Smart System of Disease Management (SSDM) is a series of applications for chronic diseases management, which develop the interaction between doctors and patients online with mobile device. The study shows that, after training, the rheumatoid arthritis (RA) patients can master the SSDM and perform self-management, including DAS28 and HAQ evaluations, as well as medication and lab test data entries.

To evaluate the feasibility and benefit of the medical economics of online consultations based on SSDM by rheumatologists.

Methods: The rheumatologists implemented the education and training programs on using SSDM for rheumatic disease patients and assist them in downloading SSDM APP in clinic.

The SSDM includes doctors' application and patients' application. The patient application includes self-assessment (DAS28, HAQ), medication management, adverse events management and laboratory records. After data entry, patients can synchronize data to the authorized doctor. On the basis of understanding of the disease activities, medication and laboratory test results, the rheumatologists can accept the request from their patients and practice consultation in the form of texting or telephone call.

Results: Between February 14, 2015 and June 22, 2015, 8 rheumatologists supplied 55 patients with 64 times free and 12 paid consultations. Paid consulting included 8 times text Q&A and four telephone consultations. The consulting fee ranged from RMB 50 to 300 yuan (USD:RMB =1:6.1) each in average of 220.83 ± 72.17 yuan, which rate match the registration fee in hospital. The total collection of fee for consultations was 2,650 yuan.

75% patients receiving online consultation lived in different city with the rheumatologists, the mean distance was 925.71 ± 803.65 (58 - 3,150) kilometers. If patients seek medical in hospital, in addition to the registration fees and medical expenses, the mean cost of transportation, accommodation, meals and lost wages was 922.37 ± 686.94 (200 - 2,000) yuan. The total of cost for all patients would have been 70,100 yuan, which is 26.45 times compare with the cost of online. Through the SSDM system for online consultations, patients can save 96.22% of the cost. Survey shows all patients were satisfied and 87.5% of them were "very satisfied" with the consultations.

Conclusion: Using SSDM system to obtain online consultation, Chinese patients with rheumatic disease can enjoy reducing cost with high rate of satisfaction. In the era lack of primary care system in China, SSDM may serve a complimentary platform to control medical care cost, as well as relieve the tensions between health care professionals and patients.

Evaluating Inter-Rater Reliability in Joint Count to Promote Quality and Trust in a Clinical Arthritis Care Team

Diane Tin[1], Lorna J. Bain[1], **J Carter Thorne**[2], Meen Jae Lee[2,3], Lois Derrick[1,4], E Jean Painter[1], Annabelle Estaban[1], Nooshin Samadi[2], Sue Charette[1], Sherry Hartnett[1], Carolyn Bornstein[1], Edward Ng[2] and Michael Aubrey[2], [1]The Arthritis Program, Southlake Regional Health Centre, Newmarket, ON, Canada, [2]Southlake Regional Health Centre, Newmarket, ON, Canada, [3]Pharmacology, McGill University, Montreal, QC, Canada, [4]The Arthritis Society, Toronto, ON, Canada
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Health Services Research Poster (ARHP)
Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Joint count assessment is essential for the diagnosis and ongoing evaluation of Rheumatoid Arthritis (RA) disease activity. In our team based, interprofessional approach to arthritis care, the attending rheumatologist must be able to trust the joint count of fellow rheumatologists and allied health care providers (AHPs). Congruency and accuracy in joint count is imperative for effective collaboration to occur.

Inter-rater variability in assessing tender and swollen joint counts has been well documented, especially with a lack of consistency in swollen joint count (SJC), (ICC range 0.29 to 0.95)1. As part of continuous quality improvement, we undergo annual joint count intervalidation. In the Spring 2015, a joint count intervalidation event was held with all team members who routinely perform joint counts. The aim of this study was two-fold: 1) to estimate the agreement between team members, and 2) to provide training for standardizing joint count assessments.

Despite a growing interest to use patient-reported joint counts as an outcome measure, some argue (and we concur) that the physician/clinician joint count should remain the standard of care on which treatment decisions are based, and as such a joint count should be conducted at every visit.

Methods:

Ten assessors (4 rheumatologists, 2 physical therapists, 3 occupational therapists, 1 kinesiologist) and six patient volunteers with RA (2 diagnosed within past 12 months, 4 have longer term disease) attended the intervalidation session. Patients were informed that the purpose of this event was quality assurance, not clinical care. Assessors were instructed to be as objective as possible, by neglecting the historical comparison of joint status, and to measure counts based on swollen vs. not swollen. All assessors and patient volunteers attended a debrief session afterwards when SJCs were compared and assessment techniques were discussed. A survey was administered to both assessors and patients to gather their feedback on the event.

Results:

Overall, inter-rater reliability between the 10 assessors on SJC for the 6 RA patients was moderate (ICC: 0.51, 95% CI: 0.30-0.91), with no difference between short and longer-term patients with RA ($p>0.05$). Nonetheless, post-event questionnaires revealed that 100% of the rheumatologists and AHPs agreed or strongly agreed that intervalidation was a critical quality assurance initiative and a collaborative process for learning. All 4 rheumatologists reported increased confidence to co-manage RA patients with AHPs after attending the intervalidation session.

Conclusion:

This is a unique quality assurance initiative designed to foster trust amongst a large interprofessional arthritis care team in a clinical care setting. In the framework of shared care and treat to target approaches, joint count intervalidation within networks of arthritis care providers may be valuable. Further research is necessary to identify opportunities to improve inter-rater agreement and more fully understand how assessor and patient-level factors may contribute to these findings.

Improving the Medication Prior Authorization Process in a University Based Rheumatology Practice

Jessica King[1], Megan E. B. Clowse[2], Stephanie Puryear[3] and Steven Collins[3], [1]Rheumatology, Duke University Health System, Hillsborough, NC, [2]Rheumatology & Immunology, Duke University, Durham, NC, [3]Rheumatology, DUHS, Durham, NC

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Health Services Research Poster (ARHP)
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: The vast majority of medications prescribed to treat rheumatologic conditions now require insurance prior authorization (PA) before the medication will be paid for by insurance and available to a patient. We found increasing clinical staff and physician time being devoted to obtaining PA's. We initiated a quality improvement project with the goal of decreasing the time between PA initiation and completion and the effort dedicated by clinical staff to completing each PA.

Methods: In our university-based rheumatology practice, we evaluated 10 PA's from 4 time periods to assess the change in the total days between initiation and completion of each PA. We also assessed the number of entries in the electronic medical record (EMR) about the PA, whether it was approved or denied, and whether an appeal was made. Inclusion criteria for evaluated PA's included: DMARD or biologic medication, on-label use, and sufficient information in the EMR to determine PA status. We reviewed 4 time periods: **1. Baseline**; **2. Covermymeds®** when multiple clinic employees were assigned to submit PA's electronically using covermymeds®, provided a PA form, and in a percentage of patients provided a real time approval/denial; **3. Insurance specialist** when we were no longer allowed to use covermymeds®, an insurance specialist from our clinic would obtain and complete the correct PA form from the insurance company and complete needed follow-up; **4. Phone line** when a dedicated phone line and full-time clinical staff member responded to both patients and insurance companies; in addition, a patient education hand-out and educational tools were developed for both clinical staff and providers.

Results: Over a 10 month period, 9,943 patient visits in the university rheumatology clinic resulting in 2,835 prescriptions requiring a PA. Approximately 29% of arrived patient visits in our clinic require a PA during this time period. The duration between PA initiation and completion as well as the number of EMR notes required per PA varied over the time periods with improvements seen with the use of covermymeds® and a dedicated phone line and staff member. The approval rate for the on-label use prescriptions was high and few appeals were needed.

Conclusion: Our findings suggest that submitting PA's electronically, minimizing the number of staff members involved in the PA process, education related to the PA process, and having a dedicated telephone line, have had the biggest impact on improving our success. This level of support requires a full-time clinical staff member, increasing our personnel cost. We suspect that a systematic change on both a state and notional level within the healthcare system will be required to force change.

Time Period	Time Period	Total days for PA process mean (range)	EMR notes mean (range)	Approval Rate	Appeal Initiated
1. Baseline	8/5/14-11/6/14	13.1 (0-26)	5.3 (1-15)	70%	1
2. Covermymeds	1/2/15-2/20/15	8 (0-27)	2.1 (1-3)	100%	0
3. Insurance specialist	2/21/15-4/17/15	24.4 (3-82)	5.3 (2-12)	90%	0
4. Phone line	4/24/15-6/11/15	3.7 (0-19)	1.9 (1-4)	100%	0

Advocating for Rheumatoid Arthritis and Cardiovascular Health (ARCH): A Collaborative and Systems-Based Approach to Improve Access to Care

Barbara Goldstein and JoAnn Zell, Medicine, National Jewish Health, Denver, CO
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Health Services Research Poster (ARHP)
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) have an increased risk of cardiovascular disease (CVD) as compared to the general population. The European League Against Rheumatism (EULAR) recommends that rheumatologists engage in assessing the CVD risks in RA patients. Multiple barriers such as limited time and lack of familiarity of CVD screening guidelines challenge the feasibility of this practice. Furthermore, recent data suggest that primary care providers fail to assess RA patients consistently or aggressively. At a tertiary referral center, we implemented an innovative system to provide RA patients direct access to cardiology for a CVD risk assessment. In the new RA-CVD clinic workflow, the rheumatologist can screen for CVD risk factors during a clinical visit and refer RA patients using a prescribed order set. Next, the patient is evaluated by cardiology and the 10-year risk for atherosclerotic cardiovascular disease (ASCVD) score is calculated to help guide therapy decisions. In this study, we examined patient access, lipid profiles and medication use before and after the intervention.

Methods: We devised an order set within the electronic medical record (EMR) that was available to all rheumatologists starting January 2015. The order set included a referral to the RA-CVD clinic, electrocardiogram, lipid profile or vertical auto profile (VAP), and hemoglobin A1C. For this study, we reviewed all RA patients presenting to our hospital for new or follow up appointments pre- and post-implementation of the program. Chart review was performed to identify elevated lipid profiles (LDL>130) and statin use. Our cardiology team devised a specific protocol to best risk assess these patients per EULAR guidelines.

Results: Since the launch of our program, 722 RA patients have been seen by the rheumatology practice, 99 (14%) of these patients agreed and were then referred to the RA-CVD clinic. Screening for diabetes and hypercholesterolemia has improved by 60% with the implementation of the program. To date, 13 patients have undergone full risk assessment, however not all patients have been seen partially due to cardiology appointment lag time. Of these patients, 5/13 (38%) patients were started on a statin based on their ASCVD score.

Conclusion: Our study suggests that the creation of a RA-CVD workflow significantly increased the rates of risk factor screening and appeared to provide a forum for necessary interventions. However, lack of cardiology access may limit the strength this program.

Can Bone Marrow Lesions be Scored More Reliably and Responsively in Knee Osteoarthritis Using a Web-Based Overlay System (KIMRISS) Than By Standard MRI Osteoarthritis Knee Scoring (MOAKS)? Data from the Osteoarthritis Initiative and a Prospective Trial of Adaluminab Therapy

Jacob Jaremko[1], Mark Buller[2], Dean Jeffery[2], David McDougall[3], Benjamin Smith[2], Robert G Lambert[1] and Walter Maksymowych[4], [1]Radiology, Radiology, University of Alberta, Edmonton, AB, Canada, [2]Radiology & Diagnostic Imaging, University of Alberta, Edmonton, AB, Canada, [3]Radiology, University of Alberta, Edmonton, AB, Canada, [4]Medicine, University of Alberta, Edmonton, AB, Canada

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Imaging of Rheumatic Diseases Poster II: X-ray, MRI, PET and CT

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Bone marrow lesions (BML) relate to pain and prognosis in knee osteoarthritis. The Knee Inflammation MRI Scoring System (KIMRISS) offers simple template-assisted binary BML scoring via a web-based interface. We tested whether KIMRISS was more reliable and responsive to change than the commonly used MRI Osteoarthritis Knee Score (MOAKS) system, particularly for naïve readers.

Methods:

The KIMRISS web-based overlay system separates the knee into multiple small regions, each scored 0 (no BML) or 1 (BML present). The reader scrolls through sagittal fluid-sensitive MRI slices and mouse-clicks (or contacts a touch-screen) each region in which BML is present. Scores are tabulated and exported automatically. In contrast, MOAKS BML grading is performed in 9 larger knee regions based

on the number of lesions present and percentages of the region containing edema and cystic change.

Exercise 1 assessed reliability, in observational data from the Osteoarthritis Initiative. We had 40 subjects at baseline and 1 year follow-up (80 MRI). Expert readings were performed by two radiologists (6 and 11 years experience) familiar with KIMRISS, and consensus score computed as the average of these readings. Two radiology residents naïve to KIMRISS and MOAKS reviewed a 55-slide presentation describing KIMRISS, three scored reference cases, and a published manuscript describing MOAKS. These readers then scored the same data by KIMRISS and MOAKS. All readers were blinded to scan time point (baseline vs. follow-up).

Exercise 2 assessed responsiveness, using data from an open-label pilot study testing adalimumab (Humira) knee OA therapy. Two blinded experienced readers scored BML by MOAKS and KIMRISS at enrolment and 12 weeks post-therapy in all 16 patients (32 MRI).

Reliability statistics were calculated using intra-class correlation coefficients (ICC), with differences significant at $p<0.05$ when the 95% confidence intervals of ICC did not overlap. To assess responsiveness in Exercise 2, we computed standardized response means (SRM).

Results:

Subjects were primarily older adults (average 62 and 58 years for Exercises 1 and 2 respectively), and female (80% and 65%), with moderate OA (K-L grade 3 or 4 in 73% and 75%).

In Exercise 1, reliability of KIMRISS and MOAKS was high and similar for baseline BML (ICC 0.89-0.98 vs 0.85-0.89). However, changes in BML were significantly more reliably detected by KIMRISS than MOAKS, whether comparing expert readings (ICC 0.82 vs. 0.53) or comparing naïve readings to expert consensus (ICC 0.87-0.92 KIMRISS vs. 0.32-0.51 MOAKS).

In Exercise 2, decrease in BML was visually obvious post treatment in most patients. This decrease in BML was statistically significant when scored by KIMRISS (mean change from 37.3 to 29.8, SRM=-0.69, p=0.015), but not by MOAKS (6.25 to 6.06, SRM=-0.12, p=0.63).

Conclusion:

Comparing two semi-quantitative MRI BML scoring systems, KIMRISS was more responsive to change in BML than MOAKS, and detected change with better reliability than MOAKS for expert and naïve readers. KIMRISS scoring may be useful in observational and therapeutic trials for knee OA.

Session Title: Imaging of Rheumatic Diseases Poster II: X-ray, MRI, PET and CT

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: There is evidence that the presence of synovitis in knee osteoarthritis (OA) is clinically relevant since it is

associated with pain and structural damage. As several methods are available on MRI to assess and quantify synovitis in knee OA, our aim was to compare different semiquantitative and quantitative methods using both non-enhanced and gadolinium-enhanced MRI.

Methods: End-stage clinical OA knees in patients undergoing a total knee replacement surgery were included in this cross-sectional study. MRI was performed and included non-enhanced (triplanar fat suppressed (FS) intermediate-weighted sequences with fat suppression) as well as gadolinium-enhanced sequences (sagittal and axial T1-weighted FS sequences). Using non-enhanced MRI, we semiquantitatively assessed two features widely used as surrogate for synovitis: "effusion-synovitis" (ES), representing a combination of joint effusion and synovial thickening; and "Hoffa-synovitis" (HS), representing ill-defined high-signal intensity of Hoffa's fat pad at the intercondylar region, both graded from 0 to 3. Using gadolinium-enhanced sequences, we semiquantitatively assessed synovial thickness (ST) in 11 regions of the knee, graded from 0 to 2. Then, we summed the scores for the 11 regions and graded whole-knee synovitis as: grade 0 (total score<5), grade 1 (5-8), grade 2 (9-12), and grade 3 (>12). Using manual segmentation we quantitatively evaluated the total synovial volume (SV) on gadolinium-enhanced sequences, in mm^3, and defined 3 grades of SV as: grade 1 (<30mm^3), grade 2 (30-60 mm^2), and grade 3 (>60 mm^3). As synovitis is ideally evaluated using gadolinium-enhanced sequences, we assessed the correlations of synovitis grades of ES and HS with synovitis grades of ST and SV, applying Spearman correlation analysis. Furthermore, we compared the sum of scores of ST with SV as continuous variables using Pearson correlation analysis.

Results: A total of 104 subjects (1 knee per subject) were included; mean age 67 ± 7; 64 females (61.4%); mean body mass index 30 ± 5. The number of knees exhibiting the different grades of ES, HS, ST, and SV is presented in Table 1. Using gadolinium-enhanced sequences, the mean summed score for "ST" synovitis was 15.0 ± 3.8; the mean "SV" synovitis was 56.0 ± 17.1 mm^3. A positive and significant correlation was found between ES and ST (r=0.41; p<.0001), as well as between HS and ST (r=0.32; p<.001). A positive and significant correlation between the summed scores of ST and total SV was found using gadolinium-enhanced sequences (r=0.53; p<.0001).

Conclusion: ES showed a better correlation with ST assessed on gadolinium-enhanced sequences, and should be preferred over HS as a surrogate marker for synovitis in knee OA studies in which gadolinium-enhanced sequences are not available. Using gadolinium-enhanced sequences, both ST and SV methods may be applied to assess knee synovitis.

Table 1. Distribution of synovitis grades in knees using both non-enhanced and gadolinium-enhanced MRI.

	N	%
Hoffa-Synovitis (non-enhanced MRI)		
0	11	10.6
1	56	53.8
2	31	29.8
3	6	5.8
Effusion-Synovitis (non-enhanced MRI)

Pain Central Sensitization Assessed By Functional Magnetic Resonance Imaging in Patients with Knee Osteoarthritis

Jordi Monfort[1], Jesus Pujol[2], Marina Lopez[3], Jone Llorente[3], Gerard Martinez[2], Didac Macià[2], Francisco Montañés[3], Miguel Angel Campillo[3], Pedro Benito Ruiz[4] and Joan Deus[2], [1]Rheumatology Department, Hospital del Mar, Barcelona, Spain, [2]Magnetic Ressonance Imaging Unit, Barcelona, Spain, [3]Rheumatology Department, Barcelona, Spain, [4]Rheumatology Service, Hospital del Mar, Barcelona, Spain

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Imaging of Rheumatic Diseases Poster II: X-ray, MRI, PET and CT

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: An important aspect in chronic pain is central sensitization (CS) which involves increased responsiveness of the central neurons and it is clinically expressed like hyperalgesia and allodynia. CS is common in patients with OA and may reduce anti-inflammatory treatment effects and increase clinical severity. The aim of this study was to typify brain changes related to pain sensitization by functional MRI (fMRI) in patients suffering from chronic knee OA.

Methods: We designed a cross-sectional, single blind study and compared OA patients following clinical and radiological ACR criteria vs healthy controls. All participants were selected during one year and a half in the OA Unit in the Hospital del Mar (Barcelona). Presence of CS was assessed in OA group. CS was clinically defined based on the evidence of regional spread of pain (spreading sensitization assessed by an extended version of the ArendtNielsen peripatellar map[1]) and increased pain response to repeated stimulation (temporal summation). The fMRI paradigm included 3 painful test: direct painful stimulation of the knee (articular interline) using a pressure of 2.5kg/cm^2, painful stimulation on the anterior tibial surface of the leg (sensitized site) by exerting a pressure of 4kg/cm^2, and painful heat stimulation on the forearm using 45º Celsius peaks.

Results: We included 60 OA patients (66.7 +/ 7.8yrs) and 30 controls (62.8 +/ 7.7yrs). A total of 33 patients showed some evidence of CS which 19 met all criteria of CS. At interline test, there was no difference on fMRI outcomes. At tibial test we found significant differences on brain activity which involved greater activation, in sensitized patients, in primary somatosensory area, supramarginal gyrus, sensorymotor cortex and basal ganglia. Correlation between brain response and clinical CS assessment was significant on somatosensory cortex, suppramarginal gyrus, anterior cingulated cortex and ventral putamen nucleus, bilaterally. No significant differences were found on brain activation between groups on the painful heat stimulation.

Conclusion: The presence of pain CS in chronic knee OA patients was very frequent. The pressure at medial interline has shown not to be an appropriate test to discriminate sensitized patients, since it is a maneuver with direct impact on the damaged structures in the disease. In contrast, relevant clinical pain in sensitized patients and increased brain response was produced by the pressure stimulation on the anterior tibial surface of the leg. Pain brain sensitization was related to a widespread activation of sensory cortices suggesting that sensitization is expressed mostly as an enhanced sensory phenomenon. At correlation maps, the changes in frontosubcortical structures may speculatively suggest that pain CS also involves alterations of elements implicated in associative painrelated learning (e.g., associations of pain with everyday contexts). Finally, negative results in the painful heat stimulation test suggest that sensitization is not a general phenomenon that may not implicate superior limbs or the processing of heatelicited pain.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Imaging of Rheumatic Diseases Poster II: X-ray, MRI, PET and CT

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To evaluate synovial inflammation on magnetic resonance imaging (MRI) before treatment and changes after treatment with intra-articular (i.a.) infliximab (IFX) or methylprednisolone (MP) injections in relation to clinical response in chronic or recurrent gonarthritis patients.

Methods: In the RIA study (Remicade Intra Articularly), a prospective double-blind trial in chronic or recurrent gonarthritis patients randomized to i.a. IFZ or MP. T1 contrast enhanced MRI of the affected knee before and 4 weeks after treatment were scored for Hoffa synovitis using the MRI Osteoarthritis Knee Score (MOAKS), and for joint effusion using the Knee Osteoarthritis Scoring System (KOSS). Outcomes of MRIs were compared between the randomization groups. Associations between MRI outcomes pre- and post-treatment and baseline characteristics were analysed by logistic regression analysis.

Results: 19 patients had baseline MRIs available. Baseline MRI outcomes were not associated with baseline characteristics. 18 patients (20 knees; 14 IFX and 12 MP) had 2 consecutive MRIs. Hoffa synovitis scores pre- and post-treatment were not associated with patient characteristics. Pre-treatment effusion scores were associated with number of previous i.a. corticosteroid injections (OR (95% CI) 0.74 (0.55;0.99)); post-treatment no associations were found. At baseline, MRI scores were similar in the randomization groups (table 2). After four weeks, Hoffa synovitis scores and effusion scores had decreased significantly in IFX injected knees (delta Hoffa synovitis score -1 (-1;0), p=0.021 and delta effusion score 0 (-1;0), p=0.007, respectively), but not in MP injected knees (p=0.157 and p=0.102, respectively). After 6 months, a recurrence of arthritis occurred in all IFX treated knees, and in 50% of MP treated knees. Median (IQR) Hoffa synovitis scores and effusion scores before injection were similar in MP treated patients with or without recurrence 2.0 (2.0;3.0) and 2.0 (1.0;2.0), p=0.080 in patients with recurrence, and 3.0 (3.0;3.0) and 2.5 (1.8;3.0), p=0.617 in patients without recurrence, respectively. MP treated patients with or without recurrence also showed no difference in improvement in Hoffa synovitis scores and effusion scores (delta Hoffa synovitis score 0.0 (-1.5;0.5), p=0.414 and 0 (-1;0), p=0.157, delta effusion score 0.0 (-1.0;0.0), p=0.157 and 0.0 (-0.5;0.0), p=0.317, respectively.

Conclusion: An apparent statistically significant decrease in Hoffa synovitis and effusion scores on MRIs was seen in chronic or recurrent gonarthritis patients treated with IFX injections, but not after MP injections. This apparent reaction to treatment on MRI, however, appears not to be related to clinical outcome after 6 months: a recurrence of arthritis occurred in all IFX treated knees and in 50% of MP treated knees.

Table 1: MRI outcomes before and 4 weeks after treatment and clinical outcome 6 months after treatment in the randomization groups.

Time point	IFX n=14	MP n=12	p-value	p-value week 0 vs. 4 IFX	p-value week 0 vs. 4 MP
Hoffa synovitis score, median (IQR)					
Baseline	2.5 (1.8-3.0)	2.0 (2.0-2.0)	0.288		
Week 4	2.0 (1.0-2.3)	1.5 (1.0-2.0)	0.826		
Delta	-1 (-1-0)	0 (-1-0)		0.021	0.157
Effusion score, median (IQR)					
Baseline	2.5 (2.0-3.0)	3.0 (2.0-3.0)	0.286		
Week 4	1.0 (1.0-3.0)	2.0 (1.0-3.0)	0.186		
Delta	-1 (-1-0)	0 (-1-0)		0.007	0.102
6 months					
Sufficient response*, n (%)	0	6 (50)			
Insufficient response, n (%)	14 (100)	6 (50)	0.004		

IFX: infliximab; MP: methylprednisolone; n: number; IQR: interquartile range.
*no clinical recurrence of arthritis requiring therapeutic intervention within 6 months after injection

Is MRI More Sensitive Than Conventional Radiographs to Detect Hand Osteoarthritis Progression over 5 Years Follow-up?

Ida K. Haugen[1], Barbara Slatkowsky-Christensen[2], Karwan Faraj[3] and Tore K. Kvien[4], [1]P.O. Box 23, Diakonhjemmet Hospital, Vinderen, Norway, [2]Diakonhjemmet Sykehus, Revmatologisk Avd, Oslo, Norway, [3]Radiology, Diakonhjemmet Hospital, Oslo, Norway, [4]Dept. of Rheumatology, Diakonhjemmet Hospital, Oslo, Norway

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Imaging of Rheumatic Diseases Poster II: X-ray, MRI, PET and CT
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose : Conventional radiographs (CR) are currently the imaging modality of choice for evaluation of structural hand osteoarthritis (OA) progression. Lately Magnetic Resonance Imaging (MRI) has been introduced as a promising tool to detect both structural and inflammatory hand OA features. No studies have compared the detection of structural hand OA progression by MRI and CR. The aim was therefore to evaluate the agreement between 1.0T MRI and CR to detect structural hand OA progression as well as the sensitivity and specificity of MRI in comparison to CR.

Methods : We included 69 persons (91% women, mean (SD) age of 68.0 (5.5) years) from the Oslo hand OA cohort with 1.0T MRI scans and radiographs of the interphalangeal joints at baseline (2008-09) and 5-year follow-up (2013). Evaluating the paired radiographs (posteroanterior view) with known time sequence, the joints were scored for radiographic osteophytes (grade 0-3), joint space narrowing (JSN) (grade 0-3) and central erosions (absent/present). Similarly, the joints were scored for MRI-defined osteophytes (grade 0-3), cartilage space loss (grade 0-3) and erosive damage (grade 0-3) using a T1-weighted sequence in coronal and sagittal planes. Progression was defined as an increase of ³1 features. We evaluated the agreement to detect progression using kappa statistics. The sensitivity and specificity of MRI to detect progression was calculated using CR as reference. We repeated the analyses focusing on osteophytes and joint damage separately. Cartilage space loss/JSN and erosions were evaluated as one combined feature (joint damage) as erosions likely affect the joint space.

Results: We analysed 549 joints (3 joints missing), of which 131 (23.9%) and 144 (26.2%) showed structural progression by MRI and CR, respectively. We found moderate agreement between MRI and CR (Table). Structural progression was detected by both modalities in 79 (14.4%) joints, MRI only in 52 (9.3%) joints and CR only in 65 (11.8%) joints. The sensitivity of MRI was modest. In joints with radiographic progression only, progression of osteophytes was most commonly observed. The specificity of MRI was high, as most joints did not progress by neither MRI nor CR. In joints with MRI-progression only, progression of joint damage was most frequently seen.

We found similar results with modest sensitivity of MRI when looking into progression of individual features (Table). However, MRI detected more joints with incident erosions as compared to CR (35 vs. 25 joints) in joints without erosive changes neither on CR nor MRI at baseline.

Table: The detection of structural hand OA progression by MRI and CR

	Kappa	**Sensitivity***	**Specificity***
Structural hand OA progression	0.43	0.55	0.87
Osteophytes	0.33	0.40	0.91
Cartilage damage/JSN or erosions	0.49	0.58	0.91

* CR as reference. OA=osteoarthritis, JSN=joint space narrowing

Conclusion: 1.0T MRI is not more sensitive than CR to detect structural hand OA progression. CR will also assess more joints to a lower price, and should therefore be the imaging modality of choice rather than 1.0T MRI in clinical trials on therapies with potential effects on disease progression. Future studies should compare OA progression by CR and MRI with higher field strength.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Imaging of Rheumatic Diseases Poster II: X-ray, MRI, PET and CT

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: It is recommended by an EULAR imaging taskforce that MR-detected inflammation is useful in the diagnostic process of Rheumatoid Arthritis. This recommendation is based on the sensitivity of MR to detect inflammation. The specificity is unknown, but knowledge on the prevalence of MR-detected inflammation in symptom-free persons is pivotal when considering MR for diagnostic purposes. This prompted us to perform this study.

Methods: From November 2013-December 2014 196 symptom-free persons were recruited from the general population. Inclusion criteria were: no history of inflammatory arthritis, no joint symptoms during the last month and no clinically detectable arthritis at physical examination. Contrast-enhanced 1.5T MR-images of the dominant MCP, wrist and MTP joints were made and scored by two readers according to RAMRIS. At categorisation, MR-inflammation was considered present if both readers scored positive.

Results: Of 193 persons scanned (age range 19-89 years), only 28% had no single inflammatory-feature. Higher age correlated with higher inflammation-scores ($p<0.001$). Individual lesions were mostly grade-1. Preferential locations for synovitis were MCP-3 (14% in persons aged 40-59 years, 17% if aged ≥60 years). MCP-2 (8%, 19% respectively), wrist joints (8-35% if aged ≥40 years) and MTP-1 (11-13% if aged ≥40 years). BME was frequent at all ages in the lunate (6-27%) and MTP-1 (10-23%). Tenosynovitis was infrequent, except for extensor carpi ulnaris (9% in persons aged 40-59 years; 12% if aged ≥60 years).

Conclusion: MR-detected inflammation is prevalent in the absence of symptoms, especially at higher age and at preferential locations. Tables with RAMRIS-based and age, location and inflammation-type dependent prevalences were constructed.

Session Date: Monday, November 9, 2015

Session Title: Imaging of Rheumatic Diseases Poster II: X-ray, MRI, PET and CT
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: The diagnostic value of Magnetic Resonance (MR) imaging for Rheumatoid Arthritis (RA) is undetermined. The main value of MR is its sensitive depiction of inflammation. A EULAR-imaging taskforce suggested MR also for early detection of joint damage. Because, the specificity of MR-detected erosions for RA is unknown, we assessed in symptom-free persons of the general population (1) the prevalence of MR-detected erosions and of these erosions (2) the preferential anatomic locations, (3) the association with gender and age and (4) the simultaneously presence of local MR-detected inflammation.

Methods: From November 2013-December 2014 symptom-free persons were recruited via newspapers and websites. Inclusion criteria were: no history of inflammatory arthritis, no joint symptoms during the last month and no clinically detectable arthritis. Contrast-enhanced 1.5T-MR of the dominant MCP, wrist and MTP-joints was made. Erosions were assessed based on RAMRIS (presence on 2 planes, with cortical break on ≥1 plane).

Results: 193 persons fulfilled the criteria (mean age 49.8 years, range 19-89). 22% of persons had no erosions. The total erosion-score correlated with age (r=0.69 p<0.001) and not with gender. Preferential locations were MCP-2 (6% of persons aged <40, 33% if aged ≥60), MCP-3 (8% in persons aged <40, 17% if aged ≥60), scaphoid (37% in persons aged ≥60), distal ulna (23% in persons aged ≥60), MTP-1 (37% in persons aged ≥60) and MTP-5 (10% in persons aged ≥60). Part of the joints with erosions also showed MR-detected inflammation.

Conclusion: In symptom-free persons MR-detected RAMRIS-defined erosions are prevalent, especially at higher age.

MRI Erosions in Undifferentiated Arthritis. Different Associations with the Collagen IIA N-Terminal Propeptide (PIIANP) and Galectin-3 in Pre-RA and Other Arthritides

Saida Farah Issa[1], Anne Duer[2], Mikkel Østergaard[3], Hanne Lindegaard[1], Kim Hørslev-Petersen[4], Merete Lund Hetland[5], Jakob M. SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Imaging of Rheumatic Diseases Poster II: X-ray, MRI, PET and CT
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Galectin-3 has been implicated as a mediator of inflammation and erosive progression in animal arthritis and rheumatoid arthritis(RA). The type IIA procollagen peptide(PIIANP) is an emerging seromarker for cartilage collagen II synthesis and we have previously reported subnormal levels in patients with newly diagnosed, untreated RA.

The aims were to study A. Baseline galectin-3 and PIIANP in patients with undifferentiated arthritis and to compare the levels in pre-RA and other arthritides; B. The relationship between galectin-3 and PIIANP with disease phenotype and MRI findings.

Methods: Patients categorized with early, undifferentiated arthritis(n=116) were followed up for at least 12 months after which they were reclassified according to appropriate criteria(TUDAR)(1). Baseline variables included demographics, biochemical and clinical disease activity measures. Baseline MRI was obtained of the dominant wrist, MCP, PIP and MTP joints. One hundred and twenty individuals

served as controls. Galectin-3 and PIIANP were measured by ELISA(R&D, Millipore/Linco Research).

Results: Galectin-3 was significantly increased in patients with undifferentiated arthritis, 4.42 ng/ml (*95% CI 4.08;4.75*) vs. controls, 3.96 ng/ml (*95% CI 3.70;4.22*, p = 0.03), particularly in the pre-RA subset, 4.99 ng/ml (*95% CI 4.30;5.67*, p = 0.002). Conversely, galectin-3 in patients with other arthritides than future RA did not differ from healthy controls (fig 1a). PIIANP was also increased in the entire group, 1800 ng/ml (*IQR 1440;2250*) vs. healthy controls, 888 ng/ml (*IQR 742;1029,* p < 0.0001). However, when stratifying according to pre-RA and other kinds of arthritis, PIIANP was equally increased in these two subsets, 1752 ng/ml (*IQR 1483.5;2067,* p < 0.0001) and 1801 ng/ml (*IQR 1436;2260,* p < 0.0001). Galectin-3 and PIIANP did not associate with clinical disease activity measures. However, PIIANP correlated negatively with total MRI erosion score in patients with pre-RA, rho=-0.83 p = 0.009.

Figure 1.a Galectin-3 levels in controls, pre-RA and other arthritides

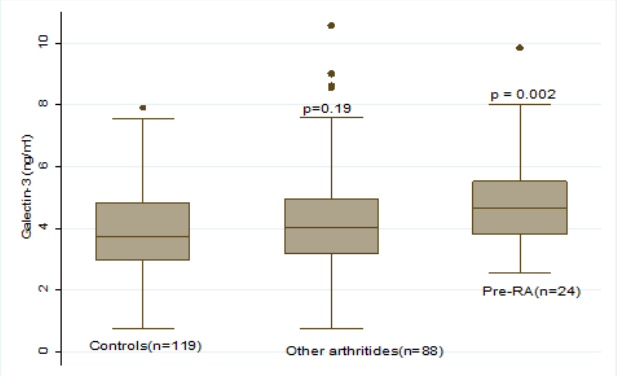

Figure 1.b PIIANP levels in controls, pre-RA and other arthritides

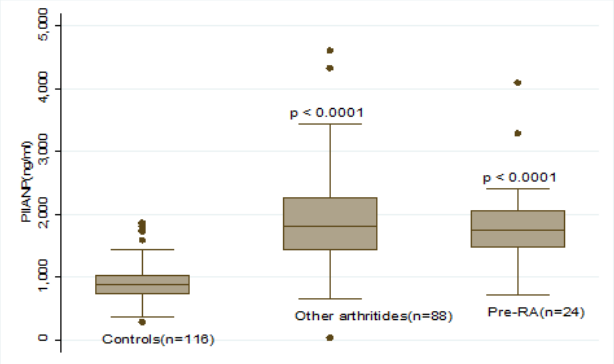

Conclusion : These findings indicate that synovitis of any origin elicits a regenerative chondrogenic response. However, the inverse correlation between PIIANP and baseline MRI erosion score in pre-RA indicates that cartilage collagen II metabolism is skewed towards a net catabolic state in this arthritis subset. This altered cartilage metabolic profile may relate to the increased galectin-3 expression in patients with pre-RA.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Imaging of Rheumatic Diseases Poster II: X-ray, MRI, PET and CT

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Functional ability of rheumatoid arthritis (RA) patients is reduced by both acute (inflammatory) and chronic (joint damage) disease manifestations. However, the impact of early erosive damage in small joints is not yet fully appreciated. Advances in automated erosion segmentation of magnetic resonance (MR) images, such as Early Erosions in Rheumatoid Arthritis (EERA) software, enable more reliable and precise measurement of erosions. Our objective was to develop multiple linear regression models to determine how small amounts of erosive damage contribute to loss of functional ability.

Methods: From a single rheumatology clinic, 131 patients satisfying early RA referral criteria were included. Clinical examinations, laboratory tests, MR images of both hands, and the Health Assessment Questionnaire – Disability Index (HAQ-DI) were captured. A single reader used EERA software to compute the total erosive damage in the metacarpophalangeal (MCP) joints, in mm^3. A multiple linear regression model was constructed (Model 1), with HAQ-DI as the dependent variable, and age, sex, symptom duration < 1 year, DMARD or biologic use over preceding 3 months, 28 joint Disease Activity Score (DAS28), and MCP erosion volume as predictors. Model 2 was constructed identical to Model 1, except MCP erosion volume was categorized into: $0mm^3$, $0\text{-}50mm^3$, $50\text{-}100mm^3$ and $>100mm^3$.

Results: Patients were 78% female, 77% Caucasian, mean (standard deviation) age 55.9 (13.3) years, symptom duration 4.2 (5.1) years, DAS28 4.48 (1.40), HAQ-DI 0.81 (0.71), with 50% using DMARD or biologic over the preceding 3 months. Mean erosive damage was low at 32.3 (78.5) mm^3. Model 1 (R^2=0.296, p<0.001) and Model 2 (R^2=0.282, p<0.001) had similar parameter estimates. Each unit increase in DAS28 was associated with a 0.25 unit increase in HAQ-DI. DMARD or biologic use in the preceding 3 months was associated with 0.27 unit decrease in HAQ-DI. Age was significantly related to HAQ-DI in Model 1, but the effect was small (0.1 increase in HAQ-DI for 10 years age increase). Erosive damage to the MCP joints was not significantly related to HAQ-DI in either model.

Conclusion: Low amount of erosive damage was not associated with decreased functional ability. Low disease activity and concurrent DMARD or biologic therapy were associated with improved functional ability. Longitudinal models controlling for additional variables may help elucidate how early erosive damage influences functional ability.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Imaging of Rheumatic Diseases Poster II: X-ray, MRI, PET and CT

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: We used data from a large clinical trial of golimumab (GO-BEFORE) to comprehensively assess associations between magnetic resonance imaging (MRI) measures of synovitis, osteitis, and bone erosion with patient-reported measures of physical functioning, pain, and global disease activity in rheumatoid arthritis (RA).

Methods: MRI of the dominant hand was performed and RAMRIS scores were determined at baseline, and at weeks 12, 24, 52. van der Heijde- Sharp scores (vdHS) were determined from radiography at baseline and 52 weeks. Standard patient-reported measures were recorded at these time-points including the Health Assessment Questionnaire (HAQ), as well as pain and patient global scores as measured by visual analogue scale. Spearman correlations as well as multivariable linear and logistic regression utilizing robust generalized estimating equations (GEE) were used to assess relationships between RAMRIS measures and patient-reported outcomes over all time-points.

Results: Correlations between all MRI measures and HAQ were noted at all time-points (Table 1). Pain and patient global scores were increasingly correlated at later follow-up times. In multivariate models incorporating all time-points, synovitis and bone erosion were associated with HAQ independent of clinical disease activity as measured by the DAS28. Greater synovitis was also associated with greater pain and greater patient global scores independent of C-Reactive Protein (CRP) and swollen/tender joint counts. Greater improvements in synovitis were correlated with improvements in HAQ at all time-points and associated with improvements in pain at early time-points (Table 2). Considering all intervals over which change could occur, changes in synovitis were associated with changes in HAQ ($p=0.001$), pain ($p=0.02$), and patient global scores ($p=0.02$). After adjusting for baseline HAQ, and baseline and 52-week change in synovitis, increases in erosion at 52 weeks (per unit) were associated with increases in HAQ (β: 0.038, $p=0.01$), pain (β: 0.18, $p=0.006$), and patient global scores (β: 0.17, $p=0.005$). In contrast increases in vdHS were not associated in similar models (all $p>0.7$).

Conclusion: Synovitis was associated with physical functioning, pain, and patient global scores, independently of measures of clinical disease activity. Improvements in synovitis correlated with improvements patient-reported outcomes, while increases in MRI erosion were associated with worsening. Changes in MRI findings are likely to have important implications for how patients experience their disease.

Table 1: Spearman correlations at 0, 12, 24, and 52 weeks between synovitis, bone edema, bone erosion, and HAQ, pain, and patient global.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Imaging of Rheumatic Diseases Poster II: X-ray, MRI, PET and CT
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Imaging-detected inflammation persists in many rheumatoid arthritis (RA) patients despite therapy. We used data from two clinical trials of golimumab to determine thresholds for RA magnetic resonance imaging scores (RAMRIS) for synovitis and osteitis associated with a low risk of radiographic and MRI progression in structural damage.

Methods: MRI of the dominant hand was performed and RAMRIS scores were determined at weeks 0, 24, and 52. X-rays were also performed and van der Heijde-Sharp scores (vdHS) determined. .In a development cohort (GO-BEFORE) the changes in MRI erosion score and vdHS score were determined over the 24-week to 52-week interval. MRI erosion and vdHS progression were defined as a change of >0.5. We aimed to identify 24-week thresholds for synovitis (total possible score 21) and osteitis (possible score 230) that provided approximately 90% sensitivity for MRI erosion progression over the 24 to 52 week interval. Rates of progression were illustrated over the range of synovitis, osteitis, and a combination (total inflammation score) at the beginning of the interval. The performance of the cutoffs was then tested in a validation cohort (GO-FORWARD).

Results: In the development cohort, subjects who reached a synovitis or osteitis score <=5 by 24 weeks had a low probability of progression on MRI and X-ray between 24 and 52 weeks (8% and 9%, respectively). The coefficient for osteitis was stronger than that of synovitis in multivariable models predicting X-ray and MRI progression. Therefore, when these scores were combined into a single inflammation score, the score was weighted on osteitis (x2). In the validation cohort, subjects who reached an inflammation score of <=10 by 24 weeks had a low predicted probability of progression from 24 to 52 weeks (7%). In the validation cohort, there was a low rate of MRI progression between 24 and 52 weeks among those with low synovitis, osteitis, and inflammation scores (Table) independent of 24-week DAS28 or C-reactive protein. A lower risk of x-ray progression was observed between 0 and 52 weeks among 34% of subjects with a low inflammation score at baseline as well as among the 47% and 49% of subjects who reached a low inflammation score by weeks 12 or 24, respectively.

Conclusion: Patients that reach low levels of MRI inflammation by 3 or 6 months are substantially less likely to have structural damage progression independent of DAS28 response. A low score by 6 months is predictive of a low risk of radiographic progression over 52 weeks, suggesting that these outcomes might potentially be used as early dichotomous endpoints in clinical studies.

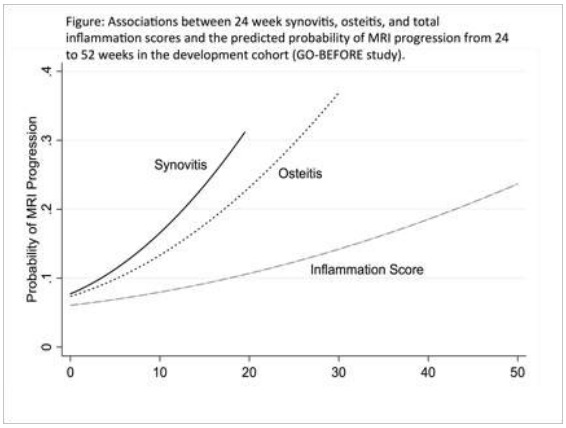

Table: Risk of progression among those above and below identified thresholds in the validation cohort (GO-FORWARD).

Percent with MRI Progression Between 24 to 52 Weeks by MRI Score

	Synovitis		Osteitis		Synovitis + (2*Osteitis)

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Imaging of Rheumatic Diseases Poster II: X-ray, MRI, PET and CT

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Previous radiographic and MRI studies have demonstrated that abatacept (ABT) can inhibit the progression of bone and joint destruction in patients with rheumatoid arthritis (RA), just like other biologic agents. However, the relations between MRI scores and other disease indexes are not well-known. And MRI scans of only single hand have been performed in previous reports. The aim of the present study is

to evaluate efficacy of ABT in patients with RA using MRI of bilateral hands and to investigate whether MRI scores are related to SDAI and HAQ scores in comparison with radiographic scores.

Methods:

Thirty-five RA patients who had not been received more than 1 biological agent were included in this study. MRI of bilateral hands was performed at baseline and 12 months of intravenous ABT treatment. MRI images were scored for synovitis (0-42), osteitis (0-138) and bone erosion (0-460) according to the Rheumatoid Arthritis MRI Scoring System. Conventional radiographs of hands and feet were also obtained at baseline and 12 months, and they were scored according to the van der Heijde modified total Sharp scoring system. These scores were read by two independent doctors, who were blinded to clinical data. Clinical assessment was performed at baseline and at 1, 3, 6, 9, 12 months. The primary endpoint was change from baseline in MRI-measured synovitis score (SS), osteitis score (OS) and bone erosion score (ES).

Results:

Thirty-one patients completed this study for 12 months. The mean SS and OS were significantly reduced at 12 months compared with the baseline (SS at baseline/ 12 months: 17.1±7.02/ 11.4±6.24 (p<0.0001), OS: 5.11±8.16/ 1.89±2.47 (p=0.003)). On the other hand, ES showed no change throughout the study (28.2±38.6/ 28.7±39.2 (p=0.380)). At 12 months, 57.1% of patients showed no progression in ES (deltaES≤0) and 63.6% of patients showed no progression in radiographic erosion score. Changes from baseline in SS (deltaSS) and ES (deltaES) were correlated with relative SDAI response (p=0.023/0.021), while radiographic scores were not correlated with SDAI score. SS, OS and ES at 12 months were correlated with HAQ score at 12 months (p=0.038/0.007/0.038), while radiographic scores were not correlated with HAQ score statistically. Patients achieving SDAI remission at 12 months (n=11) showed lower OS at 12 months (p=0.030) and lower deltaES (p=0.004) compared to those who didn't achieve SDAI remission (n=20), while radiographic scores didn't show significant differences between two groups. Patients achieving HAQ remission at 12 months (n=17) showed lower OS at 12 months (p=0.015), lower SS at 12 months (p=0.049), lower ES at 12 months (p=0.019) and lower deltaES (p<0.001) compared to those who didn't achieve HAQ remission (n=13).

Conclusion:

ABT reduced synovitis and osteitis score in MRI of bilateral hands at 12 months. Compared to radiographs, MRI of bilateral hands showed higher correlations with SDAI and HAQ scores.

Session Title: Imaging of Rheumatic Diseases Poster II: X-ray, MRI, PET and CT

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: MRI has proved to be more sensitive than clinical examination and x-ray for detection of inflammatory and destructive joint changes in early rheumatoid arthritis (RA) and to discriminate between treatment arms in clinical trials using the semi-quantitative Outcome Measures in Rheumatology Clinical Trials (OMERACT) RA MRI scoring (RAMRIS) system. We aimed to investigate whether MRI-determined measures of disease activity and joint destruction were suppressed in early RA patients following a treat-to-target strategy with methotrexate (MTX) and intraarticular (i.a.) betamethasone and to investigate whether concomitant cyclosporine (CYA) had an additional effect on MRI determined inflammatory and destructive findings over 2 years.

Methods: In the 2-year randomized, double-blind, multicenter, clinical, treat-to-target trial, CIMESTRA, 160 patients with early (<6 months) RA were treated with MTX, i.a. betamethasone and CYA/placebo CYA of wich129 patients participated in the MRI substudy. Patients had contrast-enhanced MRIs at months 0, 6, 12 and 24 that covered the non-dominant wrist (wrist-only group) and if technically possible both wrist and metacarpophalangeal (MCP) joints (wrist+MCP group). MRIs were evaluated by an experienced radiologist blinded to patient identity, clinical and biochemical data but not to chronology, using the RAMRIS scoring system assessing inflammatory (osteitis, synovitis, tenosynovisits) and destructive (bone erosion, joint space narrowing) changes. Observed data, without any data imputations, are reported. Non-parametric statistics were used. A value of $p<0.05$ was considered statistically significant.

Results: MRI-results from the wrist-only group are shown in table 1. The data in the wrist+MCP group were overall similar (data not shown). No statistically significant differences between the treatment groups were observed in any MRI characteristics at baseline or at any follow-up time point. Both the wrist-only group and the wrist+MCP group showed significant reductions compared to baseline in osteitis, synovitis and tenosynovitis at 6 months (all parameters) and 12 and 24 months (synovitis and tenosynovitis). Statistically significant, but numerically low, increases in erosion and JSN scores from baseline to 6, 12 and 24 months were seen.

Conclusion: A treat-to-target strategy with MTX and i.a. betamethasone reduced MRI inflammatory findings significantly, with no additional effect of CYA, but still minor structural damage progression was observed.

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Imaging of Rheumatic Diseases Poster II: X-ray, MRI, PET and CT
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Standard assessment of Rheumatoid Arthritis (RA) on MRI relies on semi-quantitative joint space narrowing scores that are not sensitive to cartilage focal lesions or early biochemical damage[1,2]. MRI T1ρ has been shown to quantitatively evaluate cartilage proteoglycan loss, collagen matrix changes, and water content[3]. The purpose of our study was to evaluate the feasibility of radiocarpal cartilage T1ρ as a biomarker in RA clinical trials.

Methods:

Nine patients were included in this study: 6 RA patients with active disease despite methotrexate (MTX) treatment started on certolizumab pegol (CZP) and 3 RA patients with low disease on MTX treatment alone. 3T MR was performed at baseline (immediately before CZP initiation) and after 3 months for all subjects. A coronal T1ρ sequence was used (Time of Spin-Lock = 0/10/20/50ms; spin lock frequency = 500Hz, resolution 0.21x0.21x3mm) for lunate, scaphoid, and radius cartilage segmentations. All echoes and follow-up images were registered to baseline images with piecewise rigid registration using individual bone masks (Fig. 1). Paired t-tests were used to compare T1ρ values at baseline and 3-month. Progression of T1ρ values (ΔT1ρ) were correlated (Spearman's rho) with progression of Disease Activity Scores, Michigan Hand Questionnaires, and Health Assessment Questionnaires.

Results:

Patient characteristics are presented in Tab. 1. MTX alone patients showed an increase in Global T1ρ (37.4±1.4 to 39.3±1.6 ms) after 3 months while CZP + MTX patients did not show any significant changes in T1ρ. A statistically significant correlation was found between ΔGlobal T1ρ and ΔDAS28-ESR, ΔMHQ, and ΔHAQ (Fig. 2).

Conclusion:

We previously reported excellent in vivo reproducibility of wrist cartilage T1ρ (1.42% – 5.62% CV) [4]. The overall non-significant change of cartilage T1ρ at 3 months for CZP + MTX patients suggests cartilage responds positively to anti-TNF treatment through joint structure protection. Despite the small sample size, there are already strong correlations between progression of cartilage T1ρ with DAS28, MHQ, and HAQ, encouraging further research with more patients and time points.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Imaging of Rheumatic Diseases Poster II: X-ray, MRI, PET and CT

Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is characterised by progressive joint destruction and loss of periarticular bone mass. Thus hand bone loss (HBL) has been proposed as an outcome measure for treatment efficacy. A definition of increased HBL adjusted for age- and gender-related bone loss is lacking. We aimed to establish a HBL reference material and investigate whether HBL normalises in RA patients during tumour necrosis factor inhibitor (TNFα-I) treatment in clinical practice.

Methods: Hand bone mass (DXR-BMD) was assessed by Digital X-ray Radiogrammetry (DXR), a computerised method of estimating cortical bone mineral density in the 2^{nd} – 4^{th}metacarpal bone, in a reference population and a patient cohort. The reference population was 1,487/ 2,541 randomly selected men/women who had hand x-rays done in the cross-sectional Copenhagen Osteoarthritis Study. Linear regression analyses were fitted to the data and mean age-related changes in DXR-BMD (ie. normal HBL) estimated for men and women.

The patient cohort comprised 135 patients in the DANBIO registry with hand x-rays obtained ~2 years prior to TNFα-I (pre-baseline, patients treated with conventional synthethic Disease-Modifying Anti-Rheumatic Drugs (csDMARD)), at start of TNFα-I (baseline) and ~ 2 years after TNFα-I start (follow-up). Annual HBL during csDMARD and TNFα-I treatment were calculated in the individual patients and compared with the lower 95% CI of normal HBL for the matching age and gender to assess if increased HBL was present.

Results: Table 1 presents the HBL reference material. The 135 RA patients (85% women, 71% IgM-RF positive, median age 55(range 23-84) years; median disease duration 5(range 1-53) years) had a median pre-baseline DAS28 of 4.3(range 1.6-6.9) and a baseline DAS28 of 5.3(1.4-8.2). TNFα-I treatment was infliximab (74%), etanercept (13%) or adalimumab (13%). At follow-up (DAS28 3.1(1.4-7.7) 59% received the initial TNFα-I, 27% had switched to another biological drug and 14% had withdrawn.

Compared to the reference population, 101 (75%) patients had increased HBL during csDMARD treatment while 79 (59%) patients had increased HBL during TNFα-I treatment (p = 0.17,Chi-Sq). In 38 patients with increased HBL during csDMARD treatment HBL was normalised during TNF-I. Sixteen patients had normal HBL during csDMARD treatment but increased HBL during treatment with TNFα-I.

Conclusion: We have established a reference material for HBL in the general population. Increased HBL was present in the majority of RA patients initiating TNFα-I treatment in clinical practice and was normalised in few patients during treatment.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Imaging of Rheumatic Diseases Poster II: X-ray, MRI, PET and CT

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Inflammation of the tendon sheaths (tenosynovitis) is a recognised component of rheumatoid arthritis (RA). A comprehensive assessment of inflammation will require the inclusion of tenosynovitis as well as synovitis and osteitis, and consequently it is proposed to include a semi-quantitative assessment of wrist tenosynovitis in the OMERACT RAMRIS scoring system. Active appearance models (AAM) have been successfully used to develop an automatic quantitative version of the current RAMRIS methodology.

This study was a pilot investigation in established RA to assess whether AAMs can be used to produce an automatic tenosynovitis measure and compare the response to therapy of quantitative wrist tenosynovitis and synovitis measures.

Methods: MR images of the hand were acquired at 0, 3 and 6 months from 34 established, seropositive RA patients who received a cycle of rituximab therapy in an open label study. Pre- and post-contrast VIBE images with fat saturation were acquired, and searched with AAMs to identify bones and capsular structures and generate 3D regions of interest (ROIs). Volume which enhanced with contrast was calculated using a shuffle transform. AAMs of the flexor tendons were generated from an independent training set of hand MR images. Briefly, the process includes manual segmentation of the tendons by an expert, generating 3D surfaces using a marching cubes algorithm and the generation of AAMs for each tendon. Images were automatically searched using the AAM, and visually inspected to ensure that the search process had correctly identified the tendons. A 3D region of interest (ROI) around each tendon was created by inflating the tendon shape to form a halo which included the tendon sheath. Within the ROI the tenosynovitis volume was calculated using the shuffle transform method. For this pilot study only the wrist flexor tendons within the common synovial sheath were analysed. The amount of change for the 2 methods was judged using a paired t-test.

Results:

Tenosynovitis in the flexor tendons, and synovitis volume decreased at 3 and 6 months, in an approximately linear fashion. Change was significant at 6 months for both measures (Figure 2). Although the change in the population mean was linear for both measures, the slope of change in tenosynovitis volume for individual patients did not correlate with change in synovitis volume for the same patients ($r^2 = 0.29$).

Conclusion:

It is feasible to quantify tenosynovitis using AAMs. Tenosynovitis in the flexor tendons decreased over 6 months, and only correlated weakly with change in synovitis volume within the same patient. Tenosynovitis appears to be as responsive as synovial volume, but did not correlate with synovial change in individual patients in this small study. Tenosynovitis may therefore add new information to that already provided by measures of synovitis, though this will need confirmation with a fully developed tool in a larger RA population.

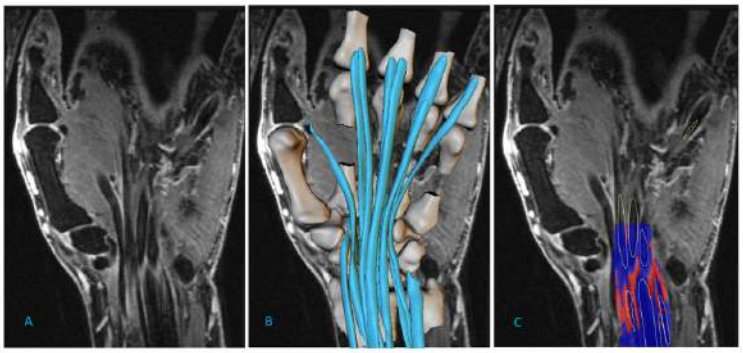

Figure 1. Using appearance models to automatically identify bone, and generate 3D regions of interest

Figure A shows a single slice in a typical post-contrast VIBE image from this study. The 3D image is searched using an active appearance model (AAM), which generates surfaces for all the bones and flexor tendons in the hand (B). C shows the areas which enhance with contrast in the 3D region of interest around the flexor tendons in the ulnar bursa group of flexor tendons (enhanced voxels coloured red, region of interest coloured blue

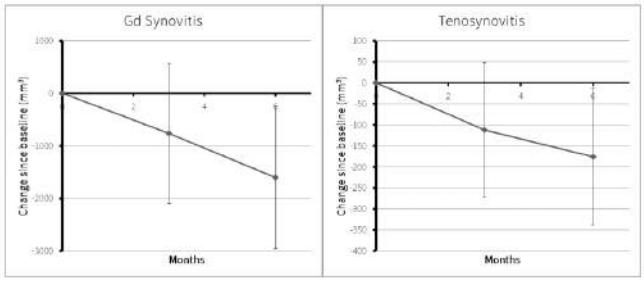

Figure 2: Change from baseline at 3 and 6 months

34 patients had images at all of 0,3 and 6 month time points. Graphs show change in synovitis volume (microliters or mm³) and tenosynovitis volume in the ulnar bursa, showing 95% confidence limits for change from baseline using a paired t-test

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Imaging of Rheumatic Diseases Poster II: X-ray, MRI, PET and CT

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Radiographs have been traditionally used to detect bone erosions and joint space narrowing (JSN) in rheumatoid arthritis (RA), but they are not sensitive to small erosions and subtle changes in erosions or JSN based on Sharp scoring, which requires at least 12 months to detect disease progression in clinical trials[1]. High-resolution peripheral quantitative computed tomography (HR-pQCT) is an emerging *in vivo* imaging technology that has an *in vivo* resolution 82 µm that allows us to detect smaller erosions[2], measure joint space width (JSW), quantify trabecular bone structure, and detect subtle changes in these measures. In this study, we examine the effects of anti-TNF on JSW and bone structure in a three-month period.

Methods: The wrists of 10 RA patients (54.8 ± 15.1 year., 8 female., DAS28-ESR: 4.97 ± 1.83) were scanned using HR-pQCT with an isotropic resolution of 82 µm. Patients were divided into two groups: Group I was given only methotrexate (MTX) (3 patients) and Group II was given certolizumab pegol (CZP) and MTX (7 patients). Scans were performed on metacarpophalangeal (MCP), and wrist joints at baseline (before anti-TNF initiation for Group II) and 3-month follow up. The second, third, and fourth MCP, and wrist JSW were measured, and the MCP and distal radius trabecular bone were quantified using previously developed methods[3]. Bone erosion dimensions were evaluated by measuring the maximal erosion dimensions on an axial 2-dimensional slice[4]. T-tests were performed to compare measures between the groups and within the groups from baseline to 3-month.

Results: DAS28-ESR of patients in Group II decreased significantly from baseline to 3-month ($p = 0.004$), and the decrease in MCP 3 JSW for Group II approached significance ($p = 0.055$). Eleven and 31 erosions were identified at baseline for Group I and II respectively, with 72.7% and 67.7% of these lesions increasing in size (change > 10%) at baseline and 3-month respectively. Six and 13 new erosions were identified at 3-month for Group I and II respectively.

Conclusion: The decrease of MCP 3 JSW in Group II may be due to decreased inflammation and less synovitis and effusion with anti-TNF treatment. We observed more than half of the erosions increased in size and the generation of new erosions for both groups within a very short time period (3 months) using HR-pQCT, indicating the high sensitivity of HR-pQCT detecting subtle changes in erosions as compared to radiographs. The significant decrease in DAS28-ESR for Group II suggests that although anti-TNF treatment suppresses the inflammation pathway, the process of structural joint damage may require more time to be arrested.

Is MRI of Use in Identifying Which Undifferentiated Arthritis Patients Will Develop RA?

W.P. Nieuwenhuis[1], E.C. Newsum[1], H.W. van Steenbergen[2], L. Mangnus[1], T. W. J. Huizinga[1], M. Reijnierse[3] and A.H.M. van der Helm-van Mil[2], [1]Rheumatology, Leiden University Medical Center, Leiden, Netherlands, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Radiology, Leiden University Medical Center, Leiden, Netherlands

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Imaging of Rheumatic Diseases Poster II: X-ray, MRI, PET and CT
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

The 2010 ACR/EULAR criteria for rheumatoid arthritis (RA) identify RA patients earlier than the 1987 ACR criteria. However, still a considerable amount of patients not fulfilling the 2010 criteria or other rheumatic diagnoses (i.e. undifferentiated arthritis, UA) develop RA.[1,2]Previous studies revealed that auto-antibodies and existing prediction rules fail to identify the UA patients that will progress to RA. In this observational study we studied the use of MRI-detected inflammation to identify these UA patients.

Methods:

202 patients presenting with 2010UA consecutively included in our early arthritis cohort were studied. Unilateral, 1.5T extremity MRI of the metacarpophalangeal, wrist and metatarsophalangeal joints was performed at baseline. Bone marrow edema (BME), synovitis and tenosynovitis were scored according the RA MRI scoring system by 2 independent readers blinded for clinical data. MRI positivity was defined as the presence of inflammation with a prevalence <5% in age matched symptom free controls. Clinical and laboratory findings were also recorded. Two outcome measures were studied; fulfilling the 1987 ACR RA criteria and initiation of DMARD therapy within the first year.

Results:

The 202 UA-patients had a median symptom duration of 8.7 weeks; 29 patients (14%) progressed to RA and 75 (37%) started DMARD therapy. A positive MRI for any MRI inflammation was associated with both RA development (OR 6.1 95%CI 1.4-26.8) as well as initiation of DMARD-therapy (OR 2.4 95%CI 1.2- 4.6). When assessing the MRI features BME, synovitis and tenosynovitis separately, only tenosynovitis was associated with RA development and initiation of DMARD-therapy (OR 5.4 95%CI 1.9-15.2 and OR 4.2 95%CI 2.3-7.8 respectively). When evaluating traditional inflammatory measures, the swollen joint count at baseline (SJC) and C-reactive protein level at baseline (CRP) were also associated with RA-development, in contrast to the presence of ACPA or RF. Multivariable analyses including SJC and CRP with RA-development as outcome, yielded ORs of 5.6 (95%CI 1.2-25.6) for any MRI detected inflammation and 6.3 (95%CI 2.1-19.3) for MRI detected tenosynovitis. Similar analyses with initiation of DMARD therapy as outcome yielded ORs of 1.8 (95%CI 0.9-3.6) and 3.6 (95%CI 1.9-6.9) respectively.

Conclusion:

Within 2010UA, a positive MRI was associated with RA development, independent of commonly used measures of inflammation (SJC, CRP). MRI detected tenosynovitis in particular was most predictive. The next step is to determine the clinical benefit of extremity MRI to enable an early diagnosis of RA.

Clinical Utility of Joint Space Width and X-Ray Radiogrammetry in RA: Markers for Early Radiographic Progression

Michael Platten[1], Yogan Kisten[2], Johan Kälvesten[3], Kristina Forslind[4] and Ronald F. van Vollenhoven[5], [1]Medicine, Karolinska Institutet, Huddinge, Sweden, [2]ClinTRID, Unit for Clinical Therapy Research, Inflammatory Diseases (ClinTRID), The Karolinska Institute, Stockholm, Sweden, [3]Sectra AB, Stockholm, Sweden, [4]Department of Medicine, Helsingborgs Lasarett, Section of Rheumatology, Helsingborg, Sweden, [5]Department of Medicine, Unit for Clinical Therapy Research, Inflammatory Diseases (ClinTRID), The Karolinska Institute, Stockholm, Sweden
First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Imaging of Rheumatic Diseases Poster II: X-ray, MRI, PET and CT
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Early prediction of radiographic progression is beneficial in rheumatoid arthritis (RA) patient management. The van der Heijde modified Sharp score (SHS) is currently the standard that quantifies radiographic progression. The digital joint space width (JSW) measurement (Kälvesten et. al, submitted 2015) is a quick method which may offer a remedy to observer dependency and measurement error. Likewise, objective quantification of hand osteopenia may be of value in the assessment of bone involvement in early RA.

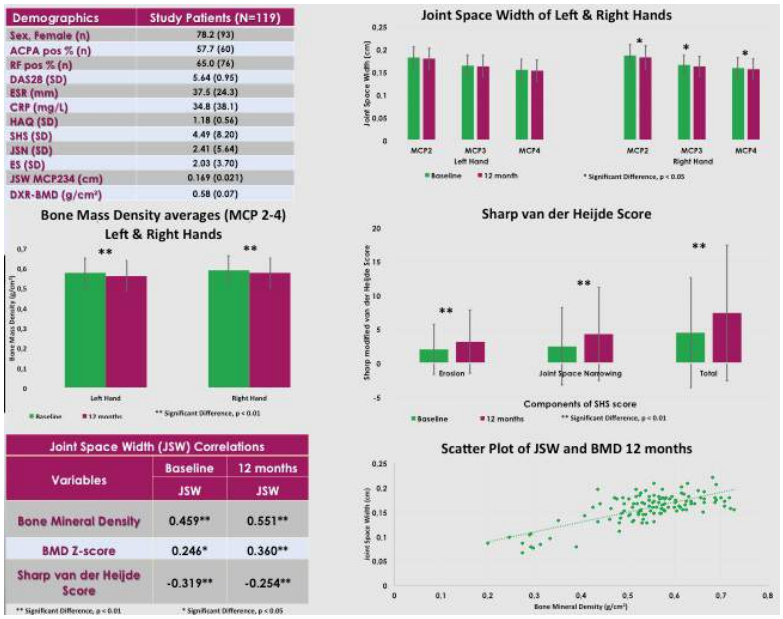
Methods:

Bilateral hand BMD and JSW measurements of the metacarpals (2, 3 & 4) and SHS of early RA patient data, acquired from the SWEFOT database were studied. Computer assisted automated measurements of the MCP joint spaces were calculated from the hand x-rays using dedicated software analysis. Hand BMD was assessed by digital x-ray radiogrammetry (DXR; Sectra, Linköping, Sweden) of the same hand radiographs, scored with SHS at baseline and at 12 months. The Z-score BMD was a calculated measure adjusted for age and gender. Measurement differences of the ΔJSW, ΔBMD scores, and ΔSHS were established and correlated.

