. †Outcome assessed in all patients.

Extrapolating the percentage of patients that received a reduced dose of bDMARD at six months, we estimated that total annual savings of 500,000 euros could be realized by biological dose optimization in this cohort.

Conclusion:

Based on the promising results of this pilot study, implementation of tight control based biological dose optimization may become a feasible and successful strategy in daily clinical practice, resulting in improved quality of care and a sizable reduction in bDMARD use.

Effects of Two Interventions on Rheumatologists Adherence to Optimal Care Recommendations in Rheumatoid Arthritis: A Combined before/after and Randomized Controlled Trial

Nienke Lesuis[1], Ronald van Vollenhoven[2], Marlies Hulscher[3] and Alfons den Broeder[1], [1]Rheumatology, Sint Maartenskliniek, Nijmegen, Netherlands, [2]ClinTRID, Department of Medicine, Karolinska Institute, Stockholm, Sweden, [3]IQ Healthcare, Radboud University Medical Centre, Nijmegen, Netherlands

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Quality Measures and Quality of Care Poster Session

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Current treatment guidelines for rheumatoid arthritis (RA) recommend using tight control strategies.[1] Despite evidence for the benefits of this strategy, physician adherence is suboptimal.[2,3] Here we investigated two strategies to improve RA care by increasing physician guideline adherence using a multimodal intervention strategy.

Methods:

A single centre, combined before/after and randomized controlled pilot study was performed to assess effectiveness of two interventions. The first intervention combined education with feedback, whereas the second intervention comprised decision support incorporated in the Electronic Medical Record (EMR).

All clinicians (rheumatologists, residents and physician assistants; n = 20) working at the study centre during the full study period could participate. All participants received intervention 1, while intervention 2 was allocated in a 1:1 intervention vs. control randomization. .

Intervention effects were measured at the patient level using a set of 13 different dichotomous indicators for RA diagnostics, treatment and follow-up. All adult RA patients with a visit to a participating clinician in the study period were eligible for inclusion. The standardized sum score (SSS) of the indicators (indicator sum score divided by number of indicators) served as the primary outcome. The effect of intervention 1 was assessed using a before/after design; whereas the extra effect of intervention 2 was assessed using a randomized controlled design. The total study duration was 10 months (pre-intervention: 6 months; post-intervention: 4 months).

Results:

All 20 clinicians participated in this study. A total of 1050 patients was included of which 527 in the pre-intervention period and 523 in the post-intervention period.

Three out of 13 indicators improved significantly after the interventions (regular disease activity- and functional status measurements, shared care with the physician assistant) with odds ratios between the 1.8 and 3.1. Intervention 1 resulted in a significant increase in the SSS, from 0.57 before the intervention to 0.63 afterwards (difference 0.06; 95% confidence interval

(95%-CI) 0.02 to 0.10; p <0.01). In contrast, the second intervention did not result in an extra effect above intervention 1 alone (difference 0.01; 95%-CI -0.04 to 0.07; p = 0.65).

Table 1 Baseline characteristics of included clinicians

	Control group *(intervention 1; n = 10)*	**Intervention group** *(intervention 1 and 2; n = 10)*
Clinician characteristics		
Age, years (SD)	42.4 (11.1)	46.0 (11.0)
Female, n (%)	5 (50.0)	6 (60.0)
Rheumatologist, n (%)	9 (90.0)	6 (60.0)
Work experience, years (SD)	8.0 (8.0)	12.0 (9.0)
Patient characteristics		
Age, years (SD)	61.9 (12.2)	61.9 (12.6)
Female, n (%)	359 (66.1)	365 (72.0)
Disease duration, years (SD)	9.7 (8.4)	9.0 (8.5)
Rheumatoid and/or anti-CCP positivity, n (%)	364 (76.6)	276 (68.5)
Erosive disease, n (%)	250 (48.9)	202 (44.4)

Conclusion:

An intervention consisting of education and feedback, but not electronic decision support, resulted in a significant increase in guideline adherence, reflected by an increase in the indicator sum score and improvement in three out of 13 indicators.

Session Title: Quality Measures and Quality of Care Poster Session

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Current recommendations for optimal rheumatoid arthritis (RA) management include routine assessment of disease activity and adjustment of medication to achieve remission or low disease activity. There are limited data describing implementation strategies for this potentially burdensome process in a real-world clinic setting. Our goal was to increase the use of disease activity measures, specifically, the Clinical Disease Activity Index (CDAI) for RA patients at an academic VA medical center rheumatology clinic using Plan-Do-Study-Act (PDSA) cycles and introduction of a simple paper form.

Methods :

Patients were diagnosed with RA by a rheumatologist. In PDSA cycle 1, a paper-based form was distributed to providers and brief one-on-one educational discussions with incoming fellows were held. The form included a patient global activity of disease visual analogue scale (VAS, 0-10cm), a physician global VAS and a 28-joint count homunculus for counting tender/swollen joints. The form also included instructions for calculation and interpretation of the CDAI. Providers were instructed to enter the total CDAI score into their clinical note. PDSA cycle 2 included two provider education talks on disease activity measurement including rationale, identification of RA patients prior to their clinic visit by investigators, inclusion of medical assistants to distribute paper forms to pre-identified patients, and separation of the form into two pages – one for the patient global (was changed from VAS to numerical in cycle 2) and one for the provider components. We generated a run chart to evaluate the effect of each PDSA cycle on the percent of RA visits with the CDAI recorded.

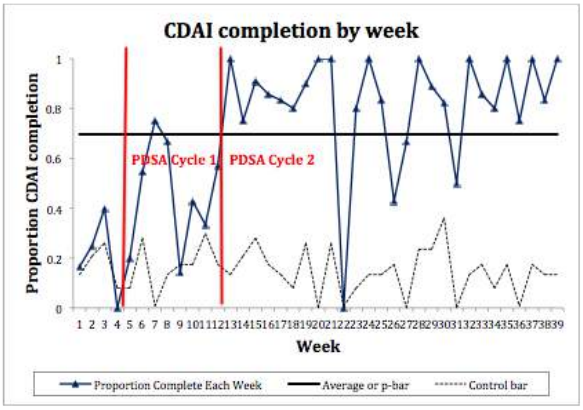
Results :

Nine rheumatology fellows, 1 nurse practitioner and 5 attending physicians participated in this quality improvement project. 107 RA patients were seen at the clinic during the study period, June 2014 through March 2015. During the 4-week pre-intervention period, there were 29 RA patient visits and 24% (n=7) had a documented CDAI. PDSA cycle 1 lasted 8 weeks with 59 visits and 44% of patients (n = 26) had a CDAI documented. Cycle 2 lasted 27 weeks with 182 visits and 85% of patients (n = 155) had a CDAI documented.

Conclusion :

We successfully increased CDAI use in an academic rheumatology clinic setting using a simple paper form coupled with brief provider education. The majority of providers were rheumatology fellows, indicating that providers can learn this skill early in their training. Our approach may be informative for other clinical settings, especially for

those without an electronic medical record or those that are unable to modify their electronic medical record to incorporate disease activity measures.



The pre-intervention, PDSA Cycle 1 and PDSA Cycle 2 separated by red bars. The dark blue line shows the proportion of CDAI completed by week. The upper control limits are not seen as they are above a proportion of 1, the lower control limit is shown and describes the variation of the denominator as different numbers of RA patients are seen in clinic each week. The p-bar is shows the average. More than six values are seen above the p-bar, indicating a successful change.

Session Title: Quality Measures and Quality of Care Poster Session

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Compared to routine care, the Treat to Target (TTT) strategy for rheumatoid arthritis (RA) has been validated to improve functional and radiographic outcomes via use of disease activity measures (DAMs) to quantify and track RA activity over time. Several DAMs have been validated for clinical use by the American College of Rheumatology (ACR), but routine use of DAMs during RA patient visits is not standard practice at the University of Texas at Houston (UT Houston) Rheumatology clinic.

Via participation in a learning collaborative (TRACTION [Treat-to-target in Rheumatoid Arthritis: Collaboration To Improve adoptiOn and adhereNce]) we sought to increase adherence to TTT strategy in RA and to increase DAM documentation to a minimum of 80% of RA visits. Our institution adopted use of the Clinical Disease Activity Index (CDAI), which consists of a 28 tender and swollen joint count (TJC/SJC), patient global assessment of disease activity, and provider global assessment of disease activity.

Methods: The initial intervention was altering the electronic chart note template to include a dedicated line for CDAI value. Simultaneously, printed CDAI forms from the ACR website were placed in all clinic exam rooms. Electronic CDAI calculators from the ACR website were also downloaded onto clinic computers. For TRACTION, percentage of faculty visits with documented DAM is calculated by reviewing 5 charts per provider over a 2 week time period on a monthly basis.

After TRACTION faculty reached goal CDAI documentation, interventions targeted our 5 fellows. To teach proper technique for performing a 28 TJC/SJC, fellows underwent a learning session wherein they viewed a TJC/SJC instructional video and practiced TJC/SJC with simultaneous use of musculoskeletal ultrasound to verify location of the palpated joint space. Individual CDAI documentation rates based on all RA visits was provided to each fellow at baseline and then bimonthly.

Results: At baseline, faculty documented a DAM for 6/25 (24%) of RA visits. Over subsequent months, faculty documented a DAM in 20/20 (100%), 19/20 (95%), 23/25 (92%), and 19/20 (95%) of RA patient visits. At baseline, fellows documented a DAM in 0% of RA visits. Over the 8 weeks post-learning session, CDAI documentation increased to 22/29 (76%), 21/17 (78%), 14/23 (60%), and 14/15 (93%) RA visits. (See Figure 1.)

Conclusion: TTT improves outcomes in RA. Validated DAMs can assess and track RA disease activity at each visit. Use of DAM without lab value input, improved access to DAM calculating tools, and use of a template-based electronic note led to increased CDAI use and documentation among faculty. A TJC/SJC learning session for fellows with bimonthly feedback about documentation improved fellow CDAI documentation from 0% to 93% of RA visits. More time is required to assess whether our efforts will lead to a sustainable change in practice patterns.

Session Title: Quality Measures and Quality of Care Poster Session

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Achieving tight control of RA with reliable methods to monitor and assess disease activity in a more objective way is imperative in clinical practice to obtain treat to target results. We conducted a longitudinal study to evaluate utility, adoption, and analysis of the correlation and agreement of the Clinical Disease Activity Disease Index (CDAI) and Simple Disease Activity Index (SDAI) scores and categories of disease. We adapted our electronic health record (EHR) (Centricity) to standardize real time assessment with the CDAI in hopes to change physicians' therapeutic behavior, in order to provide better care and afford patients with a single number to understand their disease activity.

Methods: In the first seven months a total of 153 cases were included in the analysis. Spearman rank and intraclass correlation (ICC) were computed between CDAI and SDAI scores. The Kappa agreement and McNemar's test was conducted for the agreement of CDAI and SDAI disease categories. Finally one-way ANOVA was used to test the association between categorized SDAI and CDAI and selected lab variables. The quality analysis of the project was performed with quarterly meetings with rheumatologists and the information technology (IT) department to discuss implementation and data collection.

Results: The "CDAI calculator" was launched on October 2014 during this month we had a 48% documentation rate for RA patient clinical encounters, but by December we achieved a 100% EHR documentation rate. Our study was in an 87.32% Hispanic population with 84.31% being female. Based on CDAI disease activity categories, the distribution for Remission, Low, Moderate, and High activity was 43.79%, 31.37%, 15.03%, and 9.8% respectively. The association between CDAI and SDAI scores was found to be very high with a spearman value of 0.95 (p-value <0.0001) and further confirmed with the ICC of 0.987 (CI: 0.982-0.991). There was no significant difference in proportion of discordant pairs of the SDAI and CDAI categories, showing that scores that switched classification when converted were negligible (p-value 0.4815). The agreement between the CDAI and SDAI categories was high with a Kappa of 0.87 (CI: 0.81-0.94). Of note, there was a difference between the categorized SDAI versus platelets ANOVA analysis (p-value 0.053) with platelets in Remission being 272.4 (± 91.0), Low 239.9 (± 71.1), Moderate 286.8 (± 84.9), and High 293.5 (± 72.0).

Conclusion: Incorporation of the CDAI into point-of-care visits was possible with coordination of an interdisciplinary team and the continual reassessment methodology of the Plan Study Do Act approach. On analysis, the SDAI and CDAI showed that even when a CRP was not included in composite scoring the CDAI categorization was utile for proper assessment and sensitive to change. When seeing association between lab values and the indices, the SDAI categorization was able to show the theory of thrombocytosis in higher inflammation states confirming that the index can differentiate disease activity accurately. At this time, we need more follow up CDAI scores in order to objectively see treat to target changes in both patient population and physician management behavior.

Session Title: Quality Measures and Quality of Care Poster Session

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Treat to Target (T2T) strategy becomes from the need to develop therapeutic targets and tools to achieve defined outcomes in rheumatoid arthritis (RA). Moreover, models of patient-centered care where multidisciplinary teams make disease management increasingly take place in rheumatology. The aim of this study was to describe change in Disease Activity Score 28 (DAS28) using T2T strategy for a 24-month period in patients with conventional DMARD therapy in a large cohort of patients from a specialized in RA center where a model of patient-centered management is used.

Methods: A descriptive cross-sectional study was performed. Records of patients in conventional DMARD therapy from specialized in RA center were reviewed; those patients were followed-up under T2T standards. Clinical follow-up was done strictly according to DAS28 as follows: every 3-5 weeks (DAS28 > 5.1), every 7-9 weeks (DAS28 ≥ 3.1 and ≤ 5.1), and every 11-13 weeks (DAS28 < 3.1). Tender joint count (TJC), swollen joint count (SJC), DAS28 and HAQ were measured on each visit. Therapy had to be adjusted with DAS28 > 3.2 unless patient´s conditions don't permit it; we considered this follow-up type as implementation of a T2T strategy in patients with RA. We divided patients in four groups: remission (Rem), low disease activity (LDA), moderate disease activity (MDA) and high disease activity (HDA) patients and the aim of the study was to look at what percentage of patients who were in moderate or high disease activity reached a low disease activity or remission after 24-month period. On the other hand, patients were followed-up by physiatrist, psychologist, nutritionist and therapists at least 3 times a year. Descriptive epidemiology was done, percentages and averages were calculated; the median of each variable was analyzed using t-Student assuming normality for DAS28 distribution and the level disease activity was analyzed using Pearson´s statistics.

Results: 1110 patients were included in this study, 826 (74.4%) women and 284 (25.5%) men. Average age was 61 y/o (15-89) with disease duration of 11 years (0.5-47). Concerning to treatment of entire cohort 76 (6.8%) patients were using Leflunomide alone, 114 (10.2%) Metothrexate alone, 100 (9.0%) Leflunomide plus Metothrexate, 98 (8.8%) Leflunomide plus other DMARDs, 519 (46,7%) Metothrexate plus others DMARDs and 203 (16.9%) "only" DMARDs without Leflunomide or Metothrexate. At 24 months 66.6% of patients got remission and 13% LDA and was observed a decrease in percentage of patients in MDA/HDA statistically significant. For the entire cohort, at beginning DAS28 was 3.6 and after 24 months of follow-up DAS28 was 2.6 showing improvement (p <0.00). In overall, 98% of patients rated the quality and accessibility of multi-disciplinary care as good or excellent.

Conclusion: There is a great improvement of DAS28 in a cohort of RA patients only receiving conventional therapy with following-up under strict T2T strategy. This is very important issue in those countries or environments with limited resources for health care. Regarding a model of patient-centered care, studies are needed to measure the impact of the multidisciplinary team on the clinical results obtained.

Session Date: Tuesday, November 10, 2015

Session Title: Quality Measures and Quality of Care Poster Session

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Patient safety problems are increasing in rheumatology given the growing use of high-risk immunosuppressive drugs. Electronic health record "dashboards" have been utilized in research and quality improvement to evaluate provider performance. However, safety dashboards for rheumatic diseases are lacking, despite the availability of quality measures and numerous studies indicating gaps in care. Our objective was to develop an electronic safety dashboard for an outpatient rheumatology clinic using the Institute for Healthcare Improvement's Model for Improvement.

Methods: We undertook a quality improvement project using data stored in the electronic health record (EHR) of an urban safety-net hospital to develop eMeasures for a rheumatology electronic safety dashboard. The eMeasures were evidence-based, clinically actionable metrics that address high-priority patient safety risks: (1) bone health monitoring in patients taking oral

glucocorticoids, (2) screening and treatment for latent tuberculosis (TB) prior to initiation of anti-TNF-α drugs, and (3) pneumococcal vaccination in patients using high-risk immunosuppressive medications. We built prototype electronic queries to automatically extract data and adjusted clinical workflows and documentation to standardize information collection. We used Plan-Do-Study-Act cycles to create and revise clinical workflows to improve performance on each of these eMeasures. A data analyst completed training to access the EHR data warehouse and identified numerator and denominator populations of rheumatology outpatients using standardized, coded terminologies.

Results: For the bone health eMeasure, we revised our clinical workflow to include a bone health template in the clinical note, including embedding a link to a FRAX calculator. With the introduction and refinement of this template (Figure 1), performance on bone health measures increased from 0% to 27% in a three-month period. For the TB screening eMeasure, a drug safety checklist was instituted into the workflow, and results are currently being analyzed. For the pneumococcal vaccination eMeasure, a nurse-led pre-visit planning step and provider reminder sheet were instituted. This program increased vaccination rates strikingly over time (Figure 2).

Conclusion: The development of an electronic dashboard in a safety-net rheumatology clinic coupled with workflow changes to improve performance on dashboard eMeasures led to significant improvements in delivering quality measures to rheumatology patients.

Tele-Monitoring of Disease Activity in Rheumatoid Arthritis and Psoriatic Arthritis

Alexander Langer[1] and Hans-Eckhard Langer[2], [1]Department of Computer Science, RWTH Aachen University, Aachen, Germany, [2]RHIO (Rheumatology, Immunology, and Osteology), Duesseldorf, Germany

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Quality Measures and Quality of Care Poster Session

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

There is evidence that tight control of rheumatoid arthritis improves outcome. In daily practice this aim is constricted by logistic limitations such as a small number of rheumatologists or long distances to specialized centers. By tele-monitoring the disease activity between regular routine controls and individually tailoring control intervals, we might be able to optimize disease management. In this study, we examine the acceptance and usage of an online tele-monitoring tool.

Methods:

The tele-monitoring tool was developed as a patient empowerment platform for an internet community for patients of chronic arthritis. The program includes electronic versions of the DAS28 and the HAQ as well as a form to regularly (e.g., daily) document disease activity (scale 0-10; 0=lowest, 10=highest), pain (0-10) and fatigue (0-10), swollen and tender joints, drugs taken and any noteworthy events such as flares or special occasions in the patient's life. The monitoring data can be made available to the rheumatologist who can then react appropriately.

Between 2011 and 2015, 2732 users of the internet community signed up for the program, out of which 1233 patients voluntarily provided their age, gender and diagnosis. 616 subjects with RA (n=503) or PsA (n=114) were chosen for further analysis.

Results:

The mean age at registration was 45.0 ± 12.2 years (range 13-82); 467 (76%) subjects are female. 279 patients (45%) used the program less than two weeks. The remaining 337 patients (55%) used the program for 323.8 ± 352.5 days on average, with an average frequency of once every 32.4 ± 57.4 days.

415 patients regularly entered disease activity (totaling n=17691 entries; average of 3.07 ± 2.50), pain (n=19325 entries; average 3.27 ± 2.50), or fatigue (n=18198; average 3.42 ± 2.83). The DAS28 test was performed by 275 patients; the average score after registration was 4.68 ± 1.44 (range 0.42 - 8.91; median 4.71). The average HAQ score (333 patients) was 1.11 ± 0.67 (range 0 - 2.86; median 1.13).

Conclusion:

The tele-monitoring tool is well-received. The majority of patients that signed up continued to use it regularly. Patients seem to prefer simple scores that can be entered quickly over more involved tests such as the DAS28 or the HAQ.

It remains open why some patients discontinued the usage of the tele-monitoring tool. With additional training and support by health care providers such as the primary physician it might be possible to improve the persistency in tele-monitoring as well as the acceptance of lengthier tests such as the DAS28 or HAQ. Here we see chances and challenges for a more broader application of tele-monitoring tools.

The average user of the tele-monitoring tool is rather young, has a high disease activity and reduced functional capacity. This might be an indication that particularly patients with a severe arthritis seek help in additional tools for coping with their disease.

Session Date: Tuesday, November 10, 2015
Session Title: Quality Measures and Quality of Care Poster Session
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Title: Telerheumatology: A Technology Not Appropriate For All

Background/Purpose: Access to Rheumatology care in New Hampshire (NH) and Vermont (VT) is limited, as a large proportion of the population lives in rural areas (60%) with limited resources. Telerheumatology services developed at Dartmouth-Hitchcock Medical Center (DHMC) brings care to these rural regions and improves access. Our previous work identified two issues with telerheumatology: 1) the quality of the patient presenter and 2) the appropriateness of the patient for a telerheumatology visit. We want to systematically assess the patient and provider experience to improve the quality of care delivered via telerheumatology.

Methods: As part of a quality improvement initiative we performed an IRB-exempt retrospective review of the charts for patients seen in the telerheumatology clinic at DHMC from October 2011 to December 2014. We also interviewed the participants: including providers, presenters and patients regarding their experience of care. We assessed both patient and provider satisfaction with the experience. We developed a web based educational series on rheumatic disease, including MSK examination, for the presenter. We used descriptive statistics to summarize our findings.

Results: Between October 2011 and December 2014, 176 patients were seen via telerheumatology between two clinical sites over the course of 244 patient visits. The top diagnosis for patients seen was inflammatory arthritis (n=156, 63.9%). 66.4% of the patients were on high risk medications including: steroids, biologics (infusion and injectable), and DMARDs. Providers filled out surveys on 9 visits for 70 patient encounters and found that 19% of patients (13) were inappropriate for the visit type for two main reasons: diagnosis unclear or diagnosis too complex. Telerheumatology afforded patients shorter travel distances and travel related money savings. 94% of patients were satisfied with the remote site staff and treating providers, and 73% of them would like to be seen via telerheumatology again. We previously provided presenter education which had no impact on the provider perceived quality of the visit.

Conclusion: The use of telerheumatology has successfully increased access to rheumatology care for patients in rural regions of NH and VT allowing for shorter travel and cost savings. 19% of the patient visits reviewed were inappropriate for the visit modality. This evaluation was performed in a setting without any pre-visit screening, which we believe could be an opportunity to triage patients to the appropriate visit modality. We propose a triage mechanism (Table 1) to pair patients appropriately with the telerheumatology visit type to ensure an overall high quality experience for patients and providers in the future.

Table 1. Triage tool to guide telemedicine in Rheumatology

Conditions	Disease State	Candidate for Tele-Health	Clinical Example
Diagnosis/Disease Well Established	Stable	Yes	Stable well-established disease (RA/PsA/SLE) on DMARD or Biologic therapy needing routine drug monitoring (labs for toxicity etc.)
	Flaring	Maybe	Patient with well-established disease (RA/PsA/SLE) experiencing flare requires escalation of therapy or short course of systemic steroids to control symptoms but no procedure needed
	Needs Procedure	No	Requiring arthrocentesis or MSK ultrasound to guide therapy
Diagnosis/Disease Complex	Complex	No	Complex multi-organ disease (i.e. Scleroderma/Dermatomyositis/Vasculitis) with worsening symptoms where diagnosis/treatment cannot be delayed/missed
Screening prior to in-person visit	Any	Yes	PCP calling for initial work-up recommendations or management questions
		No	If modality will lead to prolonged delay in follow up of complex disease
Failed Prior Tele-Health Visit	-	No	Prior bad experience or failure with modality
Hard of Hearing Or Poor Engagement	-	No	Poor ability to participate in care

RA=Rheumatoid Arthritis, PsA=Psoriatic Arthritis, SLE=Systemic Lupus erythematosus, MSK=Musculoskeletal, PCP=Primary Care Provider

Satisfaction with the Initial Evaluation for a Rheumatologic Complaint Using Telemedicine

Tracy Nguyen-Oghalai[1], Michael Lyon[2] and Kathy Hunter[3], [1]RHEUM, VA, Palo Alto, CA, [2]Internal medicine, Stanford University, stanford, CA, [3]Internal Medicine, VA Palo Alto, Stanford, CA

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Quality Measures and Quality of Care Poster Session

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Technological advances have facilitated the use of nontraditional forms of health care encounters, such as telemedicine. The aim of this study was to describe our experience using telemedicine for the evaluation of new patients referred to the Rheumatology Clinic at the Palo Alto VA.

Methods: This is a descriptive study of the initial rheumatologic evaluation using telemedicine conducted as a VA quality assurance project. Patients were seen at a community based outpatient clinic by a nurse practitioner (KH) with a Rheumatologist (ML) participating in the encounter via Telelink from our primary site. Patients completed a satisfaction survey immediately after this initial telemedicine encounter. All patients had a second visit in person with the same Rheumatologist (ML) at the primary site. A subsequent telephone survey was conducted by a different provider (TNO) to assess patient satisfaction with both telemedicine and in-person care methods. Patients were also asked if they had a preference for one or the other care method.

Travel data (mileage) were also collected for both visits.

Results: 37 patients underwent the initial telemedicine evaluation. All of these had a second in person Rheumatologist visit and completed both questionaires. Ten had chronic autoimmune conditions such as inflammatory polyarthritis, polymyalgia rheumatica , systemic lupus erythematosus, and ankylosing spondylitis; five had crystal arthropathies. The remaining 22 patients had non-inflammatory musculoskeletal conditions. Travel miles were less for all participants for the telemedicine visits relative to the in person visit with the Rheumatologist at the primary site.

Immediately after the telemedicine encounter, all patients gave a 10/10 rating for satisfaction. During the telephone survey after their in person visit with the Rheumatologist, 30 remained highly satisfied with the telemedicine encounter, 10/10. However, among patients with chronic inflammatory conditions or crystal arthropathies, 66% (10/15) preferred the in person visit. Among patients with non-inflammatory conditions 41% (9/22) preferred the in person visit with the Rheumatologist.

Preference	In person	telemedicine	Total
Crystal	4	1	5
Chronic autoimmune	6	4	10
No chronic autoimmune	9	13	22

Conclusion: Satisfaction with telemedicine visits was high, but patients with chronic inflammatory disorders or crystalline arthopathies preferred the in-person visits, despite greater travel distances

Barriers to Appointment Compliance and the Effect of Reminder Phone Calls on Lupus Clinic Show Rate in an Underserved Community

Anand Kumthekar[1] and Beverly Johnson[2], [1]Medicine, Albert Einstein College of Medicine/Jacobi Medical Center, Bronx, NY, [2]Jacobi Medical Center, Albert Einstein College of Medicine, Bronx, NY

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Quality Measures and Quality of Care Poster Session
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Appointment compliance is a nationwide problem with a higher prevalence in the underserved communities. For physicians it results in lost time, decreased efficiency, and for patients it results in dissatisfaction and reduced quality of care. The primary objective of this study was to identify major barriers to appointment compliance in an underserved lupus clinic. A secondary objective was to assess appointment compliance after an intervention involving reminder phone calls.

Methods:

We retrospectively assessed the clinic show rate at our lupus clinic serving a low income population with primarily Medicare/Medicaid or no insurance from November, 2013 to July, 2014. Appointment attendance was confirmed by using electronic medical records (EMR). A survey was designed based on the perceived barriers for appointment compliance from literature review, was piloted and then administered from July 1st,2014 to August 31st,2014. An intervention involving reminder telephone calls 1-3 days prior to the visit was implemented from September 1st,2014-April 30th,2015. IRB exemption was received for this study.

Results:

We collected survey results from 43 patients. The most common reason mentioned for missed appointments was forgetting the appointment date (46.5%). 13% responded that the appointment was cancelled by the clinic and 13% said they had family issues. 12% mentioned they did not have adequate child care and 11% said they did not receive an appointment before they left the clinic. Before the intervention, 352 lupus clinic appointments were analyzed with an average show rate of 58.8%. After the telephone reminder, we analyzed 378 patient visits with a show rate of 74.86%. Using Pearson's chi square test, the improvement in clinic show rate was statistically significant (p=0.046).

Study Period	Appointments Scheduled	Clinic Show Rate
Pre-Intervention	352	207 (58.8%)
Post-Intervention	378	283 (74.86%)

Conclusion:

Our study identifies barriers to care from the patient perspective in an underserved community. Limitations include the retrospective nature of the study and the pre and post intervention states were studied at different times of the year. Our data suggests that reminder phone calls significantly improves clinic show rates, which improves quality of care. In a multidisciplinary specialized lupus clinic serving a low income population we found that clinic show rate is related to lack of appointment reminders. Reminder phone calls are a low cost intervention with the potential for significant benefit and should be considered in similar low income lupus clinics.

No More No Shows: Improving the Appointment Reminder System at an Urban County Hospital Outpatient Rheumatology Clinic

Shire Beach[1], Sarah Goglin[2], Mary Margaretten[1,2], Laura Trupin[1] and Jinoos Yazdany[2], [1]University of California, San Francisco, San Francisco, CA, [2]Rheumatology, University of California, San Francisco, San Francisco, CA
First publication: September 29, 2015

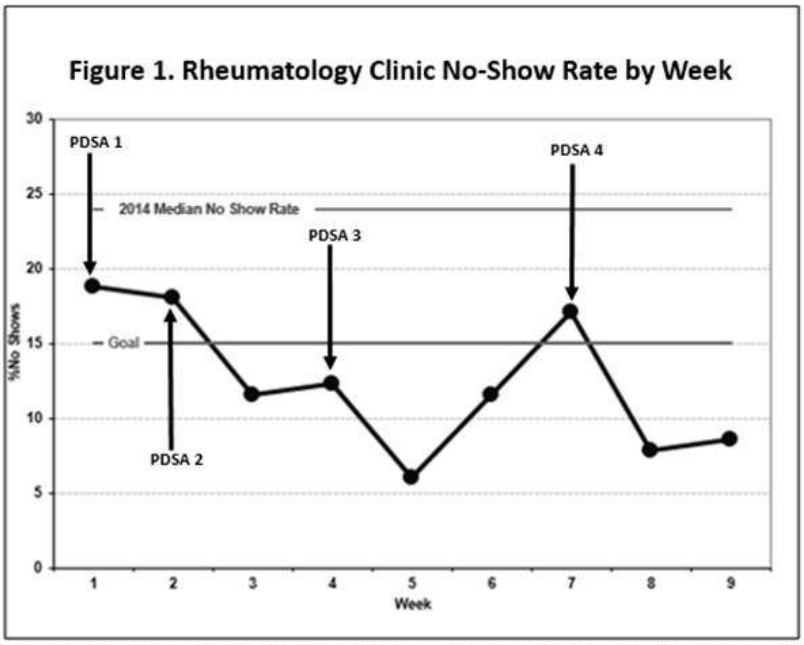
SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Quality Measures and Quality of Care Poster Session
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: High appointment no-show rates lead to disrupted delivery of care and inefficient use of healthcare resources. Appointment reminder calls are cost-effective in lowering no-show rates. Previous studies, however, have largely been performed among English-speaking populations. We aimed to improve the reminder call system at a county hospital rheumatology clinic with an at-risk multilingual patient population (Cantonese, Mandarin, Spanish and English). Using the Institute for Healthcare Improvement's Model for Improvement, we studied no-shows in this diverse population and used Plan-Do-Study-Act (PDSA) cycles to evaluate the effect of improving the clinic's appointment reminder system. Our specific aim was to reduce the no-show rate from 24%, the clinic's 2014 average, to 15% by May 2015.

Methods: First, we studied and mapped the current appointment reminder system. We developed a survey (in English, Spanish, and Chinese) to determine how clinic patients were reminded of their most recent appointment and their preferences regarding future reminders. We then used PDSA cycles to test changes to the reminder system. A multilingual clinic staff team (English, Spanish, Cantonese, and Mandarin) was assembled to deliver language appropriate reminder calls. Ultimately, this language specific call system was scaled up to include all English, Spanish, and Chinese speaking patients.

Results: While it was assumed that most patients received both letter and phone reminders for upcoming appointments, our survey (N=50) indicated otherwise; 60.3% received a letter, 27.6% received a call, 13.8% received both, and 22.4% received no reminder. Our survey also revealed patient preferences for future letter (68%), phone (54%), and text message (25.9%) reminders. These results helped focus our PDSA cycles on improving the phone call reminder system, since letters were received more reliably, and phone calls were preferred by many patients. Baseline data revealed an average no-show rate of 24% in 2014 (Figure 1). Four PDSA cycles were completed, with the final cycle resulting in more consistent reminder calls in multiple languages. The median no show rate between February and May 2015 (N=331) following implementation of the new reminder system decreased to 11.6%.

Conclusion: Coordination across clinic staff to form a multilingual team that delivered language appropriate reminder calls measurably reduced the no-show rate in our county hospital rheumatology clinic.



PDSA 1: 2 English speaking patients contacted; follow-up appointments only. **PDSA 2:** 37 English, Spanish, and Chinese speaking patients contacted. **PDSA 3:** 126 English, Spanish, and Chinese speaking patients contacted. **PDSA 4:** 166 English, Spanish, and Chinese speaking patients contacted; follow-up and new patient appointments.

Impact of Health Portal Enrollment and Electronic Appointment Reminders to Improve Appointment Attendance at an Academic Rheumatology Clinic

Arielle Mendel[1] and Shirley Chow[2], [1]Medicine, University of Toronto, Toronto, ON, Canada, [2]Division of Rheumatology, University of Toronto, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Quality Measures and Quality of Care Poster Session

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: 'No-shows' (NS) to ambulatory care reduce the quality and efficiency of healthcare delivery. We sought to identify patient, provider, and system factors associated with NS to 5 rheumatology clinics at an academic teaching hospital. We hypothesized that an online patient portal could have a role in reducing NS through electronic reminders.

Methods: We conducted a 6-month prospective chart review of consecutive NS to the clinics of 5 rheumatologists at Sunnybrook Health Sciences Centre (SHSC). A sample of NS patients participated in semi-structured telephone interviews and qualitative themes were identified. Clinic processes were studied with administrative staff participation. Patients were encouraged to enroll in MyChart™, the online patient portal at SHSC. In one clinic, an email appointment reminder was implemented for portal users. Clinic attendees were surveyed for their portal enrollment, receipt of the reminder, and satisfaction; NS occurrences were

monitored.

Results: Over 6 months there were 110 NS; rates varied among providers (2.5% - 6.8%) with a total estimated cost of >10 000$. Eighty-six (78.2%) were follow-ups, of which 57 (66%) had systemic autoimmune conditions and 51 (59.3%) were on DMARD and/or biologic therapy; 24 (28%) had active disease or severe symptoms at last visit; 22 (26%) had portal accounts. Among 28 follow-up NS interviewed, 14 (50%) forgot or were unaware of the appointment and 7 (25%) had the wrong date. The most common theme was the request for a reminder (57%). During the intervention, 120/274 (44%) surveyed patients had portal accounts. Of these, 73 (61%) received the email reminder and 72 (99%) found the email helpful. Twenty-two patients learned of the appointment from the email alone. Ninety-six percent of email recipients wanted future reminders compared with 90% of all portal users and 42% of non-portal users. Health portal enrollment did not increase, nor was an overall improvement in appointment attendance observed 4 months into the intervention.

Conclusion: Many NS are patients with systemic autoimmune conditions taking medications that require regular monitoring. Forgetfulness and date mix-ups were the most common reasons for NS. A simple email reminder has demonstrated high patient interest and satisfaction. Patients already enrolled in the portal were more receptive to email reminders, which may relate to increased comfort levels with Internet use. Future interventions could focus on improving patient portal access and addressing new patient NS.

Determining the Rate of Cardiovascular Risk Assessment in Patients with Rheumatoid Arthritis at Federally Qualified Outpatient Continuity Clinic – a Performance Improvement Project

Dewan Fahima[1] and Rafah Salloum[2], [1]Internal Medicine, Monmouth Medical Center, Long Branch, NJ, [2]Rheumatology, Monmouth Medical Center, Long Branch, NJ

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Quality Measures and Quality of Care Poster Session

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Studies have shown patients with rheumatoid arthritis (RA), a chronic inflammatory condition, have accelerated rate of coronary artery and cerebrovascular disease. Patients with RA, in particular women, are at a higher risk for silent MI. In addition to treating the underlying RA, aggressive monitoring and treatment of traditional risk factors must be addressed.

At our federally qualified health center (FQHC), as primary care physicians, while we may not prescribe biologics for our RA patients, we should focus on the traditional risk factors associated with cardiovascular disease (CVD). This performance improvement project was to examine if we as primary care physicians (PCP) at the FQHC, at the minimum, are addressing traditional modifiable risk factors for CVD in our RA patients.

Methods:

A retrospective chart review was performed. Patients were identified using clinic encounters with an associated ICD9 code for rheumatoid arthritis (714.0) in the EMR at our FQHC, from January 1, 2014 through December 31, 2014. Charts were searched to see if traditional risk factors for CVD according to the Framingham Heart Study were measured and/or addressed in 2014. They include age, diabetes mellitus (DM), smoking, systolic blood pressure, total cholesterol, HDL, and BMI. Charts were also

reviewed for documentation of smoking cessation and weight loss and lifestyle changes in patients with BMI greater than 25. The BMI was identified in one of the four categories, underweight (<18.5), healthy weight (18.5-24.9), overweight (25-29.9) and obese (>30).

Results:

A total of 78 subjects were identified. 14 were male and 64 were female. Mean age was 52 years. Of the 78 patients, 57% had their lipid profile examined and 42% did not. 17% of the RA patients had DM, of whom 79% were on anti-diabetes agent and 21% were not treated. In evaluating BMI in RA patients, 14% were healthy weight, 41% were overweight and 45% were obese. Of those who were overweight or obese, 70% had their BMI addressed and 30% did not. 26% of RA patients were smokers and of those 50% were educated regarding smoking cessation. 10% of the RA patients had documented uncontrolled hypertension either with or without anti-hypertensive agent.

Conclusion:

At FQHC as PCP, while we may not prescribe biologics to treat RA, we should at the minimum address the other modifiable risk factors such as hyperlipidemia, uncontrolled SBP, increased BMI and smoking for our RA patients. Currently, we are suboptimal at focusing in all of these factors. US Preventive Service Task Force recommends patients at higher risk for CVD, the age to begin screening lipid disorder is age 20. At our FQHC, it is only being tested 57% of the time and slightly above two thirds of the overweight or obese RA patients are being advised regarding weight loss and lifestyle modifications. Only half of the smokers were educated and informed regarding smoking cessation.

American Heart Association recognizes rheumatoid arthritis as a risk factor for atherosclerosis and increased risk of CVD. At FQHC, we need better adherence to ACR and AHA guidelines and goals of RA disease management. This may be achieved through interventions such as physician education, and use of clinical reminders in the FQHC, both of which are underway at this time.

Session Title: Quality Measures and Quality of Care Poster Session

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Invasive pneumococcal disease is approximately four times more common among patients with rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE) compared to healthy counterparts. In 2014, the Advisory Committee on Immunization Practices issued a new guideline recommending vaccination against pneumococcal organisms with the pneumococcal conjugate vaccine (PCV13) for all immunosuppressed patients, regardless of age, with the goal of reducing the rate of serious infections and

mortality among high-risk patients. Our goal was to increase the rate of PCV13 vaccinations in our immunosuppressed patients at an academic VA medical center.

Methods:

Plan-Do-Study-Act (PDSA) methodology was used over two cycles within a single clinic. Immunosuppressed patients were identified as those receiving any disease modifying antirheumatic drugs (DMARDs), biologic agents, or prednisone (dose > 10mg daily). PDSA Cycle 1 included (1) an investigator-led educational session for providers and (2) making the PCV13 vaccine available in the clinic. PDSA Cycle 2 involved the investigators identifying patients eligible for the PCV13 vaccine ahead of their clinic visit and pending the PCV13 order in the electronic medical record. Receipt of the vaccine was assessed via review of the electronic medication administration record. Provider recommendation of the vaccine was assessed by review of the clinical note. Reasons for patient refusal or lack of vaccine administration after provider recommendation were not consistently available.

Results:

Six rheumatology fellows and five faculty members participated in the quality improvement activity. Prior to the intervention, zero patients received a PCV13 vaccine in clinic as they were not available, with less than five patients receiving it outside of the clinic. PDSA Cycle 1 was 8 weeks long with 109 patients who were eligible for vaccination. 57 (52%) were recommended to have the vaccine and 35 (32%) received it. PDSA Cycle 2 was 6 weeks long with 44 patients who were eligible for vaccination, 36 (82%) were recommended to have the vaccine and 25 (57%) vaccinated (see Figure 1).

Conclusion:

One quality improvement lecture updating providers on new vaccination recommendations and availability of the vaccine can improve vaccination patterns amongst immunosuppressed patients. Identifying patients in need of vaccination prior to their clinic visit can improve vaccination rates even further.

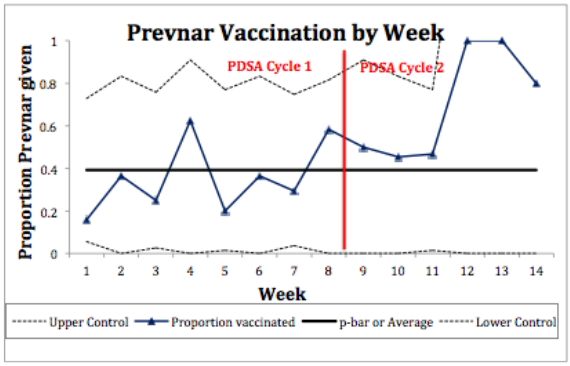

Figure 1: PDSA Cycle 1 and PDSA Cycle 2 are separated by a red bar. The dark blue line shows the proportion of patients vaccinated with PCV13. The upper and lower control limits describes the variation of the denominator as different numbers of immunosuppressed patients were seen in clinic each week. The p-bar is shows the average. More than six values are seen above the p-bar, indicating a successful change.

Session Title: Quality Measures and Quality of Care Poster Session

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Immunosuppressed patients are at higher risk for infections compared to the general population. Vaccines decrease morbidity and mortality, however vaccination status is not consistently addressed in clinic. It has been shown that lack of physician recommendation is a large barrier to vaccination. Pneumococcal vaccination is recommended for patients with rheumatoid arthritis (RA) by the American College of Rheumatology and Centers for Disease Control. The objective of this study was to evaluate and improve the pneumococcal vaccination rate in RA patients at an urban academic rheumatology clinic.

Methods:

A random sampling of 50 charts of patients with a diagnosis of RA from July 2013 were reviewed to determine the baseline pneumococcal vaccination rate. The rate was based on documentation in the electronic medical record (EMR) vaccination status section. Subsequently, 3 focus groups with rheumatology providers, including physicians, nurses, and medical assistants were conducted to discuss potential interventions to improve the vaccination rate. Based on this feedback, a multi-faceted approach was taken, including (1) an education program for providers regarding pneumococcal vaccination for immunosuppressed patients, (2) adding vaccination status to the EMR rheumatology note template, and (3) a pended order on patient's arrival to clinic. The protocol for the pended order begins with the medical assistant who reviews the patient's vaccination status and places a pended order if unvaccinated. The physician discusses vaccination with the patient and signs the order if in agreement, which is received by nursing who then administers the vaccine. The signed order automatically records the vaccination date in the vaccine section of the EMR. The vaccination rate for the post-intervention period in May 2014 was then determined from a random sampling of 50 charts of RA patients. The pre- and post-intervention rates were compared using a chi square test.

Results:

Age and gender demographics were similar in pre-intervention (mean age 52 years, 84% female) and post-intervention (mean age 57 years, 86% female) groups. The pneumococcal vaccination rate improved from 36% pre-intervention to 60% post-intervention (p=0.016), see Figure 1.

Conclusion:

This multi-faceted approach led to a statistically significant improvement in the pneumococcal vaccination rate in RA patients. The pended order and pre-loaded vaccination status section in the clinic note template both served as reminders for the physician to address pneumococcal vaccination. The education program gave providers published literature to support the decision to vaccinate. These processes have become standard in our rheumatology clinics, and we plan to extend this work to improve vaccination rates in all of our immunosuppressed patients.

Zoster Vaccination in Rheumatoid Arthritis Patients: An Unmet Care Gap

Alicia Meadows[1], Carson Maynard[2], Abraham Tacang[3], Jason Brown[4] and Eric Newman[5], [1]Rheumatology, Geisinger Health System, Danville, PA, [2]Internal Medicine, Geisinger Medical Center, Danville, PA, [3]Geisinger Medical Center, Danville, PA, [4]Henry Hood Center for Clinical Research, Geisinger Health System, Danville, PA, [5]Department of Rheumatology, Geisinger Medical Center, Danville, PA

Session Date: Tuesday, November 10, 2015

Session Title: Quality Measures and Quality of Care Poster Session

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Reactivation of the varicella zoster virus (shingles) creates a significant burden of healthcare dollars, lost work time, and extended suffering. Rheumatoid Arthritis (RA) and its treatments increase the risk of shingles 2-3x that of the general population. Despite the higher rate of reactivation and potential cost to healthcare, only about 5% of RA patients receive the zoster vaccine. Currently, the ACR recommends zoster vaccination for patients over age 60 on non-biologic DMARDs or prior to starting biologic therapy. We aimed to measure the size of our unvaccinated RA population, understand the barriers to vaccination, and develop a plan to increase shingles vaccination.

Methods: We gathered data on our RA patients over age 60 on Disease Modifying Antirheumatic (DMARD) therapy who have ever had shingles or the shingles vaccine prior to 5/29/15 using ICD-9 codes from the EPIC electronic health record. To establish why patients were un-vaccinated we surveyed RA patients at their routine clinic visits over 3 weeks. Patients were permitted to choose more than one answer. Demographics were recorded and survey results were tallied. System-wide baseline data on shingles diagnosis and vaccination rate was compared to that of our surveyed population.