Results:

We studied 119 early RA patients (78% female), with an average age of 53.6 years. In 714 joints (MCP2, 3 & 4 bilaterally), the automated JSW showed an average narrowing (ΔJSW) of -0.0492mm from baseline to 12 months. The BMD displayed an average bone loss of -0,0238g/cm^2 from baseline to 12 months. A highly significant correlation was evident for JSW and BMD averages (0.459, $p<0.01$; 0.551, $p<0.01$) at baseline and at 12-month follow-up respectively. Even the ΔJSW and ΔBMD over the 12 months demonstrated a highly significant correlation (0.417, $p<0.01$). BMD Z-Scores showed similar patterns with JSW (0.246, $p<0.05$, n=109; 0.360, $p<0.01$, n= 106) at baseline and 12 months respectively. A positive inverse relationship emerged between automated JSW and the joint space narrowing (JSN) component of SHS (-0.319, $p<0.01$; -0.254, $p<0.01$) at baseline and 12 months respectively. The average JSW measurements of both hands (n = 117) also revealed significant correlations (-0.224, $p<0.05$; -0.271, $p<0.01$) with total SHS at baseline and 12 months respectively. No significant correlation was found between JSW and SHS erosion score. The 12-month BMD displayed near significant correlations with the 12-month SHS erosion score (-0.174, p=0.060) and the 12-month total SHS (-0.157, p=0.090).

Image/graph:



Conclusion:

Automated analyses of JSW & BMD were technically feasible with reproducibility and agreement with the SHS. Correlations between JSW & BMD and JSW & SHS were noted. An inverse relationship between JSW and SHS narrowing score can be seen on individual female joints. These objective, digitally quantified measures of Joint Space Width and Bone Mineral Density may be useful as additional complementary markers for early destructive radiographic progression in RA.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Imaging of Rheumatic Diseases Poster II: X-ray, MRI, PET and CT

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The assessments of joint damage in patients with rheumatoid arthritis (RA) are mainly restricted to small joints in the hands and feet. However, the development of arthritis in RA patients often involves the large joints, such as the shoulder, elbow, hip, knee and ankle. Few studies have been reported regarding the degree of radiographic damage in large joints in patients with RA. 18F-fluorodeoxyglucose positron emission tomography combined with computed tomography (FDG-PET/CT) precisely visualizes the disease activity in large joints affected by RA. In this study, the associations between destruction of the large joints and the findings of FDG-PET/CT as well as laboratory parameters were investigated, and factors associated with large joint destruction after the administration of biological therapy were identified in patients with RA.

Methods: A total of 264 large joints in 23 RA patients (six males and 17 females; mean age of 66.9 ± 7.9 years) were assessed in this study. All patients were diagnosed according to the American College of Rheumatology criteria revised in 1987. FDG-PET/CT was performed at baseline and six months after the initiation of biological therapy. The extent of FDG uptake in large joints (shoulder, elbow, wrist, hip, knee and ankle) was analyzed using the maximum standardized uptake value (SUVmax). Radiographs of the 12 large joints per

patient obtained at baseline and after two years were assessed according to Larsen's method. A logistic regression analysis was performed to determine the factors most significantly contributing to the progression of joint destruction within two years.

Results: Among the 264 joints, radiographic progression of joint destruction was detected in 33 joints. The SUVmax at baseline and six months and the disease activity score (DAS) 28 – erythrocyte sedimentation rate (ESR) at six, 12 and 24 months were significantly higher in the group with progressive joint destruction. The SUVmax at baseline and DAS28-ESR at six months were found to be factors associated with joint destruction at two years ($p < 0.05$).

Conclusion: The FDG uptake in the joints with destruction was higher than that observed in the joints without destruction. The SUV max at baseline and the DAS28–ESR at six months after the biological treatment were identified to be significant factors predicting destruction of the large joints at two years.

18F-Fluorodeoxyglucose Positron Emission Computer Tomography and Ultrasonography for Assessing Remission in Patients with Rheumatoid Arthritis

Charline Rinkin[1], Pacôme Fosse[2], Nathalie Chapelier[1], Laurence Seidel[3], Adelin Albert[3], Roland Hustinx[4] and Michel Malaise[1], [1]Rheumatology Department, CHU of Liège, Liège, Belgium, [2]Nuclear Medicine Department, CHU of Angers, Angers, France, [3]Biostatistic Department, CHU of Liège, Liège, Belgium, [4]Nuclear Medicine Department, CHU of Liège, Liège, Belgium

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Imaging of Rheumatic Diseases Poster II: X-ray, MRI, PET and CT

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

The disease activity score based on 28 joints (DAS-28) might not be sufficient to assess remission in rheumatoid arthritis (RA). Several studies have shown that patients in remission according to DAS-28 still evidence synovitis by Ultrasound (US) and Magnetic Resonance Imaging (MRI). Those patients could eventually develop irreversible joint damage. Although ^{18}F-Fluorodeoxyglucose Positron Emission Computer Tomography (^{18}F-FDG PET/CT) is known to be correlated with DAS-28 in patients with active RA, its role in assessing remission has not yet been evaluated.

Methods:

A cross-sectional study was performed on 63 RA patients. A total of 1764 joints was assessed. Clinical assessment (DAS-28), ^{18}F-FDG PET/CT and US were performed the same day. Patients were classified in 3 groups according to their disease status : 22 (35%) were in remission (DAS-28 < 2.6), 31 (49%) had a low or moderate disease activity (2.6 < DAS-28 ≤ 5.1) and 10 (16%) had a severe disease activity (DAS 28 > 5.1). PET/CT was analyzed first visually, then semiquantitatively by determining the Standardized Uptake Value (SUV) of the positive joints. Synovitis were considered as positive in US according to OMERACT criteria. Logistic regression analysis was applied to discriminate between severe and non-severe patients and between subjects with and without remission with respect to the

number of PET/CT (or US) positive joints. Cutoff levels were determined from receiver operating characteristic (ROC) curve analysis and efficacy by the area under the curve (AUC).

Results: Of the 1724 articulations, 373 (21.2%) were tender, 242 (13.7%) were swollen, 361 (20.5%) were PET/CT positive and 152 (8.6%) were US positive. Discrimination between severe and non-severe patients was significant for PET/CT (AUC=0.77, P=0.0046) and for US (AUC=0.84, P=0.0030). Cut-off levels were 8 positive joints for PET-CT, 17.8 for the cumulative SUV and 3 positive for US. By contrast, patients in remission could not be discerned from others: AUC ranging from 0.51 to 0.60 (P > 0.05). Among the 22 RA patients in clinical remission, only 6 (27%) did not show any PET/CT positive joint and 5 (23%) had no positive joint by US. Moreover, in the remission group, 4 (18%) patients had more than 8 PET/CT positive joints and 4 (18%) more than 3 US positive joints. US and PET/CT were positive in different joints, predominantly in small joints of the hands for PET/CT.

Conclusion:

Both ^{18}F-FDG PET/CT and US identify subgroups of patients with highly positive imaging findings and low clinical activity. A prospective analysis is needed, in order to define the potential clinical relevance of such infra-clinical disease.

Session Title: Imaging of Rheumatic Diseases Poster II: X-ray, MRI, PET and CT

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Increased cardiovascular (CV) disease risk in RA has been attributed to traditional CV risk factors and/or to enhanced inflammation. Increased subclinical vascular inflammation has been demonstrated in a small sample of RA patients vs controls using ^{18}F-fluorodeoxyglucose positron emission tomography/computed tomography (^{18}F-FDG PET/CT). We examined the feasibility and reproducibility of ^{18}F-FDG PET/CT in a large cohort of RA patients in order to assess RA characteristics associated with vascular FDG uptake.

Methods : 100 RA patients underwent ^{18}F-FDG PET/CT scanning between 2013-2015 as well as coronary artery calcium (CAC) assessment, laboratory studies and clinical evaluation. ^{18}FDG-uptake was determined by three independent readers (Reading Center 1) by calculation of the mean and maximum (max) standardized uptake value (SUV) of the total ascending aorta (SUVtotal), and of the most diseased segment (SUVmds) within the ascending aorta. Inter-reader correlation among the three readers at Reader Center 1 was evaluated in 10 of the 100 scans and calculated using ANOVA. 15 scans were also read at a second independent reading center (Center #2). Inter-reader correlations were also calculated between Reading Centers 1 and 2.

Results : 91 of the 100 scans were evaluable for aortic FDG uptake. The Inter-reader correlation among three readers at Center 1 for maxSUVtotal was 0.997. Inter-reader correlations for meanSUVtotal and maxSUVtotal between Centers 1 and 2 were 0.979 and 0.939, respectively. Of the 91 RA patients, 80% were female, median DAS28-CRP= 3.7(2.8-4.5), CDAI= 16(7.6-28), mean disease duration of 7.2 years(1.6-14.4), 65% seropositive (RF or anti-CCP), 33% on current steroid with median dose of 5mg (4-10) per day, 77% on any non-biologic DMARD(s), and 40% on any biologic DMARD(s)]. In multivariable analyses, body mass index, use of antihypertensives,

and rheumatoid nodules, were positively, while anti-CCP was inversely, correlated with meanSUVtotal and meanSUVmds measurements. For meanSUVtotal and meanSUVmds, 53% and 59% of the explainable variability in the measures, respectively, were accounted for by RA factors. In separate analyses, higher aortic FDG uptake was significantly correlated with higher echocardiographic E/E' (a measure of diastolic dysfunction), and lower end-diastolic and stroke volumes (data not shown).

Conclusion: FDG aortic wall uptake can be performed and reproducibly measured in relatively large numbers of RA patients, and may serve as a feasible surrogate measure for CVD in future RA clinical trials. These analyses suggest that both conventional CV risk factors and RA disease characteristics are independently associated with FDG uptake in the aorta.

Multivariate analysis for SUVmean values of total and MDS

Modeled Covariates	SUVmean (total)		SUVmean(MDS)	
	β	P value	β	P value
BMI	0.0212	0.003	0.0271	0.005
BP medications	0.141	0.093	0.153	0.076
CCP>60 units	-0.207	0.014	-0.215	0.0143
Nodules	0.384	0.010	0.443	0.004
R^2	0.197		0.202	
%Adjusted R^2 Explained by RA factors	53% (0.529)		59% (0.590)	

B coefficient represents the average change inn SUVmeanMDS per 1 unit higher of the covariate. R^2 represents the total explainable variability in the outcome in the model containing the given covariates.
SUV: Standardized uptake value, BMI: Body mass index, BP: Blood pressure, CCP: Cyclic citrullinated peptide antibody

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Imaging of Rheumatic Diseases Poster II: X-ray, MRI, PET and CT

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Although widely used in research studies, most of the radiographic scoring systems for Rheumatoid Arthritis (RA) are not feasible in routine clinical practice as they are time-intensive and require specialized expertise. We have developed a novel method [VARA (Veterans Affairs RA) scoring method] to evaluate for the disease activity/damage in the RA hand joints. Using the VARA registry, a

multi-center database of veterans with RA, our previous study found that VARA scoring method correlated well with the widely accepted Modified Sharp/van der Hejjde scoring method when assessed by a single experienced reader. In this study we evaluated the inter-rater reliability of the VARA method using an experienced reader and a pair of Rheumatology trainees.

Methods:

The VARA radiographic method involves assessment for the presence of erosions (E) and joint space narrowing (JSN) in 3 joint regions of the hand and wrist, metacarpophalangeal (MCP) and proximal interphalangeal (PIP) joints. The presence of E or JSN each gives a score of 1 and absence gives a score of 0. Hence, the maximum E or JSN score for each hand is 3 each with a minimum of 0. Total hand scores (E + JSN) for each hand could range from 0-6, for a total score of 0-12 across both hands. The experienced reader (AE) used a standardized 30-minute presentation to train the trainees (PV and AD) to assess hand radiographs using the VARA method.

The trainees and the experienced reader independently read the most recent bilateral hand x-rays of 25 randomly selected patients using the VARA scoring method. All readers were blinded to each other's scoring results. Comparisons were made using combined scores from both hands. Inter-rater reliability was assessed several ways using a series of two-way, random, absolute agreement type intraclass correlation coefficients with single measures [ICC2 (A,1)]. Measures of E, JSN, and E + JSN were assessed using each pair of the three raters and all three together. Estimates were made of the time needed for each rater to complete the scoring of a set of radiographs.

Results:

Inter-rater reliability measures, which are estimates of the proportion of variability in scores accounted for by differences in true scores, were fairly high with E + JSN scores for any pair of raters producing an ICC in the range of 0.680-0.807 and all three raters combined yielding an ICC of 0.765 (Table). The time needed for VARA scores by the expert was estimated to be 3.3 minutes and the time needed for the trainees was 3.5 minutes.

Conclusion:

The VARA method is a very practical method of radiographic scoring and may be particularly useful for observational studies and in clinical practice where quantitative assessments of joint damage at a single time point by a single rater are needed. It is easy to learn and practical to perform in regular clinical practice and the reliability of this measure is quite good.

Table

Raters	Measure	ICC2(A,1)	95% C.I.
AD, PV	E + JSN	0.807	0.609, 0.911
AD, PV	E	0.672	0.381, 0.841
AD, PV	JSN	0.823	0.638, 0.918
AE, PV	E + JSN	0.799	0.600, 0.906
AE, PV	E	0.754	0.518, 0.884
AE, PV	JSN	0.680	0.304, 0.857
AE, AD	E + JSN	0.680	0.400, 0.845

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Imaging of Rheumatic Diseases Poster II: X-ray, MRI, PET and CT

Session Type: ACR Poster Session B

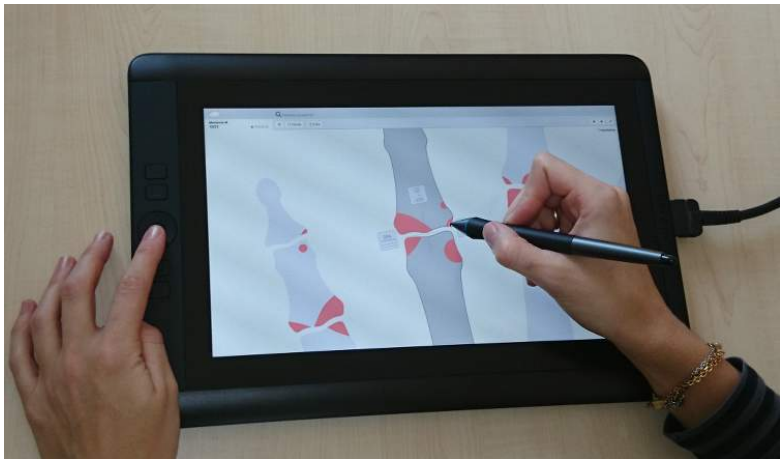
Session Time: 9:00AM-11:00AM

Background/Purpose:

Radiographic progression is a key outcome parameter in RA[1]. Manual scoring of joint damage based on the established scoring methods (e. g. Sharp Score) is a very time-consuming process with an average time of 30 minutes per image set[2]. The objective of this initial feasibility study is to evaluate a new tool for the computer based documentation of joint damage in RA.

Methods:

15 sets of X-rays of 15 patients with RA (12 female, mean age 70.9 ± 4.8 years) were read for bone erosions, joint space narrowing and bone mineralization in 54 hand areas and 28 feet areas as a consensus-reading by two experienced readers. A computer documentation system developed by the first author provides uniform templates of the hands and the feet, into which all identified erosions, joint space narrowing, (sub-)luxation and demineralization were transcribed with a stylus on a tablet (cf. Fig 1). The tool automatically computed the Ratingen[3] and Sharp/van der Heijde[4] scores from the documented structural changes. The time for the documentation in the computer was measured.



Results:

The mean time for the documentation of the structural changes in all areas was 16.0 ± 6.2 minutes (range 6-31 minutes; median: 15 minutes) per image set. The scores were automatically computed as 17.9 ± 14.1 points (range 1 - 50 points; median: 13 points) for the Ratingen score, as 32.5 ± 28.0 points (range 2 - 97 points; median: 27 points) for the erosion score segment and as 54.7 ± 27.0 points (range 11 -

105 points; median: 52 points) for the joint space narrowing segment of the Sharp/van der Heijde score.

Conclusion:

The tool allows for an easy and fast documentation. In this pilot study, the times to assess and document the structural changes on the hand and foot joints in patients with RA were significantly lower than those reported in the literature[2]. Multiple scores are computed automatically from the same source data by the system. These points might be of great potential and benefit for X-ray scoring over the time, especially in clinical and research settings.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Imaging of Rheumatic Diseases Poster II: X-ray, MRI, PET and CT

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Joint space width (JSW) is suggested as an indirect measure of arthritis disease activity and could be used as a measure of radiographic progression with consequent narrowing and cartilage loss. The current gold standard for assessing rheumatoid arthritis (RA) radiographic damage is a semi-quantitative analysis by trained physicians where JSW is calculated from radiographs [Sharp, 2005]. Alternative methods include ultrasound [Möller, 2009] and magnetic resonance imaging [Peterfy, 2013] for radiation-free visualisation, and high resolution peripheral quantitative computed tomography (HR-pQCT) for three-dimensional (3D) quantification [Barnabe, 2013; Burghardt, 2013]. HR-pQCT is a novel imaging instrument for bony damage in RA, and is undergoing validation as an outcome measurement tool. In this work, three published techniques for high-throughput, robust, and reproducible measurement of JSW from HR-pQCT derived data are compared and contrasted, in order to reach consensus on a new standard in arthritis damage assessment.

Methods: The second and third metacarpophalangeal joints (MCP) of 30 RA and control subjects (n=60 joints) were imaged at three sites – 10 from the University of Lyon (LYN), 9 from the University of California San Francisco (SFR), and 11 from the University of Calgary (CLG) – using an XtremeCT I (Scanco Medical AG, Switzerland) and the agreed Study grouP for xtrEme Computed Tomography in

Rheumatoid Arthritis (SPECTRA) protocol [Barnabe, 2012]. The data was then segmented to remove bone from background, and 3D JSW was calculated using each of three in-house methods [Barnabe, 2013; Burghardt, 2013; Boutroy, 2013]. The minimum, maximum and mean JSW were compared, and the intraclass correlation coefficients (ICC) calculated.

Results: The results demonstrate a high ICC (upper 95%CI, lower 95%CI) for minimum JSW of 0.986 (0.978, 0.991) between the three methods, with the ICC for mean JSW at 0.981 (0.971, 0.988), and for maximum JSW at 0.910 (0.861, 0.944).

Conclusion: The high correlation between the 3D methods suggest that they all calculate a minimum JSW from approximately the same volume of interest, while variation increases for mean and maximum JSW values which is directly related to the volume of interest and segmentation methods used in the individual methods. The goal in developing these methods is to detect arthritis change through longitudinal monitoring of patients. In this work three methods for assessing JSW are compared in order to reach consensus on a high-throughput, robust, and reproducible measurement of JSW from HR-pQCT.

Simplified Larsen Erosion Score Is Compatible with the Classic Larsen Score but Less Time Consuming in Practice

Michael Ziegelasch[1], Alf Kastbom[2], Thomas Skogh[3], Kristina Forslind[4] and Alf Kastbom, [1]Rheumatology Department, Rheumatology/AIR, Linkoping, Sweden, [2]Department of Clinical and Experimental Medicine, Rheumatology/AIR, Linköping, Sweden, [3]IKE/Rheumatology, Linköping University, Linköping, Sweden, [4]Department of Medicine, Helsingborgs Lasarett, Section of Rheumatology, Helsingborg, Sweden

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Imaging of Rheumatic Diseases Poster II: X-ray, MRI, PET and CT

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Untreated rheumatoid arthritis (RA) often leads to joint space narrowing (JSN) and erosions in synovial joints. Scoring systems like Sharp van der Heijde and Larsen are commonly used as outcome measures in clinical trials, but they are time consuming and thus not used in clinical practice. It would be important to introduce a simple radiographic measure to guide treatment decisions in clinical routine. For Sharp van der Heijde score the simplified score "SENS" (1) is available. As we use Larsen score in our studies, we wished to know if a simplified Larsen score would be feasible. Thus, we applied the "simplified Larsen erosion score" (SLES), documenting the number of joints with erosions, and evaluated whether or not it corresponds to radiological changes assessed by the total Larsen score.

Methods:

217 patients diagnosed with recent onset RA in the Swedish "TIRA-2" cohort participated in this study. All patients fulfilled the ACR 1987 criteria. Radiography of hands and feet were performed at diagnosis, 1, 2 and 3 years. The radiographs were scored by the classical Larsen score and by SLES where 32 joints (PIP 2-5, MCP 2-5, four quadrants in the wrist, MTP 2-5) are assessed – in Larsen score both JSN and erosions, in SLES only erosions. In Larsen score changes are graded from 0-5 (0= no changes, 5= mutilating changes). The total Larsen score range is 0-160. In SLES, erosions are graded only as present or not, i.e. 0= no change and 1= erosion(s). The SLES range is 0-32.

Results: Of the 217 patients included with radiographs at inclusion 155 had radiographs at 1 year, 119 at 2 years and 168 at 3 years. Using Spearman's Correlation test, SLES gave the same information as Larsen score regarding radiographic joint damage as well as the total

Larsen score (p<0,01) at all time points. (Table 1)

Table 1

	Total Larsen, mean	SLES, mean	Correlation coefficient	P-value
0 months	2.58	0.31	0.496	<0.01
12 months	2.83	0.40	0.433	<0.01
24 months	3.42	0.47	0.483	<0.01
36 months	4.27	0.51	0.494	<0.01

Conclusion:

Simplified Larsen erosion score provided similar information regarding radiographic changes as the total Larsen score among our patients with recent onset RA (<0.01). As being less time consuming, the SLES could be an applicable tool to rapid and easy assessment of radiographic damage.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Imaging of Rheumatic Diseases Poster II: X-ray, MRI, PET and CT
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Joint space narrowing (JSN) and erosions are the major radiologic markers of radiographic progression in rheumatoid arthritis (RA), as scored by the Sharp/van der Heijde score (SHS). JSN may also be a manifestation of (primary) osteoarthritis becoming more prominent with age. We hypothesize that the severity of JSN progression and predictors of JSN progression may differ between older and younger RA patients.

Methods:

Ten year follow-up data of the BeSt study, a randomized controlled treat-to-target (Disease activity score (DAS)≤2.4) trial in early RA were used. Annual X-rays of hands and feet from baseline to year 10 were scored with the SHS by two independent readers, blinded for patient identity and time order. Subgroups were defined by age at baseline: ≥55 (median age), ≥40<55 and <40 years. Poisson regression with multiple imputation for missing data (7% and 45% of the radiographs at baseline and year 10) was used to identify univariate predictors. Factors with p<0.2 were entered in a multivariate regression analysis. Post-hoc Bonferroni corrections were used to correct for multiple testing.

Results:

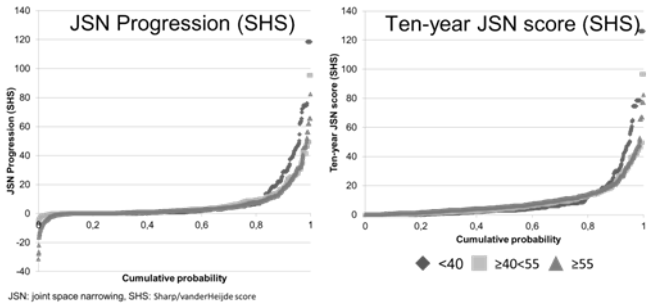
Baseline median (interquartile) SHS scores were higher in patients ≥55 compared to the other groups (≥55: 2.5 (1.0-7.4); ≥40<55: 1.0 (0.0-4.5); <40: 1.0 (0.0-3.0); p≤0.001). Also, higher baseline JSN was observed in patients ≥55 compared to the other groups: 2.0 (0.0-6.0), 1.0 (0.0-3.0) and 0.3 (0.0-3.0), p≤0.001, respectively. After ten years, total JSN and SHS scores were similar in all age-groups. Although fewer patients <40 years appear to have JSN progression, if they do show JSN progression it is more severe (figure 1).

Table 1 shows significant univariate risk factors. In the multivariate regression, in patients ≥55 mean erythrocyte sedimentation rate (ESR) over ten years follow-up (RR 1.02, 95% CI (1.00-1.03)) and the combined presence of rheumatoid factor and anti-citrullinated protein antibodies (RF+/ACPA+) (3.27 (1.25-8.53)) were significantly associated with JSN progression. In patients ≥40<55 no significant risk factors were revealed. In patients <40 baseline swollen joint count (SJC) (1.09 (1.01-1.18)) and mean ESR (1.04 (1.02-1.06)) were significantly associated.

Conclusion:

At baseline, RA patients ≥55 years had more JSN but after 10 years of DAS≤2.4 targeted treatment they do not show more often or more severe JSN progression. Independent risk factors for JSN progression were mean ESR in patients <40 and those ≥55 years, RF+/ACPA+ in patients ≥55 years and SJC in patients <40 years. This suggests that mechanisms leading to JSN progression vary between age groups.

Figure 1: JSN progression and total JSN score after ten years



JSN: joint space narrowing, SHS: Sharp/vanderHeijde score

Table 1: Univariate Poisson regression analysis

≥55 n=248	RR (95% C.I.)	≥40<55 n=179	RR (95% C.I.)	<40 n=81	RR (95% C.I.)
Mean ESR	1.02 (1.01-1.03)	Mean ESR	1.02 (1.00-1.04)	Mean ESR	1.04 (1.00-1.08)

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Imaging of Rheumatic Diseases Poster II: X-ray, MRI, PET and CT
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Several scores have been developed to assess radiographic damage in AS. However, we do not know how they perform in early phases of the disease. Our aim was to compare the performance of different radiographic scores of the spine in patients with early axial spondyloarthritis (axSpA).

Methods: Yearly radiographs from a 2-year follow-up of the DESIR cohort from patients fulfilling the ASAS axSpA criteria have been used. Spinal (cervical, thoracic and lumbar) and sacro-iliac (SI) radiographs were scored independently by two readers for the presence of the different damage aspects enabling the calculation of different scores: mSASSS (0-72), SASSS (0-72), RASSS (0-84) and BASRI-spine (0-12), using the averaged scores between readers per vertebral corner (VC)/SI joints. Additionally, a variation of the BASRI-spine was computed adding an overall score for the thoracic spine (0-16). Following the OMERACT proposal, scores were compared with regard to truth, discrimination (sensitivity to change and reliability) and feasibility. Status (at baseline of first x-ray available) and 2-year progression scores were calculated for each of the methods as well as the proportion of patients with any change (change>0).

Results: In total, 486 patients (mean age 33.0 (SD 8.6) years, 50% males) had at least one radiograph available. At baseline, scores ranged from 0 and 21.6 for the mSASSS (30% of the maximum of the scale), 20.6 for RASSS (25% of maximum), 6 for SASSS (8% of maximum), 8.5 for BASRI-spine (71% of maximum) and 10.25 for BASRI-spine with thoracic spine (64% of maximum). Status scores and 2-year progression scores available are shown in the table. The proportion of patients with any 2-year change was the following: 9.9% for mSASSS, 10.7% for RASSS, 6.9% for SASSS, 19.2% for BASRI-spine and 22.0% for BASRI-spine with thoracic spine. Absolute change scores (table) showed that the mSASSS and RASSS captured most change. 2-year RASSS progression occurred in a balanced way across segments (cervical, thoracic and lumbar), when taking the number of VCs included per segment. All scores had acceptable reliability. In what concerns feasibility, all scores seemed to be feasible, but the BASRI-spine (+/- thoracic spine) was more frequently missing (up to 15% of the cases), as it requires also the availability of SI joints.

Table - Status and 2-year progression for the different radiographic scoring methods

	mSASSS mean (SD) n = 481	RASSS mean (SD) n = 481	SASSS mean (SD) n = 483	BASRI spine mean (SD) n = 447	BASRI spine with thoracic mean (SD) n = 442
STATUS SCORES					
Total score	0.57 (2.37)	0.54 (2.34)	0.17 (1.03)	1.35 (1.62)	1.46 (1.80)
Cervical segment	0.36 (1.69)	0.34 (1.66)	--	0.16 (0.55)	0.17 (0.55)
Lumbar segment	0.21 (1.09)	0.16 (1.04)	0.17 (1.03)	0.18 (0.54)	0.19 (0.55)
Lumbar segment with thoracic segment included	--	0.19 (1.13)	--	--	--
Thoracic segment	--	0.03 (0.28)	--	--	0.09 (0.38)
Lumbar anterior	--	--	0.16 (1.03)	--	--
Lumbar posterior	--	--	0.00 (0.02)	--	--
SI joints	--	--	--	1.00 (1.13)	1.00 (1.13)
2-YEAR PROGRESSION SCORES					
	mSASSS n = 322	RASSS n = 319	SASSS n = 335	BASRI spine n = 287	BASRI spine with thoracic n = 268
Total score	0.27 (1.57)	0.36 (1.74)	0.15 (0.78)	0.05 (0.72)	0.07 (0.83)
Cervical segment	0.19 (1.16)	0.17 (1.18)	--	0.04 (0.36)	0.03 (0.35)
Lumbar segment	0.08 (0.63)	0.13 (0.66)	0.15 (0.78)	0.01 (0.40)	0.02 (0.35)
Lumbar segment with thoracic segment included	--	0.18 (0.84)	--	--	--
Thoracic segment	--	0.06 (0.38)	--	--	0.00 (0.32)
Lumbar anterior	--	--	0.13 (0.65)	--	--
Lumbar posterior	--	--	0.02 (0.33)	--	--
SI joints	--	--	--	0.01 (0.36)	0.01 (0.37)

Conclusion: The existing scoring methods to assess radiographic damage performed well in early phases of axSpA. The mSASSS and RASSS captured most change, but there was no gain in additionally scoring the thoracic spine for the RASSS. The mSASSS remains the most sensitive and most adequate scoring method in axSpA, including early phases of the disease.

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Imaging of Rheumatic Diseases Poster II: X-ray, MRI, PET and CT
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Detecting sacroiliitis on plain pelvic X-rays is known to be difficult, resulting in large variability regarding presence/absence of radiographic sacroiliitis. In addition, the number of patients with radiographic sacroiliitis in a cohort of patients with axial SpA can be expected to (slightly) increase or remain stable over time but certainly not decrease. We have investigated the change of pelvic X-ray abnormalities over time in the Assessment of SpondyloArthritis international Society (ASAS) validation cohort.

Methods: In the ASAS study, 975 patients with either chronic back pain (>3 months) of unknown origin beginning <45 years of age or undiagnosed peripheral arthritis, and/or enthesitis, and/or dactylitis were assessed at baseline. From these, 565 patients were followed and reassessed at follow-up [mean follow-up time 4.44 years (SD: 1.01)]. Patients with radiographs of the pelvis (X-SI) available at baseline and follow-up were included in this analysis (n=357). Readings were performed locally at both time points, either by the same or by a different reader. Positive cases were defined as definite radiographic sacroiliitis (grade ≥2 bilaterally or grade 3–4 unilaterally) according to the modified New York criteria (mNY).

Results: In total, 357 patients with follow-up visit had also baseline radiographs available. The mean age at baseline was 33.8 years (SD: 10.8), 47.9% were men, 50.2% had active inflammation of the sacroiliac joints on MRI and 48.7% were HLA-B27 positive. The proportion of patients fulfilling the radiographic mNY at baseline was 17.4% (62/357), whereas at follow-up 22.4% (80/357) of the patients fulfilled these criteria (table). However, more than half of the patients (36/62; 58.1%) with positive baseline X-SI were graded negative at follow-up. Moreover, 54/295 (18.3%) became positive at follow-up. However, given the percentage of the patients 'becoming negative', it is hard to decide what the real rate of progression is.

Conclusion: Our results confirm that radiographic sacroiliitis, defined by the mNY, is a poorly reliable method. Consequently, this method is difficult to use as an outcome measure to define progression in a cohort of patients, with and without treatment, although paired reading may improve the result.

Table: radiographic sacroiliitis according to the mNY at baseline and at follow-up (on average 4.4 years).

	Follow-up radiograph		
Baseline radiograph	Positive	Negative	**Total**
Positive	26	36	**62**
Negative	54	241	**295**
Total	**80**	**277**	**357**
PPV (%)	41.9		
NPV (%)	81.7		

mNY: modified New York criteria. PPV: positive predictive value; NPV: negative predictive value.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Imaging of Rheumatic Diseases Poster II: X-ray, MRI, PET and CT
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: To compare the respective performances of the pelvic plain radiograph (RX), thoraco-abdominal and pelvic CT (TAP-CT) and MRI of the sacroiliac joints (SIJ-MRI) to CT of the sacroiliac joints (SIJ-CT) for the diagnosis of structural sacroiliitis in a population suffering from spondyloarthritis (SpA) meeting the New York or ASAS criteria.

Methods: All radiographic or non-radiographic SpA patients eligible for biologic treatment who received a pretherapeutic check up including the four imaging techniques in the same year from 2005 to 2012 were selected. Sacroiliitis was assessed on Rx according to New York criteria independently by a rheumatologist and a radiologist and on TAP-CT, SIJ-MRI and SIJ-CT for the presence of erosion on at least two consecutive slices. A final diagnosis was established for conflicting exams.

Results: Of the 58 selected patients, sacroiliitis was diagnosed on RX, TAP-CT, SIJ-MRI and SIJ-CT in 32, 26, 34 and 35 times respectively. Inter-reader agreements were good for the grade of sacroiliitis (Kappas between 0.60 and 0.76) and moderate for the diagnosis of sacroiliitis (Kappas between 0.45 and 0.55) for the four imaging techniques. The sensitivities of RX, TAP-CT and SIJ-MRI in comparison to SIJ-CT were 82.8%, 71.4% and 85.7% respectively and the specificities were 86.9%, 100% and 82.6% respectively with SIJ-CT considered gold standard.

Conclusion: This study demonstrates the interest of SIJ-MRI and TAP-CT for the diagnosis of structural sacroiliitis in comparison with the SIJ-CT with the same level of performances as RX. These imaging techniques avoid redundant exams.

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Imaging of Rheumatic Diseases Poster II: X-ray, MRI, PET and CT
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: It is known that in axial spondyloarthritis (axSpA) inflammatory lesions on MRI of the SI joints (MRI-SI) can change over time. The usefulness of repeating imaging in the diagnostic process is unclear. By this study we aim to investigate how patients with short-term chronic back pain are classified by the ASAS axSpA- criteria at baseline and after 1-year follow-up, focussing on the role of imaging.

Methods: Patients in the SPACE-cohort (back pain: ≥ 3 months, ≤ 2 years, onset < 45 years) with (suspicion of) axSpA underwent MRI and X-rays of the SI-joints at baseline and 1-year follow-up. Patients with complete MRI- and X-SI data at both timepoints were included in the analysis (n=185). MRI-SI and X-SI were scored by 3 different well-calibrated readers independently according to the ASAS-definition for a positive MRI and the mNY-criteria, blinded for patient characteristics and time sequence. Fulfilment of ASAS-MRI or mNY-criteria was considered positive if 2/3 readers agreed. At each timepoint, patients were classified according the ASAS axSpA-criteria and grouped in the different arms (imaging arm: mNY+/- or MRI+/-; clinical arm, fulfilment of both arms and possible axSpA). At year one, in contrary to the normal application of the criteria, we grouped patients according to the finding at that timepoint, ignoring previous imaging findings.

Results: At baseline, 92/185 patients (49.7%) fulfilled the ASAS criteria (clinical arm: 53; imaging arm: 15, both arms: 24) (table). At 1 year, 14 additional patients fulfilled the criteria (8 clinical arm; 5 imaging arm only; 1 both arms). After 1 year, in 12 patients MRI-SI became positive. As a result,14/93 (15.1%) of the no SpA or possible SpA patients at baseline could be classified additionally as axSpA because of additional SpA features (n=8), a positive MRI (n=4) or sacroiliitis according to the mNY-criteria (n=2), On the other hand, MRI-SI became negative after 1 year in 12 other patients. Of these patients, 10 still fulfilled the ASAS criteria (clinical arm (n=7) or both arms (n=3)). Only 4 patients (classified as axSpA at baseline) would be missed if imaging would have been performed only at 1 year (due to negative MRI or x-ray findings).

Conclusion: In our cohort, a significant number of patients with no SpA or possible SpA at baseline developed (additional) SpA features leading to fulfilment of axSpA criteria at year one.

Table: impact of repeating imaging after 1 year on the ASAS axSpA classification of patients

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Imaging of Rheumatic Diseases Poster II: X-ray, MRI, PET and CT
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Axial spondyloarthritis (axSpA) can be difficult to diagnose at an early stage of the disease. Identification of structural lesions of the sacroiliac joints (SIJ) on X-rays is often delayed for several years and remains very disputable, even for trained

readers. Inflammatory lesions on MRI are taken into account in classification criteria of axSpA but the validity of MRI in detecting structural lesions in clinical practice has not been assessed. The objective of this study was to evaluate the reliability of recognising structural lesions on MRI-SIJ in patients with inflammatory back pain (IBP) suggestive of axSpA in clinical practice compared to a central reading.

Methods: Patients aged 18-50, with recent (<3 years) and chronic (≥3 months) IBP, suggestive of axSpA were included in the DEvenir des Spondyloarthrites Indifférenciées Récentes (DESIR) cohort. MRI-SIJ structural lesions (erosions, fatty lesions, ankylosis) were scored by a local reader (non specifically trained radiologist or rheumatologist, with access to clinical data) and by two trained central readers (blinded for clinical data and other imaging modalities). Local readers scored each SIJ in 3 grades (0=normal, 1=doubtful, 2=definite) regarding the presence of structural lesions. A method similar to the SPARCC SIJ Structural Score was used for central reading.

The analyses were done based on the individual scores as well as the mean score of the two central readers.Agreement was calculated (kappa; % positive and negative agreement) between central readers regarding 9 possible definitions of a positive MRI-SIJ (table), and between local readers (3 definitions).

Results: In this analysis, 664/708 patients with complete available images were included. According to the central reading 39% had a least 1 erosion, fatty lesion or (partial) ankylosis, and according to the local reading, 35.4% patients had a positive MRI-SIJ based on structural lesions(at least unilateral 'doubtful' or 'definite structural lesion'). Agreement between central readers was "moderate" for 4 definitions MRI-SIJ structural lesions, and "fair" for the other 5 definitions (data not shown).When comparing local to central reading (both definitions 1) as external standard (table, mean score central readers), there were 13.1% false positive (overclassified) and 16.7% false negative classifications (not detected).Agreements improve when adding fat lesions to erosions in the definition of a positive MRI-SIJ.

Conclusion: In this study, agreement on positive MRI-SIJ based on the presence of structural lesions was fair to moderate between local and central readers, as well as between trained central readers. The reliability improved when fat lesions are combined with erosions. The diagnostic value of MRI structural lesions needs to be determined in longitudinal follow-up.

Change in MRI in Patients with Spondyloarthritis Treated with Anti-TNF Agents : Systematic Review of the Literature

Gisèle KHOURY[1], BG Combe[2] and Cédric Lukas[3], [1]Rheumatology, Hopital Lapeyronie, Montpellier, France, [2]Lapeyronie, Montpellier, France, [3]Hopital Lapeyronie, Montpellier, France
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Imaging of Rheumatic Diseases Poster II: X-ray, MRI, PET and CT
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: The follow-up of axial spondyloarthritis (SpA) remains difficult in clinical practice, mainly based on patient-reported outcomes, whereas objective parameters in disease monitoring are often lacking, especially in axial manifestations. MRI of the spine and sacroiliac joints (SIJ) might be relevant for difficult cases, provided that its validity and correlation with clinical, biological parameters, functional and activity scores is ascertained.

The aim of this study was to assess the effect of TNF alpha inhibitors (TNF-) on MRI scoring of inflammation on spine and SIJ and to evaluate their correlation with the clinical and biological parameters used in daily practice.

Methods: A systematic review of the literature using PUBMED and the Cochrane library as well as proceedings from recent major relevant congresses was performed until January 2015. All randomized controlled trials and controlled cohorts reporting the effect of TNF- on spine and SIJ MRI scores (ASspiMRI, SPARCC, Berlin) were selected. Data were collected using a predetermined form. The outcomes were: the change in scores between baseline and follow up in TNF- and control groups, the correlation of theses changes with CRP, ESR, BASDAI, BASFI, ASDAS, pain and morning stiffness. When appropriate, statistical analysis determined the pooled therapeutic effect of TNF- on MRI scores computed by meta-analysis.

Results: Out of 365 screened references, 58 studies were included : 14 using ASspiMRI score, 8 using spine SPARCC score, 8 using SPARCC SIJ score, 7 using BERLIN spine score, 7 using BERLIN SIJ score and 14 using other scores. In ASspiMRi at 12 weeks and 2years follow up, and in SPARCC spine score at 12 weeks follow up a non significant difference in MRI score decrease between the TNF alpha inhibitor group and control group was reported. A significant decrease in the SPARCC SIJ score at 12 weeks in TNF alpha inhibitor group was reported. The correlation between MRI spine and SIJ scores on one side, and the clinical and biological data on the other side was very heterogeneous across the different reports. However, an association was usually reported between the MRI scores and CRP, ESR and ASDAS.

Conclusion: Considering our findings, MRI (especially MRI of the spine) seems to insufficiently reflect the axial activity of SpA patients to recommend its use in individual follow-up or assessment of patients. Regarding its diagnostic value or relevance in the apprehension of the pathophysiology of the disease however, it remains currently the most accurate tool.

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Imaging of Rheumatic Diseases Poster II: X-ray, MRI, PET and CT
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Conventional radiography is the main imaging modality to assess damage in the spine in ankylosing spondylitis. Modified Stoke Ankylosing Spondylitis Spine Score (mSASSS) has been endorsed by OMERACT as being more sensitive to change, therefore more commonly used in clinical trials. We aimed to compare the reliability of mSASSS on status scores by using different approaches to understand how different readers agree on overall scores and on the presence of individual findings included in mSASSS.

Methods: : The SPAR (The Spondyloarthritis Radiography) training module was used for the purpose of the study. After a standardization exercise, 4 investigators scored 68 plain radiographs of the cervical and lumbar spine of 34 patients at 2 time points with 2-year intervals. The anterior vertebral corners in lateral images were scored for erosions, sclerosis, squaring, syndesmophytes and ankylosis and a total mSASSS score was calculated. The reliability of the 4 readers was compared with 2 gold standard readers using ICC (intraclass coefficient). Additionally, the reproducibility of each finding in 1632 vertebral corners was calculated by kappa analysis and positive agreement rates.

Results: The reliability analysis using ICC revealed that all readers had excellent agreement with both gold standards with a range of ICC between 0.858-0.948. The kappa analysis showed worse agreement within lesions (table): For syndesmophytes agreement was between 0.394-0.677. The highest kappa values were detected for ankylosis, in a range between 0.624-0.889. The positive agreement rates showed that erosions were never detected at the same vertebral corner by 2 readers (positive agreement rate of 0%). The positive agreement rates for other score 1's were also very low (sclerosis mean for agreement (range): 5.2% (0-15); squaring: 22.6% (0-59.7)). Ankylosis had the highest positive agreement rate, between 77.8 % (66.1-89.6%) and syndesmophytes had a mean positive agreement of 48.9% (39.4-63.9).

Conclusion: Our results show that there is a poor agreement on grade 1's between readers which has a risk of increasing measurement error. The currently used definitions of reliability have a risk of overestimating the reproducibility (such as high ICC values) and the results of mSASSS should be interpreted with precaution.

Assessment of Focal Fat Infiltration in Sacroiliac Joints in Patients with Spondyloarthritis By 1.5T Versus 3.0T Magnetic Resonance Imaging: Is the Field Strength Important to Contrast to Noise Ratios, Reproducibility and Total Scores?

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Imaging of Rheumatic Diseases Poster II: X-ray, MRI, PET and CT

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Reporting of focal fat infiltrations (FFI) in sacroiliac joints (SIJs) is becoming more important in patients with axial spondyloarthritis (SpA) since this lesion has been shown to be an independent predictor of ankylosis. T1 relaxation times depend on magnetic field strength and hence T1 contrast behavior of bone marrow (i.e. the visualization of fat in the bone marrow) is magnetic field strengths dependent. Therefore FFI may be scored differently depending of the field strength.

Methods:

19 SpA patients (10 males age 42.8±13.8 years, 9 females age 42.5±12.5 years) and 3 healthy volunteers (1 male age 49 years, 2 females age 39.5±9.1 years) underwent MRI at 1.5T (Time to repeat (TR)/ time to echo (TE) 550/14 ms voxel dimension 1x1.5x4 mm) and 3T (TR/TE: 700/20 ms voxel dimension 1x1.5x4 mm). The cartilaginous part of the SIJs were divided into 8 quadrants and evaluated on 5 consecutive slices (1) and were analyzed for FFI in two ways: 1. If FFI was present the signal intensity (SI) was measured. On every slice normal bone marrow SI and standard deviation of the noise (SDn) was measured. Contrast to noise ratio (CNR) was calculated as the difference between normal SI and FFI SI divided by SDn. 2. All quadrants were scored for presence/absence of FFI according to the Spondyloarthritis Research Consortium of Canada (SPARCC) SIJ Structural Score (SSS)(1). The intra-observer variation of both methods was assessed in six patients and expressed as the Intraclass Correlation Coefficient (ICC). The paired t-test was used for comparing CNR results. SSS results were compared using the Wilcoxon Signed Rank test.

Results:

The ICC for CNR was 0.90 at 1.5T and 0.77 at 3T, and for SSS 0.96 at 1.5T and 0.94 at 3T. On both right and left side, CNR was higher at 3T ($p < 0.001$) compared to 1.5T. SDn was lower ($p < 0.001$) at 3T compared to 1.5T. For SSS the sum of scores was 160 (mean 7.3) at 1.5T and 169 (7.7) at 3T ($p = 0.87$)

Conclusion:

3T compared to 1.5T MRI provides a better contrast to noise ratio, but the intra-observer agreement and total scores of focal fat infiltration

are identical.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Imaging of Rheumatic Diseases Poster II: X-ray, MRI, PET and CT

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Imaging and pathology studies have established the close relationship between intraosseous tophus and bone erosion in gout. The tophus is an organised structure consisting of urate crystals and a chronic inflammatory soft tissue response. It is currently unknown whether bone erosion in gout occurs due to direct effects of urate crystals or indirect effects of the soft tissue response. The aim of this work was to examine the relationship between bone erosion and each component of the tophus.

Methods: Plain radiographs and computed tomography (CT) scans of the feet were prospectively obtained from 92 people with tophaceous gout. The ten metatarsophalangeal joints were scored on XR for Sharp-van der Heijde erosion score (scale 0-10). Conventional CT and dual energy CT (DECT) images were assessed at each joint for the presence and total volume of tophus (using manual outlining analysis of conventional CT images) and the presence and volume of tophus urate deposition at the same joints (using automated volume DECT analysis). Tophus soft tissue volume was calculated by subtracting the DECT tophus urate volume from the total CT tophus volume. In total, 918 joints were available for analysis. The readers of the XR and CT/DECT were blinded to each other's scores and all clinical characteristics of the patients. Data were analysed using generalized estimating equations to account for repeated measures in participants, and mediation analysis to examine the direct and indirect effects of urate volume on bone erosion score.

Results: XR erosion was present at 261 (28.4%) joints. Mean (SD) XR erosion score was 1.2 (2.3) in all joints and 4.1 (2.5) in those with XR erosion. CT tophus was present at 447 (48.7%) joints and DECT tophus urate was present at 443 (48.3%) joints. CT tophus was adjacent to bone in 74.7% of all XR erosions (odds ratio (OR) 10.1 [95% CI 6.8-14.8]) and DECT tophus urate was adjacent to bone in 64.8% of all XR erosions (OR 10.6 [95% CI 7.1-15.8]).

Mean (SD) total tophus volume was 1.88 (4.25) cm^3, urate volume was 0.27 (0.80) cm^3, and soft tissue volume was 1.61 (3.63) cm^3. In mediation analysis, urate volume and soft tissue volume were directly associated with XR erosion score (Figure). About a third of the association of urate volume with XR erosion score was indirectly mediated through the strong association between urate volume and soft tissue volume.

Conclusion: Urate and soft tissue components of the tophus are strongly and independently associated with bone erosion in gout. These data suggest that tophi contribute to bone erosion in gout both through direct urate crystal effects and through indirect effects of soft tissue on bone.

Figure: Summary of the mediation analysis. Values represent standardized path coefficients (n=92). The directions of these associations were dictated by biological experience. R^2 for model =0.52.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Imaging of Rheumatic Diseases Poster II: X-ray, MRI, PET and CT
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Radiographic damage is frequently observed in patients with longstanding gout. Although cross-sectional studies have described factors associated with joint damage in gout, there are very few prospective studies that have investigated radiographic progression. The aim of this prospective observational study was to determine the rate of progression and factors associated with progressive radiographic damage in gout.

Methods: People with gout according to the 1977 ARA criteria, with disease duration <10 years were recruited into this prospective observational study. At the baseline visit, detailed clinical assessment was undertaken in 295 participants including subcutaneous tophus count, joint counts, blood tests and plain radiographs of the hands and feet. Participants were invited to attend a further study visit with repeat testing three years after the baseline visit. Paired radiographs (XR) were scored for erosion and joint space narrowing (JSN) in chronological order by two readers according to the gout-modified Sharp van der Heijde XR damage score. Both readers were blinded to each other's scores and all clinical variables. Inter-reader intraclass correlation coefficient (95% CI) for the XR damage score was 0.91 (0.87-0.94). The mean scores for both readers were used in the analysis. Pearson correlation and stepwise linear regression models were used to identify variables independently associated with progressive XR damage.

Results: Paired XR were available for 135 participants. At baseline, mean (SD) erosion score was 4.9 (10.2), JSN score was 6.0 (8.6) and total XR damage score was 10.9 (16.9). At Year 3, mean (SD) erosion score was 7.7 (14.6), JSN score was 7.1 (9.7) and total XR damage score was 12.8 (19.2). Change in subcutaneous tophus count correlated with change in erosion score ($r=0.36$, $p<0.001$), change in JSN score ($r=0.33$, $p=0.001$), and change in total XR damage score ($r=0.53$, $p<0.001$). In stepwise linear regression analysis, baseline XR damage score and change in subcutaneous tophus count independently predicted change in total XR damage score over three years (model $R^2=0.48$, $p<0.001$), with the following baseline variables excluded from the model: tophus count, swollen joint count, tender joint count, C-reactive protein, and serum urate. Baseline XR score and change in subcutaneous tophus count also predicted change in the XR erosion and JSN scores when analysed as separate dependent variables in the regression models.

Conclusion : The presence of radiographic damage at baseline and development of new subcutaneous tophi are associated with progressive joint damage in people with gout. These data provide further evidence that the tophus plays a central role in joint damage in gout.

To PET or Not to PET in General Rheumatology Practice

Kavina Shah, Roshni Doshi, Joshua Balogun-Lynch, Henry Penn and Shahir Hamdulay, Rheumatology, Northwick Park Hospital, Middlesex, United Kingdom

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Imaging of Rheumatic Diseases Poster II: X-ray, MRI, PET and CT

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Fluoro-deoxy-glucose positron emission tomography with computerised tomography (PET/CT) is an imaging modality which identifies tissues with high metabolic activity. It is used in the diagnosis of patients with malignancy, infections, inflammatory diseases and pyrexia of unknown origin (PUO). Although useful, PET/CT has a high radiation dose of 14mSv and therefore should be used cautiously. We investigated the role of PET/CT in general rheumatology practice aiming to understand the indications, diagnostic yield and whether there was additional benefit to whole-body CT (WB-CT).

Methods:

PET/CT requests arranged by 8 rheumatologists between January 2008 and April 2015 were retrospectively reviewed for indication, inflammatory markers, PET/CT, WB-CT findings and final diagnoses. Definitions for analysis: true positive - PET/CT abnormality directly contributing to diagnosis, false positive - abnormality not contributing to diagnosis, true negative- normal scan, false negative- normal scan but disease process identified at 6 months follow-up. A final diagnosis was made by physician assessment, other investigations and tissue biopsy where indicated.

Results:

80 PET/CT requests were identified (55 females), mean age 63 years (range 24-86). A final diagnosis was established in 86%. Indications included large vessel vasculitis (34), disease activity progression (3), infection (2), malignancy (22), PUO (2), unexplained inflammatory response (18).

Two sub-groups were analysed; first presentation with no diagnosis (n=53) and prior established rheumatological diagnosis (n=27).

First presentation: PET/CT identified abnormalities in 23/53 (43%) cases, of which 10 (43%) contributed to diagnosis (malignancy-2, large vessel vasculitis-6, PMR-1 and infection-1). 13 (25%) identified non-specific abnormalities with no contribution to a final diagnosis. 16 (30%) were negative and no new diagnosis was apparent at 6 months follow-up. Ten patients did not reach a final diagnosis. The sensitivity in this setting was 45% and specificity 76%.

Established rheumatological diagnoses included myositis, rheumatoid arthritis, scleroderma, Takayasu's, GCA, JIA, lupus, PMR, undifferentiated and mixed connective tissue disease. PET/CT was positive in 15/27 cases (56%), identifying new diagnoses in 10 patients (5 aortitis, 1 Takayasu's, 1 Polymyositis, 2 infection, 1 vasculitic myositis) and increase in disease activity in 2 (inflammatory arthritis in scleroderma and JIA). Non-specific abnormalities were apparent in 3 cases. 12 had truly normal scans.

PET/CT added no further information to WB-CT in 31/45 (69%) patients including those diagnosed with malignancy. However PET/CT directly diagnosed Takayasu's arteritis in 1, aortitis in 3 cases and inflammatory arthritis in 2, which was not apparent on WB-CT. The mean ESR was 76 in patients with a truly positive scan versus 44 with a truly negative PET/CT.

Conclusion:

PET/CT has moderate diagnostic sensitivity and reasonable specificity in general rheumatology practice and often appears to provide no further information to WB-CT. Its main diagnostic advantage is for aortitis, and an elevated ESR may improve its diagnostic yield.

Session Title: Imaging of Rheumatic Diseases Poster II: X-ray, MRI, PET and CT

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Lung involvement in RA it is often diagnosed in advanced stage. Chest CT is the main modality for assessment of ILD. To analyze chest CT changes in a cohort of RA patients followed at our center and their correlation with RA features and prognosis.

Methods: Chest CT scans performed by RA patients were retrospectively analyzed. CT findings were classified as RA-lung and non-RA-lung and correlated to patients data (age, sex, RA duration, smoking, death, DAS28, joint erosions, extra-articular features, CRP, RF, ACPA, FVC, DLCO), and treatment. The search of the MEDLINE was performed using keyword combinations: RA and chest CT; rheumatoid lung and chest CT; RA and ILD for the period from 1991 until 2015. Statistical analysis included logistic regression. P-value <0.05 was defined as significant.

Results: 48 out of 84 patients (57.2%) had RA-lung. Positive RF (p=0.018), joint erosions (p=0.003) and reduced DLCO (p=0.005) correlated with RA-lung. Treatment with DMARDs had protective effect against RA-lung (p=0.028). Analyzed published literature (100 original articles, reviews and case reports) on chest CT in RA reported on changes in the lung parenchyma, pleura, bronchial system, and the vasculature. CT changes were attributed to RA-lung (mainly ILD) or non-related to RA (new or existing lung pathology, drug induced pneumonitis, and conventional and opportunistic infections, especially in patients treated with synthetic and/or biological DMARDs).

Conclusion: Findings on chest CT attributed to ILD-RA in the literature are variable and difficult for interpretation and classification. Correlation of CT findings with clinical data according to analyzed literature is not fully estimated. There is an unmet need to design an algorithm for prediction of CT changes compatible with ILD-RA with a high probability. Our data indicates that in RA patients with high RF, erosive disease and reduced DLCO there is a high probability for abnormal chest CT study, especially for ILD-RA. Diagnosing of ILD-RA early could allow comprehensive approach to treatment with possible control of both, RA and RA-lung disease; early intervention may change the course of RA and ILD-RA with possible slowing and prevention the progression of ILD-RA toward pulmonary fibrosis.

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To evaluate the usefulness of computed tomography (CT)-measured aortic wall thickness (AWT) as a sole imaging finding for the confirmation of clinically suspected aortitis.

Methods: CT scans of 20 patients with the diagnosis of aortitis, endorsed by the abnormally thickened aortic wall, as a single imaging finding, and 250 patients without known aortitis were reviewed and AWT manually measured at the levels of thoracic descending aorta, upper abdominal aorta and infrarenal aorta, as well as the level of maximal AWT in patients with diagnosed aortitis. Patients' charts were analyzed and demographic data and data on co-morbidities extracted. Correlations of measured AWT with patients' demographic data and co-morbidities were calculated for the control patients. Age-dependent upper 97.5 percentile points for AWT were calculated for different age groups as a reference. AWT of patients, diagnosed with aortitis, was compared with these reference values.

Results: AWT had significant positive correlation with patient age ($p<0.001$), gender ($p<0.03$) and presence of aortic wall calcifications ($p<0.001$). In 9 of 20 patients, with diagnosed aortitis confirmed by the increased CT-measured AWT, the revised values of AWT were lower than calculated upper 97.5 percentile point for the relevant age group. In 4 of these patients, the values of the measured AWT were in the range of mean+SD for AWT for the same age.

Conclusion: The confirmation of suspected aortitis by the increased CT-measured AWT only may be equivocal and necessitate more specific imaging, particularly in elderly patients.

Fig 1. Correlation plots of AWT with patients' age

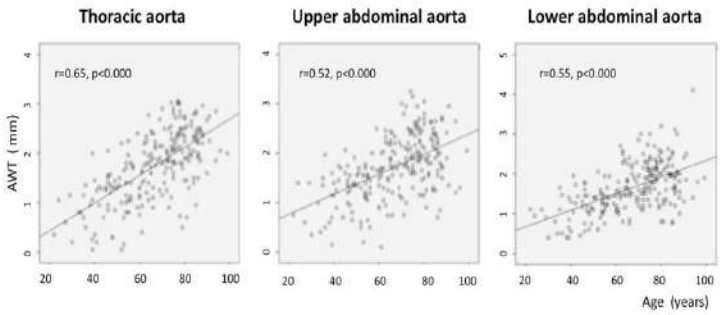

Table 1. AWT in different age groups

Age groups (years)	Thoracic Aorta		Upper Abdominal Aorta		Lower Abdominal Aorta	
	Mean SD¤	97.5¦	Mean SD¤	97.5¦	Mean SD¤	97.5¦
<50	0.998 0.49	1.96	1.188 0.46	2.08	1.063 0.42	1.89
50-70	1.544 0.57	2.66	1.535 0.53	2.57	1.504 0.47	2.43

Session Title: Imaging of Rheumatic Diseases Poster II: X-ray, MRI, PET and CT

Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

The data on the Computed tomography (CT) changes of chest in Granulomatosis with polyangiitis (GPA) is available mostly from low tuberculosis prevalence countries. We planned to study the CT findings in confirmed GPA patients from a tuberculosis endemic area and compared these with published CT chest findings of post primary tuberculosis.

Methods:

Clinical and CT chest data from 40 patients with GPA was reviewed. The CT findings were classified as pulmonary parenchymal and pleural abnormalities. Parenchymal lesions were further defined as nodules (round opacity with diameter less than 3 cm), mass like consolidation (opacity greater than 3 cm in diameter with obscured underlying vessels) and ground glass opacities (not obscuring the underlying vessels). Lesions were also classified as angiocentric, centrilobular or subpleural based on their location. Cavitation, when present, was documented based on type, centric or eccentric, shape of inner wall margin as well as wall thickness. Architectural distortion of the lung, honeycombing, traction bronchiectasis, pleural or pericardial involvement and hilar or mediastinal lymphadenopathy, if present, were also recorded. We then compared our finding with those reported from two large European cohorts (One from the French vasculitis group and the other from the German group), one cohort each from USA, Mexico, Japan and Korea, and China. We then compared our findings with well described and widely cited CT findings in non HIV patients with Post Primary Pulmonary Tuberculosis.

Results: CT abnormalities were noted in both lungs in 34 and were unilateral in six (right sided in five) GPA patients. The findings were nodules (lesions less than 3 cm in diameter) in 15 (37.5%), masses (lesions more than 3cm) in 11 (27.5%) and ground glass opacities, consolidations and septal thickening in 16 (40%) each, pleural involvement in seven (17.5%), mediastinal lymphadenopathy and pericardial involvement in two(5%) and parenchymal bands in one. Our patients had more consolidation and ground glass opacities, and much fewer parenchymal bands as compared to other series. While comparing the CT findings of GPA with Post primary tuberculosis, the consolidation in areas other than apical and posterior segment of upper lobe and superior segment of lower lobe, eccentric cavitation with smooth inner walls, widespread distribution of nodules with well-defined and clear margins along with the relative absence of mediastinal lymphadenopathy favoured GPA as compared to post primary tuberculosis.

Conclusion: Combination of CT chest findings can help in differentiating GPA from post primary tuberculosis in an endemic area.

Session Date: Monday, November 9, 2015
Session Title: Imaging of Rheumatic Diseases Poster II: X-ray, MRI, PET and CT
Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To evaluate the interest of 18F-FDG positron emission tomography-computed tomography (PET-CT) for therapeutic assessment in polymyalgia rheumatica (PMR) patients undergoing tocilizumab (TCZ) therapy at first line.

Methods:

Patients were prospectively enrolled in a twenty four weeks open label longitudinal, prospective multicenter study assessing TCZ therapy on PMR patients (TENOR: Tolerance and Efficacy of tocilizumab iN pOlymyalgia Rheumatica). They underwent 18F-FDG positron emission tomography-computed tomography (PET-CT) at baseline, after the first infusion of TCZ (TCZ 1) and after the last infusion of TCZ (TCZ 3). PMR activity score (PMR-AS), C-Reactive Protein (CRP) and Erythrocyte Sedimentation Rate (ESR) lab tests were also assessed. Maximal standardized uptake value (SUVmax) was used for assessment of FDG uptake regions usually seen in PMR (spinous processes, hips, shoulders, sternoclavicular and ischial tuberosities). Wilcoxon test was applied to evaluate parameter's changes after infusions and Spearman's rank correlation test was applied to assess the correlation between SUVmax and PMR-AS, CRP and ESR.

Results: Eighteen patients were included. On baseline PET-CT, abnormal joint uptakes (upper than the liver background) were found most frequently in ischial tuberosities and hips regions (94% of patients) following by shoulders region (89%). Cervical spinous processes were the less frequently described (56% of patients). Bioclinical parameters decreased after TCZ 1 (PMR-AS: from 37 to 18, CRP: from 82 to 1 and ESR from 56 to 4, all $p<0.05$) as well as SUVmax (SUVmax: from 5.9 to 5.4, $p<0.05$). All parameters decreased also after TCZ 3 (PMR-AS from 37 to 4, CRP from 82 to 1 and ESR from 56 to 4; SUVmax from 5.9 to 4.6; $p<0.05$). On region based analysis, all SUVmax were significantly reduced after TCZ 3, except for cervical spinous processes and shoulders regions. Concerning correlations, DSUVmax on patient based analysis was significantly correlated with DPMR-AS after TCZ 1 ($r=0.5$, $p=0.04$) such as left hip DSUVmax with DCRP after TCZ 1 ($r=0.64$, $p=0.01$).

Conclusion: FDG PET-CT uptake decreased significantly after TCZ therapy in PMR patients and might reflect disease activity.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Imaging of Rheumatic Diseases Poster II: X-ray, MRI, PET and CT

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

This project developed a new method for evaluating growing joints by employing diffraction enhanced imaging (DEI) with computed tomography (CT) using a synchrotron light source. DEI is a technique that, compared to conventional radiography, generates more detailed images with a lower radiation dose. DEI develops contrast both from absorption, the process involved in conventional radiography, and from x-ray refraction and diffraction reduction. We show that three-dimensional CT in combination with DEI yields more detailed images than DEI alone or than any other currently available conventional imaging modality. This project, the first to use DEI-CT for imaging intact growing joints, introduces a new tool for studying inflammatory joint diseases during growth.

Methods:

Explanted piglet stifle joints, which are anatomically similar to human knees, were imaged. Joints were from healthy 4-week old piglets which have skeletal maturation equivalent to a 10 month old child. Images were acquired at the Canadian Light Source synchrotron. The DEI-CT scanned slices were "stitched" together forming a three-dimensional (3D) dataset. To compare DEI-CT with other imaging modalities we imaged the stifle joint using planar DEI (with no CT) and conventional radiography, CT and MRI. To begin to explore pathology we imaged joints that were iatrogenically damaged with 200 µm diameter acupuncture needles. Bone and cartilage histology was correlated with DEI-CT features.

Results:

DEI-CT demonstrated bone and soft tissue detail within all joint tissues. Cartilage edges, cartilage-bone interfaces, cortical shell, trabecular bone, and ligaments were clearly displayed. Vascular canals within cartilage and traversing between bone and cartilage, characteristics of growing but not mature joints, were clearly visualized. Resolution of DEI-CT was more detailed than with other imaging modalities. The 200 µm traumatic sites were clearly discerned. Histological assessment confirmed the presence of vascularity in articular cartilage.

Conclusion:

This report documents DEI combined with CT and using synchrotron light yields more detailed 3D images of growing joints than conventional imaging modalities. Using DEI-CT in a large animal model during growth affords opportunities to better characterize both normal and pathologic growth. Studying inflammatory joint diseases in the piglet provides a valuable animal model to study pathology and treatment responses in juvenile arthritis. These results provide a basis and impetus for developing clinically accessible, non-synchrotron based DEI-CT technologies.

Session Title: Infection-related Rheumatic Disease: Poster Session

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Severe infections contribute significantly to the morbidity and mortality of patients with rheumatoid arthritis.

The aim of the study was to identify the characteristics of patients with RA who were admitted to intensive care unit (ICU) with Sepsis, to determine whether RA is an independent risk factors for short- and long-term mortality in patients admitted to the ICU with sepsis and to identify variables associated with mortality among patients with RA

Methods: The study was based on the data of SEPSIS-ISR, an ongoing prospective study that collects data on all patients admitted the ICUs with the diagnosis of sepsis. 124 patients with RA and sepsis were found in the database.

Controls: Age-and-gender matched controls who were admitted to the ICU with diagnosis of Sepsis were selected in a ratio of 2:1.

Results: The mean age of the patients with RA and control was 71 years with 65% of them were women. The main comorbidity included hypertension (77%), diabetes mellitus (57%), congestive heart failure (35%), renal failure (35%), and chronic lung disease (27%).

Severe sepsis and septic shock were diagnosed in 92% vs. 84% (P=0.032) and 50% vs. 39% (P=0.059) in the RA patients and controls

respectively. Pneumonia (35% vs. 30%) and urinary tract infection (9% vs. 15%) were the most common site of infection.

The 30 days mortality was 48% vs. 43% (P=0.37) in the RA and controls and the 3 years survival was 18% vs. 30% in the RA patients vs. controls (P=0.02).

In univariate analyses Variables associate with 3 years mortality included: RA (OR=2.2, P=0.009), CHF (OR=5.3 P=0.001), DM (OR=2.4 P=0.002), Charlson's Score (OR=1.6 P=0.001), HTN (OR=1.86 P=0.036) and age (OR=1.03, P=0.017)

Multivariate analyses revealed that RA (OR=3.66 P=0.005) and Charlson's score (OR=1.9 P=0.001) were the only variables associated with 3 years mortality

Conclusion: RA is an independent risk factor for adverse results in sepsis including sever sepsis, septic shock and 3 years mortality. Long term survival of patients with RA admitted to the ICU with sepsis is related to higher Charlson's score. Other factors associated with higher mortality rates among patients with sepsis includes CHF, DM, HTN and advanced age.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Infection-related Rheumatic Disease: Poster Session

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Isolation of bacteria from synovial fluid (SF) is the gold standard for the diagnosis of septic arthritis (SA). However, false positive culture results (contamination) can result in misdiagnosis and mismanagement. Little is known about the microbiologic profile of contaminated SF (cSF) cultures, the clinical presentation of such cases, outcomes and rates of alternative diagnoses. The purpose of this study is to characterize the demographic features, clinical characteristics, microbiology and outcomes of patients diagnosed withcSF and to compare them with patients with SA

Methods: We conducted a retrospective study including all patients ages 18 and older admitted to a single, tertiary-case hospital between 1998 and 2015 with suspected SA with positive SF cultures. The diagnosis of cSF was determined by infectious disease specialists involved in the patients' care.

Results: 371 patients with SA and 25 patients with cSF were identified. The groups were significantly different with regard to age (58.9 vs. 68.2; $p<0.01$). The most frequently involved joint was the knee but ankle involvement was relatively more common among those with cSF (Figure 1). The clinical presentations were different between the groups: 35.3% of the patients with SA and 16% of those with cSF presented with fever ($p<0.01$); ESR and CRP were significantly higher in the SA group (76.1 (mm/hr) vs. 52.3 (mm/hr) and 145.3 (mg/L) vs. 64.4 (mg/L) respectively; $p<0.01$ for each comparison). Similarly, the mean SF white blood cell count (in thousands) was higher in the SA group (89.2 vs. 36.7; $p< 0.01$). The mean number of days until the first positive culture results in the group with cSF was 3.2 days. The most common organism identified in the cSF group was coagulase-negative staphylococcus [Figure 2]. The mean length of stay (11 vs. 6.2), ICU admission rates (15.9% vs. 4%) and rates of alternative diagnoses (1.3% vs. 36%) within one year were significantly different ($p<0.01$ for all comparisons) between patients in the SA and cSF groups.

Conclusion: This study suggests that cSF is identified in up to 6% of patients with suspected SA and positive SF cultures . These patients present with less severe disease, better outcomes and an alternative diagnosis in 36% of the cases within one year. The unique characteristics of this group include their less severe presentation and delayed and minimal growth of organisms with low pathogenicity. Based on this study, we recommend a conservative approach for patient with suspected SA with mild disease manifestations and no growth of pathogenic organisms within the first 48 hours.

The Impact of Prior Antibiotic Treatment on Culture Results of Patients with Septic Arthritis

Ziv Paz[1], Sarah B. Lieber[1], Andrew Moore[2], Clara Zhu[3], Mary Louise Fowler[4] and Robert H. Shmerling[5], [1]Beth Israel Deaconess Medical Center, Boston, MA, [2]Medicine, Cambridge Health Alliance, Harvard Medical School, Cambridge, MA, [3]Medical School, Boston University School of Medicine, Boston, MA, [4]School of Medicine, Boston University School of Medicine, Boston, MA, [5]Medicine, Beth Israel Deaconess Medical Center, Boston, MA

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Infection-related Rheumatic Disease: Poster Session

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Synovial fluid culture and gram stain offer the most compelling proof of septic arthritis (SA); these tests are indicated in every suspected case. However, the sensitivity and specificity of these studies are not well established, especially among patient who have received antibiotic administration prior to synovial fluid sampling. The purpose of this study was to define the impact of prior antibiotic use on synovial fluid gram stain and culture results among patients with septic arthritis.

Methods:

We conducted a retrospective cohort study of patients 18 years and older admitted to a single tertiary care center from 1998 to 2015 with septic monoarthritis. The diagnosis of SA was defined by typical clinical presentation and positive blood culture, synovial gram stain and/or culture. Patients were stratified by the timing of antibiotic use with regard to joint aspiration and whether the involved joint was native or prosthetic.

Results:

Of 338 patients with SA, 207 had native joint involvement. The synovial fluid cultures were positive in 84.6% of cases while synovial fluid gram stain was positive in only 35%. Prior antibiotic use was associated with a significant reduction in synovial fluid culture positivity (90.5% without prior antibiotics vs. 67.5% with prior antibiotics; $p<0.01$) (Tables 1 and 2). There was no significant difference in the rate of gram stain positivity based on prior antibiotic treatment although there was a trend toward fewer positive gram stain results among those receiving prior antibiotics (Table 1).

Conclusion:

While it is well-known that prior antibiotic administration may affect the results of synovial fluid culture and gram stain, this is one of the few large studies that quantitate these effects. We found the most dramatic impact of prior antibiotic administration is a reduction of synovial fluid culture positivity. Further analysis is ongoing to assess the timing of prior antibiotic therapy on synovial fluid culture and gram stain results in SA.

Table 1: Culture results of septic native joint monoarthritis stratified by timing of antibiotics administration.

	Antibiotic treatment prior to joint aspiration (N= 80)	Antibiotic treatment after joint aspiration (N= 127)	P- value
Positive synovial fluid cultures, N (%)	54 (67.5)	115 (90.5)	<0.01
Positive synovial fluid gram stain, N (%)	22 (27.5)	50 (39.3)	0.14

Table 2: Culture results of septic prosthetic joint monoarthritis stratified by timing of antibiotics administration.

	Antibiotic treatment prior to joint aspiration(N=46)	Antibiotic treatment after joint aspiration (N=85)	P-value
Positive synovial fluid cultures, N (%)	34 (73.9)	77 (90.5)	0.02
Positive synovial fluid gram stain, N (%)	15 (32.6)	27 (31.7)	0.38

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Infection-related Rheumatic Disease: Poster Session

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Clinically-suspected septic arthritis is culture-negative in 18-43% of cases. These patients are often treated surgically with associated morbidity, prolonged hospital stays and high medical costs. Patients with culture-negative (CN) septic arthritis may differ in important ways from their culture-positive (CP) counterparts, including the possibility that such patients could be successfully managed without surgery. The purpose of our study is to compare the clinical characteristics and outcomes between CN and CP patients with surgically-treated septic arthritis.

Methods: We conducted a retrospective study that included all patients ages 18 and older admitted to a single, tertiary-care hospital between 1998 and 2015 who were diagnosed with monoarticular septic arthritis and were treated with antibiotics and surgery. We excluded all cases of osteomyelitis and polyarticular or prosthetic joint infection.

Results: Of 314 patients with clinically suspected and surgically treated septic arthritis, 104 were CN and 210 were CP. The groups were similar with regard to age, gender and presence of associated comorbidities [Table 1]. Though, significantly more CP patients had known, pre-existing joint pathology (p=0.003). The most common joint affected was the knee, which was more frequently involved in the CN group (p=0.03), while the shoulder was more often involved in the CP group (p=0.01) [Figure 1]. The clinical presentations and outcomes differed significantly between the two groups with more severe disease [Table 1] and less favorable outcomes [Table 2] noted among those in the CP group. Nearly 10% of patients in the CN group were diagnosed with another cause of inflammatory arthritis within one year of follow-up.

Conclusion: This study suggests that patients presenting with suspected septic arthritis have less severe disease and better outcomes when their synovial fluid cultures are negative. Many CN patients are diagnosed with another cause of inflammatory arthritis in follow-up. Non-surgical treatment may be appropriate for patients with suspected septic arthritis when synovial fluid cultures are negative.

The Presentations and Outcomes of Prosthetic Joint Septic Arthritis: a Comparison of Culture-Positive and Culture-Negative Disease

Ziv Paz[1], Sarah B. Lieber[1], Andrew Moore[2], Clara Zhu[3], Robert H. Shmerling[4] and Mary Louise Fowler[5], [1]Beth Israel Deaconess Medical Center, Boston, MA, [2]Medicine, Cambridge Health Alliance, Harvard Medical School, Cambridge, MA, [3]Medical School, Boston University School of Medicine, Boston, MA, [4]Medicine, Beth Israel Deaconess Medical Center, Boston, MA, [5]School of Medicine, Boston University School of Medicine, Boston, MA

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Infection-related Rheumatic Disease: Poster Session

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Prosthetic joint septic arthritis (PJSA) may complicate joint replacement in approximately 1-2% of cases. Synovial fluid cultures are negative in up to 25% of cases making the diagnosis of PJSA and its management challenging. Most patients with suspected, but culture-negative (CN), PJSA are managed similarly to their culture positive (CP) counterparts. We hypothesized that

patients with CN PJSA are different in their clinical course and outcomes and might warrant a more conservative approach. The purpose of this study was to compare the demographic features, clinical characteristics and outcomes of CN and CP PJSA.

Methods: We conducted a retrospective study including all patients ages 18 and older admitted to a single, tertiary-care hospital between 1998 and 2015 diagnosed with PJSA and treated with antibiotics and surgery. We excluded all cases of osteomyelitis, polyarticular or native joint infection.

Results: 220 patients with PJSA were identified; 61 were CN and 161 were CP and all received antibiotic therapy and surgery. The groups were similar with regard to age and presence of associated comorbidities; however, there was a male predominance in the CP group (p=0.013) [Table 1]. The most frequently involved joint was the knee, particularly in the CN group (p=0.001); hip involvement was relatively more common in the CP group (p=0.005) [Figure 1]. The clinical presentations and outcomes differed significantly between the two groups, with less severe disease [Table 1] and better outcomes [Table 2] noted among those in the CN group. In addition, the CN patients with PJSA tended to have a shorter hospital stay (p=0.06) and more alternative diagnoses established within one year (p=0.08).

Conclusion: This study suggests that patients with CN PJSA have less severe disease and a trend toward better outcomes. Our observations support the need for a prospective, randomized trial of patients with CN PJSA comparing the outcomes of surgical and non-surgical management.

Session Title: Infection-related Rheumatic Disease: Poster Session

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Septic arthritis (SA) is typically managed with antibiotics and surgery, though nonsurgical management may be appropriate in certain

circumstances. Little is known about how patients treated for SA with antibiotic therapy alone differ from their operatively managed counterparts. The purpose of this study is to compare clinical characteristics and outcomes of patients with SA managed with or without surgery.

Methods:

We conducted a retrospective cohort study of patients 18 years and older admitted to a single tertiary care center from 1998 to 2015 with culture-positive septic monoarthritis. Patients were stratified into operatively (OR+) and non-operatively (OR-) managed groups. Microbial profile, predisposing factors, sites of joint involvement, length of hospital stay (LOS), and 60-day readmission rate were determined.

Results:

434 patients with culture-positive SA were identified; 50 were OR- and 384 were OR+. In the OR- group, 45 patients were not offered surgery by the consulting surgeon while 5 patients declined surgery that had been recommended. The OR+ patients were older (63.8 vs. 58.6 years old; p =0.04) and the OR+ group had more pre-infection joint pathology (p<0.01); otherwise, the groups were similar with respect to baseline comorbidities [Table 1]. Prosthetic joint involvement was more commonly observed in the OR+ group (p<0.01). The knee was the most commonly involved joint in both groups, though more predominant in the OR+ group (p=0.01), and relatively more wrist involvement was noted in the OR- group (p<0.01) [Table 1]. The most commonly isolated organisms were methicillin-sensitive Staph aureus and methicillin-resistant Staph aureus. Clinical presentations and outcomes differed significantly between groups, with more severe disease [Table 1] and worse outcomes [Table 2] noted among those in the OR- group. All patients in the OR- group with prosthetic joint involvement (n=10) survived.

Conclusion:

On the basis of this large retrospective study**,** patients with culture-positive SA who were not taken to the operating room appeared to be much sicker than those who underwent surgery. Despite this, most survived, including all of those with prosthetic joint involvement. Based on these findings, future research should include randomized trials comparing conservative and operative therapy in selected patients with SA.

Clinical Characteristics and Outcomes of Septic Bursitis

Sarah B. Lieber[1], Clara Zhu[2], Mary Louise Fowler[3], Andrew Moore[4], Robert H. Shmerling[5] and Ziv Paz[1], [1]Beth Israel Deaconess Medical Center, Boston, MA, [2]Medical School, Boston University School of Medicine, Boston, MA, [3]School of Medicine, Boston University School of Medicine, Boston, MA, [4]Medicine, Cambridge Health Alliance, Harvard Medical School, Cambridge, MA, [5]Medicine, Beth Israel Deaconess Medical Center, Boston, MA
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Infection-related Rheumatic Disease: Poster Session
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Septic bursitis (SB) is a common condition that typically involves the olecranon and patellar bursae. It is unclear whether patients with SB treated surgically differ in their clinical presentation and outcomes from patients treated with antibiotics alone. Furthermore, it is unknown if preceding trauma is a risk factor for more severe disease and higher rates of surgical intervention. Finally, the factors distinguishing patients with olecranon SB from those with patellar involvement are not well understood. The purpose of this study is to describe the clinical features and outcomes of patients with SB and to address these uncertainties.

Methods:

We conducted a retrospective cohort study of patients 18 years and older admitted to a single tertiary care center from 1998 to 2015 with culture-proven olecranon and patellar (including prepatellar and infrapatellar) SB. Patients with concurrent septic arthritis or sterile bursal fluid cultures were excluded. Baseline characteristics and clinical features, microbial profile, rate of operative intervention, length of hospital stay (LOS), and 60-day readmission rate were determined. Patients were stratified by site of SB, presence or absence of preceding bursal trauma, and operative or non-operative management.

Results:

Of 44 cases of SB, 31 involved the olecranon bursa and 13 affected the patellar bursae. Patients with olecranon and patellar SB were similar with respect to age, male predominance and frequency of preceding bursal trauma. However, patients managed operatively were younger (mean 42.4 vs. 57.7 years; $p = 0.05$), as were those without preceding bursal trauma (mean 51.1 vs. 62.6 years; $p = 0.05$). Clinical features at presentation and presence of comorbidities were similar when patients were stratified by site of SB, history of preceding bursal trauma, or management strategy. The most common organisms isolated from bursal fluid were methicillin-sensitive Staph aureus (MSSA), methicillin-resistant Staph aureus (MRSA), and coagulase negative Staph. Patients managed operatively were discharged to rehabilitation less frequently ($p=0.04$) and had a lower rate of 60-day readmission than their conservatively managed peers ($p = 0.05$). A trend toward shorter mean LOS was observed among patients with preceding bursal trauma as compared to those without trauma (4.4 vs. 10.4 days; $p = 0.07$).

Conclusion:

In this study of SB, we were unable to identify factors that differentiate patients treated surgically from those treated conservatively. Similarly, there was no clear relationship between preceding trauma or site of SB and clinical course, management, or outcomes. Patients with SB treated surgically tended to be younger and have lower readmission rates. Additional study is needed to identify patients who would benefit from early surgical intervention for SB.

Session Title: Infection-related Rheumatic Disease: Poster Session

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Loop-mediated Isothermal Amplification (LAMP) is a promising nucleic-acid amplification assay. Prompt and accurate diagnosis of Osteoarticular tuberculosis (OATB) is required for early treatment, better patient outcomes and to prevent further joint destruction.The objective of the present study was to evaluate the LAMP test using IS6110 and MPB64 targets specific for *Mycobacterium tuberculosis* complex for rapid diagnosis of OATB. Comparison of results of IS6110 LAMP, MPB64 LAMP test with IS6110 PCR, culture and AFB smear

Methods:

LAMP assay using six pairs of primers (each for IS6110 and MPB64) specific for *Mycobacterium tuberculosis* were performed on synovial fluid/pus samples of 90 patients(10 confirmed, 80 suspected) of OATB and 30 non tuberculosis controls subjects.

Results:

Overall LAMP test (using any of two targets) had sensitivity and specificity of 100% for confirmed OATB cases. In 80 clinically diagnosed but unconfirmed OATB cases LAMP was positive in 71/80 (88.75%) cases. Senstivity of IS6110 LAMP, MPB64 LAMP and IS6110 PCR in clinically unconfirmed OATB cases was 81.75% (65/80), 86.25% (69/80) and 72.5%(58/80) respectively. The overall sensitivity of microscopy, culture, IS6110 PCR, IS6110LAMP, MPB64 LAMP and LAMP test (if any of the targets were used) were 3.33%, 11.1%, 73.33%, 83.33%, 87.77% and 90% respectively. Specificity of all the tests were100%.There were 4 cases which were missed by IS6110 LAMP assay and 2 cases were missed by MPB64 LAMP assay.

Conclusion:

LAMP assay using two targets is promising technique for rapid diagnosis of OATB in 60 minutes.

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Infection-related Rheumatic Disease: Poster Session
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: We have demonstrated previously that latent tuberculosis infection (LTBI) screening is effective in adult rheumatoid arthritis (RA) patients prior to anti-TNF treatment. One study suggested that prevention of tuberculosis in JIA children receiving etanercept is efficient. However, the short-term evaluation and the absence of data regarding other TNF blockage classes precludes a definitive conclusion, particularly taking into consideration that a recent population-based study reported that tuberculosis (TB) risk is significantly higher in JIA patients. Objectives: To evaluate, in an endemic country, the long-term efficacy of LTBI screening and primary prophylaxis in patients with JIA receiving TNF blockers.

Methods: This was a prospective study that included JIA patients (ILAR classification criteria) regularly followed in the Rheumatology outpatient clinic of a tertiary university hospital of Sao Paulo city, Brazil and who were refractory to non-biologic DMARDs and were eligible to anti-TNF therapy. Patients were evaluated for disease activity before starting TNF inhibitor using Juvenile Arthritis Disease Activity Score (JADAS) (patients <19 years old) or Disease Activity Score 28-Joint Counts (DAS28) (patients ≥19 years old). All patients were screened for LTBI prior to anti-TNF treatment using the tuberculin skin test (TST), chest X-ray and history of exposure to TB. When indicated computerized chest tomography was performed. All subjects were regularly followed at 1- to 3-month intervals.

Results: Sixty-nine JIA patients were included and all patients were vaccinated with BCG during neonatal period. They had current age of 17.4 ± 5.8 years, 24 (34.8%) were males and the mean disease duration until anti-TNF initiation was 5.0 ± 4.9 years. Sixty-three (91.3%) patients were under NSAIDs, 31 (44.9%) prednisone, 60 (86.9%) methotrexate, 23 (33.3%) leflunomide and 13 (18.8%) cyclosporine. At baseline, JADAS was 13.4 ± 8.4 and DAS28 3.8 (1.9-6.1). Forty-seven (68.1%) patients were treated with a single anti-TNF agent, while 22 (31.9%) patients switched to another anti-TNF agent once or twice. At the end of follow-up, 33 (47.8%) patients had received adalimumab, 57 (82.6%) etanercept and 3 (4.3%) infliximab. LTBI screening was positive in three (4.3%) JIA patients: one had TST-positive and history of TB exposure and two had solely TST-positive. During follow-up, TST was repeated in two patients due to a long period (> 1 year) of anti-TNF interruption, and TST conversion was observed in one of them. LTBI patients were treated with isoniazid (10mg/Kg/day, up to 300mg/day) for 6 months, and none of them had TB. No active TB was diagnosed during the study period (median of follow-up during anti-TNF therapy was 7.9 years).

Conclusion: The frequency of LTBI in middle class JIA was low. Long-term evaluation revealed that LTBI screening and primary prophylaxis before anti-TNF treatment were effective and TST was the most sensitive parameter to identify these patients.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Infection-related Rheumatic Disease: Poster Session
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-tumor necrosis factor-α (TNF-α) therapy is associated with an increased risk of mycobacterium tuberculosis infection. Tuberculosis (TB) reactivation can lead to severe complications in patients treated with anti-TNF-α therapy. There is little information regarding the reliability of repeated tuberculin skin tests (TST) in patients with rheumatic diseases on anti-TNF-α therapy. The aim was to assess the usefulness of repeat tuberculosis screening tests in patients with rheumatoid arthritis (RA), ankylosing spondylitis (AS), and psoriatic arthritis (PsA) on anti-TNF-α therapy, and to identify risk factors associated to positive TST conversion.

Methods: We performed a case-control retrospective study nested in a cohort of patients with rheumatic diseases on prolonged anti-TNF-α therapy (≥12 months) with baseline negative TST. The study period was from January 2009 to December 2014. Patients with at least one new TST ≥12 months on anti-TNF-α therapy were included. The patients were allocated in two groups: Group I, patients with positive TST (induration size ≥5 mm after 48-72 hours), and Group 2, patients with negative TST. We analyzed baseline variables that potentially had predictive value for TST conversion, including age, sex, rheumatic diseases, DMARD's therapy, glucocorticoid use, previous TB exposure, BCG vaccination, and anti-TNFα therapy. The statistical analysis included t-test and Chi square test. A logistic regression analysis was performed and odd ratios (OR) were calculated.

Results: We included 105 patients, 47 (56.6%) were female. The mean age was 44.3±11.1 years. The diagnoses included RA (n=53), AS (n=46), and PsA (n=6). Twenty-six patients (24.7%) had positive TST conversion. We observed a significant difference in disease evolution between Group 1 (95.42 ± 51.45 months) and Group 2 (140.66 ±104.3 months) (p=0.036). In the logistic regression analysis, infliximab use was the only associated variable with positive TST conversion (OR 2.2 [IC 95% 1.1-4.2], p=0.01) (Table).

Conclusion: Our study shows that about 25% of patients on anti-TNF-α treatment developed positive TST conversion. The incidence rate of positive TST conversion in patients on anti-TNF-α therapy seems to be high in our population, especially with the use of infliximab. The TST should be recommended in high risk population on anti-TNF-α during follow-up.

anti-TNF-α therapy		**Group 1 (TST +) n=26**	**Group 2 (TST -) n=79**	**OR (CI 95%)**	**p**
Adalimumab n (%)		5(20)	20(80)	1.07 (0.52-2.23)	0.839
Etanercept n (%)		6(16.7)	30(83.3)	0.86 (0.42-1.74)	0.680
Infliximab n (%)		15(34.1)	29(65.9)	2.2 (1.17-4.25)	0.015

Whipple's Disease: The Diagnostic Utility of Synovial Fluid Tropheryma Whipplei Polymerase Chain Reaction

Zoran Kvrgic[1], Kelly Cawcutt[2], Robin Patel[3], Abinash Virk[2], Clement J. Michet Jr.[4], Eric L. Matteson[5] and Tim Bongartz[1], [1]Rheumatology, Mayo Clinic, Rochester, MN, [2]Infectious Diseases, Mayo Clinic, Rochester, MN, [3]Medicine, Mayo Clinic, Rochester, MN, [4]Mayo Clinic, Rochester, MN, [5]Division of Rheumatology, Department of Internal Medicine and Department of Health Sciences Research, Mayo Clinic, Rochester, MN

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Infection-related Rheumatic Disease: Poster Session

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Inflammatory arthritis is a common, non-specific symptom of Whipple's disease. Recovery of the organism by conventional culture is often unsuccessful. Synovial fluid polymerase chain reaction (PCR) testing for *Tropheryma whippelii* may increase the diagnostic yield; however the diagnostic specificity of this approach is unclear. A high rate of detection of *T. whipplei* PCR in saliva of healthy individuals has been reported. To date, there has been no study of the performance of PCR for *T. whippelii* in synovial fluid PCR.

Therefore, we aimed to summarize our experience with a *T. whippelii* synovial fluid PCR test in patients seen at a single referral center and clarify whether utilization of this test in patients with inflammatory arthritis would result in a high rate of false-positive results.

Methods:

DNA was extracted from synovial fluid using the automated MagNA Pure LC instrument. Real-time PCR with FRET probe detection, targeting the heat shock protein gene of *T. whipplei*, was performed on amplified DNA. The total number of patients who had synovial fluid PCR testing for *T. whippelii* between 01/01/2003-04/01/2015 was determined using the clinical microbiology database. A detailed chart review was performed for all patients with positive PCR results. All patients were followed up for a minimum of one year.

Results:

Over the past 12 years, 302 patients underwent synovial fluid PCR testing for *T. whippelii* at our institution. The PCR was positive in only 4 patients. All PCR positive patients were middle-aged males who presented with chronic inflammatory arthritis and a variety of additional symptoms including fever, malaise, and peripheral edema and generalized weakness. They had been diagnosed and treated with various immunosuppressive drugs or antiinflammatories unsuccessfully. Small bowel biopsy to identify the organism was undertaken in 2 of the 4 patients with positive synovial fluid PCR. Tissue samples from these biopsies were negative for periodic acid Schiff stain (PAS) positive macrophages and by *T. whippelii* PCR.

All synovial fluid PCR positive patients (including the 2 with negative small bowel biopsies) were diagnosed with Whipple's disease by their medical team and subsequently treated with antibiotics (ceftriaxone 2g IV q24 for 2-4 weeks followed by trimethoprim-sulfamethoxazole 160/800 mg 1 tablet twice daily for 1 year), resulting in complete resolution of symptoms in all patients. No recurrences occurred during the follow-up period of at least 1 year.

Conclusion:

Our experience suggests that *T. whippelii* synovial fluid PCR testing in patients with inflammatory arthritis is a highly specific test for Whipple's disease. All patients who tested positive in our cohort had symptoms consistent with a diagnosis of Whipple's disease, had previously been unsuccessfully treated with immunosuppressive therapies, and had a dramatic and complete improvement after starting antibiotic therapy. No recurrences/alternative diagnoses emerged during the follow-up period. Synovial fluid PCR testing for *T. whippelii* appears to be a valuable diagnostic test in patients with inflammatory arthritis and suspected Whipple's disease even when the stain for PAS positive macrophages on small bowel biopsy is negative.

Ankle Periarthritis, a New Sign for Chikungunya : Ultrasound Study of Joint Lesions at the Acute Phase of Chikungunya

Lauren Brunier-Agot[1], Michel DeBandt[2], George Jean-Baptiste[3], Regis Duvauferrier[3], Catherine Lebris[3] and Andre Cabié[4], [1]Internal medicine and rheumatology, Zobda Quitman Hospital, Fort de France, Martinique, [2]Medicine, Abstract Medical Int'l, Boulogne, France, [3]Chu de Martinique, Fort de France, France, [4]infectious disease, Zobda Quitman Hospital, Fort de France, Martinique
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Infection-related Rheumatic Disease: Poster Session
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Chikungunya (CHIK) is a viral disease transmitted by the Aedes mosquito. The acute phase of the disease combines: fever, fatigue, arthralgia, arthritis, rash . Studies of humans and animal models have shown that disease signs and symptoms following infection are associated with viral infection of cells in musculoskeletal tissues, such as fibroblasts and osteoblasts, and infiltration of inflammatory cells.

Joint imaging studies in CHIK are rare, except one from Manimunda (3), showing joint effusion, bone edema, synovial thickening, tenosynovitis and erosions on MRI in patients with persistent pain beyond one month after the acute episode.

There are no data with ultrasound imaging.

Ultrasound showed interest in early diagnosis of rheumatoid arthritis (RA), by analogy between these two diseases (RA / Chik) we hypothesized that ultrasound could be relevant to study articular and juxta articular damage in early CHIK.

The EchoCHIK study is a prospective study part of the context of studies of CHIK - during the epidemy that began in Martinique in January 2014- aiming at describing ultrasound aspects of CHIK. Preliminary results allow a description of joint involvement during the acute phase.

Methods: patients with arthralgias and / or arthritis related to CHIK for less than 10 days were included. Confirmation of the diagnosis was made by serology or PCR. Exclusion criteria were: history of chronic inflammatory rheumatic disease, concomitant use of NSAIDs or steroids. Demographic data were recorded and clinical examination was performed by a rheumatologist. Joint ultrasound of the 3 most painful and / or swollen joints was performed in B-mode and Doppler power research, looking for subcutaneous infiltration, effusion, tenosynovitis, erosion and Doppler signal.

Results: 28 patients were enrolled, including 19 women and 9 men with a mean age of 50.75 years and mean diseases duration of 6.15 days.

At baseline, all patients had arthritis, 18 patients had fatigue, 12 had myalgia and 3 had a fever.

Mean VAS was 38.7, the average number of painful joints was 6.2 and the average number of swollen joints was 3.3.

Joint effusion and /or synovial hypertrophy were present in 92.8% of studied joints, with hand and wrist in 75%, ankle 50%, knees 35.7%, mostly unilateral (in 75% of cases). A positive Doppler signal was found in 28.3% of effusions.

Tenosynovitis were found in 2 patients only (unilateral in 1, bilateral in 2). None had erosion at that early visit.

Subcutaneous infiltration with ankles periarthritis was present in 28.6% of patients, unilateral in 3 and bilateral in 5.

2/28 patients with a confirmed diagnosis of CHIK had a normal ultrasound examination.

Conclusion: Ankle periarthritis has been described during acute sarcoïdosis in association with erythema nodosum. It's the first time ankle periarthritis is described with another acute arthritis. In epidemic situation of CHIK this finding may help the clinician diagnosis.

We describe for the first time ankle periarthritis as a new sign for acute Chik arthritis.

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Infection-related Rheumatic Disease: Poster Session
Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Hepatitis C infection (HCV) is a leading cause of chronic liver disease. It is associated with a plethora of autoimmune manifestations including clinical, serological and pathological abnormalities affecting different organs. Immune dysregulation in HCV is further indicated by the high prevalence of non-organ specific antibodies. We investigated the autoimmune manifestations in HCV including clinical, laboratory, imaging and pathological data with emphasis on serologies.

Methods:

We conducted a retrospective chart review in Rheumatology clinic on patients with HCV (confirmed by viral RNA) as a cofactor. We collected the demographic, clinical, laboratory, imaging and pathological data on these patients. We investigated the extent of autoimmune manifestations and its correlation to the degree of hepatic damage.

Results:

We obtained data on 29 patients of whom a limited number had available serological data. 41.3% had a coexisting autoimmune disease with Rheumatoid arthritis (RA) as the most common (33.3%). Arthralgia and Raynaud's were seen in 79.3% and 10.3% respectively. A positive ANA was demonstrated in 61.5% and ENA was demonstrated in 22.2%. Smith and RNP antibodies were detected in 25% and 50% respectively in the absence of clinical Lupus. ANCA was detected in 20% and cryoglobulins in 28% in the absence of clinical vasculitis. Rheumatoid Factor (RF) and Anti-CCP were seen in 45% and 22.2% respectively. 22.2% of patients with RF and 5.5% of patients with Anti-CCP did not have clinical RA. Antiphospholipid antibodies were seen in 40% in the absence of thromboembolic disease. Serologies were confounded by illicit drugs in 20%. The severity of autoimmune manifestations and serological abnormalities did not track the severity of hepatic damage.

Conclusion:

Significant autoimmune manifestations including serological abnormalities and cryoglobulinemia can be seen in hepatitis C in the absence of a clinical disease. Autoimmune manifestations do not parallel the degree of hepatic damage in hepatitis C.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Infection-related Rheumatic Disease: Poster Session
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: CMV is a ubiquitous herpes virus associated with significant immunosuppression. Immunosuppressive treatments and ageing is well known risk factors for CMV reactivation. There are only a few case series about CMV disease in patients with rheumatologic diagnosis. In this report we present descriptive data of our rheumatic patients with CMV disease.

Methods: Database of our university hospital between 2000 and 2014 years was searched for CMV disease. Totally 34 (Female/Male: 25/9) patients with Rheumatic diseases were included into the further analysis. Patients' demographic data like age and gender, rheumatologic diagnoses, receiving immunosuppressive drugs at the admission, need of intensive care unit admission, clinical presentation type and outcomes were recorded. Confirmation of CMV disease was mainly based on CMV viral load in blood samples detected by

molecular techniques (PCR), pathological examination of biopsy specimens, eye fundoscopic evaluation and radiologic imaging.

Results: The mean age was 50.4±3.08 years. Most of the patients have vasculitis (44%). Ten patients (29%) had Systemic Lupus Erythematosus, and 5 patients (15%) had Rheumatoid arthritis. Other diagnoses were Still's disease, dermatomyositis and anti-synthetase syndrome. Patients are grouped according to their co-morbidities and 9 of them (27%) had a history of hypertension while 7 (21%) had diabetes and 8 (24%) had chronic renal disease. 5 patients were consuming tobacco at the time of appeal. Median dose of steroid treatment was 40 mg/day (0-60 mg). 13 (38%) were on pulse therapy. Except for one patient, all of the patients were using steroids at the time of CMV disease. 29 (85%) patients were using any additional immunosuppressive agent. Cyclophosphamide was the mostly used immunosuppressive agent (44%). Five patients were on anti-TNF therapy (infliximab:2, etanercept: 2, adalimumab: 1) and two patients were using rituximab. Other therapeutic agents were MMF (n=4), azathioprine (n=5), methotrexate (n=2) and leflunomide (n=1). Median time between the diagnosis of rheumatologic disease and CMV re-activation was 2.5 years (0-30 years), while mean time was 6.4±1.4 years. 26 (76%) patients required intensive care unit management. 19 (56%) of patients had died. There was no difference regarding between concomitant rheumatic diseases (p=0.66). Majority of patients were presented with pneumonia (59%). 5 patients (15%) had GIS involvement, 2 (%6) patients had retinitis, 1 patient had pneumonia and GIS involvement. In 6 patients (18%) the only symptom was high fever. Mortality was significantly high in patients with pneumonia (71%) and gastrointestinal involvement (67%), p=0.01).

Conclusion: In patients with rheumatic disease, CMV infections are very rare but have a high mortality rate. Corticosteroids, cyclophosphamide and biologic agents were the mostly used immunosuppressive agents in our patients. CMV disease should be kept in mind especially in rheumatic patients with respiratory failure and gastrointestinal bleeding.

Session Title: Infection-related Rheumatic Disease: Poster Session

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

A viral infection is thought to be one of the triggers in the development of primary Sjögren's syndrome (pSS). Multiple studies have shown stimulation of antiviral response pathways in pSS tissues further suggesting the role viral infections may play in disease pathogenesis and/or progression. Yet with this data in hand, a true cause and effect relationship between a viral infection and development of Sjögren's syndrome had not been identified. Therefore, a study was designed to further define the viral landscape within the affected salivary gland tissue of Sjögren's syndrome patients and to identify potential viral-mediated triggers of this autoimmune disease.

Methods:

To better understand the viral signatures present in salivary gland tissue, a viral microarray was developed to assess the viral transcripts present in healthy salivary glands compared to patients diagnosed with primary Sjögren's syndrome. All pSS subjects studied met the American European criteria for pSS. Viral antigens were expressed in salivary glands of female C57BL/6 mice using adeno-associated viral vectors and monitored for changes in stimulated saliva flow, lymphocytic infiltrate formation and development of autoantibodies.

Results:

Two distinct viral profiles were identified by microarray analysis in the Sjögren's syndrome patients evaluated. One of the profiles identified the presence of hepatitis delta virus (HDV) in 50% of the primary Sjögren's syndrome cohort. Presence of HDV sequence and antigens were confirmed in two patient cohorts and HDV sequence was confirmed by an independent lab. Patients positive for HDV in salivary gland tissue were negative for detectible hepatitis B virus (HBV) antigen and antibody in serum and presented with normal transaminase levels. In vivo analysis of HDV antigen expression in salivary glands of female C57BL/6 mice resulted in a pSS-like phenotype including reduced saliva flow, increased lymphocytic infiltrates, and development of autoantibodies.

Conclusion:

Identification of HDV in Sjögren's syndrome patients and induction of a Sjögren's syndrome-like disease in vivo further support a viral-mediated etiopathology in Sjögren's syndrome.

Session Title: Infection-related Rheumatic Disease: Poster Session

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

The interaction between human immunodeficiency virus (HIV) disease and rheumatic disorders has been described as "an unfortunate experiment of nature" that could provide insights into the pathogenesis of both disorders . Examples of this interaction have been described for many rheumatic conditions, but limited reports have explored the association with gout. Patients with HIV infection are characteristically hypouricemic due to malnutrition and defective renal handling of uric acid ; therefore, the coexistence of gouty arthritis and HIV would be unexpected. There have been limited studies evaluating potential risk factors for the development of gout in HIV patients. Because of the scarcity of published literature, additional data are warranted to determine risk factors for the development of gout in HIV positive patients.

Methods:

The primary objective of this study is to determine potential risk factors for the development of gout in HIV positive patients. The study is 1:2 retrospective case-control design. Study duration was for 14 years(2001-2014) which included 72 case patients and 144 control patients . Case patients included HIV positive patients who have at least 2 medical visits during the study period, in whom a subsequent diagnosis of gout has been made. Control patients included HIV positive patients who have at least 2 medical visits during the study period, in whom there is no diagnosis of gout . A standardized data collection instrument was created in an Excel spreadsheet and the Electronic Medical Records were utilized for all data collection. The demographic, clinical and medication exposure data was obtained. SPSS, version 22 was used for statistical analysis

Results:

During the 14 year study period, we found the following risk factors in the development of gout in HIV infected patients.

Protease inhibitors (p value 0.006) that included atazanavir (p value 0.047) and saquinavir (p value 0.035). Nucleoside reverse transcriptase inhibitors (p value 0.003) that included abacavir (p value < 0.0005), lamivudine (p value <0.005) and stavudine (<0.036). Additional risk factors were comorbidities like hyperlipidemia (p value 0.016), coinfection with hepatitis B (0.024), chronic kidney disease (p value < 0.0005), alcohol abuse (p value 0.021) and hydrochlorthiazide therapy (p value 0.042).

In the study group, the mean CD4 count was 468 and the mean uric acid level was 8.5 mg/dl at the time of diagnosis of gout in HIV patients. In the control group, the mean CD4 count was 395 and mean uric acid level was 5.4 mg/dl.

Conclusion:

In our study, risk factors for the development of gout in HIV Patients include therapy with protease inhibitors(atazanavir and saquinavir), nucleoside reverse transcriptase inhibitors (abacavir, lamivudine and stavudine), hyperlipidemia, hydrochlorthiazide therapy, coinfection with hepatitis B, chronic kidney disease and alcohol abuse.

Session Title: Innate Immunity and Rheumatic Disease Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Yao Syndrome (YS) is a systemic autoinflammatory disease formerly termed Nucleotide-binding oligomerization domain 2 (*NOD2*)-associated AutoInflammatory Disease (NAID) due to its association with specific genetic variants in *NOD2*. This study examined the function of *NOD2* in YS patients.

Methods:

Study subjects (10 YS patients and 5 healthy individuals) were screened for *NOD2* variants by sequencing or TaqMan probes. Plasma cytokine levels, *NOD2* expression, and transcript splicing were measured by ELISA, qRT-PCR, and PCR, respectively. Functional assays were performed with peripheral blood mononuclear cells to assess *NOD2*activation in response to its ligand, muramyl dipeptide. The efficacy of tocilizumab therapy was examined in a YS patient.

Results: All YS patients were heterozygous for the *NOD2* IVS8^{+158} variant and 4 were compound heterozygous for R702W. Plasma levels of TNFα, IL-1β, IFNγ, and S100A12 were unaltered in YS patients as compared to healthy individuals. Splicing of intron 8 was unaffected by carriage of the IVS8^{+158} variant; however, *NOD2* expression was elevated in IVS8^{+158} heterozygous patients but not in IVS8^{+158}/R702W compound heterozygotes. MDP-stimulated NFκB activity was suppressed uniquely in compound heterozygotes and correlated with lower TNFα secretion. IL-6 secretion was enhanced specifically in IVS8^{+158} heterozygotes and anti-IL6 receptor antibody (tocilizumab) treatment of a YS patient with this *NOD2* genotype resulted in significant clinical improvement.

Conclusion:

Our findings indicate that YS is associated with dysfunction of *NOD2*, and specific *NOD2* genotypes associate with distinct functional

subtypes. This study suggests that *NOD2* genotype could be used as a biomarker in the selection of therapeutic modalities for YS and warrants further investigation in clinical trials.

Session Title: Innate Immunity and Rheumatic Disease Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: In previous studies we found that synovial macrophages regulate joint pathology during experimental osteoarthritis (OA). Recently, we found that high systemic levels of LDL aggravate joint pathology during experimental OA with synovitis. LDL in inflamed synovium is oxidized and taken-up by macrophages via scavenger receptor A and CD36, leading to an activated macrophage phenotype. In this study, we investigate whether direct injection of oxLDL into a normal murine knee joint induces joint pathology and elucidate the role of synovial macrophages in that process.

Methods: Knee joints of C57BL/6 mice were injected five consecutive days with 6 µl PBS, or PBS containing 1.2 mg/mL oxLDL or LDL. This same procedure was done in mice which were depleted of synovial macrophages by intra-articular injection of clodronate liposomes seven days prior to the (ox)LDL or vehicle injections. Joint pathology was investigated by immunohistochemistry and RNA expression and protein production by synovium were determined using RT-PCR and luminex, respectively. Active TGF-β was measured using a functional CAGA-luciferase assay. Data are depicted as mean ± standard deviation.

Results: LDL and oxLDL injection in naïve knee joints did not increase synovial thickening, or production of pro-inflammatory factors (IL-1β, IL-6 and S100A8/9) compared to LDL injection. Levels of active TGF-β in synovial wash-outs was, however, significantly increased by 33% (from 84.7 ± 14.4 ng/mL/g synovium to 113.0 ± 33.3 ng/mL/g synovium; $p<0.05$). Immunohistochemistry of knee joints showed that repeated injections of PBS caused low expression of aggrecanase- (NITEGE) and matrix metalloproteinase- (VDIPEN) induced neo-epitopes. Repeated injections of oxLDL could reduce expression of NITEGE and VDIPEN in areas that are prone to develop osteophytes, in contrast to LDL-injections (arbitrary VDIPEN score 0.33 ± 0.30 for oxLDL-injections and 0.96 ± 0.36 for LDL-injections; $p<0.05$).

In contrast, repeated injections of oxLDL in macrophage-depleted knee joints led to a 5.3 fold increase of synovial thickening (due to cell influx), compared to injection of LDL ($p<0.001$). Protein levels of S100A8/A9, markers for inflammation, were significantly increased in synovial wash-outs of oxLDL injected joints, compared to LDL-injection (fold increase 5.6; $p<0.05$). Protein and mRNA levels of chemokines CXCL1, CCL2 and CCL3 were also significantly upregulated after oxLDL-injections compared to LDL-injections. Further immunohistochemical investigation of infiltrating cells revealed that these were NIMP.R14-negative, mononuclear monocyte-like cells.

No raise in active TGF-β was measured in macrophage-depleted joints. Remarkably, NITEGE expression was increased in these joints at the synovial-cartilage contact areas after oxLDL injection (fold increase compared to LDL-injection 2.7; $p<0.05$).

Conclusion: Synovial macrophages promote anabolic effects after oxLDL injections in knee joints. In absence of synovial macrophages, however, oxLDL induces cell influx, production of pro-inflammatory mediators and aggrecanase activity.

Session Title: Innate Immunity and Rheumatic Disease Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Dendritic cells (DC) are a heterogeneous population of antigen presenting cells which link both innate & adaptive immunity. To date their classification within blood & skin has been well characterised however evidence identifying DC within other tissues, in particular in the context of autoimmunity is limited. In this study we aim to characterise the DC populations within the inflamed synovium & to elucidate the effect of the inflamed joint microenvironment on DC characterisation & function & subsequent effects on T cell activation.

Methods: Synovial tissue was obtained from RA patients through arthroscopy. For characterisation of tissue DC, biopsies were digested & gated on $CD45^+$ cells. DC were defined as $HLADR^+$, $Lineage^-$ & cell surface expression of CD11c, CD1c, CD141, CD123, CD80, CD83 & CD40 was assessed by flow cytometry. In parallel, RA synovial fluid (SF) & peripheral blood (PB) DC characterisation was also analysed in comparison to synovial tissue. To assess the effect of the inflamed microenvironment on DC activation & function, RA synovial tissue explants were cultured for 24hr allowing the spontaneous release of proinflammatory cytokines & mediators into the culture medium. MoDC were then cultured in the presence of RA explant conditioned media (ECM), RA SF under normoxia or hypoxia & the expression of CD80, CD83 & CD40 assessed. Furthermore MoDC were treated with RA SF & cocultured with $CD4^+$ T cells for 5 days, supernatants harvested & T cells restimulated with PMA (50ng/ml) & Ionomycin (500ng/ml) to examine intracellular expression of IFNγ.

Results: Phenotypic characterization of mDC in PB, SF & synovial tissue from RA patients demonstrated a significant increased gradient in DC maturation markers CD40 & CD80 as DC migrate from blood, to fluid & finally to the synovial tissue ($p<0.05$; $p<0.05$). This is consistent with our data showing that RA patients have a significant decrease ($p<0.05$) in CD11c mDC circulating in PB compared to age matched HC. A significant increase in $CD141^+$ DC in the SF compared to PB ($p<0.005$) was demonstrated. This DC population has not been previously identified in the joint. Furthermore analysis of RA synovial tissue DC demonstrated subpopulations of DC. CD1c DC were identified in the tissue however no CD141 DC were present which is in contrast to a strong CD141 population in the fluid. To mimic the joint microenvironment, MoDC were cultured in the presence of ECM or SF under normoxic or hypoxic conditions. A significant increase in CD80 expression in response to RA ECM or RASF was demonstrated ($p<0.05$; $p<0.0001$ respectively), furthermore hypoxia significantly potentiated the effect of ECM on CD80, CD40 & CD83 compared to basal (all $p<0.0001$). Finally, enhanced IFNγ production ($p<0.05$) & T cell proliferation was demonstrated in SF MoDC & $CD4^+$ T cells co-cultures compared media control.

Conclusion: In this study we identified differential DC subpopulations in the inflamed joint compared to systemic circulation. These cells display a more activated phenotype & can induce T cell function, effects of which are influenced by the RA joint microenvironment, through increased proinflammatory mediators & through the hypoxic nature of the joint.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Innate Immunity and Rheumatic Disease Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: to assess the inflammatory process provoked by the M_3 muscarinic acetylcholine receptor antibody from primary Sjogren Syndrome (pSS) patient's sera in rat submandibular gland by measuring the expression of mRNA COX-2 and production of PGE_2 and PGI_2.

Methods:

The levels and the generation of PGE_2, 6-keto-$PGF_{1\alpha}$ by Enzyme-linked immunoabsorbent assay (ELISA), cyclic AMP (cAMP) by cAMPc-RIA kit and COX-2 mRNA gene's expression at Real Time PCR in rat submandibular gland acini's preparations were measured in the presence of the autoantibodies alone or after incubation with different inhibitors. PGE_2 and 6-keto-$PGF_{1\alpha}$ were also measured in serum from pSS patients.

Statistical analyses

The Student's "t" test for unpaired values was used to determine the level of significance. Differences between means were considered significant if $P<0.05$.

Results:

To determine the effect of pSS IgG anti M3 peptide on gland acini's we analyzed the time-course of COX-2 mRNA expression by Real Time-PCR. COX-2-mRNA was significantly ($P<0.001$) increased in the presence of pSS IgG anti M3 versus normal serum (control). When the autoantibody was incubated in the presence of DuP697 (1x10-6 M) [a specific COX-2 antagonist] under the same experimental conditions, it abrogated the increment of COX-mRNA's expression in a significant manner ($P<0.01$).

Primary Sjogren Syndrome IgG anti M3 antibody increased the production of both prostanoids PGE2 and 6-keto-PGF1α on submandibular gland acini's in a dose-response concentration curve reaching the maximal when the antibody concentration is 1x10-8 M. The increment in the generation of both prostanoids is abrogated, reaching values similar to basal ones, when the tissue preparations are incubated with prostanoid antagonists PF-04418948 2x10-9 M and RO3244794 5x10-8 M for PGE2 and 6-keto-PGF1α respectively, and in the presence of synthetic M3 peptide 5x10-6 M.

To ascertain if cAMP increment is caused by the generation of PGE2 and 6-keto-PGF1α in our preparation, we studied the action of both prostanoids on the production of this nucleotide. Both prostaglandins were able to increase cAMP production, whereas the selective prostanoids antagonists (PF-04418948 for PGE2 and RO3244794 for 6-keto-PGF1α) blunted the stimulatory action provoked by the prostaglandins.

The levels of PGE2 and 6-keto-PGF1α were studied in serum of 28 pSS patients and in 25 healthy individuals. The concentration of 6-keto-PGF1α and PGE2 in serum of pSS patients was two standard deviations higher than that in normal individuals ($P<0.001$).

Conclusion: The present study suggests a complex interplay between different factors involved in adaptativa autoimmunity in pSS patients

at the level of exocrine glands. The presence of anti M_3 IgG autoantibody from pSS sera was able to stimulate COX-2 mRNA gene's expression and the increment in the generation of PGE_2 and 6-keto-$PGF_{1\alpha}$ abolished by M_3 specific cholinergic antagonist. The prostanoids play an important role in the inflammatory process at exocrine gland level.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Innate Immunity and Rheumatic Disease Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Characterized as a fundamental inhibitor of innate inflammation, IL 1 family member IL 37 is expressed in the synovia of patients with rheumatoid arthritis. We investigated the role of IL 37 in joint inflammation and the effects of IL 37 treatment on joint pathology in a mouse model of experimental arthritis.

Methods: Wild type mice were subjected to acute arthritis and peritonitis by instillation of streptococcal cell wall (SCW) fragments, and treated with a recombinant form of the naturally occurring human IL 37. SCW induced arthritis was induced also in mice transgenic for human IL 37 (IL 37tg). The severity of joint and systemic inflammation, changes in IL 37 gene expression, joint histology, and local and systemic cytokine and chemokine production were determined.

Results: In wild type mice, low doses of recombinant IL 37 suppressed joint inflammation by 51.7% ($p<0.001$), and significantly decreased synovial IL 1β by 84%, IL 6 by 73%, TNFα by 33%, KC by 58%, and MPO by 60%. These effects were associated with reduced recruitment of neutrophils to the joint. The anti inflammatory effects of IL 37 treatment were confirmed in SCW induced peritonitis, and shown to require the IL 1 family decoy receptor IL 1R8/SIGIRR. In IL 37tg mice, synovial expression of IL 37 reached peak levels during the resolution phase of the arthritis, and was associated with a reduction of joint swelling.

Conclusion: IL 37 emerges as a key suppressor of joint and systemic inflammation. These findings demonstrate a role of IL 37 in the pathogenesis of arthritis, and indicate a potential for IL 37 in the treatment of rheumatoid arthritis.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Innate Immunity and Rheumatic Disease Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Type 2 innate lymphoid cells (ILC2s), are recently identified as population of cells with lymphoid morphology lacking re-arranged antigen-specific receptors. Although findings in animal models of fibrotic diseases demonstrate increased numbers of ILC2s in fibrotic lesions, data on ILC2s in humans are mainly limited to allergic diseases. We aimed to evaluate the contributive role of ILC2s in the pathogenesis of systemic sclerosis (SSc), their levels and correlations with fibrotic manifestations in SSc.

Methods: Sixty-nine patients with SSc and 47 healthy controls were included into the study. Blood samples and skin sections were analyzed by flow cytometry and immunohistochemistry. ILC2 counts were correlated with clinical manifestations of SSc.

Results: Elevated numbers of ILC2s were detected in the skin (10-fold increase) as well as in the blood (4-fold increase) of SSc patients compared to healthy controls. As no single marker can sufficiently distinguish ILC2s from other cell population, we used two established sets of ILC2 markers to quantify ILC2 cells in the peripheral blood and the skin of SSc patients and healthy individuals, both of which yielded comparable results. Notably, activation markers are lacking on circulating ILC2s, however, after migration into the dermis ILC2s become activated as indicated by expression of IL-17RB and thymic stromal lymphopoietin protein (TSLP) receptor as well as by positive staining for the skin homing marker cutaneous lymphocyte antigen (CLA). Our data also suggest that ILC2s may be involved in the pathogenesis of fibrosis in SSc by showing multiple associations of ILC2 counts with fibrotic manifestations in SSc patients. Stratification of the SSc population in patients with limited (lcSSc) and diffuse cutaneous SSc (dcSSc) demonstrated increased levels of ILC2 in both subgroups with significantly higher frequencies in dcSSc compared to lcSSc. Moreover, dermal and circulating ILC2 counts correlated closely with the modified Rodnan skin score (mRSS). Increased ILC2 numbers were not only associated with more extensive skin fibrosis, but also with anti-topoisomerase antibodies and pulmonary fibrosis. ILC2 counts were highest in patients with extensive lung involvement assessed by CT scan. A comparison of circulating ILC2 frequencies between different cohorts of patients with rheumatoid arthritis, systemic lupus erythematosus and SSc demonstrated strong upregulation of ILC2s only in SSc patients.

Conclusion: Here, we provide first evidence for a role of ILC2s in the pathogenesis of rheumatic diseases by demonstrating increased ILC2 counts in the skin and blood of patients with SSc as compared to healthy individuals. Migration of circulating ILC2s into the skin, the activated state of dermal ILC2s and correlations of ILC2 counts with dermal and pulmonary fibrosis suggests a central role of ILC2s in the pathogenesis of fibrosis and encourage follow-up studies to further evaluate the potential of ILC2 as biomarkers in SSc patients.

Natural Antibodies, Not B Cells, Contribute to Acute Cell Death-Induced Inflammation

Hiroshi Kataoka, Rheumatology and Clinical Immunology, Sapporo City General Hospital, Sapporo, Japan
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Innate Immunity and Rheumatic Disease Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Alarmins, such as uric acid, released from dying cells activate inflammasomes and mediate dead cell-induced inflammation (Ref.). Since it is remains unknown whether or not local host immune factors contribute to the alarmin-related inflammatory response, we focused on the roles of B cells and immunoglobulins in Alarmin-related inflammation. The aim of this study is to test whether natural antibodies have a role in acute cell death-induced inflammation in two different models, acetaminophen-induced liver damage and dead cell-induced peritonitis.

Methods: First we looked at neutrophil infiltration into acetaminophen-damaged livers in mice genetically lacking B cells (μMT) and control wild-type (WT) C57BL/6 mice. Dead EL4 cells, murine T lymphoma cell line, that had been heat-shocked and frozen were injected intraperitoneally into μMT and controls, and the recruitment of neutrophils and monocytes to peritoneal cavity was also quantified by flow cytometry. Then, to see whether natural antibodies contribute to acute inflammation in these two settings, acute inflammatory cell recruitment was quantitated by flow cytometry in μMT mice given infusions of pooled normal serum that was collected from untreated WT mice into their tail veins in advance of commencing inflammation and compared to untreated control mice.

Results: $B220^{+}$ cells as well as neutrophils and monocytes were recruited into acetaminophen-damaged liver in WT mice, suggesting that multiple immune cells might contribute to the inflammation. The numbers of neutrophils and monocytes in damaged liver tissue were significantly reduced in μMT mice compared to WT controls (μMT:$2.6\pm1.9\times10^{5}$,$7.2\pm3.9\times10^{4}$, WT:$2.4\pm1.4\times10^{6}$,$1.0\pm0.8\times10^{6}$ (neutrophils, monocytes)), and the inflammatory response was substantially restored by reconstitution of natural antibody-containing normal serum without B cell co-transfer (figure 1). In another inflammation model, peritoneal recruitment of neutrophils and monocytes in response to injured EL4 cells was also markedly decreased in μMT mice (μMT:$2.9\pm0.4\times10^{5}$,$9.6\pm5.5\times10^{4}$, WT:$5.7\pm3.1\times10^{5}$,$2.4\pm1.5\times10^{5}$ (neutrophils, monocytes)), and also the neutrophilic response was successfully reversed by normal serum transfer to μMT to the WT level (figure 2).

Conclusion: Natural antibodies participate in neutrophil recruitment in acute cell death-induced inflammation. In contrast, B cells are also recruited to the inflammation site, but they may be dispensable for acute neutrophil response.

Session Title: Innate Immunity and Rheumatic Disease Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Antibiotic-refractory Lyme arthritis is defined as persistent synovitis for months to years after antibiotic therapy for *Borrelia burgdorferi*, the causative agent of Lyme disease. Rather than persistent infection, this condition is thought to result from inappropriate activation of inflammatory immune responses which are elicited by the spirochetes and further augmented by host genetics. Fibroblast-like synoviocytes (FLS) are the predominant cell type in hypertrophied synovial tissue, but their responses to *B. burgdorferi* are not well-defined. Here we assessed the inflammatory responses of FLS to a highly virulent *B. burgdorferi*RST1 strain and evaluated these responses according to a host TLR1-1805GG polymorphism, a risk factor for antibiotic-refractory Lyme arthritis.

Methods:

FLS were obtained from synovia of antibiotic-refractory Lyme arthritis patients who underwent synovectomies due to incomplete responses to treatment with antibiotics and then DMARDs. Protein levels of 8 matrix metalloproteinases and 21 cytokines and chemokines in *B. burgdorferi*-stimulated FLS were assessed using Luminex. mRNA expression in synovial biopsies and FLS was assessed using QuantiGene and whole-genome RNASeq analyses.

Results:

FLS sense and respond to *B. burgdorferi* by producing high levels of matrix metalloproteinases (MMP1, MMP2, MMP3, MMP9, and MMP13) which degrade cartilage and bone. In addition, *B. burgdorferi*-stimulated FLS produce large amounts of inflammatory mediators associated with both innate (IL-6, IL-8, IL-10, TNF, CCL2), and adaptive Th1-like responses (CXCL9, CXCL10). These responses corroborate in vivo findings in the joint fluid of patients with antibiotic-refractory Lyme arthritis, linking FLS to excessive joint inflammation. Moreover, FLS responded directly to stimulation with IFNγ, the prototypical Th1 effector cytokine, leading to high levels of CXCL9 and CXCL10, which are potent chemoattractants for $CD4^{+}$Th1 cells, the predominant T-effector cell type in joints of patients with refractory arthritis. These responses were amplified in FLS from patients with a TLR1-1805GG polymorphism, which leads to diminished TLR1 expression on the cell surface. Cells with 1805GG had altered SOCS3 mRNA expression suggesting that the greater inflammatory responses in the 1805GG group may be due to a loss of a regulatory pathway. In addition, RNASeq analysis revealed that a deficiency in TLR1 in patients with 1805GG also leads to increased expression of other pathogen-recognition receptors, including TLRs and NODs, which could further contribute to excessive inflammation in patients with 1805GG.

Conclusion:

FLS are an important cell type in the pathogenesis of antibiotic-refractory Lyme arthritis because of their ability to shape and perpetuate innate and adaptive immune responses. These responses are altered in patients with TLR1-1805GG polymorphism, a risk factor for antibiotic-refractory Lyme arthritis.

PMN Reactivity Contribute to Acute Onset Joint Inflammation By Increasing CXCL8 Production in Joints of RA Patients with Anti-Collagen II Antibodies

Vivek Anand Manivel[1], Azita Sohrabian[2] and Johan Rönnelid[3,4], [1]Immunology, Genetics and Pathology, Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, Sweden, [2]Department of Immunology Genetics and Pathology,Uppsala University, Uppsala, Sweden, [3]Department of Immunology, Genetics and Pathology,Uppsala University, Uppsala, Sweden, [4]4Unit of Rheumatology, Department of Medicine, Karolinska Institutet, Stockholm, Sweden

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Innate Immunity and Rheumatic Disease Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: RA patients with antibodies against collagen type II (CII) have a distinct acute onset RA phenotype, associated with cytokine induction by surface-bound anti-CII IC (Mullazehi A&R 2006, Mullazehi ARD 2007, Mullazehi ART 2012). PMN reactivity relate to early joint destruction in this phenotype (Manivel ART 2015). Hence we searched for CII-dependent mechanisms that might attract PMN to the joint.

Methods: Healthy donor PMN and peripheral blood mononuclear cells (PBMC) were stimulated together (co-cultures) and individually with surface-bound IC (anti-CII IC, tetanus toxoid (TT)/anti-TT IC, plate-bound IgG) or GM-CSF. Blocking and neutralizing studies were performed with antibodies against TLR4, FcgRIIa, FcgRIII and GM-CSF. Supernatant levels of TNF-a and CXCL8 were analyzed with ELISA.

Results: PMN alone produced negligible cytokine levels. TNF-a production was downregulated in all co-culture systems compared to PBMC cultures. CXCL8 levels were specifically upregulated in anti-CII IC-stimulated co-cultures compared to parallel PBMC cultures (fig 1). The anti-CII IC augmentation of CXCL8 was dependent on CII, as CXCL8 production was downregulated in co-cultures stimulated with the other IC; plate-bound IgG (fig 1) or TT/anti-TT IC (not shown). Blocking and neutralization studies showed that the increase of CXCL8 in anti-CII IC stimulated co-cultures was totally dependent on TLR4, partly on PMN enzymes (fig 2), FcgRIIa, FcgRIII (fig 3), and density of anti-CII in IC. Like anti-CII IC, GM-CSF alone also induced co-culture-dependent CXCL8 enhancement (fig 1), and GM-CSF neutralization abrogated the anti-CII IC-dependent CXCL8 enhancement (fig 3).

Conclusion: In anti-CII-positive RA patients, PMN amplify local inflammation by inducing CXCL8. This mechanism is dependent on TLR4, PMN enzymes, GM-CSF and the joint-specific autoantigen CII. Local TLR4 blockade, PMN enzyme inhibition or GM-CSF neutralization might be used to suppress acute joint inflammation.

Enhanced Myelopoiesis Downstream of Toll-like Receptor 9 Activation Drives a Feed-Forward Inflammatory Response

Session Title: Innate Immunity and Rheumatic Disease Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Monocytes are myeloid cells important for the initiation of inflammation and have been implicated in the pathogenesis of autoimmunity. Monocytes interact with their environment through expression of cell-surface and endosomal pattern recognition receptors, including Toll-like receptors (TLRs), which are activated by endogenous and exogenous ‘danger’ signals. Persistent activation through TLRs is thought to drive chronic inflammation in multiple rheumatic diseases. However, the cellular mechanisms driving feed-forward inflammation downstream of repeated TLR stimulation remain unknown.

Methods: We treat C57BL/6 mice with repeated doses of CpG1826, a TLR9 agonist, to induce a feed-forward inflammatory response. Yet40 interleukin (IL)-12 reporter mice are used to identify the TLR9 responsive, IL-12 producing cells in this model. C-C chemokine receptor type 2 (CCR2)$^{-/-}$ mice are used to define CCR2- dependent and independent cell trafficking during TLR9-mediated inflammation. Flow cytometric identification of myeloid progenitor cells and *in vitro* myelopoiesis assays are used to characterize inflammation-induced myelopoiesis.

Results: We demonstrate that repeated stimulation through TLR9 leads to a feed-forward inflammatory response driven by the accumulation of TLR9 responsive inflammatory monocytes. Interestingly, TLR9-activated CCR2$^{-/-}$ mice are not protected from disease and accumulate similar numbers of peripheral blood and splenic inflammatory monocytes as wildtype mice, despite previous work demonstrating defective inflammatory monocyte egress from the bone marrow in CCR2$^{-/-}$ mice. Peripheral monocytosis does not coincide with an expansion of bone marrow myeloid progenitor cells, but rather correlates with an accumulation of myeloid progenitor cells in the spleen and liver of TLR9-activated mice. Furthermore, myeloid progenitor cell accumulation at peripheral sites of inflammation is independent of CCR2, implicating *in situ* generation of inflammatory monocytes as an explanation for the peripheral monocytosis seen in TLR9-activated CCR2$^{-/-}$ mice. Finally, repeated TLR9 activation *in vivo*reprograms extramedullary myeloid progenitor cells to have increased inflammatory monocyte production capacity demonstrating another mechanism driving feed-forward myelopoiesis downstream of repeated TLR9 activation.

Conclusion: Our data indicate that profound changes in extramedullary myelopoiesis occur during TLR9-driven inflammation leading to increased production of inflammatory monocytes. The accumulation of TLR9 responsive monocytes leads to enhanced inflammatory responses downstream of repeated TLR9 activation generating a feed-forward inflammatory loop. As extramedullary myeloid progenitor cells are found in patients with rheumatoid arthritis, systemic lupus erythematous, scleroderma, dermatomyositis, and psoriasis, it is intriguing to speculate that enhanced myelopoiesis downstream of repeated TLR activation is a critical factor driving systemic inflammatory responses in multiple rheumatic diseases.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Innate Immunity and Rheumatic Disease Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Previous studies suggested that unknown plasma factors increase oxidative burst in Behçet's disease (BD), but little is known about neutrophil extracellular traps (NET) formation. Herein, we investigated in patients with active (aBD) and inactive BD (iBD): soluble CD40L (sCD40L) plasma levels; the effect of CD40 pathway activation on NET release and oxidative burst; and the expression of CD40L and its receptors.

Methods: Neutrophils and PBMC were obtained from patients with aBD (n=30), iBD (n=31), and healthy controls (HC; n=30). For each group, a pool of plasma treated or not with recombinant CD40 (rhCD40) for sCD40L blockade was created. A pool of plasma from four CD40L-deficient patients was also obtained. sCD40L plasma concentration was measured by Luminex. NET formation was quantified on neutrophils plated onto circular coverslips, followed by labeling with Hoechst 123 and antibodies to histones and neutrophil elastase. H_2O_2/O_2^-production was determined by luminol/lucigenin luminescence intensity. Cells were treated with PMA, sCD40L or the pool of plasma. Flow cytometry analysis evaluated the expression of 1) CD40, Mac-1, α5β1-integrin and α2bβ3-integrin on neutrophils and monocytes; 2) CD40L on T cells; 3) CD40L on platelets.

Results:

sCD40L plasma levels were significantly higher in iBD (median/range=17,234/2,346-19,279) and aBD (18,288.50/412.58-19,883) compared to HC (47.45/33.68-26,743; p<0.001). NET formation was constitutively increased in BD compared to HC. Stimulation of in vitro NET formation by aBD plasma or sCD40L was inhibited by CD40L blockade (Table 1). Neutrophil and PBMC production of

O_2^-/H_2O_2 was higher after stimuli with sCD40L, aBD or iBD plasma than with HC plasma and decreased after CD40L blockade (Table 2). Mac-1 expression was constitutively increased in iBD (4,615/208-8,594) and aBD (2,018/891-6,533) neutrophils compared to HC (55.35/17.5-70.5; $p<0.01$). CD40, CD40L, α5β1- and α2bβ3-integrin expression were similar in the three groups.

Conclusion: Plasma from aBD patients exerts a stimulus on NET formation and oxidative burst, probably mediated by Mac-1. Increased concentration of sCD40L might be associated with neutrophil hyperactivity in BD.

Complement-Mediated Neutrophil Lysis-a Mechanism Promoting Hypercitrullination in Rheumatoid Arthritis?

Tal Gazitt[1], Christian Lood[2], Jeffrey Ledbetter[3] and Keith B. Elkon[3], [1]Rheumatology, University of Washington, Seattle, WA, [2]University of Washington, Lund, Sweden, [3]Division of Rheumatology, University of Washington, Seattle, WA

Session Date: Monday, November 9, 2015

Session Title: Innate Immunity and Rheumatic Disease Poster II

Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Protein citrullination, the post-translational conversion of arginine to citrulline, mediated by peptidylarginine deiminase (PAD) enzymes, is considered a likely mechanism for the stimulation of anti-citrullinated protein antibodies (ACPA) in patients with rheumatoid arthritis (RA). Hypercitrullination, the citrullination of multiple intracellular proteins, was recently demonstrated in synovial fluid cells from RA patients but was not found in other physiologic processes involving citrullination, such as NETosis (Romero *et al., Sci Transl Med,* 2013). This unique form of citrullination is proposed to occur via immune-mediated, pore-forming membranolytic pathways causing neutrophil cell death; one mediated by cytotoxic cells through the perforin-granzyme pathway, and the other mediated by complement activation and formation of the membrane attack complex (MAC). Since the evidence to support this hypothesis was derived from simulated *in vitro* systems, we explored the naturally occurring humoral mechanisms required for induction of complement-mediated neutrophil lysis.

Methods:

Neutrophils (PMNs) isolated from synovial fluid (SF) or peripheral blood (PB) of RA patients as well as in healthy controls (HC) were exposed to the inflammatory milieu found in RA joints. PMNs isolated from SF (n=3) and PB (n=25) of ACPA-positive RA patients as well as PB of HC (n=10) were screened for anti-neutrophil binding IgG, C3bi and C5b-9 complement component deposition, as well as PMN viability using annexin V and propidium iodide staining by flow cytometry analysis. In addition, PMNs isolated from HC were incubated with serum or SF from RA patients or normal human serum from the same healthy controls.

Results:

In the periphery, in the majority of patient samples, RA PMNs had highly increased mean fluorescence intensity (MFI) ratio for C3bi cell-surface deposition as compared to healthy controls ($p<0.05$), but no differences were seen in MFI of C5b-9 deposition. However, in SF samples, PMNs had elevated MFI ratio of C5b-9 as compared to PB PMNs from HC ($p<0.05$) and paired RA patients ($P< 0.0001$). Complement deposition on SF PMNs was also associated with decreased cell surface expression of the complement regulatory molecule CD46, as well as increased cell death, with more than 50% of the SF PMNs undergoing secondary necrosis, consistent with the notion of complement-mediated killing of SF PMNs. Moreover, incubation of HC PMNs with 15% RA SF, but not 15% serum from paired RA patients or HC induced C3bi and C5b-9 deposition, reduction in CD46 expression, and PMN lysis via secondary necrosis.