Results: We surveyed 107 patients. 38 were excluded due to missing demographics, incorrectly completed surveys, not on DMARD, or < 50 years old (36%). 69 patient surveys were included for a total of 75 responses. System-wide, 211 out of 2259 RA patients on DMARD had a history of shingles (9.3%) compared to our survey group, where 5 out of 72 had a history of shingles (6.9%). System-wide, 184 out of 2259 received the vaccine (8.1%) compared to our survey group where 10 out of 72 (13.8%) received the vaccine. Of the patients who had a shingles diagnosis, 78 (40%) were on a DMARD at the time of diagnosis. Results of the survey are listed in the table below:

Survey Response	Number of Responses	Percentage
I am currently on a biologic	21	28%
I didn't know it was recommended or important	13	17.3%
It was never offered to me	13	17.3%
Other	11	14.7%
I've had the vaccine	10	13.8%
I had shingles less than 5 years ago	4	5.3%
The vaccine is too expensive	2	2.7%
I'm afraid of side effects	1	1.3%
I'm afraid of shots	0	0%
Total	75	100%

Conclusion: Our health system's zoster vaccine rate for RA patients was slightly above the national average but still leaves a considerable care gap. Since the largest unvaccinated population was started on a biologic prior to vaccination our biggest opportunity to close this care gap exists before patients start biologic. We believe a process change to integrate the zoster vaccine into pre-biologic initiation workflow would increase the vaccination rate. This coupled with a real time point-of-service quality measure tool actionable by the nurse and provider would provide timely feedback.

Session Date: Tuesday, November 10, 2015

Session Title: Quality Measures and Quality of Care Poster Session

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Women of child bearing age with autoimmune diseases are often prescribed teratogenic medications. Contraceptive compliance in this group of patients has been shown to be low. We conducted a quality improvement project to increase contraceptive compliance in eligible patients in the Duke Rheumatology outpatient clinic.

Methods: We reviewed charts of 18-45 year old women on teratogenic medications (methotrexate, leflunomide, mycophenolate and cyclophosphamide) to evaluate baseline contraception compliance in our practice. Contraceptive compliance was measured by reviewing documentation of 1) contraception type 2) counseling regarding contraceptives and 3) further intervention after counseling. Using Plan-Do-Study-Act (PDSA) methodology, we implemented a series of changes in our clinic based on periodic input from stakeholders. Interventions centered on inter-professional provider education, modification of the electronic medical record (EMR) templates, periodic provider reminders, in-clinic reminder sheets, and frequent feedback to providers on performance. During each monthly PDSA cycle, one week of patients' charts were reviewed for performance measurement.

Results: At baseline, eligible patients (n = 181 out of 3003 reviewed charts) rate of documentation for contraception usage was 46%, counseling was 33%, and interventions after counseling occurred in 33%. As shown in the run chart, initial education led to a non-sustained improvement in provider compliance. Modification of the EMR template improved provider compliance, but note cloning inhibited extended improvement. In-clinic reminder sheets, frequent feedback and periodic stakeholder discussions had a mixed impact. The rate of contraception type documented at the end of the project was 61%, contraception counseling was 67%, and further intervention performed after counseling was 100%. During this project, one unintentional pregnancy that led to miscarriage occurred in a patient on teratogenic medication not using contraception.

Conclusion: Overall, documentation of contraceptive type, counseling and intervention increased, but room for improvement remains. Every woman taking teratogenic medication should be using contraception, and even during a quality improvement effort in a single clinic, 100% compliance was not achieved. Therefore more creative solutions are needed, whether EMR-based alerts, provider incentives, personalized feedback, or a combination of interventions. Discovery of a miscarriage in a patient receiving one of these medications highlights the importance of the continued discussions with our patients.

Figure: Run chart demonstrating timing of interventions and rate change in contraception compliance

Session Date: Tuesday, November 10, 2015

Session Title: Quality Measures and Quality of Care Poster Session

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

This quality improvement project was conducted to increase patient education and routine pregnancy screening in girls of childbearing age prescribed teratogenic medications in the pediatric rheumatology clinic. There is currently no standard model for providing reproductive health education to young female patients taking teratogenic medications. We aimed to adapt the education and pregnancy screening practices recommended by Mycophenolate REMS (Risk Evaluation and Mitigation Strategy) to apply to all reproductive age girls prescribed teratogenic medications in our pediatric rheumatology clinic.

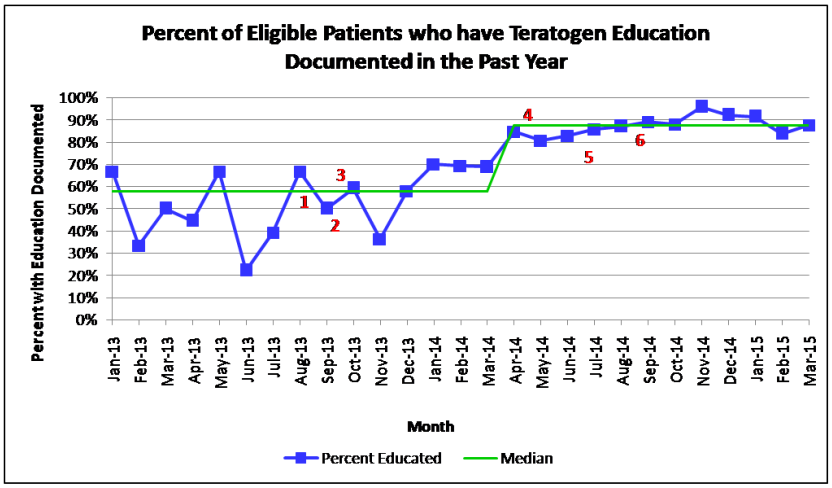
Methods:

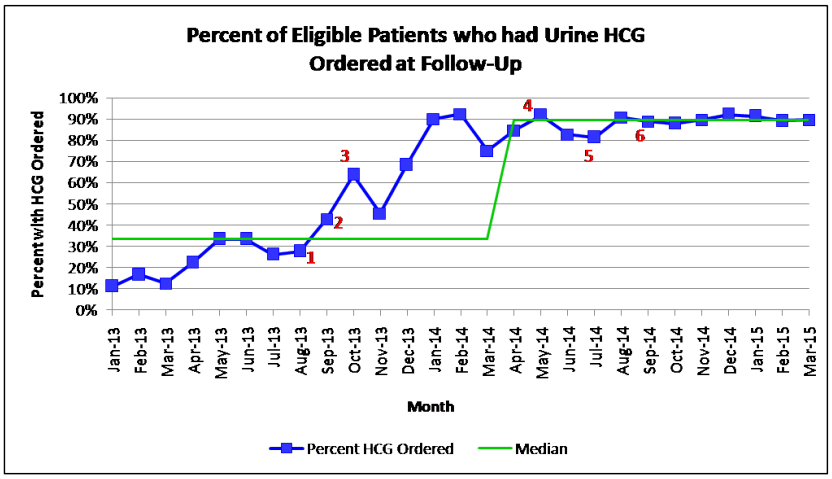
This project was initiated in a single center tertiary care rheumatology clinic comprised of 7 providers averaging 3500 visits per year. The medical records of 89 consecutive female patients age 10 and older receiving teratogenic medications were reviewed for documentation of teratogen education and pregnancy screening to establish our baseline practice. Six Plan-Do-Study-Act (PDSA) cycles were completed. Interventions included 1) visible project reminders in the clinic space, 2) targeted physician and 3) nurse education, 4) monthly progress updates, 5) pre-visit planning, and 6) development of an education template in the electronic health record (Figure 1). Ongoing chart review was performed throughout the project. Run charts were created for each aim to display improvement over time, and data reflecting overall improvement was analyzed by chi-square analysis.

Results:

At baseline, 42/89 (47.2%) female patients age 10 and older taking teratogenic medications had education documented within the last 12 months, and 21/89 (23.6%) had pregnancy screening performed at the visit. Implementation of our interventions resulted in improvement in documentation of ongoing teratogen education (616/767, 80.3%) and in routine pregnancy screening (630/767, 82.1%), both statistically significant ($p<0.0001$). Figure 1 depicts annotated run charts, which both contain shifts indicating special cause.

Figure 1. Annotated Run Charts Depicting Improvement Over Time





Intervention Key:

1) Teratogenic Medication List Posted in Clinic
2) Physician Education- Project rationale/procedures
3) Nurse Education- How to identify target patients during intake
4) Monthly Progress Updates
5) Pre-clinic Preparation Checklist
6) Education EHR Documentation Template

Conclusion:

Mindfulness of the teratogenic risks of immunosuppressive medications is important when managing adolescent patients with rheumatic disease. The interventions made through this quality improvement project increased the frequency of both teratogen education and urine pregnancy screening in these patients. Development of a simple, standardized education template in the electronic health record has helped sustain these improvements over time.

A Quality Indicator for the Screening of Latent Tuberculosis Infection and the Result of Follow-up Interferon-Gamma-Release Assays in Patients with Rheumatic Disease Receiving Biologic Agents in a Japanese Hospital

Yasuhiro Suyama[1,2], Mitsumasa Kishimoto[2], Chisun Min[3], Yuko Kataoka[2], Masei Suda[2], Ryo Rokutanda[2], Yukio Matsui[2], Ken-

ichi Yamaguchi[2], Tokutaro Tsuda[2], Shunya Kaneshita[2], Hisanori Shimizu[2] and Masato Okada[2], [1]Rheumatology, JR Tokyo General Hospital, Tokyo, Japan, [2]Immuno-Rheumatology Center, St. Luke's International Hospital, Tokyo, Japan, [3]Division of Allergy and Rheumatology, St. Luke's International Hospital, Tokyo, Japan

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Quality Measures and Quality of Care Poster Session
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Infection is one of the most devastating side effects of biologic agents use, particularly early on in the course of therapy. Prevention is considered to be more important than treatment, especially in patients with known risk factors. Quality indicators (QI) has been received an increasing attention in rheumatology field and several guidelines for the prevention of biologic agents-related infections have been published, and they recommended the screening tests for hepatitis, latent tuberculosis infection (LTBI), and pneumocystis pneumonia (PCP) before starting biologic agents. However, few studies have reported the status of the implementation as well as interventions to improve its adherence in clinical settings. Herein, we repot the efficacy of monitoring for the improvement of LTBI QI for the use of biologic agents in the treatment of rheumatic disease.

Methods: We studied retrospectively all patients who had received biologic agents (TNF and non-TNF agents) for the treatment of rheumatic diseases in our department. To evaluate the adherence of a minimal standard of care for the pre-administration screening for LTBI, we monitored a LTBI bundle (chest image, tuberculosis skin test [TST] or INH prophylaxis, and interferon-gamma-release assays [IGRAs]). Since 2010, we had started a LTBI bundle for the use of biologic agents in the treatment of rheumatic disease and clinical date from January 2007 to December 2014 were collected to evaluate the proportion. In addition, we also evaluated the results of follow-up IGRA for detection of latent and newly developing tuberculosis.

Results: We identified 342 eligible patients. The analysis of data showed increases of targeted after the investigation. Adherence to the QIs improved from 82% to 99% in LTBI bundle. We also assessed 170 patients with a negative or indeterminant IGRA results in the initial LTBI screening and evaluated by follow-up IGRA test after starting biologic agents, which showed 7% of IGRA positive conversion. Active tuberculosis was not reported in our study.

Conclusion: Implementation of monitoring of quality indicators based on guidelines leads the safety for the use of biologic agents in the treatment of rheumatic disease. Our results also indicate that although the evidence for the repeated IGRA and the positive conversion after starting biologic agents in patients with rheumatic diseases is lacking, follow-up IGRA test may be useful to prevent the activation of LTBI in areas that have a high incidence of active TB such as Japan.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Quality Measures and Quality of Care Poster Session

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Lupus nephritis not only decreases survival, but also its costs are substantial, likely due in part to deficits in care (Carls et al., 2009). A previous study by Yazdany et al (2014) showed that care varied with individual factors such as age and race.

We assessed the quality of care provided to LN patients at our rheumatology clinic according to the 2012 ACR guidelines, and analyzed whether race, age, and/or insurance status influence care.

Methods:

A retrospective chart review is performed on patients identified by the ICD9 code for LN (583.81). We exclude patients without a definite diagnosis of LN based on ACR criteria or with limited records. Since quality indicators were first published in 2009, patient data from 1/1/2010 to 10/31/2014 is collected.

Data is recorded as % adherence to the 2012 ACR guidelines (Hahn et al., 2012), which include renal biopsy indications, adjunctive treatments, and induction and maintenance therapy.

Active LN is defined by the 2012 ACR criteria, and a treatment response or relapse is defined by the 2006 ACR criteria. Inclusion and exclusion criteria, outlined by the 2012 ACR guidelines, are adhered to. Chi-squared test compares treatment compliance among insurance status, race, and age. Wilcoxon rank-sum test and Kruskal-Wallis test analyzes age as a continuous variable in relation to treatment compliance. Statistical analysis is performed using SAS 9.3®.

Results:

A total of 30 patients meeting ACR criteria for LN were included. Renal biopsy was done in 90% of patients. HCQ was offered to 100% of patients. In patients with proteinuria (n=26), 70% were treated with renin-angiotensin system blockade. A statin was given to 31% of patients (n=16), and an anti-hypertensive was given to 79% of patients (n= 14).

In patients with class III or IV disease (N=19), all patients were given appropriate induction. Maintenance glucocorticoids (GCs) were given to 95% (n=18) of patients. The majority was followed for 6 months before a treatment change (68%), and had induction within 1 month of diagnosis (68%).

In patients with class IV or IV/V disease (N=15), all patients were given appropriate induction and maintenance GCs were given to 64% (n=9) of patients, although 3 patients were not on the higher-range dosage.

In patients with class V disease (N=9), 22% of patients (n=2) were treated according to guidelines.

In patients treated with induction therapy for 6 months (N=25), 15 patients (60%) responded. Of those that did not (n=10), therapy was not switched in 5 patients (50%).

No significant association was found between race, age, or insurance type and compliance to any of the measures.

Conclusion:

There was good compliance to renal biopsy and adjunctive treatments, except for statins. This may be due to overlooking the utility of statins in LN for younger patients.

There was good compliance to initiating induction, maintenance GCs, early induction therapy, and monitoring for 6 months.

Our study was limited by its small sample size, which may have obscured significant associations.

An electronic system that collects data relevant to LN response criteria in a central location may improve therapy adjustments. Also, provider education in class V induction may improve adherence.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Quality Measures and Quality of Care Poster Session

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: One-fourth of hip fractures occur in men. Men treated with oral glucocorticoids for at least 3 months are particularly at risk. Studies have suggested that rapid bone loss begins early in steroid use, peaks at 6 months and slows with continued usage. Inflammatory disease induced hypogonadism may also increase fracture risk by lowering testosterone secretion. Male patients over the age of 50, especially with chronic rheumatic diseases on long term steroids may not be receiving adequate osteoporosis screening or treatment compared to females.

Methods: An IRB approved retrospective chart review was performed to identify male patients ≥ 50 years with a rheumatic diagnosis to compare them to age matched women in our academic practice from 2010 to 2013. Inclusion criteria were patients on any dose of prednisone for ≥ 3 months and at least 3 clinic visits. Exclusion criteria were recognized osteoporosis and prior bisphosphonate use. Demographic data, dose and length of steroid use, timing of DXA from initiation of prednisone use, T-score and calcium and vitamin D supplementation use was collected. Optimal care was defined as screening with a baseline DXA within 6 months of initiation of prednisone, calcium and vitamin D supplementation and osteoporosis treatment or prophylaxis when indicated. Patients not meeting these criteria were defined as receiving sub-optimal care. Fisher's exact test was used to compare categorical variables. A binary logistic regression model was run to account for any differences that age, ethnicity or diagnosis may have on the outcomes between the two groups.

Results: 100 male patients met the inclusion criteria. 100 women were then randomly age matched to the men. Average age was 63.4 vs 66 (M:F); 50% vs 52% (M:F) were African American and 31% vs 32% (M:F) had Rheumatoid Arthritis. 82% of females were on calcium-vitamin D vs 53% of men (P< 0.001). 82% of women had T-scores available vs 57% of men. DXA readers ordered more scans. Faculty < 5 years from training provided more optimal care. (61% vs 33% (> 5 years); p < 0.001). Osteoporosis screening for vasculitis spectrum diseases was more likely compared to other diseases in both groups. (Figure 1) Overall **67%** woman received optimal care in comparison to **22 %** men (**p = 0.001)**.

Conclusion: To our knowledge, our study is the first to analyze trends primarily in patients with chronic inflammatory disease in a large academic rheumatology practice. Physicians who were DXA readers for the clinic were more likely to order a DXA although notably not better with optimal care. Recent graduates were better at osteoporosis management overall. Men were 8 times *less* likely to receive optimal osteoporosis management as compared to women. This highlights gender gaps in management of osteoporosis in a vulnerable population with inflammatory diseases taking steroids.

Outpatient Consultation Requests: A Failure to Communicate

Andrew Sharobeem[1], Haritha Bellam[1] and Rafael Grau[2], [1]University of Arizona, Tucson, AZ, [2]Rheumatology, University of Arizona, Tucson, AZ

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Quality Measures and Quality of Care Poster Session

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Early diagnosis and intervention are central premises in the management of patients with rheumatic diseases. Nevertheless, due to the shortage of rheumatologists, patients are often subject to significant delays before consultation with rheumatology can occur. A shortage of consultants and the large demand for consultations has forced us to review consult requests and determine reasonable time periods for new outpatient referrals. We reviewed new referrals to determine if information provided was sufficient to facilitate appointment allocation and timely consultation.

Methods: We reviewed the records of 300 consecutive referral requests, over 2 months, to our service. Due to a lack of capacity, patients were triaged as routine (3 months), semi-urgent (≤2 months), urgent (≤1 month), or declined. All determinations were reviewed by a second provider (RG) and adjusted as necessary. In our review, we looked for key clinical data defined as: a referral diagnosis, mention of duration and location of pain, a musculoskeletal examination (MSK) mentioning swelling and pain (MSK), laboratory results, specifically RF, CCP, and ANA, and pertinent imaging studies. For purposes of this analysis, we

combined the urgent and semi-urgent groups. Logistic regression and multinomial logistic regression were used.

Results: The most common referral diagnosis was connective tissue disease (CTD), which included rheumatoid arthritis and systemic lupus erythematosus (43%), followed by nonspecific musculoskeletal pain (30%). Of the reviewed referrals, 58% were considered routine, 11% were either semi-urgent or urgent and 31% were declined. Information on location and/or duration of pain was provided for 55% of the referrals, examination findings of swelling and/or tenderness were provided for 38%, laboratory tests were provided for 39%, and imaging was provided for only 22%. 77% had data on at least one key clinical feature and this increased the odds of the referral being accepted ("Routine" or "Urgent") 1.64 (95% CI: [0.93-2.87]) with "Decline" as the reference. In multivariate modeling, MSK, laboratory, imaging and pain data all increased the odds of being accepted. Having information on both MSK elements increased the odds of the referral being accepted (OR=3.58 (95% CI: [1.20, 10.67], p=0.02). Imaging information also improved the odds of the referral being accepted (OR= 2.77 (95% CI: [1.11, 6.92], p=0.02).

Conclusion: We have found that referrals to our rheumatology practice often provide insufficient information to make the appropriate decisions regarding timely patient care. Targeted key information is critical and must be obtained from the referring health care providers. There is a need to improve communication with referring providers. Standardizing referral protocols can assist in facilitating timely scheduling of referrals, particularly patients with CTD.

Session Date: Tuesday, November 10, 2015
Session Title: Quality Measures and Quality of Care Poster Session
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Primary care physicians (PCP) often play a central role in the early detection and referral for patients with rheumatic diseases. Our aim was to characterize referrals from PCPs to rheumatologists and investigate diagnostic and treatment patterns of PCPs prior to rheumatologist consultation.

Methods: We performed a retrospective chart review and an analysis of structured and semi-structured data within the primary care Electronic Medical Record Administrative data Linked Database (EMRALD), representing comprehensive EMR data from 168 PCPs across Ontario, Canada. We identified patients with first-time rheumatology referrals. Using a standardized data abstraction tool, PCP and rheumatology consultation records were reviewed to identify diagnoses and treatments associated with each referral. Referrals were characterized in terms of patient demographics, provisional diagnoses/clinical impressions, laboratory diagnostic tests and treatment initiated by PCPs, and other specialists seen for the complaint prior to rheumatology referral.

Results: Among 2430 patients referred to rheumatologists, 69% were female and the mean (SD) age at time of referral was 53

(16) years. Reasons for referrals included: mechanical/degenerative conditions (787; 32%), systemic inflammatory rheumatic diseases (745; 31%), regional MSK conditions (395; 16%), chronic pain conditions (346; 14%), osteoporosis/osteopenia (45; 2%), and other (e.g., abnormal labs, 112; 5%). Systemic inflammatory rheumatic disease referrals included inflammatory arthritis (287; 38%), connective tissue diseases and other systemic autoimmune rheumatic diseases (e.g., lupus, scleroderma, Sjogren's, Raynaud's) (131; 18%), gout/crystal arthropathies (122; 16%), spondyloarthropathies (120; 16%), polymyalgia rheumatica (66; 9%), and vasculitis (19; 3%). Laboratory testing done within the 3 months prior to referral is as noted in Table 1. Among the 745 systemic inflammatory patients, 22% were also seen in the emergency room for their complaint prior to seeing the rheumatologist, and 61% received treatment by their PCP (48% received NSAIDs/COXIBs, and 20% received corticosteroids). For patients diagnosed with rheumatoid arthritis, 72% received treatment by their PCP (53% received NSAIDs/COXIBs, 27% received corticosteroids, and 6% received DMARDs). The time from 1st PCP visit for the rheumatic disease complaint to date of referral exceeded 100 days for each type of systemic inflammatory rheumatic disease, except vasculitis (table).

Conclusion: We present novel data on PCP management of patients prior to rheumatology referral. Approximately 1 in 3 PCP referrals to rheumatologists were referred for a systemic inflammatory rheumatic disease. Understanding the referral patterns of PCPs can identify opportunities to improve PCP management of patients prior to rheumatology referral.

Depot Medroxyprogesterone Acetate Birth Control May Suppress Toll-like Receptor 7-Induced Interferon-Alpha Production By Plasmacytoid Dendritic Cells in Women

Yuli McCann[1], Meredith Barnes[1] and Grant Hughes[2], [1]Medicine, University of Washington, Seattle, WA, [2]Medicine/Rheumatology, University of Washington, Seattle, WA

Session Date: Tuesday, November 10, 2015

Session Title: Reproductive Issues in Rheumatic Disorders: Basic and Clinical Aspects Poster Session

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Female sex steroids are important modulators of autoimmunity. Estrogen appears to favor the development of lupus autoimmunity via activation of adaptive and innate immune responses, especially type 1 interferon (IFN) (e.g., IFN-a). In contrast, progesterone may have protective effects. In mice, treatment with depot medroxyprogesterone acetate (DMPA, a widely used contraceptive) suppresses IFN-a production and the emergence of lupus-like autoimmunity. In vitro, DMPA selectively inhibits IFN-a release from human plasmacytoid DCs (pDCs), a major source of IFN-a in SLE patients. Whether DMPA suppresses IFN-a production by pDCs in humans is unknown.

Methods:

Peripheral blood mononuclear cells (PBMCs) were isolated from healthy women immediately before and 2 weeks after first dose of DMPA birth control and stimulated with toll-like receptor (TLR) 3, 7 and 9 specific ligands to induce IFN-a production, which was assayed by ELISA. Under these conditions, all measurable IFN-a induced by TLR7 and TLR9 ligands comes from pDCs. In addition, percentages and activation status of various PBMC subsets were determined by flow cytometry. Paired t-tests were used to compare pre- and post-DMPA values. RNA from PBMCs was stored for later analysis.

Results:

DMPA treatment had no statistically significant impact on IFN-a production. However, in 3 of the 4 subjects tested, DMPA markedly reduced TLR7-induced IFN-a production by pDCs, which could not be accounted for by changes in pDC numbers. In these same 3 subjects, DMPA generally increased TLR9-induced IFN-a, suggesting that DMPA can selectively suppress IFN-a production by pDCs encountering TLR7 ligands, e.g., RNA-containing lupus immune complexes or RNA viruses. There were no consistent effects on PBMC subset numbers or activation status, except in the case of B cell percentages, which were significantly increased after DMPA treatment.

Conclusion:

In healthy women, DMPA may selectively suppress TLR7-induced IFN-a production by pDCs, an innate immune pathway involved in lupus pathogenesis as well as protection against RNA viruses. Thus, DMPA could be a dual-benefit contraceptive for certain SLE patients. On the other hand, DMPA's ability to suppress protective IFN-a responses may help explain why women using DMPA in HIV-endemic areas are at increased risk of HIV infection. Further investigation into the immunomodulatory properties of this widely used form of contraception is warranted.

Contraception Use Amongst Women Ages 18-45 Taking Known Teratogenic Medications in an Academic Rheumatology Clinic

Rebecca Sadun, Nicholas Holdgate, Melissa Wells, Megan E. B. Clowse, Lisa Criscione-Schrieber, Stephen Balevic, Victoria Lackey, Samya Mohammad and Erica Peart, Rheumatology, Duke University Medical Center, Durham, NC

Session Date: Tuesday, November 10, 2015

Session Title: Reproductive Issues in Rheumatic Disorders: Basic and Clinical Aspects Poster Session

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with autoimmune diseases are often prescribed medications that are known to be teratogenic. Amongst women of child-bearing ages taking such medications, roughly half adhere to contraceptive guidelines. We sought to describe the contraception practices of women of child bearing age prescribed a teratogenic medication in our academic medical center outpatient rheumatology clinic.

Methods: In an academic rheumatology clinic, women ages 18 to 45 years old were screened for use of methotrexate, leflunomide, mycophenolate, and cyclophosphamide. A retrospective chart review was conducted on eligible women to determine the type of contraception documented. This project was part of an IRB-approved quality improvement project to assess rates of contraception documentation and contraceptive counseling. 3003 charts were reviewed, representing 12 one-week blocks over a period of ten. Descriptive statistics were used to quantify patient demographics and the percent of patients using each type of contraception. Women were grouped based on the relative effectiveness of contraceptive based on the pregnancy rate with 'usual use': "highly-effective"(≥95%), "moderately effective" (90-94%), or "ineffective" forms of birth control. We included abstinence in the "ineffective" group as it is only effective if practiced 100% of the time and many women in this group do not have a plan for contraception.

Results: We reviewed 3003 charts; 181 women between ages 18-45 took a teratogenic medication. The average age of eligible women was 34. Most women were receiving methotrexate (49%), followed by mycophenolate (41%), leflunomide (6%), cyclophosphamide (3%) and combination medications (2%). Of the 181 women, 67 had did not have a form of contraception documented, leaving 114 patients for whom we could describe contraception type. Of those with documented contraception, 20% were unable to conceive due to hysterectomy or menopause and another 24% were on highly effective contraception (Table). Another 29% were on effective contraception. Only 24% were on ineffective contraception and the majority of these were women who reported abstinence.

Conclusion: In this study, we found that the majority of women between ages 18-45 on teratogenic rheumatologic medications in an academic practice were either unable to conceive or on effective or highly effective contraception. Importantly, we identified a primary target cohort of patients not using any form of contraception (abstinence only) or using condoms only.

Table 1: **Type of Contraception documented (n = 106); 5-year effectiveness statistics from the Centers for Disease Control and Prevention (CDC)**		
	Number (%) of patients on type of contraception	Estimate effectiveness over a 5-year period given typical usage
HIGHLY EFFECTIVE:	***49 (46%)***	
Hysterectomy	19 (17%)	100%
Menopause	3 (3%)	n/a
Tubal Ligation	16 (14%)	99.5%
Intrauterine device (IUD)	11 (10%)	99.5%
EFFECTIVE:	***31 (29%)***	
Oral contraception pills (OCP)	15 (13%)	91%
Medroxyprogesterone acetate	14 (12%)	94%
Ring	1 (1%)	91%
Patch	1 (1%)	91%
INEFFECTIVE:	***26 (24%)***

Session Title: Reproductive Issues in Rheumatic Disorders: Basic and Clinical Aspects Poster Session

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Polymyositis (PM) affects female gender during reproductive age. Ovarian reserve and future fertility are relevant, however there is no study performing a complete assessment of ovarian function in these patients.

Methods: From March 2011 to May 2014, 32 female PM patients (Bohan and Peter criteria, 1975), with age 18-40 years old, followed at the Outpatient Myopathy Clinic, Rheumatology Division of our tertiary center were screened. Twenty-four patients were excluded due to unwillingness to participate(n=8), hormonal contraceptive use(n=6), other autoimmune diseases(n=5), neoplasia(n=2), gynaecological surgery(n=2) and current pregnancy(n=1). Thus, a total of eight PM patients and 16 healthy

volunteer age-matched women were enrolled in the study. All PM patients and healthy controls were evaluated at early follicular phase of menstrual cycle. Follicle stimulating hormone (FSH), estradiol, inhibin B and anti-Müllerian hormone (AMH) serum levels (ELISA) were determined. Transvaginal ultrasound was performed in all PM patients and controls by a blind sonographer using a 6.5 MHz endovaginal transducer. Ovarian volumes and antral follicle count (AFC) were also assessed.

Results: PM patients and controls had comparable mean age (31.4±6.5 *vs*. 30.7±6.2 years, *P*=0.946), ethnicity and socioeconomic class (*P*>0.05). PM mean age of onset was 27.3±6.5 years and disease duration of 6.5±4.1 years. Menstrual cycles were alike in both groups with a similar frequency of age at menarche, gynecological age, duration and length of menstrual cycle (*P*>0.05). The median serum level of AMH was significantly lower in PM compared to controls [0.7(0.3-3.4) *vs*. 3.1(1.4-4.0), *P*=0.021] and AMH levels ≤1ng/mL (50%*vs*. 6.3%, *P*=0.024) and very low AFC (37.5% *vs*. 6.3%, *P*=0.037) were more frequently observed in PM. The other ovarian reserve parameters (ovarian volume, FSH, inhibin B and estradiol levels) were similar in both groups (*P*>0.05). With regard to drugs, 6/8 (75%) were exposed to potentially gonodotoxic agents, one (12.5%) was treated with intravenous cyclophosphamide with a cumulative dose of 15g and five (62.5%) were treated with high cumulative methotrexate dose (>5g/m^2). Of these six exposed patients, 4 (67%) had low AMH levels and 3 (50%) had concomitant very low AFC.

Conclusion: The present study was the first to identify a subclinical ovarian dysfunction in PM patients during reproductive ages possible associated with a gonadotoxic effect of immunosuppressive drugs on ovarian follicular pool.

MEK5/ERK5, a Lynchpin of Human Cardiac Fibroblast Transdifferentiation to a Scarring Phenotype in Autoimmune Congenital Heart Block

Andrew Markham[1], Robert Clancy[2], Mukundan Attur[3] and Jill P. Buyon[2], [1]Medicine, New York University School of Medicine, New York, NY, [2]Medicine, Division of Rheumatology, New York University School of Medicine, New York, NY, [3]Rheumatology Research, NYU - Hospital for Joint Diseases, New York, NY

Session Title: Reproductive Issues in Rheumatic Disorders: Basic and Clinical Aspects Poster Session

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Transplacental passage of maternal autoantibodies (Ab) reactive with the SSA/Ro-SSB/La ribonucleoprotein complex is associated with the development of cardiac injury in the fetus passively exposed to these Ab. However, antibodies are necessary but insufficient to cause disease, and the final pathway to this rapid fibrosis may be variable: kept totally in check in most fetuses (normal sinus rhythm), subclinical in others (first-degree block), and fully executed in very few (advanced block, fibrosis and macrophage infiltration). This study was initiated to evaluate a novel profibrosing candidate, MEK5/ERK5 of the mitogen activated protein kinase (MAPK) pathway, which in the context of anti-Ro antibodies may prime fetal cardiac fibroblasts toward an irreversible scarring phenotype characteristic of heart block.

Methods:

Primary human fetal cardiac fibroblasts were treated with secreted products generated from activated macrophages (an in vitro model of heart block) or TGFβ in the presence and absence of BIX 02189 (10uM), a specific MEK5/ERK5 inhibitor. The phenotype was evaluated by the profile of profibrotic genes including ACTA2, MMP-13, and PAI-1 (qRT-PCR), and expression

of α-smooth muscle actin (α-SMA, indirect immunofluorescence).

Results:

Treatment of human fetal cardiac fibroblasts with supernatants from macrophages transfected with hY3, an ssRNA associated with Ro60 (surrogate for immune complexes), induced the expression of the myofibroblast marker α-SMA, which was inhibited by co-treatment with BIX 02189 (immunofluorescence, N=3). As expected, macrophage supernatants increased fetal fibroblast mRNA expression of ACTA2, the gene encoding α-SMA, by 4-fold (24 hr), which was completely attenuated by co-treatment with BIX 02189. In parallel conditions, other profibrosing biomarkers, including MMP-13 and PAI-1 transcripts, were similarly upregulated and subsequently inhibited by BIX 02189 (MMP-13: 15.91 vs. 3.06, respectively; PAI-1: 2.27±0.1 vs. 0.84±0.1, respectively, p=0.01, N=3). Since previous work has shown that supernatants from macrophages incubated with anti-Ro immune complexes induced the fibroblast secretion of TGFβ, this cytokine was evaluated as a comparison to the fibrotic "potency" of the macrophage supernatants. TGFβ showed a similar yet less marked upregulation of the profibrotic genes MMP-13 and PAI-1, which was significantly inhibited by co-treatment with BIX 02189.

Conclusion:

These data identify the MEK5/ERK5 pathway in fetal cardiac fibroblasts as a novel and coverable target to forestall the progression of cardiac injury toward irreversible fibrosis induced by anti-Ro immune complex activated macrophages.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Reproductive Issues in Rheumatic Disorders: Basic and Clinical Aspects Poster Session

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic autoimmune disorders may interfere with normal reproductive function resulting in negative outcome of pregnancy. Primary Sjögren's syndrome (pSS) is a common rheumatic disease that mostly effects females. There are many reports that this condition may increase risk pregnancy complications and fetal loss. However, data regarding these adverse outcomes are scarce and inconclusive. We performed a systematic review and meta-analysis of available articles that assess association between pSS and adverse pregnancy outcome.

Methods: We comprehensively searched the databases of MEDLINE and EMBASE from their dates of inception to June 2015 and reviewed papers with validity criteria. Random-effects model were used to evaluate pregnancy complications in patients with pSS and healthy control.

Results: From 20 full-text articles, 7 studies involving 544 patients and 1586 pregnancies were included in the meta-analysis. Fetal complications included spontaneous abortion, stillbirth, neonatal deaths, and intrauterine growth retardation. Compared with healthy pregnancy, patients with pSS had significantly higher chance of neonatal deaths (pooled OR=1.77, 95% CI: 1.28 to 1.46, p=0.01). However, there were no significant association between pSS and premature birth (OR=2.10, 95%CI 0.59-7.46, p=0.25), spontaneous abortion (OR=1.46, 95%CI 0.72-2.93, p=0.29), artificial abortion (OR=1.12, 95%CI 0.52-2.61, p=0.71), and still-birth (OR=1.05, 95%CI 0.38-2.97, p=0.92).

Conclusion: There is an increased risk of fetal loss in pregnant patients with primary Sjogren's syndrome. The presented evidence further supports multidisciplinary care for these patients to prevent complications during pregnancy.

Session Date: Tuesday, November 10, 2015

Session Title: Reproductive Issues in Rheumatic Disorders: Basic and Clinical Aspects Poster Session

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: 1. To study the effect of pregnancy in PSS patients on oral and ocular dryness and the salivary test for dental caries activity. 2. To study the effect of pregnancy on thyroid function in PSS patients with positive anti-thyroid antibodies (anjti-thyroglobulin and / or anti-peroxidase).

Methods: A prospective study was conducted throughout pregnancy in 12 PSS patients.

The following tests were performed at first visit and then monthly until the end of pregnancy: Schirmer tear secretion test; Whole saliva test (Heintze et al); Questionnaire on oral symptoms (Neidermaier 1998); Questionnaire on dry-eye symptoms (DEQ) (Begley et al).

To test dental caries activity, saliva samples were obtained from all patients during the first month of pregnancy and again at 3, 6 and 9 months. The following tests were performed: CRT® Buffer test was used to determine the buffering capacity of saliva to reduce pH changes; Alban® test) (0-4) was used to measure the ability of saliva to produce acid because of the microorganisms it contains; CRT bacteria system for LB and SM® was used to measure salivary levels of *Lactobacillus* (LB) and *Streptococcus mutans*(SM).

Thyroid function was prospectively studied during pregnancy in those PSS patients with positive anti-thyroglobulin and / or anti-peroxidase antibodies (n=10). At the first visit, then monthly to the end of pregnancy, TSH and free T4 were measured in all patients.

Results:

1. No significant changes in Schirmer test or whole saliva test results were observed during pregnancy. No significant changes were observed in the results of the two questionnaires.

2. The results of caries activity tests are presented in the table below:

	Patients with PSS during pregnancy (n=12)			
	1 month	3 months	6 months	9 months
CRT buffer (pH) – mean (SD)	4.9 (0.5)	4.6 (1.1)	4.3 (0.6)	4.0 (1.0)
Alban test (0-4) – mean (SD)	3.2 (0.3)	3.4 (0.4)	3.4 (0.6)	3.6 (1.1)
CRT bacteria for LB (% patients with levels ≥100.000 CFUs/mL saliva)	73.2	81.2	81.8	84.4
CRT bacteria for MS (% patients with levels ≥100.000 CFUs/mL saliva)	69.5	70.1	82.9	83.3

3. Four patients presented normal physiological changes in thyroid function during pregnancy. Three patients showed higher than normal TSH levels while maintaining normal free T4 levels. Three patients had elevated free T4 during pregnancy. Five patients were prescribed treatment with levothyroxine to maintain TSH levels within the range recommended during pregnancy.

Conclusion:

Pregnancy did not significantly alter the characteristics of xerophthalmia and xerostomia in patients with primary SS. However, periodic salivary tests for dental caries risk showed a gradual decline in the buffering capacity of these patients' saliva, as well as an increase ability to produce acid. The proportion of patients with high SM and LB values also increased as pregnancy progressed.

The presence of anti-thyroid antibodies, a common finding in patients with PSS, is a risk factor for the development of hypothyroidism during pregnancy.

Does the Cytokine Pattern, Including the IL23 – IL17 Immune Axis, Change in Pregnant Women with Psoriatic Arthritis?

Andrea Pluma-Sanjurjo[1], Peter M. Villiger[2] and Frauke Förger[3], [1]Rheumatology, University Hospital Vall d'Hebron, Barcelona, Spain, [2]Professor & Head, Bern, Switzerland, [3]Rheumatology, Clinical Immunology and Allergology, Inselspital-University Hospital, Bern, Switzerland

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Reproductive Issues in Rheumatic Disorders: Basic and Clinical Aspects Poster Session

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

During pregnancy, most patients with Psoriatic Arthritis (PsA) experience a natural improvement of their symptoms. This might be due to the immunological changes that occur in normal pregnancy to allow tolerance to the semiallogeneic fetus. Pregnancy induces a down-regulation of the adaptative immune system and generates a specific cytokine milieu. The balance between T helpers cells (Th), Th1/Th2/Th17, depends on the cytokine milieu and interleukin (IL) 23 promotes the expansion and survival of Th17 cells. The IL23-IL17 axis is up-regulated in PsA.

Objective:

The aim of our study is to investigate changes of the cytokines pattern with focus on the IL23-IL17 immune axis during and after pregnancy in PsA patients compared with non-pregnant PsA patients and healthy controls (HC).

Methods:

Nineteen PsA patients (10 pregnant, 9 non-pregnant) and 19 HC (11 pregnant and 8 non-pregnant) were prospectively studied. Clinical assessment and blood sampling was done in pregnant women before, during and after pregnancy and once in the non-pregnant group. Sera were analyzed for levels of C reactive protein (CRP) and high sensitive CRP (hsCRP) by enzyme linked immunoassay. The following cytokines and regulatory molecules were measured by magnetic bead-based multiplex immunoassay: the activation marker soluble CD40 ligand (sCD40L), the Th1 cytokines tumor necrosis factor α (TNFα) and Interleukin (IL)-1β, the Th2 cytokines IL-4, IL-10, IL-31, IL-33, IL-25 and the Th 23/17 pathway cytokines IL-6, IL-17A, IL-17F, IL-21, IL-22, IL23.

Results:

In the non-pregnant groups we observed that patients with PsA had higher levels of hsCRP, sCD40L, TNFα, IL-1β, IL-33, IL-6 and IL-22 than HC.

Though pregnant PsA patients had inactive or mild disease activity with normal CRP levels, the hsCRP levels were higher than those of pregnant HC.

In the HC group, pregnant women at the third trimester showed higher levels of IL-10, IL-33 and TNFα than at the postpartum time point. Moreover, healthy women at the third trimester had higher levels of IL-1β, IL-33 and IL-22 than age-matched non-pregnant women.

At the third trimester of pregnancy, patients with PsA displayed higher levels of hsCRP, sCD40L, TNFα and IL-6 than HC. Interestingly, pregnant PsA patients did not show any differences in the cytokine pattern compared to non-pregnant PsA patients.

Most differences appeared when comparing PsA and HC at the postpartum time point. Postpartal patients with PsA showed higher levels of sCD40L, TNFα, IL-1β,IL-10, IL-33, IL-31, IL-6 and IL-22 compared to HC.

Conclusion:

Pregnancy induces no predominance of circulating Th2 cytokines but rather a coexistence of Th1, Th2 and Th17 cytokines. Patients with PsA present a more pronounced inflammatory profile consisting of elevated hsCRP levels, Th1 and Th17 cytokines during pregnancy and postpartum. Thus, inactive disease in pregnant PsA patients was associated with persisting immunological activity including the IL-23 /Th17 immune axis.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Reproductive Issues in Rheumatic Disorders: Basic and Clinical Aspects Poster Session
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: It is recognised that active disease in women with inflammatory arthritis is associated with adverse pregnancy outcomes. Most studies however, have focussed upon patients with rheumatoid arthritis and there is much less information on pregnancy outcomes in patients with psoriatic arthritis (PsA). Therefore, we present the outcomes of pregnancy in 14 consecutive patients, seen in a specialised obstetric rheumatology clinic – dealing with pregnancy issues in patients with rheumatic disease - over a 7-year period to explore the relationship between PsA and pregnancy.

Methods: Consecutive patients with PsA referred to the obstetric rheumatology clinic at University College London Hospital(UCLH) 2008-2014 were identified retrospectively. Their medical records six months before, during and four months after pregnancy were then examined to record: PsA disease activity, using physician global activity; medication history; plus maternal and fetal outcomes.

Results: Fourteen patients, with 16 pregnancies, were identified. Age range at delivery was 28-43 (median 34) years. Eleven had peripheral PsA; 3 had axial spondyloarthropathy and psoriasis. Previous obstetric history included 3 miscarriages and 10 live births in 8 patients. Pre-pregnancy, PsA related disease activity was: mild in 10; moderate in 2; and severe in 2 patients. Therapy pre-pregnancy included: NSAIDs alone, 4 patients; sulfasalazine (SSZ) ± prednisolone, 3 patients; anti-TNFα inhibitors ± SSZ, 8 patients; leflunomide (LEF), which was stopped and washed out pre-partum, 1 patient; and no patients on methotrexate. In line with previous recommendations, anti-TNFα was stopped during the first trimester of pregnancy. During pregnancy disease activity improved in 1 patient, remained active in 2 and worsened in 5 patients during mid to late pregnancy. In two cases this was managed with a reducing dose of prednisolone, from 20mg/day; in two other cases both prednisolone and SSZ were started. Of 16 pregnancies there were 2 spontaneous first trimester miscarriages, 14 live births and no maternal complications. Data from 11 births at UCLH revealed: mean birth weight 3.2 (range 2.9-3.8) kg; mean gestation 39.5 (range 37 to 42) weeks; 8 vaginal deliveries; 2 elective and 1 emergency caesarean section; and no congenital malformations. In 8 patients disease activity increased post-partum and was managed with reducing does of prednisolone or by restarting anti-TNF therapy. Of patients who flared, two had active disease activity antenatally which did not improve with pregnancy and the rest flared during/after pregnancy.

Conclusion: Pregnancy outcomes in these patients with PsA did not display an appreciable increase in miscarriage rate or pre-term delivery. Increased disease activity however, occurred in 5/14 patients during and 8/14 within four months post-pregnancy requiring an increase in disease specific therapy. Knowledge of alterations of disease activity in relation to pregnancy is important when counselling patients with PsA in this situation and advising continuation of disease ameliorating therapies that are compatible with pregnancy.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Reproductive Issues in Rheumatic Disorders: Basic and Clinical Aspects Poster Session
Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriatic arthritis (PsA) often develops between the 3rd -4thdecades of life, including women of childbearing age. However, little is known about PsA activity during pregnancy and the postpartum period. We aimed to evaluate joint and skin activity of PsA during pregnancy and "postpartum" period.

Methods: Patients with PsA are followed prospectively according to a standard protocol. Data are stored on a computerized database. Women who had pregnancies during follow up between 1990 and 2015 and at least one clinic visit during pregnancy were identified. "Postpartum" period was defined as up to 1 year after pregnancy. PsA activity was defined by 5 states: improvement, worsening (both defined as a change in at least 2 active joints), stable low (defined as 0 or 1 active joint), stable high (defined as ≥ 2 active joints) or a combination of improvement and worsening. Skin activity was defined by 5 states: improvement, worsening (both defined as a change of 1 in the psoriatic area severity index (PASI), stable low (PASI<2), stable high (PASI ≥2) or a combination of improvement and worsening.