Conclusion:

RA PMNs, in particular SF PMNs, demonstrate increased complement deposition associated with PMN cell death both *in vivo* and *in vitro*. Elucidating the cause of complement deposition and the role of complement regulatory proteins in promoting PMN lysis may help to uncover a mechanism for hypercitrullination, ACPA formation and RA disease propagation.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Innate Immunity and Rheumatic Disease Poster II
Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Synovial inflammation is a common feature of osteoarthritis (OA) and rheumatoid arthritis (RA) patients. Comparative studies indicated that synovitis, measured by histology or imaging, is more severe in RA than in OA, which is also reflected in more infiltrating immune cells in RA than in OA. Intriguingly, mast cell numbers were found in some studies to be equal or lower in RA than OA. Here, we wished to expand these findings using immunofluorescence and to assess the possible relevance of mast cells in OA by studying their association with clinical parameters, such as radiographic damage and pain.

Methods: Synovial tissues of 56 symptomatic OA and 49 RA patients were obtained from arthroscopy (early disease) (22 OA, 23 RA) or arthroplasty (late disease) (34 OA, 26 RA). Two to three paraffin slides were used to quantify inflammation using haematoxylin and eosin staining (synovitis score 0-9), and to quantify and determine degranulation state of mast cells (per 10 high-power fields) using double immunofluorescence for CD117 and tryptase. Average scores per patient were used for analysis. Knee radiographs of OA patients were scored according to the Kellgren and Lawrence (KL) system and self-reported pain was determined in OA patients by visual analogue scale at baseline.

Results:

Median (range) of mast cells was significantly higher in OA samples 45 (1-168) compared to RA samples 4 (1-47) (p-value < 0.001), despite a lower median (range) synovitis score in OA (2.5 (0-6.0)) compared to 4.6 (0-8.0) in RA samples. This held true when comparing the subgroups of early and late samples between diagnoses. Similar percentages of mast cells were degranulated in both diseases at all stages, indicating that the abundance of these cells rather than degranulation state could be relevant for the disease process. The synovitis score correlated with the number of mast cells both in OA (Spearman's rho = 0.3, p =0.023) and RA (Spearman's rho = 0.5,p < 0.001), indicating that mast cells could contribute to synovial inflammation in both diseases, although their contribution is probably moderate. Interestingly, the number of mast cells was associated with an increased KL-grade (p-value 0.05) in OA patients, independently of synovitis. No associations were found with self-reported pain.

Conclusion:

Prevalence of mast cells in OA synovial tissue is higher than in RA. Interestingly, it appears to be associated with synovial inflammation, as well as structural damage in OA patients, suggesting a role of mast cells in this disease.

Session Date: Monday, November 9, 2015
Session Title: Innate Immunity and Rheumatic Disease Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

In macrophages, repeated stimulation of Toll-like receptor (TLR) 4 leads to a tolerant state of the cell which protects inflamed tissues from damage. We have recently shown that rheumatoid arthritis (RA) synovial fibroblasts (SF) lack these protective mechanisms and maintain the secretion of inflammatory cytokines and matrix degrading metalloproteinases also after repeated LPS stimulation. The objective was to

investigate mechanisms behind tolerizable and non-tolerizable effects in RASF.

Methods:

RASF, osteoarthtitis (OA) SF, and *in vitro* differentiated peripheral blood derived macrophages from healthy donors and RA patients were treated with LPS (100 ng/ml) for 24h and then re-stimulated with LPS (10 ng/ml) for another 24h. The expression levels of interleukin (IL) 6, IL8, chemokine (C-X-C mofif) ligand 10 (CXCL10), matrix metalloproteinases (MMP) 1 and MMP3, as well as retionoic acid-inducible gene 1 (RIG1) and 2`-5`-oligoadenylate synthetase (OAS1) were analyzed by quantitative Real-time PCR or ELISA. Nuclear factor-κB (NF-κB) and activator protein-1 (AP-1) promoter activities in RASF (n=4) were evaluated by Dual-Luciferase reporter assays after repeated stimulation with LPS. The levels of histone 3 (H3) and H4 acetylation (H3ac, H4ac) as well as H3 lysine 4 trimethylation (H3K4me3) in promotor regions of tolerizable (OAS1, CXCL10) and non-tolerizable (IL6, IL8, MMP1, MMP3) genes in SF (n=3) were analyzed by Chromatin Immune precipitation (ChIP).

Results:

As expected, the expression of IL6 decreased in double-stimulated (886 ± 596 pg/ml) compared to single-stimulated (2368 ± 315 pg/ml; $p<0.01$) macrophages from healthy donors (n=4) and RA patients (n=6, $p=0.06$). On the other hand, RASF (n=10) and OASF maintained their production of IL6 after repeated TLR4 stimulation (RASF: single stimulation: 13.2 ± 5.8 ng/ml, double stimulation: 12.4 ± 7.1 ng/ml). A lack of tolerizable effects of RASF was also found for MMP1 and MMP3, whereas the interferon-responsive genes OAS1, RIG1 and CXCL10 were tolerizable. RASF (n=5) secreted 531 ± 385 pg/ml CXCL10 after a single LPS stimulation and 111 ± 97 pg/ml CXCL10 after double stimulation ($p<0.05$). Reporter gene activities for NF-κB and AP-1 were similar in single and double stimulated RASF, excluding potential differences in the activation of these transcription factors as underlying mechanisms for tolerizable/non-tolerizable effects in RASF. Interestingly, the levels of the activating histone marks H4ac and H3K4me3 were decreased by LPS double compared to single stimulation of SF in different promoter regions of OAS1 and CXCL10, whereas these chromatin marks were not changed or even increased in promoter regions of IL6, IL8, MMP1 and MMP3. On the other hand, changes in the levels of H3ac after LPS double stimulation did not distinguish tolerizable from non-tolerizable genes.

Conclusion:

Epigenetic modifications on target gene promoters are likely to contribute to differences in tolerization between RASF and macrophages. Since many pro-inflammatory cytokines and MMPs are non-tolerizable genes in RASF, we conclude that the lack of tolerization in these cells keeps RASF aggressive in persistent inflammation.

Mucosal-Associated Invariant T- Cells Are Decreased and Functionally Immature in Peripheral Blood of Patients with Primary Sjögren Syndrome

Tatjana Banovic[1,2,3], Jing Jing Wang[4], Dimitra Beroukas[5], Pravin Hissaria[6] and Tom Gordon[2,6], [1]Immunology, Level 3, SA Pathology, Adelaide, Australia, [2]Flinders University, Adelaide, Australia, [3]Pediatrics, University of Adelaide, Adelaide, Australia, [4]Immunology, Flinders University, Adelaide, Australia, [5]SA Pathology, Adelaide, Australia, [6]Immunology, SA Pathology, Adelaide, Australia

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Innate Immunity and Rheumatic Disease Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Primary Sjögren Syndrome (pSS) is characterized by organ-specific autoimmune destruction of salivary and lacrimal glands. Patients typically experience debilitating symptoms of dry mouth and eyes and commonly develop systemic complications including renal tubular acidosis, arthritis, polysynovitis, refractory pulmonary disease, mixed cryoglobulinaemia, polyclonal hypergammaglobulinaemia and lymphoma. The risk of developing lymphoma is 30-40 times higher in patients with pSS compared to the

general population. Autoimmune destruction of glandular tissue in pSS is mediated by conventional CD4+ T helper (Th) – cells but little is known about the involvement of non-conventional, innate-like T-cells in this process. Mucosal-Associated Invariant T (MAIT) - cells are a novel sub-population of unconventional T-cells at the frontier between innate and adaptive immunity. They comprise up to 10% of peripheral blood (PB) T-cells in humans. They accumulate primarily in the intestinal lamina propria and are endowed by a "natural memory" phenotype and function. MAIT cells are able to rapidly produce high levels of Th1, Th2 and Th17 cytokines. One of their proposed roles is protection of mucosal surfaces against vitamin B-metabolizing bacteria and yeasts. To our knowledge, the role of MAIT cells in the pathogenesis of primary Sjögren Syndrome (pSS) has not yet been explored.

Methods: We studied the frequencies, immunophenotype and function of MAIT-cells in the PB of patients with pSS (N=50) and healthy control subjects (HC, N= 22) by using 8- colour flow cytometry and in vitro stimulation assays.

Results: We showed that MAIT cells are significantly decreased in patients with pSS. Furthermore, the residual MAIT cells in pSS patients showed altered immunophenotype and function. While in the HC subjects MAIT cells were almost exclusively $CD8^+$ and expressed an effector memory immunophenotype, in pSS patients they were enriched in $CD4^+$and naïve subpopulations. This is consistent with our functional studies which demonstrated that MAIT cells from pSS showed a lower level of activation with reduced expression of CD69 and CD154 (CD40L), and a lower production of TNF and IFNγ.

Conclusion: We propose that the reduced frequencies and functional immaturity of MAIT cells in patients with pSS, may result in impaired protective mucosal barrier function and dysregulation of mucosal immunity with subsequent microbial damage to mucosal surfaces and initiation of the autoimmune response. A better understanding of the immunophenotype and function of this novel innate-like T-cell subpopulation in patients with pSS is required in order to evaluate their involvement in the evolution of severe mucosal damage and systemic complications in patients suffering from this debilitating disease.

Session Date: Monday, November 9, 2015

Session Title: Innate Immunity and Rheumatic Disease Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Seronegative joint diseases such as psoriatic arthritis and juvenile idiopathic arthritis are characterized by the lack of autoantibodies, potent biomarkers used for predicting disease activity and outcome in seropositive joint diseases. Promising alternative biomarkers for detecting disease activity in seronegative arthritis are the Damage Associated Molecular Patterns (DAMPs) S100A8 and S100A9 proteins specifically expressed and released by infiltrating phagocytes in the inflamed joint. In this study, we explore the biomarker potential of serum S100A8/A9 and in vivo imaging of synovial S100A8 to assess joint inflammation and damage in IL-1 receptor antagonist deficient ($IL\text{-}1Ra^{-/-}$) mice, a mouse model for seronegative arthritis in which serum autoantibodies are not correlated to disease activity.

Methods:

Serum of $IL\text{-}1Ra^{-/-}$and WT (BALB/c genetic background) mice was collected every two weeks starting at week 4 until end-point at week 16, and swelling in the hind paws was macroscopically scored on a scale of 0 to 4. Serum levels of IL-1β, IL-6 and TNFα were measured by Luminex technology and S100A8/A9 complex levels by ELISA. Hind paws were isolated and histologically scored for cell influx,

cartilage damage and bone erosion. Paraffin sections of the hind paws were also stained for S100A8 expression. Synovial S100A8 was imaged by injection of anti-S100A8-Cy7 antibody and 24 hour p.i. fluorescent images were acquired in the IVIS Lumina optical imaging system.

Results:

Starting at week 8 up to week 16, serum levels of S100A8/A9 in IL-1Ra$^{-/-}$ mice were significantly increased (1640 ± 1008 ng/ml at week 16) compared to basal levels in WT mice (429 ± 191 ng/ml, $P = 0.005$) and strongly correlated to joint swelling (r = 0.740, $P < 0.0001$). Histological analysis of hind paws showed that joint inflammation but also cartilage and bone destruction (r = 0.672 – 0.770, $P < 0.0001$) significantly correlated to serum S100A8/A9 levels, in contrast to levels of IL-1β, IL-6, and TNFα. Serum S100A8/A9 levels already correlated to joint swelling (r = 0.410, $P = 0.047$) as early as week 8 and high serum levels at week 10 were predictive for increased joint swelling at week 16 (r = 0.563, $P = 0.004$). Local expression of S100A8 within the synovium as detected by immunolocalisation correlated to joint damage and serum S100A8/A9 levels, indicating the activated synovial lining as the source of increased serum S100A8/A9. Imaging of S100A8 using specific anti-S100A8-Cy7 antibody showed a significant uptake in inflamed joints of IL-1Ra$^{-/-}$ mice when compared to a control isotype ($P = 0.044$). In non-arthritic IL-1Ra$^{-/-}$mice no specific S100A8 targeting was observed.

Conclusion:

High levels of serum S100A8/A9 correlate to joint inflammation and destruction in experimental seronegative arthritis and local synovial expression of S100-DAMPs can be monitored in vivo by molecular imaging. These findings underline the potential of S100-DAMPs as a serum and imaging biomarker for disease severity in seronegative arthritis.

Session Title: Innate Immunity and Rheumatic Disease Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with systemic autoimmune rheumatic diseases (SARD) often have a prolonged pre-clinical phase during which they are anti-nuclear antibody (ANA)$^{+}$ but lack clinical symptoms. It has been proposed that progression from asymptomatic autoimmunity to clinical disease is accompanied by immunologic changes that could be used as predictors of disease development. Elevated levels of interferon (IFN)-induced gene expression, termed the IFN signature, are found in several SARD conditions, and IFNs appear to play an important role in disease pathogenesis. In this study we examined whether ANA^{+}individuals who lack sufficient symptoms for a SARD diagnosis share the IFN-signature.

Methods: ANA^{+}individuals who: 1) lacked clinical symptoms of SARD (ANS); 2) had a least one clinical symptom of SARD (UCTD); or 3) had a recently diagnosed steroid and immunosuppressive naïve SARD (SLE, SS, SSc, MCTD, DM) were recruited from clinics at UHN/MSH hospitals. Healthy controls (HC) were also recruited. RNA was prepared from blood archived in Tempus tubes. Expression of 5 IFN-induced genes was quantified by NanoString, normalized to expression of housekeeping genes, and summed to generate an IFN5 score. ANAs, serum complements, and levels of specific autoantibodies were measured by the hospital laboratory.

Results: : To date we have measured the IFN signature on 96 individuals (17 HC, 24 ANS, 17 UCTD, 22 SS, 8 SSc, 6 SLE, 1 MCTD, 1 DM). Higher mean IFN scores were seen in all ANA+ sub-groups as compared to HC (mean ± SD: HC 5,380 ± 1,619; ANS 25,886 ± 34,092; UCTD 28,252 ± 24,827; SSc 34,940 ± 40,940; SS 61,877 ± 33,404; SLE 62,769 ± 50,233; MCTD/DM 97,716 ± 24,973), which achieved statistical significance for ANS, UCTD, SSc, SS, and SLE subsets (corrected $p = 0.0036$, 0.0006, 0.048, < 0.0001, 0.0054, respectively). Using a cutoff of 3 SD above the mean of HC as indicative of an elevated IFN5 score, 10/24 ANS, 10/17 UCTD, 5/7 SSc, 19/22 SS, 5/6 SLE, and 2/2 MCTD/DM participants had elevated IFN levels. Marked elevations of the IFN5 score were seen in a subset of ANS and UCTD participants, which could not be attributed to recent infection. Although there was a significant correlation between the ANA titer ($p = 0.0006$) and IFN5 score for all ANA^+ individuals, this was not seen in the ANS or UCTD subsets of this population. However the IFN5 score was positively correlated with the number of different ANA specificities present in the UCTD subset ($p = 0.026$) and all ANA^+ individuals ($p < 0.0001$). The IFN5 score was significantly higher in ANA^+ individuals who were anti-Ro antibody positive, as compared to those who were negative. Within the ANS subset, there was a strong correlation between the presence of anti-Ro/La antibodies with 6/10 $IFN5^{high}$ as compared to 1/14 IFN^{low}individuals being antibody positive ($p = 0.009$). There was no association between the IFN5 score and the presence or absence of other autoantibody specificities, or complement levels.

Conclusion: An IFN signature is seen in a subset of ANA^+ individuals prior to a confirmed diagnosis of SARD and appears to correlate with the number and type of specific ANAs rather than clinical disease.

IL-22 Drives the Proliferation and Differentiation of Human Bone Marrow Mesenchymal Stem Cells (MSCs); A Novel Pathway That May Contribute to Aberrant New Bone Formation in Human Spa and Beyond

Yasser El-Sherbiny[1], Ahmed Elzayadi[2], Evangelos M. Fragkakis[1], Richard Cuthbert[1], Thomas Baboolal[3], Elena Jones[1] and Dennis McGonagle[1], [1]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom, [2]Obstetrics and Gynaecology, Mansoura University, Egypt, MD, MSc., Mansoura, Egypt, [3]PhD, Leeds, United Kingdom
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Innate Immunity and Rheumatic Disease Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

The human spondyloarthropathies (SpA) are associated with single nucleotide polymorphisms (SNPs) in the IL-23 pathway and IL-23/17 axis therapy is effective in SpA. The SpAs are also associated with new bone formation that is to a degree independent of TNF blockade. Given that IL-23R receptor signaling in lymphoid cells is associated with IL-22 production and since IL-22 is a pivotal cytokine that maintains gut and skin stem cell function[1,2], we hypothesized that IL-22 might also drive skeletal stem cells and hence contribute to the SpA bone phenotype. Therefore we explored the effect of IL-22 on bone marrow mesenchymal stem cells (MSCs).

Methods:

Human Bone marrow MSCs were expanded and tested by multi-parameter flow cytometry for expression of the ISCT criteria for MSCS and IL-22R. IL-22R priming was undertaken with IFN gamma and TNF alpha prior to recombinant IL-22 exposure. MSC proliferation and migration were tested by colorimetric XTT assay and chamber migration assays. MSC osteogenic functional differentiation was performed with and without cytokines.

Results:

MSCs expressed low level IL22RA1 which was significantly up-regulated in combination with IFN gamma and TNF alpha, Mean

fluorescent intensity (MFI) increased 1.8±0.12 fold. MSCs proliferation and migration dramatically increased following IL-22 exposure after IFN gamma and TNF alpha combined priming compared to IL-22 alone or no cytokine (p= 0.0159 and 0.028). MSCs migration function was enhanced by IL-22 after priming with IFN gamma and TNF alpha compared to no cytokine (p= 0.0159). Osteogenic differentiation was significantly higher in MSCs exposed to IL-22 alone (p=0.002), but was depressed when IL-22 combined with IFN gamma and TNF alpha compared to IL-22 alone or no cytokine (p=0.002 and p=0.003).

Conclusion:

Given that IL-22 is exclusively produced by lymphoid cells and acts on non-lymphoid cells including stem cells, our findings confirm that IL-22 can drive bone marrow MSC osteogenesis. Furthermore, IL-22 boosted MSCs proliferation and migration after priming with IFN gamma & TNF alpha *in vitro* and had variable effects depending on the inflammatory milieu. Given the IL23 axis association with SpA this work opens up a novel pathway for exploring new bone formation in SpA related disease.

AMP-Activated Protein Kinase As an Anti-Inflammatory Target for Methotrexate

Cornelia Cudrici[1], Amma Agyemang[1], Martin Pelletier[1], Gregory Steinberg[2] and Richard M. Siegel[1], [1]NIAMS, Immunoregulation Section, Autoimmunity Branch, Bethesda, MD, [2]Department of Medicine, Division of Endocrinology,McMaster University, Hamilton, ON, Canada

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Innate Immunity and Rheumatic Disease Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Methotrexate (MTX) is a first-line medication effective in multiple forms of inflammatory arthritis. The anti-inflammatory effects of MTX are more prolonged than its plasma half-life might suggest and most likely are the result of accumulation of polyglutamate metabolites in tissues. Inhibition of 5-aminoimidazole-4-carboxamide ribonucleotide (AICAR) transformylase by methotrexate metabolites result in elevation of intracellular levels of AICAR, which is a potent inhibitor of AMP deaminase and adenosine deaminase. The consequent increase in intracellular and released adenosine has led to the hypothesis that adenosine mediates the anti-inflammatory effects of MTX. In addition to regulating nucleotide metabolism AICAR is also is also an endogenous activator of the intracellular energy sensor AMPK, a highly conserved protein kinase that exists in all eukaryotic cells. AMPK is activated by an increasing cellular AMP/ATP ratio secondary to metabolic stresses or accelerated ATP consumption, and promotes ATP production by promoting catabolism and autophagy and suppressing energy-consuming biosynthetic pathways. Parallel studies of immune cell metabolism have shown that activating catabolic pathways can have anti-inflammatory effects. We hypothesize that AMPK activation through AICAR may mediates a major portion of the anti-inflammatory effects of MTX, and that this may account for some of the efficacy of MTX in rheumatic diseases.

Methods:

Human monocytes derived macrophages (MDM) and murine bone marrow-derived macrophages were treated with MTX, AICAR, folic acid and A769662, a small-molecule that activates AMPK independently of AMP. AMPK phosphorylation and total AMPK was measured by Western blotting. We have also used compound C, a selective ATP-competitive inhibitor of AMPK in order to determine whether MTX exhibits anti-inflammatory through AMPK. Cells were then stimulated with LPS and production of pro-inflammatory cytokines were measured in the supernatant.

Results:

MTX induced AMPK phosphorylation in a time and dose-dependent manner, with effects comparable to the synthetic AMPK activator A769662 and AICAR. Mitochondrial oxygen consumption and the ATP/ADP ratio were not altered by MTX, suggesting that AMPK

activation by MTX was not due to suppression of ATP generation. MTX-induced AMPK activation was associated with a reduction in production of pro-inflammatory cytokines (IL-6 and TNF) in response to LPS. Compound C is able to partially reverse the effects of MTX on LPS-induced cytokine production, suggesting that AMPK activation is responsible for these anti-inflammatory effects.

Conclusion: Methotrexate is able to induces AMPK activation in both human and mouse macrophages, and suppress pro-inflammatory cytokines in a manner dependent on AMPK activity. These results are being confirmed genetically in macrophages deficient in AMPK subunits. Our findings raise the possibility that some anti-inflammatory effects of MTX are mediated by AMPK, suggest that AMPK may be a target for the action of current 'antimetabolite' anti-inflammatory agents and a target for the development of new anti-inflammatory drugs.

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: IgG4-related disease (IgG4-RD) is a recently recognized systemic fibro-inflammatory disease of unknown etiology with multi-organ involvement. Although the organ involvement in IgG4-RD usually improve with initial glucocorticoids (GC) therapy, relapse occurs frequently during GC tapering. This study was aimed to elucidate the factors influencing the relapse of IgG4-RD during GC therapy.

Methods: Thirty-five IgG4-RD patients were enrolled. They all met Comprehensive Diagnostic Criteria for the diagnosis of IgG4-RD and were treated with GC in Kobe university hospital or Shinko hospital, Kobe, Japan. "Relapse" was defined as recurrence or new appearance of organ involvement attributable to IgG4-RD which required increase in immunosuppressive therapy. Association of various clinical parameters and relapse was determined by Students' t-test or Welch's t-test. Relapse-free survival was compared by the Kaplan-Meier estimation.

Results: Ten female and 25 male patients were retrospectively analyzed. The mean age at the time of diagnosis was 63.9±10.2 years (range 45-81). All 35 patients were treated with GC, and 14 patients relapsed (40%). The mean duration from the initiation of GC therapy to relapse was 27.0±18.7 weeks. The baseline serum IgG4 levels before GC therapy was significantly higher in patients with relapse than in those without (P=0.017; median 843 to 426 mg/dl). Minimum serum IgG4 levels during GC therapy also tended to be higher in patients with relapse than that in patients without (P=0.055; median 185 to 102 mg/dl). In contrast, sex, age at the diagnosis, numbers of involved organs, initial GC dose, and GC dose in maintenance therapy were not different between patients with and without relapses. ROC curve analysis on baseline serum IgG4 level revealed that the best cut-off level which maximized sensitivity and specificity for the prediction of relapse was 532mg/dl. The patients with baseline serum IgG4 level less than 532 mg/dl ("baseline IgG4<532 group") showed better relapse-free survival than "baseline IgG4≥532 group" (Log-rank test, (X^2 = 5.94, P=0.015)) (Figure 1). In addition, when patients were divided into two groups according to whether their IgG4 levels declined below 135 mg/dl ("minimum IgG4<135 group") or not ("minimum IgG4≥135 group") during therapy, the former showed better relapse-free survival (Log-rank test, (X^2 = 4.85, P=0.027)) (Figure 2).

Conclusion: Higher serum IgG4 concentration before and during GC therapy are risk factors for predicting relapse in IgG4-RD. Serum IgG4 levels should be monitored during the therapy.

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster Session II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: IgG4-related disease (IgG4-RD) is associated with characteristic pathological changes including lymphoplasmocytic infiltration with abundant IgG4 positive plasma cells, storiform fibrosis and obliterative phlebitis. The etiology of the disease is unknown but a chronic antigen driven process leading to the production of IgG4 and $IgG4^+$ plasmablasts is proposed. Various T cell subsets have been analyzed in the disease however in small studies. Their role remains unclear. We conducted a study to characterize peripheral blood immune cells subsets in patients with untreated IgG4-RD.

Methods:

Thirty patients with IgG4-RD were included prospectively in the study and compared to healthy controls (HC) and primary Sjögren syndrome (pSS) patients. Patients fulfilled the 2011 comprehensive IgG4-RD diagnostic criteria and the 2002 American-European Consensus Group criteria for pSS. PBMC of patients and controls were analyzed by flow cytometry on a BD FACS Canto II. T regulatory cells were characterized as $CD4^+$ $FoxP3^+$ $CD25^{high}CD127^{low}$, T cells were categorized as memory or naive by CD45RO and CD45RA expression, B cells were categorized as naive or switched memory by IgD and CD27 expression, plasmablasts were characterized as $CD19^+CD27^{high}CD38^{high}$, dendritic cells were categorized as plasmacytoid or myeloid by CD11c and CD123 expression, NK cells were characterized as $CD3^-$ $CD56^+CD16^+$.$CD4^+$ T helper subsets were analyzed after stimulation by intracellular staining for IL-4 (Th2), IFNg (Th1) and IL-17 (Th17). The cytokine production for IL-4, IL-10 and IL-17 was performed with the cytokine bead assay (CBA® kit, BD Biosciences) on supernatant of stimulated PBMC. Statistical analysis was performed on PRISM software.

Results:

The frequency and absolute number of total T cells, $CD4^+$ and $CD8^+$T cells, CD45RA and CD45RO, total DC, T regulatory cells, NK cells, B and naive B cells did not show any changes between IgG4-RD patients and HC. pDC were decreased in IgG4-RD compared with HC ($p=0.01$) and pSS ($p=0.01$). Plasmablasts frequency ($p=0.0003$) and absolute numbers ($p=0.0004$) were increased in IgG4-RD patients when compared to HC. T helper subsets analysis showed an increase of Th2 cells ($p=0.0004$), Th17 cells ($p=0.03$) but not Th1 cells when compared to HC. The cytokine production by PBMC showed an increased release of IL-4 ($p<0.0001$), IL-10 ($p=0.004$) and IL-17 ($p=0.001$) by IgG4-RD compared to HC.

Conclusion: Baseline changes of immune cells in peripheral blood of IgG4-RD patients is characterized by plasmablast expansion, as previously reported, a decrease of plasmacytoid DC and a T helper switch to Th2 IL-4 producing cells. We also show an increase in IL-10 release and an increase of both Th17 cells and IL-17 release. Further studies are required to elucidate the role of these different subsets in the pathogenesis of IgG4-RD.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster Session II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: To evaluate the relationship between cholinesterase, number of organ involvement and serum fibrotic markers in Japanese patients with IgG4-related disease (IgG4-RD).

Methods: The clinical symptoms, laboratory, pathological and FDG-PET/CT findings of Japanese patients with IgG4-RD (n=20) were assessed. Several laboratory data of IgG4-RD with multiple organs' involvements (IRDMOI) (n=10), IgG4-RD with limited organ's involvement (IRDLOI) (n=10), ANCA-associated vasculitis (AAV) (n=10) and Sjogren syndrome (SjS) (n=10) were comparatively examined. Furthermore, we studied the relationship between the numbers of organ involvement (NOI) and several fibrotic markers (ELF score and serum Dkk-1) in IgG4-RD group.

Results: Serum cholinesterase (ChE) levels were significantly lower in IRDMOI group than IRDLOI, AAV and SjS groups. All cases did not show hepatic dysfunction in laboratory examinations. Serum albumin and IgG levels were significantly lower and CRP levels were significantly higher in AAV group, compared with IgG4-RD and SjS group. There were no significant differences in these levels between IRDMOI and SjS. In total IgG4-RD cases, ChE levels inversely correlated with NOI and fibrotic score, and fibrotic score positively correlated with NOI. Finally, Dkk-1, one of Wnt inhibitors, levels in IRDMOI were significantly lower than IRDLOI and healthy subjects ($p<0.05$).

Conclusion: The ELF score and serum Dkk-1 level might be a clinically useful indicators of active fibrosis and the extent of disease in Japanese patients with IgG4-RD. Notably, serum ChE levels could predict these phenomena.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster Session II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

IgG4-related disease (IgG4-RD) is a fibro-inflammatory disorder that is known to have protean manifestations and variably elevated serum IgG4 concentrations. We present the serum IgG4 characteristics and clinical features of a unique cohort of IgG4-related disease patients in British Columbia. Anecdotally, Asians seem to have more exuberant immunoglobulin production but this has not been formally studied to date.

Methods:

All patients are residents of British Columbia and have biopsy proven IgG4-related disease according to consensus guidelines. Each patient underwent full history and physical examination by two IgG4-related disease physician experts. All patients underwent serum IgG4 levels by nephlometry. Unpaired t-test was used for serum IgG4 comparisons.

Results:

There were 19 patients with IgG4-related disease. The mean age at time of IgG4-RD diagnosis was 61 years old (range: 28-85) and the male:female ratio was 55:45. The time to diagnosis was lengthy at 9 years, on average, from start of symptoms. The organ involvement included salivary glands (n=7), lymph nodes (n=3), lacrimal gland (n=3), kidneys (n=2), genitourinary tumor (n=2), amongst others. Treatments included prednisone (n=10), rituximab (n=5), azathioprine (n=2), cyclosporine (n=2), fludarabine (n=1) and bortezomib (n=1). An additional 4 patients were undergoing observation only. Serum IgG4 levels were on average elevated at 10 g/L ± 9 (cutoff >1.25) as were IgG levels at 35 g/L ± 18 (cutoff >15.2). There was a statistically significant difference between IgG4-RD levels of Chinese and East Asians patients (n=10) averaging 13.8 g/L (range: 2.3-26.9) and Caucasians (n=9) averaging 3.0 g/dL (range: 0.418-9.75) (p=0.021).

Conclusion:

This is a unique multi-ethnic cohort of IgG4-related disease patients in Canada. There are statistically significant, possibly genetically related, differences in Asian and Caucasian serum IgG4 concentrations.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

IgG4-related disease (IgG4-RD) and lymphocyte-variant hypereosinophilic syndrome (L-HES) share elevated peripheral eosinophilia and IgE levels as well as common clinical features including atopy, cutaneous lesions and lymphadenopathy. Distinguishing between these two diseases is a diagnostic challenge. L-HES is driven by an aberrant population of T lymphocytes characterized by an abnormal immunophenotype, clonal T-cell receptor rearrangements, or both. Determining whether there is overlap in the immunphenotype of T-cells in IgG4-RD with L-HES will be helpful in the diagnosing and understanding the pathophysiology of these conditions.

Methods:

IgG4-RD patients were biopsy proven according to consensus guidelines and HES patients fit WHO criteria for HES including persistent

blood eosinophilia >1,500/mm3 at a single Canadian academic center. There were 9 patients with L-HES and 11[p1] patients with IgG4-related disease. Peripheral blood T-cell immunophenotyping was performed by multicolor flow cytometry using an antibody panel consisting of CD2, 3, 4, 7, 8, 45 and 56. Polymerase chain reaction was used to analyze T-cell receptor clonality.

Results:

There were three IgG4-related disease patients with elevated CD4+/7- T-cell subsets median 14.5% (range 11-16.5; cut-off>10) and 6 additional IgG4-RD patients had normal subsets. Two IgG4-related disease patients had elevated NK cells. None of the IgG4-RD patients had a clonal T-cell receptor rearrangement by PCR. All nine L-HES patients had an abnormal phenotype, including increased CD4+/3- (n=4), CD4+/3-/8- (n=3), CD4+/7- (n=1) and increased NK cells (n=1). There were 5 HES patients, out of 8 total measured, with clonal T-cell receptor rearrangements by PCR, including the patient with an elevated CD4+/7- population.[p2]

Conclusion:

Five of eleven patients with IgG4-RD had immunophenotypic abnormalities of the T-lymphocytes which overlap with the immunophenotypic abnormalities seen in L-HES. However, none of the IgG4-RD patients had a clonal T-cell rearrangement by PCR, indicating that the expanded CD4+/7- and NK populations seen in this disease are likely a nonspecific finding also seen in other inflammatory/autoimmune disorders.

Session Time: 9:00AM-11:00AM

Comparison of IgG4-related and Non-IgG4-related Retroperitoneal fibrosis; a 12 year Retrospective Study

Background/Purpose: Retroperitoneal fibrosis (RPF) is a rare disease characterized by a progressive proliferation of fibro-inflammatory tissue in the periaortic region leading to abdominal pain, back pain, renal failure, etc. Over 2/3rd cases of RPF are idiopathic. Prior studies, using various criteria to define IgG4 RPF, have suggested an association of idiopathic RPF (IRPF) with IgG4-related disease (IgG4RD) with a frequency between 28-58%, while little is known about the clinical outcome of these patients.

We were interested to determine the prevalence of IgG4-related RPF amongst IRPF and their clinical characteristics and outcomes compared to non-IgG4-related RPF.

Methods: Retrospective chart review of all biopsy proven cases of IRPF between 1/1/2003 to 4/3/2015 presenting at Cleveland Clinic. Data including demographics, history, labs, imaging, treatment and outcomes were collected. IgG4RD was defined as compatible clinical presentation along with characteristic HP – dense lymphoplasmacytic (LP) infiltrate; fibrosis, usually storiform and obliterative phlebitis (OP); with immunohistochemistry (IHC) showing ≥30 IgG4+ plasma cells/ HPF and IgG4+/IgG >40%. Statistical analysis was done using t-test and Fischer's exact test.

Results: 72 cases were identified and their charts were reviewed – 33 patients were found to have IRPF based on no identifiable secondary cause. Of these 6 (18%) met the criteria for IgG4RD. There was no statistical difference found in demographics, clinical features, labs, imaging, treatment modalities and outcomes in the 2 groups (see table 1 and 2). 30% needed surgical and 56% needed both surgical and medical management in non-IgG4-related RPF vs. 50% and 33.3%, respectively in the IgG4-related RPF. Two patients were on prednisone at the time of biopsy-one was IgG4-related and other was non-IgG4-related RPF. IgG4RD patients were statistically more likely to have OP, eosinophilia and lymphoid follicles than non-IgG4-related RPF; though none of these histologic features are sufficiently sensitive/specific for the diagnosis in the absence of immunostains for IgG4 to establish the diagnosis.

Conclusion: This is the largest reported cohort of biopsy proven IRPF cases presenting at one tertiary center. Only 18% cases of IRPF were IgG4RD compared to 28-58% reported in other series. There were no difference found in the treatment outcomes between IgG4-related RPF and non-IgG4-related RPF. OP, arteritis, eosinophilia and lymphoid follicles are suggestive of IgG4RD and should prompt additional testing

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: IgG4-related disease (IgG4-RD) is a systemic fibroinflammatory condition with characteristic histopathological lesions. Nearly all anatomic sites can be involved with a risk of organ dysfunction. A dramatic response to steroids is usual but relapses are frequent and steroids sparing agents are frequently required. Favorable response to B-cell depletion by rituximab (RTX) has been suggested by case reports, small series and an open label trial. However data “in real life” with a long term follow-up are sparse, especially concerning the efficacy and tolerance. We analyzed rituximab use in a national multicentric cohort of IgG4-RD patients.

Methods: Patients included in a national multicentric cohort of IgG4-related disease and treated by RTX were included in this study. All patients fulfilled the 2011 comprehensive IgG4-RD diagnostic (CDC) criteria. All differential diagnosis were systematically ruled out. Clinical, biological, histological, radiological and therapeutic data were retrospectively collected in order to evaluate efficacy and tolerance of RTX in this indication.

Results: Twenty-four patients were included in this study. All patients fulfilled the 2011 CDC criteria, with a “definite” diagnosis in 15 cases, “probable” in 6 cases and “possible” in 3 patients. Median age at RTX was 57 years [extreme 36-84]. Median duration of the disease before RTX was 35.5 months [4-180], and mean number of previous medical treatments was 1.6 [0-4], with previous steroid use in all patients but one. Median number of organ involved was 5 [1-8], and organ involvement justifying use of RTX was mainly kidney in 6 patients (25%), biliary involvement in 6 (25%), pancreas in 5 (21%), retroperitoneal and/or aortic involvement in 4 (15%). Administration was 1gx2 d1-d15 in most patients (63%), and 375 mg/m2 in 6 (25%). A clinical efficacy was noted in 18/22 patients symptomatic at treatment initiation. A decrease of IgG4 serum levels was observed 13/14 evaluable patients with pre-treatment serum

IgG4 elevation. Imagery (conventional and/or metabolic) improvement was noted in 12/18 and stability was noted in 5 over 18 evaluable patients. Among 21 responders, 7 patients (33%) presented a relapse, with a median follow-up of 11 months [1-129]. Relapse occurred with a median delay of 18 months [9-36] after RTX treatment. Corticosteroids could be stopped in only 12/23 evaluable patients (52%). Infectious events were observed in 10 patients (42%), with severe infections in 2 patients with concomitant steroid therapy (septic shock in 1, and mitral endocarditis in 1). Hypogammaglobulinemia was observed in 2 patients, requiring immunoglobulin substitution in one case.

Conclusion: Rituximab appear to be effective in more than 80% of patients with IgG4-RD. Nevertheless, complete withdrawal of steroids was possible in only half of patients. One third of patients relapsed after 1 year of follow-up. Finally, infectious events and hypogammaglobulinemia are not rare and must be monitored, even if the responsibility of RTX is difficult to assess in these multitreated patients.

Malignancy Prevalence Is Increased Among Patients before the Onset of IgG4-Related Disease

Zachary Wallace[1], John H. Stone[2], Hyon K. Choi[3], Na Lu[3] and Carly Wallace[4], [1]Division of Rheumatology, Allergy and Immunology, Massachusetts General Hospital, Boston, MA, [2]Massachusetts General Hospital Rheumatology Unit, Harvard Medical School, Boston, MA, [3]Rheumatology, Allergy and Immunology, Massachusetts General Hospital, Harvard Medical School, Boston, MA, [4]Rheumatology Unit, Massachusetts General Hospital, Boston, MA

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: IgG4-related disease (IgG4-RD) is a systemic fibroinflammatory disease of unclear etiology. Studies have suggested that patients with IgG4-RD may be at increased risk of malignancy when followed prospectively. We have observed a frequent history of malignancy preceding the onset of IgG4-RD. If true, this may inform our understanding of the pathogenesis. We therefore evaluated this further in a well-described cohort of 125 patients by comparing the prevalence of malignancy to the general US population as well as that of age- and sex-matched controls from our Center.

Methods:

We reviewed the electronic medical records of the first 125 patients with IgG4-RD evaluated in our Center, all of whom were diagnosed by strict clinicopathologic criteria. We identified those with a history of invasive malignancy and collected details from the electronic medical record, confirming details with the patients. The indirect standardization method was used to compare the rate of malignancy between our cohort and that of the US population using the Surveillance, Epidemiology, and End **Results** (SEER) database of the National Cancer Institute (NCI). Furthermore, up to 5 age- and gender- matched controls were selected among patients with either osteoarthritis or fibromyalgia evaluated in the MGH Division of Rheumatology, Allergy, and Immunology (DRAI) and identified using the Research Patient Data Registry (RPDR) at Partners HealthCare. The age of control patients at their first visit in DRAI was matched to the age of cases at the onset of findings or symptoms attributed to IgG4-RD. Patients with immune-mediated conditions (e.g., SLE, RA) were excluded because of the putatively increased risk of malignancy in some of those patient subsets. Conditional logistic regression was used to compare the rate of malignancy between our cohort and that of the matched controls evaluated in DRAI.

Results:

Of the125 patients with IgG4-RD included, 60.8% was male and the average age of onset was 50.3+/-14.9 years. The mean number of

organs involved was 2.3 +/-1.3. Twenty patients (16%) had been diagnosed with 21 malignancies before the onset of IgG4-RD. Malignancy was diagnosed an average of 6.9 years (range 1-22) prior to the diagnosis of IgG4-RD. Prostate cancer (n=7) and lymphoma (n=4) were the most common malignancies. Compared to the general US population, the observed prevalence of malignancy in patients with IgG4-RD is 2.5 times higher than expected (95% CI: 1.1-3.6). Compared to patients evaluated in the MGH DRAI, patients with IgG4-RD had a significantly higher prevalence of malignancy than age- and gender-matched controls (OR 2.9, 95% CI 1.5-5.9).

Conclusion: Our findings, derived from two separate comparison groups, suggest that patients with IgG4-RD more often have a history of malignancy prior to their diagnosis. The reason(s) for this finding remains under investigation, but potential explanations include shared risk factors for the respective diagnoses and increase in the risk of IgG4-RD resulting from the treatment of cancer. Future studies may investigate potential pathogenetic, clinical, and prognostic differences between patients with and without a history of malignancy.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

IgG4-related disease (IgG4-RD) is an immune-mediated fibro-inflammatory condition that often leads to tumefactive lesions. We describe a common but under-recognized radiologic finding in this disease: the occurrence of paravertebral masses that may mimic a number of other inflammatory, infectious, and malignant disorders.

Methods:

The medical records of 143 subjects with IgG4-RD diagnosed by strict clinicopathologic correlation were examined to identify those with relevant imaging (n = 59). The available computed tomography (CT), 18F-fluorodeoxyglucose (18F-FDG) positron emission tomography (PET), and magnetic resonance imaging (MRI) studies were reviewed by thoracic radiologists. All images were reviewed and interpreted by board-certified radiologists. Demographic, clinical, and serological features were collected from the medical record.

Results:

Of 59 patients with relevant imaging, 8 (14%) had a paravertebral mass. These lesions were typically detected on the right side, along the lower thoracic spine, and spanned multiple vertebral bodies (Figure 1). The lesions demonstrated contrast enhancement on CT and 18F-FDG avidity on PET. All patients not on treatment had elevated serum IgG4 concentrations. Multi-organ IgG4-RD was present in seven patients (88%). One of the four patients with imaging studies before and after treatment demonstrated resolution of the lesions.

Conclusion:

Paravertebral masses are often detected incidentally on pulmonary imaging in IgG4-RD. Our series of eight cases is, to our knowledge, the largest series of paravertebral masses associated with IgG4-RD reported in the literature. All of our cases had biopsy-proven IgG4-RD. Characteristic features of these lesions include their right-sided location, the extension across multiple vertebral bodies, and their common association with other manifestations of IgG4-RD.

Figure 1. (a) Axial contrast enhanced CT in a 59 year old man with IgG4-RD. The paravertebral mass is centered predominantly on the right side of the thoracic spine. The thoracic duct (arrow) can be identified anterior to, and separate from, the paravertebral mass. (b) Follow up CT with coronal reformats demonstrates the typical craniocaudal extent, spanning multiple vertebral bodies.

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster Session II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: To assess adalimumab (ADA) efficacy and safety in corticosteroid-dependent patients with inactive non-infectious, intermediate, posterior, or panuveitis enrolled in the international, double-masked trial, VISUAL II.

Methods: Patients aged ≥18 years with inactive, non-infectious, intermediate, posterior, or panuveitis requiring 10-35 mg oral prednisone to maintain an inactive state (no active, inflammatory chorioretinal and/or retinal vascular lesions, anterior chamber (AC) cell grade ≤0.5+ and vitreous haze (VH) grade ≤0.5+) were randomized 1:1 to receive placebo (PBO) or ADA (80 mg week 0, followed by 40mg every other week from week 1 for ≤80 weeks). From week 2, all patients underwent a mandatory prednisone taper to 0 mg by week 19 or earlier depending on the baseline dose. Primary endpoint was time to treatment failure (TF) in ≥1 eye at or after week 2. TF was defined as ≥1 of the following criteria: new active, inflammatory lesions; worsening of BCVA by ≥15 letters; 2-step increase in AC cell grade; 2-step increase in VH grade relative to baseline (BL). Secondary endpoints included change in AC cell grade, VH grade and BCVA from BL to the final visit, time to optical coherence tomography (OCT) evidence of macular edema (after week 2), and percent change in central retinal thickness (CRT) from BL to final visit. Adverse events (AEs) were monitored throughout the study.

Results: A total of 229 patients were randomized (female, 61%; mean age, 42.5 years; mean duration of uveitis 61.2 months); 21% had intermediate, 32% had posterior, 46% had panuveitis, and 1% had intermediate and posterior uveitis. Patients who received ADA were

less likely to have TF (hazard ratio=0.57; 95% CI, 0.39-0.84; P=0.004). Median time to TF was 8.3 months for PBO and not estimable for ADA, as more than half of the ADA-treated patients did not experience TF **(Figure)**. Secondary endpoints were numerically in favor of ADA, although significant differences between ADA and PBO were not observed. No significant differences were observed between SAEs, serious infections and the overall rate of AEs between ADA and PBO.

Conclusion: ADA significantly lowered the risk for uveitic flare or vision loss in patients with steroid-dependent inactive, non-infectious uveitis. No new safety signals were identified with ADA treatment in patients with inactive uveitis; the safety profile of ADA in this population was comparable to other approved indications. Similar results were observed in patients with active, noninfectious, intermediate, posterior, or panuveitis despite the use of corticosteroids, enrolled in the VISUAL I trial.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Many inflammatory rheumatic diseases (IRD) are associated with ocular involvement. The prevalence of these complications is not fully known. This meta-analysis was performed to systematically investigate the prevalence and type of ocular involvement in IRD.

Methods: Medline, Web of Science and Cochrane databases were searched to July 2014, to identify publications related to IRD and associated ocular conditions. Disease terms included; juvenile arthritis (JIA), rheumatoid arthritis (RA), connective tissue disease, spondyloarthropathy (SpA), ankylosing spondylitis (AS) and Behcet's disease. For eye involvement terms were; conjunctivitis,

keratoconjunctivitis sicca, xeropthalmia, uveitis, eye hemorrhage, optic neuritis, papilledema, orbital disease, retinal artery/vein occlusion, macular edema, retinitis, chorioretinitis, scleritis, iridocyclitits, choroid hemorrhage, blindness and amaurosis fugax. Data regarding the rates of ocular complications were analyzed with a random effects model.

Results: 7124 studies were found with 263 for full review. There were 13 AS studies, 30 Behcet's disease (BD), 31 JIA, 12 PsA, 11 RA and 165 others. Pooled prevalence for commonly reported ocular manifestation were uveitis rates of: 22% (95% CI: 16-24%) in AS, Behcet's 55% (41-68%), JIA [oligoarthritis 36% (20-51%), polyarticular 13% (8-19%) systemic onset 3% (0-7%)], pediatric Behcet's 33% (0-74%), and PsA 15% (5-24%) for anterior uveitis and 0.2% for posterior uveitis. In RA, keratoconjunctivitis sicca occurred in 16% (8-25%), sicca symptoms in 31% (21-42%), marginal ulcerative keratitis in 1-3%, episcleritis in 1-2% and retinal vasculitis in 0.2%. In SLE 29% of patients had dry eyes. There may have been publication bias (over reporting due to selection bias of cohorts enriched for ocular complications such as patients from university clinics where complications could be higher, and several estimates had herterogeneity. Data were lacking on confounding variables (such as screening and treatment). Figure shows some uveitis rates.

Conclusion: Extra-articular manifestations of inflammatory rheumatic diseases frequently complicate the ocular health of afflicted individuals. Although the rates vary, an awareness of potential complications can aid in early identification and treatment of these rheumatic complications. Rates of ocular involvement may not be changing over time and therefore need to be recognized and treated appropriately.

Hidradenitis Suppuritiva Is Associated with Inflammatory Eye Disease

Abrahim U. Syed[1], Didem Uzunaslan[2], Careen Y. Lowder[3], Sunil Srivastava[3], Juan J. Maya[1] and Rula A Hajj-Ali[4], [1]Internal Medicine, Cleveland Clinic, Cleveland, OH, [2]Cleveland Clinic, Cleveland, OH, [3]Cole Eye Institute, Cleveland Clinic, Cleveland, OH, [4]Rheumatic

and Immunologic Dis, Cleveland Clinic, Cleveland, OH
First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster Session II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Hidradenitis Suppurativa (HS) is an inflammatory skin condition that can cause profound morbidity. Patients can present with recurrent nodules, sinus tract formation, abscesses and/or scarring, mainly affecting intertriginous skin areas. A variety of inflammatory disorders have been associated with HS, such as inflammatory bowel disease (IBD) and spondyloarthropathies. Case reports have documented coexistence between HS and inflammatory eye disease (IED), but associations have not been described. Herein, we aimed to assess the types of IED associated with HS, risk factors for developing IED in patients with HS, and treatment outcomes.

Methods:

Case identification was performed by including all cases within Cleveland Clinic Health System with a diagnosis of HS (ICD code 705.83) and any IED. Using this strategy, 483 patients were identified. With Cleveland Clinic electronic medical records, a retrospective chart review was done to identify demographics, IED patterns, associated conditions, treatments and outcomes. Ophthalmologic notes were reviewed by an independent ophthalmologist to ensure accuracy of IED diagnosis. Patients with episcleritis and sicca were excluded given their prevalence in the general population. Only those with chronic IED were included. A total of 20 patients with HS and IED met these criteria. Qualitative variables were described with measures of frequency.

Results:

16 patients were female (80%). 12 were African American (60%) and 7 Caucasian (35%). HS was diagnosed before IED in 11 patients (55%). Mean age when HS was diagnosed was 42.15; mean age when IED was diagnosed was 43.65.

13 patients had uveitis (65%), 6 had scleritis (30%) and 1 had peripheral ulcerative keratitis. 8 patients (40%) had a co-morbid IBD: 5 with Crohn's disease, 1 with ulcerative colitis, and 2 were undifferentiated. RA and common variable immunodeficiency were each diagnosed in 2 patients. There was 1 patient for each of the following conditions: sarcoidosis, AS, psoriasis, Behcet's disease, multiple sclerosis, SLE, lymphoma, and colon cancer.

Table 1: Treatment of IED with a diagnosis of HS

Treatment	Number of Patients	Number Achieving Remission
Topical Steroid	17	6 (35%)
Systemic Steroid	7	1 (14%)
Infliximab	4	3 (75%)
Adalimumab	4	2 (50%)
Methotrexate	7	2 (29%)
Periocular steroid injection	1	0

Conclusion:

HS should be included in the etiology of IED. Female gender and African American ethnicity are common in patients with both IED and HS. The pattern of IED most associated with HS was uveitis followed by scleritis. Among the co-morbidities, IBD is the most prevalent, especially the subset of Crohn's disease. While topical steroid remains first-line treatment, systemic immunosuppressive agents show promise for refractory eye disease, particularly anti-TNF-alpha biologics among this study group.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Hidradenitis suppurativa (HS) is a chronic recurrent inflammatory disease which affects 1% to 4% of young adults. The purpose of the current study was to investigate inflammatory cytokines and growth factors in the effluent from HS lesions compared to effluent from chronic wound specimens. In differentiating the inflammatory profile of HS lesions compared to chronic wounds we hope to identify potential local drivers of inflammation unique to HS over and above inflammatory responses seen in patients with chronic wounds.

Methods:

Wound fluid specimens from 8 patients with HS and 8 age-matched patients with chronic wounds were selected for analysis. Baseline demographics were obtained from the Wound Etiology and Healing (WE-HEAL) database. The Hidradenitis Suppurativa Score a validated HS disease activity score utilized in clinical trials was used to determine extent of HS activity at the time of specimen collection. The Meso Scale Discovery V-Plex cytokine panel 1 and the V-plex proinflammatory panel 1 were used to analyze proinflammatory cytokines in the fluid specimens.

Results:

There was no significant difference in race, sex, presence of diabetes, and cigarette smoking exposures in the HS compared to chronic wound cohorts. Mean HSS in the HS cohort was 68.88 (SD ±41.45) confirming moderately active disease. Interferon-gamma (IFN-γ) was significantly elevated in the HS wound fluid compared to chronic wound samples (Table 1, 1418 ± 1501 pg/ml compared to 102.5 ± 138 pg/ml, p 0.027). HS effluent also had significantly higher levels of TNF-β than chronic wound fluid (Table 1, 9.24 ± 7.22 pg/ml compared to 1.65 ± 2.14 pg/ml, p 0.03). There was no significant difference in any other proinflammatory cytokines including TNF-α, IL-1β, IL-12p70, IL-1α, IL-17A, IL-6, IL-16 and IL12/IL23p40. The anti-inflammatory cytokines IL-10, Il-4, and IL-13, the traditional proliferation cytokines, IL-2, IL-15, Il-7 and IL-5, and the growth factors GM-CSF and VEGF were not significantly different between HS effluent and chronic wound fluid.

Conclusion:

Local molecular drivers of HS are poorly understood. In this study we were able to show that when compared with effluent from chronic wounds HS effluent contains higher levels of the cytokines IFN-γ and TNF-β suggesting that IFN-γ and TNF-β may play a crucial role in driving and perpetuating the exuberant inflammation in HS.

Azathioprine May be an Effective Steroid Sparing Agent in Patients with Isolated Recurrent Pericarditis

Adam Brown[1], Xiaobo Liu[2] and Soumya Chatterjee[3], [1]Rheumatology, Cleveland Clinic, Cleveland, OH, [2]Quantitative Health Sciences, Cleveland Clinic, Cleveland, OH, [3]Cleveland Clinic Foundation, Cleveland, OH

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Isolated Recurrent pericarditis (IRP) is a disease with high morbidity. IRP refers to recurrent pericarditis not associated with an autoimmune rheumatic disease or cardiac surgery/injury. Conventional therapy for IRP is a combination of NSAIDs, colchicine and Glucocorticoids (GC) termed triple therapy. A major cause of morbidity in these patients is the predictable side effects of prolonged GC therapy to prevent and treat flares. There is some evidence to support the use of azathioprine (AZA) as an immunomodulating agent in this setting.[1]The purpose of our study was to evaluate whether AZA can be used as an effective steroid sparing agent in IRP. This goal was achieved by evaluating the average and cumulative GC requirement over 6 months before and after initiation of AZA in patients with IRP.

Methods:

To be eligible for the study patients had to be followed for at least 6 months after initiating AZA and had to have at least 2 recurrences of IRP prior to initiation of AZA. After evaluating all patients with IRP, 13 patients satisfied the inclusion criteria. Patients' charts were reviewed to determine the total dose of GC required in 2 week intervals over the course of 6 months. Each IRP flare (as defined by the cardiologist) was also documented. Since the onset of action of AZA is thought to be 2-3 months, the number of flares after starting AZA was documented between months 3 and 6. Paired t-tests and Wilcoxon rank sum tests were used for statistical analysis. All tests were performed at a significance level of 0.05.

Results:

Twenty-eight patients were excluded because of evidence of systemic rheumatic disease or prior immunomodulator therapy. Out of 13 IRP cases, 10 were considered idiopathic or post viral and 3 were post myocardial injury. IRP patients had an average disease duration of 17 months prior to the initiation of AZA and all had at least 5 months of continuous prednisone use prior to initiation of AZA (12 patients had prednisone for >6 months). The mean daily dose of prednisone prior to AZA was 21 mg, and cumulative dose was 4,004 mg over 6 months. The mean daily dose of prednisone post AZA was 13 mg (p= 0.003), and cumulative dose was 2,229 mg (p=0.012) over 6 months. The average number of flares while on triple therapy in the 6 months prior to AZA was 3, and number of flares between months 3 and 6 of AZA therapy was 0.3 (p=0.001). The average dose of AZA was 1.8 mg/kg. Three patients were not able to lower their prednisone dose after AZA initiation and 2 of these patients were on < 1.5 mg/kg of AZA/day.

Conclusion:

This is the first retrospective study that evaluated the average and cumulative dose requirement of GC in patients with IRP to maintain clinical remission before and after initiation of AZA. After the initiation of AZA, patients were able to have a significant reduction in the dose of GC required and had a significant reduction in the frequency of flares within a given time period. In conclusion, this study suggests AZA is an effective steroid sparing agent in IRP. Further studies are needed to confirm these findings.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Sarcoidosis is a multisystemic disorder of unknown cause. About 30-60% of patients have ocular involvement consistent in bilateral uveitis. Recently, the clasification criteria proposed by the First International Workshop on Ocular Sarcoidosis (FIWOS) has been validated. The criteria classifies ocular sarcoidosis as definite (uveitis and biopsy positive), presumed (bilateral hilar lymphadenophaty and uveitis without biopsy), probable (3 ocular signs and 2 laboratory tests without biopsy and without bilateral hilar lymphadenopathy) and possible (4 ocular signs and 2 laboratory tests with negative biopsy) based of specific ophthalmological and laboratory findings. This classification is useful especially when a biopsy is not avalilable or when it is negative./Categorization of patients diagnosed with ocular sarcoidosis according to the criteria proposed by the FIWOS in the last five years in a uveitis unit of the University Hospital Donostia in Guipœzcoa, Spain.

Methods: The clinical records of patients diagnosed with ocular sarcoidosis were reviewed retrospectively. The variables measured were age, sex, systemic manifestations, pattern of uveitis, Quantiferon test, angiotensin converting enzyme, biopsy, chest radiography and treatment. The patients then were classified based on the criteria of the FIWOS.

Results: A total of 11 patients were diagnosed with sarcoid uveitis, 7 females (63.6%) and 4 males (36.3%). The median age was 58.0 years (SD 20.5). In 7 patients (63.3%) uveitis was the first manifestation of the disease, 5 of them later developed systemic symptoms and 2 showed isolated eye involvement. The remaining 4 patients (36.3%) showed systemic symptoms of: bilateral hilar adenopathy in 81.8%, respiratory symptoms 36.3%, peripheral adenopathy 18.1%, parotitis in 27.2% and erythema nodosum in 9.0%. The patterns of uveitis most frequently observed were bilateral panuveitis in 54.5%, chronic unilateral anterior uveitis in 27.2% and chronic bilateral anterior uveitis in 18.1%. The categorization of patients revealed a diagnosis of definite sarcoidosis in 4 (36.3%), presumed in 5 (45.4%), probable in 1 (9.0%) and possible in 1 patient (9.0%). The most common treatment was methotrexate in 45.4%. Two patients were treated withanti-TNF

Conclusion: 81.7% of our patients were categorized as having definite or presumed sarcoidosis. More than half of our patients who had no confirmatory biopsy were diagnosed of ocular sarcoidosis. Bilateral panuveitis and chronic anterior uveitis were the most frequent ocular patterns. Most patients with ocular involvement developed subsequently systemic symptoms.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The epidemiology and clinical characteristics of sarcoid arthropathy are not well-described as only referral-based studies have been reported. This study aimed to use the data from a geographically well-defined population to characterize the clinical characteristics of sarcoid arthropathy.

Methods: An inception cohort of patients with incident sarcoidosis in 1976-2013 in a geographically well-defined population was identified based on comprehensive individual medical record review. Inclusion required physician diagnosis supported by histopathology and radiologic features of intrathoracic sarcoidosis, compatible clinical presentation, and exclusion of other granulomatous diseases. Tissue samples were considered positive if they demonstrate non-caseating granuloma without evidence of acid-fast bacilli or fungi. The only exception to the requirement of histopathological confirmation was stage I pulmonary sarcoidosis that required only radiographic evidence of symmetric bilateral hilar adenopathy. Patients with joint pain were then identified from this cohort. Data were collected on pattern of joint involvement, associated cutaneous and systemic symptoms, physical examinations and inflammatory markers.

Results: In 1976-2013, 345 incident cases of sarcoidosis were identified (mean age 45.6 years and 50.4% female). Symptoms of joint pain occurred in 42 patients (mean age 41.2 years and 57.1% female), and 35 patients had swollen joint(s) on physical examination. Most patients had arthralgia prior to the diagnosis of sarcoidosis with an average time to diagnosis of 21 days. Approximately half of patients had fever and elevated sedimentation rate at diagnosis (48% and 46%, respectively).

Of the 35 cases with objective evidence of synovitis, oligoarthritis (two to four joints) was the most common pattern (88%) followed by monoarthritis (6%) and polyarthritis (6%). Ankles were involved in 91% of cases (14% one ankle and 77% both ankles). In the majority of patients (88%), the arthritis resolved within 6 weeks.

The most common associated cutaneous manifestation was erythema nodosum followed by subcutaneous nodule/plaque (31% and 5%, respectively). The classic Lofgren syndrome (arthritis, erythema nodosum and hilar adenopathy) was observed in 11 patients (26%).

Conclusion: Inflammatory arthritis occurred in a minority of patients with sarcoidosis. Acute oligoarthritis with bilateral ankles involvement was the most common pattern of sarcoid arthropathy. A significant portion of patients also had systemic symptoms as well as

erythema nodosum.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster Session II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Sarcoidosis is a chronic granulomatous disease. Pyrin, is encoded by the MEFV gene and has anti-inflammatory effects in the inflammasoma regulation. MEFV gene mutations affects the inflammatory cascade and cause familial Mediterranean fever. The relationship between different rheumatic diseases and MEFV gene mutations are shown in previous studies. **Aim:**The aim of this study was to determine the MEFV gene prevalence in Turkish patients with sarcoidosis and to determine the possible correlation between the occurrence of mutations and disease phenotype.

Methods: Seventy-eight sarcoidosis patients and age, gender and ethnicity compatible 85 healthy controls were included in the study. The most common eight MEFV gene mutations were investigated by PCR method.

Results: Among seventy-eight sarcoidosis patients MEFV gene mutation was detected in nine patients(%11.5). The distribution of the nine mutations; three (3.8%) V726A, two (2.5%) E148Q, two (2.5%) M680, a (1.3%) A744S, one (1.3%) of K695, respectively. None of the sarcoidosis patients were M694V, M694I, R761H and P369S and compound heterozygous carriers (Table 1). MEFV gene mutations frequency in the healthy control group was found to be 22.4%.The distribution of MEFV gene mutations in the healthy control were; E148Q 9 (10.6%), M694V 2 (2.3%), M694I 1 (1.2%), M680 1 (1.2%), V726A 2 (2.3%), A744S1 (1.2%), K695 2 (2.3%), P369S1 (1.2%), respectively, Compared with the control group, a lower carrier frequency of MEFV gene mutations were detected in patients with sarcoidosis, but it was not statistically significant(p=0.067). In the sarcoidosis group, while serum ESR and CRP levels were significantly higher in the mutation carrier group than those of the non-carrier group (p=0.01,p=0.04). In the sarcoidosis group, while arthritis,enthesitis and ankle arthritis were significantly more frequent in the mutation carrier group than those of the non-carrier group (p=0.028, p=0.05, p=0.05 respectively).

Conclusion:

In Turkish patients with sarcoidosis, we found a lower frequency of MEFV gene mutations compared with healthy control group. Sarcoidosis mutation carrier group were found to be associated with high serum acute phase response , arthritis and enthesitis. The presence of MEFV gene mutation may have a protective role for the development of sarcoidosis. Prospective studies with large patient series are need on this subject.

Session Date: Monday, November 9, 2015

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Although clinical and imaging features of neurosarcoidois (NS) have been described, few studies have reported on the long-term outcome. We report the long-term outcome of a large series of NS, focusing on overall and relapse-free survival and dependency status.

Methods: Retrospective monocenter analysis of NS patients fulfilling international criteria for NS. All NS patients had an evaluation including physical examination, dependence scoring by Expanded Disability Status Scale (EDSS), cerebral spinal fluid (CSF) analysis, brain and/or spine MRI; and for thirty-four cases a pathological study of nerve/muscle tissue. Endpoints were rates of and factors associated with: (i) overall survival after NS diagnosis (OS), (ii) relapse-free survival after NS diagnosis (RFS), and (iii) dependence at the end of the follow-up (FU), as assessed by EDSS ≥2.5. The RFS was calculated using Kaplan-Meier estimator and a multivariate Cox proportional hazard ratio model was selected to assess prognostic factors of RFS.

Results:

Among a cohort of 690 sarcoidosis patients, 242 patients with NS were identified i.e. definite NS in 34 patients (14%), probable NS in 149 (62%) and possible in 59 (24%). Median age at NS diagnosis was 41 years (IQR 30; 52), 50% were female and 53% Caucasian. Multivisceral sarcoidosis was noted in 214/242 of NS (88%) including cardiac involvement in 85 patients. Symptoms of NS preceded extra-neurological involvement in 55/242 patients (23%), while neurological symptoms were concomitant or followed extra-neurological involvement in 135/242 (56%) and 52/242 (21%) patients, respectively.

Main neurological involvements of NS were central nervous system in 184/242 patients (76%) including spinal cord in 63 patients, cranial nerve in 85/242 (35%), and peripheral nerve and/or muscle in 42/242 (17%). Overall, 148/242 patients (61%) had more than one neurological involvement. Analysis of CSF showed unspecific abnormalities in 90/242 patients (37%). The initial EDSS score was ≥2.5 in 159/242 patients (36%). Steroids were given to 224/242 patients (93%) associated to i.v. cyclophosphamide in 90/242 (37%), methotrexate in 97/242 (40%), mycophenolate mofetil in 57/242 (24%) and infliximab in 23/242 (10%).

After a median FU of 96 months, 22/242 patients (9%) died including 6 patients with no NS relapse. The OS rates at 1, 5, and 10 years were 98.8%, 95.4%, and 91.3%, respectively. At the end of FU, 25% of patients had an EDSS ≥2.5. Factors independently associated with dependence were CSF protein ≥1g/l and presence of a CNS lesion at MRI ($p<0.05$). The RFS rates at 1, 5 and 10 years were 69.9%, 38.7% and 30.7%, respectively. Factors independently associated with poor RFS were older age at NS diagnosis, neurological signs preceding multivisceral sarcoidosis diagnosis and CSF protein ≥1g/L ($p<0.01$). There was no impact of international criteria on OS and RFS.

Conclusion: Neurosarcoidosis is a severe condition with low relapse-free survival rates. However, the overall survival rate is > 90% at 10 years. International criteria of NS showed no impact on overall or relapse-free survival rates.

Successful Treatment of Cardiac Sarcoidosis with Biologic and Immunosuppressive Combination Therapy

Maya Estephan[1], Mehrdad Maz[2], Mark Hamblin[3] and Julian Magadan[1], [1]Division of Allergy, Clinical Immunology, and Rheumatology, University of Kansas Medical Center, Kansas City, KS, [2]Division of Rheumatology, University of Kansas Medical Center, Kansas City, KS, [3]Pulmonary and Critical Care Medicine, ILD Clinic, University of Kansas Medical Center, Kansas city, KS
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster Session II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Although cardiac involvement is symptomatic in only 5% of patients with sarcoidosis, it is considered an important prognostic factor and the second leading cause of death in patients with sarcoidosis. There are no formal guidelines for the diagnosis or management of cardiac sarcoidosis (CS). Due to the rarity of this disease, prospective clinical trials are lacking and difficult to conduct. Corticosteroids are the mainstay of treatment in CS. Steroid sparing agents mainly methotrexate, azathioprine, mycophenolate mofetil and TNF-alpha inhibitors (Tumor Necrosis Factor). Our aim is to report successful treatment of CS with a combination therapy consisting of a TNF-alpha inhibitors and an oral immunosuppressive agent.

Methods: This is a retrospective chart review of patients with sarcoidosis who were evaluated either by a rheumatologist or a pulmonologist at a tertiary academic medical center between January 1st2013 and December 31st 2014. Patients with biopsy proven sarcoidosis (with the exception of endomyocardial biopsy) were included. Presence of hypermetabolic activity on the cardiac fluorodeoxyglucose (FDG) positron emission tomography (PET) scan was used to establish the diagnosis of CS. PET scan was repeated after 6-12 months to assess response to therapy.

Results: The charts of 103 patients with a diagnosis of sarcoidosis were reviewed and only 81 patients with biopsy proven sarcoidosis were included. Fifteen out of 81 patients (18.5%) had cardiac FDG PET suggestive of CS. All cases had other manifestations of systemic sarcoidosis, with lymphadenopathy and pulmonary parenchymal involvement as the most common affected areas. Clinical manifestations of CS included chest pain with or without elevation of cardiac enzymes, a reduced ejection fraction, palpitations and conduction abnormalities on ECG. Out of 15 patients, 9 patients were treated with a combination regimen of TNF-alpha inhibitors (infliximab in 8 patients, adalimumab in 1 patient) and an oral immunosuppressive agent (mycophenolate mofetil in 7 patients, azathioprine in 2 patients). Prednisone was also used in all but one patient, with doses ranging from 10 mg to 60mg daily. Six patients were not included in our study as they were eventually managed elsewhere and immunosuppressive treatment was withheld in one patient due to pregnancy. A repeat Cardiac FDG PET scan after 6-12 months of therapy showed a marked improvement or resolution of the hypermetabolic activity in all 9 patients. Cardiac and extracardiac manifestations improved or resolved following treatment.

Conclusion: We describe the clinical presentation and treatment outcomes of 9 patients with cardiac sarcoidosis successfully managed with a combination of a TNF inhibitor and an oral immunosuppressive agent. To our knowledge, this is the largest series of cardiac sarcoidosis successfully treated with such a combination therapy.

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster Session II

Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Cystic fibrosis (CF) is a genetic disorder characterized by exocrine gland production of highly viscous mucus, leading to obstructive and inflammatory changes in the respiratory, digestive and reproductive systems. Musculoskeletal (MSK) burden in CF has historically been addressed in young adults when fewer therapies resulted in a greater infective and inflammatory pulmonary burden. Reported presentations included undifferentiated arthropathy, hypertrophic osteoarthropathy, fluoroquinolone induced arthropathy and osteoporosis. With an increasing lifespan and broader disease spectrum, the impact of CF on the MSK system warrants re-evaluation. Our objectives are to assess MSK burden, the prevalence of serologic and biochemical markers and the relationship of chronic infection to the MSK system in adult CF patients.

Methods:

We conducted a prospective cohort study of all adult patients in St. Michael's Hospital CF clinic (n>400). To date, 163 subjects were recruited. Subjects completed MSK specific questionnaires; multidimensional health assessment questionnaire (MDHAQ), WOMAC, Osteoporosis and Fracture History. They were examined for tender and swollen joints. Serology (RF, ANA, anti-cyclic Citrullinated peptide (anti-CCP) antibodies, ESR, CRP and carboxy-terminal collagen crosslinks were obtained. MSK specific data was linked with the Toronto CF database, a comprehensive record of pulmonary and nutritional status, microbiology, and CF genotype.

Results:

Median age was 32 years; 86 males, 77 females. Median Routine Assessment of Patient Index data 3 (Rapid3) score was 1.33 (normal range: 0-10) and median WOMAC score was 1 (normal range: 0-96). Four subjects had at least 1 swollen joint and 24 had at least 1 tender joint. Seven subjects were RF positive (21-224), 14 were anti-CCP positive (5.1-229.5) and 20 were ANA positive (1.1-6.1). Two subjects had swollen joints and positive antibodies (RF and/or anti-CCP). There was no difference in median age (p=0.55), forced expiratory volume in 1 second (FEV1) % predicted (p=0.40), or proportion of females (p=0.13) between the MSK cohort and overall CF clinic patients. There was no significant association between lung function (FEV1), and antibody status. Stenotrophomonas maltophilia infections were associated with a significantly higher anti-CCP titre (p=0.03).

Conclusion:

In adult CF, MSK manifestations are mild. However, the prevalence of confirmed seropositive inflammatory arthritis is slightly higher than the general population (1.22%). The relationship between Stenotrophomonas maltophilia and anti-CCP titre warrants further investigation.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: There are limited published studies about patterns of arthropathy seen in cystic fibrosis (CF) patients. The objective of this study was to determine the musculoskeletal involvement, clinical presentation, serological patterns, and treatments used in a cohort of CF patients.

Methods: This is a retrospective chart review of patients followed in the Pulmonary CF Clinic in a tertiary medical center from 2004 through 2014.

Results: Of 204 adult CF patients (age 18-67, median age 41, 100 males and 104 females), 88 patients presented with some form of musculoskeletal complaints. Of these, 66 had nonspecific arthropathy. Fourteen out of 66 had flare of arthralgia following CF pulmonary exacerbations. Ten out of 88 were diagnosed with CF arthropathy based on patterns described in other published cohorts (4.9%), 2 with osteoarthritis, 4 with fibromyalgia, and 6 with nonspecific myalgia/arthralgia. Of the 204 patients, ANA was measured in 25 patients and only 6 were elevated. RF was measured in 19 patients; 3 had low to moderate titers. CCP was negative in all 16 measured patients. None of the patients met the diagnostic or classification criteria for any rheumatologic diseases except for one who was diagnosed with Sjogren's syndrome with a positive ANA and SSA.

Six out of 10 CF arthropathy patients (7 women, 3 men, age 23-59) were seen by a rheumatologist and all 10 patients had polyarticular disease. Large joints in a symmetrical pattern were more often involved than small joints. Three patients not seen by a rheumatologist had documented 'generalized' polyarthralgia and a specific joint group was not identified. Only 1/10 had documented synovitis of a 4thPIP. Five out of 10 patients had x-rays of the affected joints which did not show erosions or deformities. Three out of 10 patients had elevated ANA and 1 had a positive SSA diagnosed as Sjogren's by a Rheumatologist. RF and CCP were measured in 5/10 and 4/10 patients, respectively, and all were negative. Of the 10 CF arthropathy patients, 6 had documented flares of arthralgia with CF pulmonary exacerbations; in 2 patients arthropathy did not correlate with CF exacerbations; and 2 patients did not have clear documented arthropathy with CF exacerbations. Arthralgia responded to NSAIDs in 7/10 patients. Arthralgia responded to 3/6 patients treated with varying doses of prednisone initiated either for arthropathy or for pulmonary symptoms. Four patients were treated with hydroxychloroquine and one with both hydroxychloroquine and sulfasalazine with some possible response. One patient who was managed by an outside rheumatologist was treated with leflunomide and previously with methotrexate and cyclosporine. Arthralgia improved in 2 patients treated with tramadol and in 1 patient treated with hydrocodone/acetaminophen. Arthralgia did not respond to acetaminophen alone in any of the patients.

Conclusion: In this large cohort of cystic fibrosis patients, CF arthropathy was diagnosed in about 5% of patients. Seronegative nonerosive noninflammatory polyarticular large joint disease was the dominant pattern. In some patients, the arthralgia appeared to respond to NSAIDs. The flare of arthropathy appeared to correlate with CF pulmonary exacerbations in some patients.

Hyperferritinemia and Fever in Adults

Kensuke Nakanishi and Mitsuyo Kinjo, Rheumatology, Okinawa Chubu Hospital, Uruma, Japan

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Clinical associations of hyperferritinemia include: hepatocellular injury, hemophagocytic lymphohistiocytosis (HLH), hematologic malignancy, adult-onset Still's disease (AOSD), and iron overload. Fever of undetermined origin (FUO) may or may

not co-exist with hyperferritinemia in adults. The aim of this study was to describe the associations of with hyperferritinemia and FUO in adults.

Methods: We retrospectively identified patients >16 years old with serum ferritin levels > 5,000 µg/L at a tertiary medical center in Japan between 2002-2014. FUO was defined as temperature>38.3℃ with etiology undetermined after 3 days of in-hospital evaluation. Data were collected on clinical features, medications and mortality.

Results: We identified 156 Japanese patients with hyperferritinemia. Median age was 66 years (range, 16-95); 47% were female. Median serum ferritin level was 9,369µg/L (range, 5,000-170,202); Mortality during the admission was 42%. FUO was absent in 118/156 and present in 38/156 patients (Table). The most common diagnosis was hepatocellular injury, but this was rarely seen with FUO. Among those with FUO and elevated ferritin, hematologic malignancies, HLH, AOSD, and lupus (SLE) were diagnosed. HLH and AOSD remains most prevalent for patients with serum ferritin>10,000µg/L and FUO.

Conclusion: Although hyperferritinemia commonly indicates liver disease and hemochromatosis, clinicians should be aware that hyperferritinemia in conjunction with FUO is a reliable marker for more complex diagnoses such as HLH, AOSD or SLE, especially when ferritin levels are extremely high.

Table. Differential Diagnosis of Hyperferritinemia, by FUO status.

Diagnosis	No FUO No. (%)	With FUO No. (%)
Total	118	38
Hepatocellular injury	57 (48)	2 (5)

Is There Any Difference Between Autoimmune or Hemato-Oncology Etiology of Macrophage Activation Syndrome?

César Antonio Egües Dubuc, Miren Uriarte Ecenarro, Nerea Errazquin Aguirre, Olga Maiz Alonso, Iñaki Hernando Rubio and Joaquin Maria Belzunegui Otano, Rheumatology, Donostia University Hospital, Donostia, Spain

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Macrophage activation syndrome (MAS) is a group of diseases, especially autoimmune (AI) and hemato-oncology (HO). So it will be interesting to find any clinical or analytical data to differentiate both.

Methods: Describe and compare demographics, clinical and laboratories features, mortality during hospital stay and after the discharge of

patients diagnosed with MAS secondary HO and AI diseases in the period December 2008 to January 2015, in Donostia University Hospital. A cohort of patients diagnosed with MAS was studied by reviewing medical records. We analyzed and compared only patients with AI and HO disease. The variable were diagnosis, sex, age, fever, organomegaly, hospital mortality and overall mortality (from diagnosis to the end of the study), analytical findings, hospital stay in days, days from admission to diagnosis and days from diagnosis to the end of the study (January 21, 2015) or death after discharge. Quantitative variables are shown with the median and interquartile range. For the bivariate analysis Wilcoxon and Chi square test was used. Survival in months and relative risk (RR) was calculated with the Kaplan Meier plot.

Results: 19 patients with different etiologies MAS were found, 6 and 9 were due to AI and HO diseases. Table 1 shows the etiologic diagnosis of SAM due to AI and HO diseases. Table 2 shows the descriptive analysis of 19 patients and the bivariate analysis between AI and HO group. The median survival of HO disease group was 1.2 months and AI disease group cannot be calculated. The mortality oh HO and AI disease was 77.8% and 16.7% respectively with a p equal to 0.04 by the log rank test. The RR of death among the group of HO against AI disease was 6.84.

Conclusion: In the present study the following statistically significant differences were found:

1) Patients with MAS due AI diseases have higher elevated liver enzymes compared to HO disease.

2) Patients with MAS due HO diseases have a greater pancytopenia compared to AI diseases, especially in leukocytes and neutrophils.

3) Patients with MAS due HO have a higher mortality and lower median survival after diagnosis compared to AI diseases.

Development of Systemic Juvenile Idiopathic Arthritis Manifestations Following Remission of Hemophagocytic Lymphohistiocytosis

Baruch Goldberg[1], Eyal Muscal[2], Marietta De Guzman[3] and Carl Allen[4], [1]Pediatric Rheumatology, Texas Children's Hospital, Houston, TX, [2]Pediatric Rheumatology, Baylor College of Medicine, Texas Children's Hospital, Houston, TX, [3]Pediatric Immunology, Allergy, and Rheumatology, Baylor College of Medicine, Texas Children's Hospital, Houston, TX, [4]Pediatric Hematology and Oncology, Baylor College of Medicine, Texas Children's Hospital, Houston, TX

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster Session II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Hemophagocytic lymphohistiocytosis (HLH) is a potentially fatal pathologic inflammatory process resulting from impaired immune function due to inherited gene mutations or secondary to viral infections or immune-mediated disease. Systemic Juvenile Idiopathic Arthritis (SoJIA) is also characterized by dysregulated pro-inflammatory cytokines and systemic inflammation. SoJIA can lead to Macrophage Activation syndrome (MAS), a life threatening cytotoxic T cell dysfunction, often resembling HLH. MUNC13-4 mutation are found in up to 30% of children with inherited HLH as well as some patients with MAS secondary to SoJIA. The phenotypic overlap of SoJIA, MAS and HLH may reflect shared pathways of immune dysregulation leading to overwhelming inflammation.

Methods: In an attempt to define the clinical spectra of MAS and HLH, we reviewed charts of children who met criteria for HLH (HLH-2004 criteria) and were later referred to Rheumatology for development of new immune-mediated disease. During the review period of 2008-2014, three children were referred for new symptoms of arthralgia or arthritis after completing HLH therapy. We abstracted clinical features, HLH associated biomarkers and genetic mutations both at HLH presentation and diagnosis of SoJIA by Rheumatology. We documented response to therapy and clinical outcomes.

Results: Three female patients (ages 16 months-14 years), met HLH criteria at presentation without prior history of autoimmune disease. All patients had fevers, bi-cytopenias, Ferritin levels > 20,000ng/ml (Range: 20,638 – 110,000), and Soluble IL2 receptor levels > 3,000units/ml (Range: 3545 – 10,271, normal 334-3,026). Two of the three patients had severely decreased or absent NK cell function at HLH diagnosis. One patient had hemophagocytosis on BM biopsy. A diagnosis of an autoimmune or autoinflammatory disease was ruled out at HLH diagnosis after Rheumatology evaluation. All patients were treated with dexamethasone and an additional immunosuppressive agent (etoposide or cyclosporine) as per HLH protocol. Only a teenage patient was found to have a disease-associated MUNC13-4 mutation.

All patients developed SoJIA features (fever, rheumatoid rash, and polyarthritis) within 7 months of HLH presentation (Range: 5 – 7 months). SoJIA features without laboratory evidence of MAS developed after HLH remission and corticosteroid discontinuation (range: 1.5 – 5 months). An HLH flare was excluded by oncology due to normal ferritin and Soluble IL2 receptor levels. SoJIA clinical features and systemic inflammation responded to IL-1 blockade with anakinra and canakinumab in 2 children. The teenage patient with bi-allelic MUNC13-4 mutations had SoJIA manifestations that were refractory to TNF-alpha, IL-1 and IL-6 blockade (etanercept, anakinra, and tocalizumab), and ultimately underwent allogeneic hematopoietic cell transplant.

Conclusion: HLH and MAS are life threatening inflammatory conditions with underlying immune dysregulation. We describe a novel cohort of children developing SoJIA features after achieving HLH remission. Ongoing clinical follow up and whole exome sequencing studies of these patients may elucidate shared immune-pathway dysfunction of SoJIA, MAS, and HLH.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Background: The recent discovery of the immune checkpoint blockade that targets the regulatory pathways in T cells to enhance antitumor immune responses has led to major advances in the strategy of cancer care. However, the occurrence of serious immune-related adverse events (irAEs) in the treated patients has been increasingly reported in the literature suggesting an aberrant autoimmune T cell activation. We conducted a systematic review of case reports documenting the development of irAEs in cancer patients following treatment with anti-cytotoxic T lymphocyte antigen (CTLA-4) or anti-programmed cell death 1 (PD-1), to identify the type of cancer, and the clinical scenario of the irAEs reported in these cases.

Methods: We searched Medline, EMBASE, Web of Science, PubMed ePubs, and Cochrane CENTRAL with no language restriction from inception through April 2015. We included case reports describing the occurrence of irAEs in cancer patients after being treated with anti CTLA-4 or anti PD-1/PD-L1 antibodies. Bibliography search of the included citations was also performed. We extracted data on the type of cancer, the type of immune checkpoint blockade, the nature of the irAEs and their reported outcome.

Results: Out of 2,109 unique citations identified, 152 publications met our inclusion criteria, reporting on 197 case reports. More than half of the reported cases were from the United States (56.4%). The mean age of the cases was 60.2 years (standard deviation, 12.3 years). One hundred and twenty three patients (62.4%) were male. Metastatic melanoma was reported in the majority of the cases (95.4%). Patients with metastatic prostatic cancer, lung cancer, and bladder cancer were seen in 3.0%, 1.0%, and 0.5% respectively. Patients were categorized according to the type of the immune checkpoint blockade. One hundred and eighty six patients (94.4%) were treated with anti CTLA-4 antibodies, either ipilimumab or tremelimumab. While only 11 patients (5.6%) were treated with anti PD-1 antibodies, either nivolumab or pembrolizumab. Frequency of adverse events are shown in the table. Complete resolution of the adverse events was observed in the majority of cases regardless of the type of the immune checkpoint blockade. However, persistent symptoms was reported in 13.7% of the reported cases. Death from complicated irAEs was seen in 4.1%, all of them reported in patients treated with ipilimumab.

Conclusion: Systematic reviews can help identify rare adverse events. Our findings suggest that following treatment with immune checkpoint blockade, irAEs are common. Further longitudinal studies should be conducted to better identify the incidence and quantify the risk of irAEs after treatment with these novel agents.

immune checkpoint blockade	irAEs (%)
Anti CTLA-4 antibodies (Ipilimumab/Tremelimumab = 186 cases)	
Colitis	28.0%
Hepatitis	6.5%

Death and Infection Rates Appear Reduced in a Modern Cohort of ICU Patients with Rheumatic Disease

Erin M. Wilfong[1], Sara G. Murray[2], Gabriela Schmajuk[3] and Jinoos Yazdany[4], [1]Division of Rheumatology, Department of Medicine, University of California, San Francisco, San Francisco, CA, [2]Medicine, University of California, San Francisco, San Francisco, CA, [3]San Francisco VA Medical Center, University of California, San Francisco, San Francisco, CA, [4]University of California, San Francisco, San Francisco, CA

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Prior studies of patients with rheumatic diseases admitted to ICU care have been limited to case series; none included patients admitted after 2010. We examined a modern cohort of rheumatic disease patients admitted to a tertiary care center ICU. Given recent changes in the management of rheumatic diseases, we hypothesized that infection would be a leading cause of mortality compared to mortality from disease complications [e.g. interstitial lung disease (ILD), pulmonary hypertension (PH)].

Methods:

We queried the University of California, San Francisco electronic health record (EHR) to identify patients with rheumatic disease and an ICU admission between 6/13/2012-6/5/2015. We included patients with an ICD9 code for 1 of 11 rheumatologic diagnoses listed among admission diagnoses, hospital-problem lists, discharge diagnoses, or billing data for the encounter. We assessed in-hospital mortality (primary outcome) and other covariates including reason for ICU admission and immunosuppressive use via chart review of the EHR by 1 author. ICU encounters following elective surgeries, for the sole purpose of medication titration, or for the primary reasons of myocardial infarction and arrhythmia were excluded. The primary outcome was in-hospital mortality. EHR chart review was performed to confirm diagnoses, determine the cause of ICU admission, and identify immunosuppressive use.

Results:

239 ICU encounters for 204 patients were identified. Diagnoses are listed in the Table. 37 (15%) of encounters resulted from primary rheumatic disease flare, 48 (20%) from disease complications (e.g. ILD, PH), and 109 (46%) from presumably unrelated medical illnesses. 81 (34%) encounters were caused or complicated by sepsis. Overall in-hospital mortality for this cohort was 15%, with higher mortality among patients with a new rheumatic disease diagnosis made during that same admission (25%) and disease complications (23%), although these did not reach statistical significance. Additional results are shown in the Table. Sepsis-related mortality was not higher in patients receiving significant immunosuppression (10%, p=0.77) defined as prednisone > 15 mg/day or the use of another cytotoxic agent.

Conclusion:

To our knowledge, this is the largest study of patients with rheumatic disease admitted to the ICU. Compared with prior studies, this cohort had lower overall mortality (16% vs. 17-55% in prior reports), and infection was not the major cause of in-hospital death. Additional analyses are required to control for potential confounders. In the future, we plan to investigate the performance of traditional markers of ICU mortality (e.g. APACHE scores, vasopressors, ventilation) in this cohort and expand these methods (automated extraction of structured and unstructured (text) data) to construct a registry of critically ill rheumatic disease patients to guide future research.

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster Session II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Tocilizumab (TCZ) is a humanized anti-IL-6 receptor-blocking monoclonal antibody used for the treatment of rheumatoid arthritis (RA), idiopathic juvenile arthritis (IJA) and off-label in Adult Onset Still Disease (AOSD). The development of anti-TCZ antibodies could reduce treatment efficacy or induce treatment failure. Our aime was to analyse TCZ serum levels and antidrug antibodies (ADA) in a cohort of RA, IJA and AOSD patients treated with TCZ, and to evaluate its relationship with Disease Activity Score using a 28-joint count (DAS28), C-reactive protein (CRP) levels and the presence of combined treatment with glucocorticoids or DMARDs

Methods: Cross-section study including all patients undergoing chronic treatment with TCZ in a tertiary academic hospital. Referral area: 850,000 inhabitants. Twenty-two patients were included. TCZ serum and ADA levels were measured by ELISA (Theradiag) at baseline (before infusion), 15 days and 30 days after infusion.

Results: Twenty-two patients were studied: 18 RA, 3 IJA and 1 AOSD, 81.8% female; mean age and mean disease duration: 54.2 (±13) and 15.5 (±12) years respectively; 73% of the RA patients were positive for anti-CCP and 70% for rheumatoid factor, mean DAS28-CRP at day 0 and 30: 2.9 and 2.6 respectively. Fifteen patients were treated with TCZ for more than 1 year (range 12-58 months), 19 were treated with TCZ at 8 mg/kg, 2 at 6mg/kg, and one at 5mg/kg every 4 weeks due to low disease activity. Thirteen patients received TCZ in monotherapy, 9 received DMARDs combined treatment, 10 with glucocorticoids (mean dose 4mg/day, range 2-10mg) . TCZ serum levels were at baseline: 1.2- 61.7 µg/ml, 15 days: <1-130.1 µg/ml and 30 days: <1-97.1 µg/ml. No patient showed presence of ADA. No correlation was found with DAS28-CRP, but there was inversely relation between CRP and TCZ serum levels (p=ns) . The mean CRP levels were 14.4, 64.2 and 17.6 mg/dL at day 0, 15 and 30. TCZ Serum levels were higher in patients with combined therapy with DMARDs than those with monotherapy at day 15 and 30 (p=ns, 71 vs 55 µg/mL / 23 vs 12 µg/mL, respectively). Patients treated without glucocorticoids had high levels of TCZ (68.62 vs 59.96 µg/mL at day 15 and 20.2 vs 13.68 µg/mL at day 30, p=ns)

Conclusion: Levels of TZC were heterogeneous. Our patients showed no presence of ADA, this data suggest that TCZ has a low immunogenic potential. No correlation was found in disease activity and TCZ serum levels, but we found a relation with CRP levels. Patients with DAMRDs or without glucocorticoids showed higher levels of TCZ. We did not find correlation between combined treatment with DMARDs or glucocorticoids and levels of TCZ. Our study was limited due to a low sample size; we cannot exclude the correlation between TCZ and DAS28-CRP in a higher sample of patients.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: While various studies have looked at possible RA therapies for undifferentiated arthritis (UA), there remains no consensus on optimal management strategies. We undertook a systematic review and meta-analysis to evaluate the efficacy of treatments used in patients with UA.

Methods: We searched in electronic databases (Medline, EMBASE, Web of Science, and The Cochrane Library) with no restrictions up to April 2014. We also searched the clinicaltrials.gov website and the list of references of relevant articles. Two reviewers independently screened citations and evaluated the risk of bias of the included studies. Data was extracted by one reviewer and cross-checked by another. We performed direct comparison meta-analyses.

Results:

Eight studies (nine publications) reporting on 931 participants were included. The majority (88%) had a low risk of performance and detection bias, but did not provide details to judge their risk of reporting bias. After reviewing the manuscripts, we decided to include five comparisons: (1) intra-articular triamcinolone combined with Sm-153 PHYP (a radiation synovectomy agent) versus triamcinolone alone, (2) methylprednisolone versus placebo, (3) methotrexate versus placebo/no intervention, (4) infliximab versus placebo, and (5) abatacept versus placebo. Patients on methylprednisolone were less likely to have started a DMARD compared to patients receiving placebo, at 6 months (RR 0.81, 95%CI 0.68-0.96). Patients on methylprednisolone had less swollen (MD -1.0; -1.6, -0.40) and tender joints (MD -1.0; -2.0, -0.05), improved physician global assessment (MD -6.1; -11.7, -0.52) and quality of life (measured by the EQ5D; MD 0.08; 0.01, 0.15) compared to placebo, at 2 weeks to 12 months; however, compared to placebo there were more patients reporting adverse events in the methylprednisolone group (RR 1.8, 95% CI 1.0-3.3). Patients treated with methotrexate were less likely to develop RA (RR 0.31, 95% CI 0.18-0.53) or have radiographic progression (RR 1.3 95% CI 1.0-1.5) compared to patients treated without methotrexate, at 12-18 months. However, this difference was not observed at 30 months (RR 0.76, 95% CI 0.50-1.1) or 60 months (RR 0.86, 95% CI 0.59-1.3). Higher ACR20 response rates (RR 3.7; 1.3, 10.6), reduced swollen (MD -5.0; -9.8, -0.17) and tender joint counts (MD -13.0; -23.5, -2.5) and fatigue (MD 35.0; 15.6, 54.4) were observed in patients receiving infliximab compared to placebo at 3-6 months. Similarly, patients receiving abatacept had better outcomes compared to patients receiving placebo including disease remission (RR 2.0; 1.1, 3.9), reduced swollen and tender joint count (RR 4.4; 1.5, 13.1), radiographic (MD -0.31; -0.40, -0.22) and MRI changes (MD -5.0; -7. 6, -2.4), at 6-12 months. No other statistically significant differences were found.

Conclusion: Treatment benefits were observed with all alternatives except for intra-articular use of a radiation agent plus triamcinolone versus triamcinolone alone. Transient delay of RA development was only observed with methotrexate compared to control.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster Session II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: The dominantly inherited pyogenic arthritis pyoderma gangrenosum and acne (PAPA) syndrome is caused by mutations in *PSTPIP1*. It is one of the least understood of the known monogenic autoinflammatory diseases, both from a pathogenic and treatment perspective. Associated symptoms include arthritis, cystic acne, and pyoderma gangrenosum without discernable infection. Therapy revolves around the suppression of the systemic inflammation, typically with corticosteroids, interleukin-1 receptor antagonists, and tumor necrosis factor inhibitors. This abstract documents the continued expansion of clinical manifestations of disease as two PAPA patients have recently presented with the features of noninfectious epiglottitis and sterile osteomyelitis.

Methods: A retrospective medical records review of not previously published rare complications of two patients with PAPA syndrome. Complete histories were obtained and physical exams were performed. Radiographic imaging, complete blood count with differential, CRP and ESR were examined.

Results: One patient with PAPA developed a severe sore throat, which upon further clinical and radiographic evaluation showed piriform sinus swelling consistent with supraglottitis. CRP and ESR were elevated, while WBC was normal. Treatment was initiated with IV clindamycin and ceftriaxone; doxycycline was later added. The patient continued to have severe sore throat and repeat radiographic findings showed ongoing swelling. Clindamycin was stopped and methylprednisolone as well as a scheduled dose of golimumab was initiated with significant improvement in symptoms and normalization of radiographic findings. CRP and ESR improved.

Another patient developed severe right wrist pain and swelling. MRI findings revealed distal right radial epiphysis marrow abnormalities consistent with osteomyelitis without synovitis. ESR and CRP were elevated and WBC was normal. The patient was treated with clindamycin without benefit in symptoms or improvement in MRI findings. Clindamycin was discontinued and methylprednisolone and anakinra were initiated which resulted in decreased pain and improvement in marrow inflammation on MRI. CRP and ESR improved.

Conclusion: Our findings indicate new clinical features in PAPA that include aseptic supraglottitis and non-bacterial osteomyelitis. Improvement in clinical symptoms, radiographic findings, and acute phase reactants as well as a normal WBC support an inflammatory rather than infectious process.

Cogan Syndrome: Differential Response to Biologic Agents and Role of PET-CT in the Increased Diagnosis of Aortitis

Bahtiyar Toz[1], Burak Erer[2], Sevil Kamali[2], Ilknur Tugal-tutkun[3], Lale Ocal[2] and **Ahmet Gul**[4], [1]Department of Internal Medicine, Division of Rheumatology, Istanbul University, Istanbul Faculty of Medicine, Istanbul, Turkey, [2]Department of Internal Medicine, Rheumatology Division, Istanbul University, Istanbul Faculty of Medicine, Istanbul, Turkey, [3]Department of Ophthalmology, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey, [4]Department of Internal Medicine, Rheumatology Division, Istanbul University, Istanbul Faculty of Medicine,, Istanbul, Turkey

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster Session II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Cogan syndrome (CS) is a rare inflammatory disorder typically characterized by interstitial keratitis and audiovestibular symptoms, and patients may also develop other inflammatory ocular symptoms, sensorineural hearing loss and systemic manifestations including aortitis, aortic insufficiency. We herein aimed to investigate the diagnostic and therapeutic characteristics of five CS patients followed-up in a tertiary referral center.

Methods: We retrospectively reviewed the charts of the five patients diagnosed with CS according to their clinical manifestations. All of

the clinical findings, laboratory and imaging results and treatment responses were recorded using a standard form. Because of the sample size, no statistical analysis was carried out, and results are summarized as descriptive findings.

Results: The mean age of the patients diagnosed with CS was 34 years, and the mean follow-up duration was 7.6 years. Demographic and clinical characteristics of CS patients are summarized in Table 1. Sensorineural hearing loss and intraocular findings were present in all patients. We observed variability in ocular findings, which included typical interstitial keratitis in three, and scleritis in two patients. Although aortitis has rarely been reported previously, diagnostic work-up included PET-CT imaging in three patients, and it revealed positive findings compatible with aortitis. One of our patients needed aortic valve replacement due to severe aortic regurgitation. All patients responded well to high dose corticosteroids, but complete remission was achieved in 1 patient with a mild disease course with methotrexate. Remaining 4 patients required biologic agents to control inflammatory activity. One patient with polyarthritis responded adalimumab and methotrexate combination. However, no response or even exacerbation of findings were observed in two patients with anti-TNF, and a partial or near-complete remission could be achieved with IL-1 blockade.

Table 1. Demographic and clinical features of Cogan syndrome patients.

Patient #	**Sex, age**	**Disease duration (year)**	**Disease Manifestations**					**Treatment (in order)**	**Treatment response**	**Outcome**
			ENT	Eye	Aortitis	Arhritis	Other			
1	F, 25	9	SNHL	Interstitial keratitis	Yes	Oligoarthritis	Aortic valve regurgitation	ANK, CAN	Partial	Deafness
2	M, 33	2	SNHL	Scleritis	Yes	Polyarthritis	Aortic valve regurgitation	TCZ, ETN, ADA, ANK, CAN	Partial	Aortic valve replacement
3	M, 30	9	SNHL	Interstitial keratitis, uveitis	Yes	-	-	MP, MTX	Complete	Hearing loss
4	F, 33	13	SNHL	Scleritis	-	Polyarthritis	Leukocytoclastic vasculitis	ADA, MTX	Complete	Hearing loss
5	F ,49	5	SNHL	Nodular scleritis, interstitial keratitis, and retinal vasculitis	-	-	Skin rash No mutation in NLRP3 gene	INF (exacerbation), ANK	Near complete	Deafness and scleritis sequelea

SNHL: sensorineural hearing loss ,MP: methylprednisolone; MTX: methotrexate; ANK: anakinra; CAN: canakinumab; ETN: etanercept; ADA: adalimumab; TCZ: tocilizumab.

Conclusion: Patients with CS comprise a heterogeneous group, which may include some yet undiagnosed hereditary autoinflammatory conditions. Aortic involvement has rarely been reported in CS patients, but PEY-CT imaging may help diagnosing asymptomatic patients with inflammatory imaging findings in aorta. Early and effective treatment may prevent organ damage, and a differential response to IL-1 blocking biologic agents requires further investigation for both understanding its pathogenesis and better management of refractory patients.

Subglottic Stenosis: A Unique Inflammatory Disorder

Robert S. Katz[1] and Robert Bastian[2], [1]Rush University Medical Center, Chicago, IL, [2]Bastian Voice Institute, Downers Grove, IL

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases Poster Session II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Inflammatory subglottic stenosis may present with discomfort, stridor, and hoarseness. In these patients granulomatosis with angiitis needs to be ruled out.

A diagnosis using direct visualization and biopsy is made during videoendoscopy. Biopsy is often combined with a dilatation procedure performed in the operating room under general anesthesia. Inflammatory subglottic stenosis appears to always recur after dilatation, but intervals between dilatations may possibly be lengthened due to the use of corticosteroid AND immunosuppressive and biologic response modifier medication.

Methods: We describe 16 patients with inflammatory subglottic stenosis

Results: The patients were diagnosed and followed in a laryngology office. Mean age 35 (21-63). All patients presented with SOB and stridor. Ten also had nasal symptoms, 2 had saddle nose deformities. 3 pts were positive for cANCA and 4 had pANCA. The patients did not have symptoms of cutaneous or systemic vasculitis, sinusitis, pulmonary or renal involvement or other features of granulomatosis with polyangiitis. The patients all had biopsies showing acute and chronic inflammatory changes. Granulomas and vasculitis were not seen. All had dilation procedures. One had a cricotracheal resection. 3 pts had a tracheotomy. In cases of recurrent inflammatory subglottic stenosis, corticosteroids were very helpful in treatment. Five pts were treated with methotrexate, and one with cyclophosphamide. Almost all patients were negative for the presence of cytoplasmic antibodies.

Conclusion: Recurrent inflammatory subglottic stenosis is described in 16 patients. All experienced shortness of breath and stridor.

Inflammatory subglottic stenosis appears to be a unique entity, not related to granulomatosis with polyangiitis.

Treatment with corticosteroids was helpful, but did not avoid the eventual need for subsequent dilation. Methotrexate was moderately effective. One patient received cyclophosphamide. The use of TNF blockers as other biologic response modifiers is unknown.

Prolotherapy Versus Corticosteroid Injections and Phonophoresis for the Treatment of Plantar Fasciitis: A Randomized Controlled Trial

Gulseren Demir[1], Muyesser Okumus[2], Aynur Karagoz[3] and Turgut Kultur[4], [1]Clinic of PMR, Health Ministry Ankara Training and Research Hospital, Ankara, Turkey, [2]Department of Physical Medicine and Rehabilitation, Kirikkale University Faculty of Medicine, KÄ±rÄ±kkale, Turkey, [3]Dept of Physical Medicine and Rehabilitation, Ministry of Health, Ankara Training and Research Hospital, Ankara, Turkey, [4]University of Kirikkale, Faculty of Medicine, Department of Physical Medicine and Rehabilitation, Assistant Professor, Kirikkale, Turkey

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Orthopedics, Low Back Pain and Rehabilitation Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Proximal plantar fasciitis is the most common cause of plantar heel pain in adults. Plantar fasciitis is a degenerative syndrome of the plantar fascia resulting from repeated trauma at its origin on the calcaneus. Prolotherapy has evolved as a new treatment option for refractory Plantar Fascitis. In this study we compared the efficacy of prolotherapy versus corticosteroid injection and phonophorezis for the treatment plantar fasciitis.

Methods: A hundred and fifty patients with clinically determined plantar fasciitis were recruited. Patients were assigned to receive dextrose prolotherapy, corticosteroid injection or corticosteroid phonophoresis for treatment of plantar fasciitis. The first group underwent at baseline followed by a second injection 2 weeks later. The second group was performed local corticosteroid injection as single dose and the third group received phonophoresis. All patients were given an exercise program. Heel Sensitivity Index (THI), Visual Analogue Scale (VAS), Foot Function Index (FFI), Foot and Ankle Outcome Score (FAOS) and SF-36 were measured at baseline and at 1 and 3 months' follow-up. Besides plantar fascia thickness was measured by Ultrasonography (USG) before treatment, 1 and 3 months after treatment.

Results: Within each group, the analysis demonstrated statistically significant improvements in all parameters from baseline to 1 and 3 months ($p < 0.05$). There was no significant difference between groups in terms of efficacy of treatment ($p > 0.05$). Aside from injection-associated pain, no adverse reactions were reported. The plantar fascial thickness between the baseline and final measurements revealed a mean decrease in thickness, statistically significant difference ($p < 0.05$) in three groups. Between groups before treatment, 1 and 3 months after treatment in terms of plantar fascia thickness there was no statistically significant difference ($p > 0.05$). (Table 1)

Table 1. The Distribution of Plantar Fascia Thickness of between Treatment Groups and within Each Group

Plantar fascia thickness	Before treatment	A month after treatmant	Three months after treatment	p
	Mean±S	Mean±S	Mean±S	
Prolotherapy	5,45±1,04[bc]	3,43±1,33	3,53±1,41	**<0,001**
Corticosteroid Injection	5,31±1,07[bc]	3,22±1,24	3,74±1,36	**<0,001**
Phonophoresis	5,37±0,93[bc]	3,56±1,28	3,92±1,49	**<0,001**
p	0,728	0,369	0,451	

[b]In post-hoc pairwise comparisons result of "Post-Therapy First Month" with no significant difference was found.

[c] In post-hoc pairwise comparisons result of "Post-Therapy Third Month" with no significant difference was detected..

Conclusion: Prolotherapy, corticosteroid and phonophorosis therapies were generally well tolerated and appeared to provide benefit of patients with plantar fasciitis. As a result prolotherapy can be an effective way to treat plantar fasciitis

A Double-Blind, Randomized, Placebo-Controlled Trial of Mesenchymal Stem Cells for the Treatment of Patients with Full-Thickness Rotator Cuff Tears

Jose Ramon Lamas[1], Pilar Tornero-Esteban[2], Carlos García Fernández[3], Luis Rodriguez Rodriguez[2], Fernando Marco[4] and Benjamín Fernández-Gutiérrez[5], [1]Rheumatology Service, Hospital Clínico San Carlos, Instituto de Investigación Sanitaria del Hospital Clínico San Carlos (IdISSC), Madrid, Spain, [2]Rheumatology, Rheumatology Service, Hospital Clínico San Carlos, Instituto de Investigación Sanitaria del Hospital Clínico San Carlos (IdISSC), Madrid, Spain, [3]Ortopaedics Surgery and Traumatology Service, Hospital Clínico San Carlos, Instituto de Investigación Sanitaria del Hospital Clínico San Carlos (IdISSC), Madrid, Spain, [4]Traumatology, Ortopaedics Surgery and Traumatology Service, Hospital Clínico San Carlos, Instituto de Investigación Sanitaria del Hospital Clínico San Carlos (IdISSC), Madrid, Spain, [5]Department of Rheumatology, Hospital Clínico San Carlos, Madrid, Spain
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Orthopedics, Low Back Pain and Rehabilitation Poster
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Rotator cuff lesions cause shoulder pain and disability. The outcome after surgical repair of full-thickness rotator cuff tears has been controversial due to the high rate of re-rupture. New therapeutic alternatives are needed to overcome the limited tendon healing, including the use of growth factors, cytokines and/or tissue engineering approaches using mesenchymal stem cells (MSCs). The purpose of this study was to evaluate the safety and effectiveness of autologous MSCs implantation in patients with full-thickness rotator cuff tears.

Methods:

Thirteen patients were included in the study. They were double-blind randomized into two groups. Control group: (n=5) was treated with a

collagen type I implant (OrthADAPT™). Treatment group: (n=8) was treated with type I collagen membrane combined with $20x10^6$ autologous Bone Marrow-MSCs (BM-MSCs).

Bone marrow (BM) was aseptically drawn under local anesthesia from right posterior superior iliac spine and immediately anticoagulated by heparin. Collected bone marrow (50ml) was processed to isolate and to expand BM-MSCs in vitro. The day of surgery, $20x10^6$cells BM-MSCs were resuspended in 1ml of saline solution and seeded over the OrthADAPT™ for 10 minutes prior implantation into the patient.

Patients were evaluated preoperatively and at one year follow-up by: (1) tendon status by MRI (Magnetic Resonance Imaging), (2) functional recovery using the Constant Score (CS) and (3) pain score (10 cm visual analog score [VAS]). The primary endpoint of the study was to achieve a functional improvement of at least 20 points in the CS. Differences between groups were analyzed using the Mann-Whitney U test, values of $p \leq 0.05$ were considered significants. The study was registered (Eudra-CT: 2007-007630-19) and was in accordance with ethical standards for research on human subjects.

Results:

Only the treatment group met the clinical functional improvement criteria, registering differences of 31 points in the CS one year post-intervention (p=0.0073). Additionally, comparable reductions in mean VAS, re-tear rate and repair integrity were found in both groups.

Constant's Score	**Control group (n=5)**		**Treatment group (n=8)**	
	Preoperative	12 months	Preoperative	12 months
Contralateral Shoulder	81 [77.5−94.5]	84[75−91.5]	89 [79−91]	91 [87−96]
Injured shoulder	55 [42.5−58]	71 [49.75−78.5]	45.5 [35.25−51.75]	76.5 [62.25−85]a

Three patients enrolled in the treatment group (37.5%) and one in the control group (25%) developed postoperative complications. These 4 patients showed swelling and symptoms of recurrent tear including pain and reduced range of motion within 3 months post-operation. The 4 patients underwent surgery to remove the patch. Histological analysis revealed the existence of chronic synovitis with granulomatous tissue. Microbiological tests were negative in all cases. These complications were solved after additional surgery.

Conclusion:

These results provide preliminary satisfactory clinical outcomes related to the use of MSCs for the treatment of full thickness rotator cuff tears. Nevertheless, the occurrence of adverse events, likely related to patch instability indicated the need for further controlled studies.

Thread Carpal Tunnel Release (TCTR) Completely Divides the Transverse Carpal Ligament (TCL) As Well As Open and Endoscopic Surgery: A Cadaver Study

Nathan Wei, Arthritis Treatment Center, Frederick, MD

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Orthopedics, Low Back Pain and Rehabilitation Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The gold standard for definitive treatment of severe carpal tunnel syndrome is surgery, either endoscopic or open. Unfortunately, both surgical procedures have pitfalls including relatively long term recovery, complications, and lack of success, which often is due to incomplete transection of the TCL.

The Guo TCTR technique is an innovative method for releasing the carpal tunnel. Performed using local anesthetic with ultrasound needle guidance, a loop of proprietary metal-impregnated cutting thread is looped around the TCL. This is accomplished by inserting an 18 gauge spinal needle just proximal to the superficial palmar arterial arch (SPA) and guiding it proximally, superficial to the SPA, then deep, to pierce the proximal part of the palmar aponeurosis and run on the *deep* surface of the TCL. This needle is ultrasonographically guided proximally, until it surfaces through the skin at the exit point, 1 cm proximal to the proximal wrist crease, in the Nakamichi safe zone, between the median nerve and the ulnar artery. The thread is passed through this needle and the needle is removed. A second spinal needle is then passed through the same entrance and exit points, except that this 2nd needle is guided along the *superficial* surface of the TCL. When the 2ndneedle is in place, the proximal end of the thread is passed through it, and the needle is removed. This results in the thread looped around the TCL with both ends of the thread protruding through the skin at the initial entry point. The operator grasps the two ends of the thread, and uses a to-and-fro sawing motion. The thread cuts through the TCL.

Methods: To determine whether this method performed a complete TCL transection, we performed eight carpal tunnel release procedures in eight cadaver wrists. After each case, surgical dissection was done to directly view the results. Dissection of the first case performed with the entry point at the typical site of carpal tunnel release (trapezium/hamate line) showed incomplete distal release of the TCL and the proximal palmar aponeurosis, creating an incomplete release. The subsequent seven procedures used a more distal needle insertion point, and we added initial hydrodissection of the proximal palmar aponeurosis with a 27 gauge needle to move the "duck's beak" of the distal TCL edge to a more volar position. This permitted more exact placement of the thread loop to encompass the entirety of the distal TCL.

Results: All seven of the procedures using the revised more distal approach resulted in total TCL release from the proximal to the distal TCL border. No damage to neural or vascular structures occurred. Previous clinical experience with this method has shown excellent results with minimal morbidity. (Guo D, Tang Y, Ji Y, Sun T, Guo J, Guo D. A non-scalpel technique for minimally invasive surgery: percutaneously looped thread transection of the transverse carpal ligament. Hand. 2015; 10:40-48). **Conclusion:** The advantages of this procedure are the relative lack of invasiveness, use of local anesthetic only, shorter recuperation, decreased likelihood of complications, and greater assurance of complete transection of the TCL.

Medial Meniscus Extrusion and Spontaneous Osteonecrosis of the Knee

Tadashi Yasuda, Soichiro Masuda, Yuka Miyazaki, Makoto Hayashi, Yusuke Yamawaki, Mutsumi Watanabe, Hisataka Takeuchi, Satoshi Ota, Satoshi Fujita, Eijiro Onishi, Koichi Iwaki and Hiroshi Yamamoto, Department of Orthopaedic Surgery, Kobe City Medical Center General Hospital, Kobe, Japan

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Orthopedics, Low Back Pain and Rehabilitation Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Although the pathogenesis of spontaneous osteonecrosis of the knee (SONK) remains unclear, two main etiologies have been suggested in the pathogenesis of SONK: vascular and traumatic. Recently, the presence of medial meniscus tear has been proposed as a potential third etiology behind development of SONK. Meniscal extrusion is associated with the progression of osteoarthritis. However, there has been no information on correlation between meniscal extrusion and SONK. Our purpose was to determine whether the extent of meniscal extrusion is associated with the severity of SONK.

Methods:

We examined 12 knees in 12 patients with a diagnosis of SONK in the medial femoral condyle between November 2010 and April 2015. All patients were examined by plain radiography and magnetic resonance imaging (MRI), which confirmed the diagnosis of SONK. No patient had a history of taking steroids or excessive alcohol consumption. There were four men and eight women, with a mean age of 70 years (55 to 82). The stage of progression of SONK was determined according to the radiological classification system. After measurement of anteroposterior, mediolateral, and superoinferior dimensions of the lesion by magnetic resonance imaging (MRI), its ellipsoid volume was calculated from the three dimensions. The extent of medial meniscus extrusion and its degeneration and tear were

also evaluated by MRI.

Results:

The mean volume of the lesions in 12 patients with SONK was 2837 mm^3 (324 to 7464). Degeneration and tear of the medial meniscus were found in 12 and 11 patients, respectively. The mean extrusion of the medial meniscus was 6.7 mm (3.0 to 10.2). Of the 12 knees with SONK, 2 knees showed the radiographic stage 2 lesions, 7 knees the stage 3, and 3 knees the stage 4. When the ellipsoid volume of SONK lesion was compared among stages, the volume tended to increase with the stage progression (*P*=0.062 by ANOVA). Medial meniscal extrusion was likely to increase with the stage progression, although no statistically significant difference was found (*P*=0.234 by ANOVA). The simple linear regression of the ellipsoid volume of SONK lesion on medial meniscal extrusion showed a significant correlation (R=0.761, *P*=0.004).

Conclusion:

The extent of medial meniscal extrusion was significantly associated with the size of the lesion of SONK, which could determine the prognosis of the disease.

Comparison of Surgical and Conservative Therapy of Lumbar Disc Herniation with Radicular Signs and Symptoms in a Quality Management Program

Marinella Gugliotta[1], Bruno R. da Costa[2], Essam Dabis[3], Robert Theiler[4], Stephan Reichenbach[2], Peter Jüni[2], Hans Landolt[1] and **Paul Hasler**[3], [1]Neurosurgery, Kantonsspital Aarau, Aarau, Switzerland, [2]Clinical Epidemiology and Biostatistics, University of Bern, Bern, Switzerland, [3]Rheumatology, Kantonsspital Aarau, Aarau, Switzerland, [4]Rheumatology, Stadtspital Triemli, Zürich, Switzerland

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Orthopedics, Low Back Pain and Rehabilitation Poster
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Current evidence for outcomes of surgical versus conservative treatment of lumbar disc herniation with nerve root compression is ambiguous. To compare the effectiveness of surgical versus conservative treatment in patients with symptomatic lumbar disc herniation we followed cases prospectively in a quality control setting.

Methods: Validated instruments (North American Spine Society (NASS) questionnaire and SF-36) were used to measure patient-reported back pain, physical function, neurogenic symptoms and quality of life. Primary outcomes were pain symptoms at 6 and 12 weeks after the end of the treatment. Conservative treatment encompassed ergonomic instruction, active physical therapy, education/counseling with instructions for home-based exercise, analgesia, physical therapy and periradicular infiltrations and/or radicular pulsed radiofrequency application. Surgical treatment consisted of standard open discectomy and the appropriate components of the conservative approach. Effectiveness was assessed at 6, 12, 52, and 104 weeks after the end of the treatment.

Only cases with non-missing primary outcome data were included in the analysis. Missing data was filled in with multiple imputations, and mixed-effects models were used to account for repeated measures within cases. Baseline group differences were adjusted for by inverse probability weighting.

Results: Three-hundred-and-seventy patients were consecutively sampled and assigned to surgical (n=297) or conservative (n=73) treatment. Patients receiving surgical treatment tended to have more severe neurogenic symptoms at baseline (P=0.098) and were more likely to be from a higher social class (P=0.065). There was no significant difference between groups for all variables at baseline after adjustment using inverse probability weighting (P≥0.72).

Patients receiving surgical treatment reported less back pain than those receiving conservative treatment at 6 week follow-up (-0.97; 95%

confidence interval -1.89 to -0.09), had a higher proportion with ≥50% decrease in back pain symptoms from baseline to 6 weeks (48% vs 17%, risk difference: 0.34; 95% confidence interval 0.16 to 0.47), and less physical function disability at 1 year follow-up (-3.7; 95% confidence interval -7.4 to -0.1). For other assessments, between-group differences were minimal for all outcomes, with confidence intervals including the null effect.

Conclusion: Surgical treatment appears to provide faster relief for back pain symptoms than conservative treatment in the management of patients with lumbar disc herniation. However, surgical treatment did not show a clear benefit over conservative treatment in mid- and long-term follow-up.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Orthopedics, Low Back Pain and Rehabilitation Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Low back pain and obesity are both major public health problems. Known risk factors for back pain include age, female gender, lower educational attainment, strenuous physical activity and mood disorders. Obesity has also been linked with low back pain with recent studies reporting an association between increased fat but not lean tissue mass and back pain. However, these studies predominantly examined women. The relationship between body composition and low back pain in men is unknown. Therefore, the aim of this study was to examine the relationship between body composition and low back pain and disability in a population-based sample of men.

Methods: 978 male participants from the Geelong Osteoporosis Study, which is a population-based Australian study designed to investigate the epidemiology of osteoporosis among adults, were invited to participate in a follow up study in 2006. Participants completed questionnaires on sociodemographics and health status. Low back pain was determined using the validated Chronic Back Pain Grade Questionnaire and the presence of mood disorders was assessed using the Hospital Anxiety Depression Scale. Body composition was measured using dual energy x-ray absorptiometry. Binary logistic regression and estimated marginal means were used to examine the relationships between obesity measures and body composition in participants with high intensity pain and disability compared to those with no or low pain and disability. Multivariate analyses included adjustments for age, mood disorder, education, mobility and body mass index (BMI). To examine the multivariate associations between body composition and back pain, adjustment was also made for the alternate body composition measure. Interactions between risk factors for low back pain and measures of obesity, including measures of body composition were also examined.

Results: Of the 820 respondents (84% response rate), 124 (15%) had high intensity low back pain and/or disability. Participants with high intensity pain and/or disability were older, more likely to have a mood disorder, less likely to have completed secondary school and more likely to have poor mobility than those with no or low back pain and disability ($p<0.002$ for all). Low back pain was associated with higher BMI (28.7±0.4 vs 27.3±0.2 kg/m^2, $p=0.02$) and waist-hip ratio (0.97±0.006 vs 0.96±0.006, $p=0.04$), with increased tendency towards having a higher fat mass index (8.0 vs 7.6 kg/m^2, $p=0.08$), but not fat-free mass index ($p=0.68$). The relationships between back pain and measures of obesity were stronger in those with a mood disorder, particularly for waist-hip ratio ($p=0.05$ for interaction) and fat

mass index (p=0.06 for interaction).

Conclusion: In a population-based sample of men, high intensity low back pain and/or disability were associated with increased levels of obesity, particularly in those with mood disorders. This provides evidence to support a biopsychosocial interaction between mood disorders and obesity with low back pain.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Orthopedics, Low Back Pain and Rehabilitation Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Biologic agents have been associated with an increased risk of infection, thrombosis and delayed wound healing. However, there is no definitive consensus on suspension or continuity in the perioperative period, with few data assessing the risk of complications in rheumatic patients in use of these medications. The aim of this study is to evaluate the rate of complications after orthopedic procedures in rheumatic patients, assessing the effect of the disruption of biological therapy and trying to identify other potential predictors of complications.

Methods: We retrospectively assessed a monocentric cohort of patients with autoimmune rheumatic diseases who underwent orthopedic surgery from January 2007 to December 2014.

Results: A total of 87 patients underwent orthopedic surgery in the period, accounting for 178 procedures. Baseline diagnosis were rheumatoid arthritis (54%), juvenile idiopathic arthritis (17.2%), psoriatic arthritis (5.7%), ankylosing spondylitis (18.4%), systemic lupus erythematosus (1.1%), enteropathic spondyloarthropathy (1.1%), adult onset Still's disease (1.1%) and reactive arthritis (1.1%). The main cause of surgery was osteoarthritis secondary to the underlying disease (57.4%). The main surgeries were total hip arthroplasty (40.4%) and total knee arthroplasty (14%). A hundred twenty six patients were on nonbiologic disease-modifying antirheumatic drugs (DMARDs) and 53 were on biological therapy. Infliximab accounted for the majority of cases (33.9%), followed by etanercept (26.4%), adalimumab (18.9%), abatacept (11.3%), rituximab (5.7%), and tocilizumab (3.8%). In almost all cases the biological therapy was suspended in the preoperative period (98%), from an average of 20 days. Seven patients had postoperative infectious complications (3.9%), including superficial wound infection to necrosis and amputation of the affected limb. Five patients (2.8%) had severe complications requiring hospitalization or intravenous antibiotics. From these 7 patients, 2 (28.6%) were on abatacept, 2 (28.6%) on infliximab, 1 (14.3%) on tocilizumab, 1 (14.3%) on adalimumab and 1 on DMARD only. DMARDs associated with infections were leflunomide (3 patients, 42.9%), methotrexate (1 patient, 14.3%) and azathioprine (1 patient, 14.3%); 2 patients were on biologic agents only. Primary hypertension, dyslipidemia, diabetes mellitus and chronic kidney disease were present in 85.7, 57.1, 42.8 and 14.3% of patients with complications, respectively.

Conclusion: In our cohort, the rate of postoperative complications in orthopedic surgery performed in rheumatic patients treated with biological therapy was low compared to the literature (3.9% vs. 6.5%). Patients with complications had a high prevalence of comorbidities, which may have contributed to this outcome. Biological therapy discontinuation occurred in the majority of cases and seems to be a safe strategy for this population, however the ideal period of the suspension should be subject of further studies.

Rural Residence Does Not Impact Total Ankle Arthroplasty Utilization and Outcomes

Jasvinder A. Singh and Rekha Ramachandaran, University of Alabama at Birmingham, Birmingham, AL
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Orthopedics, Low Back Pain and Rehabilitation Poster
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: It is not known whether there are rural-urban disparities in Total Ankle Arthroplasty (TAA), given that TAA is a relatively new procedure and is an elective procedure. Our objective was to assess whether patient's residence (rural vs. urban) was associated with any disparities in TAA utilization and TAA outcomes. We hypothesized the utilization rates will be lower and poor outcomes more common in rural residents, compared to urban residents.

Methods: We used the Nationwide Inpatient Sample (NIS) from 2003-11 to compare utilization and outcomes (post-arthroplasty discharge disposition, length of hospitalization and mortality) by rural vs. urban residence.

Results: 10,833 patients in urban and 3,324 patients in rural area underwent TAA. Compared to rural residents, urban residents had: lower mean age, 62.4 vs. 61.8 ($p < 0.0001$), higher percent of women, 49% vs. 56% ($p=0.0008$) and lower proportion of Whites, 93% vs. 86% ($p=0.0005$). There were rural-urban disparities in TAA utilization in 2003 (0.32 vs. 0.39/100,000; $p=0.021$), but not in 2011 (1.19 vs. 1.17/100,00; $p=0.80$). TAA outcomes did not differ by rural vs. urban residence: (1) 11.3% rural vs. 14.2% urban residents were discharged to an inpatient facility ($p=0.098$); (2) length of hospital stay above the median stay, 44.8% vs. 42.2% ($p=0.30$); and (3) mortality, 0.2% vs. 0.1%, respectively ($p=0.81$). Multivariable-adjusted logistic regression models did not show any significant differences in discharge to home, length of stay or mortality, by residence.

Conclusion: Our study demonstrated no evidence of rural-urban differences in TAA outcomes. The rural-urban differences in TAA utilization noted in 2003 were no longer significant in 2011.

The Importance of Comorbidity in Understanding the 6-Month Trajectories of Pain and Function after Total Hip Arthroplasty

C. Allyson Jones[1], Gian S. Jhangri[2], Lauren A. Beaupre[1] and Maria E. Suarez-Almazor[3], [1]Physical Therapy, University of Alberta, Edmonton, AB, Canada, [2]School of Public Health, University of Alberta, Edmonton, AB, Canada, [3]General Internal Medicine, The University of Texas, MD Anderson Cancer Center, Houston, TX
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Orthopedics, Low Back Pain and Rehabilitation Poster
Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Osteoarthritis (OA) is chronic condition associated with a number of other comorbidities which may affect the 6 month pattern of recovery of total hip arthroplasty (THA). It is not clearly understood which comorbidities affect 6-month pain relief and functional recovery. We looked at the pattern of recovery for THA to determine which comorbid conditions had the most impact on the recovery following THA in terms of pain relief and functional improvement.

Methods:

Longitudinal prospective inception cohort of 305 patients receiving elective primary THA were followed within a month prior to surgery, and then at 1, 3, 6 months after surgery. The outcome measures, hip pain and function were measured using the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC). Comorbid conditions were extracted from the chart and reported by the patient using a standardized list. Patients who reported conditions also rated the impact of the specific condition on routine activities. Health status was measured using a generic health measure, Health Utilities Index Mark3 (HUI3). The Center for Epidemiologic Studies-Depression (CES-D) was used to screen for depressive symptomology. Measurements were repeated at each of the follow-up interviews. Linear mixed models were developed for pain and functional recovery of THA to evaluate changes over time while adjusting for covariates.

Results:

The mean age of participants was 65.9 (SD10.1) yrs; 175(57%) were female. Mean pre-operative WOMAC pain improved from 56.0(SD 16.7) to 10.8 (SD 13.2) over the 6 months ($p<0.001$). The mean pre-operative WOMAC function improved from 54.7 (SD 16.4) to 18.7 (SD 12.8) over this time ($p<0.001$). At baseline, the mean overall HUI3 score was 0.42 (SD 0.26). At baseline, 101(33%) had low back pain, 80(26%) had chronic respiratory disease, 60 (20%) had depressive symptomology, and 77 (25%) urinary incontinence. After controlling for age, sex, baseline pain and time, depression score (coeff 2.2, p=0.06), low back pain (coeff 2.8, p<0.01), chronic respiratory disease (coeff 4.4, p<0.01) had a deleterious effect on pain relief. Urinary incontinence (coeff 2.0, p=0.03), after controlling above mentioned variables, affected functional improvement.

Conclusion:

Patients with low back pain, depression and chronic respiratory disease are likely to have slower pain relief after THA. Urinary incontinence had a deleterious effect on functional improvement over a 6 month recovery. Using patient-centered care in managing these conditions before surgery may help patients attain more favourable outcomes.

Increasing Comorbidity Is Associated with Worsening Physical Function during Intermediate-Term Follow-up of Primary Total Knee Arthroplasty

Maren Hilton[1], Terence Gioe[2] and **Jasvinder A. Singh**[3], [1]Arthritis and Rheumatology Consultants, Edina, MN, [2]Department of Orthopaedic Surgery, Minneapolis VA Medical Center, Minneapolis, MN, [3]University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Orthopedics, Low Back Pain and Rehabilitation Poster
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Total knee arthroplasty (TKA) is associated with significant gains in function and pain improvement. However, decline in function has been noted in patients who have undergone TKA. We were interested in what factors, changing through time, may be associated with this decline in function. In this study, we examined the relationship of the change in comorbidity with the change in SF-36 and WOMAC

physical function and pain scores. To our knowledge, none of the previous studies have addressed this question.

Methods:

We performed a retrospective chart review of veterans who had completed Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) and Short Form-36 (SF36) surveys at regular intervals after primary TKA using structured data abstraction form. Comorbidity was assessed using a variety of scales: validated Charlson comorbidity score, local musculoskeletal morbidity (back and lower extremity), TKA complications and a novel Medical Comorbidity Severity Index, at multiple time-points post-TKA. We used mixed model linear regression to examine the association of worsening comorbidity, with worsening WOMAC and SF36 scores, controlling for age, length of follow-up, and repeated observations.

Results:

The study cohort consisted of 124 patients with a mean age of 71.7 years (range 58.6-89.2, standard deviation (SD) 6.9) followed for a mean of 4.9 years post-operatively (range 1.3-11.4; SD 2.8). We found that post-operative worsening of the Charlson Index was significantly associated with worsening SF-36 Physical Function (PF) ($p<0.0001$) and worsening WOMAC PF ($p=0.012$). Worsening scores on novel medical Comorbidity Severity Index scores were significantly associated with worsening SF-36 PF ($p<0.001$), and a non-significant trend of association with WOMAC PF ($p=0.056$). Local comorbidity index was significantly associated with SF-36 PF ($p<0.001$), WOMAC PF ($p<0.001$), and WOMAC Pain ($p=0.004$). TKA complications were not significantly associated with SF-36 or WOMAC domain scores.

Conclusion:

Worsening medical comorbidity was significantly associated with worsening physical function and worsening lower extremity and spine morbidity with declining physical function as well as worsening pain during intermediate term follow-up after primary TKA. Further studies should examine which comorbidity had the greatest impact on these outcomes.

Session Title: Orthopedics, Low Back Pain and Rehabilitation Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: In the US, the annual rate of TKRs in people 65 years or older increased almost 9-fold between 1979 and 2006, with similar if not greater growth in younger age groups. There is increasing debate regarding the appropriate utilization of TKRs. We examined change in pain and function, quality of life (QOL), and patient satisfaction at 6-month post-surgery stratified by their pre-surgery pain and function status.

Methods: We used data from the Function and Outcomes Research for Comparative Effectiveness in TJR (FORCE-TJR), a national cohort of TJR patients of more than 150 surgeons in 22 sites nationwide. Participants had: primary, unilateral TKRs indicated by osteoarthritis; surgeries between April 2011 and May 2014; completed pre-operative Knee Injury and Osteoarthritis Outcome Score (KOOS) including QOL items and Short-Form 36-item (SF-36) functional health survey; and the respective 6-month post-operative surveys, with satisfaction

measured by Self Evaluated Transitions items. We classified patients as having high or low pain (KOOS Pain<70 vs. ≥70), and low or high physical function (SF-36 PCS <40 vs. ≥40) and grouped then as follows: 1) Low pain-High function (LP-HF), 2) Low pain-Low function (LP-LF), 3) High pain-High function (HP-HF), and 4) High pain-Low function (HP-LF). Change from baseline to 1-year post-surgery pain and function scores were calculated. Cohen's unadjusted standardized differences in absolute post-op scores accounting for pooled SD were calculated with LP-HF as referent group.

Results: This study included 4,563 participants: 5% pre-op LP-HF, 20% either HP or LF, and 75% both HP-LF. By 6-month post-op **(Table)**, in Group 1, 85% remained the same but 4% became much worse among people with pre-op LP-HF: in Group 4, 18% remained the same and 52% achieved much improvement among people with pre-op HP-LF. Mean change (SD) in 6-month KOOS pain score in LP-HF group was 8.3 (14.6) compared with 37.2 (19.7) in the HP-LF group. Patients in LP-HF had the near highest absolute mean (SD) post-op pain score (88.9 (13.0)) and the HP-LF group the lowest (79.9 (17.3)); the unadjusted standardized effect size was 0.59. Similarly, the mean change in PCS function was 2.6 (7.8) in the LP-HF group, and was 11.9 (9.0) in the HP-LF group. The LP-HF group had the highest absolute mean 6-month post-surgery function of 50.0 (7.4) while the HP-LF group had the lowest score of 42.0 (9.5); the unadjusted standardized effect size was 0.94. The groups reported similar satisfaction, but QOL items indicated better QOL among the pre-surgery LP-HF than the HP-LF groups.

Conclusion: While TKR patients with low pain and high function pre-op achieved the smallest mean change in pain and function, they reported better absolute outcomes at 6-months. The majority of TKR patients with high pain and poor function achieved the greatest mean improvement in pain and function.

Table. 6 Month-Change in Pain and Function by Pre-Operative Pain and Function Status

The Risk Factor of Preoperative Deep Vein Thrombosis in Patients Undergoing Total Knee Arthroplasty

Hiroki Wakabayashi[1], Masahiro Hasegawa[1], Sho Kato[1], Rui Niimi[1], Shinichi Miyazaki[1], Noriki Miyamoto[1] and Akihiro Sudo[2], [1]Department of Orthopaedic Surgery, Mie University Graduate School of Medicine, Tsu City, Japan, [2]Orthopaedic surgery, Mie University Postgraduate School of Medicine, Tsu-city, Japan

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Orthopedics, Low Back Pain and Rehabilitation Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Total knee arthroplasty (TKA) reliably relieves pain and improves function in patients with end-stage arthropathy of the knee such as rheumatoid arthritis (RA). The most common complication after knee arthroplasty is DVT. The significance of DVT lies in the possibility of PE and the occurrence of chronic venous insufficiency at a later stage. PE is a potentially life-threatening disorder and is among the most common causes of death postoperatively. Previous studies have reported elevated risks of DVT in patients with RA. If a high risk of DVT is identified in the patient's background and medical history, it might be useful in early diagnosis. It is not reported whether the prevalence of DVT in the RA patients undergoing TKA is higher compared with non-RA patients or not. Thus, we investigated the patient's background and medical history in patients admitted to hospital for TKA and identified the risk factors, including RA, for DVT development before TKA.

Methods:

Patients

From 2003 to 2013, 319 patients admitted for TKA at Mie University Hospital were eligible for the present retrospective study. The surgical diagnoses were degenerative osteoarthritis (OA) in 274 patients and rheumatoid arthritis (RA) in 45 patients. The patients' sex, weight, body mass index (BMI, weight in kilograms divided by the square of the height in meters), and data from the medical history and medical condition were recorded.

Diagnosis of DVT

B-mode ultrasonography with compression and color Doppler imaging were performed for bilateral common femoral veins, the superficial veins, the popliteal veins, and the calf veins.

Results:

The preoperative diagnosis was OA in 274 patients (85.9%) and RA in 45 patients. Moreover, admissions for joint replacement in this population were for primary procedures in 300 patients (94.0%) and revision TKA in 19 patients. The most frequent preoperative medical history or medical condition was hypertension (52.7%). The second most frequent preoperative medical history or medical condition was major surgery (50.5%), including a history of primary TKA and cancer surgery

Preoperative DVT was diagnosed in 57 of 319 (17.9%) patients overall. Significantly elevated risks of DVT were found in patients who were female ($p = 0.039$), who had RA ($p=0.006$), and who were admitted for revision TKA ($p=0.033$) using Fisher's exact test. Multiple linear regression analysis was performed to test the association of DVT with putative risk factors. The analysis showed that admission for

RA (p=0.049) and revision TKA (p=0.009) were significant independent risk factors for preoperative DVT.

Conclusion: RA and admission for revision TKA surgery were risk factors for DVT among those admitted to the hospital for TKA. The results also suggest that instrumental screening should be encouraged, at least in subgroups at higher risk for preoperative DVT.

Pain after Total Knee Arthroplasty: Poverty Modifies the Effect of Race and Education

Background/Purpose: Race and education are important predictors of pain after total knee arthroplasty (TKA) in the United States (US). However, whether community poverty modifies the effect of race and education on pain following TKA is unknown. We assessed the interaction between poverty and race, and poverty and education on WOMAC pain 2 years after TKA.

Methods: Individual patient level variables were obtained from a single institution registry of TKA performed between 5/1/2007 and 7/1/2010 including demographics, baseline and 2 year WOMAC pain (0-100; 100 best), HSS Expectations Score (1-100, 100 best) and geocodable US addresses. Individual patient level variables were then linked to US Census Bureau data at the census tract level. Statistical models including both patient level variables and census tract level variables were constructed within multilevel frameworks. Two multivariate linear mixed effect models with separate random intercepts for each census tract were used to assess the interaction between race and census tract poverty level, and the interaction between education and census tract poverty level as predictors of WOMAC pain 2 years after TKA.