Results: 29 PsA women with 42 pregnancies were identified. Of the 42 pregnancies 38 (90%) resulted in live healthy babies, 2 in miscarriages (at the end of the 1sttrimester) and 2 are still pregnant. The mean age at pregnancy was 33.8 ± 4.6. The mean PsA duration was 12 ± 7.4 and the mean psoriasis duration was 19 ± 8.9 years. The mean damaged joint count was 6.3 ± 11.2 and the mean Stienbrocker score was 2 ± 5.5. The majority (24, 58.5%) of pregnancies had either PsA improvement or stable low disease activity, while 13 (31.7%) had either worsening or stable high disease activity (table 1). During the "postpartum" period, 22 (55%) had either improvement or stable low PsA disease activity, while 18 (45%) had either worsening or stable high disease activity. The skin activity during pregnancy had either improved or stayed in a stable low state in 30 (88.3%), worsened in 3 (8.8%) and initially improved with following worsening in 1 pregnancy (table 1). The skin activity during the "postpartum" period had either improved or stayed in stable low in 15 (42.9%) pregnancies, or worsened in 20 (57.1%). During pregnancy, 17 (40.5%) used NSAIDS, 18 (42.9%) used DMARDS, 7 (16.7%) used biologic treatment (6 used anti TNFα agents and 1 Ustekinumab).

Table 1: Joints and skin activity during pregnancy and "postpartum" period

Time	**Favorable course**		**Unfavorable course**		**Mixed course**
Activity in joints	**Improved**	**Stable low**	**Worse**	**Stable high**	**Improved-worse**
Pregnancy, number (%)	11 (26.8)	13 (31.7)	8 (19.5)	5 (12.2)	4 (9.8)
Total	24 (58.5)		13 (31.7)		
"Postpartum", number (%)	9 (22.5)	13 (32.5)	17 (42.5)	1 (2.5)	0
Total	22 (55)		18 (45)		
Skin activity					
Pregnancy, number (%)	14 (41.2)	16 (47.1)	3 (8.8)	0	3 (8.8)	1 (2.9)
Total	29 (88.3)				
"Postpartum", number (%)	3 (8.6)	12 (34.3)	20 (57.1)	0	20 (57.1)	0
Total	15 (42.9)				

Conclusion: The outcome of pregnancy among patients with PsA is excellent. Disease activity in both skin and joints is variable with the majority (60%) improving during pregnancy but worsening in the "postpartum" period.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Reproductive Issues in Rheumatic Disorders: Basic and Clinical Aspects Poster Session
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: The assumption of spontaneous remission among pregnant women with rheumatoid arthritis (RA) is common. Nevertheless, prospectively collected data describing the course of disease activity during pregnancies in women with long-standing severe RA are rare. Further, observational data suggest that biologic disease modifying anti-rheumatic drugs (bDMARDs) can be safely used until conception but the impact of bDMARD treatment during pregnancy is unclear. We aimed to study pregnancy outcomes and courses of disease activity in women with bDMARD use prior to conception.

Methods: We investigated all pregnancies and their outcomes that were reported to the German biologics register RABBIT until end of 2014. Pregnancies were stratified by treatment in A) biologic-naive, B) bDMARD stopped before or C) bDMARD exposed at time of conception. In a subgroup of patients with pregnancies reported until 2011, additional interviews with a focus on the course of disease activity and treatment during pregnancy were conducted. Descriptive statistics were applied to study associations of pregnancy outcomes, disease activity and treatment.

Results:

In 1,981 female RA patients ≤ 45 years, 106 pregnancies in 88 patients were reported. At time of conception 57 pregnancies were exposed to bDMARDs (C) (29x etanercept, 11x adalimumab, 5x tocilizumab, 4x certolizumab pegol, 3x rituximab, 3x abatacept, 1x infliximab, and 1x golimumab), 11 were biologic naive (A) and 38 had received their last bDMARD infusion or injection at least 4 weeks (rituximab 6 months) before conception (B) (12x etanercept, 9x adalimumab, 2x tocilizumab, 2x infliximab, 13x rituximab). Only 43% of the women being in remission prior to pregnancy remained in remission. From 49 women not in remission prior to conception only 7 (14%) reached remission during pregnancy. In all pregnancies of group C bDMARD treatment was stopped after awareness of pregnancy. In 13 of those (23%) bDMARDs had to be re-started during pregnancy due to high disease activity. No adverse influence of this treatment decision on the childs' health or pregnancy course was observed.

The rates of spontaneous abortions were not significantly different between treatment regimens (A: 0, B:13%, C:19%) and in range of general population rates. Induced abortions were reported in 4 out of 106 pregnancies (one due to trisomia 21 with cardiac defect in a 38 year old woman).

Among all live births one major malformation (anal atresia) was detected in a child born to a mother exposed to bDMARDs until 4 weeks prior to conception (group B). Ten premature births occurred: one in a biologic naive woman, and 4 in groups B and C, respectively. In those women disease activity during pregnancy was considerably higher compared to women with mature children.

Conclusion: Within our cohort observing women with long-standing severe RA, we could not confirm the assumption of spontaneous remission during pregnancy. A considerable proportion of women experienced ongoing or worsening disease activity or flares during pregnancy. We confirmed previous reports and found no increased risk of major malformations or other harmful consequences in patients exposed to bDMARDs at time of conception.

Session Title: Reproductive Issues in Rheumatic Disorders: Basic and Clinical Aspects Poster Session
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Optimal treatment of women with Rheumatoid Arthritis (RA) during pregnancy remains a challenge, mainly due to safety concerns. TNF inhibitors (TNFi) are now routinely used in young patients with pregnancy wish. Nevertheless it is recommended to discontinue treatment as soon as pregnancy is recognized because of lacking data concerning the long-term follow up of children exposed in utero. However, this approach may increase the risk of flares during pregnancy. We sought to explore the frequency of flare in pregnancies of women with RA who discontinue TNFi at conception. **Methods:** Pregnancies from a prospective pregnancy registry were evaluated before conception and during each trimester. Clinical characteristics, disease activity (DAS28-CRP), medication use, and pregnancy outcome were analyzed. A flare was defined as increase in clinical activity leading to intensifying treatment (new treatment with prednisolone or increase in dosage ≥5 mg/day and/or treatment with intraarticular glucocorticoids and/or (re-)treatment with DMARDS/TNFi). We applied a multivariate logistic regression model to assess the association between the use of TNFi at conception and the occurrence of flares during pregnancy. Adjustment for potential confounders was performed using logistic regression. **Results:** 42 pregnancies in women with RA were enrolled (median age 33 yrs, 71 % RF/ACPA positive). Eighteen (41%) pregnancies occurred in women with TNFi at conception. Twenty-four pregnancies in women without TNFi at conception served as controls. At conception, in 71 % disease activity was mild or in remission (DAS ≤ 3.2). We observed at least one flare in 16 pregnancies. Discontinuation of TNFi at conception was significantly associated with the occurrence of flares (OR 10.0, 95% CI 2.3-42.8, p=0.002). The strength of association was nearly constant after adjusting for age, RF, CCP, previous joint surgery, DAS28-CRP at conception, use and dosage of prednisolone during pregnancy. Twelve pregnancies had poor outcomes [10 (24%) with preterm delivery, 2 (4.7%) with preeclampsia]. The risk of preterm birth increased with every cumulative milligramme of Prednisolone [OR 1.08 (95% CI 1.02-1.15, p < 0.01)]. **Conclusion:** Women with RA who discontinue TNFi at conception face a high risk for flares during pregnancy, independently of known risk factors like sero-positivity. Flares are usually treated with Prednisolone. We found a dose-dependent significant increased risk for preterm birth associated with Prednisolone. In this era of treat-to-target management of RA, our paradigm for RA pregnancy management may need adjusting. By controlling RA activity with medications considered relatively safe in pregnancy, we may be able to improve both the pregnancy experience and pregnancy outcomes.

	All pregnancies	Pregnancies with TNFi exposure until conception	Pregnancies without TNFi exposure	P value
DAS ≤ 3.2 (1 st trim.)	30 (71 %)	12 (67 %)	18 (82 %)	0.37
DAS ≤ 3.2 (2nd trim.)	28 (66 %)	9 (50%)	19 (79%)	0.09
DAS ≤ 3.2 (3rd trim.)	28 (66%)	12 (67%)	16 (66%)	0.80
Flare	16 (38 %)	12 (67%)	4 (17 %)	0.003

Session Date: Tuesday, November 10, 2015

Session Title: Reproductive Issues in Rheumatic Disorders: Basic and Clinical Aspects Poster Session

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Data on the impact of anti-TNF medications on pregnancy outcomes are limited. Certolizumab pegol (CZP) is a PEGylated Fc-free anti-TNF approved in more than 50 countries for the treatment of rheumatoid arthritis (RA) and/or Crohn's disease, psoriatic arthritis (PsA) and axial spondyloarthritis (axSpA). The objective of this project is to provide information on pregnancy outcomes in women receiving CZP.

Methods: The UCB Pharma safety database was searched for CZP-exposed pregnancies through 1 February 2015. Maternal and paternal CZP exposure, prospective and retrospective reports were included. This abstract focuses on maternal exposure pregnancies that are prospectively reported to reduce bias in outcome reporting rates. Available data on CZP exposure, pregnancy dating, pregnancy outcomes, comorbidities and infant events were independently extracted by 2 internal reviewers. The number of live births, miscarriages, induced abortions and stillbirths for CZP-exposed pregnancies were examined.

Results: There were a total of 723 CZP exposed pregnancy reports, of which 572 were prospectively reported. 540 pregnancies were maternally exposed (256 with known pregnancy outcomes, 47.4%) and 32 were paternally exposed (18 with known outcomes, 56.3%). Of the 256 maternally exposed pregnancies with known outcome, there were 207 live births (80.9%), 26 miscarriages (10.2%), 22 induced abortions (8.6%), and 1 stillbirth (0.4%) (Figure). The majority of pregnancies were reported through routine surveillance (65.9%); clinical trials accounted for 9.1% of pregnancy reports. Indications for CZP use included rheumatic disease (n=100, 39.1%) and Crohn's disease (n=140, 54.7%). The mean maternal age at estimated delivery date was 31.3 (SD 5.4) years. Many pregnancies (n=70, 44.6%) were exposed only during the first trimester, when the majority of fetal organ and organ system development takes place; 52 were exposed to CZP in all 3 trimesters (Table). 9 cases of congenital malformations were prospectively reported among 210 infants (including 3 sets of twins) with no discernable pattern in the reported malformations.

Conclusion: The analysis represents a uniquely large number of pregnancies exposed to a single anti-TNF. The majority of pregnancies had first trimester CZP exposure, and up to a third of prospectively-collected pregnancies continued treatment into the second and/or third trimesters. A limitation of this study is that the majority of the data originated from spontaneous post-marketing reports, which can be affected by bias and inherent limitations due to the passive and voluntary nature of the reporting systems. The data collectively suggests that CZP exposure *in utero* does not adversely affect pregnancy outcome.

Session Date: Tuesday, November 10, 2015

Session Title: Reproductive Issues in Rheumatic Disorders: Basic and Clinical Aspects Poster Session

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-TNFalfa agents have been used to control disease activity of patients with Chronic Arthritides (Rheumatoid Arthritis, Psoriatic Arthritis, Ankylosing Spondylitis) during the wash-out period of teratogenic DMARDs and are usually discontinued at positive pregnancy index. Moderate to severe maternal disease activity during pregnancy can justify the use of the drugs in the 2nd-3rd trimester and in the postpartum period. This is a case-control study on the health and developmental conditions of children exposed in utero and/or during breastfeeding to anti-TNFalfa agents and non-exposed children born to women with the same disease.

Methods: An ad-hoc created questionnaire was submitted to women who were followed during pregnancy by a multidisciplinary team (rheumatologist, gynaecologist, neonatologist). Data on birth, lactation, weaning, growth parameters, developmental milestones, vaccinations and disease conditions were collected.

Results: The table reports the characteristics of 25 cases (9 male, 16 female) (21 exposed to etanercept, 3 to adalimumab, 1 to certolizumab) and 25 controls (12 M, 13 F). Eighteen children were exposed during the first trimester (discontinuation of anti-TNFalfa agent at positive pregnancy index), while 7 during the 2nd-3rd trimester (discontinuation at 34th-37th week, mean exposure of 13.3 weeks). Both cases and controls underwent vaccinations without any severe complications. Vaccinations were protective; only one child with periconception exposure to etanercept developed chicken-pox despite vaccination. Five children (3 cases and 2 controls) were breastfed during maternal anti-TNFalfa therapy (3 etanercept, 2 adalimumab).

Conclusion: No differences in birth parameters, congenital malformations and developmental steps in the first 24 months of life have been found between cases and controls. Growth parameters were within the curves of the general population. Cases received more vaccinations than controls: this may be due to the feeling by either parents or paediatricians that these children exposed to immunosuppressive agents could be more susceptible to infectious diseases. No relevant infectious diseases nor post-vaccine complications have been noted in the 6 children exposed to anti- TNFalfa during the 2nd-3rd trimester of gestation nor in the 5 exposed during lactation. Globally, the long-term follow-up of children supports the safety of use of anti-TNFalfa agents, either preconceptionally or during the 2^{nd}-3^{rd}trimester of pregnancy. Data on use during breastfeeding are still anecdotal but can be helpful for counseling the patients who are strongly motivated to breastfeed.

Session Title: Reproductive Issues in Rheumatic Disorders: Basic and Clinical Aspects Poster Session

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

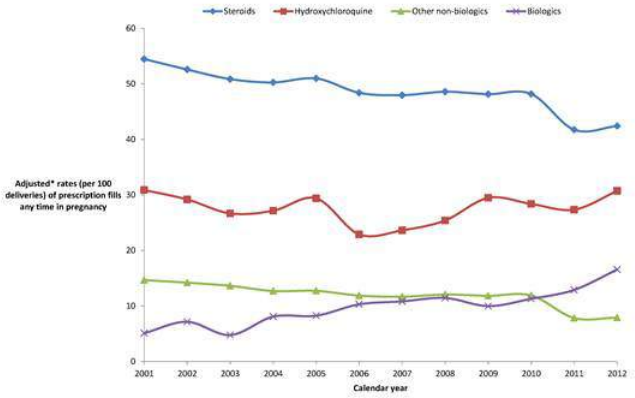
Background/Purpose: Systemic inflammatory conditions such as systemic lupus erythematosus (SLE), rheumatoid arthritis (RA), psoriatic arthritis (PsA), and ankylosing spondylitis (AS) affect many women during their childbearing years. Empirical data describing the time-trends and patterns of use of immunosuppressive agents during pregnancy in routine practice are scarce. Therefore, we designed this study to describe patterns and secular trends in use of immunosuppressive agents in pregnant women with SLE, RA, PsA, or AS.

Methods: A cohort of women with SLE, RA, PsA, or AS enrolled in public (Medicaid, 2001-2010) or private (OptumClinformatics, 2004-2012) health insurance was identified and women filling prescriptions for immunosuppressives- including steroids, non-biologic disease-modifying agents, and biologics- in the 3-month period immediately prior to their pregnancy were included. The proportion of women continuing or discontinuing individual agents during pregnancy was reported. Annual prescription fill rates, estimated after accounting for patient characteristics and random variability from year-to-year in mixed-effect regression models, were used to conduct time-trends analysis.

Results: A total of 2,645 women actively treated with immunosuppressive agents prior to pregnancy were included. More women with PsA or AS stopped filling immunosuppressive prescriptions in pregnancy (61%) than those with SLE (26%) or RA (34.5%). From the first to the third trimester, the proportion of women filling prescriptions for immunosuppressive agents decreased across all indications. Overall, steroids (48.4%) and hydroxychloroquine (27.1%) were the most frequently used agents in pregnancy. The rates (reported per 100 deliveries in our cohort) for steroid prescription fills during pregnancy fell significantly from 54.4 to 42.4; while rates for biologics increased from 5.1 to 16.6 between 2001 and 2012 ($p<0.001$ for both trends).

Conclusion: Steroids and hydroxychloroquine remain the most widely prescribed treatment options in pregnancy; but the use of biologics is becoming increasingly common.

Figure: Time-trends in use of immunosuppressive agents during pregnancy in a cohort of women with systemic lupus erythematosus, rheumatoid arthritis, ankylosing spondylitis or psoriatic arthritis.



* Adjusted for maternal characteristics (age, region), insurance type (Medicaid or private), case-mix (underlying treatment indication-SLE, RA, PsA, or AS), and random variability across years using a mixed regression model.

Perinatal Patterns of Medication Use in Women with Rheumatoid Arthritis: A Population-based Study

Background/Purpose: Although the incidence of RA peaks during the 4th and 5th decades of life, a substantial proportion of women are also affected during the more common childbearing years. Given the limited data on perinatal medication use, including traditional and biologic DMARDs as well as other medications, our objective was to characterize real-world therapy patterns among women with RA before, during, and after pregnancy.

Methods: We linked population-based health data on all visits to health professionals and hospital admissions (01/01/1992 – 12/31/2012) and all dispensed medications, regardless of payer (01/01/1996 – 12/31/2012) with a perinatal registry capturing information on >99% of births in hospitals and homes in the province of British Columbia, Canada (01/01/2002 – 12/31/2012). Unique to this pregnancy cohort is valid, clinically-derived information on date of conception according to gestational age or date of last menstrual period as confirmed by ultrasound. The case definition for RA was 2 outpatient ICD9 codes for RA ³2 months apart and we excluded individuals with a non-RA coded subsequent visit to a rheumatologist or no subsequent RA-coded visits during the last 5 years of follow-up. Using information on prescription date and days supply, we determined the use of traditional and biologic

DMARDs, glucocorticosteroids, and NSAIDs for the following periods: **1)** pre-conception 1 (366-730 days before conception); **2)** pre-conception 2 (1-365 days before conception); **3)** 1st trimester; **4)** 2nd trimester; 5) 3rd trimester; and **6)** post-delivery (1-365 days after delivery).

Results: We identified 513 pregnancies in 414 women with RA; 80% of women were primipara and 20% multipara. At delivery, mean age was 31.3 ± 5.4 years. We tabulated the proportion of exposed pregnancies according to each period and medication class (**Table**). The majority of traditional DMARD pregnancy exposures were to hydroxychloroquine and/or chloroquine (proportion of pregnancies exposed during the 1st, 2nd, and 3rd trimester were 17.0, 10.7 and 9.2%, respectively) and the majority of biologic pregnancy exposures were to anti-TNFs (4.7, 2.1 and 2.1%). For all medications, we observed a decline in use during pregnancy followed by increased use in the year following delivery.

Conclusion: This population-based study provides data on real-world patterns of perinatal medication use among women with RA. Findings emphasize the importance of counseling women regarding childbearing decisions as well as the need for evaluation of the risk-benefit profiles of medications in pregnancy.

	Exposed RA Pregnancies (%)					
	Pre-conception 1	**Pre-conception 2**	**1st trimester**	**2nd trimester**	**3rd trimester**	**Post-delivery**
Traditional DMARDs	43.9	44.3	24.0	15.0	11.5	38.0
Biologic DMARDs	7.4	8.2	4.7	2.1	2.1	8.0
Anti-TNFs	*7.4*	*8.0*	*4.7*	*2.1*	*2.1*	*7.8*
Glucocorticosteroids	22.0	24.8	13.5	11.5	11.3	25.9

Neonatal Outcome to Paternal Exposures with Anti-Rheumatic Therapy

Elisabeth Solau-Gervais[1] and **Antoine Brigaud Jr.**[2], [1]Rhumatologie, University Hospital, Poitiers, France, [2]University hospital, Poitiers, France

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Reproductive Issues in Rheumatic Disorders: Basic and Clinical Aspects Poster Session

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: There is a lack of studies about preconceptional paternal exposure to disease modified anti-rheumatic drugs (DMARDs) and the data of literature are controversial. The objectives are to study the difference in neonatal outcome between exposed fathers and non exposed fathers and to know information about preconceptional treatment management.

Methods: For this retrospective study, questionnaires have been sent to all the men followed in the department for rheumatic diseases (rheumatoid arthritis, spondyloarthritis or psoriatic arthritis). In this questionnaire there were questions about number of children, date of birth, treatment received during preconception, environmental factors of father and mother (tobacco, alcohol, other treatments and diseases and age) and information about preconceptional treatment management. Patients who received treatment during preconception period have been contacted to confirm their preconceptional treatment and neo-natal outcome, birth weight and term. For the neonatal outcome, two groups of patients were analyzed: paternal exposed children and non exposed children.

Results: From 407 questionnaires sent, 200 answers were received. Forty five men had a rheumatic disease diagnose at the preconceptional period. There were 77 births, 29 exposed children (11 to sulfasalazine, 7 to adalimumab, 6 to etanercept, 1 to infliximab, 1 to methotrexate and sulfasalazine, 1 to methotrexate and etanercept) and 48 non exposed children. There were 2 major birth defects in the exposed group (1 William and Beuren syndrome and 1 Turner syndrome) and no in the non exposed group, the difference was not statistically significant ($p = 0.138$). There was no statistical difference between the two groups when birth weight is concern with 3.27 kg in the exposed group versus 3.07 kg in the non exposed group ($p = 0.09$) and no difference concerning the

gestational age: 41.6 weeks in the exposed group versus 39,6 in the non exposed.

On 200 patients, 52 patients were on DMARDs and under 45 years old and only 15 (28.8%) have discussed with the practitioner about paternal exposure and 32 (61.5%) estimated not having enough information on risk of paternal exposure.

Conclusion: In this study, even if there is no increased risk in neonatal outcome after paternal exposure to DMARDs, due to a weak birth rate in this population, fathers are left behind when pregnancy is concerned

Session Title: Reproductive Issues in Rheumatic Disorders: Basic and Clinical Aspects Poster Session
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: To examine difference in the prevalence of immunosuppressive medication use during pregnancy by type of autoimmune disease and by insurance (Medicaid versus commercial) in an analysis of administrative claims databases.

Methods: We identified women who were diagnosed with rheumatoid arthritis, psoriatic arthritis, psoriasis, and inflammatory bowel disease (ulcerative colitis and Crohn's disease) and had a live birth between 2006-2010 (Medicaid) and 2005-2012 (commercial). Eligible women were identified by requiring ≥ 2 physician diagnoses for the diseases or one diagnosis plus ≥ 1 filled prescription(s) for an immunosuppressive medication at any time prior to and during pregnancy. In addition, they were required to have both medical and pharmacy coverage continuously during the 12 months period prior to delivery. We determined the use of immunosuppressive medications by examining filled prescriptions and calculated the prevalence of each medication during 4 separate time periods: preconception (90 days prior through conception), 1st trimester (day 270-180 prior to delivery), 2nd trimester (day 180-90 prior to delivery), and the 3rd trimester (day 90 prior through delivery). In addition, among biologic users during preconception with Medicaid coverage, we examined the proportion of patients who had discontinued by the 3rd trimester.

Results: We identified 5,909 pregnant women with autoimmune diseases enrolled in Medicaid and 1,104 commercially insured. Women with Medicaid coverage were younger compared to those commercially insured at time of delivery (mean age 27 versus 31 years). Biologics were the most commonly used DMARDs across all diseases and throughout the 4 time periods (Table). We observed a decline in the prevalence of biologics use from preconception to 3rd trimester in both Medicaid and commercially insured populations and across all diseases (Table). Among RA patients, 12-14% had a filled prescription during preconception compared to 3% in the 3rd trimester. Despite a lower prevalence (7-8%) of biologics use during preconception among women with inflammatory bowel disease, the prevalence (3-5%) in the 3rd trimester was similar to that among RA patients. Among biologic users during preconception enrolled in Medicaid, 83% of RA patients had discontinued by the 3rd trimester compared to 65% of IBD patients.

Conclusion: Irrespective of type of insurance, biologics were the most commonly used DMARDs during and immediately prior to pregnancy among women with inflammatory autoimmune diseases. Prevalence rates of biologics use differed by diagnoses but were not different between Medicaid and commercially insured. Further research to evaluate potential under-treatment of these diseases during pregnancy is warranted.

Session Title: Reproductive Issues in Rheumatic Disorders: Basic and Clinical Aspects Poster Session

Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: The increased rates of preeclampsia, preterm birth, and intrauterine growth restriction in SLE pregnancy are only partially explained by the vascular effects of anti-phospholipid antibodies. SLE patients themselves are born preterm more often than expected, suggesting a heritable defect in maternal-fetal tolerance. PD-L1 is one candidate gene, in that it has been implicated in the both autoimmunity and maternal-fetal tolerance: PD-L1 is expressed on healthy antigen presenting cells to downregulate inflammatory responses, and also on placental trophoblasts at the maternal-fetal interface, where it inhibits alloreactive T cells. Peripheral blood antigen presenting cells from SLE patients are deficient in PD-L1 expression compared to remission or healthy controls. Little is known about placental costimulatory molecules in women with autoimmune diseases. This study tested the hypothesis that placental PD-L1 expression is abnormally regulated in SLE pregnancy.

Methods: Expression of PD-L1 was quantified by immunohistochemistry in placentas from full-term pregnancies of 4 SLE patients, 7 rheumatoid arthritis patients (RA) and 11 healthy control women obtained from the Global Alliance for the Prevention of Prematurity and Stillbirth Repository. PD-L1 mRNA expression was assayed by RT-PCR and normalized to GAPDH expression. PD-L1 on peripheral CD14+/CD11c+ monocytes was assayed by flow cytometry. Significant differences between groups were tested by T-test.

Results: By immunostaining, PD-L1 expression in SLE placentas was significantly reduced compared to control groups. The difference was most pronounced on the fetal side of the placenta. PD-L1 mRNA expression correlated with protein expression, although the differences were not significant. On peripheral blood monocytes, PD-L1 expression was low in juvenile SLE patients compared to healthy controls (55% of SLE monocytes v. 93% of healthy monocytes, p=0.001). Although in the normal range, mothers of SLE patients also had relatively low PD-L1 expression compared to control mothers (87% v. 94%, p=0.04).

Table 1. Relative median PD-L1 expression in the placenta in patients and controls.

	Controls	SLE	P*	RA	P**
Protein					
Overall	16.8	5.3	0.013	14.5	0.39
Fetal	19.4	7.2	0.004	14.5	0.41
Maternal	16.4	6.1	0.09	15.3	0.73
mRNA	109	72	0.21	300	0.08

*SLE versus controls; **RA versus controls.

Conclusion: PD-L1 expression is dysregulated in pregnant women with SLE (in placenta), in SLE patients, and in mothers of SLE patients (in blood). Inadequate expression of PDL-1 in the placentas of patients with SLE could result in loss of maternal-fetal tolerance, contributing to the high rate of pregnancy complications in SLE.

Session Title: Reproductive Issues in Rheumatic Disorders: Basic and Clinical Aspects Poster Session
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Antiphospholipd antibodies (aPL) positivity is considered as a risk factors for a poor obstetric outcome. The aim of this work was to determine risk factors in patients (pts) with established aPL positivity with/without a diagnosis of primary antiphospholipid syndrome (PAPS) despite the administration of low dose aspirin (LDA) and heparin (LMWH).

Methods: Two hundred women were prospectively followed in the 3 Institutions involved between 2000 and 2014. None of the pts had a concomitant systemic autoimmune disease, while 28 had an organ autoimmune disease. Data were retrospectively collected from clinical charts using a common database. Adverse pregnancy outcome (APO) was considered the occurrence of pregnancy loss, perinatal deaths, preterm deliveries before the 34 weeks due to preeclampsia and HELLP syndrome.

Results: Among the 200 pts, 127 fulfilled the criteria for PAPS and 73 did not. During the study pts had 283 pregnancies. According to their clinical and biological characteristic we created 4 groups: 85 pts with obstetric (O-APS, 124 pregnancies), 42 thrombotic with/without obstetric (T-APS, 66 pregnancies), 39 incomplete clinical criteria (I-APS, 54 pregnancies) and 34 aPL carriers without any clinical manifestation (39 pregnancies).

The mean age at the onset of pregnancy was 32.4 years, the global rate of live births was 88%; APO was observed in 50 cases (18%). In the table 1 are reported the features statistically associated with APO at the univariate and multivariate analysis. T-APS was the group with the higher rate of APO (24%) followed by the aPL carrier and O-APS (18%), few occurred among the I-APS (9%). In table 2 we reported APO divided for clinical group and features statistically associated. We collected 14 maternal complications: 7 thrombotic events (3 DVT, 1 pulmonary embolism, 1 myocardial infarction, 2 CAPS) and 7 non-criteria manifestations (thrombocytopenia, hemolytic anemia, epilepsy). The thrombotic events occurred mostly in T-APS pts (71%), triple positive (53%) and during puerperium (53%).

Conclusion: A non-negligible considerable rate of APO and other maternal complications were observed even if the patients were treated according the recommended guidelines confirming that these pregnancies have to be considered at high risk for maternal and fetal health. With this study we identified 3 profiles of patients with a higher risk: thrombotic history, a more systemic APS phenotypes (other APS manifestations, or complement reduction) and triple positive aPL even without full criteria for APS.

Session Date: Tuesday, November 10, 2015

Session Title: Reproductive Issues in Rheumatic Disorders: Basic and Clinical Aspects Poster Session

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

<>**Background/Purpose:** Previous studies have found a relationship between overall systemic lupus erythematosus (SLE) activity and adverse pregnancy outcomes. We sought to investigate whether specific types of SLE activity either in the 6 months prior to conception or during pregnancy were related to adverse pregnancy outcome. <> <>**Methods:** We identified women with confirmed SLE by 1997 ACR Revised Criteria, >2 visits to our Lupus Center, and ³1 pregnancy lasting >12 weeks from 1990-2013. Data collected from electronic medical record included demographics, SLE medications and labs, obstetric history, pregnancy outcomes, and presence of 5 specific types of SLE activity 6 months before conception and during pregnancy: hematologic (WBC <4K, hemolytic anemia, or platelets <100K), nephritis (proteinuria >0.5g/d, WBC or RBC >5, or casts), serositis (pleuritis or pericarditis), arthritis (>1 joint), and skin (discoid or malar rash). Adverse pregnancy outcome was defined as pre-eclampsia, preterm delivery (<37 weeks), spontaneous abortion ³12 weeks, or stillbirth. Univariable analyses identified predictors of adverse pregnancy outcome. Multivariable analyses evaluated each specific type of SLE activity as a primary predictor of adverse outcome, adjusting for significant univariable predictors. Generalized linear mixed models were used for both univariable and multivariable analyses to account for correlated data, as some women had >1 pregnancy. <> <>**Results:** 147 pregnancies occurred in 113 women with mean age 23.7 (SD 6.8) years at SLE diagnosis and 31.0 (SD 5.3) at conception. 68% were White, 15% Hispanic, 10% Black, 7% Asian. Five women had a history of antiphospholipid syndrome and 21 had a prior adverse pregnancy outcome. During the study period, 38 (26%) pregnancies had an adverse outcome. Hematologic disorder (16%) and nephritis (10%) were the most common types of SLE activity during pregnancy. In univariable analyses, nephritis 6 months before conception (OR 6.4, 95%CI [1.3, 32.8]) and hematologic disorder during pregnancy (OR 5.2 [1.8, 15.4]) were significantly associated with adverse outcome. Hispanic ethnicity, prior adverse pregnancy outcome, and steroid and/or azathioprine use during pregnancy were also associated with adverse outcome. In multivariable analyses, only hematologic disorder during pregnancy was associated with adverse outcome (OR 3.4 [1.1, 10.6]). (Table) <> <>**Conclusion:** The majority of pregnancy outcomes were favorable in this SLE cohort. After adjusting for ethnicity, prior adverse pregnancy outcomes, and medications during pregnancy, only hematologic disorder during pregnancy was associated with an elevated risk of adverse pregnancy outcome. Prior studies have suggested variable impact of lupus nephritis on pregnancy outcomes, but this study uniquely demonstrates an association between cytopenia during pregnancy and adverse pregnancy outcomes.

Table. Predictors of Adverse Pregnancy Outcome⁺ in 147 Pregnancies

Predictor	Univariable OR* (95% CI)	Multivariable OR* # (95% CI)
Specific Type of SLE Activity Six Months Prior to Conception		
Hematologic	2.7 (0.8, 9.1)	1.5 (0.4, 5.4)
Nephritis	**6.4 (1.3, 32.8)**	3.0 (0.5, 17.0)
Skin disease	1.1 (0.3, 4.2)	1.1 (0.3, 4.3)
Arthritis	0.8 (0.2, 3.9)	0.5 (0.1, 2.5)
Serositis	1.9 (0.2, 15.2)	1.3 (0.2, 10.4)
Specific Type of SLE Activity During Pregnancy		
Hematologic	**5.2 (1.8, 15.4)**	**3.4 (1.1, 10.6)**
Nephritis	3.4 (0.9, 12.2)	1.5 (0.4, 6.2)
Skin disease	1.5 (0.4, 6.5)	0.89 (0.2, 4.1)
Arthritis	3.4 (0.6, 17.7)	2.2 (0.4, 12.3)
Serositis	3.8 (0.7, 22.1)	2.7 (0.4, 17.0)

⁺ Adverse pregnancy outcome: pre-eclampsia, preterm delivery (<37 weeks), spontaneous abortion ≥12 weeks, or stillbirth
* OR from generalized linear mixed models to account for correlated data among 113 women carrying a total of 147 pregnancies
# Multivariable models adjusted for ethnicity (Hispanic/non-Hispanic), prior adverse pregnancy outcome, and corticosteroid and/or azathioprine use during pregnancy

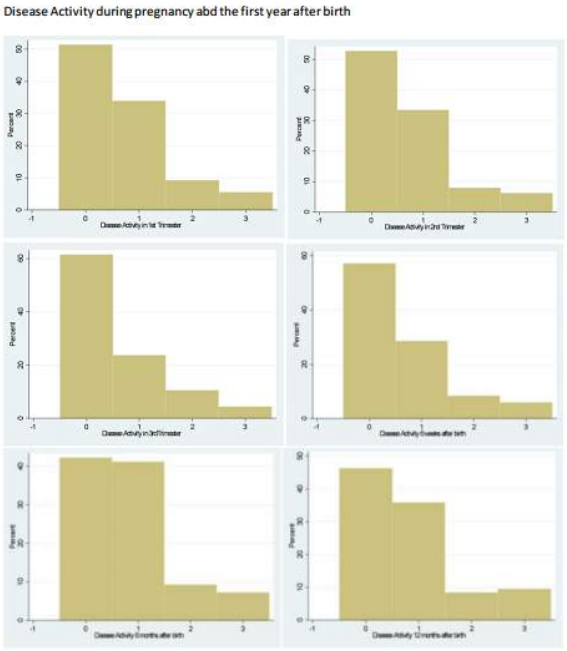
Disease Activity in women with SLE during pregnancy and the first year post partum

Background/Purpose: Disease activity measured by validated methods has been sparsely examined during and after pregnancy in women with SLE. The purpose was to examine disease activity by the Lupus Activity Index in Pregnancy(LAI-P) during pregnancy and in the first year post partum (pp).

Methods: RevNatus is a research database were patients are included nationwide at all departments of Rheumatology in Norway. Women who plan pregnancy or are already pregnant are included after informed consent. Data for the SLE- cohort was obtained in 2007 – 2015. LAI-P is a modified version of Lupus Activity Index (LAI), with a good ability to measure disease activity and diagnose disease flares in pregnancy. To explore variation in disease activity throughout pregnancy and after birth disease activity was measured by LAI-P/LAI at 6 time points: in each trimester, 6 weeks, 6 months and 12 months pp. A general mixed model was applied, using the last time point as reference, and comparing baseline (12 months post partum) with measures in each trimester, 6 weeks and 6 months pp. LAI and LAI-P measures disease activity on a continuous scale from 0 – 3; 0 indicating no disease activity and 3 indicating very high disease activity. As the assumption of normal distribution was not fulfilled, the dependant variable was categorized. We adjusted for mothers age in 1st trimester, disease duration, parity, prednisolon use and Plaquenil use .

Results: A total of 145 pregnancies in 127 women with SLE were included in the analysis. More than half (51,6%) of the measures on disease activity indicated remission and only 6,3% of the measures exceeded 0,5. A change in disease activity > 0,25 is perceived as a clinically relevant change, and the four categories chosen were no disease activity (LAI-P =0,), very low disease activity (LAI-P 0,01 – 0,25), low disease activity (LAI-P >0,25 – 0,50), and moderate disease activity or above (LAI-P>0,50), corresponding to category 0,1,2 and 3 in the figure. It illustrates the percentage of each category at the separate time points, showing that the disease activity declines during pregnancy and increase after delivery. There is a significantly increased odds of higher disease activity 6 and 12 months pp.



Conclusion: In 145 pregnancies in women with SLE, the disease activity decreased during pregnancy, but increased during the first year after delivery. This points to the importance of tight control not only during pregnancy, but also in the first year after delivery in women with SLE.

Session Title: Reproductive Issues in Rheumatic Disorders: Basic and Clinical Aspects Poster Session

Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: The frequency of pregnancy complications, including miscarriage, stillbirth, preeclampsia, and preterm birth varies between lupus cohorts. This analysis compares pregnancy outcomes that occurred before and after the diagnosis of SLE.

Methods: We analyzed data from a registry of approximately 1700 patients with SLE from 17 lupus centers in the United States and Canada. At study enrollment, all women reported the outcomes of their prior pregnancies and, when known, the year of delivery. The timing of onset for each ACR criteria was obtained and the date of the accrual of the 4th criteria as the formal diagnosis of SLE. All pregnancies with a reported date of completion and in women with at least four ACR criteria at enrollment were included in this analysis. Pregnancies were divided into two groups: 1) pregnancies completed prior to the year of SLE diagnosis and 2) pregnancies delivered in the year of or the years following SLE diagnosis. Descriptive statistics, t- and chi square tests were used to compare the enrollment variables between the two groups. Generalized estimating equations were used to compare pregnancy outcomes between the groups to accommodate for multiple pregnancies in some women.

Results: A total of 2,277 pregnancies were reported in 860 women. Of these pregnancies, 499 occurred after the diagnosis of SLE, 1444 occurred before the diagnosis of SLE and 277 were unassigned due to no reported date of pregnancy completion. Compared to pre-SLE pregnancies, those after SLE diagnosis had a significantly lower risk of live birth and a higher risk of spontaneous abortions/miscarriage (see table). There was not a significant difference in the risks of fetal demise/stillbirth or in elective termination. Over a third of post-SLE pregnancies were low birth weight and/or delivered preterm. The risk of preterm birth and delivering a low birth weight infant was several-fold higher post-SLE than pre-SLE. While the pre-SLE risk of preeclampsia was similar to the general population, it was over 2.5-fold higher in the post-SLE pregnancies. The risk of preterm preeclampsia, a serious condition for both mother and infant, was almost 6-fold higher post-SLE diagnosis. Of the cases of preeclampsia, only 30.1% pre-SLE diagnosis were preterm, compared to 69.6% of those post-SLE.

Conclusion: Compared to pregnancies preceding the diagnosis of lupus, pregnancies following the diagnosis of lupus had higher risks of spontaneous abortion, preterm birth, low birth weight, preeclampsia, and preterm preeclampsia.

Table: Pregnancies before and after SLE diagnosis

Pregnancy Outcomes	Pregnancies after SLE	Pregnancies prior to SLE	Relative Risk (95% CI)	p-value
Total pregnancies	499	1444		
Live birth	316 (63.3%)	1054 (70.4)	0.87 (0.81-0.94)	<0.001
Fetal demise	13 (2.8%)	40 (2.8%)	0.89 (0.44-1.83)	0.77
Spontaneous abortions	99 (19.8%)	193 (13.4%)	1.48 (1.13-1.87)	<0.01
Termination	71 (14.2%)	157 (10.9)	1.29 (0.95-1.74)	0.09
Of LIVE BIRTHS: (with reported outcomes)	(n=316)	(n=1054)		
Low birth weight (<2500g)	108 (34.2%)	134 (12.7%)	2.69 (2.08-3.47)	<0.0001
Extreme low birth weight (<1500g)	29 (9.2%)	20 (1.9%)	4.84 (2.77-8.44)	<0.001
Preterm birth (<37 weeks)	123 (38.9%)	129 (12.2%)	3.18 (2.46-4.11)	<0.0001
Extreme preterm birth (<30 weeks)	24 (7.6%)	24 (2.2%)	3.45 (1.72-6.45)	<0.01
Neonatal lupus	8 (2.5%)	5 (0.5%)	5.34 (1.24-23.01)	0.03
Preeclampsia	56 (17.7%)	71 (6.7%)	2.58 (1.78-3.74)	<0.0001
Preterm & preeclampsia	39 (12.3%)	22 (2.1%)	5.91 (3.47-10.08)	<0.0001

Session Title: Reproductive Issues in Rheumatic Disorders: Basic and Clinical Aspects Poster Session

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Allergic conditions seem to be more prevalent in patients with SLE than in the general population. To date, a handful of small observational studies have evaluated the risk of allergic conditions in offspring born to women with SLE, showing a potentially increased likelihood. In a large population-based study, we aimed to determine if children born to SLE mothers have an increased risk of allergic conditions compared to children born to mothers without SLE.

Methods: The "Offspring of SLE mothers Registry (OSLER)" includes all women who had ≥1 hospitalization for delivery after SLE diagnosis, identified through Quebec's universal healthcare databases (1989-2009). OSLER also includes a randomly selected control group of women, matched at least 4: 1 for age and year of delivery, who did not have a diagnosis of SLE prior to or at the time of delivery. We identified children born live to SLE mothers and their matched controls, and ascertained allergic conditions (including asthma, allergic rhinitis, eczema, cutaneous allergy, urticaria, angioedema, and anaphylaxis) based on ≥1 hospitalization or ≥2 physician visit with a relevant diagnostic code. We performed multivariate analyses to adjust for maternal age, education, ethnicity, and obstetrical complications (i.e. preterm birth, small for gestational age), as well as calendar year of birth and sex of the child. Moreover, in a subsample analysis of children with maternal public drug coverage throughout pregnancy, we further adjusted for relevant maternal medications (i.e. antimalarials, corticosteroids, and immunosuppressive drugs).

Results: 509 women with SLE had 719 children, while 5824 matched controls had 8493 children. Mean follow-up was 9.1 (SD 5.8) years. As opposed to controls, children born to mothers with SLE experienced more allergic conditions [66.1% (95% CI 62.5, 69.5) versus 59.3% (95% CI 58.3, 60.4)]. In SLE offspring, the most frequently observed allergic conditions were eczema (43.8%) and asthma (28.5%), while anaphylaxis was the least frequent (0.8%). In control children, eczema (38.9%) and asthma (25.4%) were also the most frequent, while anaphylaxis was the least frequent (0.3%). In multivariate analysis (n=9212), children born to SLE mothers had an increased risk of allergic conditions versus control children (OR 1.36, 95% CI 1.14,1.61). In the subsample analysis further controlling for relevant maternal medications (n=1925), though a trend remained for increased risk of allergic conditions for offspring of SLE mothers versus controls, due to reduced sample size the 95% CI was wider and included the null value (OR 1.23; 95% CI 0.79, 1.91).

Conclusion: Compared to children from the general population, children born to women with SLE have an increased risk of allergic conditions. Genetic factors, shared environmental exposures, as well as in utero exposure to maternal autoantibodies and cytokines might be at play. Further research is warranted to investigate the relative importance of these potential predisposing factors.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Reproductive Issues in Rheumatic Disorders: Basic and Clinical Aspects Poster Session

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Although adverse obstetrical complications are more frequent in SLE women, no one has evaluated healthcare

costs during SLE pregnancies. Thus, we aimed to evaluate if SLE pregnancies result in higher direct healthcare cost components (including physician services during pregnancy and neonatal period, and delivery-related costs) compared to pregnancies from the general population.

Methods: We used data from the "Offspring of SLE mothers Registry (OSLER)" including all women who had ³1 hospitalization for delivery after SLE diagnosis, identified through Quebec's healthcare databases (1989-2009) which provide information on all physician services and hospitalizations in the province. OSLER also includes a randomly selected control group of women matched ³4:1 for age and year of delivery. We determined average physician costs for the SLE and non-SLE pregnancies from first gestational week until birth and the neonatal period (for both mother and child) from birth until postnatal gestational age of 44 weeks. We also estimated average hospitalization costs for the SLE and non-SLE deliveries (including inpatient physician costs). Costs were normalized to 2014 Canadian dollars.

We performed multivariate random effect log-linear and linear regression analyses to establish whether costs during pregnancy and the neonatal period were associated with SLE status, adjusting for relevant covariates.

Results: We identified 509 women with SLE who had 712 deliveries and 5824 controls who had 8363 deliveries during the study period. SLE deliveries occurred at a lower mean gestational age compared to control deliveries, and birth weight was lower in SLE offspring as opposed to unexposed offspring (Table 1). In addition, the maternal length of hospitalization for delivery was longer for SLE deliveries versus controls (Table 1).

Compared to control pregnancies, we observed substantially higher costs for both physician services and hospital stays for delivery, resulting in higher costs for SLE pregnancies [10 833$ vs 6 828$; difference 4 004$ (95% CI 3 300, 4 709)]. In multivariate analyses, SLE pregnancies had a 32% (95% CI 29, 36) increment in costs, or alternatively a 3 690$ (95% CI 2 814, 4 567) increase in costs, compared to control pregnancies (Table 2).

Conclusion: Compared to pregnancies from the general population, SLE pregnancies are associated with substantially higher direct healthcare costs, including costs for physician services and hospitalization for delivery. Our study is the first to highlight the economic burden of SLE pregnancies, identifying an area of heavy healthcare use.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Reproductive Issues in Rheumatic Disorders: Basic and Clinical Aspects Poster Session

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Women with Systemic Lupus Erythematosus (SLE) and Anti-Phospholipid Antibodies (aPL) have pregnancies with higher rates of preterm labor, preeclampsia, and fetal loss than healthy women. While 80% of pregnancies in SLE patients with quiescent disease are uncomplicated by adverse pregnancy outcomes (APOs), limited data exist on differences in pregnancy outcomes by race/ethnicity. In this study we examined rates of APOs according to race/ethnicity among women with SLE with and without aPL

and, if racial/ethnic differences in APO existed, whether socioeconomic status (SES) accounted for those differences

Methods: Analyses use data from the PROMISSE study, a multicenter, prospective observational study (2003 – 2014) of pregnant women 18 – 45 years with SLE and aPL. Subjects with SLE were enrolled by 12 weeks and subjects with aPL by 18 weeks at 9 U.S. and 1 Canadian site. Women with blood pressures of >140/90, taking prednisone ≥ 20 mg daily, or with active renal disease (> 1 gram on 24 hour urinalysis or spot, RBC casts, Cr >1.2 mg/dl) were excluded. APOs were defined as at least one of the following: fetal death after 12 weeks; neonatal death prior to hospital discharge; preterm delivery < 36 weeks due to gestational hypertension, preeclampsia or placental insufficiency; small for gestational age (<5th percentile). We examined the role of age, race/ethnicity (non-Hispanic white vs. other), self-reported disability status, percentage of visits attended, and measures of SES including level of educational attainment and median income by zip code, in a series of bivariate and multivariate logistic regression models, clustering by site. For all analyses the referent group was white patients with SLE alone.

Results: Data were available for 408 women for the analyses; 6 had missing APO data and were omitted from the analysis. Mean age was 30.9 years and 50% were racial/ethnic minorities. Seventeen percent of non-Hispanic whites and 29% of minorities met criteria for APO. Minorities with SLE alone had higher odds of APO than their white counterparts, a difference which diminished after adjustment for covariates, including measures of SES such as level of educational attainment and median income by zip code. Both white and minority women with SLE and aPL had higher rates of APO compared to white patients with SLE alone. In this SLE and aPL group, the risk of APO in minority women was more than double that of white women, and these differences remained after adjustment for covariates.

Conclusion: In minority women with SLE alone, SES appears to account for a large portion of the elevated risk of APO. In contrast, in minority women with SLE and aPL, the elevated risk of APO persisted after adjustment for SES, and large disparities in APO remained. Further evaluation of disparities including clinical measures and more robust measures of SES are needed for better understanding.

Table: Unadjusted and Adjusted Odds of Adverse Pregnancy Outcomes in Women with SLE with and without APL

	Unadjusted		Adjusted*	
	White	Minority	White	Minority
SLE	reference	2.0 (1.0,4.1)	reference	1.6 (0.7,3.4)
SLE and aPL	3.3(1.4,7.1)	8.2 (2.3, 29.4)	3.7 (1.7,8.2)	7.3 (1.8,30.2)

Reported odds Ratio (CI).

Race: individuals not self-identifying as non-Hispanic white were categorized as minorities.

*Model adjusted for (1) Education: HS education or less (completed high school education or less), beyond HS (education beyond high school). (2) Age (3) Rheumatology visits: percentage of rheumatology study visits attendance (4) Median income: derived from zip code U.S and Canadian census data. (5) Disabled: self reported disability status. SLE defined as ≥ 4 revised ACR criteria.

aPL defined as (at least one of the following on two occasions: anti-cardiolipin IgM or IgG ≥ 40 MPL units, anti-β2 glycoprotein IgM or IgG ≥ 40 MPL, positive lupus anticoagulant), both SLE and aPL:

Abstract Number: 2537

Prescription Medication Use in Sweden Among Pregnant Women with Systemic Lupus Erythematosus and General Population Comparators

Kristin Palmsten[1], Julia F Simard[2,3], Christina D Chambers[1,4] and Elizabeth V Arkema[5], [1]Department of Pediatrics, University of California, San Diego, La Jolla, CA, [2]Division of Epidemiology, Health Research and Policy Department, and Division of Immunology & Rheumatology, Department of Medicine, Stanford School of Medicine, Stanford, CA, [3]Clinical Epidemiology Unit, Dept of Medicine, Karolinska Institutet, Stockholm, Sweden, [4]Department of Family Medicine and Public Health, University of California, San Diego, La Jolla, CA, [5]Department of Medicine, Clinical Epidemiology

2006-2012). Prevalent SLE during pregnancy was defined as 1) ³2 SLE ICD coded visits in inpatient or outpatient care in the National Patient Register (NPR) including ³1 SLE code from a specialist and ³1 SLE discharge before pregnancy or 2) ³1 SLE code from a specialist in the NPR and ³1 self-reported diagnosis of SLE in the MBR. Women without SLE were sampled from the Total Population Register. The Prescribed Drug Register was used to identify prescription medications dispensed in the 3 months pre-pregnancy, during pregnancy, each trimester, the 3 months after delivery (postpartum 1), and the 3-6 months after delivery (postpartum 2). No information was available on intravenous infusions and medications obtained over-the-counter. We reported the prevalence of non-biologic disease modifying antirheumatic drugs (nbDMARDs), systemic corticosteroids, and nonsteroidal anti-inflammatory drugs (NSAIDs; aspirin reported separately) in SLE pregnancies by pregnancy period. Then we calculated prevalence estimates of other medications (excluding vitamins) that were dispensed during pregnancy to ³10% of women with SLE and for the same medications among non-SLE pregnancies.

Results: We identified 483 pregnancies from 391 women with prevalent SLE and 5,723 pregnancies from 4,322 women without SLE. In SLE pregnancies, 49.3% had ³1 dispensing for nbDMARDs during pregnancy; the prevalence was 48.0% for corticosteroids, 40.8% for aspirin, and 6.0% for other NSAIDs and varied by period (Figure 1). Shorter exposure opportunity for preterm births contributed to decreased prevalence in the 3rd trimester. The prevalence of common medications among SLE pregnancies was 1.2 to 20-fold higher than among non-SLE pregnancies: dalteparin (20.9% vs 1.0%), paracetamol (18.2% vs 2.9%), levothyroxine (15.9% vs 4.9%), phenoxymethylpenicillin (14.3% vs 11.6%), pivmecillinam (10.8% vs 4.7%), and omeprazole (10.4% vs 2.3%).

Conclusion: In nearly half of SLE pregnancies from this population-based study, women were dispensed nbDMARDs and corticosteroids. Other commonly used medications among women with SLE had far higher prevalence estimates versus the general population. Research regarding the benefits and risks of these commonly used medications on SLE pregnancies, breast milk, and long-term offspring outcomes is needed.

Figure. Proportion of SLE pregnancies with ³1 dispensing for nbDMARDs, corticosteroids or NSAIDs by period.

	Pre-pregnancy	1st trimester	2nd trimester	3rd trimester	Post-partum 1	Post-partum 2
nbDMARD	35.0	38.9	36.7	28.6	37.1	40.2
Steroids	29.8	31.5	35.8	32.3	40.0	34.2
NSAID	8.5	5.0	0.8	0.4	11.0	8.1

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Reproductive Issues in Rheumatic Disorders: Basic and Clinical Aspects Poster Session
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: SLE women with unplanned pregnancies might be at increased risk of both disease and pregnancy complications. Until now, there has been no population-based estimate of the induced abortion (IA) rate in women with SLE, and no one has explored disease-related factors that might affect IA rates. Thus, we determined the rate of IA in women with SLE and compared this with general population rates. In addition, in women with SLE, we investigated potential disease-related predictors of IA.

Methods: We identified women with SLE using Quebec's universal healthcare databases (01/1996-12/2011). All women with SLE, 15-45 years, were identified based on ³1 hospitalization with a SLE diagnosis, or ³2 physicians' claims for SLE within any 2-to-24-month period. We determined the number of IA during the interval, as defined by procedure codes or physicians' claims for IA. We applied age-specific and relevant calendar-period IA rates to the observed years of follow-up to determine the expected number of IA. We then calculated the standardized incidence ratio (SIR) of observed to expected IA.

To investigate predictors of IA in SLE women, we conducted a nested-case control analysis, where SLE women with an IA (i.e. cases) were matched to ³1 control SLE women (i.e. without an IA at the index date) for age, calendar time, and cohort entry. Within this nested case-control cohort, we performed a multivariate conditional logistic regression including teratogenic (i.e. mycophenolate mofetil, methotrexate, leflunomide, cyclophosphamide) and non-teratogenic (i.e. azathioprine, cyclosporine, sulfasalazine) immunosuppressive exposure, corticosteroid use, and hospitalization for SLE in the previous year. Only SLE women covered by the public drug plan for ³16 weeks prior to the index date were included in this multivariate analysis.

Results: We observed 293 IA among 2508 women with SLE, yielding an incidence rate of 17.1 IA per 1000 person-years (95% CI 15.2, 19.2). Compared to the general population, we were unable to detect a difference among women with SLE in the number of IA (SIR 1.10; 95% CI 0.98, 1.24). In the multivariate analysis, including 78 cases and 1066 corresponding SLE controls, we did not see higher rates of IA among women exposed to teratogenic immunosuppressives (RR 0.37; 95% CI 0.13, 1.07) and those using corticosteroids (RR 0.67; 95% CI 0.39, 1.16). Results were inconclusive for the effect of non-teratogenic immunosuppressive use (RR 1.12; 95% CI 0.49, 2.57) and prior hospitalization for SLE (RR 1.32; 95% CI 0.80, 2.17) on IA.

Conclusion: Our findings suggest that women with SLE have a similar rate of IA compared to the general population. Although teratogenic drug exposure was not necessarily associated with a higher IA rate, the numbers do indicate that some unplanned pregnancies occur in women exposed to teratogenic immunosuppressives. Our results should prompt further research on contraceptive counseling and practices in women with SLE.

Session Title: Research Methodology Poster (ARHP)
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: The Jenkins Sleep Scale has 4 questions to assess the estimation of sleep problems in clinical research. It was developed in USA (1).

Aim: To assess the validity and reliability of the Jenkins Sleep Scale (JSS) in a Turkish population with Rheumatoid Arthritis (RA).

Methods: The Jenkins Sleep Scale was translated from English to Turkish with back translation method. Patients with RA according to ACR 2010 criteria were recruited into the study consecutively. The internal consistency (Cronbach's alpha) was assessed for reliability. Face validity and construct validity (convergent and divergent validities) were evaluated to assess its usefulness in Turkish population. The relation of the JSS with the Pittsburgh Sleep Quality Index (PSQI), Multidimensional Assessment of Fatigue (MAF) scale, subgroups of Nottingham Health Profile (NHP) (energy level-EL, pain-P, emotional reactions-ER, sleep-S, social isolation-SI, physical mobility (PM) and Health Assessment Questionnaire (HAQ) were assessed for convergent validity. The relation of the JSS with age, disease duration, VAS-patient global and DAS28 were assessed for divergent validity. Spearman's correlation coeficient (rho) was used to assessed the relation between quantitative parameters. $P<0.05$ was accepted as significant.

Results:

Sixtyone RA patients (48 female, 13 male) with 50.52 (SD:10.84) mean of age were recruited into the study. The Cronbach's alpha of JSS was 0.80. All questions and the answer choices of the JSS were well understood by patients which showed the face validity. The JSS has good correlation with functional parameters (convergent) and it has poor or not significant correlations with non functional parameters (divergent) (Table). It means that JSS has good construct validity. The JSS has the best correlation with the Pittsburgh Sleep Quality Index (rho=0.76).

Convergent validity of JSS	**Spearman's (rho)**	**Significance (p)**
PSQI	0.76	<0.0001
NHP-EL	0.56	<0.0001
NHP-P	0.57	<0.0001
NHP-ER	0.60	<0.0001
NHP-S	0.45	<0.0001
NHP-SI	0.55	<0.0001
NHP-PM	0.56	<0.0001
HAQ	0.55	<0.0001
MAF	0.47	<0.0001
Divergent validity of JSS	**Spearman's (rho)**	**Significance (p)**
Age	0.21	0.1130
Disease duration	0.22	0.0860
VAS-patientglobal	0.38	0.002
DAS28	- 0.044	0.73

Conclusion: The Jenkins Sleep Scale is valid and reliable instrument in RA patients in a Turkish population. It is practical and non time consuming scale to use in daily practice and the clinical researches.

Session Title: Research Methodology Poster (ARHP)

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The Patient-Reported Outcomes Measurement Information System (PROMIS¨) initiative is a cooperative research program designed to develop, evaluate, and standardize item banks to measure patient-reported outcomes across medical conditions. The PROMIS-29 measure contains 29 items, which include four items each for domains reflecting physical function, anxiety, depression, fatigue, sleep disturbance, pain interference, and ability to perform social roles, plus a single item on pain intensity. Scores are standardized with a mean of 50 and standard deviation (SD) of 10. Higher scores represent more of the domain being measured (e.g., greater sleep disturbance, greater ability to perform social roles). The purpose of this study was to examine feasibility and construct validity of the PROMIS29 in patients with systemic sclerosis (SSc) enrolled in a large multinational study.

Methods: English-speaking patients with SSc and ³18 years of age were enrolled in the Scleroderma Patient-centered Intervention Network (SPIN) Cohort between July 2014 and June 2015 from 19 centers across Canada, the USA and the UK. Baseline medical data are provided by the enrolling physician, and SPIN Cohort patients completed the PROMIS-29 at baseline. Floor and ceiling effects were defined as >15% of patients having the lowest or highest possible domain score, respectively. To examine convergent validity of domains, hypotheses were formulated a-priori about the associations of domains and legacy measures. The magnitude of the correlations was interpreted as small (|r| ² 0.3), moderate (0.3 < |r| < 0.5), or large (|r| ³ 0.5).

Results: In total, 473 patients were included in analyses. Mean age was 55 years (SD=11.9) and mean time since onset of the first non-Raynaud symptom was 11.8 years (SD= 8.7). Most patients were female (n=411, 86.9%) and diagnosed with limited SSc (n=277, 59.1%). Means for the PROMIS-29 domains were: function 42.8 (SD=8.7), anxiety 51.5 (SD=9.6), depression 50.9 (SD=9.2), fatigue 55.9 (SD=11.2), sleep 51.8 (SD=5.0), roles 47.5 (SD=9.6), pain interference 55.9 (SD=9.8), and pain intensity 3.7 (SD=2.7). There was a floor effect for anxiety (33.6%) and depression (37.6%), and ceiling effects for function (20.5%), roles (15.2%) and pain interference (23.7%). Most hypotheses were confirmed (7 of 9) and all were in the hypothesized direction (Table 1).

Conclusion: Results of our study support the construct validity of the PROMIS-29 in patients with SSc. Future studies should examine the influence of floor- and ceiling effects for some domains, as well as other psychometric properties of the measure.

Table 1. Hypotheses and correlations of PROMIS-29 domains and legacy instruments

PROMIS-29 domain	Legacy instrument(s)	Hypothesis for correlation[1]	Pearson correlation [95% CI]
Function	Health Assessment Questionnaire-Disability Index (HAQ-DI)	Large, negative	-0.79 [-0.82, -0.75]
	Cochin Hand Function Scale	Large, negative	-0.57 [-0.63, -0.50]
Anxiety	Brief Fear of Negative Evaluation	Moderate, positive	0.49 [0.42, 0.55]
Depression	Patient Health Questionnaire (PHQ)-8	Large, positive	0.72 [0.68, 0.76]
Fatigue	PHQ-8 item 4 (Feeling tired)	Large, positive	0.80 [0.76, 0.83]
Sleep disturbance	PHQ-8 item 3 (Trouble sleeping)	Large, positive	0.55 [0.48, 0.61]
Social roles	HAQ-DI	Moderate, negative	-0.64 [-0.69, -0.59]
Pain interference	Pain interference numeric rating scale	Large, negative	-0.82 [0.79, 0.85]
Pain intensity	Pain severity numeric rating scale	Large, positive	0.89 [0.87, 0.91]

[1]The magnitude of the correlations was interpreted as small (|r| ² 0.3), moderate (0.3 < |r| < 0.5), or large (|r| ³ 0.5).

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Research Methodology Poster (ARHP)
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Treat to target (TTT) is a recommended paradigm in the management of rheumatoid arthritis (RA). However, various data sources suggest that TTT is implemented in only a minority of routine care settings in the US. We designed a cluster-randomized controlled trial of a Learning Collaborative (LC) to facilitate uptake of TTT.

Methods: We recruited 11 rheumatology practices from across the US using sampling. They were randomized into two groups: one is receiving the LC intervention in Phase 1 (months 1-9) and the second formed a wait-list control group to receive the intervention in Phase 2 (months 10-18). The sites were permitted to choose a disease activity index from among 6 approved by an ACR committee. The LC intervention is a modified version of the Institute for Healthcare Improvement's Breakthrough Series Collaborative method, using the Model for Improvement, a Change Package (see Figure), and monthly metrics. Phase 1 intervention practices were brought together for one face-to-face learning session. Continuous collaboration and process improvement has been facilitated by several means: monthly webinars to share results of Plan-Do-Study-Act (PDSA) cycles; a web-based tool for sites to share aggregated site-level data and PDSA results; and monthly improvement metrics collected at each practice. The wait-list control group sites have had no TTT interventions during Phase 1.

The primary trial outcome is degree of uptake of ("adherence with") TTT as measured by chart review of select patients within participating sites, comparing the differences in adherence from baseline to end of Phase 1 between patients in intervention and control practices. Specifically, the chart reviews measures 4 aspects of TTT: evidence of shared decision-making, description of a treatment target, measurement of disease activity, and response to disease activity (i.e., change in treatment if not at target or reason for no change). Secondary outcomes include: resource use, adverse events, disease activity, and sustained adherence with TTT during Phase 2.

Results: Phase 1 will finish in October 2015. All intervention sites have remained engaged in the LC with a total of 38 providers (31 physicians, 6 nurses and 1 pharmacist) participating. The primary trial outcome measures will be collected by the study team through medical record review at completion of Phase 1.

Conclusion: If this LC is an effective means for improving uptake of TTT in rheumatology practices, this process could serve as a way of disseminating TTT more widely. As well, LCs may be considered for other rheumatology quality improvement efforts.

The Multidimensional Assessment of Fatigue Scale: A 25-Year Review and Evaluation

Basia Belza[1], Christina Miyawaki[2,3], Minhui Liu[1], Xi Zhang[4] and Melissa Fessel[1], [1]University of Washington School of Nursing, Seattle, WA, [2]University of Houston Graduate College of Social Work, Houston, TX, [3]Group Health Research Institute, Seattle, WA, [4]Henan Provincial People's Hospital, Zhengzhou, China

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Research Methodology Poster (ARHP)

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

The Multidimensional Assessment of Fatigue (MAF) scale was originally developed in 1990 for adults with rheumatoid arthritis. Since then, the MAF has been translated to 25 languages and used for patients with various diseases due to its relatively short, thus low burden for patients and potential for clinical usefulness. The purpose of this paper was to comprehensively review the MAF with particular attention to clinical relevance, reliability, and validity, and evaluate how the MAF has been used over the past 25 years.

Methods:

Database, and hand searches were conducted. We searched databases including CINAHL Plus, Health Source Nursing, MEDLINE, PsycINFO, and PubMed using multidimensional assessment of fatigue or MAF as key terms. All selected articles were peer-reviewed, published papers in English from January 1993 through May 2015. We located 463 articles on the topic and 98 articles met inclusion criteria.

Results:

Of the 98 articles, 79 (81%) were empirical studies and 19 (19%) were reviews/evaluations. The main purposes of the empirical studies were to 1) measure the level of fatigue in different types of disease; 2) investigate relationships between fatigue and health-related variables; and 3) assess fatigue as the outcome to evaluate efficacy, effectiveness and safety of interventions. The review/evaluation studies were comparisons of the MAF with other fatigue measures. Research was conducted in 17 countries (U.S., Turkey, U.K., Korea, Taiwan) and tested in 9 different languages (English, Turkish, Italian, Korean, Chinese) for 24 different diseases

(rheumatic diseases, osteoarthritis, depression, HIV, ankylosing spondylitis, cancer, chronic fatigue syndrome, fibromyalgia, multiple sclerosis, systemic lupus erythematosus). The sample sizes varied from 12 to 2193. The mean of global fatigue index ranged from 18.7 to 44.6, and its Cronbach's alpha was, on average, 0.93 (0.88 to 0.99). Strengths of the MAF were noted as an easy-to-use instrument with good reliability and validity in various populations, its multidimensionality, and adaptability in different languages while weakness was the needs of further validation of fatigue in more diseases and cultures.

Conclusion:

We conclude that the MAF is an appropriate assessment tool to measure fatigue, as well as intervention effectiveness in various diseases in clinical settings. Its feasibility with good internal consistency, adaptability with consistent, high reliability and validity, sensitivity to the levels of fatigue, and multidimensionality have allowed its applicability for international use. Continued use, translations, and assessments in different populations will enhance the cultural sensitivity as well as comprehensiveness of the MAF and strengthen its validity as a culturally sensitive fatigue instrument.

Session Title: Research Methodology Poster (ARHP)

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Developed in general population, rheumatoid arthritis and osteoarthritis patients, the Improved Health Assessment Questionnaire (iHAQ, formerly PROMIS HAQ) assesses physical function. The objective of this study was to evaluate the content validity of the iHAQ in patients with knee OA.

Methods: In a cross-sectional analysis using the baseline data from a Tai Chi versus physical therapy for knee osteoarthritis trial, persons meeting ACR criteria for knee OA patients self-administered the Improved HAQ, Patient Global Health Visual Analog Scale (Global VAS score range 0-10, 10=poor health), SF-36 survey (range 0-100, 100=good health), and WOMAC (range 0-1700, 1700=worst). We calculated two iHAQ scores having the same score range (0-100, 100=poor function) but based on the 20 items (method A) or 16 items (method B). To evaluate content validity, the iHAQ was compared with Global VAS, SF-36 Physical Function and Mental Health Component (PCS and MCS), and WOMAC pain and function using Spearman's rank correlation coefficients (rho). ANOVA with Bonferroni adjustment was used to test the differences in the iHAQ scores across the tertiles of WOMAC function score.

Results: In 204 knee OA patients (70% female and 53% white), the mean age was 60.2 years. The median (Interquartile Range, IQR) of iHAQ scores by the 20-item A and 16-item B methods were 21.9 (9.4, 34.4) and 18.8 (9.4, 31.3), respectively. **Table 1** summarizes iHAQ scores compared with SF-36 PCS and MCS, WOMAC pain and function, and Global VAS scores. Both iHAQ methods A and B were significantly correlated with other measures, with method B being slightly better. For physical function, higher iHAQ (poorer function) was more strongly correlated with lower SF-36 PCS scores (method A: rho=-0.66, p<.0001, method B: rho=-0.68, p<.0001) than with higher WOMAC function score (method A: rho=0.34, p<.0001, method B: rho=0.43, p<.0001). The iHAQ scores also corresponded to different levels of physical function as measured by WOMAC function (**Figure 1**). Higher iHAQ scores were however only weakly correlated with higher WOMAC pain scores (method A: rho=0.26, p=.0002, method B: rho=0.295, p<.0001), lower SF-36 MCS scores (method A: rho=-0.36, p<.0001, method B: rho=-0.37, p<.0001), and higher Global VAS scores (method A: rho=0.28, p<.0001, method B: rho=0.31, p<.0001).

Conclusion: The Improved HAQ has content validity for assessing physical function in knee OA patients. It also correlated more modestly with pain, mental health and global health status. Investigation for its longitudinal validity (responsiveness) is warranted.

Table 1. Results of Spearman's Rank Correlation Coefficients Analysis					
Instruments	**Median (IQR)**	**Method A**		**Method B**	
		rho	**P value**	**rho**	**P value**
Improved HAQ method A	21.9				
(0 best - 100 worst)	(9.4, 34.4)	1.0000	-	0.9756	<0.0001

Representing the Variability in Patients' Preferences

Raluca Cozmuta[1], Sonal Bhalla[2] and Liana Fraenkel[3], [1]Rheumatology, Yale University School of Medicine, New Haven, CT, [2]Yale University School of Medicine, New Haven, CT, [3]Medicine, Yale University School of Medicine, New Haven, CT

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Research Methodology Poster (ARHP)

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Data describing patients' priorities, concerns, and preferences are essential to inform important decisions in health care, including treatment planning and the development of programs to improve access and delivery of care. Traditional statistical approaches which measure the association between patient characteristics and aggregate preferences have failed to explain preference heterogeneity. In this study, we sought to examine the value of latent class analysis (LCA) as a means to describe variability in patients' preferences.

Methods: We administered a discrete choice experiment to examine preferences for a hypothetical medication varying across 4 attributes (each having 3 levels): route of administration, benefit, risk of a rare adverse events and cost for a standardized patient with joint pain, migraines and fatigue. Subjects were women, between the ages of 20 and 49 years, admitted to the hospital or infusion center. Gender and age were restricted to decrease the known influence of these factors on treatment preferences. We used LCA to calculate part-worth utilities (value computed for each level of each attribute on an interval scale), and to determine whether the importances of each attribute clustered into distinct groups.

Results: Subjects' (N=271) mean age was 34 (SD=8) years; 94 were non-Hispanic White, 95 non-Hispanic Black, and 82 Hispanic, 27% of all subjects had a college degree, 41% had an annual income of at least $40,000 and 45% rated their health as being fair or poor. LCA revealed that preferences could be clustered into 4 distinct groups. Importance scores for each attribute by group membership are summarized in the Table. Subjects in Group 1 were influenced primarily by the risk of TB and cost, those in Group 2 focused mostly on benefit, while subjects in Group 3 were most concerned with cost. A distinct group of subjects (Group 4) were strongly influenced by route of administration. An illustrated example of the difference in incremental value assigned to varying levels of each attribute is provided in the Figure below. For instance, subjects in Group 1 gained utility (or value) as the risk of TB was progressively lowered, whereas subjects in Group 3 were not sensitive to changes in the risk of TB.

Conclusion: LCA is able to generate unique sets of preferences that can then be used to inform decisions. It can identify which sets of attributes are preferred by unique groups of patients and which priorities are shared across groups, thus enabling end users to allocate resources that are most likely to benefit the greatest number of patients and/ or tailor programming to focus on patients with specific needs.

Table. Attribute Importance by Group Membership

	Group 1	Group 2	Group 3	Group 4
Attribute Importance	21.7% (n= 59)	36 % (n= 97)	24.8% (n= 67)	17.6% (n= 48)
Route of administration	23	6.8	7.1	**41.7**
Benefit	8.3	**53.5**	24.3	27.4
Risk of TB	**35.1**	14.8	1.3	15.6
Cost	33.6	24.9	**67.2**	15.4

Psychometric Testing of the Valued Life Activities Questionnaire in People with Rheumatoid Arthritis in the UK: Rasch Analysis

Yeliz Prior[1], Alan Tennant[2] and Alison Hammond[3], [1]Centre for Health Sciences, University of Salford, Greater Manchester, United Kingdom, [2]Human Functioning Sciences, ICF Unit, Swiss Paraplegic Research, Nottwil, Switzerland, [3]Centre for Health Sport & Rehabilitation Research, University of Salford, Salford, United Kingdom

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Research Methodology Poster (ARHP)

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Developed in the USA, the Valued Life Activities Scale (VLAs) measures participation in daily activities. We have linguistically and culturally adopted the VLAs 33 item scale for use in the adults with RA in the United Kingdom (UK) using the recommended guidelines for cultural adaptation.

Methods: We recruited participants through 17 Rheumatology clinics in National Health Service (NHS) Hospitals across the UK. The internal construct validity (unidimensionality) was assessed using (i) Confirmatory Factor Analysis (CFA) (ii) Mokken scaling and (iii) Rasch model (including the stochastic ordering of items, unidimensionality and local independence). The RUMM2030 software was used, utilising the partial credit parameterisation of the Rasch model.

Results: Responders (n=340) had a mean age of 62 years (SD 12.1), and average disease duration was 14.4 years (SD 11.7). Of these, 73.8% were women and a third (32.3%) were employed. Just over half (55.9%) were on combination therapy, and 7.4% were on biologic drugs. A CFA failed to support a total score from the 33 items (Chi Square 3552:df 464:p<0.0001; RMSEA 0.066 (90% CI: 0.064-0.068); CFI .985; TLI 0.984); the 25 items (Chi Square 2836:df 275:p<0.0001; RMSEA 0.078(90CI: 0.076-0.081); CFI .987; TLI 0.986; or the 14 item version (Chi Square 1228:df 77:p<0.0001; RMSEA 0.099(90CI: 0.094-0.104). Based on the 25 item version the three domain structure (i.e. Obligatory, Committed and Discretionary activities) of the item set also failed (Chi Square 2693:df 272:p<0.0001; RMSEA 0.076(90CI: 0.074-0.079); CFI .987; TLI 0.986). Fit of the data from the VLA to the Rasch model is shown in Table 1. The stochastic ordering (fit) and unidimensionality assumptions were not satisfied. The VLAs was characterised by

multidimensionality and misfit, which may have been influenced by extensive clusters of residual item correlations. While reliability was high in all cases, this could be expected to be inflated in the presence of local response dependency, as identified through the residual correlation patterns. Unfortunately, out of the 1545 cases collected in this study, only 79 subjects had complete data on the items that comprise the 'activities' (obligatory + committed) and 'participation' (discretionary) domains, due to the 'does not apply to me' response option.

Table 1. Rasch Analysis of Various versions of the scale.

Scale	*Chi-Square* *	Df	P	Residual item SD	Residual Person SD	PSI/ Reliability	*Unidimensionality % t-Tests*	95% CI
RA-33	315.3	165	<0.001	2.0134	1.0995	0.95	6.67	4.3-9.5
RA-25	214.2	200	0.233	1.5988	1.1197	0.95	10.64	8.3-13.0
RA-14	141.5	112	0.031	1.7771	1.1493	0.92	8.51	6.2-10.9
Ideal			**>0.05***	**<1.4**	**<1.4**	**>0.70**	**<5.0**	**LCI <5.0**

*Bonferroni Adjusted (for 33 items fit is >0.001)

Conclusion: The UK version of the VLA, across various scales, fails to satisfy classical and modern psychometric standards. The raw score cannot be considered a valid estimate of the persons' ability within any domain. The 'does not apply to me' response option renders valid scoring impossible in routine settings. It is recommended that the VLA set of items should be reconfigured and considered as a measure of Activities and Participation, consistent with ICF terminology.

Targeting Synovial Fibroblasts By the Intra-Articular Delivery of microRNA-140-3p and -5p Ameliorates Experimental Autoimmune Arthritis

Chrong-Reen Wang[1], Jia-Shiou Peng[2], Shih-Yao Chen[3], Chao-Liang Wu[4] and Ai-Li Shiau[5], [1]Rheum/Immun Sec/Int Med Dept, Medical Coll/Nat'l Cheng Kung, Tainan, Taiwan, [2]Institute of Basic Medical Sciences, Medical Coll/Nat'l Cheng Kung, Tainan, Taiwan, [3]Internal Medicine, Medical Coll/Nat'l Cheng Kung, Tainan, Taiwan, [4]Biochemistry and Molecular Biology, Medical Coll/Nat'l Cheng Kung, Tainan, Taiwan, [5]Microbiology and Immunology, College of Medicine, National Cheng Kung University, Medical Coll/Nat'l Cheng Kung, Tainan, Taiwan

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Animal Models Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Synovial fibroblasts (SF) with aberrant expression of microRNAs (miRNA) are critical pathogenic regulators of rheumatoid joint, and studies examining the effect of overexpressing or silencing miRNA expression levels in arthritis models can contribute to the development of miRNA-based therapeutics in rheumatoid arthritis (RA). We hypothesized that miR-140-3p and -5p are involved in the RA pathogenesis, and examined whether targeting SF by the intra-articular (i.a.) delivery of these molecules can ameliorate autoimmune arthritis in mice.

Methods:

Synovial tissues were obtained from RA and osteoarthritis patients, and two experimental models in mice were used in this study, collagen-induced arthritis (CIA) and collagen antibody-induced arthritis (CAIA). Recombinant lentiviral vectors were produced by transfecting 293T cells with pre-miR-140, the miR-140 precursor molecule cloned downstream of a CMV promoter, the packaging plasmid psPAX2 and the envelope plasmid pMD2.G by using a calcium phosphate precipitation method. Overexpressing miR-140-3p and -5p in SF and joints was performed by the lentivirus (LV)-mediated transfer of pre-miR-140 with a precursor scramble construct as the negative control. Quantitative real-time PCR was used to examine the expression levels of miR-140-3p and miR-140-5p in SF and synovial tissues. Clinical, histopathological and radiological scores were evaluated in CIA and CAIA joints receiving the i.a. delivery of miR-140-3p and -5p lentiviral vectors. Quantitation of sirtuin 1 (SIRT1) and stromal cell-derived factor-1 (SDF-1), target molecules

of miR-140-3p and miR-140-5p, respectively, was carried out by immunoblot/ELISA and real-time PCR in SF, and by immunohistochemical staining and real-time PCR in synovial tissues. For *in vitro* experiments with SF, cell migration, apoptosis and proliferation were analyzed with Boyden chamber, TUNEL and WST-1 assays, respectively.

Results:

Lower expression levels of miR-140-3p and -5p were detected in SF and synovial tissues from RA patients and two arthritis models. In both CIA and CAIA mice, the LV-mediated i.a. transfer of miR-140-3p and -5p significantly ameliorated arthritis by clinical, histopathological and radiological evaluations with reduced densities in SF. Overexpressing miR-140 resulted in lower expression levels with correlated kinetic patterns of SIRT1 and SDF-1 in SF and joints. *In vitro* overexpressing miR-140 in SF enhanced apoptosis, reduced migration and proliferation, and regulated the expression of miR-140 in the presence of pro-inflammatory cytokines.

Conclusion:

Our results demonstrate that targeting SF by the i.a. delivery of miR-140-3p and -5p can ameliorate autoimmune arthritis, and these findings might facilitate the pharmacological development of miRNA-based molecular therapeutics in RA.

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Animal Models Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Non-selective Janus kinase (JAK) inhibitors have shown long-term efficacy in treating rheumatoid arthritis (RA). However, clinical efficacy is limited due to concerns of dose-limiting toxicity related to JAK2/3 inhibition such as anemia, malignancies and infections. The objectives of this study were to reveal pharmacological profiles of a novel JAK1-selective inhibitor, NIP-565, and to estimate its therapeutic potential and safety in the treatment of RA patients.

Methods:

Enzyme assays and cell-based assays were conducted to assess the JAK1 selectivity of NIP-565. As therapeutic activity for RA patients, in vitro JAK1 signaling inhibitory activity was evaluated by IL-6-induced STAT1 phosphorylation using human peripheral blood. In vivo therapeutic potential of NIP-565 was evaluated the reduction of paw swelling in collagen-induced arthritic (CIA) rats. In order to estimate the risk of adverse events caused by JAK3 inhibition, NK cell numbers and NK cell cytotoxic activity were compared in the NIP-565 or tofacitinib treatment animals. The effect on erythropoietin -stimulated erythropoiesis using human bone marrow cells was examined to assume the risk of anemia caused by JAK2 inhibition. Human pharmacokinetics prediction was performed by allometric scaling methods.

Results:

NIP-565 inhibited JAK1 in the nM range, and showed more than 10-fold selectivity towards JAK2, JAK3, and Tyk2. NIP-565 inhibited IL-6-induced phosphorylation of STAT1, at sub-μM IC_{50} value. This inhibition was 37-fold stronger than the inhibitory effect on GM-CSF-induced STAT5 phosphorylation as cellular JAK2 activity, and 2-fold stronger than the inhibitory effect on IL-15-induced phospho-STAT1 production as cellular JAK1/JAK3 activity. In a rat CIA model, NIP-565 attenuated paw swelling in a dose-dependent manner after repeated oral administration once per day for 15 days. Both NIP-565 and tofacitinib completely suppressed at 30 mg/kg dosing. NK cell numbers in the peripheral blood of CIA model rats were 2-fold higher in the NIP-565-treated group than in the

tofacitinib-treated group at 30 mg/kg. In tumor-bearing mice model, NIP-565 (30 mg/kg, 2 weeks) maintained NK cell cytotoxic activity compared with control, while tofacitinib (30 mg/kg) reduced that activity. These data suggest that the risk of adverse events caused by NK cell attenuation with NIP-565 treatment may be lower than that with tofacitinib treatment. Additionally, NIP-565 showed weaker inhibitory effect than other JAK inhibitors (e.g., tofacitinib, baricitinib and peficitinib) in human erythropoiesis assay. As a result of analysis with human pharmacokinetics prediction, NIP-565 could be enough exposure to provide high therapeutic efficacy without anemia in clinical practice by once daily oral administration.

Conclusion:

NIP-565 is a novel JAK1-selective inhibitor, and expected to provide potent anti-inflammatory effects while minimizing the adverse effects that would result from JAK2/3 inhibition in the treatment of RA patients.

Session Title: Rheumatoid Arthritis - Animal Models Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Colony-stimulating factors (CSF) are simply defined as haemotopoitec growth factors. However, CSFs have been implicated to have additional functions in various autoimmune diseases. Specifically M-CSF has been shown to effect the progression of CIA, a murine model of RA. Additional studies have also shown that M-CSF is required to maintain the monocyte derived macrophage population in the ankle. However, all of these studies utilized M-CSF or MCSFR knockout or mutant mice. Here we generated MCSFR conditional mice that lack the receptor in myeloid cells. We hypothesize that M-CSF is integral to the development of monocytes and subsequent macrophage differentiation, and will affect the development of other autoimmune diseases.

Methods:

We generated mice lacking M-CSF-R specifically in myeloid cells (M-CSF-$R^{fl/fl}Cre^{LysM}$) and assessed mice at 4 months of age for characterization of RA-like disease. Monocyte turnover/proliferation and differentiation were examined *in vivo*using flow cytometric analyses.

Results:

M-CSF-$R^{fl/fl}Cre^{LysM}$ displayed a normal response and recovery to RA in our K/BxN serum transfer arthritis (STIA) model. However flow cytometry analysis revealed differential cell populations in multiple tissues within M-CSF-$R^{fl/fl}Cre^{LysM}$ mice compared to M-CSF-$R^{fl/fl}$ mice. We observed a marked decreased in the non-classical monocytes in which the M-CSF-$R^{fl/fl}$ was deleted. Since blood monocytes are directly linked to the formation of tissue inflammatory macrophages we also examined synovial macrophages in the ankle. We previously characterized synovial macrophages as $MHCII^-$, tissue resident macrophages, and $MHCII^+$ macrophages. M-CSF-$R^{fl/fl}Cre^{LysM}$ mice showed a significant decrease in $MHCII^+$macrophages.

Conclusion:

M-CSF plays a central role in both monocyte differentiation in the blood and MHCII^{+} macrophage proliferation in the ankle. The lack of M-CSF-R depletion in both intermediate and non-classical monocytes, in the blood, suggests that expression of M-CSF-R is required for classical monocytes to differentiate into non-classical monocytes. This data also suggest that M-CSF can act as either an active or passive participant in the replenishment of synovial macrophages. M-CSF could be directly required for the differentiation of monocytes into synovial macrophages. The decrease in MHCII^{+} cells could also be due to the decreased ability of classical monocytes to differentiate into non-classical monocytes, suggesting that non-classical monocytes directly replenish the synovial macrophage populations. The M-CSF-R$^{fl/fl}$Cre^{LysM} provides an important model to study autoimmune disease and identify the specific role of M-CSF in classical and non-classical monocyte differentiation and their ability to replenish both tissue resident and bone marrow derived macrophages during the progression of disease.

Session Title: Rheumatoid Arthritis - Animal Models Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: RPTPσ (gene *PTPRS*) is a protein tyrosine phosphatase that binds heparan sulfate- and chondroitin sulfate-containing proteoglycans with its extracellular immunoglobulin domains 1 and 2 (Ig1&2). RPTPσ is expressed at minimal or low levels in immune cells, while in neurons the competition between heparan sulfate and chondroitin sulfate for RPTPσ binding controls axon outgrowth and is called the proteoglycan switch. We recently reported that RPTPσ is highly expressed in fibroblast-like synoviocytes (FLS) and the proteoglycan switch exists in these cells. Treatment of FLS with decoy RPTPσ Ig1&2 competes with surface heparan sulfate proteoglycans, which flips the proteoglycan switch and reduces rheumatoid arthritis (RA) FLS migration, invasion and attachment to cartilage. Systemic administration of RPTPσ Ig1&2 reduces arthritis severity and cartilage damage in the K/BxN serum transfer mouse model of RA. To further characterize RPTPσ Ig1&2 as a putative FLS-targeting treatment for RA, we tested its selectivity for FLS, as well as its effectiveness in an additional mouse model of arthritis.

Methods: Migration was assessed using a scratch-wound assay with RA FLS and normal human dermal fibroblasts (NHDF). Collagen production in NHDF was assessed by measuring collagen 1A2 mRNA expression in TGFβ-stimulated cells. RPTPσ and heparan sulfate proteoglycan mRNA expression were measured by qPCR. Surface expression of heparan sulfate was assessed by flow cytometry. Collagen antibody-induced arthritis (CAIA) was induced by injection of mice with an anti-collagen antibody cocktail (ArthritoMab®).

Results: RPTPσ Ig1&2 decreased migration of RA FLS by 27%, but did not affect migration of NHDF. This was not due to differences in *PTPRS* expression; however, surface heparan sulfate levels and expression of heparan sulfate proteoglycans were higher in RA FLS (> 4-fold and > 2-fold increase, respectively). RPTPσ Ig1&2 did not affect collagen production by NHDF upon TGFβ stimulation, a characteristic function of these cells important for wound-healing. Finally, RPTPσ Ig1&2 administration decreased arthritis severity by 30% in the CAIA mouse model of RA.

Conclusion: RPTPσ Ig1&2 treatment ameliorates arthritis in multiple models by selectively targeting FLS due to their high expression of heparan sulfate proteoglycans. These results support further testing of RPTPσ Ig1&2 alone and in combination with conventional immune-targeting RA therapies.

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Animal Models Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Given the complexity and heterogeneous nature of rheumatoid arthritis (RA), it is unlikely that a single biomarker may provide sufficient discrimination; therefore biomarker signatures may represent more realistic approach for the future of personalized medicine in RA. These signatures may represent different subsets in this heterogeneous disease. The study of metabolomics represents a new approach to develop biomarker signatures. Given that metabolism and metabolome are similar between species, biomarkers field might benefit from animal models studies in which pathogenic mechanisms can be controlled, and correlations with joint metabolome can be evaluated.

Methods: Ankles from 10 weeks old K/BxN mice (an IL-1b-driven mouse model of arthritis; n=6) and from 10 weeks old TNFARE mice (a TNF-driven mouse model of arthritis; n=6) and its corresponding littermates, were snap frozen, pulverized and then homogenized using a biphasic chloroform/methanol/water extraction method for polar and lipid metabolite analysis. The phases were separated, dried, and then reconstituted before injection and analysis on a 5600 Triple-TOF LC-MS (MS; AB Sciex). Peak integration, alignment, and statistical analysis were performed using Markerview software (AB Sciex).

Results: Multivariate statistical analysis of the MS spectra successfully discriminated between inflamed joints samples and controls. Several metabolites were upregulated in both mouse models compared to their respective littermates. Among them, metabolites in purine (AMP, GMP, xanthosine and deoxyinosine), pyrimidine (uridine and thymidine), TCA cycle (malate, fumarate and citrate), and phospholipid (lysophosphatidylcholine) pathways were statistically increased in joints from both murine models, which suggest that there may be common metabolic perturbations in these disease models. However, some metabolites were upregulated uniquely in the K/BxN model such as metabolites in phenylalanine/tyrosine metabolism, branched chain amino acid metabolism (leucine, isoleucine and valine) and eicosanoid metabolism (15-HEPE, 13-HOTrE, 12-oxo-ETE).

Conclusion: The differences between up-regulated metabolites in both murine models suggest different metabolic signatures secondary to different pathogenic pathways. More metabolic profiles studies using controlled animal models are needed to determine if metabolic signatures can distinguish subsets of RA patients and help in diagnoses, prognosis and predicting drug choice in this disease.

Antibodies to Malondialdehyde-Acetaldhyde Adducts Are Increased in the Serum of Mice Following Infection with P. Gingivalis and/or Injection of Citrullinated Mouse Type II Collagen: a Model of Human Disease Response

Session Title: Rheumatoid Arthritis - Animal Models Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with RA complicated by periodontal disease (PD) have been shown to have higher anti-citrullinated protein antibody (ACPA) levels, which have also become predictive markers of the disease and its severity. Recent studies by our group have shown that Malondialdehyde-Acetaldehyde Adducts (MAA) are present in synovial tissues and antibodies to MAA are detected in the serum of patients with RA. Also, the presence of these antibodies in serum correlated with the severity of the disease. Therefore, it was the purpose of this study to determine whether animal models of RA in the context of *P. gingivalis* (Pg) infection results in the development of anti-MAA antibodies.

Methods: DBA/1J mice were subjected to sulpha-methoxazole in their water for 10 days and then gavaged with Pg 3 times over a 1 week period. Control mice were subjected to antibiotics in the absence of Pg and injected with mouse type II collagen (C-Il) or citrullinated Col (Cit-C-II) in parallel as previously published. Serum was tested for the presence of antibody to C-II, Cit-C-CII, Pg outer membrane antigen (PGMA), CCP, and MAA.

Results: At week 6, Pg infected (3.25) and Cit-C-II immunized mice 3.25 ($P \leq 0.001$) had higher inflammation indexes as compared to controls. There was nearly a 2-fold increase in serum CCP in the Pg infected mice (11.2 U/ml) compared to uninfected controls (6.89 U/ml) ($p=0.002$). There were fairly high concentrations of IgM anti-MAA antibodies in the serum of mice injected with nothing or C-II (954 ± 139 and 1025 ± 230 U/ml, respectively). These values increased when Pg (1578 ± 153 U/ml) was administered to the mice in the presence of C-II (1458 ± 262 U/ml) or Cit-C-II (1250 ±161 U/ml). In contrast, IgG anti-MAA levels (Figure) were only increased in mice infected with Pg (51 ± 19 U/ml), and were further increased only in the presence of Cit-C-II (86 ± 30 U/ml), but not C-II (59 ± 19 U/ml). Thus, it appears that the IgG anti-MAA responses were affected by the addition of these two unique antigens. Finally, IgG anti-MAA antibodies in Pg infected mice correlated with CRP levels ($p = 0.019$), and mice infected and immunized with Cit-C-II correlated with both CRP ($p = 0.01$) and CCP (0.012) levels.

Conclusion: These data show that following infection with Pg and immunization with C-II or Cit-C-II anti-CCP response is not increased. However, serum IgG anti-MAA antibody responses increased when Cit-C-II immunization was coupled with Pg infection. More importantly, IgG anti-MAA antibody significantly correlate with CRP levels in this same group of animals. A correlation that also is prevalent in the serum of patients with RA. Thus, this animal model appears to mimic many of the interactions of anti-MAA, CCP, and Pg, observed in humans and may be useful for further investigations into these interactions with respect to inflammatory responses in RA.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Animal Models Poster
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Alterations in resident bacteria, termed dysbiosis, is present in patients in early stages of rheumatoid arthritis, psoriatic arthritis, and spondyloarthritis. However, it remains unclear if dysbiosis is causative or occurs as a result of the disease. Using the collagen-induced arthritis (CIA) model in mice, we aimed to determine if microbiome changes occur and, if so, at what point during the development of disease.