Results: 507/4225 (11.3%) of the TKA registry patients were non-white, and non-white patients were less likely to be college educated than whites (48.2 vs 62.8%, p-value≤0.0001). In univariate analysis, race, education and census tract poverty level (the percent of the community living below the poverty level) were significantly associated with WOMAC pain 2 years after TKA. In the first multivariate linear mixed effect model it was estimated that non-whites had worse WOMAC pain scores than whites and this difference increased with the increasing census tract poverty level (**Table 2**). The second multivariate linear mixed effect model showed that patients without college education had worse WOMAC pain 2 years after TKA than those with at least some college education, and this effect was magnified by greater levels of census tract poverty (**Table 3**).

Conclusion: Non-white race and a lack of college education are both associated with worse WOMAC pain 2 years after TKA and this effect is magnified by higher community poverty level. The differential impact of poverty, race, and education on pain after TKA needs more study.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Orthopedics, Low Back Pain and Rehabilitation Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Blacks in the United States (US) are less likely to undergo total knee arthroplasty (TKA) than whites, in part because they expect to benefit less. Whether their lower expectations are justified is unclear. The objective of this systematic literature review was to compare Health Related Quality of Life (HRQOL), pain, function, and satisfaction after TKA in US blacks andUS whites.

Methods: A librarian assisted search was performed on 12/14/2014 using PUBMED, EMBASE and the Cochrane Central Register. In addition, a hand search of journals focusing on disparities was performed. The following key terms were used: total knee replacement, quality of life, outcomes, and satisfaction. The search was limited to studies published during or after the year 2000. The population of interest was black US adults, the intervention was TKA, and the comparator was white US adults. Outcomes were HRQOL, pain, function and satisfaction following TKA. High quality observational cohorts with ≥ 6 month follow-up after TKA were included.

Results: 4781 studies were identified and screened by title, 346 by abstract, and 18 by full text. Only 7 studies met inclusion criteria and included race in the analysis. These studies represented a total of 4559 TKA patients of whom 482 (11%) were black. Because the studies used different outcome measures and were inconsistent in their adjustment for confounders, we could not perform a quantitative synthesis of the results. In 4 studies US blacks had worse pain, in 4 worse function, and in 1 less satisfaction 6 months-2 years after TKR.

Conclusion: US blacks may derive less benefit from TKA than whites as measured by HRQOL, pain, function and satisfaction, and this may contribute to lower rates of TKA utilization by blacks. Many large studies assessing predictors of patient related TKA outcomes fail to analyze race as a variable, which limited our study. More studies assessing the impact of race and socioeconomic factors on TKA outcomes are needed.

Barriers to Primary Care Clinician Adherence to Clinical Guidelines for the Management of Low Back Pain: A Systematic Review and Meta-Synthesis of Qualitative Studies

Susan Slade[1], Peter Kent[2], Shilpa Patel[3], Tracey Bucknall[4] and **Rachelle Buchbinder**[1], [1]Monash Department of Clinical Epidemiology, Cabrini Institute and Monash University, Melbourne, Australia, [2]Department of Sports Science and Clinical Biomechanics, University of Southern Denmark, Odense, Denmark, [3]Warwick Clinical Trials Unit, The University of Warwick, Warwick, United Kingdom, [4]School of Nursing & Midwifery, Deakin University and Alfred Health, Melbourne, Australia

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Orthopedics, Low Back Pain and Rehabilitation Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Low back pain is the highest ranked condition contributing to years lived with disability according to the most recent Global Burden of Disease study and is associated with significant societal and individual cost. Despite the availability of consistent evidence-based treatment recommendations for low back pain, management in primary care remains suboptimal with overreliance on imaging and medical intervention. We performed a systematic review and meta-synthesis of qualitative studies that explored what primary care clinicians believe about clinical practice guidelines for low back pain, including perceived enablers and barriers to guideline adherence.

Methods: The study was registered with PROSPERO (CRD42014012961) and our methods conformed to Cochrane Collaboration guidelines, the PRISMA Statement and the COREQ Checklist. Studies investigating perceptions and beliefs about low back pain guidelines were included if participants were primary care clinicians and qualitative methods had been used for both data collection and analysis. Only English-language studies were included. Eight electronic databases were searched from inception until July 2014. Pairs of reviewers independently screened titles and abstracts, extracted data, appraised method quality using the CASP checklist, conducted thematic analysis and synthesized the results in narrative format.

Results: From a search yield of 1880 titles, 32 papers were read in full and 17 papers fulfilled inclusion criteria. Studies were conducted in UK, Canada, USA, Netherlands, Germany, Israel, New Zealand and Norway and included general practitioners, physical therapists, chiropractors, osteopaths and occupational therapists.

All studies reported research aims, a justification for qualitative methods and a purposive sampling strategy and the majority reported recruitment and data collection details. However, many studies failed to report other key study components to allow full method quality assessment. We identified three key themes: clinicians have beliefs/perceptions that influence guideline implementation and adherence; they have beliefs/perceptions about patient expectations within the clinician-patient relationship; and they have beliefs/perceptions that act as barriers to guideline adherence.

Clinicians believe that guidelines are categorical, prescriptive and constrain professional practice, that popular clinical practices supersede the guidelines, and imaging can be used to manage consultations. Their perceptions reflect lack of content knowledge and

understanding of how guidelines are developed.

Conclusion: Addressing misconceptions and other barriers to uptake of evidence-based guidelines for managing low back pain is needed to improve knowledge transfer and close the evidence-practice gap in the treatment of this common condition.

Current Tobacco Use and the Rates of Complications after Total Hip Arthroplasty

Jasvinder A. Singh, University of Alabama at Birmingham, Birmingham, AL

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Orthopedics, Low Back Pain and Rehabilitation Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

The risk of postoperative complication with tobacco use disorder and complication after total hip arthroplasty (THA) are not known. Our objective was to compare the rates of complications in current tobacco users and non-users who underwent primary THA.

Methods:

All patients who underwent primary THA at the Mayo Clinic from 2010 to 2013 were included. Current tobacco use was defined as the use of cigarettes, cigars, pipes or smokeless tobacco reported by the patients at the time of their surgery. We used Cox proportional hazards regression to assess the association of current tobacco use status with each post-THA complication, using hazard ratio (HR) and 95% confidence intervals (CI), and Kaplan-Meier survival to estimate the implant survival.

Results:

Tobacco use status was available for 3,649 patients (95%) and not available for 197 patients (5%); 3,312 (92%) were current tobacco users. Among current tobacco users, higher proportion were male ($p<0.001$), or were 71-80 or ≥80 years old ($p=0.02$ and $p<0.001$; reference ≤60); no differences were noted for BMI, cemented vs. uncemented implant, Charlson index or ASA class.

Compared to current tobacco non-users, the hazards were significantly higher in current tobacco users for deep infection, hazard ratio of 2.89 (95% CI: 1.26,6.64; $p=0.01$). Non-significant trends for higher hazards were noted for rates of any infection at 1.66 (0.78,3.49; $p=0.19$), and any revision, 1.66 (0.82,3.35; $p=0.16$). No significant differences were noted for superficial infection and periprosthetic fracture by current tobacco use.

Conclusion:

We noted that current tobacco use was associated with high risk of infection after primary THA. Future studies should determine the optimal time for tobacco use cessation before elective surgeries such as THA.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Pain: Basic and Clinical Aspects Poster
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoporotic patients with no evidence of fractures sometimes experience vague low back pain. Bone pain associated with bone metastasis may also be related to increased osteoclastic bone resorption suggesting that osteoporosis-related bone pain is caused by increased osteoclastic bone resorption. J.Mysliwiec et al suggested that Interleukin-6 (IL-6) plays a considerable role of in the pathogenesis of thyrotoxicosis-related disturbances of bone turnover in estrogen-deficient women. In prospective study, IL-6 receptor inhibitor (IL-6Ri) increased the BMD of RA patients who had osteopenia. In addition, anti-IL-6R antibody inhibits systemic bone loss in the collagen-induced arthritis model mice. In this study, we investigated the effect of anti-IL-6R antibody on pain-related behavior and bone morphometry in ovariectomized mice.

Methods: 8-week-old female ddY mice were ovariectomized (OVX) and assigned to 3groups; SHAM-operated mice treated with vehicle (SHAM), OVX mice treated with vehicle (OVX), OVX mice treated with anti-IL-6R antibody (IL-6Ri). Starting immediately after surgery, vehicle or 2mg anti-IL-6R antibody was injected subcutaneously once a week for 4 weeks. The bilateral proximal tibial metaphyses were analyzed three-dimensionally by μCT 4 weeks after surgery (each group; 8 mice). Mechanical sensitivity was tested using von Frey filaments 4 weeks after surgery. The frequency of the withdrawal response and the withdrawal threshold to the application of von Frey filaments to the planter surface of the hindpaws was examined. To evaluate the frequency of the withdrawal response, three von Frey filaments with forces of 0.4, 0.6 and 1.4 were applied 5 times each in ascending order of force, and the number and intensity of withdrawal responses were noted. **Results** were expressed as the percent response frequency of paw withdrawals. To evaluate the withdrawal threshold, each von Frey filament was applied once, starting with 0.008g and increasing until a withdrawal response was reached, which was considered a positive response. The lowest force producing a response was considered the withdrawal threshold.

Results:μCT analysis of the femoral distal metaphysis and the proximal tibial metaphysis showed that bone volume/tissue volume (BV/TV) and trabecular number (Tb.N) were significantly less in the OVX group than in the SHAM group, whereas trabecular separation (Tb.Sp) was significantly greater in the OVX group than in the SHAM group. IL-6Ri treatment was no effect on bone morphometry compared with OVX group. The withdrawal threshold was significantly lower in the OVX group than in the SHAM group, and was significantly improved in the IL-6Ri group than in the OVX group. The paw-withdrawal-frequency stimulated by von Frey filaments with strength of 0.4, 0.6 and 1.4 g was significantly higher in the OVX group than in the SHAM group, and von Frey filaments with strength of 1.4g was significantly higher in the OVX group than in the IL-6Ri group. Anti-IL-6R antibody improved mechanical hyperalgesia in hindlimbs.

Conclusion: In this study, anti-IL-6R antibody prevented mechanical hyperalgesia in hindlimbs in hindlims of OVX mice, but did not prevent ovariectomy-induced bone loss.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Pain: Basic and Clinical Aspects Poster
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Mirogabalin (DS-5565) is a novel ligand of the $\alpha_2\delta$ subunit of voltage-gated calcium channels. Mirogabalin possesses unique binding characteristics to $\alpha_2\delta$ subunits, and potent and long-lasting analgesic effects in peripheral neuropathic pain models. Phase III clinical trials of mirogabalin in patients with postherpetic neuralgia, diabetic peripheral neuropathic pain and fibromyalgia are ongoing. In the present study, we investigated the analgesic effects of mirogabalin in two animal models of fibromyalgia, the intermittent cold stress model in mice and the intramuscular acid saline injection model in rats.

Methods: Female ddY mice were exposed to intermittent cold stress for three days, and male SD rats received two repeated intramuscular injections of acid saline (pH 4.0) into the gastrocnemius muscle. After development of hyperalgesia, the animals received the test compounds (mirogabalin and pregabalin) orally and the pain responses to mechanical stimulation were determined by von Frey test.

Results: In both models, mechanical hyperalgesia was demonstrated by increased pain scores or decreased pain thresholds to von Frey filaments. A single oral administration of mirogabalin (1, 3 and 10 mg/kg) significantly inhibited mechanical hyperalgesia in both models. The effects of mirogabalin were significant up to 6 or 8 hours after administration. Pregabalin, a standard $\alpha_2\delta$ ligand showed similar effects at 30 mg/kg.

Conclusion: Mirogabalin showed potent and long-lasting analgesic effects in two non-clinical models of fibromyalgia. Mirogabalin may provide effective pain relief for patients with fibromyalgia.

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Pain: Basic and Clinical Aspects Poster
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Bone histomorphometry can define OA changes in rodents and in Antigen-Induced arthritis (AIA) in rats. We produced painful inflammatory monoarthritis in mouse knees with IA CFA. IA neurotoxins reduced pain behaviors in murine CFA arthritis. Ttreatment with anti-nerve growth factor in humans rarely produced rapid joint destruction requiring arthroplasty. We used micro CT of knees to correlate pain behaviors with histomorphometric bone changes and to determine whether IA neurotoxin treatment worsened changes.

Methods:

Chronic Inflammatory arthritis was produced by IA injection of 30 µl CFA into the left knee of C57BL6 male mice 3 weeks prior to pain behavior testing using evoked pain score (EPS) and automated dynamic weight bearing (ADWB) device. EPS was a tally of fights and vocalizations/min with knee palpation at 15.6 psi. Percent weight and time on each limb was measured with ADWB apparatus (Bioseb, Vitrolles, France). IA vanilloids resiniferatoxin (RTX) and capsaicin (CAP) (10µl each of 0.001%RTX, 0.003% RTX or 0.01% CAP) were given 7 days prior to pain testing. IA botulinum toxin A (10µl 0.02 IU) was injected 3 days before testing. Knees were imaged on a micro-CT scanner (micro-CT40; Scanco Medical AG, Bassersdorf, Switzerland). Subchondral trabecular bone volume fraction (BV/TV), trabecular thickness (Tb.Th in µm), trabecular spacing (Tb.S in µm), and number (Th.N in 1/mm) were calculated from coronal slices using 3D Calculator (Erasmus Medical Center, Rotterdam, Netherlands).

Results:

Arthritis pain behavior was low in naïve mice - EPS (0.5) and ADWB proportions for weight (40.9%) and time (97.4%) were normal. IA CFA arthritis significantly increased EPS (2.5) and decreased ADWB for weight (34.1) and time (92.3). Arthritic knees had significantly reduced BV/TV (42.4 vs 50.3%), Tb.Th (252 vs 352 µm), and increased Tb.S (183 vs 112 µm) compared to naive knees. There was a significant negative linear relationship between EPS and BV/TV (R^2= 0.626, $p<.05$) with higher EPS when BV/TV was lower. ADWB measures trended in the same direction but were not statistically significant. IA neurotoxin treatments did not decrease BV/TV or Tb.Th or increase Tb.S. High dose IA-RTX in CFA mice normalized Tb.Th but not Tb.S or BV/TV.

Conclusion:

We confirmed that IA CFA monoarthritis increased evoked and spontaneous pain behaviors. MicroCT measured significant changes in BV/TV proportion, Tb.Th and Tb.Sp in CFA inflammatory arthritis. These findings are consistent with bone histomorphometry in rats with AIA. IA neurotoxins treatments with BOT, RTX and CAP did not worsen these subchondral changes. Interestingly high dose IA-RTX actually normalized Tb.Th. The negative relationship between BV/TV proportion and pain behaviors (ie increased pain with lowest BV/TV) suggests that more severe arthritic subchondral structural changes may be associated with increased pain behaviors.

The Effect of Gabapentin and Cyclooxygenase Inhibitors on Evoked and Ongoing Pain-like Behavior in Two Arthritis Models in Mice

Katalin Sandor[1], HueJung Park[2], Johanna McQueen[3], Sarah Woller[3], Maripat Corr[4], Camilla Svensson[1] and Tony Yaksh[3], [1]Department of Physiology and Pharmacology, Karolinska Institutet, Stockholm, Sweden, [2]College of Medicine, Department of Anesthesiology and Pain Medicine, The Catholic University of Korea, Seoul, South Korea, [3]Anesthesiology, UCSD, La Jolla, CA, [4]Division of Rheumatology, Allergy, and Immunology, UCSD, La Jolla, CA

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Pain: Basic and Clinical Aspects Poster
Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Induction of K/BxN serum transfer arthritis and collagen antibody-induced arthritis (CAIA) leads to transient joint inflammation but persistent mechanical hypersensitivity lasting at least 2 weeks after the inflammation has resolved (late phase). While mechanical hypersensitivity during the inflammatory phase is reversed by analgesics such as ketorolac/diclofenac (cyclooxygenase inhibitors) and gabapentin (calcium channel blocker), only gabapentin has effect in the late phase. Assessment of mechanical hypersensitivity is based on a stimulus-evoked response. Non-evoked or "ongoing pain" is another aspect of pain in RA that is more difficult to monitor in animal models. A current question is if changes in spontaneous behavior can be used as a measure of ongoing pain-like behavior. The aim of this study was to examine if K/BxN and CAIA which induce mechanical hypersensitivity also induce changes in locomotor activity and condition place preference (CPP) and if those are similarly sensitive to treatment with cyclooxygenase inhibitors and/or gabapentin.

Methods:

K/BxN arthritis was induced in C57BL/6 mice by i.p. injection of 100 µl K/BxN serum and CAIA in BALB/c and B10.RIII mice by i.v. injection of 4 mg collagen type II antibody cocktail. Joint inflammation was assessed by visual scoring and mechanical hypersensitivity by von Frey filaments. Locomotor activity was recorded overnight using a Comprehensive Lab Animal Monitoring System. CPP was assessed by monitoring the number of crossings between distinctly different chambers (wall pattern and floor texture). CPP paradigm: 2 days adaptation with free access to all chambers, 2 days conditioning with restriction to one chamber (vehicle in morning and drug in afternoon), preference testing on day 5 with free access to all chambers. Effects of gabapentin (50 or 100 mg/kg) and cyclooxygenase inhibitors (ketorolac: 15 mg/kg; diclofenac: 30 mg/kg; naproxen 30 mg/kg) were assessed.

Results:

Gabapentin reversed mechanical hypersensitivity during both phases of the K/BxN and CAIA models. Ketorolac and diclofenac only attenuated mechanical hypersensitivity during ongoing inflammation in the K/BxN and the CAIA model, respectively, and had no effect in the late phase in both models. Ketorolac did not reduce CAIA-induced mechanical hypersensitivity. Locomotor activity was reduced in the early phase in the CAIA model (not assessed in the K/BxN model), which was normalized by naproxen, but not by gabapentin. Diclofenac reduced locomotion in naïve mice. A significant preference for both the gabapentin and ketorolac-paired compartment was observed in the early phase of the K/BxN model, while in the late phase only gabapentin treatment resulted in CPP. In the CAIA model, gabapentin produced a preference in the early phase and a trend in the late phase, whereas ketorolac was ineffective in both phases.

Conclusion:

We found that the K/BxN and the CAIA models induce changes in spontaneous behavior. Locomotor activity was affected by sedative side effects of the drugs. While somewhat different responses to cyclooxygenase inhibitors were noted in the two arthritis models, there was correspondence between the anti-hyperpathic pharmacology as defined by thresholds and CPP.

Peripheral HMGB1 Regulates Arthrtis-Associated Pain-like Behaviour

Nilesh Agalave[1], Teresa Fernandez Zafra[2], Peter Lundback[3], Ulf Andersson[4], Helena E. Harris[3] and Camilla Svensson[5], [1]Physiology and Pharmacology, Karolinska Institutet, Stockholm, Sweden, [2]Physiology and pharmacology, Karolinska Institutet, Stockholm, Sweden, [3]Center for Molecular Medicine, Karolinska Institutet, Stockholm, Sweden, [4]Center for Molecular medicine, Karolinska Institutet, Stockholm, Sweden, [5]Department of Physiology and Pharmacology, Karolinska Institutet, Stockholm, Sweden

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Pain: Basic and Clinical Aspects Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: HMGB1 has received attention for its emerging roles in the extracellular environment acting as damage associated molecular pattern molecule. The redox state of HMGB1 is key in determining which receptors HMGB1 activates and partially reduced HMGB1 (disulfide HMGB1) functions as a cytokine-inducing TLR4 ligand. Accumulating data indicate that HMGB1 plays important roles in the pathogenesis of inflammatory and autoimmune diseases. Blocking the action of HMGB1 with neutralizing antibodies ameliorates experimental arthritis in both mice and rats. Peripheral HMGB1 has also been linked to induction of pain-like behavior in experimental models of neuropathic and low back pain. However, the role of peripheral HMGB1 in pain hypersensitivity subsequent to development of arthritis has not been investigated. Thus the aim of the current study was to investigate if peripheral HMGB1 regulate arthritis-induced pain-like behavior.

Methods: BALB/c and C57BL/6 male and female mice (12-18 weeks) were used for this study. Collagen antibody-induced arthritis (CAIA) was induced by i.v. injection of anti-collagen antibody cocktail (1.5 mg/mice) followed by i.p. injection of LPS (25 ug). Disulfide HMGB1 (1 µg) was injected intraarticularly to the ankle joint. Mechanical hypersensitivity was assessed by von Frey filaments and the degree of joint inflammation by visual inspection and joint histology (H&E). The HMGB1 neutralizing antibody 2G7 (4 mg/kg) and the recombinant Abox protein (12 mg/kg) (blocks extracellular HMGB1 activities, although the exact mechanisms of action are unknown) were injected once/day for 6 consecutive days in both the inflammatory and late phase. Primary neuronal cultures were prepared from dorsal root ganglia and calcium flux subsequent to HMGB1 stimulation (100 nM) examined by calcium imaging. KCl (50 mM) was used as positive control to detect functional neurons.

Results: While CAIA mice developed transient joint inflammation with visual and histological arthritis scores, induction of mechanical hypersensitivity, which coincided with the inflammatory phase, did not resolve and remained pronounced throughout the study ("late phase" from day 38 to 51). Repeated systemic injection of 2G7 and Abox reversed CAIA-induced mechanical hypersensitivity in the inflammatory phase while in the late phase, Abox, but not 2G7, partially reversed the pain-like behavior. Intraarticular injection of dsHMGB1 in naïve mice induced mechanical hypersensitivity for at least 6h in both male and female mice. Stimulation of primary DRG neurons with dsHMGB1 did not evoke calcium flux in KCl responding neurons.

Conclusion:

Our findings suggest that extracellular HMGB1 is an important factor in arthritis-induced pain during ongoing inflammation, but that it has a less pronounced role in mechanisms that maintain nociception subsequent to a period of joint inflammation. The TLR4 activating redox form of HMGB1 has nociceptive properties in the joint in naïve conditions, most likely via actions on immune cells as dsHMGB1 does not directly activate DRG neurons. Future studies are warranted to define the mechanisms by which peripheral HMGB1 contribute to arthritis-induced pain.

Age and Sex Impacts the Development of Hypersensitivity in the Murine Partial Medial Menisectomy Model of Osteoarthritis

Ada Delaney[1], Azar Barharpoor[1], Tianle Gao[1], Jie Su[1], NIlesh Agalave[1] and Camilla Svensson[2], [1]Dept. of Physiology & Pharmacology, Karolinska Institutet, Stockholm, Sweden, [2]Department of Physiology and Pharmacology, Karolinska Institutet, Stockholm, Sweden
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Pain: Basic and Clinical Aspects Poster
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Osteoarthritis (OA) is the leading cause of chronic pain in European adults (37%; painineurope.com). Pain is the foremost symptom of OA, with both episodes and severity becoming more constant or frequent with progression of the disease. Current therapies to reduce pain are often ineffective and have use limiting side effects. Thus the development of efficacious analgesics is crucial to improve the lives of individuals with OA, to this end the use of animal models is required to understand the underlying mechanisms of OA-induced chronic

pain. We aimed to further characterize the partial medial menisectomy model of OA, by assessing the development of hypersensitivity to mechanical stimulus, the impact on burrowing behaviour, and the response to Gabapentin a known analgesic used in the treatment of neuropathic pain, in both young and aged adult male and female mice.

Methods:

C57/Black6J male and female mice approx. 3-4 or 16-18 months of age at the time of surgery were randomized into partial medial menisectomy or sham surgery groups, all groups received post-operative analgesia of buprenorphine. Hypersensitivity to mechanical stimulus was assessed using von Frey filaments applied to the hindpaw, to determine secondary mechanical allodynia. Burrowing behaviour was used as an outcome measure of general wellbeing and is thought to reflect ongoing pain. All behaviour was monitored before and up to 16-30 weeks post-surgery. Mechanical allodynia was assessed following administration of Gabapentin (50mg/kg; i.p.). Osteoarthritic pathology of the knee joints were analyzed by hematoxylin and eosin and/or Safranin-O staining.

Results:

In both aged (14 weeks post-surgery) and young (27 weeks post-surgery) female groups significant development of mechanical hypersensitivity and signs of osteoarthritic pathology (cartilage loss) were observed. Mechanical hypersensitivity was not observed in young adult male mice and less pronounced in aged male compared to aged female mice. Mechanical hypersensitivity in female mice was significantly reversed by Gabapentin. No significant deficit in burrowing behaviour was noted between the groups.

Conclusion:

The partial medial menisectomy model is a slowly developing model of OA-induced mechanical hypersensitivity in adult female mice (with earlier onset in aged mice), which is reversible by Gabapentin. No deficit in burrowing suggests this model does not have a negative impact on the overall wellbeing or lead to ongoing pain for the mice. This model reflects the clinical condition and could aid the translation of preclinical findings into clinical outcomes.

Session Date: Monday, November 9, 2015

Session Title: Pain: Basic and Clinical Aspects Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Quantitative sensory testing (QST) can be used to assess pain processing mechanisms, and theoretically identify a subset of chronic pain patients that has central sensitization or centralized pain. However, measures of "evoked pain" from experimental stimuli obtained via QST typically are only marginally related to clinical pain reports. This study looked the relationship between manual algometry pressure-pain thresholds (PPT) at multiple sites and clinical pain measures in knee osteoarthritis (KOA) patients.

Methods: Fifty-four subjects meeting ACR criteria for osteoarthritis of the knee (mean age: 62.04 years; range: 37 – 83 years; 24 male, 34 female) presented for QST and a clinical pain battery including WOMAC, PainDETECT, Michigan Body Map (MBM), and Brief Pain Inventory (BPI). PPT was measured three times (Wagner FDX 25: 0.5 kg/s ramp rate, 20 inter-stimulus interval) bilaterally at four body sites: lateral patella (knee), tibialis anterior, trapezius and wrist. Associations between PPTs and clinical pain were assessed by Pearson's product-moment correlations (r) and partial correlations controlling for gender were assessed for significance using SPSS 22.

Results: WOMAC was significantly correlated to left and right knee PPT, r = -0.37 and -0.52 ($p < 0.05$), respectively. WOMAC pain, stiffness and functional limitation subscales were all significantly correlated to right knee PPT, r = -0.32, -0.39 and -0.52 (all $p < 0.05$), respectively; however, only functional limitation was significantly correlated to left knee PPT, r = -0.38, $p < 0.05$. PainDETECT was significantly correlated to all sites (knee, trapezius, tibialis anterior and wrist) and correlation coefficients for left and right side were r = -0.52, -0.51, -0.45, -0.34 and -0.59, -0.59. -0.50, -0.37 (all $p <0.05$), respectively. MBM, a measure of clinical pain distribution, correlated with both knee PPT (r = -0.33, $p < 0.05$) and trapezius PPT (r = -0.43, $p < 0.01$) on the right side; however, the left side was not significantly correlated. BPI severity and interference were not correlated to PPT at any body site (all $p > 0.31$). All correlations remained significant when controlling for gender.

Conclusion: These data suggest that the MBM and painDETECT assess pain quality associated with augmented central pain processing in patients with symptomatic knee OA. These results provide a foundation for future assessment of correlations between evoked and clinical pain measures. Additional studies are needed to determine the specific sites best suited for assessment of OA pain.

Table 1. Pearson correlation coefficients between PPT site and clinical pain measures

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Pain: Basic and Clinical Aspects Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Recent studies have suggested that a subset of individuals with arthritis have a component of sensitization to their pain. This subset of patients with centralized pain can theoretically be identified via self -report measures, quantitative sensory testing, or a combination of the two. This study examined whether phenotyping patients by self-report or QST measures of pain centralization predicted a differential response amongst OA patients to a centrally-acting (duloxetine) vs. peripherally-acting (topical diclofenac) analgesic, or both together.

Methods:

Fifty-two subjects meeting ACR criteria for osteoarthritis of the knee were enrolled in a double-blind crossover trial where each was treated with 20 mg of duloxetine or four times daily 1.5% topical diclofenac solution. Assessments included WOMAC, PainDETECT, Pain Quality Assessment Scale (PQAS), PROMIS physical function Short Form, Pressure Pain Threshold, and Conditioned Pain Modulation. Subjects were treated for eight weeks in a counter-balanced fashion, followed by a four-week washout period, and then another eight weeks of treatment. A subset of individuals entered a third treatment period of combined duloxetine and diclofenac. The primary endpoint was a change in the WOMAC pain subscale at eight weeks.

Results:

Treatment with duloxetine resulted in a significant decrease in WOMAC pain subscale whereas there was no significant improvement in the group means in the 1.5% diclofenac treatment period. Patient reported outcome measures predicted response to duloxetine, including total scores on PainDETECT and PQAS Intensity subscale. QST assessment for baseline pressure pain threshold predicted the response to duloxetine based on change in WOMAC pain subscale, but there was no association between QST measures of conditioned pain modulation and response to duloxetine. An increase in the PainDETECT score was associated with an increase in pain as measured by the WOMAC pain subscale by an average of 0.22 per unit increase in pain DETECT score (SE 0.059, p=0.0005). There were no differences in adverse events or rescue medication usage between the arms.

Conclusion:

PainDETECT, PQAS, and Pressure Pain Threshold predict response to duloxetine. Pain control in this cohort was most favorable for duloxetine alone or in combination with topical diclofenac.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Pain: Basic and Clinical Aspects Poster
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

There are few studies in the literature indicating that neuropathic pain occurs in rheumatoid arthritis (RA). The aim of this cross sectional

study was to evaluate frequency of neuropathic hand pain in RA patients and to determine the relation with clinical variables and occurrence of neuropathic pain.

Methods:

A hundred-nineteen RA patients, who were not having any comorbid disease and/or using drugs that would cause neuropathy, were recruited to the study. Demographic properties (age, sex, disease duration) and clinical characteristics (pain by VAS, functional status, disease activity and quality of life (QoL) assessed by HAQ, DAS28 and RAQoL respectively) were recorded. The neuropathic property of hand pain was assessed by both Leeds assessment of neuropathic symptoms and signs pain scale (LANSS), Douleur Neuropathique4 (DN4) and Pain-DETECT scales. Descriptive statistics was used for clinical variables and frequency of neuropathic pain. The difference of clinical variables between patients with and without neuropathic pain, were examined using t tests and chi square tests for continuous and categorical variables respectively. Correlation coefficients of clinical variables and neuropathic pain scores were analyzed with Spearman correlation analyses. The significance threshold was set as p values less than 0.05.

Results:

61 female, 58 male RA patients with a mean age of 50.51± 12.45 years, were included to the study. Neuropathic pain was detected in 76 (%63.9), 70 (%58.8), 61(%51.3) RA patients depending on the LANSS(scores>12), DN4(scores>4) and painDETECT(scores>12) questionnaires respectively. The mean levels of VAS-pain, HAQ and RAQoL scores were significantly higher in patients having neuropathic pain than in patients not having ($p<0.05$) (Table 1,2). The scores of the neuropathic pain scales were correlated with each other but not with the scores of disease activity.

Conclusion:

Neuropathic hand pain is determined in more than half of the patients with RA and related with pain intensity, functional status and QoL. Diagnosis and treatment of neuropathic pain are warranted in order to improve pain, disability and quality of life in RA patients.

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Pain: Basic and Clinical Aspects Poster
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Chronic pain continues to be a significant problem for patients with rheumatoid arthritis (RA), even when the disease is medically controlled or in remission. RA patients often develop a generalized increase in pain sensitivity at remote sites from the inflamed joint, suggesting that central sensitization may play an important role. We have previously shown that joint inflammation is associated with an upregulation of inflammatory mediators in the central nervous system (CNS) of humans and mice. Here we sought to investigate if anti-citrullinated protein antibodies (ACPA) can be detected in the cerebrospinal fluid (CSF) of RA patients and if ACPA can be linked to central pain sensitization.

Methods: Clinical study: CSF (via lumbar puncture) and serum was collected from 13 female RA patients with anti-CCP positive (+) ($ACPA^+$) antibodies. CSF from age-matched i) individuals with no neuroinflammatory or rheumatic disease (n=10) and ii) multiple sclerosis (MS) patients (n=26) was used as controls. ACPA IgGs were measured using a commercial anti-CCP2 ELISA according to the manufacturer's protocol (serum diluted 1:100, CSF undiluted).Experimental study: Purification of IgG from plasma and sera from 36 separate $ACPA^+$ patients was done by HiTrap Protein G columns and ACPA IgG was further purified using CCP2 affinity columns. IgG not binding to the CPP2-column was used as control and denoted flow through (FT). Balb/c/AnNRJ female mice (>12 weeks old) were used and ACPA or FT (100-300) µg was injected intrathecally into CSF by lumbar puncture. Mechanical hypersensitivity was assessed using von Frey filaments and cold sensitivity by the acetone test. Tissues were collected at day 20 for western blot analysis.

Results: Clinical study: 7/13 serum $ACPA^+$ RA patients had ACPA also in CSF (29-154 U/ml). ACPA levels in controls were significantly lower; non-inflammatory controls: 2.19 +/- 0.09U/ml, and MS patients: 2.54 +/- 0.16U/ml. In RA patients, there was a strong correlation between the presence of ACPA in CSF and significantly higher serum ACPA levels (1453 +/- 82U/ml in RA ACPA pos serum and CSF vs 90 +/- 46U/ml; ACPA neg CSF, $p<0.01$). Experimental study: Intrathecal injection of ACPA, but not FT, led to a reduction in mechanical thresholds from day 10 to day 18. In addition, 100 µg and 300 µg ACPA, but not FT, induced cold hypersensitivity at day 11. Western blot analysis showed a time dependent elimination of ACPA. Human IgG was not detectable in spinal cords or joints of ACPA injected mice 20 days post injection.

Conclusion: Our data show that ACPA can be detected in CSF of RA patients with high ACPA serum titers. We did not find indications of intrathecal ACPA production. In mice, intrathecal injection of ACPA induced pain-like behavior, indicating changes in spinal/brain facilitation of nociceptive signaling. Interestingly, the delayed onset of pain responses, and the long lasting effect being present despite clearance of antibodies, suggest antibody-induced secondary events at the spinal cord/brain level or redistribution of ACPA to peripheral sites. Altogether, these results give support to the hypothesis that ACPA may enter the CNS and possibly affect central pain mechanisms in RA.

Abstract Number: 1436

Characterization of Patient Reported Pain Medication in Early Vs. Established Rheumatoid Arthritis

Apoorva Kelkar, Angela Cesta, Xiuying Li and **Claire Bombardier**, Toronto General Hospital Research Institute, University Health Network, Toronto, ON, Canada
First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Pain: Basic and Clinical Aspects Poster
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Pain control in rheumatic diseases is complex and various pharmacotherapy approaches can be utilized for management of rheumatic pain. Currently, systematic clinical practice guidelines for pain management in Rheumatoid Arthritis (RA) are lacking; however, there are several evidence-based expert recommendations provided by a broad panel of rheumatologists from the 3e initiative[1]. Based on these recommendations, the aim of this study was to describe patient-reported pharmacotherapy regimens involved in the management of rheumatic pain in early vs. established RA.

Methods: Patient-reported medication data was collected from the Ontario Best Practices Research Initiative (OBRI), a clinical cohort of RA patients followed in routine care. As recommended by the 3e initiative, patients receiving NSAIDs, acetaminophen (APAP), opioids, antidepressants (AD) and neuromodulators (NM) at cohort-entry or while in the OBRI were selected (n = 1,470) and followed till a change in pain therapy was reported. Based on disease duration, patients were categorized into early RA (disease duration ≤1 year) or established RA (disease duration >1 year). For each group, patient demographics, common pharmacotherapy regimens and the number of patients receiving each regimen were determined.

Results: From the selected cohort, 384 patients met the criteria for early RA and 1,054 patients for established RA. 32 patients did not indicate their disease duration and were excluded. In early RA, the mean age ± SD of patients was 56.4±14.2 years, 73.2% were female and mean disease duration ± SD was 0.42±0.49 years. In established RA, the mean age ± SD of patients was 57.4±12.0 years, 80.0% were female and mean disease duration ± SD was 11.9±9.41 years. The most common pharmacotherapy regimens and % patients receiving each regimen are shown in figure 1.

Conclusion: Our study showed that NSAID use as monotherapy or in combination with other agents was highly prevalent across both groups. Patients with established disease were more likely to use a combination of NSAIDs + APAP and NSAIDs + opioids + APAP possibly due to worsening pain with disease progression. The use of NSAIDs + opioids was higher in early RA. Physicians may feel more comfortable prescribing opioids in early RA due to the advent of Ontario's Narcotic Monitoring System as well as better patient education and follow-up with dedicated pain clinics. Further work is required to determine the association between pain therapy regimens and disease activity measures in early vs. established RA.

Session Title: Pain: Basic and Clinical Aspects Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Despite advances in the treatments available for rheumatoid arthritis (RA), many patients continue to experience musculoskeletal pain. Untreated and under-treated pain are well known to increase disability and negatively impact overall well-being. Recently, multinational evidence based guidelines have been published in an attempt to improve overall pain management in these patients. To date, no studies have evaluated the prevalence and magnitude or impact of pain on Australian patients with RA. The pattern and type of analgesics used is also not known. The purpose of this study was to determine the prevalence and severity of pain and its impact on functional capacity and quality of life in Australian patients with RA and to describe current analgesic use.

Methods: We performed a descriptive analysis from the Australian Rheumatology Association Database (ARAD). ARAD is a voluntary registry that collects longitudinal health outcome data from Australian patients with inflammatory arthritis (RA, psoriatic arthritis, ankylosing spondylitis and juvenile idiopathic arthritis). The latest data entry point between 1st Januray 2014 and 31st December 2014 for all adult patients (≥18 years) with RA was used. Patient demographics, pain scores (VAS 0-100mm), medication use, responses to the HAQ, Assessment of Quality of Life (AQOL), and European Quality of Life-5 Dimensions (EQ-5D) were extracted and analysed. For the prevalence calculation pain was defined as being present if >4mm (0-100mm VAS).

Results: In 2014, 1548 patients with RA (76% female, mean age 60 years (range 21 to 90, mean disease duration 19 years) completed an ARAD questionnaire. 85% were receiving biological therapy. Mean HAQ was 0.94 (SD 0.75), EQ-5D 0.65 (0.24), AQOL 0.56 (SD 0.24). Overall 95% of patients reported pain (>4mm) in the preceding week (mean 41.1mm, SD 25.7) with 37% having mild pain (5-34mm), 39% moderate pain (35-69mm) and 19% severe pain (70-100mm) . Females reported higher mean pain (42.3mm versus 37.2mm, p =0.001), as did those using biological agents (41.7mm versus 36.4mm, p=0.02) or receiving the disability pension (53mm versus 39mm, p<0.0001). Seventy-three percent of patients reported taking an analgesic medication, most commonly paracetamol (60%), NSAID (37%), opioid (26%), and/or an antidepressant/neuromodulator (1%). A single analgesic medication was used by 49%, with 37% taking two and 14% consuming three or more. Higher pain scores were associated with use of a higher number of analgesic medications (F (3,1542) = 79.2, p<0.0001), poorer quality of life (lower EQ-5D (ß=-0.01, p<0.0001), lower AQOL (ß=-0.01, p<0.0001)) and poorer function (higher HAQ (ß=0.02, p>0.0001)).

Conclusion: Despite use of multiple analgesic medications, the prevalence of moderate to severe pain is high in patients with RA and is associated with lower levels of function and quality of life.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Pain: Basic and Clinical Aspects Poster
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

National Health and Nutrition Survey III (1988-94,USA) data showed a low K+ body status in RA. Further information is scanty. K+ is critical to 'pain' [nociceptive processing, K+ ion channel downregulation (Tsantoulas. Trends Neurosci 2014; 37:146) and related process e.g. oxidant tissue damage and T lymphocytes function [K2P5.1 (Bitner. Arthritis Res Therapy 2011;13:R 21), Kv1.3 & KCa3.1 channels (Lam. Drug Dev Res 2011; 72: 573] and cortisol secretion. Using Indian standards (National Institute of Nutrition, Hyderabad) and controlled diet survey, we showed that K+ was low ($p<0.5$) in RA patients, more so in women (EULAR 2014).

Methods: 172 consenting chronic RA patients (ACR 1987 classified, mean age 49.9 years, 89 % women, mean duration 9.9 years,74% seropositive RF) with active pain(visual analogue scale > 4 cm) were randomized into an assessor blind, three arm study of 16 week duration in a community rheumatology center. Standardized oral K+ intake was based on K+ rich vegetarian balanced diet in Arm A (3.5-4 gm K+ daily) and an additional K+ supplement powder (K+ rich pulses & seeds plus oral rehydration salt(3 gm K+), Indian pharmacopeia) in Arm B (7.5-8 gm K+ daily); local diet preferences considered. Arm C was control (routine diet , 2-3 gm K+ daily). Patients continued pre-study suprvised standard rheumatology care/drugs (72% methotrexate, mean weekly dose 14 mg;60% prednisolone, mean4 mg daily); analgesic rescue permitted and monitored as per protocol. No other non-drug intervention advised. Standard efficacy/safety measures and diet intake were evaluated every month. Compliance check included urinary K+ assay. The study (80% power, significant $p<0.05$) was analyzed using SPSS; NS: p, not significant. Arms were well matched for several measures (for mean DAS 28: A=4.9; B=5.5; C=4.9) and withdrawals (A: 8.8%; B:12.1%; C: 8.8%).

Results:

Pain and several ACR efficacy measures improved ($P<0.05$) by intervention; difference was NS by intent to treat analysis/ITT (mean change pain VAS: A=-1.3 cm; B=2 cm; C= 1.2; p=0.17, ANOVA).But completer analysis showed significant change (p=0.04) in mean pain VAS in the B intervention arm (high K+ intake). B arm also showed best response (ITT, $P<0.05$) in proportion patients with at least 50% reduction and minimal clinical important difference in pain VAS on completion from baseline. Maximum improvement (NS) in HAQ (Indian validated version) and SF 36 physical score was seen in the B arm. There was reduction (NS) in the mean DAS 28 score by intervention (A:-1.4; B:-1.2; C: -0.9). Only mild AE were reported (<8% patients by study arm). On completion, B arm demonstrated a maximum serum cortisol (AM) increase. K+ intervention arms showed reduction in systolic BP. Ongoing medication, dietary factors and compliance, disease activity status may confound results.

Conclusion:

This pragmatic interventional control study in patients suffering from chronic symptomatic RA showed a clinically important pain reduction over and above standard drug treatment using dietary K+ augmentation. Other possible benefits were reduced disease activity and improved BP (cardiovascular) status. Overall, this seemed to be a gentle useful and safe adjunct therapy.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Pain: Basic and Clinical Aspects Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients ≥65 taking naproxen with previous GI symptoms have a 29% annual incidence of significant upper gastrointestinal events.(1) Those patients who are older, with previous ulcer history, and on low dose aspirin (LDA) are particularly at risk for gastric ulcers. Prophylaxis with gastroprotective agents can help reduce adverse GI effects. Here we report the comparative incidence of gastric ulcers (GUs) with a fixed combination of naproxen 500 mg/ esomeprazole 20 mg (NAP/ESO) versus naproxen 500mg (NAP) alone given twice daily to patients with a previous history of ulcers who required continued NSAID therapy.

Methods: We pooled data from two large randomized, placebo controlled trials (n=854) which reported a significant reduction in the incidence of cumulative GUs over 6 months with NAP/ESO (n=428) compared with NAP (n=426). (2) Efficacy in a subset with 1) a history of GU within 5 years, 2) aged ≥ 50 + history of GU, and 3) use of aspirin + history of GU were assessed. The CMH test was used to compare the treatment groups for differences at the 0.05 level. Relative Risk Reduction (RRR) and number-needed-to-treat (NNT) were calculated.

Results: In total, 69 patients (N=33, NAP/ESO, N=36, NAP) had a history of GUs (Figure 1). NAP/ESO use was found to statistically significantly reduce the risk for GUs over 6 months as compared with NAP alone in those 1) with a history of GU [RRR=0.81, NNT= 2.62], 2) aged ≥ 50 + history of GU [RRR=0.91, NNT=1.97]and 3) use of aspirin + a history of GUs [RRR=1, NNT=1.67].

Conclusion: The fixed combination of NAP/ESO significantly reduces the risk for gastric ulcers associated with high dose naproxen in those at high inherent risk. Numbers of patients needed to be treated to prevent one event were low (< 3).

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Pain: Basic and Clinical Aspects Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Sonographic needle guidance (USG) of musculoskeletal injections has improved outcomes of intraarticular (IA) injections, but is associated with increased procedural costs. This practical randomized controlled pilot study was designed to determine: 1) the overall costs and cost-effectiveness of the USG technique of IA corticosteroid injections in the shoulder, and 2) provide preliminary power data to determine whether USG IA injections were more effective than the conventional anatomic landmark palpation-guided (ALMPG) method.

Methods: 29 patients with intractable shoulder pain (glenohumeral joint (GHJ) arthritis with tenderness to deep palpation anteriorly) were randomized to injection by either conventional ALMPG (15 patients) injection USG (14 patients) injection. A two-step technique was utilized for IA procedures using one needle and two syringes. The USG method comprised: 1) interrogation of the shoulder to find the GHJ, 2) needle introduction into the GHJ using the anterior approach under USG, 3) 3 ml 1% lidocaine injected with US visible dilation of the IA space, 4) a syringe exchange leaving the IA needle in place, and 5) injection of 80 mg triamcinolone acetonide (2 ml) through the IA needle. Demographics, baseline pain, procedural pain, pain at 2 weeks, pain at 24 weeks, therapeutic duration, physician satisfaction, total cost per procedure, and yearly cost per patient were collected and analyzed. Pain was measured with the 10 cm Visual Analogue Pain Scale (VAS).

Results: There were no complications in either treatment group. Both groups significantly improved at 2 weeks post-injection ($p<0.005$), supporting that both USG and ALMPG were both effective as has been previously demonstrated. There was no significant difference in total cost (yearly cost per patient) between US and non-US methods ($p<0.23$), despite increased upfront procedural costs. The USG data suggested potentially improved outcomes due to statistical trends for reduced post-procedural costs ($p<0.101$), reduced injection pain ($p<0.113$), and prolongation of time to next procedure ($p<0.06$). With the current subject numbers, compared to conventional ALMPG methods, USG injection did not demonstrate statistically significant improvement in pain at 2 weeks post-injection ($p<0.69$), pain at 24 weeks post-injection ($p<0.63$), pain from baseline compared to 2 weeks post-injection ($p<0.78$), pain from baseline to 24 weeks post-injection ($p<0.60$), or duration of therapeutic effect ($p<0.39$).

Conclusion: USG does not increase the overall costs of IA shoulder injections and with a trend of decreasing post-procedure costs, findings of importance for medical economics. Further, the present study trends suggest that USG may improve overall clinical outcomes of IA shoulder injections permitting power determination for future definitive studies

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Pain: Basic and Clinical Aspects Poster
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Marine oil supplements (MOS) are suggested to have anti-inflammatory properties, but there is no consensus regarding the efficacy of MOS in the management of arthritis. The objective was to evaluate whether oral MOS improve pain and other clinical features in patients with any type of arthritis.

Methods: Included in the systematic review were randomized trials comparing an MOS, with no marine oil supplementation (i.e., add-on designs) with trial duration of at least 2 weeks in patients with any type of arthritis, at any age and gender. Trials that collected some patient-reported pain outcome were considered eligible for meta-analysis. A systematic search was applied (02.24.15) to Medline, Web of Science, The Cochrane Central Register of Controlled Trials, EMBASE, ClinicalTrials.gov, and the World Health Organization International Clinical Trial Registry Platform portal. Assessment for inclusion, data extraction and bias assessment were done independently by 2 reviewers. Data were extracted using a standardized form. Risk of bias was assessed using the Cochrane Risk of Bias tool. Standardized mean differences (SMD) were calculated, using Hedges's adjustment. Random-effects meta-analysis was used to pool the trial data and heterogeneity was explored using REML-based meta-regression analysis (R software).

Results: From 65 potentially eligible trials included in the systematic review, 42 trials met inclusion criteria for the meta-analysis. Of these, 30 trials had complete data for inclusion, where data on 1509 patients, of whom 781 received an oral MOS, were used. Although substantial heterogeneity was present (I^2, 63%), the pooled SMD suggested a favorable association with MOS compared with control (SMD, -0.24; 95%CI: -0.42 to -0.07); corresponding to an improvement of 8 % on a VAS pain scale. Inclusion of the trials with non-complete data on pain outcome, and high risk of outcome reporting bias, using a null imputation, resulted in a lower effect size (42 trials; SMD, -0.16; -0.28 to -0.03). Meta-regression analysis on the trials with complete data showed a statistically significant effect in rheumatoid arthritis (RA) patients (22 trials; SMD, -0.21; -0.42 to -0.0043) but not in patients with osteoarthritis (OA) (5 trials; SMD, -0.17; -0.57 to 0.24); other/unclear/mixed diagnoses were described in three trials (-0.63; -1.2 to -0.06). Inadequate blinding of participants and high risk of attrition bias were associated with higher effect sizes, compared to those with an adequately reported procedure.

Conclusion: Meta-analytic pooling of all studies across arthritis conditions showed a statistically significant association between oral MOS and pain (SMD>0.20 indicating clinical significance). A statistically significant effect was seen in RA patients but not in OA patients. However, our confidence in the estimate(s) is rated to low-quality evidence due to heterogeneity, and the empirical evidence suggesting a high risk of bias.

Descriptive Characteristics of Patients Prescribed Opioids for the Treatment of Chronic Pain

Jenna Goesling[1], Stephanie Moser[2], Afton L. Hassett[3], Chad Brummett[1] and Natalie Gulau[1], [1]Anesthesiology, University of Michigan, Ann Arbor, MI, [2]Department of Anesthesiology, University of Michigan, Ann Arbor, MI, [3]Anesthesiology, University of Michigan Medical School, Ann Arbor, MI
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015

Session Title: Pain: Basic and Clinical Aspects Poster
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Opioids remain the cornerstone of acute pain therapy. However, there is little empirical evidence supporting the use of long-term opioid therapy for chronic pain. In clinic settings, one of the challenges faced by physicians is determining what to do with patients who were started on opioids for therapeutic use (i.e. pain relief) but who continue to use opioids even when benefit is not apparent. The goal of this study was to describe the unique characteristics of patients currently taking opioids. **Methods:**

This study included 150 new patients between the ages 18-70 seeking treatment for chronic pain at an outpatient tertiary pain clinic. As part of their visit, all patients completed self-report measures of pain severity (Brief Pain Inventory), physical functioning (PROMIS Short Form) and psychiatric symptoms (Hospital and Depression Scale). During the new patient visit, a research assistant approached eligible patients in an exam room and completed a structured interview developed by the investigative team. For patients reporting current opioid use, additional data was collected including duration of use, helpfulness of opioid across multiple domains, motivation to continue opioids, and interest in learning alternative ways to manage pain. The Opioids Difficulties Scale (PODS) and Domains of Change Opioid Scale (DCOS) were collected on all participants currently taking opioids. Chi-square and t-tests were conducted. **Results:**

Of the 150 patients, 55.26% (N=84) reported current opioid use. Current opioid use was associated with a worse clinical phenotype, including higher pain severity, worse physical functioning, and more symptoms of depression (See Table 1). Descriptive data on the characteristics of opioid use is presented in Table 2 and opioid related beliefs are presented in Table 3. **Conclusion:**

These data question the benefits of long term opioid use. For instance, 41% of patients report less than an hour of pain relief after taking an opioid. The data from this study also highlight important target areas for helping patients not benefiting from opioids taper off opioids. For instance, patients report low confidence in their ability to manage pain without opioids. Importantly, the majority of patients report interest in learning alternative strategies for managing their pain.

Table 1. Patients using opioids had a worse pain phenotype when compared to those not using opioids, including higher pain severity, worse physical function and higher symptoms of depression

	Opioid Use		p°
	Yes N=85	No N=66	
Gender (% Male)	41.67	40.91	0.93
Race (% Caucasian)	88.89	84.48	0.46
Age (years)	48.75 (11.8)	47.06 (13.4)	0.41
BPI Pain Severity (range = 0 – 10)	6.59 (1.8)	5.42 (2.1)	<0.001
PROMIS Physical Functioning (range = 22 – 62)	36.61 (7.6)	40.41 (7.8)	0.007
HADS Depression	8.49 (4.2)	7.05 (4.5)	0.065
HADS Anxiety	8.63 (4.9)	7.88 (4.4)	0.375

Note. BPI= Brief Pain Inventory; HADS=Hospital Anxiety and Depression Scale. Lower values on the PROMIS Physical functioning scale are t-scores and represent worse physical functioning. Chi-square tests were conducted for categorical variables and independent samples t-tests were conducted for continuous variables. Mean and standard deviation reported for continuous variables.

Table 2. Descriptive characteristics of opioid use

	N	%
Duration of current opioid use (%)		
< 90 days	18	21.95
90 days to < 1 year	23	28.05
1 year – 5 years	27	32.93
5 plus years	14	17.04
Schedule (%)		
Fixed only	25	30.49
Before pain starts only	5	6.10
After pain starts only	31	37.80
Combination of all three	21	25.61
Average duration of pain relief		
No relief	14	16.44
Less than 1 hour	18	24.66
1 to < 2 hours	9	12.33
2 to < 4 hours	10	13.70
4 to < 6 hours	14	19.18
6+ hours	10	13.70
	Mean	SD
Amount of pain relief (range 0 – 10)	4.98	2.41
Improvement in functioning (range 0 – 10)	4.41	2.88

Note. Amount of pain relief: "On a scale of 0 to 10 where zero is no relief and 10 is complete relief, what number best describes how much pain relief you get on average after taking this medication"; Improvement in functioning: "Thinking about your ability to do day to day activities, on a scale of 0 to 10 where 0 is no improvement and 10 is complete return to your normal activity level, what number best describes how much your ability to function improves after taking this medication".

Table 3. Patients' perceived effects of opioids and interest in continuing opioids

	Mean	SD	Median	IQR	Min	Max
Desire to continue taking an opioid	4.13	3.97	4	8	0	10
Confidence in managing pain without an opioid	3.52	3.57	2	5	0	10
Interest in learning alternative coping strategies	8.56	2.61	10	2	0	10
% pain improvement needed before considering stopping opioids	71.82	22.57	75	40	0	100
PODS scale (range 0 – 5)	1.01	0.70	0.72	1	0.19	2.6
DCOS Pain (range 0 – 6)	3.12	1.84	4	3	0	6
DCOS Physical Activity	2.78	1.55	3	2	0	6
DCOS Mood	2.95	1.10	3	1	0	6
DCOS Anxiety	2.80	1.10	3	1	0	6
DCOS Sleep	2.99	1.30	3	2	0	6

Note. "On a scale of 0-10 where 0 is no desire and 10 is full desire, which number best describes your want to continue taking an opioid for your current pain"; "On a scale of 0-10 where 0 is not at all confident and 10 is very confident, how confident are you in your ability to manage pain without opioids?"; "On a scale of 0-10 where 0 is no desire and 10 is full desire, which number best describes your interest in learning different ways of managing pain other than opioids? "; "What % of pain improvement would you need to experience before you would consider stopping use of your opioid medication?" PODS =The Perceived Opioids Difficulties Scale; Lower values on the PODS indicate patients have few difficulties with their opioids; DCOS= Domains of Change Opioid Scale; Higher values on the DCOS indicate that the domain has improved since the patient began taking opioids.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Pain: Basic and Clinical Aspects Poster

Session Type: ACR Poster Session B

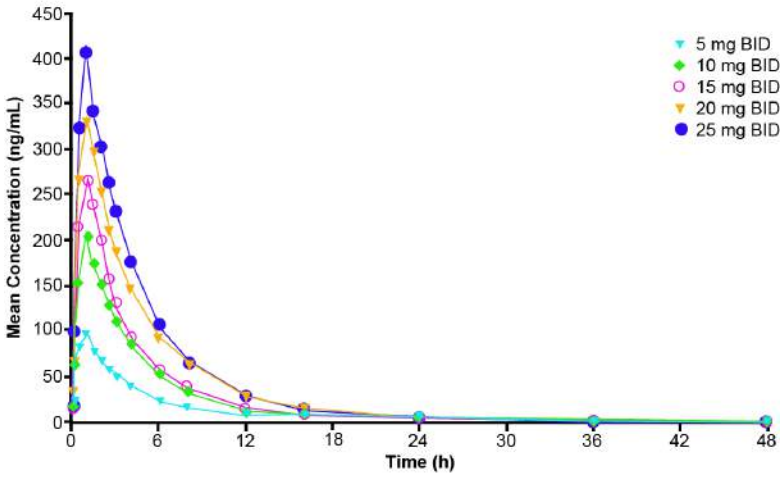
Session Time: 9:00AM-11:00AM

Background/Purpose: Mirogabalin (DS-5565) is a preferentially selective a2d-1 ligand intended for treatment of pain associated with fibromyalgia and neuropathic pain. We evaluated the safety, tolerability, pharmacokinetics (PK), and pharmacodynamics (PD) of mirogabalin after multiple doses in healthy elderly subjects to guide dose selection for further clinical development.

Methods: A randomized, double-blind, placebo- and active-controlled, multiple ascending-dose study was conducted in healthy subjects aged 55─75 years inclusive. Subjects were randomly assigned (6:2:2) to receive multiple oral doses of mirogabalin (5, 10, 15, 20, and 25 mg BID [25 mg QD followed by 25 mg BID]), pregabalin (75 mg followed by 150 mg BID), or placebo for 14 days. PK samples (blood and urine) were collected after each treatment, and PD assessments evaluated sedation, attention, dizziness, and ataxia. Safety was based on treatment-emergent adverse events (TEAEs), clinical laboratory evaluations, vital signs, suicidality, and physical examinations.

Results: In total, 48 subjects participated (6 subjects each received mirogabalin 5, 10, 15, 20, or 25 mg BID, 8 received pregabalin, and 10 received placebo). Mean mirogabalin concentrations increased with increasing doses (Figure), though exposure appeared to increase in a slightly less than proportional manner. Mean clearance and volume of distribution were comparable across all mirogabalin dose levels. Half-life of mirogabalin ranged from 3.6─7.5 h. There was no significant plasma accumulation of mirogabalin on day 14. Mirogabalin did not appear to increase sedation or decrease attention; however, subjects receiving 15, 20, or 25 mg BID reported increases in dizziness and ataxia from day 3; highest rates were in the 20 mg BID cohort. Mirogabalin 5, 10, and 15 mg BID doses were generally well tolerated, though 15 mg BID was associated with a higher incidence of dizziness/somnolence. Mirogabalin 20 and 25 mg BID doses were not well tolerated. One subject in the mirogabalin 10 mg BID group discontinued on day 8 due to a mild TEAE of elevated hepatic transaminases that subsequently resolved. Most common TEAEs after mirogabalin administration were somnolence (47%), constipation (33%), headache (27%), and dizziness (27%). Somnolence and dizziness tended to resolve within 4 days. Pregabalin PK and PD parameters were comparable to those previously reported for healthy subjects.

Figure. Mean mirogabalin concentration-time profiles after administration of mirogabalin 5 mg to 25 mg BID on study day 14.



Conclusion: Mirogabalin plasma concentrations increased with increasing doses, with no significant accumulation over 14 days of dosing. Doses up to 15 mg BID were well tolerated. Based on these data, 15 mg BID was selected as the highest target dose for clinical development. Somnolence and dizziness observed with mirogabalin were expected based on the mechanism of action but tended to resolve spontaneously, suggesting possible development of tolerance after repeated dosing.

Title: Validation of a Revised Version of the Michigan Body Map

Background/Purpose:

One of the hallmark features of fibromyalgia and other centralized pain states is widespread body pain. We developed the original Michigan Body Map (MBM) as a self-report measure to assess widespread body pain in clinical care and in epidemiological studies (Fig 1a). It is a one-sided body image with check boxes for 35 body areas and a box for "No Pain." Whereas patients preferred the original MBM to the Widespread Pain Index used to describe the body areas for the 2011 Survey Criteria for Fibromyalgia (FM), there were some issues with distinguishing left from right side body areas and some preferred the two-sided image from the Brief Pain Inventory. We developed a new body map (Fig 1b) that consists of the same 35 body areas, but is a two-sided image depicting front and back. The aim of the present study was to assess patients' understanding of and accuracy when completing the new MBM, as well as to assess preference when compared to the original MBM.

Methods:

80 patients from the University of Michigan's Physical Medicine and Rehabilitation Spine Center were included in this study. Written informed consent was obtained. Patients completed both the original MBM and the new MBM. Order of completion was counterbalanced across participants. Understanding, accuracy and preference between the two body maps were assessed.

Results:

Participants completed the original body map (34.5 sec) more quickly than the new map (44 sec) ($p = 0.003$). Compared to the original map, the new map was more frequently preferred, better allowed participants to show pain, and was easier to accurately show painful areas on left and right sides (Table 1). 12 (15%) participants incorrectly flipped left and right sides on the original MBM compared to only 4 (5%) participants on the new MBM ($p = .046$). Participants incorrectly endorsed an average of 2.5 body areas on the original body map compared to only 1.6 on the new map ($p = 0.004$). No differences were found in the calculation of the count of 19 body areas used in the 2011 survey criteria for FM in the original map (4.78 ± 3.01) compared to the new map (4.79 ± 3.3) ($p = 0.922$).

Conclusion:

Overall, participants demonstrated good understanding of the new MBM and generally preferred it to the original MBM. There were no significant differences in the FM survey scores between the old and new body maps suggesting that data from the two different versions can be combined when necessary.

Table 1. Preferences between the original and revised Michigan Body Map.

	Original MBM	New MBM	No Preference
Preference	31.25%	61.25%	7.5%
Best depicts areas of pain	25%	53.75%	21.25%
Easier to complete	46.25%	38.75%	15%
Best distinguishes left from right	32.5%	52.5%	15%

Participants preferred the revised (new) Michigan Body Map (MBM). Participants also felt the new MBM depicted areas of pain better, was easier to complete and better distinguished left from right.

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters. Juvenile Arthritis and Miscellaneous Rheumatic Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Chronic nonbacterial osteomyelitis (CNO), also known as chronic recurrent multifocal osteomyelitis (CRMO), is an autoinflammatory bone disease of unknown cause that can result in persistent bone pain, destruction and pathological fractures. Currently, no guidelines exist in managing patients with CNO. Understanding the practices of pediatric rheumatologists in diagnosing and treating CNO would provide us with important information to refine the diagnostic criteria and guide the development of consensus treatment plans. The objectives of this study were to determine (1) which disease features physicians consider important for ordering a bone biopsy, (2) physicians' approaches in monitoring disease activity and (3) physicians' treatment choices.

Methods: After IRB approval, we surveyed members of the Childhood Arthritis and Rheumatology Research Alliance (CARRA) using a web-based questionnaire regarding diagnosis and management of CNO. Data was analyzed using descriptive statistics.

Results: 135 of 369 (38%) members responded to the survey and 124 completed the survey. Thirteen chose an early survey exit point because of lack of experience in managing CNO. 84.2% of responders were pediatric rheumatology attending physicians with 50% of responders having practiced >10 years, and 13.4 % were fellows. The majority of these providers cared for 1-4 patients (70.5%) and diagnosed 0-3 new cases (90.2%) each year. Most providers felt "very or moderately" confident with diagnosing (81.8%) and treating (86.6%) patients with CNO.

Reported bone biopsy frequencies were: never 0%, rarely 11.6%, sometimes 25.6%, often 39.7%, or always 23.1%. The top three reasons for performing a biopsy were constitutional findings (84.8%), unifocal bone lesions (82.6%), and nocturnal bone pain (57.6%). The top three reasons for not performing a biopsy were involvement of typical sites such as the metaphyses of long bones and clavicles (83.5%), presence of multiple bone lesions (79.1%), and presence of conditions known to be associated with CNO, such as psoriasis and inflammatory bowel disease (63.7%). Biopsy sites were usually determined by the orthopedic surgeon or interventional radiologists (67.5%).

Among all imaging modalities, regional MRI and X rays were most commonly used. 36.5% of responders used whole body MRI often or always. 53.3% of responders used imaging regularly to monitor disease activity, 53.1% of which monitored every 6 months and 25% of which obtained imaging every 12 months.

Almost all responders (98.3) routinely prescribed NSAIDs as initial therapy. For patients who failed NSAID treatment, methotrexate (68.6%), TNF inhibitors (66.9%) and bisphosphonates (46.6%) were the next most commonly used treatments. Presence of a spinal lesion increased the use of bisphosphonate treatment.

Conclusion: The diagnostic approach and disease activity monitoring for CNO varied among physicians. NSAIDs remained the first line treatment for CNO. Methotrexate, TNF inhibitors and bisphosphonates were most commonly used after NSAIDs failed. These findings provide important background to move forward with development of consensus treatment plans for CNO.

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters. Juvenile Arthritis and Miscellaneous Rheumatic Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Abatacept (ABA) is a widely approved and used biologic in children with juvenile idiopathic arthritis (JIA). The purpose of this study was to describe the longitudinal effectiveness and safety of ABA in JIA patients (pts). **Methods:** Using a standardized protocol, clinical sites in the Pediatric Rheumatology Collaborative Study Group (PRCSG) and Paediatric Rheumatology International Trial Organization (PRINTO) enrolled JIA pts currently on or starting ABA in this longitudinal registry. Planned duration of follow-up is 10 yrs. Visits are every 3 mths for Yr 1, every 6 mths for Yrs 2–5 and annually for Yrs 6–10. After ≥4 mths on ABA, pts remain in the registry even if ABA is stopped. Data shown are those collected through March 26, 2015 (up to 2 yrs follow-up). **Results:** *Overview*. Of 146 JIA pts enrolled, 133 provided data for this analysis (6 had no data entry; 7 discontinued the study: 1 lost to follow-up, 1 withdrew consent, 3 moved to other site, 2 other). The total person-yrs of observation were 79.4: 67.9 yrs on ABA, 11.5 after ABA. In this registry, 33% (44/133) of pts were new starts on ABA and 28% (38/133) were biologic naïve; 39% had received ABA treatment for 0–1 yrs and 28% for 1–2 yrs. ABA was continued during follow-up in 85% of pts (113/133). Reasons for ABA discontinuation were inefficacy (18), surgery (1) and therapy complete (1). *Baseline*. 86% of pts were female, mean/median: age at enrollment was 13.4/13.8 yrs, disease duration was 5.9/5.4 yrs, height percentile (WHO standards for healthy children) 47.9/52.8, weight percentile 50.8/48.2 and 3.0/1.0 active joints. Baseline clinical, functional and HRQoL scores are shown in the **Table**. 15% had a history of uveitis and 4% had active uveitis. JIA subtype was systemic 3%, oligoarticular 21%, polyarticular RF– 54%, polyarticular RF+ 10%, psoriatic 5%, enthesitis-related 2%, undifferentiated 6%. 86% were taking a concomitant JIA medication (64% MTX, 49% NSAIDs, 17% systemic steroids, 5% leflunomide, 5% hydroxychloroquine, 1% cyclosporine, 1% sulfasalazine). ABA was given IV every 4 weeks in 83% and SC weekly in 17%. *Follow-up effectiveness*. Results up to 2 yrs are shown in the **Table**. *Follow-up safety*. Eleven AEs were seen (10 serious; all single occurrences) in 10 pts (8% of study population) for an AE rate of 12.6 per 100 pt-yrs of exposure (95% CI 6.9, 21.0). There were 2 infections of special interest (1 non-serious, candida esophagitis; 1 serious, methicillin-resistant *Staphylococcus aureus* wound infection). 1/133 (<1%) discontinued ABA due to a safety event (anaphylaxis). No new autoimmune diseases, deaths, malignances or tuberculosis cases were reported.