Methods: DBA1/j mice were injected intradermally with bovine type II collagen emulsified in complete Freund's adjuvant at days 0 and 21 to induce CIA. Fecal pellets were harvested from the mice at days 0, 21, and 39 after immunization. The microbial DNA was extracted from the feces using a commercially available kit. 16S rRNA sequencing was performed and the sequences aligned using SINA with a reference taxonomic database Silva 111 NR. Microbial ecology such as diversity and relative abundance of the 16S rRNA sequences was evaluated using Explicet software. Statistical analyses of the changes in identified species were done by non-parametric ANOVA.

Results: The mean arthritis severity in our cohort of mice at day 39 after immunization was 6.67 ± 1.05 (based on a scale of 0-12); no mice had observable arthritis before day 24. Our microbiome sequencing results demonstrate significant differences in the beta diversity of the microbial community at day 0 (1.000) compared to day 21 (0.866) and at day 39 (0.920). We now plan to evaluate the relative abundance of specific bacterial species at each of our time points.

Conclusion: These data indicate that dysbiosis occurs during the initial stages of CIA, when immune responses that lead to disease are developing. Such findings suggest that dysbiosis may be causative in pathogenesis of disease rather than reflective of the disease presence. An interesting finding was that beta diversity was most affected at day 21 compared to day 39. This is consistent with microbiome studies in patients with RA in which dysbiosis were most pronounced in new-onset patients compared to those with established disease. With our additional analyses, we expect to identify changes in specific bacterial species that may shed light on the role of the microbiome in developing arthritis.

Session Title: Rheumatoid Arthritis - Animal Models Poster
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Synovial lining macrophages play an important role in initiating and maintaining joint inflammation in arthritis. Classically activated pro-inflammatory macrophages and alternatively activated anti-inflammatory macrophages are generally referred to as M1 and M2 macrophages, respectively. The CD163, CD204, and CD206 proteins are predominantly expressed by M2-phenotype macrophages. Monocyte/macrophage-restricted expression of CD163 has been confirmed and observed in affected joint tissues of patients with RA

and spondyloarthropathy. However, the pathogenic role of M2 macrophages in inflammatory arthritis remains unclear. We investigated the involvement of M2 macrophages in the development of arthritis in mice.

Methods:

Collagen antibody-induced arthritis (CAIA) was induced using a combination of monoclonal anti-type II collagen antibodies and lipopolysaccharide. C57BL/6 (B6) background CD163 knockout (KO) mice and BALB/c background CD204 KO mice were used in an autoantibody-induced RA mouse model. Arthritis was graded using a 0–16 clinical scale (0–4 per paw). Histological assessment was conducted using paraffin-embedded 4-mm sections stained with hematoxylin and eosin. Total RNA was isolated from mouse ankle joints. Gene expression of M2 macrophage markers including CD163, CD204, and CD206 and the pro-inflammatory cytokines IL-1β and IL-6 was determined before and 10 days after CAIA induction by quantitative RT-PCR.

Results:

CD163 gene expression in inflamed synovium was significantly lower than that in normal synovium. In contrast, CD204 mRNA expression was significantly greater in inflamed synovium. No significant differences in CD206 mRNA expression were observed between normal and inflamed synovium. Thus, we focused our attention on involvement of CD163- and CD204-positive macrophages in the development of arthritis. CD163 KO mice exhibited significantly higher clinical scores for arthritis than did control wild-type B6 mice. Histomorphometric quantification of arthritic changes in the joint tissues confirmed the clinical assessment, with higher inflammation in CD163 KO mice. Correspondingly, mRNA expression of IL-1β and IL-6 was significantly up-regulated in inflamed ankle joints of CD163 KO mice compared to those of control mice. CD204 KO mice were found to be normally susceptible to arthritis.

Conclusion:

In the present study, we aimed to identify the involvement of M2 macrophages in CAIA. CD163 deficiency exacerbated disease severity in autoantibody-induced arthritis via up-regulation of synovial tissue IL-1β and IL-6 expression. Thus, CD163-positive M2 macrophages may play a role in inhibiting the pathogenesis of RA.

Inhibition of IL6 Receptor Improves Arthritis and Atherosclerosis in a Mouse Model of Rheumatoid Arthritis

Amy Archer[1], Carla Cuda[2], Alexander Shaffer[2], Emily Alex Waters[3], Chad Haney[4], Rana Saber[2], George Kenneth Haines III[5], Jason Low[6] and **Harris R. Perlman**[7], [1]Rheumatology, Northwestern University, Chicago, IL, [2]Northwestern University, Chicago, IL, [3]Chemistry of Life Processes Institute, Northwestern University, Evanston, IL, [4]Center for Advanced Molecular Imaging, Northwestern University, Evanston, IL, [5]Mount Sinai, New York, NY, [6]Genentech, San Francisco, CA, [7]Feinberg School of Medicine, Northwestern University, Chicago, IL

Session Title: Rheumatoid Arthritis - Animal Models Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis is a chronic, systemic, autoimmune disease associated with an increased risk of cardiovascular disease. However, it is unclear what role patients' dyslipidemia plays in enhancing this cardiovascular risk. Moreover, the impact that treatments for rheumatoid arthritis have on both dyslipidemia and cardiovascular disease is under investigation. Anti-IL6 receptor (aIL6R) therapy is an effective treatment for rheumatoid arthritis but can be associated with an unfavorable lipid profile. Our study examines whether treatment with aIL6R is able to improve both inflammatory arthritis and early atherosclerosis in a mouse model of rheumatoid arthritis (K/BxA^{g7}).

Methods: K/BxA^{g7}mice on a high fat diet were treated with a murine aIL6R monoclonal antibody (cMR16-1) three times a week for 12 weeks. Arthritis was histologically assessed by a blinded pathologist and with SPECT/CT. Atherosclerosis was determined with whole mount sudan IV staining, sections though the aortic root and MRI. Serum cholesterol levels and cytokine levels were determined

via enzymatic and luminex assays respectively.

Results: Our data show that cMR16-1 improves both articular and extra-articular inflammation, but does not influence bone resorption. In addition, sudan IV staining showed a decrease in the area of early atherosclerosis by 30%. As expected there was an associated increase in serum IL6. We also observed an increase in adiponectin, leptin, VEGF and RANTES, as well as a decrease in GRO-alpha. However, in our model treatment with cMR16-1 was not associated with any changes in the lipid profile of the K/BxA^{g7} mice.

Conclusion: Thus our data suggest that cMR16-1 is able to improve arthritis and early atherosclerosis in the absence of changes to the lipid profile in our mouse model of rheumatoid arthritis. This suggests that changes to the standard lipid profile may not be the ideal parameter to monitor in assessing the ability of treatments for rheumatoid arthritis to improve atherosclerosis.

14-3-3η As a Novel RA Drug Target: Anti-14-3-3η Monoclonal Antibody Delays the Onset and Mitigates the Severity of Arthritis in CIA Mice

Abedelnasser Abulrob[1], Mario Mercier[1], Slavisa Corluka[1], Roger MacKenzie[1], Shalini Raphael[1], Sara Michienzi[2], Jane Savill[2], Yuan Gui[2], Walter Maksymowych[3] and **Anthony Marotta**[2], [1]National Research Council of Canada, Ottawa, ON, Canada, [2]Augurex Life Sciences Corp., Vancouver, BC, Canada, [3]Department of Medicine, University of Alberta, Edmonton, AB, Canada

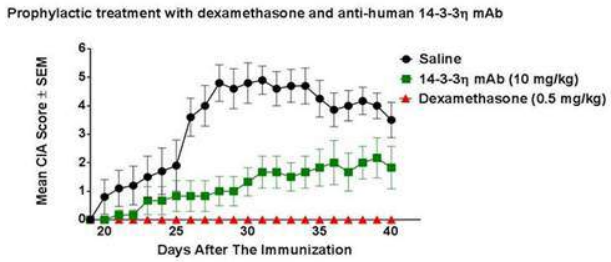
Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Animal Models Poster
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: As an extracellular ligand, 14-3-3η potently and concentration-dependently upregulates the expression of multiple factors including TNFα, IL-6, and RANKL and its clinical detection is associated with joint damage progression risk. Several disease modifying agents are available for the treatment of RA with remission efficacy rates around 30%. Since RA is driven by multiple factors to varying degrees, within and between patients along the disease course, personalized medicine that enables the specific targeting and measurement of disease potentiators, such as 14-3-3η, is highly desirable. This study evaluated the *in vivo* feasibility of targeting 14-3-3η with a monoclonal antibody to mitigate the onset and severity of collagen-induced arthritis (CIA) in mice.

Methods: 27 DBA/1 mice were randomized to four study groups: non-induced mice (negative control, N=5), 0.5 mg/kg of dexamethasone group (positive control, N=6), saline injected mice (placebo group, N=10), and the treatment arm that was administered 10 mg/kg of 14-3-3η mAb (N=6). Treatments were initiated 2 days prior to immunization with collagen and administered daily for 6 weeks. A collagen booster was injected on day 18 of the study for all immunized mice. Arthritis scores were determined daily by an established and standardized chart evaluating inflammation and swelling of each paw (0 to 4). All animals were sacrificed 42 days after the beginning of the treatments. Paws were further analysed by x-ray. Student t-test was performed to examine differences (onset CIA, maximum, and end scores, and paw scores) amongst the two groups. Kruskal Wallis test was used to compare group daily score differences over the course of disease.

Results: Non-induced and dexamethasone mice did not develop visible signs of arthritis over the course of disease while 100% of the mice within the saline arm did. 17% of the mice in the 14-3-3η mAb group did not develop any signs of arthritis. The CIA score for the 14-3-3η mAb arm had significantly lower onset scores (0.83 ±0.41 vs 2.7 ±1.57, p=0.0119), maximum scores (2.33 ±1.75 vs 5.3 ±1.83, p=0.0052), and end scores (1.83 ±1.84 vs 4.3 ±1.7, p=0.0197) than the saline treated groups. Figure 1 further demonstrates that 14-3-3η mAb treated mice have significantly lower disease over the disease course than animals in the saline group, $p<0.01$, with x-ray paw analysis also demonstrating significance (p=0.0041).



Conclusion: 14-3-3η is a mechanistic joint damage factor involved in the pathogenesis of RA. A research program to exploit modifying the 14-3-3η pathway is underway to develop improved antibody therapeutics for delaying the onset and reducing the severity of this disease.

Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Animal Models Poster
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Several genome-wide associations studies have in recent years linked polymorphisms in the *PTPN2* locus to rheumatoid arthritis (RA) and other autoimmune diseases. *PTPN2* encodes for the tyrosine phosphatase TC-PTP, an important regulator of cytokine signaling in hematopoietic cells. Complete loss of TC-PTP has previously been shown to result in development of spontaneous erosive arthritis in mice. Also, recent work has reported that lack of TC-PTP in T-cells leads to systemic autoimmunity in mice. Disease-associated variants of *PTPN2* are believed to result in a partial loss of protein expression. To model the functional genetics of RA-associated *PTPN2* variants in mice, we studied the effect of *PTPN2* haploinsufficiency in the SKG mouse, a spontaneous $CD4^+$T-cell-driven model of autoimmune arthritis.

Methods: Mice homozygous for the SKG Zap-70^{W163C} mutation develop IL-17 dependent spontaneous arthritis, which is due to reduced TCR signaling resulting in altered thymic selection and emergence of autoreactive $CD4^+$ T-cells. Arthritis in SKG mice can also be induced by administration of the fungal cell wall component mannan. Development of both spontaneous and mannan-induced arthritis was assessed in $PTPN2^{+/+}$ and $PTPN2^{+/-}$ SKG mice. Also, CD4 T-cells isolated from $PTPN2^{+/+}$ and $PTPN2^{+/-}$ SKG mice were transferred to $RAG2^{-/-}$mice and development of spontaneus arthritis was monitored. Clinical scoring of arthritis was followed by histological scoring and micro-CT analysis. Flow cytrometry was used to asses thymic T-cell development and T-cell effector populations in arthritic joints.

Results: Haploinsufficiency of *PTPN2* significantly increased the severity of arthritis in SKG mice. Importantly, transfer of $PTPN2^{+/-}$ $CD4^+$ T-cells to $RAG2^{-/-}$ mice was sufficent to increase severity of arthritis when compared to transfer of $PTPN2^{+/+}$ $CD4^+$ T-cells. Further investigation into the effect of *PTPN2* haploinsufficiency in T-cell function revealed no alterations in thymocyte development or

selection; however, arthritic *PTPN2*$^{+/-}$ SKG mice showed an increased accumulation of Th17 cells in arthritic joints.

Conclusion: Haploinsufficiency of *PTPN2* enhances CD4^{+} T-cell mediated autoimmune arthritis in mice.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Animal Models Poster
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Tremendous progress has been made in the development of non-conventional therapies for rheumatoid arthritis (RA). Mesenchymal stem cells (MSC) present multiple immunosuppressive capacities and may have the potential to exert therapeutic effect in RA. In this study, the effects of MSC transplantation on established collagen-induced arthritis (CIA) were evaluated and compared with two kinds of biologic agents, anti-tumor necrosis factor (TNF) and anti-CD20 antibody.

Methods: CIA was induced with the immunization of type Ⅱ collagen (CⅡ) in DBA/1 mice. Human umbilical cord derived MSC (5×10^6), anti-TNF antibody (100μg) and anti-CD20 antibody (200μg) were injected i.p. into mice on day 28 after the immunization, respectively. The control group was treated with PBS or human fibroblasts (5×10^6). All mice were sacrificed 3 weeks later and arthritis severity was assessed by clinical and histology scoring. The frequency of CD4^{+} T cell subsets, B cells and plasma cells in spleen was analyzed by flow cytometry. Serum levels of autoantibody to mouse CⅡ were also determined. The ability of MSC to regulate the balance of T helper cell subsets in CⅡ stimulated CIA CD4^{+} T cells was assessed *in vitro*.

Results: MSC treatment significantly decreased the severity of arthritis and pathology scores, which was comparable to anti-TNF or anti-CD20 treatment. All of the three treatments resulted in a decrease in Th1 subset, but none of them altered the percentage of Th2 subset. Except anti-CD20 treatment, both MSC and anti-TNF treatment significantly decreased Th17 subset. Anti-CD20 treatment depleted nearly half of B220+ cells, and markedly reduced the frequency of plasma cells and serum levels of autoantibody compared to the control group [(738±187) U/ml vs (1817±447) U/ml, $P<0.001$]. The decrease of autoantibody level was also detectable in the group of anti-TNF treatment (663±336 U/ml) or MSC treatment (1057±362 U/ml), but neither of these two treatments showed significant effect on the percentage of B cells or plasma cells. MSC inhibited the generation of T follicular helper (Tfh) cells which play a key role for supporting B cells and antoantibody production. MSC treatment also enhanced the proportion of regulatory T (Treg) cells compared to the control group. In vitro MSC inhibited the generation of IL17^{+} or IFNγ^{+} T cells, induced Foxp3^{+} T cells, and also reduced pathogenic IL17^{+}IFNγ^{+} or IL-17^{+}Foxp3^{+} T cells.

Conclusion: These results indicated that MSC may have a role in preventing the pathogenic plasticity of CD4^{+} T cell subsets in arthritic milieu. Umbilical cord (UC)-MSC could exert comparable effects to biologic agents and effectively correct the immune imbalance in CIA. UC-MSC may provide a promising approach for the treatment of RA.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Animal Models Poster
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Several observations implicate a critical role for T cell dysregulation as a central problem in RA. We present a method for suppressing T cell activation by activating natural inhibitory receptors called leukocyte associated immunoglobulin-like receptor-1 (LAIR-1). We used the collagen-induced arthritis model and DR-1 tg mice to study the importance of LAIR-1 in autoimmune arthritis.

Methods: a.) *Murine* splenocytes (LAIR-1 +/+ or LAIR-1 -/-) were stimulated with soluble CD3 in the presence or absence of collagen and supernatants were collected for cytokine analysis. b.) DR-1 mice were immunized with CII/CFA to induce arthritis and were injected intra-articularly with 0.3mg of either the stimulatory monoclonal antibody to LAIR-1 or a hamster IgG control. c.) DR1/LAIR-1 -/- and DR1/LAIR-1 +/+ mice were immunized to induce arthritis and mean severity scores were recorded thrice weekly.

Results: a.) In the presence of LAIR-1, CD3-induced cytokine secretion was significantly suppressed in the presence of collagen, while LAIR-1 -/- cells had no attenuation. b.) Treatment with the stimulatory monoclonal antibody to LAIR-1 attenuated CIA in the mice (severity scores 1.5 ± 1.9 vs. 6.4 ± 2.4, $p = 0.007$). c.) DR1/LAIR-1-/- mice that were immunized with CII developed more severe arthritis and had a greater percentage of limbs affected with arthritis than did the wild type (DR1/LAIR-1 +/+) group ($p<0.05$).

Conclusion: Taken together, these data demonstrate that collagen can suppress T cell cytokine response in the presence of LAIR-1. Treatment with stimulating mLAIR-1 antibodies suppresses CIA while DR1/LAIR-1 -/- mice develop more severe arthritis than wild type controls. These data suggest that LAIR-1 may be a potential therapeutic target for suppressing RA.

PRO-Resolving Mediators Issued from Apoptotic CELL Efferocytosis (SUPERMAPO) Modulate Antigen Presenting CELL Properties Toward a Tolerogenic Profile: Efficacy in the Treatment of Collagen- Induced Arthritis

Francis Bonnefoy[1], Romain Vallion[2], Mélanie Couturier[3], Anna Daoui[3], **Eric Toussirot**[4] and Sylvain Perruche[1], [1]UMR1098 INSERM, EFS Bourgogne Franche Comté, Besançon, France, [2]INSERM UMR 1098, EFS Bourgogne Franche Comté, Besançon, France, [3]INSERM UMR1098, EFS Bourgogne Franche Comté, Besançon, France, [4]Service de Rhumatologie, CHU J Minjoz, Besancon, France

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Animal Models Poster
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Pro-resolving mediators produced by macrophages eliminating apoptotic effector cells during the resolution of inflammation have been shown to stop inflammation, favor tissue repair and return to homeostasis. In immune-mediated inflammatory diseases such as rheumatoid arthritis (RA), one may believe that reintroducing proresolving mediators would allow the control of the

disease. We have developed a cell culture system of macrophages and apoptotic cells that mimics this phase of resolution. The supernatant of this cell culture system called SuperMApo (SUPERnatant issued from Macrophage APOptotic cell culture) is enriched in pro-resolving factors including anti-inflammatory cytokines like TGF-b.

Objectives: to evaluate the effects of SuperMApo in the treatment of collagen-induced arthritis (CIA).

Methods: SuperMApo is obtained after 48h of culturing macrophages from peritoneal cavity with apoptotic cells obtained from thymus after X-ray irradiation. CIA was used as a model of RA. SuperMApo (200 µL of 5x concentrated SuperMApo,IV, for 2 days) was injected in score 8 CIA mice. The effect of SuperMApo was first evaluated on APC and T cells from naïve mice in terms of phenotype, profile and properties such as maturation of APC before or after TLR-ligand stimulation and T cell polarization assays. Then, SuperMApo was evaluated in vivo in CIA mice.

Results: Macrophages, cDC and pDC submitted to SuperMApo demonstrated robust insensitivity to TLR ligand-induced activation, particularly in terms of co-stimulatory molecules expression. Spleen cells cultured with SuperMApo demonstrated a strong Treg increase. This was confirmed using naïve CD4+CD25– T cells cultured in the presence of SuperMApo showing Foxp3 expression. CIA mice received 2 injections of SuperMApo (over 48h) and demonstrated a significant long term decrease of CIA (joint score before and after SuperMApo: 8-10 and 1-4, respectively; sustained response to 60 days). This clinical improvement was associated with a higher suppressive function of Treg. Treg transfer from mice treated by SuperMApo to arthritic mice induced joint improvement. Finally, we tested SuperMApo effect on PBMC issued from 4 patients with RA, with and without TLR ligand activation. Our results were that monocytes from 3 patients showed a decreased inflammatory phenotype after overnight exposure to SuperMApo (CD80, CD86, CD40 and HLA-DR expression).

Conclusion: these data demonstrated that macrophages eliminating apoptotic cells produced pro-resolving mediators affecting Antigen Presenting Cell properties therefore allowing the control of arthritis in the CIA model

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Animal Models Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Rheumatoid arthritis (RA) is a chronic autoimmune disease characterized by a hyper-inflammatory response in synovial joints. In joints of patients with active RA, few apoptotic cells are detected, and experimental data suggest that apoptotic cells delivered into the joint are protective. One of the receptors involved in uptake of apoptotic cells, a process called efferocytosis, is the Mer tyrosine kinase receptor. In addition, the Mer receptor is involved in an anti-inflammatory natural feedback mechanism. The local role of Mer during arthritis, however, has not been elucidated.

Methods: One day after the booster injection of collagen-induced arthritis (CIA) in mice, a commercially available antibody against Mer was injected intravenously or an adenovirus overexpressing the Mer ligand Protein S (Pros1) was injected intra-articularly into the knee joints. Mice were macroscopically scored until they were euthanized at day 30 or 31, respectively. Knee joints were taken for histology and synovial biopsies were isolated for cytokine profiling. The KRN serum transfer model was induced by two injections of serum on day 0 and 2 in either Mer-deficient mice or in wild type mice that overexpress Pros1 in their knee joints. Mice were macroscopically scored for 7 days or 14 days, respectively, and knee joints were taken for histology.

Results:

CIA mice treated with anti-Mer antibodies showed increased incidence and higher macroscopic knee score compared to those receiving an isotype control (IgG). Histological analysis showed significantly enhanced synovial inflammation, and higher synovial expression of the apoptosis marker caspase 3 after anti-Mer treatment. This indicates reduced efferocytosis in the anti-Mer treated animals. On the other hand, anti-Mer antibody treatment induced phosphorylation of the Mer receptor in these mice and upregulated synovial expression of the suppressor of cytokine signaling (SOCS) 1 and 3 genes. This could, however, not reduce the synovial expression of matrix-metalloproteinases (MMPs) 3, 9, and 13 and the pro-inflammatory mediator TNFα. In concordance with these data, CIA mice which locally overexpressed Pros1, a ligand that bridges apoptotic cells to the Mer receptor, in the knee joint showed a significant reduction in knee inflammation and expression of TNFα and several MMPs. Resolution of joint inflammation in the KRN-serum arthritis model is dependent on the development of apoptotic cells. We found that in Mer-deficient mice, induction of passive KRN arthritis caused an accelerated onset of disease and enhanced the macroscopic score in both knee and ankle joints. In contrast, intra-articular overexpression of Pros1 before KRN serum injections markedly reduced arthritis severity in wild type mice.

Conclusion: These data indicate the importance of Mer in controlling the severity and resolution of inflammation in experimental arthritis. Our data suggest that promoting Mer-mediated uptake of apoptotic cells in the arthritic joint might be therapeutically beneficial.

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Animal Models Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Bruton's tyrosine kinase (BTK) is a member of the Tec family kinases, and is expressed in B cells, monocytes/macrophages, mast cells, basophils and osteoclast[1,2]. BTK regulates cell proliferation and survival of B cells, and the expression of inflammatory factors in macrophages[3]. In osteoclast, RANKL (receptor activator of NF-kB ligand) binds to its receptor RANK, and induces differentiation and bone resorption of osteoclast through BTK-PLCγ signaling pathway[4]. These various effector cells are reported to be associated with disease progression of rheumatoid arthritis[4,5]. Therefore, BTK would be a potential target for a therapeutic agent in rheumatoid arthritis.

Methods: The phosphorylation of BTK and the expression of CD69 on B cells, which were stimulated by anti-IgM, were examined using western blotting or flow cytometry. In macrophages, the expression of inflammatory factors induced by IgG was measured with ELISA assay. The bone resorption activity of mouse osteoclast was evaluated using osteoclast culture kit. To establish collagen-induced arthritis, male DBA/1 mice were injected on day-27 and-6 with an emulsion of complete Freund's adjuvant and bovine type II collagen. On day 0, mice were randomized into treatment groups. TAS5315 was administrated orally once daily for 15 consecutive days. Disease severity was evaluated by clinical score of paw swelling, and the bone destruction of ankle was also measured by micro-CT imaging analysis at the end of treatment period. The scoring of inflammation, pannus, cartilage and bone damage in four joints of the CIA mice was performed by a single blinded pathologist using a modified Mankin score system.

Results: TAS5315 showed a potent inhibitory activity against anti-IgM-induced phosphorylation of BTK with an IC50 in sub nmol/L range. The up-regulation of CD69 on stimulated mouse splenic B cells was suppressed by TAS5315 in a dose-dependent manner (IC50 = 0.2 nmol/L). TAS5315 inhibited the expression of TNFα and CCL3 stimulated by IgG in macrophages, and also suppressed bone resorption activity of osteoclast induced by RANKL. In a mouse collagen-induced arthritis model, TAS5315 dose-dependently and significantly decreased the clinical score in arthritic mice compared with that in vehicle-treated mice, with an ED50 value of 0.12 mg/kg. In the histopathological analysis, TAS5315-treated mice had a marked reduction in the severity of inflammation, pannus, cartilage destruction and bone destruction in a dose-dependent manner. TAS5315-treated mice also showed a remarkable recovery of

bone mineral density compared with vehicle-treated mice by the micro CT analysis of hind paws of CIA mice.

Conclusion: Our study demonstrates that a novel BTK inhibitior, TAS5315, shows significant efficacy in an animal model of rheumatoid arthritis. These data suggests that TAS5315 could be a promising novel therapeutic agent for RA by inhibiting inflammation and bone destruction.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Animal Models Poster
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is an inflammatory joint disorder, the progression of which leads to the destruction of cartilage and bone. Fibroblast-like synoviocytes (FLS) display an important role in the pathogenesis of RA. Wnt signaling pathway act several important biological functions, such as cell differentiation, embryonic development, limb development and joint formation. Accumulated evidence has suggested that this signaling pathway plays a key role in the FLS activation, bone resorption and joint destruction in RA. The purpose of this study was to investigate the therapeutic effect of lapatinib on collagen-induced arthritis (CIA) in rats.

Methods: Forty Wistar albino female rats were randomized to 4 groups (n=10 in each group): Group-I as the control group, Group-II as the arthritis (sham) group, Group-III as the Paricalcitol group and Group-IV as the Pyrvinium group were assigned. Arthritis was induced by intradermal injection of chicken type II collagen combined with incomplete Freund's adjuvant. One day after the onset of arthritis, paricalcitol (0.3 µg/kg/day) was injected subcutaneously, and pyrvinium (5 mg/kg/day) was given via oral gavage, until they were killed on day 29. Animals were sacrificed at the 15th day after the onset of arthritis. The paws of the rats were obtained for further analysis. Perisynovial inflammation and cartilage-bone destruction were determined histopathologically in the paws. Tissue axin-2, Wnt-5a and DKK1 mRNA expressions were determined by real-time polymerase chain reaction (RT-PCR).

Results: Arthritis was clinically developed at 12 to 13 days after the injection of collagen (Figure). The 29th day scores were decreased in the paricalcitol and pyrvinium groups compared to the own 13th day score ($p<0.05$ for both), while it was increased in the sham group ($p<0.05$). Histopathological analysis demonstrated the extensive perisynovial inflammation and marked cartilage-bone destruction in sham group rats. Paricalcitol and pyrvinium treatments decreased the perisynovial inflammation and cartilage-bone destruction in the paws. Moreover, the tissue mRNA expressions of axin-2 (22 folds), Wnt5a (11 folds) and DKK1 (3 folds) were increased in the sham group compared to the control group. Their mRNA expressions in paricalcitol and pyrvinium groups were similar in the control group.

Conclusion: The present study shows that Wnt signaling pathway is active in CIA model. Moreover, paricalcitol and pyrvinium those are inhibit Wnt pathway ameliorate CIA. These agents may be candidate to further research in human RA.

Session Title: Rheumatoid Arthritis - Animal Models Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Mesenchymal stem cells (MSCs) function as immune regulators in inflammatory conditions. However, it is unclear how to control local inflammation by systemically administered MSCs. We aimed to evaluate the therapeutic effect of human MSCs on inflammatory arthritis and to delineate the underlying mechanisms.

Methods: Mice with collagen antibody induced arthritis (CAIA) were intraperitoneally injected with human bone marrow-derived MSCs (5×10^6 cells/500 µl of PBS, two times at three-day interval) or control vehicle. The clinical score and histological features of tarsal joints were compared between two groups. The synovial and spleen tissues of CAIA mice were stained with human anti-nuclear antibody (ANA) to confirm the migration of injected human MSCs. After analysis of multiple cytokines on peritoneal cells, migration assay of MSCs was performed in the presence of SDF-1a and/or CCL5. We evaluated the effect of MSCs on induction of regulatory T cells by coculture system *in vitro* and mRNA profiling *in vivo*.

Results: Treatment with human MSCs alleviated the joint inflammation of CAIA mice. The clinical score was consistently lower in mice injected with MSCs compared to control mice. Histological analysis also revealed the conserved articular structure by MSCs. The joints and spleens of CAIA mice treated with human MSCs were positively stained with human ANA, suggesting recruitment of MSCs to inflamed tissues. Peritoneal lavage cells in mice treated with MSCs expressed a higher level of SDF-1a and CCL5, known as chemoattractants. MSCs migrated more easily in the presence of SDF-1a and/or CCL5. The synovia and spleens of CAIA mice treated with MSCs showed the upregulated expression of FOXP3 mRNA, which was supported by enhanced differentiation into regulatory T cells in coculture of CD4+ T cells and MSCs.

Conclusion: This study suggests that MSCs would directly induce the differentiation of regulatory T cells through migration into inflamed tissues. Systemic administration of MSCs can be a therapeutic option for rheumatoid arthritis.

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Animal Models Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: The orphan nuclear receptor 4A2 (NR4A2 / NURR1) is emerging as a critical transcription factor in chronic inflammatory joint diseases. We have demonstrated elevated expression of NR4A2 in joint tissues from patients with arthritis, and this receptor promotes synovial hyperplasia and cartilage degradation *in vitro*. NR4A2 transactivates the MMP-13, IL-8, and prolactin promoters in synovial fibroblasts and may therefore contribute to the onset and progression of arthritis. TNF-alpha rapidly and potently induces NR4A2 expression and nuclear localization, suggesting that NR4A2 controls transcriptional responses to inflammation *in vivo*. The current study tests the hypothesis that NR4A2 is an early transcriptional mediator of synovial inflammation in the human TNF-alpha transgenic mouse model of rheumatoid arthritis.

Methods: The hTNF-alpha transgenic model exhibits deregulated expression of the human proinflammatory cytokine due to incorporation of the beta-globin 3' UTR which stabilizes the transcript (Taconic Biosciences, Model 1006). Mice develop severe polyarthritis by 10 weeks of age with 100% penetrance. To address early changes in gene expression, RNA was extracted from 8-week old male hTNF-alpha and wild-type mice and NR4A1-3 mRNA was detected by RT-qPCR. Gene expression patterns were compared between hTNF-alpha and wild-type joints using RT-qPCR panels specific for 88 genes involved in RA pathogenesis and housekeeping controls.

Results: Joints from 8-week old hTNF-alpha mice lacked clinical signs of arthritis, yet several genes involved in pathogenesis were upregulated: CCL5 (15-fold), IL-1-beta (13-fold), TNFRSF1b(10-fold), ICAM1 (7-fold), CCR5 (5-fold), TNF (5-fold), IL-6 (4-fold), NF-kappa-B (3-fold), and CREB (2-fold). All three NR4A receptors were expressed at detectable levels by RT-qPCR, however only NR4A2 was selectively increased by 50% in the forepaws and hindpaws of hTNF-alpha mice relative to wild-type controls ($p<0.05$).

Conclusion: Upregulation of NR4A2 mRNA precedes clinical signs of arthritis in the hTNF-alpha model, suggesting that NR4A2 is an early transcriptional mediator of synovial inflammation. In line with this, several genes involved in inflammation and cell signaling are expressed at elevated levels, demonstrating that molecular pathogenesis is underway. Future studies will examine the expression and distribution of NR4A2 throughout the course of disease and examine the therapeutic potential of targeting NR4A2 in the hTNF-alpha model of RA.

Session Title: Rheumatoid Arthritis - Animal Models Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Administration of intravenous-immunoglobulin (IVIg) is a recognized safe and efficient immunomodulatore therapy for many autoimmune diseases. Anti-idiotypic antibody binding to pathogenic autoantibodies was proposed as one of mechanisms attributed to the protective activity of IVIg in autoimmunity. The aim of this study was to fractionate the anti-anti-citrullinated protein anti-idiotypic-antibodies (anti-ACPA) from a IVIg preparation and to test it as a treatment for collagen-induced arthritis in mice.

Methods:

IVIg was loaded on an ACPA column. The eluted fraction was defined as ACPA-specific-IVIg (ACPA-sIVIg). Collagen-induced-arthritis (CIA) was induced in mice. Mice were treated weekly with ACPA-sIVIg, low-dose-IVIg, high-dose-IVIg and PBS. Sera-ACPA titers, anti-collagen Abs and cytokine levels were analyzed by ELISA; antibody-forming-cell activity by ELIspot assay; expansion of T-regulatory cell (Treg) population by FACS.

Results:

ACPA-sIVIg inhibited ACPA binding to citrullinated-peptides (CCP) *in-vitro* 100 times more efficiently than the IVIg compound. ACPA-sIVIg was significantly more effective than IVIg-preparation in attenuating development of collagen-induced arthritis. Splenocytes from CIA mice treated with ACPA-sIVIg reduced the ACPA and anti-collagen-antibody titers including the number of anti-collagen and ACPA antibody-forming cells. In parallel, splenocytes from ACPA-sIVIg treated mice secreted higher levels of anti-inflammatory cytokines and lower proinflammatory cytokines. The ACPA-sIVIg inhibitory potential was accompanied with expansion of the Treg population. Low dose IVIg did not affect the humoral and cellular response in the CIA-mice, in comparison to PBS treated mice.

Conclusion:

Based on our results, IVIg may be considered as a safe compound for treating patients with rheumatoid-arthritis by neutralizing pathogenic autoantibodies , reducing proinflammatory cytokines and expanding Treg population.

Session Title: Rheumatoid Arthritis - Animal Models Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Treatment with helminthes and ova from helminthes, improved clinical findings of several autoimmune diseases in patients and in animal models. We aimed to decipher the tolerogenic potential of Tuftsin- Phosphorylcholine (TPC), a helminth based compound in collagen induced arthritis (CIA) a mouse model of rheumatoid arthritis (RA).

Methods:

CIA DBA mice were treated with TPC, subcutaneously (5 µg/0.1 ml) or orally (250 µg/0.1 ml), starting 3 days before disease induction. The control groups were treated with PBS. Collagen antibodies were tested by ELISA, cytokines protein levels by DuoSet ELISA and T and B-regulatory cells phenotypes by FACS.

Results:

TPC treated mice had a significantly lower arthritis score 1.5 with comparison to the control mice 11.8 ($p<0.0001$) in both the subcutaneous and orally treated groups at Day 31. Moreover, histology analysis demonstrated highly inflamed joints in the CIA DBA mice, whereas the TPC treated mice maintained normal joint structure. Moreover, TPC decreased the titers of circulating collagen II antibodies in the sera of the mice ($p<0.0001$) as well as enhanced the expression of IL-10 ($p < 0.001$), and inhibited the production of

TNFα, IL-17 and IL-1β ($p < 0.0001$). TPC significantly expanded the CD4+CD25+FOXP3+ T-regulatory (Treg) cells and CD19+IL-10^{high}+$CD5^{high}CD1d^{high}$TIM-1^{+} B-regulatory (Breg) cells phenotypes ($p < 0.0001$) in the treated mice.

Conclusion:

Our data indicate that treatment with TPC attenuate CIA development in DBA mice which was exemplified by a low arthritic score, normal joints histology, reduced pro-inflammatory cytokines and increased anti-inflammatory cytokine expression, as well as expansion of Treg and Breg cells. Our results may lead to a new approach for a natural therapy for early RA patients.

Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Animal Models Poster
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: *SPACIA1/SAAL1* is a gene associated with abnormal synovial proliferation. We previously showed that *SPACIA1/SAAL1* small interfering RNA inhibited the proliferation of rheumatoid arthritis synovial fibroblasts *in vitro* and that *SPACIA1/SAAL1* transgenic mice exhibited early onset and rapid progression of collagen-induced arthritis (CIA). Therefore, SPACIA1/SAAL1 could be involved in the progression of synovitis. In the present study, we generated *SPACIA1/SAAL1*-deficient mice and investigated the gene's potential as a druggable target.

Methods: To ablate the functional mouse *SPACIA1/SAAL1* locus, we deleted its exon 4 in the C57BL/6 genome using the Cre/loxP system to cause a frameshift mutation. After backcross mating with the DBA/1J strain for 8 generations, we examined the effect of SPACIA1/SAAL1 in CIA. In *SPACIA1/SAAL1*-deficient and wild-type (control) mice, the serum levels of anti-type II collagen antibody and the bone destruction score were measured on day 56 after the first collagen injection.

Results: Heterozygous ($SPACIA1^{+/-}$) and homozygous ($SPACIA1^{-/-}$) mice systemically lacking SPACIA1/SAAL1 developed normally and did not show abnormalities. In the $SPACIA1^{-/-}$ mice, the incidence of arthritis and its score were significantly reduced on days 35 and 56, respectively, when compared with values in wild-type mice. However, all tested mice developed CIA eventually. The mean anti-type II collagen antibody level and bone destruction score in the $SPACIA1^{-/-}$ mice decreased by half compared with those in wild-type mice, but this difference was not significant.

Conclusion: Consistent with our previous study of CIA using *SPACIA1/SAAL1* transgenic mice, this study also indicated that SPACIA1/SAAL1 may be involved in the progression of CIA. However, we conclude that there is almost no potential for SPACIA1/SAAL1 itself as a druggable target, although SPACIA could be related to regulation of crucial factors in CIA. We previously found that SPACIA1/SAAL1 is related to cyclin-dependent kinase 6 expression, at least in cultured rheumatoid arthritis synovial fibroblasts. We are currently studying downstream targets of SPACIA1/SAAL1, including cyclin-dependent kinase 6, to find potential druggable targets.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Animal Models Poster
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Today many treatment options for Rheumatoid Arthritis (RA) and degenerative inflammatory musculoskeletal diseases are available, however, not all patients respond properly or have to reduce or stop their medication due to adverse reactions. In such cases treatment with low dose-radiotherapy (LD-RT) with X-rays can be beneficial to attenuate inflammation, reduce pain and improve the quality of life, as suggested by studies by Ott et al. (2012-2014) and Seegenschmiedt et al. (1998). Preclinical *in vitro* models have revealed that doses of X-ray ranging from 0.1 Gray (Gy) to 1.0 Gy have an impact on immune cells and reduce the inflammatory phenotype of endothelial cells, neutrophils, and macrophages. A dose of 0.5 Gy has been shown to be the most efficient. Even though these mechanisms are well known and accepted, health care professionals and patients often refrain from low LD-RT. The main reasons for that are fear of radiation, lack of randomized trials and lack of *in vivo* examinations with inflammatory animal models. We therefore aimed to examine the impact of local LD-RT with 0.5 Gy on inflammation and bone homeostasis in human *TNF-α* transgenic (h*TNF-α*tg) mice.

Methods: Inflamed joints of h*TNFα* tg mice were locally irradiated (0.5 Gy, 250 kV, 15mA) and monitored over a time course of 30 days. Afterwards, paw sections were analyzed using histomorphological methods and the OsteoMeasure™ Software. In an *ex vivo* setting, we investigated the effects of LD-RT on bone marrow-derived osteoclasts (OC) of h*TNFα*tg mice as well as on murine and human fibroblast-like synoviocytes (FLS) using qPCR, ELISA and flow cytometry.

Results: A significant improvement of grip strength over 30 days in mice treated locally with 1x 0.5 Gy of X-rays was observed. Further histological analysis of irradiated paws showed a significant reduction of the inflammatory area as identified by decrease of leukocyte infiltration, reduction of bone loss, and OC numbers in comparison to mock treated control animals. *Ex vivo* differentiation of h*TNFα*tg mice derived OCs was also significantly reduced after exposure to X-rays in the dose range of 0.5 to 2.0 Gy. Further, OC function seems to be down-regulated after an irradiation with 2x 0.5 Gy as indicated by qPCR analysis. Irradiation of human RA FLS resulted in a dose-dependent reduction of cell growth and increased numbers of apoptotic cells.

Conclusion: On a mechanistic preclinical osteoimmunlogical basis our findings support that LD-RT can influence TNF dependent arthritis. The results from our OC experiments further imply that LD-RT does not only have a considerably decelerating effect on inflammation, but also on bone erosion. Future placebo controlled studies in humans need to address its effect in RA patients.

Session Title: Rheumatoid Arthritis - Animal Models Poster
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Monocyte may differentiate to osteoclasts in bone and macrophages in joint. so, blocking of monocyte differentiation maybe effective target in RA (rheumatoid arthritis) treatment. in this study, we interrupted monocyte differentiation via SIRT1 and proposed potential strategy in treatment of RA.

Methods: In this study, monocytes from synovial fluid of RA patients (RAMCs), THP-1 monocytes, bone marrow–derived monocytes (BMDCs) from mice and RAW 264.7 cells were studied. Expression of macrophages surface markers (CD11b, CD14 and CD36) were analysis by real-time PCR. TNF-α, IL-1β and IL-6 levels were measured in the conditioned medium by ELISA. The effects of SIRT1 on osteoclast formation were detected TRAP activity and pit formation. In addition, RANKL [receptor activator of nuclear factor kappa B (RANK) ligand]-induced RANK expression in bone marrow–derived monocyte/macrophage precursors (BMMs) and RAW 264.7 cells were measured using western blot. Anti-arthritic effects of SIRT1were evaluated in CIA mice.

Results: PMA-induced expression of macrophages surface markers (CD11b, CD14 and CD36) and proinflammatory cytokines (TNF-α, IL-1β and IL-6) secretion was inhibited by resveratrol, SIRT1 activator in RAMCs. BMDCs from SIRT1 TG mice were inhibited differentiation by PMA than control BMDCs from C57BL/6 mice. These effects were associated with decrease in proinflammatory cytokines (TNF-α, IL-1β and IL-6) secreation by decreasing mRNA expression in BMDCs from SIRT1 TG mice. Further, resveratrol suppressed the PMA-induced PU.1 activation, which is critical transcription factor for macrophages differentiation. SIRT1 activity and expression were elevated by cilostazol. Cilostazol inhibits monocytes to macrophages differentiation through the down-regulates PU.1 activity and cilostazol elevated SIRT1 mRNA and protein levels in 12 - 24 h and increased SIRT1 activity, and these effects were also inhibited by sirtinol, a SIRT1 inhibitor. Furthermore, the RANKL-induced nuclear expression of PU.1 was suppressed by cilostazol, a SIRT1 activator. In addition, marked RANKL-induced RANK immunofluorescence staining in Raw264.7 cells was strongly attenuated by cilostazol and by rSIRT1, and these attenuations were prevented by sirtinol. Extensive RANK staining of knee synovial tissues in a mouse model of collagen-induced arthritis (CIA) was also markedly reduced by cilostazol (30 mg/kg/day), and in BMMs both RANKL- and M-CSF-induced differentiation of BMMs to multinucleated $TRAP^+$ giant cells and resorption pit formation were inhibited by cilostazol in association with a decrease in TRAP (a marker enzyme of osteoclasts) activity.

Conclusion: SIRT1 have dual a role in anti-osteoclast formation BMMs of RA bone and inhibiting differentiation monocyte to macrophage in RA synovium. so, regulation of SIRT1 maybe a potential strategy for perfect RA treatment.

Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Rheumatoid arthritis (RA) is believed to be induced by environmental, genetic and immunological factors. Monoclonal Anti-citrullinated protein/peptide autoantibodies (ACPA) target different citrullinated proteins years before RA is diagnosed but their role is still largely unknown. As a prerequisite to identify genetic factors involved in rheumatoid arthritis, we analyzed the susceptibility of PWD Mus musculus musculus subspecies, separated from Mus musculus domesticus about one million years ago to collagen antibody-induced arthritis (CAIA) and the role of ACPA antibodies in the CAIA model of arthritis.

Methods:

Collagen antibody-induced arthritis (CAIA antibody cocktail provided by Modiquest GmbH) was induced by administration of collagen antibodies followed by lipopolysaccharide injection. Two genetically distinct mouse strains, representatives of the subspecies *Mus musculus domesticus* and *Mus musculus musculus* as well as their F1 hybrids, and consomis strains thereof were analyzed for the development of clinical and histological signs of arthritis upon CAIA treatment. ACPA antibodies were tested by adding it to the CAIA cocktail and their autoantigenic profile was analysed using protein macroarrays as previously described (**Leidinger et al., 2009)**

Results:

The wild-derived mouse strain PWD/Ph was highly susceptible to CAIA induced arthritis, whereas the classical laboratory strain C57BL/6J was resistant (2mg CAIA cocktail). Mice carrying chromosomes 5 or 12 from PWD on a B6 background display a B6-like phenotype in the CAIA model as well as the F1 hybrids (B6xPWD and PWDxB6) implicating the presence of dominant resistance modifiers in the C57BL/6J genetic background. The two mouse strains differ highly in their autoantigenic profile induced and the PWD strain shows decrease of B-cells and IgA, IgG, IgM levels.

Injecting specific monoclonal ACPAs reactive with the citrullintated H1 and H4 were able to block the CAIA induced arthritis. This inhibition can be explained in part by a Toll dependent inhibition of osteoclasts. Moreover we show the first time that TLR2 activation via Porphyromonas gingivalis LPS or vesicles and lipomannan treated animals show a 80% reduction of arthritis score compared to E. coli LPS in a C57BL/6J CAIA model.

Anti-collagen specific antibodies are increased in both strains B6 and PWD when arthritis is induced. Rheumatoid factor RF was not detected in PWD or B6 mice before and after the CAIA-treatment nor in the LPS-treated control animals. Interestingly, the commercial CCP2 ELISA detected ACPA in some animals regardless of the treatment. Using the arginine and citrulline containing peptides as control shows that this response is directed to the arginine containing peptide and in most of the animals citrullination downregulates the antigenicity of the autoantibody targeting of uncitrullinated proteins or peptides.

Conclusion:

The *Mus musculus musculus* derived mouse strain PWD/Ph is a highly susceptible CAIA mouse strain to study new genetic arthritis markers. TLR2 activation of P. gingivalis LPS blocks CAIA and specific ACPAs inhibit osteoclast activation and may be used as therapeutic antibodies in the future that protect from RA destructive development.

Session Title: Rheumatoid Arthritis - Animal Models Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a disease that typically induces secondary osteoporosis, which increases the risk

of bone fractures and, consequently, mortality. Bone fracture is induced not only by lower bone mineral density (BMD) but also by deterioration in bone structure. Anti-IL-6 receptor antibody is used as RA treatment, however its effect on bone strength is not clear. The purpose of this study is to clarify the influence of IL-6 on the changes of bone strength in arthritis, using a mouse model of collagen-induced arthritis (CIA). Additionally, we analyzed what correlates with bone strength in CIA mice.

Methods: CIA was immunized in DBA/1J mice by an intradermal injection of bovine type II collagen on Days 0 and 21. Mice were injected intraperitoneally with anti-mouse IL-6 receptor antibody (MR16-1) on Days 0 and 21. Urine and serum were sampled on Day 33-35. Urinary collagen type 1 cross-linked C-telopeptide (CTX), a bone resorption marker, and serum procollagen type 1 N-terminal propeptide (P1NP), a bone formation marker, were measured by ELISA. Femurs and feet were excised on Day 35, the peak of swelling of joints. As the bone structure, trabecular bone volume (BV/TV) of distal femur, and cortical bone thickness (Ct) of femur shaft, BMD of femur shaft and foot were analysed by micro-computed tomography (μCT). The bone strength of femur shaft was measured a maximum load by bending test.

Results: In CIA mice, urinary CTX and serum P1NP were significantly higher and lower, respectively, than in non-immunized mice. All parameters of bone structure (BV/TV of the distal femur, Ct of the femur shaft, BMD of the femur shaft and the foot) in CIA mice significantly decreased than in non-immunized mice. Moreover, maximum load of the femur shaft in CIA mice was significantly lower than in non-immunized mice. Maximum load of the femur shaft more strongly correlated with Ct of the femur shaft than BMD of the femur shaft and swelling score in hind limb. On the other hand, swelling score in the hind limb most strongly correlated with BMD of the foot, but did not correlate with Ct of the femur shaft. MR16-1 suppressed the development of arthritis. An increase in urinary CTX and a decrease in serum P1NP during development of CIA were suppressed by MR16-1. MR16-1 treatment significantly prevented a decrease in BV/TV of the distal femur, BMD of the foot and maximum load of the femur shaft by CIA induction.

Conclusion: We demonstrated that CIA induced loss of bone strength through a deterioration of bone structure and that cortical thickness has possibility of playing the most important role in bone strength. Moreover, our results indicated that IL-6 played an important role in bone strength because anti-IL-6 receptor antibody prevented the loss in bone strength in CIA.

Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Animal Models Poster
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Inflammatory (M1) macrophages and T helper 17 (TH17) cells are central to rheumatoid arthritis (RA) pathogenesis. Although the growth hormone [GH]/insulin-like growth factor 1 axis is involved in joint repair, little is known of the GH function in control of innate and adaptive immunity. To analyze the potential clinical and immunological effects of GH treatment in RA, we use a murine collagen-induced arthritis (CIA) model, compile data on disease development, and study the molecular and cellular mechanisms involved.

Methods:

We tested the *in vivo*inhibitory effect of GH in a murine CIA model. Disease was induced in 8- to 10-week-old transgenic C57BL/6J mice expressing bovine GH (Tg-bGH), Wild type (WT) littermates, and DBA1 mice, by intradermal immunization with 200 mg chicken type II collagen (CII) in complete Freund's adjuvant.

To assess clinical effectiveness in DBA1 mice, we administered recombinant human (rh)GH subcutaneously for 20 days as a

therapeutic regime. At disease onset, DBA1 mice with a clinical arthritis score >1 (scale: 0-12) were randomized to receive rhGH treatment (100 mg/kg/day; n = 10) or vehicle (n= 10). Statistical differences were analyzed by ANOVA and Mann-Whitney U-test. P values <0.05 were considered significant.

GH effect was analyzed by flow cytometry (FC) to detect Treg (FoxP3+), Th1 (IFNg+) and Th17 (IL17+) CD4 T cells in secondary lymphoid tissues. T cell responses were evaluated *in vitro*by CII-induced proliferation as measured by incorporation of the colorimetric reagent WST-1. Serum levels of anti-CII antibodies were determined by ELISA. T cell differentiation was determined in various tissues by quantitative PCR using probes for the specific transcription factors t-bet, RORgT and FoxP3, and for Th1/Th17/Treg-specific cytokines. To test the ability of dendritic cells (DC) from WT and Tg-bGH mice to present antigen to T cells from OT-II mice, we loaded DC with the ovoalbumin peptide 329-337 and assessed T cell activation and proliferation by FC and CellTrace Violet dilution.

Results:

We found significant reduction in GH transgenic compared to control mice in disease incidence (25% vs. 70%) and onset time (34.5±1.7 vs. 23.2±3.5; p<0.001), and a tendency to lower clinical scores (1.5±0.7 vs. 3.8±1.8 at day 37 post-immunization, p=0.13). GH treatment of arthritic DBA1 mice ameliorated disease, with a reduced cumulative arthritis score (2.5±0.8) compared to the vehicle group (4.0±0.6)(p=0.06).

The molecular mechanism involves an increased Treg/Th17 ratio and a shift to a non-pathogenic phenotype in Th17 cells and in joint-infiltrated macrophages in Tg-bGH mice; these mice had a M2 (non-inflammatory) macrophage profile compared to M1 in WT counterparts. Although serum anti-CII antibodies and *in vitro*collagen-induced T cell proliferation were low in Tg-bGH mice, DC showed no differences in phenotype or in antigen-presenting activity; anti-CD3+IL2-induced T cell activation was similar in both mouse groups.

Conclusion: GH prevents and has therapeutic effects in CIA by modulating macrophage and Th17 cell differentiation. Targeting the GH signaling pathway could thus be a therapeutic approach to RA treatment.

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Animal Models Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Epigenetics can contribute to the pathogenesis of rheumatoid arthritis (RA). A DNA methylation signature that distinguishes RA fibroblast-like synoviocytes (FLS) from osteoarthritis (OA) FLS has been characterized in previous studies using RA, OA and normal samples. To confirm the pattern, we evaluated DNA methylation patterns of an independent group of 19 RA and 5 OA FLS and compared them to previous findings.

Methods:

Genomic DNA from FLS was isolated from 19 RA and 5 OA syovia obtained at the time of total joint replacement. Methylation levels were measured using Illumina HumanMethylation450 chip. Differentially methylated loci (DMLs) were identified using Welch's t-test and mapped to gene promoter regions to define differentially methylated genes (DMGs). Both sets of DMLs and DMGs were compared to our previously characterized methylation patterns. To confirm enriched biological pathways, Ingenuity pathway analysis was applied.

Hierarchical clustering and principal component analysis (PCA) were performed to assess the relationships between 19 RA and 5 OA FLS and also the combined dataset (30 RA/16 OA).

Results:

2,956 DMLs were identified between 19 RA and 5 OA, and 72.5% were overlapped with DMLs identified in previously reported data; after mapping DMLs to gene promoter region, 71.5% of 450 DMGs were overlapped (p-value = 4.26e-284). With established DMLs, distinct methylation patterns were confirmed between RA and OA. 13 out of 31 significantly enriched pathways were overlapped with pathways identified previously (p value < 0.05). Interestingly, "Role of Osteoblasts, Osteoclasts and Chondrocytes in Rheumatoid Arthritis" ranked No.1 among them. Additional overlapped pathways such as "Role of Macrophages, Fibroblasts and Endothelial Cells in Rheumatoid Arthritis", "Atherosclerosis Signaling", "Leukocyte Extravasation Signaling", and "Angiopoietin Signaling" suggested the DMGs contribute to inflammation, immunity and joint destruction. With the combined dataset (30 RA/16 OA), 13,577 DMLs in 1,714 DMGs were found, and 43 out of 66 significantly enriched pathways overlapped with previous data, especially in pathways involving inflammation and immune responses. Using hierarchical clustering and PCA, the 30 RA and 16 OA segregated into two groups (Figure 1).

Conclusion:

The significantly overlapped DMLs/DMGs between the new and previously reported FLS lines confirmed the consistency of DNA methylation signatures and FLS imprinting. In addition, overlapping enriched biological pathways suggest that the methylation patterns might contribute to the pathogenesis of RA. With the expanded dataset, DNA methylation signatures of RA become more powerful and can provide insights into pathogenesis of the disease and identify potential therapeutic targets.

Session Title: Rheumatoid Arthritis - Animal Models Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is an autoimmune disorder characterized by joint inflammation and destruction. Pain is the major symptom in RA, which often persists despite resolution of inflammation. This indicates a deregulation of central nervous system processing of pain in RA, but the underlying mechanisms remain largely unexplored.

The aim of this study was to examine whether joint inflammation was associated with changes in the brain. Expression of genes involved in inflammation and neuroprotection was studied.

Methods: Arthritis was induced in DBA/1 mice by immunization with collagen type II. Development of arthritis and behavioral pattern of each mouse were followed clinically by regular assessment and filming. Behavioral pattern including locomotion, rearing, grooming, minor movements, and immobility, was compared to that of naïve healthy siblings, recorded simultaneously. Quantification of gene expression by RT-PCR was performed in cerebellum, medulla, basal ganglia and motor cortex.

Results: Arthritis decreased locomotion and rearing, and increased periods of minor movements. These changes were apparent already in early arthritis, and increased with the arthritis severity. The brain of arthritic mice showed increased expression of inflammatory cytokine IL-1, which correlated with duration of minor movements. mRNA levels of CD68, a marker of activated microglia, were increased, predominantly in the motor cortex. The expression of IGF1R and S100A4, known to be important for neuroprotection and regeneration, was down-regulated with arthritis. The alterations in gene expression correlated with changes of behavior of the arthritic mice.

Conclusion: Arthritis changes the behavior of mice potentially by altering gene expression in the brain. The expression of inflammatory and microglia activation marker genes were increased, and the expression of neuroprotective genes was decreased, resembling the situation in neurons during Alzheimer's disease.

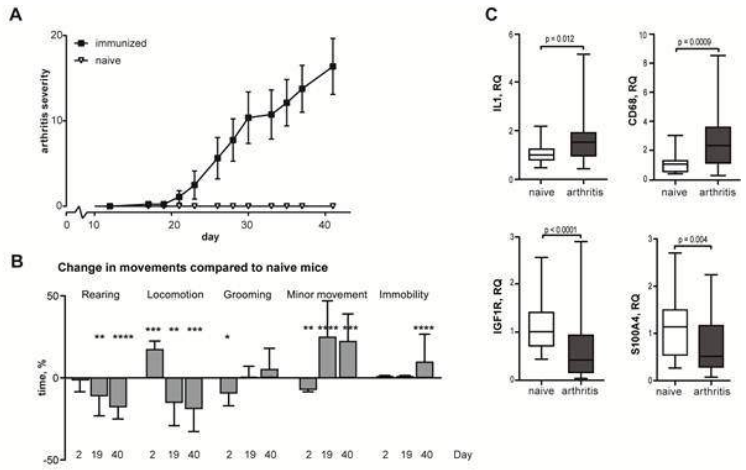

Figure 1. Arthritis affects the behavioral pattern. DBA1 mice where immunized twice with collagen II, resulting in polyarthritis, judged clinically (A). The mice were filmed after immunization (day 2), at early arthritis (day 19), and at overt arthritis (day 40). Change in movement pattern compared to naïve mice shown (B). Arthritis induced change in gene expression of in the brain, as measured by real time-PCR, day 40 (C).

The Effect of mPGES-1 Deletion on Platelet Function in Mice

Joan Raouf[1], Fariborz Mobarrez[2], Karin Larsson[1], Per Johan Jakobsson[1] and Marina Korotkova[1], [1]Medicine, Department of Medicine, Rheumatology Unit, Karolinska University Hospital, Karolinska Institutet S-171 76, Stockholm, Sweden, Stockholm, Sweden, [2]Department of Medicine, Karolinska Institutet, Rheumatology Unit, Karolinska University Hospital, Stockholm, Sweden

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Animal Models Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Microsomal prostaglandin E synthase-1 (mPGES-1) is an essential player in inflammation and has an indispensible role in the generation and maintenance of autoimmune disease such as rheumatoid arthritis (RA). It is an inducible terminal synthase that generates PGE_2. Pharmacological inhibition and genetic deletion of mPGES-1 has been proven to be protective in experimental models of inflammation. Platelets play a vital role in homeostasis and modulation of inflammatory processes by releasing a diversity of cytokines, chemokines and other lipid mediators. It has been recognized that activated platelets and formation of platelet-derived microparticles (PMPs) play a major role in RA pathogenesis. We hypothesize that mPGES-1/PGE_2 pathway may contribute to platelet activation and mPGES-1 inhibition might have beneficial effects on platelet-mediated functions during inflammation. The aim of the study was to investigate the outcome of mPGES-1 deletion on platelet function in mice stimulated with LPS.

Methods:

mPGES-1 wild type (WT) and knockout (KO) DBA mice were injected with 2µg LPS i.p, for 24h. Mice were anesthetized and blood was slowly drawn from the heart by a syringe containing 100µl 3.8% sodium citrate and was transferred to tubes. The numbers and activation of platelets and PMPs were measured in whole blood by flow cytometry. Briefly, blood samples were labeled with CD61-Alexa 488 together with CD62P-PE and CD154-APC. The platelet and PMP numbers where defined by their size characteristics and CD61 expression. The platelets were then investigated for co- expression of CD62P or CD154 respectively. In addition, platelet-leukocyte interaction was also measured in the leukocyte gate. To investigate platelet aggregation, a flow cytometry–based platelet aggregation assay (FCA) was used. Briefly, whole blood is divided into two tubes and labeled with either CD61-Alexa 488 or CD61-PE. After incubation, the tubes were combined and platelets were activated with ADP (6.5µM). Platelets expressing both markers were considered as platelet aggregates.

Results:

Upon LPS stimulation the number of platelets in WT mice was significantly reduced compared to KO mice ($p<0.001$). Platelet activation (assessed by CD62P and CD154 expression) was significantly higher in WT mice compared to KO mice upon treatment with LPS ($p<0.01$ for both). Moreover, the levels of platelet-leukocyte interaction were higher in WT mice ($p<0.05$). PMP numbers were also higher in WT mice compared to KO ($p<0.01$). In addition, platelet aggregation measured with the FCA assay, yielded significantly higher numbers of platelet aggregates in WT compared to KO mice ($p<0.001$).

Conclusion:

mPGES-1 deletion affects platelet concentration and activation as well as PMP formation in LPS stimulated WT mice. The data suggest possible role of mPGES-1 in platelets function in inflammation.

Session Title: Rheumatoid Arthritis - Animal Models Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Nearly 2% of the US population suffers from inflammatory arthritis, and while there are effective treatments that reduce the joint destruction, over 20% of affected individuals to do derive benefit from currently available treatments. We have previously described the bone sparing effect of a stem cell recruiting peptide (LLP2A) chemically linked to the osteoaffinity compound

alendronate. The goal of this experiment was to determine if the hybrid compound, LLP2A-Ale, alone or in combination with concomitantly administered mesenchymal stem cells (MSCs) could reduce inflammatory joint destruction in the collagen induced arthritis model and if there was an immunomodulating role of MSCs in the inflammatory joint and in the lymphoid tissues.

Methods: 8-week-old DBA1/J male mice were immunized with CFA/100 µg chicken collagen (Chondrex Inc) and on Day 21 boosted with 100 µg chicken collagen in IFA subcutaneously. On Day 22 the mice were randomized into groups and received the individual treatments: PBS, vehicle (2% DMSO), alendronate 500ug/kg ip, LLP2A-Ale 250 ug/kg iv, LLP2A-Ale 500 ug/kg, MSC $2x10^6$, MSC+LLP2A-Ale 250 ug/kg iv, or MSC+ LLP2A-Ale 500ug/kg iv. On Day 24 all mice received 50ug LPS in NS and were sacrificed on day 48. Study endpoints included ankle thickness assessed with microcalipers, 28 joint count for swelling, histologic assessment of right hind limbs (erosion, cartilage thickness, inflammation), bone volume assessed by microCT of left hind limb, levels of anti-CII antibodies and serum cytokines by Luminex. Lymph nodes and spleen were analyzed by flowcytometry. Each experiment was performed on two occasions.

Results: Mice developed clinically detectable arthritis on day 23 (two days after the boost with IFA/CII) and the swelling resolved by day 35. Arthritis developed in all immunized groups; however all of the treatment groups had statistically significantly less swelling and lower joint scores than the mice treated with vehicle (AUC for swelling $p<0.001$ for all treated groups from vehicle). There was a trend toward lower levels of anti-CII antibodies in the treatment groups compared to the vehicle control. There were no significant differences in the number of CD4+CD25+FoxP3+ T regs in the draining lymph nodes or in the splenic B220+, CD4+ or CD8+ populations. There was an incresae in splenic Gr1+ cells. The vehicle treated group had significant histological changes compared to nonarthritis controls, but was not statistically difference than other treated mice. Erosive changes were confirmed in microCT scans of the knee joints; however there were no significant differences in the bone volume density of the distal femur, proximal tibia and the paws. There was an overall trend toward increased cytokine production in mice treated with MSCs.

Conclusion: reatment of CIA with LLP2A-Ale with and without MSCs appeared to reduce joint swelling, with modest effects on immune modulation and joint tissue destruction.

Ablation of Fc Gamma Receptors Leads to a Decreased Bone Erosion in Experimental Arthritis Not By Altering Osteoclast Numbers within the Inflamed Joint but By Inhibiting Osteoclast Activation

Irene Di Ceglie[1], Sjef Verbeek[2], Peter van der Kraan[1], Wim van den Berg[1] and Peter van Lent[1], [1]Experimental Rheumatology, Radboud university medical center, Nijmegen, Netherlands, [2]Human Genetic, Human Genetic, Leiden University Medical Center, Leiden, Netherlands

Session Title: Rheumatoid Arthritis - Animal Models Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Rheumatoid arthritis is characterized by immune complex dependent chronic joint inflammation and severe cartilage and bone destruction. In earlier studies we showed that Fcγ receptors (FcγRs) are crucial in regulating cartilage destruction during immune complex mediated antigen induced arthritis (AIA)(1,2). In this study we investigated the role of FcγRs in osteoclast-mediated bone erosion comparing development of AIA between mice lacking all FcγRs (FcγRI,II,III,IV $^{-/-}$) and their wild type controls.

Methods:

AIA was induced by injection of 60 µg mBSA into the knee joint of FcγRI,II,III,IV$^{-/-}$and wild type (WT) control mice previously immunized with mBSA/CFA. Joint inflammation and bone destruction was determined in total knee joints sections. mBSA antibody titers were measured using ELISA and T cell response monitored with a lymphocyte stimulation test. The percentage of osteoclast precursors in the bone marrow was defined through FACS analysis. Gene expression was measured using RT-PCR and protein levels measured with ELISA or Luminex. S100A8 positive cells in the synovium were detected with immunostaining.

Results:

In FcγRI,II,III,IV $^{-/-}$ mice the development of bone erosion in knee joints was significantly reduced both at days 7 and 21 after induction of AIA (30% and 25% lower) when compared to WT controls. The immune response against mBSA (serum level of specific anti mBSA (total IgG, IgG1, IgG2a, IgG2b) and mBSA specific T-cell response) was comparable between the two strains. The percentage of osteoclast precursor population within the bone marrow (CD11b $^{low\text{-}neg}$/ Ly6C ^{high}, described to be upregulated during arthritis) was comparable between FcγRI,II,III,IV $^{-/-}$ and WT controls. Moreover FcγRI,II,III,IV $^{-/-}$ bone marrow cells showed the same ability to differentiate towards osteoclasts upon stimulation with M-CSF and RANK-L *in vitro*.

At day 7 after AIA induction, the decrease in bone erosion in FcγRI,II,III,IV $^{-/-}$ was associated with a significantly decrease in the number of inflammatory cells present within the joint (infiltrate and exudate 29% and 27% lower respectively compared to WT control). Interestingly no differences were present in the number of mature osteoclasts present at locations of bone erosion along patella, femur and tibia (32 +/- 13 osteoclasts/section in FcγRI,II,II,IV-/- versus 28 +/- 9 osteoclasts/section in WT). Gene expression of osteoclast activation factors (RANK-L, IL-1β, S100A8) within the synovium were however significantly lower in FcγRI,II,III,IV-/- (ddCt -2.7, -2.6, -3, respectively). IL-1β and S100A8 were decreased also at the protein level in the synovium wash out and the immunostaining showed a significantly lower amount of S100A8-producing cells in the synovium of FcγR I,II,III,IV -/- animals compared to the WT.

Conclusion:

FcγRs promote bone erosion in AIA not by increasing the number of osteoclasts present on the bone surface but by enhancing influx and activation of inflammatory cells within the synovium thereby releasing factors able to stimulate osteoclast activity.

Session Title: Rheumatoid Arthritis - Animal Models Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Rheumatoid arthritis (RA) is associated with increased cardiovascular (CV) morbidity and mortality secondary to endothelial dysfunction (ED). Growing evidence suggests that TNFα-inhibitors may reduce ED in RA patients, but the underlying mechanisms are still unclear. In this study, we investigated the impact of Etanercept on endothelial function and related pathways as well as on traditional CV risk factors in the adjuvant-induced arthritis (AIA) rat model.

Methods:

AIA was induced by an intradermal injection of *Mycobacterium butyricum* in the tail of male Lewis rats. At the first signs of arthritis (day 11 post-immunization), Etanercept (10 mg/kg/3 days, sc) was administered for 21 days. AIA control rats received saline. Body

weights and arthritis scores were daily monitored. At the end of treatment, blood pressure was measured by invasive method. Blood was collected to measure triglycerides, cholesterol and glucose levels. Endothelial function was studied in aortic rings relaxed with cumulative concentrations of acetylcholine (Ach, 10^{-11}-10^{-4} moles/liter) in the presence or not of inhibitors of nitric oxide synthase (eNOS), cyclooxygenase-2 (COX-2), Arginase, endothelium-derived hyperpolarizing factor (EDHF) and superoxide anions ($O_2^{-\circ}$) production. Aortic expression of eNOS, phospho-ser1177-eNOS, COX-2, Arginase-2, p22phox and p47phox was evaluated by western blotting analysis.

Results:

As compared to control AIA, Etanercept significantly improved Ach-induced relaxation ($p<0.05$) as a result of increased NOS activity, decreased COX-2 and arginase activities, and decreased $O_2^{-\circ}$ production. These functional effects relied on increased eNOS expression and phosphorylation, decreased COX-2, Arginase-2 and p22phox expressions, respectively. By contrast, there was no change in EDHF production and p47phox expression. Etanercept reduced arthritis score by about 34% ($p<0.001$). Of note, no correlation was found between arthritis score and Ach-induced relaxation ($r=-0.195$; $p=0.246$, all AIA rats). The treatment did not affect triglycerides, cholesterol and glucose levels but significantly increased systolic blood pressure ($p<0.05$).

Conclusion:

Our data show the involvement of the NOS, Arginase, COX-2 and NADPH oxidase pathways in Etanercept-induced improvement in endothelial in AIA even though the pivotal common effector of these pathways remains to be identified. They also reveal that the beneficial effect on endothelial function is disconnected from its impact on traditional CV risk factors which are worsened or unchanged. This latter result, associated with a lack of correlation between endothelial function and arthritic scores suggests that the vascular effect of Etanercept is, at least in part, independent on the reduction of disease severity and other traditional CV risk factors. From a therapeutic point of view, they suggest that Etanercept could be a good choice in RA patients at high risk of CV events.

Session Title: Rheumatoid Arthritis - Animal Models Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Although the effects of tacrolimus on T cells are well known, its direct effects on osteoclastogenesis remain unclear. We previously revealed that thapsigargin (TG)-induced endoplasmic reticulum (ER) stress modulates receptor activator of nuclear factor kappa-B ligand (RANKL)-mediated osteoclastogenesis in vitro. We have also shown that tacrolimus downregulates ER-

mediated osteoclastogenesis *in vitro*. We examined whether the regulatory effect of tacrolimus on ER stress-mediated osteoclastogenesis and inflammation could be detected in collagen-induced arthritis (CIA).

Methods: CIA was induced by immunization of female Lewis rats with an emulsion of bovine type II collagen and incomplete Freund's adjuvant. Tacrolimus at doses of 3.2 mg/kg or a placebo formulation were orally administered to rats for 28 days from the day after immunization. The histopathological changes in osteolysis and the expression of specific ER stress-mediated inflammatory signaling pathway biomarkers (IRE1α, GRP78/Bip, c-Fos, and NF-κB) were examined. In addition, pro-inflammatory cytokines and osteoclastogenic molecules (RANKL and M-CSF) were assessed in the knee and ankle joints in the CIA mouse model. Changes in bone mass and structure were assessed based on micro-CT scans of ankle and knee joints.

Results: In the mouse model, tacrolimus administration resulted in a dramatic amelioration of osteolysis and a significant reduction in ER stress intensity. Simultaneously, tacrolimus lessened inflammatory cell infiltration, reduced osteoclastogenesis capability, and reduced the inflammatory response via reduced levels of IRE1α, GRP78/Bip, c-Fos, and NF-κB. Based on the Micro-CT analysis, bone erosion on the hind paw in CIA was augmented compared with that of CIA + tacrolimus mice.

Conclusion: These findings suggest that tacrolimus has the potential to inhibit the progression of joint damage by inhibiting ER stress and has anti-inflammatory effects in established rheumatoid arthritis.

Session Title: Rheumatoid Arthritis - Animal Models Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Arthritis is among the most common chronic diseases in both children and adults. Joint inflammation is a feature in both age groups but there are age-related disparities in clinical manifestations, disease courses, and treatment efficacy and safety. Collagen-Induced Arthritis (CIA) in rodents is a model of arthritis that has utility in assessing pathogenic processes and efficacy of treatments. However, the CIA model has been applied to adult animals but not to juveniles. This study compared clinical, imaging and biologic characteristics of CIA in adult and juvenile animals. Determining age-related differences of CIA should improve understanding of age-specific inflammatory processes and help design treatment interventions tailored to age.

Methods: Juvenile (5 wks old) and young adult (13 wks old) male Wistar rats were immunized with an emulsion of bovine type II collagen/incomplete Freund's adjuvant. Naïve juvenile and adult rats served as controls. Baseline measures included paw thickness, thermal and mechanical thresholds and footprint analysis. Following arthritis onset, measures were repeated every 3 days. For each animal, the Maximum Daily Arthritis Index (MAI) score and daily weight were measured. Fourteen days after arthritis onset, animals were euthanized and blood and tissues collected. Paws were imaged by Micro-CT and quantified with a 6 point scale to rate bone destruction and density. Plasma was assayed by enzyme immunoassay with a rat 27-plex cytokine/chemokine array. Dorsal root ganglia and spinal cord immunohistochemistry assessed pro-inflammatory high mobility group box-1 (HMGB1), receptor for advanced glycation end products (RAGE) and the resolvin D1 receptors G-protein coupled receptor 32 (GPR32) and formyl peptide receptor 2 (FPR2).

Results: Juvenile CIA rats had significantly lower MAI compared to adults ($p<0.0001$). Adult CIA rats had significant increases in the thickness of the ankle ($p=<0.0001$), the paw distal to the tarsus ($p=<0.0001$) and the phalanges ($p=<0.0001$) while juvenile rats had significant increase only in paw thickness distal to the tarsus ($p=<0.0001$). Analysis of chemokine/cytokine profiles revealed that Juvenile CIA rats had lower levels of interleukin-10 ($p=0.04$); and higher levels of the chemokine fracktalkine ($p=0.02$). Levels of HMGB1 and RAGE were highest in adult CIA rats while juvenile rats had higher levels of GPR32 and FPR2. Adult CIA rats had a decrease in toe spread compared to juvenile CIA rats ($p<0.0001$). Micro-CT scores were not significantly different between the two groups ($p=0.40$).

Conclusion: Adult rats have more severe CIA than juveniles. Our results indicate age-related differences in arthritis severity are related to the balance between HMGB1 and resolvins and their respective receptors with the balance favouring promotion of inflammation in adults associated with higher levels of HMGB1 and lower levels of resolvins. Juveniles produce more resolvins that may impede transition from acute to chronic arthritis. We postulate that anti-inflammatory effects of endongenous resolvins are mediated by impeding production of HMGB1 and/or HMGB1 binding to its receptors.

Session Title: Rheumatoid Arthritis - Animal Models Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: TNF-α is a key regulator of inflammation, which induces signal transduction by binding to two structurally and functionally distinct receptors on target cells: TNF receptor 1 (TNFR1) and TNF receptor 2 (TNFR2). The development of TNF inhibitors has revolutionized the management of rheumatoid arthritis, ankylosing spondylitis, Psoriatic arthritis and inflammatory bowel disease. However, previous studies have suggested a positive role for TNFR2 signaling in maintaining the numbers and function of regulatory T cells (Tregs). The aim of this study was to further investigate the role of TNFR1/2 signaling in Tregs.

Methods: To study the influence of TNF signaling on Tregs, we first isolated splenic cells, thymus and lymph node cells from na•ve TNFR1$^{-/-}$, TNFR2$^{-/-}$ and wild-type mice. The number of Tregs was measured by flow cytometry. The gene expression profiles of Treg related markers in spleen and thymus were then compared by real-time qPCR.

Results: Flow cytometry analysis showed that neither TNFR1 nor TNFR2 altered the number of regulatory T cells. However, there was a significant decrease in Foxp3 expression intensity in Tregs from TNFR2$^{-/-}$ mice (Figure 1), which was confirmed in the gene expression study of Treg related markers from spleen (Figure 2) and thymus (Figure 3). The gene expression study of spleen and thymus showed no significant difference of CTLA-4, GITR, IL-10 and IL-4, but a marked decrease of TGF-β in TNFR2$^{-/-}$ mice compared to wild type mice.

Conclusion: Our data reveal that TNFR2 signaling is critical in maintaining the expression of Foxp3 in Tregs in healthy mice, and we are currently exploring its role in arthritis. We hypothesize that TNF signaling affect the expression of Foxp3 through decreased production of TGF-β. Our data suggest that the use TNF inhibitors may affect the phenotype and function of Tregs in which may influence treatment response in some patients.

Session Title: Rheumatoid Arthritis - Animal Models Poster

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic debilitating condition with a 2-3 fold greater prevalence in women than men. Additionally, women have worse disease outcomes and a suspected increased mortality. However, the etiology of sex differences in RA remains unclear. Tumor necrosis factor-transgenic (TNF-Tg) mice, a model of inflammatory arthritis, display similar sex differences as RA patients. To formally test the hypothesis that female TNF-Tg mice have greater morbidity and mortality versus male littermates, we assessed arthritic signs, function and time to death in a large cohort of TNF-Tg mice and wild type (WT) controls. **Methods:** Male (n=30) and female (n=38) TNF-Tg mice (3647 line) and WT littermates (n=33) were monitored over six months, and dates of death were recorded for Kaplan-Meier analysis. Grip strength, as an indicator of arthritis, and weight was measured in male and female TNF-Tg mice with active arthritis at five months of age. The same measurements were taken in a cohort of mice at two months of age, prior to onset of clinical signs, and four weeks later when frank arthritis was present. **Results:** Female TNF-Tg mice have significantly shorter median lifespans than males (5.9 vs 8.1 months, $p<0.05$) (Fig. 1). Male and female TNF-Tg mice have significantly decreased normalized grip-strength at five months of age compared to WT sex-matched controls (0.05±0.001 vs 0.03±0.004 vs 0.10±0.01 vs 0.01±0.001, $p<0.0001$). At two months of age, female TNF-Tg mice have decreased normalized grip-strength compared to age-matched male TNF-Tg and female WT mice (0.079±0.01 vs 0.095±0.02 vs 0.10±0.01, $p<0.05$). Interestingly, there was no clinical evidence of arthritis at this time. However, four weeks later, tarsal joint swelling and an inability to splay digits was noted in hind limbs of TNF-Tg mice, which was indistinguishable between sexes. Moreover, female TNF-Tg displayed a significantly decreased rate of weight gain measured from two months to three months of age compared to male TNF-Tg and female WT mice (1.01±1.71% vs 7.11±1.18% vs 12.53±2.08%, $p<0.001$). **Conclusion:** We show for the first time that TNF-Tg female mice with chronic inflammatory arthritis have shorter lifespans than male littermates. Grip-strength was decreased in female TNF-Tg earlier than age-matched TNF males, indicating earlier onset of disease, although gross signs of arthritis between sexes were not noted. Similarly, rate of growth as measured by change in weight gain was decreased in female TNF-Tg mice at the earliest manifestations of disease compared to male TNF-Tg mice. This is similar to RA in which females are suggested to have increased morbidity and mortality compared to males. Potential implications include sex hormone interactions during TNF-mediated inflammation, raising the possibility that modulating the hormonal environment could lessen the burden of RA in women.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Animal Models Poster
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Dendritic cells (DCs) play an important role in bridging the innate and the adaptive immune response by serving as antigen presenting cells and are therefore implicated in the initiation of chronic autoimmune diseases, including rheumatoid arthritis. Using two different models of inflammatory arthritis, K/BxN serum transfer arthritis as well as hTNFtg arthritis, both depending only on the innate immune system, we investigated the innate role of dendritic cells in inflammatory arthritis

Methods:

We analyzed histological sections of K/BxN serum transfer arthritis as well as hTNFtg arthritis for the presence of $CD11c^+$ cells by immunohistochemistry. We also performed synovial biopsies and analyzed the cellular composition of the inflammatory infiltrate with respect to DCs. We used CD11c-diphteria toxin receptor (DTR) transgenic mice, which express the human diphtheria-toxin receptor under the CD11c promoter, allowing for specific depletion of $CD11c^+$cells by administration of diphtheria toxin (DT). K/BxN serum transfer arthritis was induced, and mice were given either DT or PBS or in wt and BATF3 deficient mice. In addition CD11c DTR mice were crossed into hTNFtg animals and also received either DT or PBS. The severity of arthritis was determined clinically and histologically.

Results:

We show that $Cd11c^+$ cells are present in significant numbers in the synovia of K/BxN and TNF driven arthritis. Both myeloid dendritic subsets, $CD8^+CD11c^+$ and $CD11b^+CD11c^+$, can be found in synovial tissue. In K/BxN serum transfer arthritis, clinical scores showed that CD11c-DTR transgenic mice that received DT had significantly reduced paw swelling and loss of grip strength compared to PBS treated animals. Histological analysis found reduced inflammation after the depletion of $CD11c^+$ cells in K/BxN arthritis. In addition local bone destruction and the number of osteoclasts was significantly reduced. To exclude unspecific effects of DT in mice, wild type animals received DT showed identical clinical and histological signs of arthritis as PBS treated animals. Analysis of K/BxN arthritis in wt mice and $BATF3^{-/-}$ mice, which lack $CD8^+CD11^+$ DCs revealed no difference in arthritis severity between the two groups. In addition to K/BxN arthritis, we found that also in TNF-driven arthritis depletion of $CD11c^+$cells led to a significant reduction of synovial inflammation, as well as local bone erosions.

Conclusion:

These data show that in addition to initiating an adaptive immune response, $CD11c^+$ dendritic cells are also involved in innate effector mechanisms of inflammatory arthritis and suggest that dendritic cells could be an important therapeutic target for patients suffering from inflammatory arthritis.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: To analyze the role of multi-biomarker disease activity (MBDA) in predicting disease relapses in rheumatoid arthritis (RA) patients in sustained remission, tapering disease modifying anti-rheumatic drug (DMARD) therapy in a prospective randomized controlled trial.

Methods: Twelve individual inflammation markers were analyzed from baseline serum samples of 100 patients from the RETRO study by the standardized MBDA test (Vectra® DA). MBDA scores range from 1-100 and are categorized as low (<30), moderate (30-44) or high (>44). The scores were calculated and compared between patients relapsing or remaining in remission when tapering DMARDs. Demographic and disease-specific parameters were recorded and included in multivariate logistic regression analysis for defining predictors of relapse.

Results: Moderate to high MBDA scores were found in 35% of RA patients, with doubling in patients relapsing (58.3%) than those remaining in stable remission (25%). Baseline MBDA scores were significantly higher in RA patients relapsing than those remaining in stable remission, when analyzing the entire population (N=100; p=0.0034), those tapering (N=36; p=0.0017) or stopping DMARDs (N=28; p=0.0036). Multivariate regression analysis identified MBDA scores as independent predictors for relapses next to anti-citrullinated protein antibody (ACPA) status. Relapse rates were low (13%) in MBDA-/ACPA- patients, moderate in MBDA+/ACPA- (33.3%) and ACPA+MBDA- (31.8%) patients and high in MBDA+/ACPA+ patients (76.4%). (Figure 1)

Conclusion: MBDA score improves the prediction of relapses in RA patients in stable remission undergoing DMARD tapering. If combined with ACPA testing, MBDA allows a correct case classification of relapse in more than 80% of the patients.

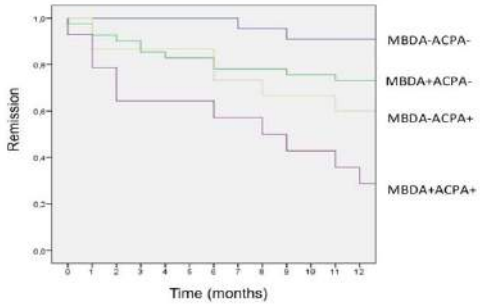

Figure 1. Relapse rates of RA dependent on ACPA and MBDA status: Kaplan-Meier curves indicate loss of remission over 12 months in patients with rheumatoid arthritis in relation to ACPA and MBDA status: (blue) ACPA/MBDA double-negative, (green) ACPA+/MBDA-, (yellow) ACPA-/MBDA+ and (purple) ACPA/MBDA double positive. Y-axis indicates the percentage of patients with rheumatoid arthritis in sustained remission (100% at baseline). X-axis indicates time.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: 14-3-3η is an emerging soluble Rheumatoid Arthritis (RA) biomarker that activates intracellular pathways that lead to the upregulation of inflammatory and joint damage factors. It is reported to be highly specific and sensitive for RA as a diagnostic marker, higher levels are associated with greater joint damage progression risk[1,2] and 14-3-3η's modulation with treatment suggests a role in disease monitoring. In this study, we examine the specificity of 14-3-3η in an independent, clinically well-characterized cohort of moderate to severe RA and disease control subjects.

Methods: Serum 14-3-3η levels were measured in a total of 147 patients using the Augurex 14-3-3η ELISA. The patient set comprised 36 with RA and 111 controls consisting of 20 with asthma (A), 20 with Crohn's Disease (CD), 12 presumed healthy (H), 16 with psoriasis (PsO), 20 with sarcoid arthritis (S), and 23 with spondylarthropathies (SpA). Sample testing was done independently of Augurex. Mann-Whitney testing together with Kruskal-Wallis analysis with the post-hoc Dunn's multiple comparison test was performed to assess group differences. Receiver operator characteristic curve (ROC) analysis was performed to assess the specificity of 14-3-3η for RA.

Results: Median (IQR) serum 14-3-3η levels were significantly higher in RA [2.35ng/ml (0.28-19.41)] than all controls [0 (0-0)],

p<0.0001. ROC curve analysis further underscored this differential expression yielding a significant area under the curve (AUC) of 0.86, p<0.0001. At the diagnostic positivity cut-off of ≥0.19 ng/ml, the ROC curve delivered a sensitivity of 81% with a corresponding specificity of 84%. Kruskal-Wallis testing revealed that serum 14-3-3η levels were significantly higher in RA in comparison to all other diseases, p<0.0001. This differential expression is illustrated in Figure 1.

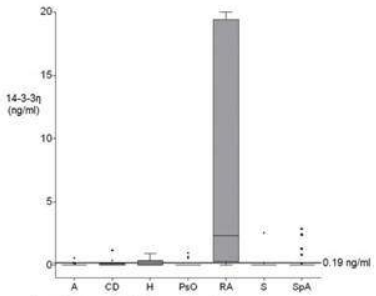

Figure 1. Serum 14-3-3η Expression by Disease.

Conclusion: Serum 14-3-3η is a highly specific RA biomarker. As a novel mechanistic disease factor, 14-3-3η is expected to provide new insights and approaches to RA management and clinical studies.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

In rheumatoid arthritis (RA), cardiac involvement is common and frequently subclinical. We used cardiac MRI to identify myocardial abnormalities in patients with active RA, free of symptoms and signs of cardiac disease.

Methods:

Sixty female patients with active RA under age of 70 years (31 patients with early RA awaiting the start of treatment with conventional DMARDs and 29 patients with chronic RA awaiting the start of treatment with biological therapy) and 21 sex and age-matched control subjects (10 patients with FM and 11 healthy volunteers) underwent either 1.5T or 3T cardiac MRI for analyses of T1 relaxation times, late gadolinium enhancement (LGE), volumes and function of both ventricles.

Table 1. Clinical features of RA patients

	Early RA	Chronic RA	p-value
Age, years; mean ± SD	48 ± 15	48 ± 14	0.57
RF positivity; n (%)	26 (84)	23 (85)	1.000
ACPA positivity; n (%)	27 (87)	26 (93)	0.673
CRP; mean + SD	16 + 26	7 + 7	0.076
Number of swollen joints; median (IQR)*	8 (4-10)	6 (2-7)	0.037
Number of tender joints; median (IQR)*	7 (3-12)	6 (2-11)	0.726
DAS28-CRP; mean ± SD	3.7 ± 1.05	3.4 ± 1.15	0.267
Extra-articular manifestations; n (%)	5 (16)	14 (48)	0.007
Erosions on radiographs; n (%)	5 (17)	23 (85)	<0.001
Duration of symptoms, years; median (IQR)	0.4 (0.3-0.8)	13.0 (4-26)	<0.001
BMI, kg/m^2; mean ± SD	23.7 ± 4.1	25.5 ± 3.6	0.069

* 66/68 joints evaluated

Results:

By using 1.5T cardiac MRI, native left ventricular (LV) septal T1 time averaged 1010 ± 45 ms in 20 RA patients v.s. 977 ± 18 ms in 11 controls (p = 0.045). With 3T cardiac MRI, the T1 time measured 1170 ± 33 ms in 29 RA patients v.s. 1047 ± 113 ms in 9 controls (p = 0.002). Myocardial LGE was detected in 55% of RA patients, but in none of FM controls. Increased likelihood of LGE was associated with increasing DAS28-CRP (OR 1.87, 95% CI 1.05 to 3.35, p=0.035) and increasing age (OR 1.05, 95% CI 1.00 to 1.09, p=0.040) in multivariate logistic regression model, but not with disease duration or ACPA positivity. Compared with controls, RA patients had impairments in systolic and diastolic function of both ventricles (Table 2). In patients with early RA, right ventricular (RV) dysfunction was more obvious (Table 3).

Table 2. Cardiac MRI findings in RA patients and controls

Variable	RA patients = 60 Mean ± SD Median (IQR)	Controls together = 21 Mean ± SD Median (IQR)	p-value
LVEF, %	58.9 ± 4.3	66.7 ± 6.8	<0.001
LVEDV-index, ml/m2	82.3 ± 11.6	75.1 ± 11.0	0.022
LVESV-index, ml/m2	34 (30-40)	25 (21-29)	<0.001
LVSV-index, ml/m2	47 ± 11	43 ± 6	0.24
LVPFR/EDV, 1/s	2.95 ± 0.85	3.44 ± 0.70	0.012
LV mass-index, g/m2	51.3 ± 7.6	53.1 ± 7.2	0.29
RVEF, %	59 ± 6	58 ± 6	0.65
RVEDV-index, ml/m2	82 ± 13	74 ±8	0.03
RVESV-index, ml/m2	34 ± 9	31 ± 6	0.21
RVSV-index, ml/m2	44 (40-45)	48 (45-49)	0.02

SD = standard deviation, IQR = interquartile range, LV = left ventricle, EF = ejection fraction, EDV = end-diastolic volume, ESV = end-systolic volume, SV = stroke volume, PFR = peak filling rate, RV = right ventricle

Table 3. Cardiac MRI findings in early and chronic RA

Variable	Early RA Mean (±SD) Median (IQR)	Chronic RA Mean (±SD) Median (IQR)	p-value
LV EF %	57 (56-58)	60 (59-61)	0.05
LV EDV-index ml/m2	83±11	81±13	0.56
LV ESV-index ml/m2	35±7	33±6	0.13
LV SV-index; ml	48±6	46±14	0.96
LV PFR/EDV; 1/s	3.04±1.67	3.21±0.88	0.61
LV mass-index; g/m2	51±8	52±8	0.86
RV EF %	57±5	61±6	0.008
RV EDV-index ml/m2	84±12	79±13	0.16
RV ESV-index ml/m2	37±8	32±8	0.02
RV SV-index ml/m2	47±5	48±7	0.49

Conclusion:

Patients with active RA show myocardial abnormality on cardiac MRI: prolonged myocardial T1 relaxation times suggesting diffuse inflammation or fibrosis and LGE indicating local myocardial scars. RA patients also had impairments of LV and RV systolic and diastolic functions. Inflammatory activity observed in patients with early RA with lower systolic ventricular functions compared to patients with chronic RA can reflect systemic inflammation.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

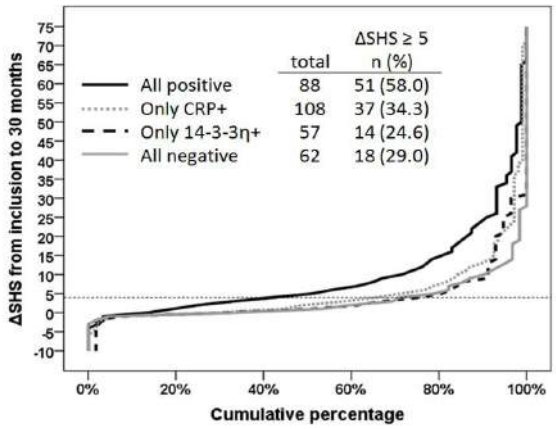
Background/Purpose: As a marker of inflammation and an acute phase reactant, C-reactive protein (CRP) is routinely used in clinical practice and in RA classification criteria. Higher or sustained levels of CRP are associated with a worse prognosis. 14-3-3η is a joint derived mechanistic marker that up-regulates factors that perpetuate disease. Similar to CRP, higher or persistent levels of 14-3-3η are associated with a worse prognosis, and lower circulating levels are associated with better clinical outcomes. Inflammation and joint damage are now understood to be processes that uncouple along the course of disease and treatment strategies have been tightened to achieve both clinical and joint damage remission. The aim of this study was to examine both the independent and combined effects of CRP and 14-3-3η on radiographic progression.