Table. Follow-up effectiveness

Endpoints	Baseline n=133	3 months n=76	6 months n=52	12 months n=49	24 months n=3
Clinical					
MD Global	1.9/1.0	1.45/1.0	1.7/1.0	1.3/0.5	1.0/1.0
CID,[1] %	33	38	31	49	50
JADAS	7.3/4.5	6.6/4.5	6.3/3.5	6.8/2.5	2.0/1.0
JADAS ID, %	32	18	10	12	2
JAMAR Functional[2]	4.0/2.0	3.6/3.0	3.8/3.0	3.7/2.5	0.5/0.5
JAMAR HRQoL	6.5/3.0	5.9/5.0	6.4/6.0	5.3/3.0	1.4/1.0

Data are mean/median unless otherwise indicated

CID=clinical inactive disease (Wallace criteria); JADAS=Juvenile Arthritis Disease Activity Score (range 0–91); JADAS ID=Juvenile Arthritis Disease Activity Score Inactive Disease (JADAS ≤1); JAMAR Functional=Juvenile Arthritis Multidimensional Assessment Report Functionality Scale Child (range 0–15); JAMAR HRQoL=Juvenile Arthritis Multidimensional Assessment Report HRQoL Scale Child (range 0–15); MD Global=MD Global Disease Activity (VAS 0–10); VAS=visual analog scale

Conclusion: In this JIA cohort, abatacept demonstrated persistent effectiveness with low MD Global, low number of active joints and over 30% of pts were in CID. Abatacept was well tolerated and no new safety signals were seen.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters. Juvenile Arthritis and Miscellaneous Rheumatic Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Prior ultrasound (US) studies in patients with juvenile idiopathic arthritis (JIA) in clinical remission have demonstrated the presence of subclinical synovitis. However, the significance of subclinical synovitis and positive power Doppler (PD) signal in these patients is still not well understood. The objectives of this study were to evaluate possible factors associated with clinical flare over a 30-month evaluation in a group of patients with JIA in remission and assess if the presence of US features could predict disease flares.

Methods: In this two years longitudinal, single-center study we performed clinical, laboratory (every 6 months) and US evaluations (initial, after 12 and 24 months) in 35 JIA patients in clinical remission according to Wallace criteria (34 joints/60 articular recesses). US parameters included synovial hypertrophy, PD signal and evidence of bone erosions. Subclinical synovitis was defined by the presence of synovial hypertrophy and/or positive PD signal. Flare was defined according to Wallace criteria.

Results: Of the 35 patients (80% female), 14 (40%) had persistent oligoarticular, 12 (34.3%) extended oligoarticular and 9 (25.7%) polyarticular JIA. Twenty patients (57.1%) were antinuclear antibodies (ANA) positive and none were rheumatoid factor (RF) positive. The mean age was 11.6 ± 3.8 years, the mean age of onset of JIA was 4.4 ± 3.2 years and the mean disease duration was 7.1 ± 3.5 years. Twenty-six (74.3%) patients were in remission on treatment and 9 (25.7%) were in remission off medication, for a median of 1.9 years. Twenty (57.1%) patients flared during the 30 months follow-up. Knees and ankles were most commonly affected. Eighteen (90%) were on treatment at the time of clinical flare. Of the 20 clinical flare patients, 7 (35%) had subclinical synovitis, 10 (50%) had synovial hypertrophy and 2 (10%) had positive PD signal at the time of flare. A Cox regression analysis found that both a positive PD signal ($p=0.046$) and the use of medications ($p <0.001$) were significantly associated with flare, and the risk of flare in patients with a positive PD signal was five times greater than in patients without a PD signal. Patients who were in remission on treatment showed a 14 times higher risk of clinical flare than patients off treatment.

Conclusion: The presence of subclinical synovitis detected by US in JIA patients in clinical remission did not predict flare of the disease. On the other hand, a positive PD signal showed a greater risk of JIA clinical flare. The remission on medication was also a risk factor for

JIA flare. Patients in remission on treatment with a positive PD signal should be cautiously tapered due to the higher risk of clinical flares.

Progressive Pseudorheumatoid Arthropathy of Childhood (PPAC) – a Single Center Case Series

Renate Haefner, Boris Huegle and Johannes Peter Haas, German Center for Pediatric and Adolescent Rheumatology, Garmisch-Partenkirchen, Germany

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters. Juvenile Arthritis and Miscellaneous Rheumatic Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Progressive pseudorheumatoid arthropathy of childhood (PPAC, OMIM #208230) is a bone dysplasia caused by mutations in the WISP3 gene. Due to its presentation with joint stiffness and finger swelling, it is frequently misdiagnosed as polyarticular juvenile idiopathic arthritis (JIA). However, PPAC has some characteristics which distinguish it from JIA; early diagnosis avoids unnecessary treatments and allows adequate therapy for an optimum long-term outcome.

The objective of this study was to retrospectively document a single center cohort of PPAC and describe presentation and clinical course of this rare disease.

Methods: The database of the German Center for Pediatric and Adolescent Rheumatology was searched to identify all patients with a diagnosis of PPAC seen between 1997 and 2015. Clinical and molecular genetic data was extracted from patient files, and results were analyzed using descriptive statistics.

Results: 8 patients were included (6 male, 2 female), including 2 sibling pairs. Median age at presentation was 8 years (range 6 - 13 years), median follow-up was 8.5 years (range 3 – 18 years). Median age of first symptoms was 3 years (range 1 – 4 years). Four patients (50 %) were diagnosed as JIA prior to diagnosis of PPAC. Mutations in the WISP3 gene were detected in 5/5 tested patients. Typical symptoms at onset were abnormal gait (7/8 patients), swelling of the interphalangeal finger joints (4/8 patients) and muscular weakness (2/8 patients). All patients developed short stature with height below the 3rd percentile and an abnormally short trunk, mainly due to vertebral dysplasia which became apparent during elementary school in most cases. Other radiographic abnormalities included overgrowth of the epiphyses (8/8 patients), widening of the heads of the basal phalanges (8/8 patients) and malformation of vertebral bodies (8/8 patients). Functional impairment progressed in all cases, with severely impaired ambulation on last follow-up. Two patients regained longer walking distances after joint replacement of the hips, one patient also received knee arthroplasty. Avascular necrosis developed in 5/8 patients, involving the femoral head, the proximal tibia and the talus bone.

Conclusion: PPAC is frequently misdiagnosed as JIA, but history, typical symptoms and radiographs of the hands and spine can help to differentiate the two disease entities. Patients uniformly develop short stature and are at risk for avascular necrosis. Joint replacements can significantly improve function.

The Effect of IL-1 Receptor Antagonist Anakinra (Kineret®) on Measures of Central

Nervous System Inflammation and Headaches in Pediatric Patients with Severe Cryopyrin-Associated Periodic Syndromes

Hans Olivecrona[1], Raphaela Goldbach-Mansky[2], Torbjörn Kullenberg[1] and **Mika Leinonen**[3], [1]Swedish Orphan Biovitrum, Stockholm, Sweden, [2]Translational Autoinflammatory Diseases Section, NIAMS, NIH, Bethesda, MD, [3]4Pharma AB, Stockholm, Sweden

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters. Juvenile Arthritis and Miscellaneous Rheumatic Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Cryopyrin-Associated Periodic Syndromes (CAPS) include a group of rare inherited autoinflammatory diseases consisting of Familial Cold Autoinflammatory Syndrome (FCAS), Muckle-Wells Syndrome and the most severe form, Neonatal-Onset Multisystem Inflammatory Disease (NOMID). Data on the effect of anakinra on measures of central nervous system (CNS) inflammation and headaches have been reported in a broad range of severe CAPS patients, showing that headaches and cerebrospinal fluid (CSF) leukocytosis improved dramatically during anakinra treatment[1,2]. The objective of this analysis is to evaluate the effect of anakinra on CNS inflammation and headache scores in CAPS children initiating anakinra treatment at an early age compared with adolescents/adults.

Methods: A prospective, open-label, long-term study of anakinra treatment in a total of 43 patients with severe CAPS was conducted at the National Institutes of Health[1,2]. The patients were treated with anakinra for up to 5 years. CNS inflammation was evaluated with CSF white blood cell (WBC) count and magnetic resonance imaging (MRI) was used to characterize different CNS lesions (presence of leptomeningeal enhancement). Headaches were assessed daily with diaries and scored on a scale from 0 (no symptoms) to 4 (severe symptoms). The patients were classified as children (age <12 years) or adolescents/adults (age ≥12 years) based on age at anakinra treatment start, including subgroup analysis in infants/toddlers (age <2 years at treatment start). The changes from baseline in children versus adolescents/adults were compared using Mixed Model for Repeated Measures. References: [1]Goldbach-Mansky R, et al. NEJM. 2006;355:581-592.[2]Sibley CH, et al. Arthritis Rheum. 2012;64:2375-2386.

Results: Children (N=22) and adolescents/adults (N=8) presented with comparable symptoms at baseline, as assessed by CSF WBC count and presence of leptomeningeal enhancement as well as headache scores. For CSF WBC count and leptomeningeal enhancement, both children and adolescents/adults showed significant decreases from baseline and had comparable low values throughout the treatment period. The average (standard error) headache scores at baseline were 0.8 (0.2) for children and 1.1 (0.4) for adolescents/adults. Following the initiation of anakinra treatment, the headache scores decreased significantly. The decrease among children (average score of 0.1 or lower for up to Month 60) was larger than in adolescents/adults (average score of 0.3 to 0.6 at different visits); p=0.026. Among the 4 infants/toddlers, the headaches were present in 2 patients at baseline and decreased or disappeared during the treatment.

Conclusion: Both children and adolescents/adults presented with comparable CNS inflammation measures and headache scores at baseline. All measures improved after initiation of anakinra treatment and the headache scores decreased even more in children compared with adolescents/adults. The headaches decreased or disappeared in infants/toddlers with symptoms at baseline. These data further suggest that every effort should be made for early diagnosis and treatment initiation to preserve normal organ function in children with CAPS.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters. Juvenile Arthritis and Miscellaneous Rheumatic Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The incidence of *Clostridium difficile* infection (CDI) has increased among children, and CDI is associated with significant morbidity and mortality. Cases of *C. difficile* infection-associated reactive arthritis (CDIAREA) in children have been described, but the epidemiology of this complication is poorly understood.

Methods: We performed a descriptive cohort and nested case-control study of CDIAREA in individuals aged 2-20 years using the electronic medical record of two large pediatric care networks from 2004-2013. Cases of CDIAREA were defined as presence of acute arthritis and/or tenosynovitis between ²4 weeks before and ³12 weeks after confirmed, symptomatic CDI with 1) no other apparent cause for arthritis and 2) negative synovial cultures (if obtained). Each case was compared to up to 4 controls with CDI without arthritis/tenosynovitis, randomly selected at the time of CDIAREA diagnosis ±3 months, using conditional logistic regression. Incidence of CDIAREA was calculated based on cases and unaffected children seen as an outpatient in the respective care network within the last 2 years. Attack rate was calculated as cases of CDIAREA per total number of CDIs during the same time period.

Results: We identified 26 cases of CDIAREA during the study period, with an incidence of 5.0 cases per million person-years (95% CI 3.0, 7.8) and an attack rate of 6.4 cases per 1000 CDIs (95% CI 3.6, 10.5). Among cases of CDIAREA, the acute onset of joint symptoms began a median of 11 days (IQR 7, 15) after gastrointestinal symptom onset. CDIAREA typically involved multiple joints (median 5, IQR 3, 8) in migratory fashion (77%), most commonly the hip and knee (Figure). About half of children with CDIAREA had fever (58%) or rash (54%). Among those with CDIAREA, 5 (19%) were treated for a presumed septic hip arthritis even though all had negative synovial cultures. All cases with CDIAREA and presumed septic hip arthritis had post-antibiotic diarrhea and/or other joints affected before surgical drainage. Not including those with hospital-onset CDI, cases with CDIAREA were more commonly treated in the emergency room and/or hospitalized (P=0.02), despite having fewer comorbidities and more community-onset CDI (Table). Treating providers made a diagnosis of CDIAREA in only 36% of cases (95% CI 18%, 57%).

Conclusion: CDIAREA is an acute, under-recognized, potentially morbid reactive arthritis associated with *C. difficile* infection that is often confused with septic arthritis. Better recognition of CDIAREA in children is needed.

Figure. Joint involvement for children with *C. difficile* infection-associated reactive arthritis.

Session Time: 9:00AM-11:00AM

Background/Purpose: To describe the evolution of neurologic symptoms and neuroradiologic findings in patients with ECDS and PRS.

Methods: The medical records database at St. Louis Children's Hospital was searched to identify patients diagnosed with "linear scleroderma" who had been evaluated by Rheumatology, Dermatology or Neurology between 1999 and 2015. Each chart was initially reviewed to identify children who had been diagnosed with ECDS or PRS. The resulting charts were then reviewed to characterize skin manifestations, identify associated neurologic symptoms and evaluate for neuroradiologic abnormalities.

Results:

15 patients with ECDS or PRS were identified. Mean age of cutaneous lesion onset was 7.5 years (0-16 years). 14 patients had brain MRI performed, with serial brain MRI available in 7 patients (50%) over an average of 3 years (1-4 years). Of the 14 patients, 6 had abnormal MRI findings which were ipsilateral to the cutaneous lesion in 5 patients. The most common findings were T2/FLAIR white matter hyperintensities (83%). Brain lesions remained stable in 4 patients (80%), while 1 patient had progression in the setting of non-compliance with mycophenolate mofetil, which restabilized with compliance. All patients with abnormal imaging had neurologic symptoms, including migraines (67%), developmental delay (50%), seizures (33%) and facial palsy (17%).

Conclusion: Unilateral and commonly ipsilateral T2/FLAIR white matter hyperintensities were the most common neuroradiologic abnormalities identified. Lesions remained stable or improved over time with treatment. All patients with abnormal imaging had neurologic symptoms. Our results emphasize that patients with ECDS or PRS would benefit from serial neuroimaging, neurocognitive testing and ongoing neurologic follow-up.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters. Juvenile Arthritis and Miscellaneous Rheumatic Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Immune mediated and pauciimmune pulmonary capillaritis are rare causes of diffuse alveolar hemorrhage and associated childhood diffuse lung disease. As such ideal therapies and prognosis are unknown. The purpose was to review the clinical presentation and outcome in children with pulmonary capillaritis through a single institution review.

Methods: Retrospective review of children with biopsy proven pulmonary capillaritis at our institution between 1995-2015 was performed with case ascertainment through the pathology database and clinical billing queries. A modified Fan Survival-of-Illness score was calculated to measure risk of severe morbidity or death (Calculation measured 0-6; >3 indicates increased risk for severe

morbidity/death from disease).

Results: Of 74 biopsies reviewed, 7 cases of alveolar hemorrhage with capillaritis were identified. Median hematocrit at presentation was 21.7; interquartile range (IQR) of 16.3 and 31.9. Five subjects presented with respiratory symptoms; the other two presented with pallor and/or lethargy. Median age at presentation was 5.2 years (IQR 2.3, 8.2) while median age at follow up was 7.8 years (IQR 4.7,13). The median time between presentation and diagnosis was 0.08 years (0.08, 0.33). The Fan score decreased over the course of treatment in only two subjects. Five of the patients had bilateral opacities detected on chest roenterogram. Five of 6 subjects evaluated by chest computed tomography had ground glass opacities. Only 2 subjects had autoantibodies, leading to diagnoses of microscopic polyangiitis and antiphospholipid antibody syndrome. Five subjects were diagnosed with pauciimmune pulmonary capillaritis. All subjects received systemic steroids. Those with the most severe Fan scores (>3) received escalated therapy regardless of autoantibodies. Two subjects have had multiple relapses requiring hospitalization. Morbidities included restrictive lung disease, cataracts, pulmonary hypertension, sleep disturbance and exercise intolerance. At 0.5-5.8 years of follow up, transplant free survival was 100%.

Conclusion: Unlike other vasculitides, pulmonary capillaritis affected prepubescent males disproportionately. Patients presenting with more severe disease despite absence of disease-associated autoantibodies received escalated therapies including plasmapheresis with improvement. Normal hematocrit at presentation did not preclude the diagnosis of pulmonary capillaritis. Morbidity was moderate with risk of relapse in a subset of patients. Mortality risk appears favorable.

Table 1. Clinical characteristics of patients at diagnosis

Subject	Sex	Age at Diagnosis (years)	Hematocrit %	Bilateral opacities on CXR*	Ground glass opacities on Chest CT*	Autoantibodies	Other significant biopsy findings
1	M	3.4	15.3	Yes	Yes		Deficient growth, lymphoid hyperplasia
2	M	2.3	13.2	Yes	Yes		Pulmonary arteriopathy, deficient growth
3	M	1.9	21.7	Yes	ND*		Pulmonary arteriopathy, deficient growth
4	M	5.2	32.0	Yes	Yes		Lymphoid hyperplasia, remodeling
6	F	6.6	17.3	Yes	Yes		None
8	F	15.8	31.7	No	No	ANCA, ASO, MPO, PR3*	Pulmonary arteriopathy
9	M	10.4	34.9	No	Yes	Cardiolipin, B2 glycoprotein, Lupus anticoagulant	Arterial thrombi
Median		5.2	21.7

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters. Juvenile Arthritis and Miscellaneous Rheumatic Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To estimate the incidence of periodic fever syndromes in the Canadian paediatric population, to describe the patterns of presentation, and to raise awareness in the medical community.

Methods: This study was initiated through the Canadian Paediatric Surveillance Program (CPSP), and was carried out over a three year period ending in September 2014. The case definition included patients less than 18 years of age presenting with a newly diagnosed periodic fever syndrome (PFS). Conditions under surveillance included Familial Mediterranean fever (FMF), Tumor necrosis factor receptor-associated periodic syndrome (TRAPS), Hyperimmunoglobulin D syndrome (HIDS), cryopyrin-associated periodic syndromes (CAPS), Periodic fever, aphthous stomatitis, pharyngitis, and adenitis (PFAPA), and Undefined periodic fever syndromes. The study protocol outlined established clinical and/or genetic criteria for diagnosis. Participating pediatricians and pediatric subspecialists across the country were sent monthly reporting forms. Detailed questionnaires were completed by physicians who report a recent diagnosis. Submissions were screened for accuracy and confirmed cases then entered into a database.

Results: Between September 2011 and August 2014 a total of 221 cases of PFS were reported. Detailed questionnaires were completed on 192 (87%), from which 13 were excluded. Of the 179 confirmed cases, 84 (47%) were PFAPA, 72 (40%) were undefined PFS, 17 (10%) were FMF, and the remaining 6 cases were CAPS, TRAPS, and HIDS. The mean age at diagnosis was 5.5 years (range 12 months - 16 years). On average symptom onset occurred 2.5 years before diagnosis (range 1-4 years). The majority of reporting physicians were rheumatologists (58%), and paediatricians (36%). Cases were identified in all provinces across Canada with the majority (103, 58%) from Ontario. For the 72 undefined PFS cases the reporting physicians described 36% as PFAPA-like, 10% FMF-like, 5% HIDS-like, 4% CAPS-like, and 1% TRAPS-like. Such cases had features of the specified PFS but either did not meet the full criteria, or confirmatory tests were not available at the time of reporting. Among all cases reported in the study, 58% had genetic testing completed as part of their diagnosis. The majority of cases without any genetic testing had been diagnosed as PFAPA.

Conclusion: Periodic fever syndromes represent rare forms of autoinflammatory disease, which affect many Canadian children. This CPSP study identified that the most common PFS diagnosed was PFAPA followed by undefined PFS and FMF. CAPS, HIDS, and TRAPS were rarely diagnosed. Children with PFS were seen by multiple physicians over an average of two to three years before a diagnosis was made. It is hoped that increased awareness of these rare conditions will facilitate earlier diagnosis and the initiation of effective treatments for these children.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters. Juvenile Arthritis and Miscellaneous Rheumatic Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Familial Mediterranean fever (FMF) is an autosomal recessively inherited autoinflammatory disease which is clinically manifested with periodic episodes of fever, polyserositis and arthritis. The severity of the disease depends mostly on the MEFV gene mutation variations. The objective of this study is to reveal a single center follow-up experience of a wide amount of childhood FMF patients from different regions around Turkey in terms of the demographic and clinical features, the genetic diversity and treatment response.

Methods: 708 children diagnosed with FMF and under treatment of colchicine for at least 6 months that are seen out patiently in our Pediatric Rheumatology Clinic between November 2014 and March 2015 were reviewed retrospectively with the data based on the patient records and also taken from the parents.

Results:

708 patients consisting 362 males and 246 females that are diagnosed with FMF were included in the study. The mean age of the patients by the time of the study was found to be 12,3±4,4 years, while the mean age at the onset of the disease was 4,8±3,4 years and at diagnosis was 7,3±3,8 years. The consanguinity rate was resulted to be %29,2 and positive family history was detected in 370 (52,3%) patients.

In 634 (89,5%) of patients, episodes of abdominal pain for at least 6 hours due to peritonitis; in 629, (88.8%) periods of fever for at least 12 hours and in 122(17,2%), chest pain probably due to pleuritis was found. 213 (30,1%) patients experienced erysipelas like erythema and 288 (40,7%) were diagnosed with findings of arthritis that last for at least a day. In 467 (66%) cases exertional leg pain and in 29(4,1%) myalgia are among the complaints and enthesitis was reported in 26(3,7%) patients. Pericarditis was developed only in 2(0,3%) patients. The mean duration of the attack was found to be 64,8±38,5 hours. In 38(53,4%) patients with appendectomy was performed due to unresolved episodes of abdominal pain.

The patients were investigated about the MEFV gene mutations and M694V homozygote mutation was found in 154(21,8%) and M694V heterozygote in 141 (19,8%) children. All the other mutations in exon 10 region (M680I, V726A, M694I) in a compound heterozygous manner with M694V mutation were detected to be in 90 (12,7%) cases and the rate of patients that is a carrier of only one copy of exon 10 region mutations other than M694V was 13%. The rest of the mutations (in exon 2,3,5 regions) were revealed in 45 (6,4%) children. In 45 (6,4%) of patients none of the so far known main mutations were shown.

Amyloidosis had been developed only in two cases both of whom were suffering from the disease process for at least 10 years and showing defective compliance to the colchicine treatment. One of them was a 20 years old M694V homozygote mutation carrier and the other was happened to be compound heterozygous with M694V/M680I mutations.

Conclusion:

The diagnosis of childhood FMF is frequently encountered in our country. The most severe clinical presentation occurs as a result of M694V and other exon 10 region mutations. With the absolute compliance to treatment; the episodes disappear and amyloidosis, the most dreadful complication of the disease, can be prevented.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters. Juvenile Arthritis and Miscellaneous Rheumatic Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: : Juvenile spondyloarthropathies (JSpA) are a group of chronic childhood rheumatic diseases which emerge especially before 16 and after 6 years-old. While enthesitis and oligoarthritis are the major signs of the early period, axial skeletal involvement and sacroiliitis are the late period signs. Although the diagnosis of the spondyloarthropathy is easy in adults, it is quite difficult in children. The aim of the study to determine clinical and demographical features of the JSpA cases that is followed-up in our department, and to evaluate treatment modalities and long term complications of disease together with the side effects of the drugs.

Methods: 107 children (21 female, 86 male) that admitted to our clinic with the diagnosis of JSpA between January 2005-December 2014 were involved in our study. Enthesitis related arthritis and Juvenile Ankylosing Spondylitis were included under the topic of JSpA. Clinical and laboratory variables were obtained from patient records.

Results: While the mean age of the disease onset and diagnosis were 11,4±3 years (range 3 -17 years) and 12,4±2,8 years (range 5-18 years) respectively, the mean duration of follow-up period was 2,7±2,5 years (range 2 months-12 years). Lower extremity arthritis (n=83, 77,6%), hip pain (n=63, 58,9%) and inflammatory low back pain (n=47, 43,9%) were the major clinical findings. The most seen involvement of the lower extremity was ankle joint arthritis (n=60, 72,3%) followed by enthesitis (n=76, 71%) and tarsitis (n=30, 28%). Axial skeletal involvement was noted in 57% (n=61) of patients and mean inflammatory low back pain duration was 8,3±6,9 months (range 1-24 months). Magnetic resonance imaging could be studied in 77 patients (72%) that imaging results of 52 children (48,6 %) were consistent with sacroiliitis. Lumbar movement limitation in Schober's test was seen in 42 cases (39.3%). Family history of spondylitis in 29 children (27.1%) and familial Mediterranean fever (FMF) in 4 cases. Furthermore, 5 patients diagnosed as FMF and treated with colchicine. None of the family history were consistent with inflammatory bowel disease. Uveitis was seen in 11 children (10.3). HLA-B27 was positive in 73.8 % (n=79) of the patients. First line therapies were methotrexate in 51 patients (47.5%) and sulphasalazine in 40 cases (37.4%). Anti-TNF alpha agents were used in 51 patients (47,7%) that were resistant to first line therapy. In the last medical visits we evaluated the patients in the terms of treatment modalities; 60.7% (n=65) of cases were noted as using drugs and in remission, 12.1% (n=13) gave up drugs and in remission, 16.8% (n=18) as minimally active and 6,5% (n=7) as active.

Conclusion: Initial signs of JSpA are usually lower extremity arthritis and enthesitis in children that is quite different from adults. JSpA should be strongly suspected in the case of a boy that is older than 6 years-old with lower extremity arthritis and the family history of spondyloarthropathy. Afterwards, axial skeletal evaluation must be investigated immediately and in order to prevent this complication true and efficient therapy must be started. FMF should be kept in mind in the differential diagnosis of JSpA in our country.

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters. Juvenile Arthritis and Miscellaneous Rheumatic

Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Macrophage activations syndrome (MAS) is a potentially life-threatening complication of systemic juvenile idiopathic arthritis (sJIA). It is common view that sJIA associated MAS bears a close clinical resemblance to the group of hemophagocytic lymphohistiocytosis (HLH), including familial HLH (FHL). This has led to suggest the use of the HLH-2004 guidelines to diagnose MAS in sJIA. However, MAS develops in the context of an underlying highly inflammatory condition, whereas FHL is a primary disorder with genetic basis. It is thus conceivable that some differences exist in the clinical expression and severity of the two conditions. However, their clinical picture has previously been compared only in small studies. The aim of our study was to compare the demographic, clinical, laboratory and histopathologic features of sJIA-associated MAS and FHL.

Methods : Data on sJIA associated MAS were collected by both pediatric rheumatologists and pediatric hemato-oncologists in a large multinational collaborative effort. Data on FHL patients were gathered from the HLH-94 and HLH-2004 trials. Clinical and laboratory features at disease onset were compared between by means of Mann-Whitney U test or chi-square/Fisher exact test, as appropriate.

Results : A total of 620 patients were enrolled: 362 (58.4%) sJIA-associated MAS and 258 (41.6%) FHL. The main differences in demographic, clinical, laboratory and histopathologic features between the two patient groups are presented in Table 1.

	sJIA-associated MAS (n = 362)	FHL (n = 258)	p value
Median age, yr	8.1	0.3	<.0001
Female, n (%)	208 (57.5)	128 (49.6)	0.05
Fever, n (%)	341/355 (96.1)	236/257 (91.8)	0.03
Lymphadenopathy, n (%)	178/346 (51.4)	28/110 (25.5)	<.0001
Hepatomegaly, n (%)	245/ 350 (70.0)	234/254 (92.1)	<.0001
Splenomegaly, n (%)	201/347 (57.9)	142/248 (96.2)	<.0001
CNS involvement, n (%)	122/349 (35.0)	89/253 (35.2)	0.96
Jaundice, n (%)	49/351 (14.0)	35/99 (35.4)	<.0001
Median laboratory values at onset			
Hemoglobin, g/dl	9.8	7.3	<.0001
Neutrophil count, x 10^3/l	5.4	0.6	<.0001
Platelet count, x 10^9/l	144	29	<.0001
Aspartate aminotransferase, U/l	134	171	0.01
Lactate dehydrogenase (LDH), U/l	1,203	696	<.0001
Triglycerides, mg/dl	234	325	<.0001
Fibrinogen, mg/dl	267	98	<.0001
Ferritin, ng/ml	5,352	2,919	0.003
Patients with hemophagocytosis	159/252 (63.1)	178/236 (75.4)	0.003

Conclusion : Although MAS and FHL showed similar clinical features and laboratory abnormalities, the frequency of most clinical manifestations and the severity and trend of laboratory changes were different. FHL patients had greater frequency of hepatosplenomegaly and more profound cytopenia, hypofibrinogenemia and hypertransaminasemia, whereas MAS patients had higher levels of ferritin and LDH. The prevalence of CNS disease was comparable between the two groups. Hemophagocytosis was detected more commonly in FHL. The observed differences suggest the use of different diagnostic criteria for the two conditions.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters. Juvenile Arthritis and Miscellaneous Rheumatic Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Early recognition and treatment of Macrophage Activating Syndrome (MAS) can improve outcome. Various diagnostic criteria are available to optimize the diagnosis if suspected by the treating physicians. However, low index of suspicion and the non-specific nature of the criteria can present a barrier to prompt and early recognition. This study utilizes an established MAS dataset in a cohort of systemic juvenile idiopathic arthritis (sJIA) patients to determine organ based predictors of MAS by admitting physicians for early recognition.

Methods:

The data from international multicenter cohort of MAS (Minoia et. al. Arthritis Rheumatol. 2014; 66:3160-9) was used. Retrospective data was collected from 95 investigators in 33 countries, including 362 patients with sJIA with MAS, 404 patients with active sJIA without MAS, and 345 patients with systemic infection. The dataset included demographics, clinical, laboratory, and histopathological variables. Data describing dysfunction in heart, lung, and kidney function; elevations in serum ferritin and triglyceride (TG) levels were defined as > 3,000 ng/dL, and 250 mg/dL, respectively. Other organ dysfunctions were defined as below:

- Coagulopathy: fibrinogen level <100 mg/dL, platelet count <40,000 /mm^3, d-dimers >2-times the upper normal value.
- Hepatobiliary dysfunction (HBD): liver enzyme elevation at least 3-times the upper normal value or bilirubin > 5.8 mg/dL.
- Hematological dysfunction: counts below normal limits, or 50% reduction in hemoglobin or leukocytes.

Univariate and multivariate statistical analyses were performed to identify correlates of MAS, and entered into a logistic regression model to assess independent predictors of MAS.

Results:

A total of 1,111 patients were included. Despite the statistically significant association in Univariate analysis, logistic regression did not identify a meaningful association with kidney, lung, or cardiovascular system (CVS) dysfunction (Table-1). Six independent parameters strongly correlates with MAS includes: central nervous system dysfunction (CNS), HBD dysfunction, coagulopathy, hematologic dysfunction, elevated ferritin and TG. Presence of 2 out of these 6 parameters was considered suggestive of MAS and 3 out of these 6 parameters was found to be confirmatory.

Conclusion:

MAS is associated with dysfunctional reticuloendothelial clearance, manifesting as CNS, hematologic, hepatobiliary, and coagulation dysfunction, with high levels of ferritin and TG. Presence of MAS should be suspected when at least 2 of the 6 parameters are noted, which should prompt further investigation and early identification.

Table 1: Univariate and multivariate analyses show CNS dysfunction, HBD, coagulopathy, hematologic dysfunction, ferritin and TG as strongest independent parameters in predicting MAS.

	MAS (n=362) N(%)	Non-MAS (n=744) N(%)	Odds Ratio (95% CI)	P Value
Kidney	54 (15.3)	22 (2.95)	5.9 (3.5-9.9)	**<0.0001**

Session Date: Monday, November 9, 2015

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters. Juvenile Arthritis and Miscellaneous Rheumatic Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Macrophage Activation Syndrome (MAS) is a life-threatening systemic inflammatory syndrome that complicates several rheumatic diseases. Current MAS-related serum biomarkers (ferritin, neopterin, CD163, and CD25) mark active disease but normalize with quiescence and may lack specificity. Serum IL-18 elevation has been associated with many inflammatory and infectious diseases, but extremely high levels have been reported in Still's Disease and Systemic Juvenile Idiopathic Arthritis, particularly in patients with a history of MAS.

Methods: We measured serum levels of several cytokines across a complex cohort of patients with idiopathic or genetically-defined autoinflammatory diseases (NCT00059748). Samples were obtained from healthy adults (24 patients) and children (4), and patients with cryopyrinopathies (Neonatal Onset Multisystem Inflammatory Disease/NOMID (18) and Muckle-Wells Syndrome (1)), NLRC4-MAS (2), Non-infectious Osteomyelitis (3), Deficiency of IL-1 Receptor Antagonist (3), CANDLE (Chronic Atypical Neutrophilic Dermatosis with Lipodystrophy and Elevated Temperature (3), SAVI (STING-Associated Vasculopathy with onset in Infancy (2), XIAP-deficiency (2) and undifferentiated (11). Cytokines were measured by Bio-Plex Luminex technology, except IL-37 (adipogene) and IL-18BP (R&D systems).

Results: We examined 142 samples from 27 controls and 49 patients. Of these patients, 13 had a clinical history of one to 4 episodes of MAS (as determined by the investigators based on the criteria established by *Ravelli et al.*, J. Pediatr. 2005). Serum levels for total active IL-18, IL-18 binding protein (BP), and IL37 in healthy controls were 29-308, 3648-7889, and 40-505 pg/mL, respectively. Median serum IL-18 was 8773 (Interquartile Range (IQR) 1560-13581) pg/mL in patients with a history of MAS, and 176 (IQR 88-432) pg/mL in those without ($p<0.0001$, Mann-Whitney-U-test). Serum IL-18 levels did not correlate with disease activity or treatment, but stratified patients into normal, elevated (~10x normal), or extremely elevated (~100x normal) groups, with 12 of 13 MAS patients in the highest group. Levels of IL-18BP and IL-37, anti-inflammatory cytokines known to inhibit the bioactivity of IL-18 did not correlate with total IL-18. Interestingly, a patient with clinical NOMID but no *NLRP3* mutation developed recurrent MAS and was our only cryopyrinopathy patient with chronically highly elevated IL-18 levels.

Conclusion: Extraordinary serum IL-18 elevation, even during quiescence, is associated with a clinical history of MAS. The utility of this

biomarker in predicting MAS risk needs to be tested prospectively in patients at risk for developing MAS.

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters. Juvenile Arthritis and Miscellaneous Rheumatic Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Childhood uveitis can lead to poor visual outcomes. Our data from single center studies suggests that non-Hispanic African American children (NHB) with non-inflammatory uveitis have increased ocular complications, and that African American race is a predictor of vision loss and blindness. Our aim is to characterize the epidemiology and clinical course of non-Hispanic White (NHW) and NHB children with idiopathic uveitis in the CARRA Registry.

Methods: There were 65 NHW and 11 NHB children with idiopathic uveitis enrolled in the CARRA Registry. Demographic and uveitis-related data were collected from time of diagnosis to enrollment. We compared clinical characteristics of NHB and NHW children using 2 sample t-tests and chi-square tests. Logistic regression was used to model risk factors for vision loss.

Results: The 11 (14.5%) NHB children had a mean age of uveitis onset of 8.4 ± 3.0 years, 6 (55%) were female, and 3 (30%) were ANA positive (Table 1). Uveitis was primarily anterior in location (73%) and bilateral (82%). Ocular complications were common (64%): cataracts (36%), increased intraocular pressure (27%), posterior synechiae (27%) and keratic precipitates (27%). Uncorrected abnormal or blind vision was reported in the right eye in 86%, and in 71% in the left eye.

Comparing NHW and NHB children (Table 1), there were no significant differences in gender, smoking exposure, ANA positivity, age of uveitis onset, location of uveitis, laterality, or presence and type of ocular complications. There were also no differences in insurance status, age at first rheumatology visit, or time to first rheumatology visit from disease onset. Medication use was similar except for increased use of oral methotrexate in NHW (p=0.003). There was a trend towards increased vision loss or blindness in NHB children overall, but this was only statistically significant in the right eye for uncorrected vision (85.7% vs. 36.4%, p = 0.034). This may be secondary to our sample size or to one eye being most affected. On logistic regression analysis, NHB race was a significant predictor of vision loss in the right eye (OR = 10.5, (95% CI 1.16-95.11). This was not significant in the left eye (OR = 3.61, (95% CI 0.63 – 20.71).

Conclusion: In the CARRA registry, 14% of children with idiopathic uveitis were NHB. The odds of developing vision loss were 10.5 times greater in NHB children compared to NHW. Although the numbers of NHB children in this registry are small, these results support our previous findings of racial differences in the visual outcomes of children with uveitis. This highlights the need for further exploration of the impact of race in a racially diverse cohort.

Association of Vitamin D Receptor Polymorphism with Juvenile Idiopathic Arthritis (JIA)

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters. Juvenile Arthritis and Miscellaneous Rheumatic Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: JIA is the most common chronic arthritis of childhood. Vitamin D is a potential immuno-modulator in many conditions, including autoimmune diseases. Its influence in JIA is still unclear. Specific polymorphisms of vitamin D receptor gene (*VDR*) have recently been associated with different biologic responses to vitamin D itself.

Methods: 90 Italian children, adolescents and young adults with poli- or oligoarticular onset of JIA were studied. *VDR* polymorphisms were analysed by PCR-based sequencing (*CDX2* in the promoter region) and PCR-based enzymatic digestions (*FokI* in exon 2, *BsmI* and *ApaI* in intron 8, and *TaqI* in exon 9) in the genomic DNA from blood of patients. 2221 healthy Italian unrelated individuals have been used as controls for *VDR* polymorphism frequencies. Distribution of *VDR* polymorphisms has been evaluated in patients *vs* controls, in patients with active and inactive disease, and in patients with poli- or oligoarticular JIA.

Results: The distribution of *FokI*, *BsmI*, and *TaqI* polymorphisms did not show any significant difference between subjects with JIA and controls. Conversely, significant statistical differences in the distribution of *CDX2* and *ApaI* genotypes were found, respectively with the *CDX2* GG genotype (Yates-corrected chi-square 6.56; Odds ratio=1.80; p=0.0104) and the TT *ApaI* genotype (Yates-corrected chi-square 20.97; Odds ratio=2.67; p=0.0000), both more frequent in JIA than in controls. Also the G allele of *CDX2* (Yates-corrected chi-square 6.12; Odds ratio=1.60; p=0.0134) and the T allele of *ApaI* (Yates-corrected chi-square 19.69; Odds ratio=2.05; p=0.0000) was more frequent in JIA. No statistical differences were found for all the analysed *VDR* polymorphisms, between the poliarticular *vs* oligoarticular forms. No significant association was found between *VDR* polymorphisms and active or inactive forms of JIA, neither with osteopenic or normal bone mineral density status.

Conclusion: Pathogenetic mechanisms influencing the predisposition to JIA are poorly elucidated and autoimmune dysfunctions are strongly suspected. This genetic study found a significantly higher frequency of the GG genotype of *VDR CDX2* polymorphism and TT genotype of *VDR ApaI* polymorphism in patients with JIA. The *CDX2*polymorphism is located in the promoter region of the *VDR* gene and has been associated with *VDR* mRNA expression, while the ApaI polymorphism has been associated with the stability of *VDR* mRNA. Therefore, we can speculate that *CDX2* GG genotype and *ApaI* TT genotype can both influence the expression of the VDR protein, presumably resulting in a reduced receptor activity with subsequent decreased response to vitamin D and potential immunity deregulation, favouring the development of JIA. Conversely, *VDR* polymorphisms seem not to have any influence for patients' active or non-active status, both for the oligoarticular and poliarticular form of the disease.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters. Juvenile Arthritis and Miscellaneous Rheumatic Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic juvenile idiopathic arthritis (sJIA) is an autoinflammatory disease accompanied by systemic symptoms including lymphadenopathy, serositis, and hepatosplenomegaly. Recently, we encountered a patient previously diagnosed with sJIA three years ago who developed hematochezia and weight loss with endocscopy findings consistent with indeterminate colitis, a form of inflammatory bowel disease (IBD). This association is scantly known with only one case report detected in the literature search.

Methods: We distributed a survey to all members of the Childhood Arthritis and Rheumatology Research Alliance (CARRA) and the Pediatric Rheumatology Bulletin Board asking physicians to report their cases of patients with both sJIA and IBD. Demographic, clinical, laboratory, and therapeutic information were collected on identified patients to gain further insight into this possible association. The data was analyzed, using descriptive statistics, specifically, means, median, and ranges for continuous variables and frequencies and proportions for categorical variables.

Results: Our survey identified 14 patients with diagnoses of sJIA and IBD. 13 of the patients were first diagnosed with sJIA. Five patients were from the United States, 7 from Europe, and 2 from South America. The average age at sJIA diagnosis was 9.9 years (range 6-14.5 years). Nine patients had a persistent sJIA course; 4 patients had a monocyclic course and 1 patient had a polycyclic course. Prior to their IBD diagnosis, the majority of patients were treated with corticosteroids (79%), NSAIDs (79%), and methotrexate (71%) for sJIA. Seven patients received TNF-α inhibitor (etanercept in 5/7). 7 patients received anti-IL-1 therapy, and 4 patients received an IL-6 inhibitor. The average age of the patients at IBD diagnosis was 12.3 years (range 9-17 years). During the 3 months prior to the IBD diagnosis, 6 patients were in remission, 6 were in an active flare, one had not yet received the sJIA diagnosis, and one answer was missing from the survey. Ten patients were diagnosed with Crohn's disease and 4 with indeterminate colitis. 11/14 patients received a TNF-α inhibitor for IBD, with 10/11 demonstrating a full response to this class of medications. Other medications used in treatment include corticosteroids (57%), methotrexate (36%), azathioprine (43%), oral antibiotics (29%), and enteral formula therapy (36%). After both diagnoses were made in this cohort, 4 patients had quiescence of both sJIA and IBD diseases, 6 experienced an IBD flare with quiescent sJIA disease, 3 patients had a sJIA flare with quiet IBD, and one patient had a flare of both diseases.

Conclusion: IBD morbidity is rare in patients with sJIA. It is most commonly manifest as Crohn's disease with persistent sJIA. Its appearance and flares do not typically correlate with sJIA activity, and the majority of these patients respond to monotherapy with a monoclonal TNF-α inhibitor. The therapeutic implications, however, are notable, given that many children with sJIA with systemic features do not respond to TNF inhibition. The biology underlying the association of these two diseases and their response to therapy is not clear and warrants further study.

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters. Juvenile Arthritis and Miscellaneous Rheumatic Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Farber disease (Farber lipogranulomatosis; acid ceramidase deficiency) is a rare lysosomal storage disorder resulting from the inherited deficiency of the enzyme acid ceramidase due to mutations in the ASAH1 gene. Inheritance is autosomal recessive. The enzyme deficiency leads to accumulation of the potent pro-inflammatory and pro-apoptotic lipid substrate, ceramide. This, in turn, induces macrophage-driven inflammation in tissues, including synovitis and lipogranuloma formation. The phenotype generally includes joint swelling, contractures and pain. Farber patients do not usually have organomegaly and none have coarse facial features. The clinical similarity of the moderate Farber phenotypes to polyarticular juvenile idiopathic arthritis (JIA) can lead to misdiagnosis. Differential diagnosis can be made by accounting for progressive symmetric arthritis, presence of subcutaneous nodules, and an unusual, hoarse voice (due to nodule formation on the larynx) in Farber disease patients.

Methods: A cohort of 19 Farber disease patients who have not undergone hematopoietic stem cell transplantation (HSCT) provides insight into the phenotypic spectrum of the disease, as well as the clinical history, diagnostic evaluations, symptomatic treatments and their effects. Retrospectively, whenever possible, the presenting symptoms, clinical history, biochemical, and genetic diagnostic evaluations were recorded. Treatment modalities and response to treatment were registered.

Results: Patients in the cohort vary in age from 5 months to 25 years of age. Phenotypes range from infantile onset with systemic inflammation, to late childhood onset and very mild disease. All patients demonstrated the three typical symptoms of Farber disease (arthritis, subcutaneous nodules, dysphonia). However, in several cases years passed between the appearance of the individual symptoms. Treatment varied from biologics (incl. anti-TNFa and anti-IL-6), joint injections with corticosteroids, DMARDs, NSAIDs, intensive pain relief, to no chronic treatment at all.

Conclusion: This study represents the largest collection of clinical data on Farber disease to date. It is clear that the spectrum of phenotypes includes mild presentations not previously associated with Farber, and that in most cases a pediatric rheumatologist is involved in patient care. The fact that 19 patients can be referenced and potentially followed prospectively (30 patients including those

who have undergone HSCT) implies that the disease is not as rare as earlier supposed. These results also suggest that acid ceramidase deficiency may likely account for a larger number of polyarticular JIA patients than previously thought, with mild disease even possibly diagnosed in adulthood. Therapy with biologics may improve some symptoms, but will not resolve them completely. This shows that lack of adequate response to biologics can also contribute to the indication for Farber testing. It is therefore important to increase awareness of Farber disease among rheumatologists. Clinical screening studies and a natural history study are planned for the near future. Enzyme replacement therapy for Farber is currently under development.

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters. Juvenile Arthritis and Miscellaneous Rheumatic Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Raised levels of Rheumatoid Factor (RhF) and antibodies to citrullinated proteins (ACPA), detected in the clinic using combinations of cyclic citrullinated peptides (CCP), are persistently demonstrated in adult Rheumatoid Arthritis (RA) serology. Multiple isotypes of both autoantibodies can be detected months or years prior to the onset of clinical manifestations. IgG-ACPAs are generally accepted as having greater diagnostic specificity than IgM-RhF, which are present in ~10% of the healthy population. IgG-ACPAs have also been detected in sera of patients with Juvenile Idiopathic Arthritis (JIA); in particular those with IgM-RhF+ve polyarticular JIA (poly-JIA), a subset often considered comparable to adult RA. The prevalence and predictive value of ACPA of IgG, IgM and IgA isotype has been extensively studied in adults with RA, but not, to our knowledge, in a juvenile population. This study profiles a large adolescent JIA cohort using CCP as substrate, with the aim to establish a distinct ACPA phenotype for RhF+ve poly-JIA patients, when compared to other JIA subtypes.

Methods:

Levels of anti-CCP antibodies from a total of 95 patients with poly-JIA (RhF–ve; n=67 and RhF+ve; n=24) were compared with age-matched disease controls (Enthesitis-Related Arthritis (ERA) n=29; Extended-Oligoarthritis (EOA) n= 38) and 31 age-matched healthy controls (HCs). Sera were tested for IgG, IgA and IgM isotypes of anti-CCP, using commercial ELISA plates, coated with second generation citrullinated peptides (CCP2). Cut-offs for positivity were defined by manufacturer's instructions for IgG-CCP (5U/ml). The median age of the poly-JIA patients was 17.4 yrs (IQ range 15.9 to 19.0), with a median disease duration of 8.6 years. RhF status of the poly-JIA cohort was determined from the clinical records. Statistical analysis determined by Mann-Whitney U test.

Results:

In the poly-JIA cohort 87.5% (21/24) of IgM-RhF +ve patients were IgG-CCP+ve, compared with only 6.0% (4/67) of IgM-RhF-ve patients. Furthermore, when compared to control groups, only 2.6% of EOA patients (1/38) and none of the ERA (0/29) or HCs (0/31) were IgG-CCP positive. When results for IgM-RhF+ve/IgG-CCP+ve (n=21) poly-JIA patients were compared with those of the seronegative poly- JIA cohort (IgM-RhF -ve/IgG-CCP–ve; n=67) levels of IgA-CCP (6.47 (IQ range 4.43-15.74) vs 2.95 (IQ range 2.48-4.37);p<0.0001) and IgM-CCP (69.03 (IQ range 38.03-180.5) vs 40.52 (IQ range 27.0-66.88);p=0.0223) were significantly higher in the seropositive (IgM-RhF+ve/IgG-CCP+ve) group.

Conclusion:

This is the first study to our knowledge that profiles autoantibodies against CCP in a large adolescent JIA patient cohort. Results suggested a significantly higher proportion of poly-JIA patients who are IgM-RhF +ve being IgG-CCP positive when compared to those who were IgM-RhF–ve. Additionally, patients who are IgM-RhF+ve/IgG-CCP+ve had significantly higher levels of both IgA-CCP and IgM-CCP antibodies when compared to patients who were IgM-RhF–ve/IgG-CCP–ve. This data suggests that the serological profile of IgM-RF +ve poly-JIA patients mirrors that described in seropositive adult patients with RA.

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters. Juvenile Arthritis and Miscellaneous Rheumatic Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Assessment of Left Ventricle Functions in Children with Familial Mediterranean Fever with Tissue Doppler and Strain Echocardiography

Background/Purpose: The effects of Familial Mediterranean Fever (FMF) on cardiac functions are generally without typical symptoms. Global strain is a sensitive and relatively more objective indicator of early myocardial deformation due to various conditions. We aimed to evaluate cardiac functions in children with FMF using tissue Doppler and strain echocardiography methods.

Methods: This is a cross sectional study in 37 children with FMF with a mean follow up of 4 years (range: 1-13 years) and 29 healthy children. We performed tissue Doppler and strain echocardiography in addition to standard echocardiography in all of the subjects. We did longitudinal strain measurements using apical 2, 3, and 4 chamber views.

Results: Gender ratio and mean age were similar between the groups (Table 1). Left ventricular ejection fraction, similar between the patients and controls. Global strain (GS) was significantly worse in patients with FMF compared to controls. None of the patients or controls had an abnormal GS (>-15). The rate of borderline GS was more common in the FMF group. There was also a borderline significant difference between E'/A' ratio which was lower in patients with FMF. GS was significantly lower in males compared with females (-18.8±2.2 vs. -21±2, p<0.001). Mean ages of the male and female subjects were similar (12.5±4.1 vs. 13.5±3.2, respectively, p=0.3)

Global strain was significantly correlated with disease duration (r=0.33, p=0.046) in patients with FMF and with E/A ratio in the whole

group (r=0.34, p=0.005). There was also an inverse correlation between GS and ejection fraction (EF) in the whole group (r=-0.39, p=0.001). Linear regression analysis revealed independent correlates of GS (r^2 of the model 0.44) as FMF group (B=1.8 95%CI 0.83-2.7, p<0.001), ejection fraction (B=-0.08, 95%CI [-0.1]-[-0.04], p<0.001), and gender (B=1.4 95%CI 0.5-2.4, p=0.005). In patients with FMF, disease duration (B=0.2, 95%CI 0.03-0.4, p=0.023) and EF (B=-0.13, 95%CI [-0.2]-[-0.02], p=0.026) seemed to be independently associated with GS while there was no significant gender association.

Conclusion: Global strain was significantly worse in patients with FMF with no established cardiac problems. Male gender and a lower EF seemed to be other independent determinants of a worse GS. In patients with FMF, longer disease duration is another factor associated with a worse GS. These are our preliminary findings and this study is going on. No strict conclusions can be done because of the currently limited sample size.

Table 1. Comparison of the study groups

	FMF (37)	Controls (29)	P
Current age (years)	12.3 ± 4.1	13.1 ± 1.9	0.99
Gender (%female)	56.8	79.3	0.054
GS	-19.5 ± 2	-21.3 ± 2.3	**0.001**
Borderline GS (%)	43.2	13.8	**0.015**
Global EF	68.8±5.864.7±15.6	64.7±15.6	0.15

Musculoskeletal Anomalies in Children with Trisomy 21

charlene foley[1], Orla G killeen[1] and emma Jane macDermott[2], [1]Our Lady's Children's Hospital Crumlin, National Centre for Paediatric Rheumatology, Dublin, Ireland, [2]our Lady's Children's Hospital Crumlin, National Centre for Paediatric Rheumatology, Dublin, Ireland
First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters. Juvenile Arthritis and Miscellaneous Rheumatic Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Musculoskeletal complications of Trisomy 21 (T21) are common. Almost all children with T21 have muscle hypotonia and joint laxity. The combination of this ligamentous laxity and low muscle tone contribute to an increased risk of a number of musculoskeletal disorders, a delay in acquisition of motor milestones and lower levels of physical activity. Inappropriately low expectations of physical activity and motor function from family, health care workers and self, and over-attributing motor difficulties to low tone and hypermobility may lead to missed pathology and misdiagnoses.

Objective(s)

1. To describe the musculoskeletal anomalies observed in a national cohort of children with T21
2. To calculate the average age children with T21 walked unaided in our cohort

Methods: Over an 18-month period, children with T21 were invited to attend for a musculoskeletal assessment by a paediatric doctor. Relevant musculoskeletal history and clinical findings were documented.

Results: 503 children with T21 were examined (56% male). Median age 8.1 years (0.6-19.2 years). ***Musculoskeletal Anomalies and Trisomy 21***. Pes Planus was the most common musculoskeletal anomaly detected, occurring in 91.1% of the children with T21 examined. Just under a quarter of these children did not avail of orthoses (23.6%). A range of other anomalies were observed, inflammatory arthritis (7.1%) and scoliosis (4.8%) occurring most frequently after pes planus. Other spinal abnormalities included the well-documented T21 associated c-spine instability, absent C2 vertebra and spondylolisthesis. Common hip and foot pathologies included dislocations, Perthes disease, slipped upper femoral epiphysis (SUFE) and hallux valgus. ***Ambulation and Trisomy 21***. The median age our cohort walked was 28 months (12-84 months). This is comparable to the literature that reports children with T21 walk at 23 months (range 13-48), compared with 12 months (range 9-17) for the general paediatric population.

Conclusion: Children with T21 are at increased risk of a number of potentially debilitating musculoskeletal problems. These conditions can present in a variety of ways, with differing symptoms and signs. Pes planus is common therefore early consideration of orthotics and life-long appropriate supportive footwear is advised. Significantly delayed ambulation is noted in children with T21. Early multi-disciplinary intervention is important to ensure these children obtain their full potential with regards to acquisition of walking unaided. Compulsory annual musculoskeletal assessment for all children with T21 would enable early detection of potential problems, allowing for timely intervention and in-turn better clinical outcomes.

Assessment of Transition Readiness in Adolescents and Young Adults with Chronic Health Conditions

Paul Jensen[1,2], Gabrielle Paul[3], Stephanie LaCount[4], Brendan Boyle[5], Manmohan K. Kamboj[6] and Stacy P. Ardoin[7], [1]Rheumatology, Nationwide Children's Hospital, Columbus, OH, [2]Medicine, Ohio State University Medical Center, Columbus, OH, [3]College of Medicine, Ohio State University, Columbus, OH, [4]Pediatrics, Nationwide Children's Hospital, Columbus, OH, [5]Gastroenterology, Nationwide Children's Hospital, Columbus, OH, [6]Endocrinology, Nationwide Children's Hospital, Columbus, OH, [7]Pediatric & Adult Rheumatology, Ohio State University, Columbus, OH

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters. Juvenile Arthritis and Miscellaneous Rheumatic Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

The transition from pediatric to adult care is a vulnerable period associated with increased morbidity and mortality. Guidelines call for assessing patients' transition readiness to help individualize plans. Several measurement tools have been created, but none have been prospectively evaluated. The Transition Readiness Assessment Questionnaire (TRAQ) was developed to measure transition readiness with regards to self-management (Domain 1) and self-advocacy (Domain 2). Our aim was to evaluate the TRAQ's validity by assessing whether baseline score influenced successful transition over a 3 year period. We previously reported baseline demographic information and TRAQ scores. Here we report the transition outcomes after three years of follow up.

Methods:

89 adolescents and young adults with chronic diseases at a single pediatric center were enrolled. Participants completed a baseline survey which included demographic information, transition experience, and a TRAQ questionnaire. Study personnel conducted telephone interviews every six months for three years to determine participant health status and time at which they transitioned. Attendance at adult

subspecialty provider visit was confirmed by the adult providers. Successful transition was defined as attending at least one adult provider visit.

Results:

The 89 participants were mostly female, Caucasian, and non-Hispanic and had rheumatic (56%), gastrointestinal, (21%) or endocrine (22%) conditions. Each unit increase in TRAQ Domain 1 score increased the odds of successful transition by 1.28 (p=0.32) and each unit increase in Domain 2 score increased the odds by 1.67 (p=0.14). Of other variables measured (age, disease duration, gender, race, insurance status), only baseline age significantly predicted transition (p=0.028).

Conclusion:

This is the first study, to our knowledge, which prospectively measures the effectiveness of a transition assessment tool over a prolonged period of time. While increased baseline TRAQ scores were associated with increased odds of transition, the finding did not reach statistical significance. Additionally, disease duration, race, gender, and insurance status failed to predict transition. Although not statistically significant, the TRAQ domain 2 score predicted transition better than the domain 1 score which suggests that training in self-advocacy may help prepare the emerging adult for transition. Further research is necessary to determine optimal measurement of transition readiness in adolescents and young adults with chronic diseases.

Table 1 . Baseline TRAQ Scores

Health Related Quality of Life Is Reduced in Pediatric Patients with Juvenile Idiopathic Arthritis and Juvenile-Onset Fibromyalgia

Michal Feldon[1], Catherine Donnelly[2], Hermine I. Brunner[3], Anne Louis Johnson[1], Lukasz Itert[4], Lisa G Rider[5] and Edward H. Giannini[3], [1]Pediatric Rheumatology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Internal Medicine, University of Cincinnati, Cincinnati, OH, [3]Rheumatology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [4]Division of Pediatric Rheumatology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [5]Environmental Autoimmunity Group, NIEHS, NIH, Bethesda, MD
First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters. Juvenile Arthritis and Miscellaneous Rheumatic Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose : A number of validated measures are now available for the evaluation of health related quality of life (HRQOL) in children with rheumatic diseases, but most are lengthy and not feasible for use in a clinical setting.

The objective of this study was to document the degree of HRQOL impairment in juvenile idiopathic arthritis (JIA) and juvenile-onset fibromyalgia (JFM) patients using the SF-10v2® questionnaire.

Methods : Patients ages 5-18 years with a diagnosis of JIA or JFM were recruited during routine clinic visits in Cincinnati Children's Hospital Medical Center (CCHMC) over 6 months. Demographic data as well as disease severity scores, including the physician's global, parental overall wellbeing and pain scores, were recorded from the patients' medical records. HRQOL was ascertained via the SF-10v2® Health Survey questionnaire. The SF-10v2® is a 10-item caregiver-completed, generic measure of children's functional health and wellbeing over the preceding 4 weeks; the SF10v2® features 2 summary measures - the physical summary score [PHS] and the psychosocial summary score [PSS].

This was an exploratory, cross-sectional descriptive study that examined the variation in HRQOL scores in relation to different patient and disease characteristics, and compared the scores of JIA and JFM patients to U.S age-and-gender-matched healthy and physically ill children.

Results : 133 JIA and 9 JFM patients were included in the analysis. For JIA patients, mean age at study entry and the mean duration of disease were 11.5 and 4.1 years, respectively; 63% were female and 90% were Caucasian. All JFM patients were Caucasian females with a mean age and mean duration of disease of 12.2 and 1 years, respectively.

Both summary scores of the SF-10v2® were lower among JFM patients compared to JIA patients and to the age-and-gender-matched healthy and physically ill populations. In contrast, the PHS only was lower for JIA patients compared with the healthy and physically ill populations (Table 1).

Among the different JIA categories, PHS scores for enthesitis-related arthritis (ERA) patients were lower than those for polyarticular RF (-) JIA patients (31.72 vs. 45.31 p=0.018). For the JIA patients, PHS scores were lower with active disease, abnormal parental scores and reported pain. Age, gender, race, disease duration and additional autoimmune disease were not associated with reduced scores (Table 2).

Conclusion : HRQOL was lower among JIA and JFM patients compared to healthy and physically ill children. Active disease and reported pain were the most important predictors of reduced HRQOL among JIA patients.

Table 1: One-way ANOVA of HRQOL summary scores of JIA and JFM patients relative to age-and-gender-matched healthy and other physically ill U.S. children

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters. Juvenile Arthritis and Miscellaneous Rheumatic Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Juvenile idiopathic arthritis (JIA) associated uveitis is one of the most severe comorbidities of JIA and occurs in around 10% of JIA patients. There are currently no specific established outcome measures for this specific uveitis. The Standardization of Uveitis Nomenclature (SUN) group made the first attempt to establish outcome measures for uveitis, which were not aimed at JIA associated Uveitis. Adopting part of it, we developed and proposed specific outcome measures for JIA associated Uveitis over a consensus process specific for JIA associated uveitis. Here we are presenting the results of the validation study.

Methods:

Patients were considered eligible, if they started a nonbiologic or biologic disease modifying agent , as indicated by active the uveitis. At baseline, follow up at 3 months and at 6 months following parameters were collected: demographics, rheumatologic assessment (JIA type, activity of arthritis, JIA-related disability), ophthalmologic assessment (duration of uveitis, activity and damage of uveitis,visual acuity, ocular complications, topical and systemic medications, surgical procedure, uveitis-related disability).

Results:

Sixtynine patients were included in the study and up till now 38 patients had a complete follow-up for 6 months. 50/69 (72.5%) of the patients were female. The mean age at inclusion into the study was 8.0 years (range 3-18 years). 98% of the patients were Caucasian. The JIA subset distribution was 56.3% oligoarticular, 14.1% extended oligoarticular, 18.8 % RF negative polyarticular and 4.7% enthesitis related. At inclusion the median disease duration of JIA was 55 months for arthritis and 32.5 months for uveitis. All patients had anterior uveitis. The left eye was more frequently involved (90.3%) then the right eye (83.6 %). Cellcount at baseline was +0.5 or more in 68.3 % of the right eyes and 62.3% of the left eyes, and at 6 months only 30.6% the left eyes. The cell count before dilatation ($p=0.005$) and after dilatation ($p<0.001$) improved significantly over time. Flare was ≥ 0.5+ (graded by SUN) at baseline in the right eyes in 76.7% and in the left eyes 70.2% and at 6 months at the right eyes in 21.2% and the left eyes in 23.5%. The flare grade according SUN ($p<0.001$) improved significantly comparing time point zero to 6 months. The flare grad according MIWGUC;flare >0.5 in 82.4% at time point 0 and after 6 months 35.3%, improved singifiacnatly to ($p=0.021$). The VAS score (0-100) for uveitis related disability decreased from 43.2 to 18.8 ($p=0.001$) and JIA associated disability, decreased from 33.3 to 8.0 ($p< 0.001$). The assessed complication of uveitis decreased from

86.7% to 61.9% after 6 months follow up (p=0.102).

Conclusion:

These results regarding the standardized assessment of the JIA associated uveitis are promising. The newly suggested Uveitis disability score showes significant correlation with cell count and flare grade after 6 months. Further evaluation of these items and the other suggested items will help to establish standardized measures to assess the activity of uveitis and the effecacy of a drug in treatment trials. The assessment of the newly published JIA associated Uveitis QOL is planned.

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters. Juvenile Arthritis and Miscellaneous Rheumatic Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: We aim to determine the extent to which pain severity differs between patients with JPFS and other rheumatic diseases and if the degree of association between pain and functioning is unique to JPFS.

Methods: We evaluated demographics, pain, functional measures (ACR functional class, current and worst, childhood (C) HAQ, health-related quality of life (HRQoL)) and health status scores from the baseline visits of patients in the CARRA Registry from 5/2010 – 6/2014. CHAQ assesses activities of daily living; 0 (no disability) to 3 (high disability). ACR functional class is a 4-point scale indicating patient's ability to do usual self-care. HRQoL is a 5-point scale ("excellent" to "very poor"). Subjective well-being is a 0-10 scale assessing how well patient is doing considering their disease. General linear models with Dunnett's post-hoc tests compared JPFS to other diseases on pain and function and Fisher's r-to-z transformation compared disease groups on the correlation between pain and function.

Results: 9523 patients from infancy to 33 years (M = 12.1, SD = 4.83) (Table 1). Pain ratings were 1.8±2.6 (Vasculitis) to 6.4±2.4 (JPFS), with pain being significantly higher in the JPFS group (score 6.4/10) than any other group (effect sizes = .22 to 1.05). Ratings on disability measures were significantly worse for JPFS patients (effect sizes = .62 to 1.06) regardless of physician-rated disease severity (Fig. 1). However, the *relationship* between pain severity and function/disability was in most cases significantly greater for rheumatic disease patients relative to JPFS and was highest among dermatomyositis, JIA, and MCTD patients (Fig. 2).

Conclusion: JPFS is unique with regard to the perceived severity of pain and disability, yet pain appears to be comparably or more highly associated with disability in other rheumatic diseases. Given the association of pain severity with functional ability across most rheumatic diseases, regardless of disease severity, pain needs further research and increased prioritization in treatment.

Table 1. Demographic data for JPFS and disease cohorts

Variable	JPFS Cohort (*n* = 180)	Rheumatic Disease Cohort (*n* = 9343)

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters. Juvenile Arthritis and Miscellaneous Rheumatic Diseases
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: The impact of juvenile idiopathic arthritis (JIA) is not confined to joint involvement in children but rather widespread effects extending to adulthood. This study evaluated outcomes of patients with JIA compared to matched controls.

Methods: Population based cohorts of all residents of a geographically defined area who first met ILAR criteria for JIA in 1994-2013 and age- and sex-matched non-JIA comparator subjects were identified. Outcomes during childhood utilized all patients and outcomes during adulthood were evaluated in 38 pairs, with follow-up beyond age 18. Employment and educational status based on patient report were obtained via medical record review. Occurrences of hospitalizations and surgeries (both joint and non-joint related) were abstracted. Pregnancies and comorbidities including depression and malignancy based on physician diagnosis were collected and evaluated.

Hazard ratios (HR) with 95% confidence intervals (CI) adjusted for age, sex, and calendar year of incidence/index date were obtained from Cox models to evaluate differences in first occurrence of joint surgery, non-joint surgery, and hospitalization. Poisson methods were used to obtain rate ratios (RR) with 95% CI to compare rates of outcomes.

Results: Eighty-nine patients with JIA were identified with 89 non-JIA comparators. Each group had 57 (64%) females. The mean (standard deviation [SD]) age at diagnosis was 8.6 (5.1) years. The length of follow-up after age 18 in patients with JIA 8.0 (5.5) years and non-JIA 8.9 (5.7) was similar.

There was no difference in educational achievement; 25 (66%) versus 22 (58%) in patients with JIA versus not, respectively, had some education beyond high school (p=0.48). Similarly, there was no difference in employment status with only 3 (8%) in each group who were unemployed or disabled (p=1.0).

It was more common for patients with JIA to have a joint surgery as compared to non-JIA both as children and adults, RR 3.93 (1.18, 24.94) and 8.50 (2.27, 120.1). It is more likely for patients with JIA compared to non-JIA to have non-joint surgery as a child RR 1.90 (1.05, 3.67) and perhaps as adults, RR 1.92 (0.89, 4.57). Similarly, hospitalization rates were higher during childhood, RR 2.25 (1.04, 5.53), and somewhat during adulthood, RR 1.79 (0.69, 5.25), when comparing patients with JIA versus non-JIA.

There was an increased risk of developing depression during childhood following JIA diagnosis/index date with HR 2.49 (1.01, 6.13). However, in those who were not diagnosed with depression as children, there was no difference in depression during adulthood, HR 0.48 (0.10, 2.26).

No patients developed a malignancy over the course of follow-up.

There was no difference in the rates of pregnancies between JIA and non-JIA women, RR 0.68 (0.38, 1.20).

Conclusion: In a modern population based cohort of patients with JIA compared to non-JIA subjects, there were higher rates of joint surgery both as children and adults, non-joint surgery as children, and hospitalizations as children. The risk of depression during childhood was higher in JIA than non-JIA. There were no differences in educational or employment outcomes.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters. Juvenile Arthritis and Miscellaneous Rheumatic Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The association of HLA-B27 with spondyloarthritis is well-established. Under the International League of Associations for Rheumatology (ILAR) criteria most children with spondyloarthritis are classified as enthesitis-related arthritis (ERA). It is unknown if the clinical features vary between children with ERA who are HLA-B27 positive (pos) versus HLA-B27 negative (neg). Therefore, we aimed to test whether ERA manifests differently in these serologically distinct populations.

Methods: We performed a retrospective multicenter cohort study that included subjects from 5 pediatric rheumatology centers who were diagnosed with ERA from 1989-2012. Baseline visit for patients was defined as the first rheumatology appointment at which the patient exhibited enthesitis, arthritis or acute, symptomatic uveitis. To be included in the study, patients had to have a documented HLA-B27 test result and had to fulfill the ILAR criteria for ERA within the first 6 months from baseline visit. Patient data collected included the following: demographics, clinical features, patient reported outcomes, and medications prescribed both at the time of diagnosis of ERA and over the following 12 months. Differences in clinical and demographic characteristics by HLA-B27 status were assessed using the Mann-Whitney or chi-squared test, as appropriate.