Methods: Baseline (BL) serum 14-3-3η titres were assessed in 331 recent onset polyarthritis patients from the Sherbrooke EUPA Cohort with 5 years of radiographic follow-up data. Patients were DMARD naïve at BL, median age was 60 years, and 62% were female. CRP and 14-3-3η positivity were defined as >8mg/L and ≥0.19ng/ml, respectively. Spearman correlation was performed to assess the relationship between 14-3-3η and CRP titres. Radiographic changes (change in total Sharp/van der Heijde (ΔSHS) score over 30 months were assessed in relation to CRP and 14-3-3η co-expression using ANOVA analysis. Chi-square was used to assess the relationship between CRP positivity with radiographic changes at 30 months based on ΔSHS ≥1, 3, and 5 unit cut-offs.

Results: Of 331 patients, 207 (63%) and 153 (46%) were CRP and 14-3-3η positive at BL, respectively. Spearman correlation revealed that titres of CRP and 14-3-3η did not correlate, r= -0.00025 p=0.996. As noted in Table, Chi-square analysis returned both CRP and 14-3-3η as significantly associated with radiographic changes.

	ΔSHS BL to Year 3 ≥ 1		ΔSHS BL to Year 3 ≥ 3		ΔSHS BL to Year 3 ≥ 5	
	n = 233		n = 168		n= 120	
Variable	OR	p-value	OR	p-value	OR	p-value
CRP positivity	1.73	0.034	2.47	<0.001	2.22	0.001
14-3-3η positivity	1.69	0.046	1.74	0.016	1.70	0.023
CRP and 14-3-3η positivity	2.82	0.002	3.68	<0.001	3.16	<0.001

The cumulative probability plot illustrates that patients who were positive for both CRP and 14-3-3η had the significantly greatest increase in radiographic progression (p<0.001) with over 50% of patients having ΔSHS≥5 over the 30 month period.



Conclusion: CRP and 14-3-3η are both associated with joint damage progression at 3 years and titres do not correlate consistent with their distinct roles in RA disease processes. Interaction analysis further reveals that the combination of these two markers is a better predictor of future radiographic damage than either marker alone. Concomitant serial testing of both these modifiable markers may assist with tight control RA treatment strategies.

Session Date: Tuesday, November 10, 2015

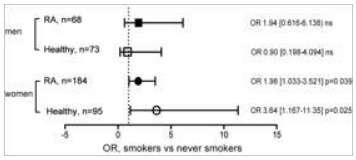
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose : Patients with rheumatoid arthritis (RA) are predominantly female, smokers and positive for autoantibodies, rheumatoid factor and antibodies to citrullinated peptides. The oncoprotein survivin has recently emerged as an early marker for RA being frequently found in seropositive patients. High levels of survivin may be measured in serum several years before disease onset. Presence of survivin in serum is also a risk factor for an aggressive and treatment resistant disease. This study elucidates associations between smoking and survivin.

Methods : To study if smoking contributes to higher levels of survivin in serum we measured survivin in 252 (184 women, 68 men) RA patients and 168 healthy controls (95 women, 73 men)**.** Information about smoking habits was collected via extended questionnaire. Serum survivin was analysed with a sandwich ELISA, where the level >0.45ng/ml was considered positive. Production of survivin isoforms of wild type, survivin-2B and survivin-deltaExon3 and estrogen receptor alpha (ERa) by peripheral blood mononuclear cells (PBMC) was measured by qPCR.

Results: The prevalence (43% vs 22.8%, $p<10^{-5}$) and the absolute levels of serum survivin were significantly higher in smokers compared to never smokers (p=0.0024). In women, the estimated risk to be survivin-positive was significantly higher for healthy smokers (OR 3.64[1.17-11.35], p=0.025) and for RA patients (OR 1.98[1.03-3.52], p=0.039). In contrast, no significant increase in risk was found in men.



High serum levels of survivin were associated with combined expression of all three survivin isoforms in PBMC. To study gender-dependent effects of smoking, we compared ERa transcription in PBMC of smoking and non-smoking women RA patients. We observed a smoking-dependent increase of ERa in young women (age <50 years) compared to the older women (p=0.0056). Also, young survivin-positive smokers had higher ERa compared to survivin-negative non-smokers (p=0.0137). Finally, these young survivin-positive women had higher estimated risk for the combined expression of all three survivin isoforms (p=0.012). Functional studies in mouse model proved synergistic effect of smoking and ERa on survivin transcription in leukocytes.

Conclusion: Smoking significantly increases risk for high serum levels of survivin in healthy women and in women with RA potentially decreasing the threshold for the disease. ERa has experimentally been shown as a mediator of survivin production in leukocytes predisposing to an active and proliferating phenotype of these cells.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Genome-wide association studies (GWAS) and meta-GWAS studies have identified >50 single nucleotide-polymorphisms (SNPs) that are associated with susceptibility to rheumatoid arthritis (RA). It is, however, not known whether these susceptibility SNPs are also associated with disease activity in early RA. The purpose of this study was to analyze for associations between 49 susceptibility SNPs and disease activity including radiographic damage in early untreated RA patients.

Methods:

315 patients with DMARD naïve RA and disease duration <6 months were included from two randomized controlled trials (1,2), Table 1. The two trials had similar inclusion and exclusion criteria, which resulted in similar demographic and clinical characteristics and thus, the two cohorts were combined in the analysis. We genotyped 49 SNPs previously associated with disease susceptibility in two large meta-GWAS studies (3,4) with the TaqMan OpenArray system, Table 2 shows rs-numbers. The genotype associations with disease activity score of 28 joints (DAS28) and radiographic damage (modified Total Sharp Score, mTSS) were evaluated using linear regression analysis adjusted for age, sex, treatment, anti-CCP status and smoking.

Results:

Baseline characteristics were similar in the two cohorts, Table 1. Table 2 shows the linear regression analysis between the 49 SNPs and DAS28 and mTSS at baseline and after one year. Three SNPs were associated with mTSS at both baseline and year one (rs13315591 *PXK*, rs26232 *C5orf30*, rs2793108 *ZEB1*) and neither with DAS28 at baseline nor at year one. There were modest effects on radiographic damage judged by a β ranging from 1.04 to 2.43, with *PXK* having the strongest effect. In summary, we found 12 P values <0.05 in 8 SNPs, but none had a P value ≤0.001. Five associations were found with DAS28 and 7 with mTSS. None of the 196 associations tested were significant when using the Bonferoni's or Sidak's adjustment for multiple testing (both P=0.00026).

Conclusion:

We found three out of 49 susceptibility SNPs to be associated with radiographic damage in 315 early RA patients before and after one year's treatment. No SNPs were consistently associated with DAS28. The results should be interpreted with some reservation due to the large number of associations investigated.

Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Anti-citrullinated protein antibody (ACPA) positivity is associated with more rapid radiographic progression in rheumatoid arthritis (RA). A majority of prior studies, however, have assessed ACPA status using only the commercially available anti-CCP2 antibody assay. Thus, it is unknown to what extent any antigen-specific ACPA might drive this relationship. The objective of this study was to simultaneously evaluate the association between anti-CCP2 antibody and antigen-specific ACPA with radiographic disease progression in a well-characterized cohort.

Methods:

This is a secondary analysis of the 48-week Rheumatoid Arthritis Comparison of Active Therapies (RACAT) trial. RA patients with active disease despite methotrexate (MTX) were randomized to receive triple therapy (MTX + sulfasalazine/hydroxychloroquine) or MTX + etanercept. Baseline serum was tested for anti-CCP2 using a commercially available ELISA and 29 antigen-specific ACPA using a multiplex peptide array (Table footnote). Radiographs from baseline, 24- and 48-weeks were scored by blinded experts using a modified Sharp score. Generalized linear mixed effects models assuming a negative binomial distribution were used to model associations of ACPA with Sharp scores over time. Models were adjusted for age, gender, race, smoking status, BMI and disease duration. Statistical significance was defined at a p-value < 0.05 after adjusting for multiple comparisons using the Benjamini-Hochberg method.

Results:

RA patients (n=281) had a mean (± SD) age of 56 (12) years, 88% were white and 58% were male. Although not reaching statistical significance, anti-CCP2 positive patients had higher baseline Sharp scores compared with anti-CCP2 negative patients (16.1 vs. 11.1; p=0.45). In adjusted analyses modeling for Sharp scores, anti-CCP2 positivity was associated with 1.14 to 1.18 times the radiographic progression of anti-CCP2 negative patients at 24 and 48 weeks (p=0.01) (Table). Assessing ACPA fine specificity, only antibody to citrullinated histone 2A concentration was associated radiographic progression; each natural log unit increase was associated with 1.05 and 1.06 times higher Sharp score changes from baseline to 24 and 48 weeks, respectively (p=0.0007). No other antigen-specific ACPA were significantly associated with radiographic scores after adjusting for multiple comparisons.

Conclusion:

These novel findings suggest that the well-described association of ACPA positivity with structural joint damage in RA, may at least in part of driven by autoantibody targeting citrullinated histone 2A. In addition to required verification in an independent cohort, future efforts will be needed to identify the “source” of this autoantigen and mechanisms underpinning the relationship of this antigen-specific ACPA with radiographic disease progression.

Table 1 Associations of ACPA with change in modified Sharp scores over time.

Variable	Visit	Exponential of Coefficient‡	P
Anti-CCP2 Positive	24 Weeks	1.14	0.01
	48 Weeks	1.18	
Histone 2A [1-20] cit cyclic†	24 Weeks	1.05	0.0007*
	48 Weeks	1.06

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Previous publications have suggested that patients in clinical remission with residual ultrasound (US) synovitis flare more often and do not stay in remission as long as those without residual US synovitis[1]. Those studies have been performed in single centers by a few highly skilled operators. Before recommending the use of US as a predictor of flare in daily practice, those observations need to be

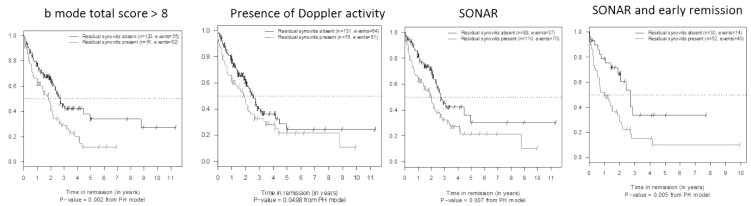
confirmed in real life studies.

The objective of this study was to investigate the predictive value of US residual synovitis on loss of remission in a national cohort of patients followed in real life by many different rheumatologists operating on many different US machines

Methods: US significant residual synovitis has been defined on the Swiss SONAR score, which adopted the single joint definition of pathologies according to OMERACT for 22 joints. Recently, the SONAR score was validated against clinical disease activity parameters and the ACR/EULAR remission status in a large cross-sectional setting among patients in the Swiss RA registry (SCQM) [2]. For each patient we identified the first visit in clinical remission (defined as a DAS28 < 2.6) belonging to the first remission phase during which an assessment of residual US synovitis was available as the baseline and analyzed time to relapse during follow-up. Relapse was defined as a DAS28 >= 2.6, start of a biologic, start of an sDMARD, or start of glucocorticosteroid (GC) therapy or an intensification of GC therapy, whatever occurred first.

Results:

Up to 211 RA patients had US synovitis data and a follow-up. The majority of patients received a biological treatment at baseline. Significant residual US synovitis was present in 110 of 198 patients based on SONAR and in 91 of 211 patients considering only b and in 76 of 207 considering only Doppler mode for defining residual synovitis. Median time to relapse was 2 yrs (95% CI: 1.4, 2.6) for SONAR+, and 2.7 yrs (95% CI: 2.4, not estimable) for SONAR-. When we restricted the analysis to the 82 patients who were known to have been in remission for at most 6 months at baseline (confirmed early remission), median times to relapse were 1 year (95% CI: 0.7, 2) for SONAR+ and 2.7 yrs (95% CI: 2.1, not estimable) for SONAR-. The same conclusions were obtained with b or Doppler mode only defined residual synovitis. The figure displays Kaplan-Meier plots of time to relapse for SONAR+ and SONAR- (all patients and subgroup of confirmed early remission patients) and for b mode and Doppler mode only defined residual synovitis.



Conclusion:

Our study in real life patients supports the earlier finding that residual US synovitis is predictive of duration of remission in RA in particular in early remission.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) are frequently positive for one or several autoantibodies like rheumatoid factor (RF), anti-citrullinated protein antibodies (ACPA) and anti-carbamylated protein antibodies (Anti-CarP). Seropositive and seronegative patients differ in respect of risk factors and disease outcome.[1,2] However, it is unclear whether these patients differ at baseline. Therefore, this study aimed to investigate whether the number of autoantibodies is associated with phenotypic characteristics at presentation in RA patients.

Methods: Two independent cohorts of early RA patients were analysed: the Leiden Early Arthritis Cohort (EAC) (845 patients) and the Swedish BARFOT (Better Anti-rheumatic Farmaco-therapy) study (805 patients). All patients fulfilled the 1987 ACR criteria for RA and had a symptom duration of less than 24 months. Autoantibody status was determined at baseline. RF was measured with commercial enzyme linked immunosorbent assays (ELISAs) in the EAC and with commercial agglutination tests in the BARFOT. Commercial ELISAs were also used to determine anti-CCP2 status in both cohorts. Antibodies against carbamylated fetal calf serum (Anti-CarP) were measured for both cohorts in Leiden using in-house ELISAs. Baseline characteristics between patients with few (0 or 1) and many (2 or 3) autoantibodies were compared using logistic regression. Variables with a univariate p <0.10 were included in a multivariate model. The multivariate analysis was repeated after exclusion of highly correlated variables and variables with >15% missing values.

Results: The distribution of the autoantibodies in both cohorts was similar. In both cohorts, patients with many RA-associated antibodies were younger, more often smokers, had a longer symptom duration, more often an intermittent onset of symptoms and a higher erythrocyte sedimentation rate (ESR) compared to patients with few autoantibodies (Table 1). Furthermore, patients having many autoantibodies differed with respect to distribution of affected joints and swollen joint count in the EAC (Table 1). Other variables which were significantly associated with the number of autoantibodies in univariate analysis, were BMI, family history of RA and HAQ in the EAC, and C-reactive protein (CRP), SHS and erosions at baseline in the BARFOT study. When these variables were included in the multivariate model, only erosions was significant: OR 2.62 (1.63-4.21).

Conclusion: Patients carrying few and many autoantibodies differ with regard to initial clinical presentation. Patients with many RA-associated autoantibodies are younger, more often smokers, have a longer symptom duration, more often an intermittent onset of symptoms and a higher ESR compared to patients with few autoantibodies.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Total management including reconstructive joint surgery and rehabilitation should be needed for further improvements of physical function for long-standing RA patients. It is very important to set treatment goal for those management using index of activity speed [Time Up and Go (TUG)] and range of motion (ROM). The purpose of this study is to explore the characteristics of functional impairment and relationship TUG and physical function in RA patients who were needed joint surgery using multicenter prospective cohort.

Methods:

We started the prospective study in September, 2012 (Study registration: UMIN000012649). We collected data at pre- and post-operation (0.5 years, 1 year) on age, sex, disease duration, drug therapies, and disease activity. Functional evaluations were made using the TUG, HAQ-DI, DASH (upper limb function), and patient subjective evaluations using the EQ-5D (QOL) and BDI-II (depression). Joint range of motion was also measured as part of this evaluation.

Results:

347 surgical patients were registered. Mean values for age, disease duration, and sex were 65.2 years, 18 years, and 88% female, respectively. Actually, even long-standing RA patients who were needed joint surgery had remission or low disease activity in this baseline data (median values for DAS28 (3.0) and CRP (0.33 mg/dl). 23.8% of the patients were treated with biologics. We confirmed the significant correlation between TUG and disease duration, HAQ-DI, patient-reported outcome (EQ-5D, BDI-II) and range of motion (hip, knee, shoulder ankle). We also found significant relationship between TUG and the level of disability in 18 of 20 components in HAQ-DI. TUG was significantly associated with high ADL status (total HAQ point <6/60: upper quartile value of study population) based on ROC curve (Fig. A). Cut-off value of TUG for high ADL status was 8.98 seconds (sensitivity 67%, specificity 59%).Cut-off of TUG (9 seconds) was associated with the TUG value of patients without disability of HAQ-DI component (Fig.B). As for total knee and hip arthroplasty, TUG was significantly improved after operation (14.0 s to 11.1 s). TUG before operation significantly associated with that after operation. To achieve TUG=9 seconds after operation, the cut-off of TUG before operation was 10.3 s (sensitivity 74%, specificity 82%).

Conclusion:

TUG was significantly associated with many kinds of daily activity and patient-reported outcome. The information should be important for assessment of disability in patients with long-standing RA. TUG as shown in this study could provide target of surgical procedure and rehabilitation program and index of timing for better outcome of joint arthroplasty.

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Prediction which rheumatoid arthritis (RA) patients in low disease activity (LDA) can successfully discontinue TNF inhibition (TNFi) may improve the cost-effectiveness of RA management. We evaluated the multi-biomarker disease activity (MBDA) score, which is based on 12 serum biomarkers, as a predictor of flare after TNF-i discontinuation.

Methods:

Data were used from the 439 RA patients who were randomized to stop TNFi treatment in the Dutch multi-center POET trial. All patients had been in DAS28 LDA for ≥12 months. In the study TNFi was allowed to be restarted if RA flared according to reimbursement criteria: DAS28 exceeding the 3.2 again, but patients and/or physicians were allowed if DAS increase was minor to escalate the dose from the conventional disease modifiers. In our current analysis 4 definitions of flare were assessed during the 12 months from TNFi discontinuation: 1) re-initiating TNFi treatment, 2) escalation of any medication and 3) physician-reported flare. MBDA score, which measures RA disease activity on a scale of 1 to 100 with validated levels of low (<30), moderate (30 to 44) and high (>44), was assessed at baseline. Associations between baseline MBDA score and each definition of flare by 12 months post-TNFi discontinuation were evaluated using univariate analysis and multivariate logistic regression.

Results: At baseline, 50.1%, 35.3% and 14.6% of patients had low, moderate or high MBDA scores and 94.1%, 5.9%, 0% had low, moderate high DAS28. Within 12 months, 49.9% of patients who discontinued TNFi treatment at baseline had restarted TNFi medication, 59.0% had escalation of any medication and 57.2% had experienced at least one physician-reported flare. MBDA scores at baseline were predictive for each definition of flare. At least one definition of flare was observed by 12 months in 59.5%, 68.4% and 81.3% of patients with low, moderate, or high MBDA score at baseline, respectively (*P*=0.004) (Table 1). Adjusted for baseline DAS28-ESR, disease duration, BMI and erosions, high MBDA scores (>44) were associated with an increased risk for TNFi re-initiation (OR=1.85, 95% CI 1.00–3.40), medication escalation (OR=1.99, 95% CI 1.01–3.94) and physician-reported flare (OR=2.00, 95% CI 1.06–3.77).

Table 1: Occurrence of flare by four definitions at 12 months for patients classified by baseline MBDA score

Flare definition	**Low (<30) n=220**	**Moderate (30–44) n=155**	**High (>44) n=64**	**P-value**
TNF-inhibitor re-initiation	102 (46.4%)	74 (47.7%)	43 (67.2%)	0.011
Medication escalation	117 (53.2%)	92 (59.4%)	50 (78.1%)	0.002
Clinician-reported flare	116 (52.7%)	87 (56.1%)	48 (75.0%)	0.006
Any flare	131 (59.5%)	106 (68.4%)	52 (81.3%)	0.004

Any flare = TNFi re-initation, medication escalation, clinician-reported flare or DAS28 flare. P-value by Pearson χ^2test.

Conclusion:

In RA patients with DAS28 LDA, a high MBDA score at baseline was an independent predictor of flare within 12 months of discontinuing TNFi therapy. The MBDA score may be a clinically useful tool for identifying a subgroup of patients at higher risk of flare when stopping TNFi treatment.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: We compared the ability of anti-CCP2, anti-mutated citrullinated vimentin (anti-MCV) and anti-citrullinated fibrinogen (AhFibA) antibodies to predict 1-year rapid radiographic progression (RRP; total Sharp score variation ≥ 5 points), in early rheumatoid arthritis (RA).

Methods: We analyzed 566 patients from the ESPOIR cohort with early RA fulfilling the 2010 ACR/EULAR criteria at inclusion. Prediction of 1-year RRP was analyzed by receiver operating characteristic (ROC) curves for the 3 ACPA assayed by ELISA on baseline sera. One-year RRP risk was assessed by ACPA titers. Logistic multivariate regression was used to analyze RRP risk in terms either of positivity or of titer: high, >3 times the cut-off (>3N) and low (1 to 3N).

Results: 333 patients were positive for at least one of the three ACPA tests and 145 patients displayed RRP (Table 1). The areas under the ROC curves were similar for the 3 antibodies, about 0.60. Low+ anti-MCV titers were not associated with RRP (Odds ratio (OR) 0.68; 95% confidence interval (95%CI) 0.29-1.59), whereas low+ anti-CCP2 titers (OR 3.80; 95%CI 1.11-13.10) and low+ AhFibA titers (OR 2.39; 95%CI 1.04-5.49) were significantly associated (Table 2). In multivariate analysis, 1-year RRP was associated with high anti-MCV titers (OR 2.17; 95%CI 1.45-3.24), with anti-CCP2 positivity (OR 2.14; 95%CI 1.43-3.21) and with AhFibA positivity (OR 2.39; 95%CI 1.57-3.63) (Table 3).

Conclusion: Anti-CCP2 antibodies and AhFibA were predictive of 1-year RRP in early RA whatever their titer was, whereas only high anti-MCV antibodies titers were predictive potentially making them more discriminant to predict 1-year RRP risk.

Table 1. Demographic, biologic and radiographic data for patients with early rheumatoid arthritis

	Patients (n = 566)	Patients without RRP at 1 year (n = 421)	Patients with RRP at 1 year (n = 145)	P value

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Studies report that obese and overweight patients with rheumatoid arthritis (RA) are less likely to attain remission and more likely to have limited therapeutic response, as compared to non-obese RA patients. Our objective was to determine the association between synovitis musculoskeletal ultrasound measures (Power Doppler [PDUS]) and disease activity measures (DAS28) in obese RA patients.

Methods: Cross sectional clinical and ultrasound data was collected on 43 RA patients, and divided into three groups based on their

body mass index (BMI): <25, 25 to 30, and >30. Clinical joint assessments included patient global visual analogue scale (VAS), physician global VAS and 28 swollen and tender joint counts. The sedimentation rate, anti-cyclic citrullinated pepide (ACPA) and rheumatoid factor (RF) were also measured. DAS28/ESR-4 item and clinical disease activity index (CDAI) were calculated. Ultrasound of the wrist, metacarpalphalangeal joints 2, 3 and 4, proximal interphalgeal joints 2 and 3 and metatarsalphalangeal joints 2 and 5 included synovitis assessments with gray scale (GSUS) and PDUS of the most affected side. GSUS and PDUS were categorically scored as per OMERACT published guidelines on a scale of 0-3. We then categorized the 0-3 scale into two PDUS groups 0/1=non-active, 2/3=active synovitis. Demographic and clinical characteristics were compared across BMI groups with Kruskal-Wallis test (KW) for continuous variables and chi-square tests for categorical variables. Mixed effects models were used to evaluate the relationship between BMI and the PPV and NPV.

Results: Demographic characteristics and disease activity were similar among BMI groups; however, PDUS scores significantly differed as seen in the Table. Using PDUS activity as the gold standard for synovitis and clinically swollen joints (SJ) as the test, the positive predictive value (PPV) of SJ was lower in higher BMI groups and significantly different across the BMI groups in KW analysis (0.71 in BMI<25, 0.58 in BMI 25-30 and 0.44 in BMI<30) (p= 0.01). Similarly, the negative predicative value (NPV) was significantly higher in higher BMI groups (p=0.04). In the mixed effects models, BMI was significantly predictive of PPV and a one unit increase in BMI was associated with a 0.1 unit decrease in PPV (p=0.02). BMI was not significantly predictive of NPV in the mixed effects model.

Conclusion: This study suggests that for obese RA subjects, clinically swollen joints have a higher PPV and a trend for lower NPV for true synovitis, while the opposite is found for normal BMI patients. This implies that clinically assessed swollen joints are less likely to represent true synovitis in obese RA patients. Therefore, RA disease activity may be overestimated by CDAI and DAS28 calculations in this subpopulation.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Heart failure (HF) is a leading cause of excess deaths in RA. We previously found an association between left ventricular mass index (LVMI) and anti-citrullinated peptide antibodies (ACPA) in rheumatoid arthritis (RA) patients without CVD. Our objective was to validate these findings in a different RA cohort of patients without CVD.

Methods: Seventy-four patients without known CVD from underwent 3D Echocardiography and concurrent serum testing of a panel of 30 specific ACPAs using a custom Bio-Plex bead array. With a high ACPA level defined as $\geq 75^{th}$ percentile, a cross-sectional analysis of the association of specific ACPAs and LVMI was performed. Traditional CVD risk factors and RA characteristics were adjusted for.

Results: The mean age of the patients was 54 years (±13), with 85% being females and 36% self-identified as non-Hispanic White. The median disease duration was 7 years (IQR: 3-17), 67% had a positive anti-CCP antibody, and the mean current RA disease activity, based on the DAS28-CRP, was 3.9 (IQR: 2.9-4.5). Forty percent were hypertensive, 11% had diabetes, and 7% were current smokers. Except for a higher proportion of patients with rheumatoid factor level> 40units, no differences were seen between those with high vs. low anti-CCP titers. High anti-citrullinated fibrinogen, anti-citrullinated vimentin, and anti-citrullinated fibronectin antibody levels were associated with a higher LVMI compared to low levels of these antibodies (68 vs. 58 g/m^2, p=0.02; 67 vs. 58 g/m^2, p=0.003; and 69 vs. 57 g/m^2, p=0.004; respectively). These associations remained significant in the adjusted analyses (69 vs. 58 g/m^2, p=0.04; 67 vs. 58 g/m^2, p=0.004; 72 vs. 57 g/m^2, p=0.009; respectively) (figure 1).

Conclusion: In concordance with our previous findings, specific ACPAs were associated with a higher LVMI in RA patients without CVD. This independent association suggests a link between autoimmunity and cardiac structure in RA.

Figure 1. Association of ACPA status with Left Ventricular mass index.

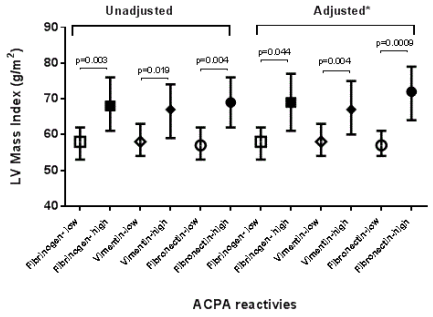

Figure 1. High anti-citrullinated-vimentin, anti-citrullinated-fibrinogen, and anti-citrullinated fibronectin antibody levels were associated with higher LVMI. *Adjusted for hypertension.

Neutrophil Extracellular Trap Levels Measured By Cell Free Nucleosome ELISA in Serum Are Highly Specific and Sensitive for Rheumatoid Arthritis

Paul Hasler[1], Stavros Giaglis[1], Ulrich A. Walker[2], Erik Deman[1], Christoph Hemmeler[1], Christina Ryser[1], Samuel Kretzschmar[1], Guenther Schaefer[3], Juliane Franz[1] and Sinuhe Hahn[4], [1]Rheumatology, Kantonsspital Aarau, Aarau, Switzerland, [2]Rheumatology, University Hospital, Basel, Basel, Switzerland, [3]Dept. of Biomedicine, Laboratory of Prenatal Medicine, University Hospital Basel, Basel, Switzerland, [4]Dept. of Biomedicine, Laboratory for Prenatal Medicine, University Hospital Basel, Basel, Switzerland

Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid factor (RF) or anti-citrullinated peptide antibody (ACPA) detection have limited clinical utility for the diagnosis of rheumatoid arthritis (RA), as the specificity and sensitivity of RF is low and ACPAs seem restricted to a subgroup of RA patients. Neutrophil extracellular trap (NET) formation, the extracellular extrusion of chromosomal components from the nucleus upon specific stimulation, reported principally as a response to infectious agents, has also been linked to the pathogenesis of autoimmune and inflammatory diseases such as preeclampsia (PE), systemic lupus erythematosus (SLE), and recently RA[1,2]. We have previously observed that serum samples from RA patients showed significantly higher cell-free DNA levels than those of healthy controls and that the serum concentration of cell free nucleosomes (cfNucs) is a surrogate marker for NET formation[3,4].

Our aim was to validate cfNuc measurement in the serum for the diagnosis of RA and to assess its potential to differentiate rheumatoid arthritis cases from similar autoimmune inflammatory conditions and healthy controls.

Methods: Serum from healthy controls and groups of patients with RA, SLE, psoriatic arthritis (PsA) and ankylosing spondylitis (AS) were analyzed for cfNuc levels by ELISA. Healthy and disease control groups were compared by one way ANOVA. Receiver operator characteristic (ROC) curves were calculated with the standard errors. The results presented are from an interim analysis of a targeted 120 cases with RA and 30 each with SLE, PsA and AS.

Results: The mean cfNuc level of the healthy control group (n=47) was 0.3244, of the RA patients 1.813 (n=64), of the SLE patients 0.5753 (n=18), of the PsA patients 0.4684 (n=6) and of the patients with AS 0.6328 (n=10).

The difference between healthy controls and RA was significant at $P<0.0001$, between RA and SLE 0.0011, between RA and PsA 0.0007, and between RA and AS 0.0001.

Significance between RA and all disease controls and between RA and all controls was $P<0.0001$. The ROC area under the curve (AUC) for RA versus healthy controls was > 97%, the sensitivity and specificity being 87.5% and 91.5%, respectively, at a 0.58 cutoff. The ROC AUC for distinguishing RA from SLE was 88%, from PsA 92%, from AS 86% and disease controls as a group 88% (sensitivity 81.25%, specificity 80-89% at a cutoff of 0.78). For RA versus all controls, the ROC AUC was 93% (sensitivity 81.25%, specificity 93% at a cutoff of 0.78).

Conclusion: The detection of cell free nucleosomes in the serum of patients with autoimmune conditions can be utilized to discriminate between healthy controls and cases with RA with remarkable sensitivity and specificity. Sensitivity and specificity against disease controls, albeit less, were in a similar range. Upon reaching our target case numbers, we intend to analyze whether cfNuc could provide a tool to monitor and/or predict the response of RA patients to treatment with biologics and to optimize the ELISA assay.

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

To describe the longitudinal changes in the number of swollen and tender joints and HAQ scores in 345 African Americans with early RA and to assess factors influencing improvement and side effects of medications.

Methods:

This is a prospective observational cohort study of African American RA patients with early disease (<2 years) taken from the CLEAR1 registry who were followed longitudinally for up to 5 years after diagnosis. A total of 626 clinical visits were performed on 345 subjects (~54% of subjects had the 5 year disease duration visit). Clinical outcome data (number of tender and swollen joints based on 28 joints and HAQ scores) were subjected to repeated measures analysis. The statistical models were adjusted simultaneously for 7 baseline covariates (gender, age, BMI, family history of RA, smoking status, poverty and education level) and 5 time-dependent covariates (prednisone therapy divided daily and single daily, methotrexate treatment, diabetes, hypertension and osteopenia/osteoporosis).

Results:

The mean age at enrollment was 51 years, 82% of the cohort was female, and the mean disease duration at enrollment was 12 months. The prevalence of low dose oral prednisone use at baseline was 77% (265/345) and median prednisone dose at baseline was 10 mg/day. AA with early RA had significant reduction during follow-up in number of swollen joints, tender joints and in HAQ scores (all $p < 0.001$, univariable analyses). At baseline, 18% of patients had diabetes mellitus, 56% hypertension, 45% osteopenia and 5% osteoporosis. During follow-up approximately 5% of the patients developed diabetes mellitus, hypertension or new osteoporosis.

Multivariable analyses indicated similar improvement in number of swollen joints and HAQ scores for patients on divided daily low dose oral prednisone (n=x) or single daily low dose oral prednisone (n=y). However, the adjusted mean tender joint count was lower for patients on a divided daily dose of prednisone (covariate-adjusted mean= 7.1) compared to a single daily dose of prednisone (covariate-adjusted mean= 9.6) with a mean difference (divided daily minus single daily) in number of tender joints=-2.5 joints (95% CI: -2.8 to -2.2; $P < 0.01$). The adjusted mean number of tender joints for patients not on prednisone was approximately 9 tender joints.

Conclusion:

During the 5 years of follow-up, clinical outcomes improved in AA patients with early RA. Reduced number of tender joints appears to be associated with divided daily low dose prednisone treatment. The development of new diabetes mellitus, hypertension and osteoporosis was uncommon and not related to prednisone use.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

Events in the lungs might contribute to generation of anti citrullinated protein antibodies (ACPA) in rheumatoid arthritis (RA). We investigated if signs of immune activation are present in the bronchial biopsies and bronchoalveolar lavage (BAL) of early-untreated RA patients in the absence of concomitant lung pathology.

Methods: 24 RA patients with symptom duration less than one year and naïve to disease-modifying antirheumatic drugs (DMARD) were subjected to bronchoscopy where bronchoalveolar lavage (BAL) and mucosal large bronchial biopsies were retrieved. For comparison 15 bronchial biopsies and 79 BAL samples from healthy volunteers were available. Histological examination was performed to evaluate lymphocyte infiltration, presence of immune cells (T and B cells, plasma cells, dendritic cells and macrophages) and immune activation markers. Cells composition of BAL samples was analyzed by differential counting and flow cytometry.

Results:

Lymphocyte infiltration was more frequently found in ACPA-positive patients (9 out of 18 patients, 50%) as compared to ACPA-negative patients (1 our of 6, 17%, $p>0.05$) and controls (2 out of 15, 13%, $p<0.05$). Occasional formation of germinal center like structures was observed only in ACPA-positive RA patients (2 out of 18, 11%). These structures were positive for B cells markers and activation-induced cytidine deiminase and stained positively with biotinylated cit-enolase.

B cells and plasma cells were only found in ACPA-positive patients, while T cells were more frequently detected in bronchial biopsies of ACPA-positive (median 2, range 1-3) as compared to ACPA-negative (median 1, range 1-3) RA patients. Similar, expression of immune activation markers was higher in ACPA-positive as compared to ACPA-negative RA patients for both HLA-DR (median of 3, range 2-3 as compared to a median of 2, range 1-3, $p<0.05$) and HLA-DQ (median of 2, range 0-3 as compared to a median of 1, range 1-3, $p<0.05$). BAL samples of ACPA-positive but not ACPA-negative RA patients had significantly higher relative numbers of lymphocytes and expressed higher levels of activation markers compared to controls.

Conclusion:

Signs of immune cell accumulation and activation are present in the bronchial tissue of untreated early-RA patients without concomitant lung pathology, strengthening the role of the lung compartment as a critical initiating factor in the development of ACPA-positive RA.

The Multi-Biomarker Disease Activity Score in a TNF Inhibitor Tapering Study in Rheumatoid Arthritis Patients: Predictive Value for Successful Tapering, Flaring and Radiographic Progression

Chantal A.M. Bouman[1], Aatke van der Maas[1], Noortje van Herwaarden[1], Eric H. Sasso[2], Frank H.J. van den Hoogen[1] and Alfons A. den Broeder[1], [1]Rheumatology, Sint Maartenskliniek, Nijmegen, Netherlands, [2]Crescendo Bioscience Inc., South San Francisco, CA

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

We evaluated the predictive value of the multi-biomarker disease activity (MBDA) score for clinical outcomes and radiographic progression in a TNFi tapering study in RA patients with sustained low disease activity.

Methods:

DRESS is an 18-month randomised trial on non-inferiority of tapering of adalimumab or etanercept compared with usual care (UC). TNFi was tapered every 3 months until stopping or clinical flare (ΔDAS28-CRP >1.2 or >0.6 if current DAS28-CRP ≥3.2; major flare: >3 months). Patients were assessed every 3 months and at flare. For flares, TNFi was restarted or escalated. X-rays of hands and feet were scored with modified Sharp-van der Heijde score (mSHS) at baseline (BL) and 18 months. Correlations between MBDA score and DAS28-CRP were determined at BL, 9, 18 months and first flare. MBDA scores at BL, 9 and 18 months and ΔMBDA score from BL to 9 months were analysed for successful stopping, successful tapering, and no tapering possible. AUROC evaluated the predictive value of: 1) BL MBDA score for a) successful tapering vs. no tapering possible, b) stopping vs. no tapering possible, c) occurrence of (major) flares, d) incidence of radiographic progression (RP); 2) ΔMBDA score from BL to 9 months for clinical outcomes and RP; 3) MBDA scores at first and second visits preceding a flare for occurrence of that flare; 4) ΔMBDA score between first and second visits preceding a flare for occurrence of that flare.

Results:

Of 180 patients, 171 (115 tapering, 56 UC) had serum and month 18 outcomes available: 64% female, mean disease duration 12.1 (SD 8.3) years, 73.3% ACPA positive. TNFi had been successfully stopped in 19%, tapered in 44%, and re-escalated to baseline dose in 37%. MBDA scores and DAS28-CRP are summarized in Figure 1. Correlation of DAS28-CRP and MBDA score was greatest at 18 months (Spearman's $r=0.45$, $p<0.01$) and lowest at BL ($r=0.19$, $p<0.01$). AUROCs for predicting successful stopping, tapering and flare by BL MBDA score were not significant. AUROC for major flare by BL MBDA score was significant in the UC group (10% flared; AUROC 0.72, 95% CI 0.56-0.88) and not the taper group (12% flared). RP (ΔmSHS >0.5 from BL to 18 months) occurred in 26% of 167 patients with available data and was not predicted by MBDA score. ΔMBDA score from BL to 9 months was not predictive for clinical outcomes or RP. MBDA scores at first and second visit preceding a flare were not predictive for any flare. AUROC for ΔMBDA score between first and second visit preceding a flare was borderline significant (0.56, 95% CI 0.50-0.63).

Conclusion:

Neither BL MBDA score nor ΔMBDA score from BL to 9 months was predictive for successful stopping; tapering; occurrence of flare; or radiographic progression. However, exploratory analyses showed that: 1) BL MBDA score was predictive for flare in patients who received UC and 2) ΔMBDA score between visits preceding a flare was borderline significant for predicting flare.

Figure 1. Mean MBDA scores and DAS28-CRP at BL, 9 and 18 months, and change from BL to 9 months†

Outcome at 18 months (n=171)	Mean MBDA baseline (SD)	Mean DAS28-CRP baseline (SD)	Mean MBDA 9 months (SD)	Mean DAS28-CRP 9 months (SD)	Mean MBDA 18 months (SD)	Mean DAS28-CRP 18 months (SD)	Change MBDA BL to 9M (SD)
Successful stopped (n=22)	33.6 (13.1)	2.05 (0.62)	39.7 (12.0)	2.07 (0.66)	40.8 (11.4)	2.14 (0.70)	6.09 (14.0)

CCP Antibody Negativity Is Associated with Higher Fatigue in Rheumatoid Arthritis

Laura Cappelli[1], Susan J. Bartlett[2,3], Michelle Jones[4] and Clifton Bingham[4], [1]Ste 4500, Johns Hopkins University, Baltimore, MD, [2]Division of Rheumatology, Johns Hopkins School of Medicine, Baltimore, MD, [3]Medicine , Divisions of Clinical Epidemiology, Rheumatology, Respirology, McGill University, Montreal, QC, Canada, [4]Johns Hopkins University, Baltimore, MD

SESSION INFORMATION
Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: Fatigue in rheumatoid arthritis (RA) is common and highly debilitating. Emerging evidence suggests that seronegative RA patients differ from their seropositive peers in genetic susceptibility, immunology, and clinical characteristics. One pathway shown to have increased activity in seronegative RA patients is the IL-6/STAT3 signaling pathway. We hypothesized that selected symptoms (fatigue, pain, sleep) and impacts (physical function and social participation) would be worse in CCP negative participants.

Methods: Data are from a prospective cohort study of patients receiving guideline-based RA care in an academic clinic. Baseline visits conducted from 10/12 to 1/14 were included in this cross sectional analysis. Patients meeting ACR criteria for RA and for whom information on CCP status was available were included in this study. Selected symptoms and impacts were assessed using The NIH Patient Reported Outcome Measurement Information System (PROMIS) computer adaptive tests and compared by CCP status with t-tests. Linear regression models were used to evaluate the impact of CCP status on fatigue after adjusting for potential confounders.

Results: The 165 participants were 82% female with mean age of 56 (SD 13.1). CCP negative and positive participants differed only by disease duration, with CCP negative patients having shorter duration (Table 1). Exploratory analysis evaluating average T-scores of eight PROMIS domains and pain VAS showed statistically significantly higher levels of fatigue in CCP negative patients as compared to their CCP positive counterparts (table 1). Similar trends with higher anxiety levels and pain interference, and impairments in physical function and participation were seen in the CCP negative group ($p<.10$). Associations between greater fatigue and CCP negativity persisted after adjustment for sociodemographic and other characteristics (table 2).

Conclusion: In RA, CCP negativity is a robust independent predictor of greater fatigue and may be associated with greater impairments in disability and participation. These results suggest that some symptoms are associated with autoantibody status and may indicate differential activity of IL-6/STAT3 signaling.

Table 1. Participant characteristics by CCP status (n = 165) .

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose :

The Health Assessment Questionnaire (HAQ) remains the gold standard for measuring patient-reported functional status in rheumatoid arthritis (RA) and is included among the measures suggested by the American College of Rheumatology for making treatment decisions in routine care. We have previously shown that significant variability exists in the correlation of individual HAQ questions with patient-reported and clinical outcomes. The aim of this analysis was to assess, in routine care, the timelines of HAQ improvement as compared to clinical improvement and to examine possible differences in the improvement of individual questions.

Methods :

BioTRAC is an ongoing, prospective registry of patients initiating treatment for RA, ankylosing spondylitis, or psoriatic arthritis with infliximab (IFX) or golimumab (GLM). Eligible people for this analysis included RA patients treated with IFX who were enrolled since 2002 or with GLM enrolled since 2010. Time to achieving minimal important difference (MID; $\Delta \geq 0.22$) in HAQ, HAQ$\leq$1, minimal disease (MD) in individual HAQ questions (no or some difficulty), CDAI low disease activity (LDA), or CDAI remission was assessed with the Kaplan-Maier estimator of the survival function and cox regression.

Results:

A total of 1205 patients (75.3% female) were included with mean (SD) age of 56.0 (13.6) years and disease duration of 8.4 (8.9) years at baseline. Mean (SD) HAQ and CDAI were 1.55 (0.72) and 33.8 (17.4), respectively.

Statistically significant and clinically meaningful improvements in both HAQ and CDAI were observed over time. The cumulative probability of achieving HAQ MID, HAQ$\leq$1, CDAI LDA, and CDAI remission by 12 months was 69.5%, 54.5%, 54.1%, and 18.1%, respectively. Time to achieving HAQ MID [Hazard Ratio (95% CI): 3.6 (3.2-4.2)], HAQ$\leq$1 [2.9 (2.6-3.4)], and CDAI LDA [3.1 (2.7-3.6)] was significantly lower as compared to CDAI remission.

With respect to individual HAQ questions, at baseline, the most predominant usual activities that patients were unable to do were taking a tub bath (27.9% of patients), reaching and getting down a 5-pound object from the head (21.8%), and doing chores such as vacuuming or yard work (23.2%). In accordance, time to having no or some difficulty in these activities was significantly higher compared to the remaining HAQ items (Figure 1).

Conclusion:

The results of this analysis show that the timelines for achieving HAQ targets in routine care is comparable to that of achieving CDAI LDA. Significant differences were observed in terms of improvement in individual HAQ items with the inability to take a tub bath, getting heavy overhead objects down, and doing chores being the most persistent.

Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose:

The role of vitamin K and undercarboxylated osteocalcin (ucOC) on BMD in RA is present. Up to our knowledge no other works have discussed the relationship between ucOC and BMD in premenopausal RA patients and its correlation with disease activity.

Methods:

Sixty Premenopausal rheumatoid arthritis female patients and thirty healthy premenopausal controls with matched age were included in this study.All were subjected to demographic data , clinical examination, Laboratory investigations:-including serum level of ucOC, disease activity assessment by DAS 28 score and bone mineral density measurement in the lumbar spine L2–4 ,hip and distal radius by dual-energy X-ray absorptimetry (DEXA) equipment.

Results:

In our study the level of ucOC was significantly higher in patients of RA than controls ($p < 0.001$). BMD in patients was found to be

significantly lower than controls in spine,femoral neck and distal radius areas. The most frequent osteoporotic site according to Z score was spine(16.7%) followed by femoral neck (8.3 %) then distal radius (6.7%).While the commonest osteopenic site according to (Z score ≤ -1) was spine(31.7%) followed by femoral neck (21.7 %)then (16.7%)in the distal radius. Our work showed that ucOC level was found to be high in premenopausal RA patients with higher DAS values than those with lower DAS value ($p<0.001$) . In our work BMD measured by DEXA scan was found to be lower with higher DAS values and vice versa.

Conclusion:

Serum level of ucOC (which is amirror of vitamin K defficency) was found to be higher in premenopausal RA patients than control and correlated positively with disease activity and inversely with BMD measurement.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Serum 14-3-3η is an RA diagnostic marker that is associated with radiographic progression risk. *In vitro* studies describe 14-3-3η's potent, dose-dependent up-regulation of factors that perpetuate inflammation and joint damage. In this study we investigated the association of 14-3-3η cut-points with standard RA disease activity measures at a treatment-change clinical juncture.

Methods: Serum 14-3-3η levels were measured in 149 Japanese RA patients prior to the initiation of therapy (BL) and at Yr1. 14-3-3η positivity was defined at 3 cut-points: the diagnostic cut-off of ≥0.19 ng/ml, and 2x and 4x this cut-off, 0.40 and 0.80 ng/ml respectively. Contingency analysis provided the relationship between 14-3-3η positivity and DAS, CDAI and SDAI categorization. Patients were grouped into 4 categories based on the Yr1 14-3-3η positivity (≥0.19 ng/ml): remaining negative (RN), becoming positive (BP), remaining positive (RP) or becoming negative (BN). Non-parametric ANOVA analysis and the Mann Whitney U-test were utilized to assess group differences in disease activity measures. The Fisher Exact Test was used to assess 14-3-3η's association with Good EULAR response.

Results: The mean (SD) age was 57 (15) years and 86% of the patients were female. The median (IQR) disease duration was 51 (9-150) months. At the diagnostic cut-point of ≥0.19 ng/ml, 14-3-3η positive patients had worse disease based on significantly higher median DAS28ESR [5.62 (4.64-6.57) vs. 4.77 (4.10-5.86), p=0.010], CDAI [24.7 (16.2-36.3) vs 16.0 (11.5-27.0), p=0.015], and SDAI [26.8 (16.7-38.6) vs 18.8 (11.7-32.7), p=0.024]. Titres of 14-3-3η correlated significantly with DAS28ESR [r=0.29], CDAI [r=0.25], SDAI [r=0.24], TJC28 [r=0.21], SJC28 [r=0.26] and JSN [r=0.18]. As shown in Table 1, a stronger and more significant association with DAS28, CDAI and SDAI categorization was observed at higher 14-3-3η positivity cut-offs.

Table 1. Baseline 14-3-3η positivity and association with Disease State.

	BL DAS Category		BL SDAI Category		BL CDAI category	
BL Cut-point	LR	p-value	LR	p-value	LR	p-value
≥ 0.19ng/ml	10.6	0.0011	3.7	0.16	6.2	0.045
≥ 0.40ng/ml	16.3	<0.0001	9.7	0.0077	8.8	0.012
≥ 0.80 ng/ml	25.2	<0.0001	16.3	0.0003	14.0	0.0009

The match pairs t-test revealed that the 14-3-3η serum concentrations significantly decreased from 0.70 ng/ml [0.17-5.96] at BL to 0.37 ng/ml [0.11-1.82] at Yr1 ($p<0.0001$). At BL and Yr1, 110 (74%) and 97 (65%) were 14-3-3η +ve. At Yr 1, 18 of the 110 patients that

were BL +ve were BN and 92 RP. In the BL-ve group, 5 patients sero-converted (BP) and 34 were RN at Yr1. ANOVA and the U-test revealed that median Yr1 DAS28ESR was significantly lower in the 18 BN patients compared to the 92 RP patients [2.0 (1.6-2.8) vs 2.7 (2.0-3.8), p=0.004]. The unpaired t-test, assuming equal variances, revealed that mean DAS28ESR Yr1 levels were significantly lower in the 18 BN patients compared to 5 BP patients [2.1 vs 3.1, p=0.033].

Conclusion: Serum 14-3-3η is a mechanistic marker that is involved in the pathogenesis of RA. Patients who present with higher 14-3-3η titres reflect a higher disease status and may be considered for a post-treatment measurement of 14-3-3η toward negative levels.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

MRP8/14 are calcium binding proteins produced by myeloid cells. Recently baseline serum levels of MRP8/14 have been shown to predict response to biologicals in rheumatoid arthritis (RA). Since methotrexate (MTX) is the first line therapy in RA we studied if MRP8/14 levels can predict response to MTX.

Methods:

Patients with RA (ACR 2010 criteria), DMARD naïve with active disease were enrolled. All patients were treated with MTX by gradually increasing dose to a maximum of 25mg/week or the maximal tolerated dose.No corticosteroids were given. Patients were followed up monthly telephonically and 2 monthly in the clinic. At 4 months disease activity was measured by DAS 28 and EULAR response was assessed.All patients who needed rescue therapy after 2 months or did not respond at 4 months were classified as non-responders.

Results:

90 patients were enrolled in the study, of which 3 were excluded(discontinued MTX within 4-6 weeks due to toxicity). Thus 87 patients (74 females) with mean age 40.8±12.1yr, mean duration of disease 28±25.5months and mean DAS28 4.5±0.7) were analyzed. The mean serum MRP 8/14 level at baseline was 27.612±21.353µg/ml.The serum MRP8/14 had good correlation with DAS28CRP (r = 0.35; p=0.001).The MRP8/14 levels fell significantly after 4 months of treatment (12.734 ± 9.966µg/ml; p<0.001).

Among 87 patients 69 were classified as responders (good 43, moderate 26) while 18 were non- responders. The mean baseline level of MRP 8/14 was higher among responders as compared to non- responders (29.280 ± 20.411µg/ml vs 19.152 ± 23.341µg/ml; p=0.002). Comparing the fall in responders and non-responders separately, the levels reduced significantly only in the responders(29.280 ± 20.411 µg/ml to 12.487± 9.987 µg/ml; p<0.001), but not in the non-responders(19.152 ± 23.341µg/ml to 15.173±10.189 µg/ml; p=0.687).Receiver-operation characteristic (ROC) analysis showed that MRP8/14 was a good predictor of response with an area under curve(AUC)of 0.719 better than that of DAS28CRP(AUC-0.635) and DAS28ESR (AUC-0.489).

Conclusion:

MRP8/14 is a good biomarker of disease activity in RA and higher levels predict response to MTX.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Tobacco smoke has been associated to anti-cyclic citrullinated peptide (anti-CCP) antibodies positivity. Recently, in wood-smoke-induced chronic obstructive pulmonary disease (COPD) patients without rheumatoid arthritis (RA), anti-CCP antibody higher titers have been reported than in healthy individuals and tobacco-induced COPD. The anti-CCP and rheumatoid factor (RF) titers have not been examined in rheumatoid arthritis patients with biomass smoke exposure. The objective of the present study is to report the correlation between anti-CCP, IgG, IgM and IgA RF to biomass exposure index (BEI).

Methods:

A cross-sectional study was designed based on a cohort of Hispanic RA patients recruited from September 2014 to April 2015. All fulfilled the 1987 ACR and the 2010 ACR/EULAR classification criteria for RA. Biomass smoke exposure was expressed with the BEI calculated as the average hours of exposure per day multiplied by the number of years. Patients with a minimum exposure of 1 BEI were included. RF and Anti-CCP were measured by ELISA with cutoff points of <5U/mL and <20U/mL respectively. Sample calculation expecting a 0.5 correlation determined the need of at least 30 subjects.

Results:

Out of the 102 patients in the cohort, 46 (44.6%) had a BEI equal to or higher than 1 and were included in the analysis. A total of 41 (89.1%) were women with a mean age of 61.06 ±8.82 years and mean disease duration of 12.47 years ±8.81. None had renal or pulmonary disease at baseline. Activity by DAS28 ESR was 3.69 ±1.50 (moderate activity). The median BEI was 42 (p25=30, p75=80.25). All of the exposure was due to in-house cooking with wood. Anti-CCP positivity was present in 33 (71.7%) with a median titer of 150.10 U/mL (p25=2.74, p75=200). IgG RF was present in 11 (23.9%) at a median titer of 8.88 U/mL (p25=4.31, p75=19.98), IgA in 28 (60.9%) with a mean titer of 79.75 U/mL ±77.93, and IgM in 41 (89.1%) with a median of 112.91 U/mL (p25=67.77, p75=200). Spearman's rho correlation showed no significant correlation between BEI and anti-CCP (p=0.386, rho= -0.131), IgG RF (p=0.147, rho= -0.217), IgA RF (p=0.501, rho= -0.102) and IgM RF (p=0.874, rho=-0.024). Additionally, no difference was found between exposed and not exposed patients regarding anti-CPP (p=0.715), IgG (p=0.335), IgA (p=0.954) and IgM (p=0.433) RF within the cohort.

Conclusion:

In this Hispanic cohort of established rheumatoid arthritis patients with moderate disease activity exposed to biomass smoke, no correlation was found between BEI and anti-CCP, IgG RF, IgA RF, or IgM RF.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: The "Rheumatoid Arthritis Impact of Disease" (RAID) score is a Patient Reported Outcome (PRO) that comprises seven domains of disease[1], that may reflect the patient's perspective more widely than other PROs. A cut-off corresponding to the patient acceptable symptom state (PASS) has been defined as RAID score <=2 [2]. This study aims: 1) to assess the associations between the RAID and established measures used in RA (disease activity measures and other PROs); 2) to analyse the relationship between clinical remission and PASS by RAID.

Methods: Consecutive RA patients (ACR/EULAR 2010 or ACR 1987 criteria) followed in a tertiary rheumatology department were included in this cross-sectional study. Patient demographics and clinical data collected were: DAS28, SDAI, CDAI and HAQ; patient and physician global assessment (PGA and PhGA); the Hospital Anxiety and Depression Scale (HADS), the Happiness Scale (HS) and the EuroQOL (EQ5D) score. RAID and DAS28 (4vCRP) scores were classified according to PASS and remission definitions (<=2 and <=2.6, respectively). We used Spearman correlation coefficient, Qui-square and Kappa as statistic tests.

Results: 101 patients were included (82% females, 58.8±12.4 years and 13.0±8.6 years of disease duration). Disease impact and activity were moderate: mean RAID=4.8±2.2 and mean DAS28(4vCRP)=2.9±1.2. RAID showed moderate correlations with most of the established combined indices of disease activity, with the HAQ having the highest correlation (r=0.66). Regarding other PROs, RAID was strongly correlated with PGA (r=0.70) and moderately with the remaining (Table 1).

Table 1 – Spearman's correlations between RAID and Disease Activity scores, Patient and Physician Global Assessment and other PROs (n=101)

	DAS283vESR	DAS284vESR	DAS283vCRP	DAS284vCRP	SDAI	CDAI	HAQ
RAID	0.28*	0.43*	0.32*	0.54*	0.61*	0.62*	0.66*
	PGA	**PhGA**	**Happiness**	**EQ5D**	**HADS-D**	**HADS-A**	--
RAID	0.70*	0.26*	-0.41*	-0.45*	0.55*	0.63*	--

*p<0.05

Out of 50 patients in DAS28 remission, 11 had a RAID score consistent with PASS but 39 had higher scores. Of the 51 patients not in remission, only one patient had a RAID score consistent with PASS (Table 2). This difference of proportions was statistically significant (X2(1)=9.684; p=0.002; Kappa=0.20).

Table 2 – Proportion of RA patients in PASS and in remission (n=101)

			DAS28(4vCPR)		
			Remission	Non Remission	Total
RAID	PASS	Count	11	1	12
		% of Total	10,9%	1,0%	11,9%
	Non PASS	Count	39	50	89
		% of Total	38,6%	49,5%	88,1%
Total		Count	50	51	101
		% of Total	49,5%	50,5%	100,0%

Conclusion: RAID correlates well with different PROs and moderately with disease activity scores. Its use in clinical practice may allow a better representation of the global impact of RA in patient's lives.

As disease remission by DAS and PASS by RAID are in disagreement for a considerable percentage of patients, further research on this

topic is warranted.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: In course of rheumatoid arthritis (RA) ther is often impaired glucose metabolism, which leads to the development of diabetes mellitus (DM). One of the parameters allowing to assess the risk of DM and cardiovascular disease (CVD) is the concentration of advanced glycation end products (AGE). In rheumatoid arthritis patients increase in the level of AGE also occurs due to the underlying disease. The aim of the study was to assess correlation of AGE skin concentration with other laboraotry tests and to compare the levels of AGE concentration between RA patients and healthy subjects.

Methods: The study involved 148 patients divided into three groups: Group I - patients with RA (n = 102, 79F / 23M, average age 51.5), group II - patients with RA and DM (n = 21, 14F / 7M average age: 51.9), group III - healthy persons (n = 25, 16F / 9M, average age 48.8). Each patient had a skin test using the AGE Reader, which allows the assessment of AGE skin concentration by evaluation of skin autofluorescence (SAF) signal and a laboratory tests panel including total cholesterol, HDL, LDL, triglycerides and HbA1C and the calculated body mass index (BMI).

Results: Average SAF value in arbitrary units [au] was: group I 2.54 au and group II 2.74 au, group III 1.96 au. The average SAF value in the group III differed significantly from the average SAF value in group I and II ($p < 0.1$ and $p < 0.05$ respectively). There was no statistically significant difference between the mean AF values for Groups I and II. Based on AGE Reader tests risk groups of developing DM and CVD can also be separated. Significant differences in the distribution of patients in each risk group between the group III and group I and II ($p < 0.001$) was observed. There was a correlation between an increased SAF value in groups I and II and the following laboratory results compared to the group III: HDL (mean values in the groups were as follows: 60.52 mg/dl, 57.48 mg/dl, 84.08 mg/dl) and Hb1AC (mean values in the groups were respectively 5.5 mm/hr, 5.6 mm/h and 5.3 mm/h) ($p < 0.01$). In case of groups II and III a significant differences between the results of ESR (average values were 24 mm/h and 13 mm/h) and triglycerides concentration (mean values were 135 mg/dl and 95 mg/dL) ($p < 0.01$. were also observed.

Conclusion: These results confirm that the value of AGE skin concentration is associated with increased RA activity and may be an important indicator in the assessment of disease progression and its potential complications.

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Tocilizumab (TCZ) is approved for the treatment of adults with rheumatoid arthritis (RA) either as monotherapy or in combination with disease-modifying antirheumatic drugs (DMARDs). However, to date, data on its real-world utilization and durability are limited. The aim of this analysis was to describe its real life use over 6 months and assess its safety in Canada.

Methods: ACT-UP CARE (ACT-UP Canadian Physician Observance of RA Patients on TCZ [CARE]) is an ongoing, multi-national, observational study with TCZ. As of January 2015, 1,432 patients have been enrolled from 18 countries. In this analysis, data from the 200 Canadian patients participating in ACT-UP are presented. The Framingham Cardiovascular (CV) Risk Score (FCRS) was measured at baseline (BL) as an exploratory assessment. Within-group changes in disease parameters were evaluated with the paired-samples t-test. Safety was described with the incidence of adverse events (AEs).

Results: The mean (SD) RA disease duration was 12.6 (10.4) years, and 79% of patients were on a previous biologic. Low, moderate and high FCRS category was reported for 52.6%, 36.8%, and 10.5%, respectively, of patients with available data. The most frequent CV risk factors were hypertension (36.7%), hyperlipidemia (21.6%), and current smoking (18.6%). Concomitant methotrexate (MTX) use was reported for 51.5% of patients at BL (mean dose: 19.5 mg/week) and 57.7% of patients over 6 months of treatment (mean dose: 18.7 mg/week). Corticosteroid use was reported for 40.5% of patients at BL (mean prednisone dose: 10.8 mg/day). Among patients on prednisone at BL, stable dose was reported for 50.6%, decreased dose for 22.8%, increased dose for 10.1%, and steroid discontinuation for 16.5% over 6 months. Mean (SD) disease and lipid parameters at BL and 6 months are shown in Table 1.

There were 20 (10.0%) discontinuations due to: AEs (n=6), lack of efficacy (n=5), withdrawal of consent (n=5), other (n=3), and death (n=1), without any significant differences based on prior use of a biologic (10.8% for bio-experienced vs. 7.1% for bio-naïve; P=0.772) and presence of comorbidities (8.7% for presence vs. 17.9% for no presence; P=0.168). A total of 351 AEs were reported by 144 (72.7%) patients (353.0 events /100 PYs), the majority of which (93.4%) were non-serious. Most frequently reported AEs included upper respiratory tract infection (n=14, 7.1%), headache (n=9, 4.5%), and fatigue (n=8, 4.0%). Serious infections were reported by 5 (2.5%) patients. One death due to pneumonia was reported which was judged by the treating physician as not related to TCZ.

Conclusion: The results of this real-world Canadian study show that TCZ is well tolerated and effective in significantly improving clinical parameters and patient reported outcomes as early as 6 months of treatment.

Table 1: Disease and Lipid Parameters over 6 Months

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose : Interstitial pneumonia (IP) is one of the most critical complications in rheumatoid arthritis (RA). Severe IP is developed in zymosan-treated SKG mice, and this IP is completely blocked by neutralization of granulocyte macrophage colony-stimulating factor (GM-CSF) (Shiomi A, et al. J Immunol. 2014;15;193(2):849-59). GM-CSF induces expression of soluble vascular endothelial growth factor (VEGF) receptor-1 from human monocytes (Eubank TD, et al. Immunity. 2004;21(6):831-42). Here we aimed to explore the associations between IP and biomarkers including GM-CSF, VEGF, and circulating monocyte count in biologic-naive patients with RA.

Methods : Consecutive biologic-naive patients with RA were enrolled in our prospective cohort study at the timing of initiating biologics. Our cohort started in February 2010, and the patients were analysed as of April 2012. Before initiating biologics, we evaluated chest X-rays for all of the patients, and if IP was suspected, a chest computed tomographic (CT) scan was taken. At the enrollment of our cohort we assessed variables including the patients' characteristics (sex, age, disease duration, prednisolone dose, methotrexate dose, Clinical Disease Activity Index, Health Assessment Questionnaire-Disability Index) and blood biomarkers (GM-CSF [pg/mL], VEGF [pg/mL], TNF-α [pg/mL], Interleukin(IL)-6 [pg/mL], IL-17 [pg/mL], osteopontin [ng/mL], C-reactive protein

[mg/dL], white blood cell count [/μL], neutrophil count [/μL], and monocyte count [/μL]) to extract factors associated with CT scan-proven IP using univariate analyses. The extracted factors were entered into a multivariate logistic regression model to obtain factors associated with IP.

Results : A total of 127 patients (108 females and 19 males) were included in our study. The mean age and disease duration of the patients were 56.2±12.9 years and 6.7±7.7 years, respectively. CT scan-proven IP was noted in 17 patients. Prednisolone was used in 33 patients and methotrexate was used in 110. In the univariate analyses, sex, age, prednisolone dose, methotrexate dose, GM-CSF, VEGF, and monocyte count were significantly associated with IP ($P<0.05$). In the multivariate analyses, age (OR 1.081, 95% CI 1.010-1.174), methotrexate dose (OR 0.820, 95% CI 0.686-0.970), and monocyte count (OR 1.005, 95% CI 1.001-1.010) were identified as factors associated with IP.

Conclusion : The large number of circulating monocytes as well as advanced age and low methotrexate dose is significantly associated with IP in biologic-naive patients with RA.

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: A number of composite outcome measures have been validated to quantify disease activity in Rheumatoid Arthritis (RA). Few studies have been published on the use of a multi-biomarker disease activity (MBDA) blood test (Vectra DA®) in a real world setting. The published articles that attempt to define the impact of this test in clinical practice have been an exercise on the use of the MBDA in RA case vignettes and a study evaluating the effect of the MBDA on treatment decisions. As there are no published studies using the MBDA in a true clinical practice compared to a validated outcome measure, in this study we compared the MBDA to the CDAI using the clinical registry JointMan® (JM).

Methods: This is a retrospective, observational study. JM captures RA diagnostic criteria and selected disease features, formal joint counts, outcome measures, serology, medication efficacy and safety and reason for discontinuation of medications. Due to the retrospective analysis methodology not all data was available.

Results:

Over 5700 unique RA patients and 133,000 encounters have been recorded since 2009.

The total distinct Vectra patient count was 687 and the total number of Vectra results was 1079. The total JM entries where a Vectra and CDAI score are within 20 days of each other was 436. Total distinct Vectra patients with more than one Vectra score was 274.

We calculated three correlation coefficients: the Pearson, the Cohen-Kappa, and the Weighted Kappa. The correlation coefficients are delineated in **Table 1**. The results demonstrate a Cohen Kappa estimate of 0.093 ($p<0.006$), a Weighted Kappa of $\kappa = 0.298$ ($p<0.001$)

and a Pearson score, ρ = 0.4185 (P<0.001). **Table 2.** Contains the distribution of the paired data.

Table 1.

	Lower CI	Estimate	Upper CI
Unweighted Kappa (κ)	0.035	0.093	0.15
Weighted Kappa (κ)	0.213	0.298	0.38
Pearson (ρ)	0.338	0.419	0.493

Table 2.

		Vectra			
		High	**Moderate**	**Low**	**Remission**
CDAI	**High**	59	29	3	12
	Moderate	67	51	7	29
	Low	37	52	6	15
	Remission	4	26	10	29

Conclusion: This is the first study using the MBDA in a true clinical practice setting. In this study the MBDA was compared to CDAI. The Cohen Kappa indicates "slight" agreement, whereas the weighted score of K = .298, is a "fair" correlation according to Landis and Koch. The Vectra DA score achieved almost 3/10 of the way between the expected accuracy (random) and perfect classification accuracy (CDAI being the standard). The Pearson ρ score of 0.4185 (P<0.001) falls into the category of a strong positive linear relationship between Vectra and CDAI scoring metrics. The qualitative nominal interpretations of the scores indicate that there is a valid, yet incompletely characterized relationship between the metrics. Additional prospective studies are needed in real world settings are needed to continue to define the role of the MBDA score.

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Lipolysis is increased in rheumatoid arthritis (RA), and lipid-induced insulin resistance coincides with anabolic resistance. Ability to maintain skeletal muscle mass is impaired in insulin-resistant conditions. Low grade inflammation prevents protein synthesis in peripheral muscles. Phenylalanine is associated with whole body protein turnover; protein synthesis and break down.We have investigated the relationship between amino acids and patient reported outcomes: general health (GH, patient global estimate, VAS), pain (VAS) and HAQ, among patients with newly diagnosed RA in a population based cohort.

Methods:

For quantification of amino acids and alpha-1-acyl glycoprotein (GP) levels serum nuclear magnetic resonance platform operating at 500 MHz was used in native serum samples from patients with RA participating in Northern Savo 2010 Study. Crude, age and BMI adjusted correlations between HAQ, phenylalanine, and inflammatory parameters were counted.

Results:

Serum samples from 63 patients, 34 females and 29 males with RA satisfying the ACR/Eular 2010 classification criteria, were studied. The mean age (SD) of the patients was 59.1 (12.0) years and the mean BMI 27.3 (5.4) kg/m². 69.8 % had anti-CCP antibodies. The mean DAS28(ESR) was 4.4 (1.3), GH 52.7 (25.7), pain 56.4 (29.1), HAQ 0.70 (0.65), and GP 1.62 (0.29) mmol/L. DAS28(ESR) correlated with HAQ 0.41 (0.18 to 0.59), $p < 0.01$, with ESR 0.36 (0.12 to 0.56), $p < 0.05$, GH 0.38 (0.13 to 0.57), $p<0.05$, and physical function (HAQ) 0.61 (0.43 to 0.75), $p< 0.001$. HAQ-levels increased with increasing phenylalanine serum levels, adjusted for age, gender, BMI, duration of symptoms, tender joint count, swollen joint count, Charlson comorbidity index score, GP level and seropositivity, p for linearity = 0.029.

Conclusion:

Patient reported physical function correlates with phenylalanine serum levels in untreated RA. The result reflects changes in muscle metabolism in RA, in which inflammation induces protein break down and prevents protein synthesis in peripheral muscles.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

14-3-3 proteins are chaperonins found in all eukaryotic cells. There are multiple isoforms which are thought to be involved in intracellular signaling and transcription regulation. Among their targets are phosphatases, kinases and transmembrane receptors. There are seven known isoforms in mammals. The η (Eta) isoform has been implicated as having diagnostic potential in inflammatory arthritis. In this study we investigated the utility of measuring 14-3-3η when evaluating inflammatory arthritis.

Methods:

Measurements of 14-3-3η were obtained during evaluation of joint pain in patients presenting between July 2013 and April of 2015. Rheumatoid factor (RF) and anti-cyclic citrullinated peptide antibodies (anti-CCP Ab) were measured. Joint imaging was evaluated for erosive changes and use of biologics was recorded. A chart review was later conducted to evaluate the utility of standard measures versus 14-3-3η.

Results:

214 patients were evaluated. 49 had a diagnosis of rheumatoid arthritis (RA), 17 had psoriatic arthritis (PsA). 43 patients had

connective tissue disease (CTD), 8 had undifferentiated inflammatory arthritis, and 97 had other rheumatological disorders.

Of the 49 RA patients, 37 were RF positive, 36 were anti-CCP Ab positive, and 25 were 14-3-3η positive. Of the 25 who were 14-3-3η positive, 22 were both anti-CCP Ab and RF positive, 2 were RF positive but anti-CCP Ab neg, and 1 was negative for both RF and anti-CCP Ab. Of the 24 who were 14-3-3η negative, 12 were both RF and anti-CCP Ab positive, 2 were only anti-CCP Ab positive, 1 was only RF positive, and 9 were seronegative. 20 patients in total had erosive disease of which 13 were positive for 14-3-3η, 10 were positive for all three markers, 1 was positive for just RF, and 1 was negative for both RF and anti-CCP Ab. Of the RA patients with erosive changes on biologic medication, 5 were 14-3-3η positive and 8 were 14-3-3η negative.

All 17 patients with PsA were seronegative with one exception, who was 14-3-3η positive. 6 PsA patients had joint erosions and they were seronegative. Of the 43 patients with CTD, 6 were 14-3-3η positive. 2 patients had enteropathic arthritis and were seronegative.

	14.3.3η alone	RF and CCP	Triple Positive	14.3.3η and RF	14.3.3η and CCP	Any seropositivity
RA sensitivity	0.51	0.69	0.45	0.49	0.45	0.82
RA specificity	0.90	0.97	0.98	0.94	0.98	0.79
RA PPV	0.49	0.50	0.50	0.50	0.50	0.49
RA NPV	0.88	0.92	0.86	0.87	0.86	0.95

Conclusion:

The 14-3-3η protein can be detected in inflammatory arthritis, with the highest percentage in RA patients. However, there was no correlation between 14-3-3η titers with RF or anti-CCP Ab. No significant association was found with PsA patients in our small sample. There was also no correlation with biologic use. One 14-3-3η positive patient who was negative for RF and anti-CCP Ab had erosive disease.

Changes in a Patient-Reported Measure of Physical Function, PF-10a, Are Most Strongly Associated with Changes in the Patient Global Assessment Portion of a Composite Measure of RA Disease Activity

Elizabeth R. Wahl[1,2], Andrew Gross[2], Vladimir Chernitskiy[2], Patricia P. Katz[2] and Jinoos Yazdany[3], [1]Medicine/Rheumatology, San Francisco Veterans Affairs Medical Center, San Francisco, CA, [2]Medicine/Rheumatology, University of California San Francisco, San Francisco, CA, [3]University of California, San Francisco, San Francisco, CA

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: A brief patient-reported measure of physical function, the PROMIS PF-10a, is sensitive to changes in disease activity among patients with rheumatoid arthritis (RA). However, less is known about which components of composite disease activity measures--swollen and tender joint counts, patient and provider global assessments, pain, or inflammatory markers--are most strongly associated with reported changes in physical function. Better understanding the impact of each of these domains on physical function is critical to interpreting changes in PF-10a and understanding its role in the clinical setting. The current study evaluates the relative contribution of patient and provider assessments, pain, and inflammatory markers, on self-reported physical function.

Methods: Clinical and demographic data were abstracted from the electronic health record for all patients seen at a university-based rheumatology clinic between February 2013 and February 2015 with at least two ICD-9 codes for RA. All patients had PF-10a and Clinical Disease Activity Index (CDAI) scores recorded on at least two occasions. Pain was assessed at each visit using a visual

analog scale (0-10cm). The inflammatory marker C-reactive protein (CRP) was assessed at least every 3 months. Mixed effects linear regression was used to model the relationship between change in CDAI score over baseline and change in PF-10a score, and then to model the relationship between changes in each component of the CDAI (patient global assessment (PGA), evaluator global assessment (EGA), swollen (SJC) and tender joint count (TJC)) and changes in PF-10a score over time. The model was adjusted for age, gender, pain, and CRP.

Results: Of 326 patients, 82% were women with a mean (SD) age of 59 (14). The group was racially/ethnically diverse. About half of patients had moderate-severe CDAI scores (≥ 10) at baseline. In an unadjusted model, changes in CDAI and PF-10a were significantly associated ($p<0.001$); a 12-point increase in CDAI, the Minimal Clinically Important Improvement threshold, was associated with an average 3.3 point decrease in PF-10a, 95% CI (2.7-3.8). In the multivariate model, changes in CDAI remained significantly associated with changes in PF-10a; changes in pain but not CRP were associated with changes in PF-10a score (Table). In a model isolating CDAI components, changes in PGA and pain level were associated with changes in PF-10a score, while changes in EGA, SJC, TJC, and CRP were not.

Conclusion: Changes in the patient global assessment and in pain levels were significantly associated with reported changes in physical function as measured by the PROMIS-PF10a, while changes in the evaluator global assessment, tender and swollen joint count, and CRP level were not. These findings suggest that PF-10a measures a distinct construct, self-reported physical function, that may reflect patients' global assessment and pain level but is unrelated to provider assessments.

Table. Mixed effects linear regression model coefficients (95% CI) representing the association between average change in physical function score (PF-10a) and change in CDAI components, pain, and CRP for 326 RA clinic patients.

	Adjusted Models*	
	Composite CDAI Model	Component CDAI Model
CDAI score (0-76)	**-0.1 (-0.2 -- -0.04)**	
Patient Global Assessment (0-10)		**-0.8 (-1.2 -- -0.5)**
Provider Global Assessment (0-10)		-0.4 (-0.8 -- -0.0004)
Tender Joint Count (0-28)		0.05 (-0.1 -- 0.2)
Swollen Joint Count (0-28)		-0.05 (-0.3 -- 0.2)
Pain score, VAS (0-10)	**-1.2 (-1.5 -- -1.0)**	**-0.6 (-0.9 -- -0.3)**
CRP, mg/L	-0.01 (-0.04 -- 0.01)	-0.01 (-0.04 -- .01)

*Models adjusted for age and gender. Results from the unadjusted model were similar.

Higher PF-10a scores reflect better function and lower CDAI scores reflect less disease activity.

Bolded covariates reached statistical significance, $p<0.05$

Session Date: Tuesday, November 10, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III
Session Type: ACR Poster Session C
Session Time: 9:00AM-11:00AM

Background/Purpose: A newly discovered anti-carbamylated protein antibody (anti-CarP) is found prior to disease-onset, associates with the conversion towards arthralgia and with a more severe disease course in patients negative for ACPA. We here studied anti-CarP in 141 rheumatoid patients who were clinically active and under treatment with biological DMARDs with reference to anti-CCP2 protein antibody2 (ACPA2) and ACPA3.

Methods: ACPA2, ACPA3, anti-CarP-Fetal Calf Serum (aCarPFCS) and anti-CarP-Fibrinogen (aCarPFib) were measured by using ELISA in sera of 141 Japanese patients with RA who were clinically active (fulfilling either DAS-CRP > 4.0 or DAS-ESR > 4.2 and either CDAI > 22 or SDAI >26) and under treatment with biological DMARDs (53 with ETN, 40 with IFX, 19 with TCX, 15 with ADA, 8 with ABA, and 6 with GLM). Data were compared by classifying into ACPA2b (0~0.6 U/mL; below assay limit), ACPA2n (0.7~4.4; negative) or ACPA2p (4.5~20; low positive) subgroups.

Results: Among ACPA2b group (n=41), ACPA3, aCarPFCS and aCarPFib were positive in 8 (19.5%), 0 (0%) and 4 (9.8%), respectively. Likewise, among ACPA2n group (n=31), they were positive in 16 (51.6%), 3 (9.7%) and 6 (19.4%). Among ACPA2p group (n=69), they were 64 (92.8%), 26 (37.7%) and 18 (26.1%). Within ACPA2b and ACPA3-positive groups (n=8), aCarPFCS and aCarPFib were 0 and 3 (37.5%). Within ACPA2n and ACPA3-positive groups (n=17), they were 3 (17.6%) and 2 (11.8%). Within ACPA2p and ACPA3-positive groups (n=64), they were 24 (37.5%) and 17 (26.6%). It was noted that among ACPA2b and ACPA3-negative groups (n=1) and ACPA2n and ACPA3-negative groups (n=2), aCarPFCS was all negative, however, aCarPFib was positive in 1/1 (100%) and 2/2 (100%), respectively. These 3 anti-CarP sole positive patients were with DAS28-ESR3: 5.1, 7.0, and 5.4, and ΔTSS: 4, 0, 4.

ACPA3	aCarPFCS	aCarPFib	ACPA2below	ACPA2negative	ACPA2positive
-	-	-	32	12	3
+	-	-	5	12	31
+	+	-	0	1	16
+	+	+	0	2	8
+	-	+	3	2	9
-	+	-	0	0	1
-	+	+	0	0	1
-	-	+	1	2	0
Total			41	31	69

Conclusion: Anti-CarP was positive in a substantial fraction of ACPA2 negative subset, in which most of them were also ACPA3 positive. There existed 3 patients who were sole positive for anti-CarP whose disease was clinically active despite treatment with biological DMARDs.

This study is a co-work with Drs. Verheul MK and Trouw LA, Department of Rheumatology, Leiden University, Netherlands.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose: Tissue distribution of the chaperonin 14-3-3η (eta) is limited to synovial tissue and brain. Synovium releases proinflammatory 14-3-3η into synovial fluid and serum in rheumatoid arthritis (RA) patients and, to a lesser extent, erosive psoriatic arthritis (PsA) patients. Serum measurement aids RA diagnosis (sensitivity 64% in early RA and 77% in established RA) and prognosis, and may have utility in assessing disease activity.[1,2] Differentiating RA or PsA from osteoarthritis (OA), or identifying inflammatory arthritis in the presence of co-existing OA can be difficult. The purpose of this study was to estimate the specificity of 14-3-3η among a cohort of subjects with physician-confirmed OA.

Methods: Participants in the U.S.-based Arthritis Internet Registry (AIR) were surveyed by questionnaire. Physician and/or medical records were queried. Serum samples from patients with physician-confirmed diagnoses of OA (n=169) were tested for C-reactive protein (CRP) and rheumatoid factor (RF) by nephelometry, cyclic citrullinated peptide antibody (CCP) by ELISA, and 14-3-3η by a proprietary laboratory-developed ELISA test.

Results: Of 169 physician-diagnosed OA patients tested, 11 (6.5%; 95% CI 3.3% to 11.3%) were positive for 14-3-3η. However, for 1 of the 11, CRP was 0.3 mg/dL, (normal, <0.8 mg/dL), RF was 123 IU/ml (normal <14 IU/mL), CCP was >250 Units (normal, <20 Units), and 14-3-3η was 1.9 ng/mL (normal, <0.2 ng/mL); the subject was subsequently reclassified as RA. Another subject's CRP, RF, and CCP were nomral, but 14-3-3η was 3.1 ng/mL; subsequently, the subject was diagnosed with PsA based on new onset dactylitis in 2 fingers, joint pain, and changes in fingernails, all in the absence of prior psoriasis. A third subject had previously been treated for RA with methotrexate and entanercept; CRP was 4.4 mg/dL, RF was >1,200 IU/mL, CCP was >250 Units, and 14-3-3η was >20 ng/mL. Excluding the 3 subjects with subsequent diagnoses of RA or PsA, 8 of 166 OA subjects were 14-3-3η positive, or 4.8% (95% CI 2.1% to 9.3%). The specificity in OA subjects for 14-3-3η as a marker of inflammatory arthritis was 95.2% (95% CI 90.7% to 97.9%).

Conclusion: In the present study, the low frequency of 14-3-3η in a cohort of individuals with OA supports the high specificity of 14-3-3η observed for RA. Further, 14-3-3η may be used to help identify RA or PsA patients amongst those being followed for OA. 14-3-3η may be particularly useful in the primary care setting to screen OA patients for misclassification of RA or PsA as OA, or for concurrent inflammatory arthritis in the setting of OA.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Rheumatoid arthritis (RA) is a systemic inflammatory disease that is characterized by synovitis and the destruction of articular structures of multiple joints. The goal of treatment for RA is to control the progression of these articular lesions. MTX is an antirheumatic drug that is expected to have an excellent suppressive effect on articular destruction. Recently, MTX has been used as an anchor drug for the treatment of RA (1). On the other hand, RA patients have a high risk of onset of lymphoproliferative disorders (LPD) (2). Although MTX-LPD occurs mainly in RA patients, it has not been established if MTX administration is an independent risk factor for LPD in RA patients.

We examined the clinical characteristics of MTX-LPD in Japanese RA patients and attempted to determine the risk factors for MTX-LPD development.

Methods: We performed a nested case-control study on RA patients. We enrolled 5,873 RA patients from Kagawa Prefecture, Japan between June 2003 and May 2015. Patients were diagnosed according to American College of Rheumatology 1987 classification criteria, and treated with disease modifying antirheumatic drugs (DMARDs) including MTX. In age and gender matched patients, we separated patients who did not develop LPD under MTX treatment (MTX non-LPD group) from those that did (MTX-LPD group), and conducted a comparative examination. We used multivariate analysis to determine the independent risk factors for MTX-LPD onset.

Results:

There were 36 patients in the MTX-LPD group and 158 patients in the MTX non-LPD group. The number of patients with DMARDs (except MTX) treatment showed no significant difference in two groups. Furthermore, there was no difference between two groups about that with corticosteroid and biologics treatment. Also, the complication rates for Sjögren's syndrome did not differ significantly. Using univariate analysis, significant differences were found in the duration of RA disease, total MTX dose and mean MTX dose between the two groups. Furthermore, multivariate analysis of the parameters extracted by univariate analysis revealed that the mean MTX dose was a risk factor for MTX-LPD after adjusting for age.

Conclusion:

We revealed the mean MTX dose was demonstrated to be an independent risk factor regarding MTX-LPD onset in RA patients. This data strongly suggest that the treatment with higher MTX dose promotes LPD onset in Japanese RA patients.

Session Time: 9:00AM-11:00AM

Background/Purpose: Serum 14-3-3η is a diagnostic marker for RA. Recent *in vitro* evidence indicates that it may play a casual role in the pathogenesis of RA. As such the clinical usefulness of 14-3-3η is being more extensively investigated to include prediction of RA in arthralgia subjects and efficacy of drugs used to treat RA. In this study, we investigated whether serum 14-3-3η level is useful as a marker to predict therapeutic efficacy of tocilizumab (TCZ) in RA.

Methods: Sera 14-3-3η were measured in 41 patients (median age 54 yrs, range 20–78 yrs) with RA before and 3, 6, and 12 months after treatment with TCZ (8 mg/kg iv every 4 weeks), using the 14-3-3η ELISA kit (Augurex). 14-3-3η positivity was defined as ≥ 0.19

ng/ml. Median DAS28-ESR (DAS28) and clinical disease acrivity index (CDAI) before treatment were 5.1 (range 2.1–7.5) and 22.7 (range 10.4–60.8), respectively. 31 of 41 patients were ACPA positive, 37 were MMP3 positive and 1 was negative for both markers. Mann-Whitney U-tests and Fisher's exact tests were performed for comparison between treatment groups. A regression analysis was performed to determine if serum 14-3-3η was an independent predictor of diseases activity scores by comparison to DAS28 and CDAI.

Results: At pre-treatment, 28 of 41 patients were 14-3-3η positive and the 14-3-3η positive group tended to have higher baseline DAS28 (4.5 *vs* 5.3, $p = 0.055$) and CDAI (20.0 *vs* 25.4, $p = 0.046$). The 14-3-3η levels were significantly lower post-treatment with TCZ (4.7 *vs* 3.7, $p = 0.028$). The patient group with decreased 14-3-3η after 3months of treatment had significantly greater changes in MMP3 levels compared to the group with no decrease (54.8 *vs* 8.0, $p = 0.027$). According to the EULAR response criteria, the good responder group ($n = 17$) had significantly lower pre-treatment 14-3-3η levels compared to the moderate and non-responder group ($n = 24$), 0.37 *vs* 1.76 ng/ml, $p = 0.0252$. Similarly, the pre-treatment 14-3-3η levels were significantly lower in the group of patients that achieved remission by DAS28 < 2.6 and CDAI ≤ 10 (as remission and low diseases activity), after treatment. Neither ACPA nor MMP-3 levels were different between these responder groups. Fisher's exact testing revealed an association ($p = 0.045$) between DAS28 remission and 14-3-3η negativity delivering an odds ratio (OR) of 3.4 (95% CI: 0.9–13.3). Regression analysis controlling for baseline DAS28 revealed that 14-3-3η levels were an independent predictor of remission yielding a likelihood ratio (LR) of 7.8, $p= 0.0052$.

Conclusion: Serum 14-3-3η is a potential marker for predicting efficacy of TCZ treatment for RA. Further study is being achieved to establish the usefulness of 14-3-3η in longer term administration of TCZ.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

Anti-carbamylated protein (anti-CarP) antibodies have been described as a new type of autoantibodies specific of patients with rheumatoid arthritis (RA). They seem useful as a new biomarker of disease severity with independence of anti-CCP antibodies (1). In addition, they could also be a biomarker of future development of RA, at least, among patients with arthralgia (2). The aim of this study was to explore the predictive value of anti-CarP antibodies in early arthritis (EA) patients. Identification of the subgroup of EA at high risk of developing RA is a priority for prevention of joint damage and achievement of long-term remission.

Methods:

All the EA patients from a dedicated clinic with a minimum follow-up of two years have been included. These patients were recruited if they have shown 2 or more swollen joints for at least 4 weeks and symptoms for less than a year. Classifiation as RA was done according with the 1987 ACR criteria. Baseline sera from 552 EA patients were analyzed for anti-CarP fetal calf serum (FCS) antibodies by ELISA. Anti-CarP titre was obtained after subtracting reactivity to native FCS from the reactivity to carbamylated FCS. We used as a cut-off the 95 % percentil of 208 healthy donors.

Results:

Near half of the 552 patients (45.6%) fulfilled RA criteria at the end of the 2 years of follow-up. Baseline anti-CarP was 53.4% sensitive and 79.5% specific for RA at study end. These antibodies were found in 65.0% of the RA patients, which is similar to the percentage found in established RA. Presence of anti-CarP was significantly correlated with anti-CCP antibodies and with RF status. However, we observed that 13.0% of the anti-CCP negative RA patients tested positive for anti-CarP antibodies. Baseline anti-CCP and RF combination resulted in 91.9% positive predictive value (PPV) and a 79.6% negative predictive value (NPV) for RA. These values did not change by the addition of anti-CarP antibodies (91.5 and 81.6 %, respectively). In the anti-CCP negative RA patients, anti-CarP antibodies were 49.2% sensitive and 64.4% specific, and their combination with RF antibodies increased only modestly the PPV (from 36.3 with RF to 47.6% with the combination) withouth changing the NPV for RA (from 79.6% to 81.6%). Analysis of the 66 incident RA patients (fullfiling RA criteria by 2 years, but not at baseline) showed similar PPV and NPV with the inclusion of anti-CarP to the obtained with RF and anti-CCP antibodies alone (PPV = 70.6 with the three antibodies, and 72.9 with anti-CCP and RF, and NPV 90.9% in the two analyses). No association was found between anti-CarP status and smoking or DAS28 values.

Conclusion:

Anti-CarP antibodies were present in EA patients and their presence was associated with RA, both prevalent RA at baseline and incident RA during follow-up. However, they did not add to the prediction of RA available with the already known antibodies except for a modest increase in PPV among the anti-CCP negative patients.

Session Date: Tuesday, November 10, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster Session III

Session Type: ACR Poster Session C

Session Time: 9:00AM-11:00AM

Background/Purpose:

We examined the clinical features of the cases after discontinuation or decrease of dosage of MTX in the MTX-LPD.

Methods:

We retrospectively examined a patient background, a clinical presentation, a histopathology, and clinical course in 19 patients of Osaka City University Hospital rheumatology clinic from 2006 through 2014.

Results:

These cases were average age 64.5 y.o. (37-81), 3 male/16 female , 8.1 mg/week of MTX average dosage, 1,510 mg (312-6110 mg) of MTX average total doses, and mean DAS28(CRP) of 3.65 (2.3-5.46) at the MTX-LPD onset.

Lymph node biopsy performed in 16 patients showed reactive lymphadenopathy syndrome 6, Diffuse large B-cell lymphoma (DLBCL) 5, Hodgkin's lymphoma 3, primary effusion lymphoma (PEL) 1, and non-specific Peripheral T-cell lymphoma 1. Epstein-Barr virus (EBV) DNA in blood specimen was examined in 4 cases resulting 2 positive, 2 negative.

16 cases improved by discontinuation of MTX spontaneously, but 3 cases required chemotherapy. It is reported that MTX-LPD often showed EBV-positive in histopathology, and the pathological type of EBV-positive LPD could show both the B-cell and the T-cells. One of 16 patients which performed lymph node biopsy was diagnosed T-cell lymphoma, and EBV was proved even in this case histologically. This case also improved spontaneously after discontinuation of MTX. The mechanism is not revealed, but the EBV infects both B-cells and T-cells.

Conclusion:

There was no difference in the ratio of the histopathology compared with malignant lymphoma besides iatrogenic immunodeficiency-associated lymphproliferative disorders. Contribution of the EBV infection is suggested in MTX-LPD development. In this study, it is suggested that the mechanism is applicable in T-cell lymphoma, although all cases are not EBV-positive in histopathology. Further study is necessary on revealing the mechanism of pathogenesis of MTX-LPD, and EBV infection to T-cells.