Results: Data was collected from 301 children and a total of 296 were included in the study. Patients were predominantly male (69%) and Caucasian (83%). Median age at diagnosis was 12 years (IQR: 10-14) and 53% were HLA-B27 pos. HLA-B27 positivity was associated with male gender ($p<0.01$) and older age at diagnosis ($p=0.03$). Symptom duration at time of diagnosis was shorter in the HLA-B27 neg group with a median of 6 versus 7 months, respectively ($p=0.04$). Table 1 shows the ILAR criteria, clinical features and patient reported outcomes at the time of diagnosis as well as the incidence of arthritis and enthesitis throughout the duration of the study, and compared between HLA-B27 pos and neg groups. Not only did a greater proportion of HLA-B27 neg patients have enthesitis at diagnosis (78% vs. 59%; $p<0.01$), but these children also had greater tender entheses counts at diagnosis ($p<0.01$) and a greater number of affected entheses during the first year after diagnosis ($p<0.01$). Sacroiliac tenderness and uveitis were not associated with HLA-B27 status. Disease activity scores and patient reported outcomes were not significantly different between the two groups.

Conclusion: In this retrospective cohort, the clinical phenotype of children with ERA differed significantly based on HLA-B27 status. In comparison to HLA-B27 pos children, HLA-B27 neg children are younger, more likely to be female, and have more peripheral enthesitis. Future studies should address differences in response to therapy and outcomes between these 2 groups.

Table. Patient Characteristics Based on HLA-B27 Status

	All (n=296)	HLA-B27 pos (n=158)	HLA-B27 neg (n=138)	P-value*

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters. Juvenile Arthritis and Miscellaneous Rheumatic Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Information regarding incidence, prevalence, and mortality in juvenile rheumatoid arthritis is scarce, particularly since the advent of recent classification criteria for juvenile inflammatory arthritis (JIA). Estimates are based on varying populations, classification criteria, follow-up durations, and disease validation methodology.

Methods: Incident cases of juvenile arthritis were identified between January 1, 1994 and December 31, 2013 in a geographically well-defined population using individual medical record review for case validation. Cases meeting ACR criteria for juvenile rheumatoid arthritis (JRA) and ILAR criteria for juvenile idiopathic arthritis (JIA) were included. Individuals who met criteria for JRA were combined with a prior cohort of incident cases from 1960-1993.[1] Incidence and prevalence rates with 95% confidence intervals (CI) were sex- and age-adjusted to the 2010 U.S. white population. The standardized mortality ratio (SMR) with 95% CI was calculated with expected deaths based on age, sex and calendar year specific life tables for the U.S. population and displayed using Kaplan-Meier methods.

Results: Fifty-nine incident cases met JRA criteria in 1994-2013. Disease subtypes included 48 (81%) with pauciarticular disease, and 9 (15%) with polyarticular and 2 (3%) with systemic disease. These JRA patients were combined with the additional 59 patients from the previously identified 1960-1993 cohort for a total of 118 patients. There were no differences in the subtypes of JRA, age at diagnosis, sex, or time from symptoms to diagnosis comparing the 2 cohorts. The incidence of JRA in 1994-2013 was 9.5 per 100,000 (95% CI 7.1, 12.0). Prevalence of JRA on 1/1/2010 was 54.4 per 100,000 (95% CI 28.5, 80.2). There was no significant change in the incidence of JRA over the entire time period.

Utilizing JIA criteria, 71 incident cases were identified in 1994-2013. Incidence was 10.3 per 100,000 (95% CI 7.9, 12.7). Prevalence on 1/1/2010 was 57.6 per 100,000 (95% CI 31.0, 84.5). Oligoarthritis was the most common subtype accounting for 63%. Joint erosions were noted in 17% and eye involvement in 7%.

A total of 4 deaths occurred during 2180.7 person-years of follow-up in patients with JRA. No deaths have occurred in children with incident JRA in 1994-2013. None of the deaths were directly related to juvenile arthritis. The SMR was 1.50 (95% CI 0.41-3.83); the survival curve is shown in figure 1.

Conclusion: The incidence of JRA did not change significantly between 1960-2013. Incidence is higher when using the more inclusive criteria of JIA as compared to JRA. When specifically evaluating the more homogeneous group of patients who met ACR JRA criteria, there was no demonstrated increase in mortality compared to the general population.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters. Juvenile Arthritis and Miscellaneous Rheumatic Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To assess the demographic, clinical, and radiographic manifestations, health questionnaire (HQ) scores (physician global assessment, Health-related Quality of Life, parent/subject overall well-being and parent/subject pain), family history and drug regimens at enrollment and after one year follow up (F/U), in children with juvenile psoriatic arthritis (JPsA) in an international registry.

Methods: The study population included all JPsA patients in the registry between May 2010 - December 2013. We analyzed cross-sectional data at enrollment visit, stratified according to the age at disease onset (< or ≥ 6 years) and compared with information at 1 year F/U. Chi square or Fisher's exact tests were used for categorical characteristics, t-tests for continuous variables, and Mann-Whitney-U tests for non-normally distributed variables. Comparison of binary variables between enrollment and F/U was performed using McNemar Test, and Wilcoxon Signed Rank Test for continuous variables. A multivariable logistic regression model was used to assess the influence of 1 year of treatment with DMARDs, biological DMARDs, NSAIDS or glucocorticoids (GCs) on objective outcome (improvement in ≥ 5 from the following: arthritis, dactylitis, enthesitis, skin psoriasis, sacroiliitis and nail pitting), and on subjective outcome (improvement in all 4 HQ scores) adjusted for age, gender, race and ethnicity.

Results: 361 children with JPsA were entered in the registry. The majority (93.9%) were white and not Hispanic (91.7%); 68.14% had symptom onset ≥ 6 years. Comparison between data in the two age groups at disease onset is presented in Table 1. Data after 1 year F/U were available for 222 patients. Statistically significant improvements were noted in the number of patients with ≥ 5 joints involved, nail pitting, dactylitis, psoriasis, enthesitis, sacroiliitis and uveitis [(126 (61.8%) vs 21 (10.2%,), (70 (35.9%) vs 31 (15%), (60 (30.9%) vs 5 (2.4%), (137 (68.2%) vs 73 (34.8%), (57 (29.5%) vs 17 (8.1%), (35 (18.1%) vs 13 (6.2%) (27 (15.1%) vs 8 (4.3%) P<0.0001 respectively]. Improvement in objective outcome was associated with disease onset < 6 years (OR 3.69, 95% CI 1.3-10.48), female gender (OR 2.44, 95% CI 1.07-5.56) and lack of biological DMARD (bDMARDS) therapy (OR 2.73 95% CI 1.16-6.44). Improvement in subjective outcome was associated with the presence of enthesitis (OR 4.14, 95% CI 1.12-15.25).

Conclusion: JPsA onset at or after age 6 is diagnosed earlier after symptom onset, with a male predominance and higher prevalence of psoriasis, nail pitting, enthesitis, sacroiliitis and less uveitis. This group is treated more often with daily NSAIDS and MTX and less often with intraarticular GCs. Females with disease onset before age 6 and not receiving bDMARDs have a better objective outcome, while patients with enthesitis had a better subjective outcome.

Table 1: Comparison between JPsA onset before and after the age of 6

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters. Juvenile Arthritis and Miscellaneous Rheumatic Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Long-term studies have shown that many patients with juvenile idiopathic arthritis (JIA) still suffer from persistent inflammation and disability as adults. Because of the heterogeneity of JIA, there are not many clinical or laboratory parameters that could be used to clarify the prognosis of a single patient. The human leukocyte antigen HLA-B27 is known to be related to spondyloarthritides in adults. Some children with JIA have the antigen, but at least so far, it has a primary role in the classification. The aim of the study was to find out if there are major differences between HLA-B27 positive and negative children with JIA with respect to disease characteristics during 8-years' follow-up.

Methods: This study is part of a multicentre population-based cohort study in the Nordic countries based on consecutive patients with a new diagnosis of JIA according to ILAR criteria. They were enrolled 1997-2000 from a defined area of Southern Finland. Information regarding clinical data, serology, and disease activity was registered at certain intervals for 8 years.

Results: 163 of 187 children fulfilled the criteria for 8-year study. HLA-B27 was analysed in 141 patients. 20% of the children were HLA-B27 positive and 67% negative. The most common ILAR categories were enthesitis-related arthritis (41%) among the HLA-B27 positive patients and oligoarthritis (51%) among the negative, when combining the persistent and extended oligoarthritis categories together. At 8-years' time 41% of the antigen positive patients were not in remission vs. 33% of the antigen negative ones. Also the percentage of current users of biological agents was higher in the HLA-B27 positive group, 28 vs. 18%. The highest incidence of uveitis (30%) was among the HLA-B27 negative patients, who also had the maximum mean number (9) of cumulative joints. A larger proportion of HLA-B27 positive boys with older age at disease onset was found (p=0.004), which is consistent with the findings in other Nordic studies.

Conclusion: Some trends for differences were found regarding the presence of HLA-B27, including the main ILAR subgroups, rates of remission and use of biological agents. However, a statistically significant older age at disease onset was found in HLA-B27 positive boys.

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters. Juvenile Arthritis and Miscellaneous Rheumatic Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Juvenile Idiopathic Arthritis (JIA) is one of the most common rheumatic diseases in childhood, affecting at least 1 in 1000 children (1). Children with JIA, experience joint inflammation and swelling, pain and tenderness, morning stiffness, limited mobility. Also, children with JIA and their parents complain fatigue easily and sleep disturbances such as falling asleep, fragmented sleep with more nightly awakenings, and daytime sleepiness. The aim of this study to determine the prevalence of fatigue, disturbed sleep and pain in patients with JIA, at the same time to identify relationship between fatigue, pain, sleep quality and activity limitation and participation restriction.

Methods:

84 patients (51 female, 33 male) with JIA and their parents were enrolled in the study. The subjects were recruited in a pediatric rheumatology clinic. They were diagnosed with JIA by a pediatric rheumatologist based on the ILAR diagnostic criteria. Patients with recent diagnoses of JIA and those with mental deficits were excluded. PedsQL Multidimensional Fatigue Scale was used to evaluate fatigue.

Pittsburg sleep quality index (PSQI) was used to evaluate quality of sleep, daytime sleepiness. Pain was evaluated with 10 cm Visual Analog Scale (VAS). Childhood Health Assessment Questionnaire (CHAQ) was used to evaluate activity limitation and participation restriction.

Results:

Respectively, the mean age, disease duration and number of affected joint were 12.90±3.50 years, 5.70±3.76 years and 1.99±1.94. The mean of scores of CHAQ was 1.20±1.69, the mean of PSQI-daytime sleepiness was 0.76±0.81, the mean of PSQI-sleep quality was 0.89±0.74, the mean of PSQI-Total was 4.34±2.34 and the mean of scores was PedsQL-fatigue 66.21±23.27. The relationships of scores of VAS, PedsQL-fatigue, PSQI and CHAQ were demonstrated Table I.

Conclusion:

This study confirmed that patients with JIA suffer from pain, fatigue and sleep disturbances. In addition to, sleep disturbance and fatigue are strongly associated with increased pain. Due to this relationship, activity limitation and participation restriction may be observed in patients with JIA. Strategies aimed at improving sleep quality and reducing fatigue and pain should be studied as possible ways of improving participation in activities in children with JIA.

Table I. The correlations scores of VAS, CHAQ, PedsQL-fatigue, PSQI

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters. Juvenile Arthritis and Miscellaneous Rheumatic Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: During the last decade there is evidence of a rising improvement regarding the long-term outcome of patients with Juvenile Idiopathic Arthritis (JIA). The aim of the study was to compare long-term outcome between patients with disease onset before and after 2000.

Methods: Patients (pts) > 18 years with an established JIA, a disease onset >5 years and no history of > 6 months care from external rheumatologists, were enrolled in the study. Clinical, laboratory and radiographic examination were performed at the last follow-up visit, 17.2 years post-diagnosis. The outcome variables were: radiographic damage assessed by the Total modified Sharp/van der Heijde Score (TmSvdHS), articular and extra-articular damage by Juvenile Arthritis Damage Index (JADI-A and JADI-E) and physical ability by the Health Assessment Questionnaire-Disability Index (HAQ-DI). In the multivariate analysis, possible explanatory variables were characteristics present at onset and active disease duration within 5 years of onset.

Results: A total of 102 (72 F) pts were enrolled. The age at disease onset (mean ±SD) was 7.7 ±4 yrs, the interval from onset to last visit 17.2 ±6.7 yrs and the pts' current age 25 ±5.9 yrs. Twenty eight patients were diagnosed after 2000 (Group 1) and 74 patients before 2000 (Group 2). The 2 Groups didn't differ in demographic and clinical characteristics, as gender, type of disease onset and ACPA positivity. At the last follow-up visit, Group 1 had better TmSvdHS, better JADI-A and better JADI-E score as compared to Group 2 ($p<0.001$, $p<0.001$, $p=0.003$, respectively). In contrast, HAQ-DI score did not differ between the 2 Groups ($p=0.55$). Disease duration within 5 yrs of onset was longer in Group 2 ($p=0.02$). In the multivariate analysis, disease duration within 5 yrs of onset was a prognostic factor for joint damage [B (95%CI) 2.114 (0.206,4.022), $p=0.03$], cumulative % time spent in a state of active disease [B (95%CI) 0.007 (0.004,0.011), $p<0.001$] and cumulative time spent in a state of clinical remission off medication over the entire disease course [B (95%CI) -0.667 (-1.048,-0.286), $p=0.001$].

Conclusion: Patients diagnosed after 2000, had a better long term outcome as compared to those before 2000. Despite the difference in disease duration, active disease duration within 5 years of onset proved to be a critical prognostic factor, probably reflecting the availability of biologics nowadays and the treat-to-target strategies.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters. Juvenile Arthritis and Miscellaneous Rheumatic Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Juvenile idiopathic arthritis (JIA) encompasses a heterogeneous group of diseases characterized by chronic joint inflammation with presence of enthesitis as an important classification criteria. Although joint count and enthesitis are represented in the ILAR criteria, their pattern is not taken into consideration. We studied these patterns using data-driven pattern recognition techniques aiming at identifying homogeneous subgroups of children with JIA and enthesitis.

Methods: We included 116 patients from a Canadian multicenter prospective inception cohort. Inclusion criteria consisted of a diagnosis of JIA according to the ILAR criteria <3 months prior to study entry, treatment-naivety except for NSAIDs and enthesitis at baseline. Non-negative matrix factorization (NMF) was performed on baseline enthesitis and arthritis data to identify factors that describe major patterns distinguishing groups from each other. A feature of NMF is that each factor lends itself to a cluster.

Results: NMF identified 3 factors and clusters: (1) predominantly involvement of the knees, with symmetric involvement of enthesitis around the patella and tibial tuberosities and knee arthritis together with enthesitis at the base of the 5th metatarsal bone and sacroiliitis (38 patients); (2) foot/ankle and hip/pelvis involvement with enthesitis at the calcaneal insertion of the achilles tendon and the plantar fascia, arthritis of all the ankle joints and enthesitis at the pelvic bones, greater trochanter with arthritis in the hip and SI joints (43 patients); and (3) peripheral and axial polyarthritis with a non-specific pattern of enthesitis involvement (36 patients).

Conclusion: Using computer-driven analysis we detected distinct patterns of enthesitis and arthritis at presentation of disease. These will be helpful in characterizing homogeneous patient subgroups and disease trajectories and potentially identify predictors of treatment response and disease outcome.

Figure 1: Contributions of individual joints and entheses to factors. Shades of gray indicate the degrees to which individual joints and entheses (y-axis; entheses are marked with "E"s) contribute to factors (x-axis). Shades nearer black indicate stronger contributions. Traces (lines represent 0 loadings and dots indicating absolute loadings) provide an alternative means of visualizing the loadings. Arrows indicate the side of body.

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters. Juvenile Arthritis and Miscellaneous Rheumatic Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: We aimed to compare patient reported outcomes between adults with juvenile idiopathic arthritis (JIA) and adults with rheumatoid arthritis (RA) with similar disease duration and treatment era.

Methods: This cross sectional study used a random observation from JIA and RA participants in the National Data Bank for Rheumatic Diseases (NDB), a longitudinal cohort of patients that complete biannual questionnaires. Participants were included in the JIA group if they were <55 years old at enrollment and had a physician diagnosis of JIA, a self-diagnosis of JIA (with a physician diagnosis of arthritis), or a physician diagnosis of RA with symptoms prior to age 16. Each JIA patient was matched to 3 RA patients based on sex, calendar year of observation, and calendar year of diagnosis. This produced matching disease duration and treatment era while minimizing effects of comorbid conditions unrelated to arthritis. The demographics, patient reported outcomes, and disease characteristics were compared between the JIA and RA groups using Chi square or t tests. The SF-36 physical and mental component summary scores, the patient activity score (PAS), and PAS-II were compared between groups using stepwise reduced linear regression models.

Results: We identified 596 JIA patients who were matched to 1788 RA patients; 90% were female. The JIA patients had a mean (SD) age of 34.3 years (10.0) and 82% were white; the RA patients had a mean age 53.1 (7.4) and 86% were white. Patients with RA were more likely to have a history of total joint replacement, cancer, heart disease, liver disease, or cataract and have a higher rheumatic disease comorbidity index. Patients with JIA report higher pain scores, longer morning stiffness, have a higher PAS and PAS-II, and lower SF-36 MCS (Table 1). After including 18 potential confounders, JIA diagnosis was not significantly associated with the SF-36 PCS (beta 0.39, 95% CI -0.70, 1.49), MCS (beta 0.06, 95% CI -1.73, 1.86), PAS (beta -0.06, 95% CI -0.26, 0.13), or PAS-II (beta 0.09, 95% CI -0.12, 0.31). Each final model included 8-12 variables; variables with significant associations in all 4 models were the number of rheumatology visits in the prior 6 months, meeting fibromyalgia criteria, household income, having a total joint replacement in the prior 6 months, the rheumatic disease comorbidity index, and the cumulative number of biologic medications.

Conclusion: JIA patients have different disease characteristics and patient reported outcomes compared to RA patients matched on disease duration and treatment era. JIA patients had active disease in adulthood with similar number of visits to rheumatology and higher pain scores than RA patients. Comorbidities, disease severity, and fibromyalgia may explain the lower SF-36 MCS and higher PAS-II among JIA patients rather than age of diagnosis. This is the first study to compare patient reported outcomes of adult JIA patients to RA patients.

Table 1: Demographics, disease characteristics, and patient reported outcomes for JIA and matched RA patients in the NDB. Not all variables had 100% response rate. * indicates $p < 0.05$

	All JIA (n=596)	RA (n=1788)
Female (n,%)	539 (90.44%)	1617 (90.44%)
Age, years (mean, SD) *	34.30 (9.95)	53.08 (7.42)

Qualitative Assessment of Patient Important Long-Term Outcomes in Juvenile Idiopathic Arthritis

Melissa L. Mannion[1], Michelle Williams[2], Nataliya Ivankova[3], Gerald McGwin Jr.[4], Kenneth G. Saag[5] and Timothy Beukelman[6], [1]Pediatrics, University of Alabama at Birmingham, Birmingham, AL, [2]School of Public Health, University of Alabama at Birmingham, Birmingham, AL, [3]Health Services Administration, University of Alabama at Birmingham, Birmingham, AL, [4]Epidemiology, University of Alabama at Birmingham, Birmingham, AL, [5]University of Alabama at Birmingham, Birmingham, AL, [6]Pediatric Rheumatology, University of Alabama at Birmingham, Birmingham, AL

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters. Juvenile Arthritis and Miscellaneous Rheumatic Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The aim of this study was to identify and characterize the factors that JIA patients in young adulthood use to define a successful disease outcome, with the ultimate goal of creating an outcome assessment tool to provide a gold-standard for comparing different treatment approaches for JIA.

Methods: In depth personal interviews were conducted with adolescents (ages 14-18) and young adults (ages 19-40) with JIA and parents of children with JIA to generate themes regarding successful treatment, acceptable disease states, and optimal disease management outcomes for young adults with JIA. Interviews were recorded and transcribed; then they were coded using in vivo coding to generate mutually exclusive categories that were further combined into themes and quantized. The outcome topic categories were also quantized

based on the number of participants who mentioned the category. Outcome themes were compared to themes generated from interviews with pediatric rheumatologists. 4 adolescents with JIA, 6 young adults with JIA, and 10 parents of children with JIA were interviewed with representation of all US census regions. 13 pediatric rheumatologists from the US were interviewed.

Results: The initial in vivo codes were regrouped into 15 outcome topics and quantized; chronic arthritis/joint damage, physical/functional, medication, pain/fatigue, expectations, vocation/profession, social/participation, daily life/activities of daily living, health, vision, family, independence, appearance, mental health, and community. The categories with the most patient/parent codes were medication, social/participation, and community while the categories with the most physician codes were chronic arthritis/joint damage, physical/functional, and medication. The categories mentioned by all patients and parents were physical/functional, medication, social/participation, and community. The transcripts were recoded for description of outcomes resulting in 9 mutually exclusive categories; ability, active disease/remission, interference/burden, feel normal, everything that they want to do, understanding, satisfaction, indistinguishable from peers, and acceptance. The categories with the most patient/parent codes were interference/burden and indistinguishable from peers; the categories with the most physician codes were ability and interference/burden. Interference/burden was mentioned in all interviews, indistinguishable from peers was mentioned by all patients and parents and ability was mentioned by all physicians.

Conclusion: This study begins to characterize the factors that adolescents with JIA, young adults with JIA, and parents of children with JIA use to define a successful disease outcome for JIA in young adulthood. Patients prioritize medication burden and effects, social and participation impacts, and the idea of a supportive community in the definition of successful JIA management. With additional studies, the definition of a gold standard based on physician and patient input will enable patients to be better informed about their treatment options and expected future outcomes.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters. Juvenile Arthritis and Miscellaneous Rheumatic Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To assess the adiposity/BMI of children diagnosed with JPsA in a North American registry, examining differences between overweight and non-overweight patients with regard to demographic data, family history, clinical characteristics, radiological manifestations, and scores on Physician Global Assessment, Health-Related Quality of Life, parent/subject overall well-being (PSOWBS), parent/subject pain scale & the Childhood Health Assessment Questionnaire (CHAQ).

Methods: The study population included all JPsA patients in the Childhood Arthritis and Rheumatology Research Alliance (CARRA) registry for whom age, height and weight were recorded at baseline visit. We assessed adiposity according to CDC 2010 recommendations —in children < 2 years, the ratio of weight to length was plotted on WHO curves, and in children ≥ 2 years, BMI was calculated according to height, weight and age using the CDC/NCHS growth references. Children were divided into two groups: non-overweight including underweight (<2.3rd percentile for children < 2 years and calculated BMI < 5th percentile in children ≥ 2 years old) and normal weight (2.3rd - 97.7th percentile for children < 2 years and calculated BMI ≥ 5-85th percentile in children ≥ 2 years old) children and an overweight group including overweight (>97.7th percentile for children < 2 years and calculated BMI > 85th percentile in children ≥2 years old) and obese (BMI ≥ 95th percentile in children >2 years) children. Descriptive analysis of BMI subgroups was performed using

prevalence and percent for the categorical characteristics and mean ±standard deviation or median for continuous parameters. Comparisons of categorical characteristics between two independent groups (non-overweight and overweight) were done by Chi square or Fisher's exact test. Comparison of continuous parameters between BMI subgroups was performed by T-test or Mann Whitney test, as appropriate.

Results: 320 out of 361 (88.6%) children with JPsA were included in the study: 116 (36.3%) were overweight and 204 (63.8%) were non-overweight. The majority of patients were white (90.6%), non-Hispanic (91.3%) and female (64.7%). Between the two groups, children in the overweight category were significantly older at symptoms onset (9.26 ± 4.48 vs. 7.74 ±4.67 years, P=0.005). There were no significant differences between the two groups for other demographic parameters (race/ethnicity, gender, age at first rheumatology assessment), family history, number of joints involved, nail pitting, dactylitis, psoriasis, enthesitis, sacroiliitis, uveitis and radiological manifestations. In health assessment questionnaires, overweight patients scored worse on the PSOWBS (2.64 ± 2.32 vs 2.15 ± 2.15, p=0.04) and CHAQ (0.42 ± 0.52 vs 0.31 ± 0.47, p=0.05).

Conclusion: More than 1/3 of patients with JPsA from this registry were overweight and around 19% were obese. Patients who were overweight developed symptoms later and had worse patient reported outcomes as shown by PSOWBS and CHAQ scores. Not only does this JPsA subgroup feel subjectively worse, but patients with increasing adiposity/BMI also may have poorer long-term outcomes with regards to growth and health.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters. Juvenile Arthritis and Miscellaneous Rheumatic Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The chronic and complex nature of pediatric-onset rheumatic diseases (PRD) necessitates the need for effective health care transition from pediatric to adult providers. Prior studies suggest suboptimal transition and health outcomes for patients with PRD. We utilized the Childhood Arthritis and Rheumatology Research Alliance (CARRA) registry to describe a large transition aged cohort with JIA and jSLE.

Methods: Baseline, cross-sectional data were obtained from the CARRA registry, a pediatric rheumatology database contributed to by 60 pediatric rheumatology centers in North America. Patients (pts) included were diagnosed with JIA or jSLE at ≤18 years (yrs) of age. Pts ≥18 yrs of age were considered "transition aged." Data abstracted included demographics, measures of disease activity (Systemic Lupus Erythematosus Disease Activity Index (SLEDAI), Childhood Arthritis Questionnaire (CHAQ), Health Related Quality of Life (HRQOL), parent or self-report pain scores with a Likert scale: 0 = no pain,10 = very severe pain) and current and past medications at baseline visit. Descriptive statistics and tests of comparison were used to compare the variables between pts younger and older than 18 yrs with JIA and jSLE.

Results:

Data from 6572 JIA and 1014 jSLE pts were analyzed; 466 (7.1%) JIA pts and 251 (24.7%) jSLE pts were ≥18 yrs old at baseline visit (Table 1).

Transition JIA pts were more likely than younger JIA pts to have enthesitis related arthritis or rheumatoid factor positive polyarticular JIA

subtypes and had higher pain scores (3.2 vs 2.6, p=0.000). There was no difference in insurance, CHAQ, or HRQOL between transition and younger JIA pts. Among the transition JIA pts, 13% were on oral steroids, 45% were on methotrexate and 67% were on a TNF inhibitor.

Transition jSLE pts had longer disease duration and were more likely to be uninsured than younger jSLE pts (6% vs. 2.8%, p=0.03), but there was no difference in CHAQ, HRQOL and pain scores. SLEDAI scores were moderate (median of 4.0, range 0-45), and younger pts had higher SLEDAI scores than transition pts (5.1 vs. 4.3, p=0.046). As in transition JIA pts, older jSLE pts demonstrated polypharmacy with 62% taking steroids, 48% taking mycophenalate mofetil, and 30% ever prescribed intravenous cyclophosphamide.

Disease measures in transition JIA and jSLE cohorts were also compared (Table 2).

Conclusion: In this large cohort of transition aged pts with PRD, there was significant disease activity and polypharmacy. This analysis highlights the need for comprehensive transitional support for disease management, medication monitoring and follow-up care.

Table 1.

	Transition cohort (n = 717)
JIA, n (%)	466 (65)
jSLE, n (%)	251 (35)

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters. Juvenile Arthritis and Miscellaneous Rheumatic Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Joint pain is a primary symptom in Juvenile Idiopathic Arthritis (JIA). Experience of pain has been shown to be a significant predictor of impaired physical and psychosocial function. Although pain in JIA overall is a well-known feature and pain-related beliefs were significantly associated with pain in children with JIA, perception and impact of pain of the temporomandibular joint (TMJ) in patients with JIA is not well researched. Therefore a TMJ specific pain questionnaire was developed by the Clinical Recommendation group of euroTMjoint, an international network established in 2010 to enhance multidisciplinary, multicenter TMJ research in JIA. The aim of this study is to report the frequency and pattern of pain in the TMJ area and describe the impact on TMJ function.

Methods:

A specific TMJ pain questionnaire was developed based on a Delphi study and systematic review. The following items were incorporated: pain frequency; pain intensity; pain location; TMJ function; TMJ symptoms; changes in facial or TMJ pain since last visit; changes in TMJ function since last visit. All consecutive JIA patients visiting one orthodontic clinic in Aarhus, Denmark, were included.

Results:

180 patients were approached to participate in the study. All patients agreed, however 8 did not complete the questionnaire, and were therefore excluded. 172 questionnaires were included. 58% (100/172) of patients reported the presence of TMJ pain with a median VAS of 3.6 (range 0.4-8.9). Imaging of the TMJ (CBCT or MRI) was available in 112 of the 172 patients (65%); 69% in patients with TMJ pain and 60% in patients without TMJ pain. Evidence of TMJ involvement on imaging was present in 61/69 (88%) of patients with TMJ pain and in 34/43 (79%) of patients without TMJ pain. The most frequent orofacial pain location was the masseter area followed by the TMJ region (58% and 46% respectively); and in both the masseter and TMJ regions in 15% of patients.Patients with TMJ pain reported significantly more functional problems, such as difficulty chewing, than those without pain. (70% compared to 7%, $p<0.0001$).

Conclusion:

More than half of JIA patients experience orofacial pain. Most frequently this involves the masseter and TMJ region. TMJ pain seems to be more frequent in patients with TMJ pathology on imaging, however is also present when imaging is normal. Pain in the TMJ area is significantly correlated with functional TMJ problems.

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters. Juvenile Arthritis and Miscellaneous Rheumatic Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Mentoring usually targets academic advancement in medicine, but it may also foster success in non-academic aspects of professional life, such as work-life balance. The American College of Rheumatology (ACR) and the Childhood Arthritis & Rheumatology Research Alliance (CARRA) developed the ACR/CARRA Mentoring Interest Group (AMIGO) in 2011 to foster mentoring in pediatric rheumatology. We assessed pre-AMIGO measures of career satisfaction in pediatric rheumatology, including career aspirations, confidence with professional tasks, and self-reported burn-out.

Methods: Internet-based survey of US and Canadian pediatric rheumatologists in 2011, before AMIGO implementation.

Results: Respondents included 277 pediatric rheumatologists, estimated at >75% of pediatric rheumatologists in the US and Canada. Of 129 who responded to the question about their "ideal job," 81% indicated that the ideal job included doing "primarily clinical work"; 61% reported it included "mentoring in clinic"; 57% reported "research," 20% reported "mentoring in research," and 5% reported "administration." About 50% responded that they were likely to obtain their ideal job.

Of the198 who responded to questions about confidence in work-related tasks, most respondents stated they were quite/extremely confident about advocating for patients, contributing to educational programs and meeting clinical productivity goals (Table 1). Most reported being somewhat/slightly/not at all confident in accessing grant funding, working with industry, achieving work-life balance, advocating for themselves at work, and managing their practices (Table1). Of 190 who responded to questions about burn out, 31% reported burn out at work at least once a week.

Conclusion: Most pediatric rheumatologists feel confident about meeting their clinical and educational responsibilities but a significant proportion have concerns about their ability to obtain grants, work with industry, manage administrative aspects of their jobs and achieve work-life balance. Burn-out is reported by a substantial fraction. Follow up evaluations of AMIGO mentees will assess whether improved access to mentoring through AMIGO has helped to address these needs. Further exploration of reasons behind burnout and work-life balance concerns is warranted.

Table 1: Data on confidence among pediatric rheumatologists

	Not confident at all	Slightly/ somewhat confident	Quite/ extremely confident	N/A
Meet goals for clinical productivity	2 (1%)	60 (30%)	128 (63%)	9 (5%)
Advocate for patients	2 (1%)	29 (15%)	158 (80%)	9 (5%)
Contribute to educational programs	2 (1%)	66 (33%)	128 (64%)	3 (1.5%)
Keep track of teaching activities	7 (4%)	90 (43%)	96 (48%)	6 (3%)
Access grant funding	61 (31%)	86 (43%)	37 (19%)	15 (8%)
Work with industry	52 (26%)	82 (41%)	28 (14%)	37 (19%)
Manage your practice	27 (14%)	76 (38%)	60 (30%)	36 (18%)
Advocate for yourself at work	18 (9%)	105 (53%)	76 (38%)	
Achieve success in your job (as defined by the person)	7 (4%)	87 (44%)	105 (53%)	
Work-life balance	19 (10%)	111 (56%)	66 (33%)	2 (1%)

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters. Juvenile Arthritis and Miscellaneous Rheumatic Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: There are lots of effects of auto-inflammatory diseases (e.g. pain, fatigue, fear of attack, lifelong drug use, being nervous and angry, problems at school) and those are quite important to patients but have not been measured with the outcome instruments currently included in clinical trials of auto-inflammatory diseases. The aim of this study is to develop and validate a new multidimensional questionnaire for assessment of children with auto-inflammatory disease (AID) in standard clinical care.

Methods: JAIMAR includes 16 parent or patient-centered measures and four dimensions that assess functional status, pain, therapeutic compliance and health-related quality of life (physical, social, school, emotional status) with disease outcome. The JAIMAR is proposed for use as both a proxy-report and a patient self-report, with the suggested age range of 8-18 years for use as a self-report. The study was conducted both children with FMF and their parents in seven different paediatric rheumatology centers from Turkey. To validate the JAIMAR, the Outcome Measures in Rheumatology Clinical Trials (OMERACT) filter for outcome measures in rheumatology was applied.

Results: The analysis data set was collected from the parents of 250 children with FMF in 351 visits and from 179 children in 187 visits. The median age of the children was 10.64 ± 4.38. The JAIMAR was found to be feasible and to possess face, content, criterion and construct validity. Completing and scoring of the JAIMAR is quick and can be finished approximately in 15 minutes. The Cronbach's alpha coefficient for internal consistency for the JAIMAR dimensions was between 0.507-0.998. Between the test-retest scale scores, there is a significant and a positive correlation from medium level to high level (0.607-0.966). For construct validity all the factor loadings are above 0.30. When the criterion validity is considered, we would say that the correlation level between the each subscale and the related scale spanned from medium ($r = 0.329$, $p < 0.0001$) to large ($r = 0.894$, $p < 0.0001$). Parents' proxy-reported and children's self-reported data were outstandingly concordant. Cronbach's alpha values were between 0.770-0.989.

Conclusion: The development of the JAIMAR introduces a new and a multi-dimensional approach in pediatric rheumatology practice. It is a valid tool for children with autoinflammatory disease and will help enhance the quality of care of in this group of patients.

Session Date: Monday, November 9, 2015

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects Posters. Juvenile Arthritis and Miscellaneous Rheumatic Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Camptodactyly-arthropathy-coxa-vara-pericarditis (CACP) syndrome is an autosomal recessive disorder caused by mutations in PRG4 gene that encodes for proteoglycan 4, the main lubricant for joints and tendon surfaces. It is non-inflammatory arthropathy, characterized by joint effusions and synovial hypertrophy. So far, there is no effective treatment for this disorder. We evaluated the effectiveness of yttrium-90 radiosynovectomy in arthropathy of patients with CACP syndrome

Methods:

Consecutive patients with CACP syndrome prospectively evaluated at the enrollment and 3 months after the right knee injection with yttrium-90. The outcome variables were patient/ parent and physician's global assessment measured by a 3-point scale, right knee swelling and range of motion on a 3-point scale, in addition to *Magnetic Resonance Imaging*(MRI) assessment of the right knee for bone, cartilage, fluid, synovial hypertrophy and soft tissue changes.

Results:

Six (3 boys, 3 girls) patients with mean age of 12 years and mean follow-up duration of 8.5 years completed a single right knee intra-articular yttrium-90 injection with 5 mCi. The procedure was well tolerated without adverse events apart from mild and transient joint pain in 2 patients. There was a minimal radioisotope leakage to soft tissue in 2 patients. During the 3 months follow-up interval, there was no improvement in the outcome variables. Patients and parents did not notice favorable therapeutic effects and global physician assessment was unsatisfactory. No difference in knee joint swelling or range of motion. Furthermore, MRI findings were unchanged. However, there was minimal increase in synovial fluid post injection.

Conclusion:

Yttrium-90 radiosynovectomy seems to be safe and well tolerated procedure, but with the given dose and interval time it didn't show a beneficial therapeutic effect in arthropathy of CACP syndrome.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Quality Measures and Quality of Care Poster Session (ARHP): Clinical Practice/Patient Care

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Clinical assessment instruments to accurately assess disease activity in the fibromyalgia population have been difficult to develop because of the subjective nature of the disease. The Symptom Severity (SS) scale is an instrument completed by the healthcare provider based on the provider's perception of the patient's symptoms. The Revised Fibromyalgia Impact Questionnaire (FIQR) is a tool completed by the patient and based on the patient's perception of their symptoms severity. The purpose of this study was to determine whether a provider-generated assessment tool, the SS scale, would provide comparable results to a patient-generated assessment tool, the FIQR, for evaluation of symptom severity in adults with an established diagnosis of fibromyalgia.

Methods:

One hundred fifty five participants were recruited from a convenience sample of adult patients at a private rheumatology office in the south central United States. The participants had an established diagnosis of fibromyalgia. After providing consent for study participation, the participants were provided with a copy of the FIQR to complete prior to their appointment with the medical provider. During the medical assessment, the healthcare provider completed the SS scale based on the provider's perception of the patient's symptoms. The assessment instruments were completed at the same clinic visit and kept separated and blinded from each other.

Results:

Spearman's rank-based correlation coefficients showed that SS-fatigue was weakly correlated with FIQR Domain 1 (ρ = .285) and moderately correlated with Domains 2 and 3 (ρ = .438; ρ = .447) and the FIQR total score (ρ = .420). Similarly, SS-waking unrefreshed was weakly correlated with FIQR Domain 1 (ρ = .250) and moderately correlated with Domains 2 and 3 (ρ = .353, ρ = .385) and FIQR total score (ρ = .358). SS-somatic symptoms and SS-total scores were moderately correlated with all three FIQR domains and the FIQR total score (ρs ranging from .371 to .527). FIQR scores were, on average, higher than were SS scores (M = .559 compared to M = .479), and the difference between them was statistically significant, t (154) = 5.094, p < .001.

Conclusion:

All five subscales of the Symptom Severity scale were significantly related to the four FIQR domains and the FIQR total score. Higher scores on the SS scale were associated with higher scores on the FIQR questionnaire. The strength of the relationships, however, was moderate. The FIQR completed by the patient had significantly higher total scores than the SS scale completed by the healthcare provider. These findings suggest that the study participants perceived their FM disease activity to be higher than was perceived by the healthcare provider.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Quality Measures and Quality of Care Poster Session (ARHP): Clinical Practice/Patient Care
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Tocilizumab is a humanized monoclonal antibody that binds to IL-6 receptor, blocking its effects. The efficacy and safety of tocilizumab in rheumatoid arthritis (RA) patients were evaluated in a comprehensive global clinical development program with several phase III studies, following the initial development in Japan. The long-term efficacy of tocilizumab was also established based on the follow-up of prior pivotal studies. Although efficacy and safety of the drug is consistent in the literature, efficacy and safety data in Brazilian population are scarce. The RITMO study collected the long-term safety and efficacy of tocilizumab associated with methotrexate in patients with RA with inadequate response to disease-modifying antirheumatic drugs (DMARD) therapy. The Brazilian cohort of RITMO study followed patients over a period of 2 years. Therefore, the aim of the present study is to evaluate safety and efficacy of tocilizumab 8 mg/kg associated with methotrexate in the treatment of Brazilian patients with moderate to severe RA with inadequate response DMARDs therapy.

Methods: RITMO was an open-label, phase 3, single-arm study conducted in 10 countries from Latin America to evaluate follow-up of intravenous tocilizumab, in association with methotrexate, in patients with moderate to severe active RA with inadequate response to DMARDs. Brazilian patients were enrolled to the extension study and were followed during 2 years, receiving treatment for 96 weeks. Efficacy and safety-related outcomes were analyzed. This analysis includes only Brazil data. (Clinicaltrials.gov NCT00754572).

Results: 98 patients were included in this analysis. Patients presented early response to the study drug with rapid improvement, of which 32% of the patients achieved ACR20 response in the second week of treatment. In addition, the functional disability in patients decreased during the study, through reduction of HAQ-DI mean value from 1.6 ± 0.7 to 0.80 ± 0.40. After 24 weeks of treatment, patients achieved response rate of 77%, 57% and 39% for ACR20, ACR50 and ACR70, respectively; these response rates remained stable after this period. After 96 weeks, 46.1% of the patients met DAS28 remission criteria. Prevalence of adverse events was 115.6 events/100 patients-year, with 14 serious adverse events (2/100 patients-year); 145 infections in 63 patients (20.2/100 patients-year) were reported, of which 6 were serious infections (0.8/100 patients-year).

Conclusion: Tocilizumab associated with methotrexate in RA patients with inadequate response to DMARDs therapy was safe and effective. The analysis of the Brazilian cohort of RITMO study was consistent with prior reported phase III studies.

Session Date: Monday, November 9, 2015
Session Title: Quality Measures and Quality of Care Poster Session (ARHP): Clinical Practice/Patient Care
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Adverse events (AEs) and serious adverse events (SAEs) from disease modifying drugs (DMARDs) for Rheumatoid Arthritis (RA) can result in significant morbidity and even fatality. The American College of Rheumatology (ACR) has published drug safety disease modifying drug (DMARD) guidelines for doctors to follow so that they can monitor side effects. The aim of our study was to audit our practice to see if the ACR guidelines were followed and what impact that had on RA patients with AEs and SAEs.

Methods: We collected data on DMARD and biologic usage of 250 RA patients in a Musculoskeletal clinic in the United Arab Emirates (UAE) and audited the practice to see how many of the ACR drug safety guidelines were being followed. Subsequently we analyzed how

many patients suffered from AEs and SAEs (death, initial or prolonged hospitalization, persistent or significant disability, cardiac failure, or myocardial infarction). Outcomes of the AEs and SAEs were recorded.

Results: 518 DMARDs were prescribed to 250 patients (Methotrexate, Arava, Sulfazalazine, Imuran, Plaquenil, Enbrel, Humira, Xeljanz, Simponi, Acterma, and Mabthera). The average duration of DMARD use was 52.4 months. The average age was 47 years, 51 males (20.4%), 199 females (79.6%) and the ethnicities represented were 131 Asian (52.4%), 53 Arab (21.2%), 53 Caucasian (21.2%), 12 African (4.8%), and 1 other (0.4%). All six guidelines; informing patients about risk, prophylaxis for patients at risk for gastrointestinal bleeding, hemoglobin tests, serum creatinine tests, baseline studies, and drug toxicity monitoring were applied to 100% of the patients. 15.6% of all the patients experienced some sort of AE and 0.4% experienced a SAE. Of these patients 74.4% of them discontinued the medication that caused them to have an AE and changed to another DMARD. The reported AEs consisted of increased LFT (27.2%), intolerance (9.1%), infection (9.1%), allergy (9.1%), hair loss (7.3%), skin pigmentation (7.3%), chronic cough (5.5%), chronic low WBC (5.5%), severe injection site reaction (3.6%), discomfort in chest (1.8%), menorrhagia (1.8%), dizziness (1.8%), neoplastic lesion in thyroid (1.8%), psoriasis (1.8%), upper GI bleed (1.8%), asthma (1.8%), eye toxicity (1.8%) and pulmonary hemorrhage (1.8%). Of these AEs only pulmonary hemorrhage (1.8%) was deemed a SAE. All AEs were resolved due to early detection and careful monitoring.

Conclusion: Of the 250 patients administered with 518 drugs, 39 (15.6%) reported AEs of which 1.8% of them were deemed SAEs and 29 patients (74.4%) discontinued the DMARD. All adverse events were resolved with drug discontinuation and no patients had irreversible side effects. We believe that adherence to the ACR DMARD safety guidelines for RA treatment can limit the impact of AEs and SAEs and enhance the safety of patients.

Key Point: Strict adherence to the ACR drug safety guidelines results in patient safety and effective RA treatment.

Promoting Smoking Cessation Among Rheumatoid Arthritis Patients: What Motivations and Barriers Are Reported after Being Offered a Smoking Cessation Intervention?

Lisa K. Stamp[1], Megan Gath[1], Pip Aimer[1], Simon Stebbings[2] and Gareth Treharne[3], [1]Medicine, University of Otago, Christchurch, Christchurch, New Zealand, [2]Dunedin School of Medicine, University of Otago, Dunedin, New Zealand, [3]Department of Psychology, University of Otago, Dunedin, New Zealand

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Quality Measures and Quality of Care Poster Session (ARHP): Clinical Practice/Patient Care

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) may experience specific barriers to smoking cessation but may also be motivated to quit to improve their health, particularly if informed of the possible impact of smoking on disease activity, treatment efficacy, and outcomes. Qualitative research on the perspectives of smokers and ex-smokers with RA is needed to help design, implement, and evaluate smoking cessation interventions that can be applied in clinical practice if efficacious.

Methods: Semi-structured interviews were carried out with 29 ongoing smokers and 10 ex-smokers with RA who had previously been invited to participate in a randomized controlled trial of a novel RA-specific smoking cessation intervention (14/19 in the intervention group; 14/19 in the control group; 11/18 who had declined being in the trial). The interviews were led by a researcher with no involvement in the participants' clinical care. Interview transcripts were subjected to thematic analysis to investigate the motivations and barriers to smoking cessation that are most pertinent to RA patients, which led us to formulate themes outlining what we call ‘incentives' and ‘drives' to quit.

Results: Participants described five incentives to quit (health, arthritis, social relationships, coping mechanism, and costs) and four drives to quit (commitment, mental preparation, will power, and interventions). In particular, participants highlighted how their health (in general and relating to their RA) could provide an incentive to quit or be used as a rationalization for not having quit. Living with RA contributed to the stress and negative emotions experienced by participants and also limited the availability of coping methods that might be used in

places of smoking, particularly those coping methods requiring mobility. None of the 10 participants who had quit smoking mentioned having previously relied on smoking as a coping method.

Conclusion: When RA patients have been informed that continued smoking may impact on the outcomes of their RA it can provide an important incentive to quit smoking that may bolster other general incentives to quit. At the same time, RA patients experience stress and mobility difficulties that often make it difficult to quit smoking despite knowing the general and RA-specific health benefits. Overall, the incentives and drives revealed in this research also indicate ways that RA patients might be supported in developing the motivation to quit smoking and ways of overcoming barriers. RA patients who report using smoking to cope may benefit from psychological interventions to help them replace or reframe that coping method and bolster other psychological processes that can drive smoking cessation.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Quality Measures and Quality of Care Poster Session (ARHP): Clinical Practice/Patient Care
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Knee and hip osteoarthritis (OA) are the clinical outcome of a functional and structural failure resulting with pain and physical dysfunction. Total joint arthroplasty is increasingly utilised surgical treatment at the end stage (OA). The ultimate goal of arthroplasty surgery is for the patient to be able to forget the artificial joint during daily activities. The traditional main outcomes are clinically objective surgeon-reported endpoints. Patient-reported outcome assessment is the primary indicator of patient satisfaction with their operated joint results. The aim of this study is to investigate long-term patient functional outcomes and relationship with the ability to forget their artificial joint according to patients' perspective.

Methods: Consecutive 72 patients undergone unilateral cemented total hip arthroplasty or total knee arthroplasty (THA; n=42; TKA; n=30) for primary OA in Hacettepe University Hospital between January 2010 and January 2014, participated in the study. Patients were asked to complete the patient-reported outcome (PRO) assessments such as the Western Ontario and McMaster Universities (WOMAC) osteoarthritis index, Tampa Kinesiophobia Scale (TKS) and the Forgotten Joint Score (FJS-12). WOMAC Index was used to assess pain, stiffness and function. The TKS assessed the fear of movement. The FJS-12 consists of 12 questions where subjects were asked to rate their awareness of their joint arthroplasty during various activities.

Results: Average age 61.9 ± 14.6 years; 82% female, 50% obese (BMI>=30kg/m^2). Average time after surgery was 30.8±16.1 months. Mean post-operative WOMAC pain score was 13±3.2, WOMAC stiffness score was 7±1.4, WOMAC function score was 48±18.4. Mean TSK was 43.0±8.7 and mean FJS-12 score was 66.1±21.5. Correlations between FJS-12 and WOMAC and TKS scores were as follows: r=-0.68 for WOMAC-Pain, r=-0.53 for WOMAC-Stiffness, r=-0.65 for WOMAC-Function, and r=-0.63 for TKS in patients with TKA. Correlations between FJS-12 and WOMAC function score and TKS scores were as follows: r=-0.58 and r=-0.62 in patients with THA.

Conclusion: Assessing patients' perception about their artificial joint is becoming more important in clinical area following total joint arthroplasty. The true success of the surgery may not equate to the sum of a set outcome variables. Long-term follow-up with PROs showed that there is a need for a greater focus on understanding the perspectives of patients following arthroplasty surgery to improve the efficacy of interventions focused on better functional outcomes in TKA and THA recipients.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Quality Measures and Quality of Care Poster Session (ARHP): Clinical Practice/Patient Care

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: While the introduction of the treat-to-target (T2T) strategy is associated with lower disease activity scores in rheumatoid arthritis (RA), the potential for increased toxicity due to more intensive use of concurrent DMARDs could adversely affect patient reported outcomes (PROs). The objective was to determine the effects of DMARD related toxicity on PROs in early RA patients treated according to T2T strategy for 3 years

Methods: A total of 149 patients from an inception cohort of recent onset RA were included. The occurrence and severity of toxicity were monitored at each clinic visit over three years. PROs studied were function (measured using health assessment questionnaire), helplessness (assessed using the rheumatology attitudes index), pain, fatigue and patient global assessment (PGA) all assessed using a 100mm visual analogue scale and health-related quality of life (HRQoL) (assessed using SF-36).

For each PRO, the effect of drug withdrawal was measured by comparing mean change from baseline among patients with no/temporary withdrawal *versus* those with permanent drug cessation. The effects of the frequency of minor side effects, frequency of drug withdrawals, weeks to withdrawal and number of drugs withdrawn were analysed using linear regression.

Results: After 3 years, 56 (37.6%) patients ceased at least one drug permanently due to toxicity. Patients with no/temporary withdrawal (n=93) achieved significantly greater improvement in function, pain, fatigue and PGA compared to their counterparts (n=56). Drug-related toxicity did not have a significant effect on HRQoL and helplessness (Table 1).

Table 1: Improvement in PROs, *mean change (SE),* according to withdrawal due to toxicity				
	No/temporary withdrawal (n=93)	Permanent withdrawal (n=56)	*Between group mean differences (95%CI)*	*P-value*
Function	-0.54 (0.06)	-0.31 (0.09)	-0.23 (-0.44 to -0.02)	0.033
Pain	-39.82 (3.44)	-25.02 (5.50)	-14.80 (-27.03 to -2.56)	0.018
Fatigue	-29.14 (3.43)	-14.76 (4.89)	-14.38 (-25.97 to -2.80)	0.015
PGA	-29.64 (3.16)	-17.00 (4.21)	-12.64 (-23.03 to -2.25)	0.018
Helplessness	-4.44 (0.62)	-3.69 (0.75)	-0.75 (-2.73 to 1.23)	0.455
SF-36 Summary				
Physical	10.85 (1.32)	6.84 (1.78)	4.01 (-0.36 to 8.38)	0.072
Mental	4.31 (1.38)	4.48 (1.83)	-0.17 (-4.71 to 4.37)	0.941

After adjusting for other relevant baseline variables, regression analysis indicated that higher frequency of withdrawals was associated with lesser improvements in function, pain, fatigue and PGA, while the number of drugs withdrawn and the time to withdrawal had lesser effects. The occurrence of minor side effects did not affect change in PROs (Table 2).

Table 2: Relationship between drug-related toxicities and improvement in PROs over 3 years.

The Beta sign indicates whether the PROs improved or not as a result of drug-induced toxicity. Negative scores indicate inverse relationship while positive scores indicate direct relationship.								

Conclusion: In the setting of a T2T strategy where use of multiple DMARDs and frequent dose escalation were common, DMARD withdrawal due to toxicity was significantly associated with less improvement in function, pain, fatigue and PGA while toxicity had little impact on helplessness and broader measures of HRQoL.

Implementation in Clinical Practice of a Medication Assessment Tool Specific for Rheumatoid Arthritis, Rhmat

Louise Grech[1,2], Anthony Serracino Inglott[1], Victor Ferrito[1] and Lilian M. Azzopardi[1], [1]Department of Pharmacy, University of Malta, Msida, Malta, [2]Clinical Pharmacy Practice Unit, Department of Pharmacy, Mater Dei Hospital, Msida, Malta
First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Quality Measures and Quality of Care Poster Session (ARHP): Clinical Practice/Patient Care
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: The RhMAT is a medication assessment tool developed to specifically analyse pharmacotherapy adherence to evidence based medicine and guidelines on the management of rheumatoid arthritis. The RhMAT was developed to identify any gaps within management care plans. The objective of this study was to implement the innovative RhMAT within a pharmaceutical care plan model for rheumatoid arthritis patients.

Methods: Rheumatoid arthritis patients regularly attending the rheumatology clinic at Mater Dei Hospital who were 18 years or older, able to understand Maltese or English were eligible to participate in the study. The University of Malta Ethics approval and the patients' consent was obtained. The study was run between January and December 2014. The patients' medical notes were screened. Patient interviews were conducted where necessary to fill in gaps in the documentation. The RhMAT was completed for the patients taking part in the study. For each criterion given in the RhMAT the researcher can choose one of four options between adherence (yes), non adherence no justified, non adherence not justified, not applicable and insufficient data (table 1). The RhMAT adherence rate achieved was calculated. A score of 50% or less was determined as low adherence, a score between 51% and 74% showed intermediate adherence and a score of 75% or more was determined as high adherence to the RhMAT.

Results: A total of 78 patients (56 females, 22 males) were recruited for the study. More than half of the patients (55% n=43) were prescribed a traditional disease modifying antirheumatic drug (tDMARD) with 81% (n=35) being on monotherapy tDMARD. Methotrexate was the most commonly prescribed tDMARD whether monotherapy or in combination with other tDMARDs (n=29, 67%). Overall, a score of 75% or more, determined as high adherence rate, was achieved in 80% (n=62) and a score 51% to 74% or intermediate adherence rate was achieved in 19% (n=15). A low adherence score was achieved only in 1 patient.The mean score for the methotrexate section was 99.5% (n=54). The mean score for the biologic section was 97.9% (n=35). Time taken to complete each RhMAT for each patient was 15 minutes.

Conclusion: Methotrexate was the most common tDMARD prescribed. The average time taken to complete each RhMAT was realistic,practical and feasible for a busy clinic. The overall high adherence rate achieved indicates that the majority of the current pharmacotherapy of the study patient population is in agreement with established guidelines. A high adherence rate was also observed with respect to methotexte prescribing and monitoring and screening for biologic drugs. The RhMAT was useful in identifiying gaps in agreement to established guidelines thereby enabling the clinical pharmacist to discuss these issues with the clinicians further improving the quality of service offered.

Table 1. Extract from the RhMAT – Methotrexate section

	Methotrexate	N/A	Yes	No justified	No unjustified	Insufficient Data	Comments	Reference
1	Used as first line DMARD in the absence of contraindications							
2	Pre-treatment screening including Chest X ray, CBC, ESR, CRP, LFTs, U&Es, Creatinine have been completed							
3	Regular monitoring according to monitoring protocol schedule including mouth ulcers, nausea and vomiting and dyspnoea							
4	Contraindications namely pregnancy, breastfeeding, active local or systemic infection, bone marrow suppression excluded							
5	The patient has been prescribed methotrexate at a dose that is unambiguously expressed as a *ONCE A WEEK* administration

Adherence in Patients Who Are on Stable Doses of Methotrexate

Sandra M. Robinson[1], Peta S. Heslop[1], Stacey Duffy[2] and David Walker[3], [1]R&D, North Tyneside General Hospital, North Shields, United Kingdom, [2]R&D, Northumbria Healthcare NHS Foundation Trust, North Shields, United Kingdom, [3]Rake Lane, Northumbria Healthcare, Newcastle Upon Tyne, United Kingdom

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Quality Measures and Quality of Care Poster Session (ARHP): Clinical Practice/Patient Care

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Methotrexate has become the mainstay of DMARD treatment in Rheumatoid Arthritis and is also used in other rheumatological conditions. It is a drug that carries many tolerability problems with 56 to 85% prevalence of adverse symptoms, even in patients who continue on therapy (Robinson et al 2015). Adherence to drug regimes is not thought to be good with the WHO estimating that 40% of patients not being fully adherent. In a situation where there are also tolerability problems then adherence may be worse. We were interested to explore the

views of patients who were on stable ongoing doses of methotrexate about their adherence.

Methods: 450 patients from seven units spread across the UK and Ireland who were taking a stable dose of methotrexate, and planning to continue on it, were asked about how often they had either "forgotten" or "chosen" not to take their methotrexate and for how many weeks. Two centres surveyed 100 patients whilst the other five centres surveyed 50 patients. In four centres the patients were asked to complete the questionnaire by a doctor and in the other three by a nurse.

Results: A total of 48 (11%) patients revealed that they had chosen to miss one or more doses in the past year. This varied from 2 (4%) patients in the Barnsley centre to 13 (26%) patients in the North Tyneside centre. Patients reported forgetting to take their Methotrexate more readily; 95 (21%) of the whole group. The variation in this reporting was interesting – zero in Barnsley and 25 (50%) in Waterford the only difference being that the survey was carried out by a doctor in Barnsley and a nurse in Waterford.

Overall, in the 4 centres where the survey was completed by a doctor (300 patients were surveyed), 25 (8%) patients said they had chosen not to take their Methotrexate for at least 1 week and 36 patients (12%) said that they had forgotten to take it. In the 3 nurse centres, (150 patients were surveyed), the figures were higher; 23 (15%) patients said that they had chosen not to take their Methotrexate for 2 – 4 weeks and 59 (39%) patients said they had forgotten to take it for 1 – 6 weeks.

Conclusion: There is a substantial amount of missed Methotrexate. Patients seem more comfortable to admit to forgetting rather than choosing to miss drug. Patients seem more comfortable to admit to missing drug to nurses rather than doctors. Studies of adherence need to take account of how and who asks the questions.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Quality Measures and Quality of Care Poster Session (ARHP): Clinical Practice/Patient Care
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Patients with chronic arthritis have a higher risk of cardiovascular (CV) events than the general population. This is possibly due to the combination of a high prevalence of classic cardiovascular risk factors (CVRF) and persistent inflammation due to their rheumatic disease. T2T approaches and other advances have increased our control of disease activity, however, classic CVRF are often monitored and treated exclusively by the GP.

Aim: To describe the implementation of a specific program for patients with chronic inflammatory arthritis based around a nurse-led clinic and aimed at:

1) Detecting classic CVRF and

2) Optimizing the treatment of these classic CVRF

Methods:

Following the EULAR 2010 recommendations, we developed a screening program for CVRF. Patients with the diagnosis of RA, SpA or PsA who were followed up at a single Rheumatology Department were offered participation in this program by their managing rheumatologist. In a single visit to a nurse-led clinic CV risk was evaluated through a clinical interview. Patients were asked about smoking status, diet, exercise, prior diagnosis of hypertension (HBP), diabetes (DM), dyslipemia (Dlp), personal and familial CV events, other comorbidities and their current treatment. Weight, height, BMI, and blood pressure were registered. Laboratory tests were then reviewed. SCORE tables were applied to calculate the CV risk; adjustment of the SCORE in RA patients was performed according to the EULAR recommendations. Those patients who did not achieve their target for the CVRF were sent to the rheumatologist for consultation. In the rheumatology nurse clinic, an educational program was initiated in order to modify diet, exercise, lifestyle and smoking cessation, where appropriate. The project is currently ongoing; preliminary results are presented.

Results:

133 patients (85 female) have been screened at the nurse-led clinic up to June 2015. Mean age was 59.1 years (SD 10.6). Diagnoses of the screened patients were 93 RA, 29 PsA and 11 SpA. At baseline, 11 patients had a history of CV events, 26 patients had a prior diagnosis of DM (9 (35%) with HbA1C>8%), 64 had HBP (32 (50%) with BP>140/90 at the nurse visit), 60 had Dlp (24 (40%) with cholesterol >220mg/dL). 42 patients were active smokers and 48 were obese (BMI>30).

In the patients without prior DM, the nurse clinic detected 4 patients (3/107, 4%) with glycemia ≥126mg/dL. In these patients a new blood test was ordered to confirm the diagnosis of DM. In patients without prior HBP 26 patients (26/69, 38%) had BP>140/90. In patients without prior Dlp 20 patients (18/73, 27%) had total cholesterol levels >220mg/dL and 37 (37/73, 51%) had LDL-cholesterol levels over their therapeutic target.

Overall, this screening strategy allowed the detection of classical CVRF which were previously undetected or poorly controlled (DM, HBP, Dlp) in 105/133 (79%) of the evaluated patients. In all patients, the nurse-led educational program was initiated.

Conclusion:

A nurse led single-visit screening program allows the detection of classic CVRF in a high proportion of patients. If proper treatment for the classic CVF is initiated, this might result in a decrease of CV events with a favorable impact on the general health of chronic arthritis patients.

Person-Centred Care Can Help Patients to Become More Effective Consumers in the Use of Health Information Than Regular Care – an RCT in Patients with Arthritis Undergoing Biological Therapy

Ingrid Larsson[1,2], Stefan Bergman[2,3,4] and Ann Bremander[2,3,5], [1]School of Health and Welfare, Halmstad University, Halmstad, Sweden, [2]FoU Spenshult, Halmstad, Sweden, [3]Department of Clinical Sciences, Lund, Section of Rheumatology, Lund University, Lund, Sweden, [4]Primary Health Care Unit, Department of Public Health and Community Medicine, The Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden, [5]School of Business, Engineering and Science, Halmstad University, Halmstad, Sweden

Session Date: Monday, November 9, 2015
Session Title: Quality Measures and Quality of Care Poster Session (ARHP): Clinical Practice/Patient Care
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Person-centred care (PCC) is a holistic approach with respectful and individualized care allowing negotiation of care where persons with health problems are empowered to be involved in health decisions. Patients' illness narratives constitute a starting point for building a collaboration with health care professionals and to empower them to play an active role in their health care. Little is known of the impact of PCC vs. regular care on patients' skills as health care consumers. The aim was to study the impact on effective consumers' skills over 6 and 12 months as measured by the Effective Consumer Scale (EC17) in patients undergoing biological therapy and randomly assigned to either a nurse-led rheumatology clinic (NLC) based on PCC or to a rheumatologist-led clinic (RLC) based on regular care.

Methods:

A 12 month RCT in 107 patients with chronic inflammatory arthritis[1]. Inclusion criteria were ongoing biological therapy and a DAS28 ≤3.2. All patients met a rheumatologist at inclusion and after 12 months, while the 6 month follow-up was randomized to either at an NLC (PCC) or at an RLC (regular care). Outcome measure was the EC17, developed and endorsed by the OMERACT, including five subscales; 1. Use of health information, 2. Clarifying personal priorities, 3. Communicating with others, 4. Negotiating roles and 5. Deciding and taking action. EC17 total score ranges from 0-100, worse to best. Differences between and within NLC and RLC were analyzed with Friedmans' test or Mann Whitney U-test.

Results:

After 12 months 97 patients completed the RCT (NLC n=47, RLC n=50), mean (SD) age 55.4 (12.7) years, disease duration 16.7 (11.5) years, DAS28 2.1 (0.7), HAQ 0.54 (0.38), global health 20.4 (17.1), pain 21.1 (18.0) and 56% were women. There were no statistically significant differences within or between the two intervention groups at baseline nor in EC17 total score mean (SD) at baseline (NLC 83.5 (9.4) vs. RLC 83.2 (10.8), 6 months (NLC 85.4 (10.4) vs. RLC 82.9 (10.9) and 12 months (NLC 85.3 (11.1) vs. RLC 82.3 (10.9)). However, in NLC there was a statistically significant improvement in EC17 subscale "1. Use of health information" at both 6 and 12 months (p=0.041 and p=0.004 respectively).

Conclusion:

Replacing just one of three visits over 12 months to an NLC based on PCC instead of an RLC based on regular care resulted in more effective consumers concerning the use of health information. Larger studies over longer time frames focusing on PCC are needed to better understand its full impact on effective consumer skills measured by EC17.

Session Title: Quality Measures and Quality of Care Poster Session (ARHP): Clinical Practice/Patient Care

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Poor adherence to medications is a common problem among rheumatology patients that can lead to irreversible negative outcomes. We piloted an intervention using patient navigators- laypeople trained in care coordination, basic rheumatology, and relevant pharmacology- to improve adherence to oral disease-modifying antirheumatic drugs (DMARDs). Navigators aimed to identify and understand barriers to adherence to DMARDs that may be missed during clinical encounters and to work with patients to develop personalized strategies to overcome these barriers.

Methods: We recruited patients ≥18 years old from a large academic Arthritis Center. Eligibility included a rheumatic disease diagnosis by a board certified rheumatologist and initiation of an oral DMARD within the prior 6 months. Navigators conducted baseline interviews to assess patients' understanding of their rheumatic disease and their adherence to DMARDs. Then, depending on need, navigators contacted patients once every 1-4 weeks by phone or in person, and these conversations were thoroughly documented. Navigators connected patients with hospital resources, provided education about diagnoses and medications, and developed individually tailored strategies to circumvent barriers. Five team members independently reviewed the documentation from patient call notes to categorize issues raised by participants and subsequent navigator actions. Multiple issues and actions could be recorded per patient but each was counted only one time per patient. Differences in coding were adjudicated by the team.

Results: Two navigators followed 88 patients for up to six months. Mean age was 54 years (SD 17) and 92% were female. 81% had inflammatory arthritis, 10% had lupus or mixed connective tissue disease, and 9% had other rheumatic diseases. Seven main categories of patient issues relevant to adherence were identified: adverse events (45%), challenges with medication acquisition (31%), concerns about medication effectiveness (30%), lack of knowledge about medications or diagnosis (20%), need for social support (14%), financial/insurance difficulties (11%), and interruptions in medication use (9%) (**Table**). 19% of patients raised no issues, 25% discussed one, and 56% ≥ 2 issues. The most common navigator actions included: facilitation of patient-doctor communication (33%), medication and diagnosis education (30%), development of individualized strategies to improve adherence (18%), and assistance with financial/insurance issues (11%) (**Table**).

Conclusion: Most patients described one or more issues related to their oral DMARD adherence or to their rheumatic disease. Navigators played a key role uncovering and addressing concerns not identified by routine clinical care. Further analyses will assess the impact of navigators on DMARD adherence and rheumatic disease-related outcomes.

Table. Patient issues and navigator actions related to medication adherence (N= 88)

Categories of Patient Issues	**N (%)**
Adverse events (e.g. alopecia, rash, gastrointestinal side effects)	40 (45%)
Challenges with medication acquisition (e.g. refills and prior authorizations)	27 (31%)
Concerns about medication effectiveness (e.g. onset of action)	26 (30%)
Lack of knowledge about medications or diagnosis	18 (20%)
Need for social support (e.g. expression of depressive symptoms)	12 (14%)
Financial/Insurance difficulties obtaining medications (e.g. high co-payments, billing errors)	10 (11%)
Interruptions in medication use (e.g. surgery, infections)	8 (9%)
Navigator Actions	**N (%)**
Facilitation of patient-doctor communication (e.g. notified rheumatologists of patients symptoms or concerns)	29 (33%)
Medication or diagnosis education (e.g. explained side effects, described expected timing of medication effects, helped manage side effects)	26 (30%)
Development of individualized strategies to improve adherence (e.g. pillboxes, text messages, set-up of automatic refills, magnet reminders)	16 (18%)
Assistance with financial and insurance issues (e.g. referral to financial counselor, interactions with insurance companies)	10 (11%)
Coordination of care (e.g. helped patients obtain referrals to other specialties)	8 (9%)
Provision of social and emotional support	7 (8%)
Facilitation of expedited mental health referrals	6 (7%)

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Quality Measures and Quality of Care Poster Session (ARHP): Clinical Practice/Patient Care
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: The purpose of this Consensus is to update the PANLAR recommendations for hand, hip and knee osteoarthritis (OA) based on a combination of the available evidence and expert opinion.

Methods: Recommendations were developed by a group of 40 specialists of 18 countries of Latin America, and patients suffering from OA of the referred joints. A systematic review of articles, meta-analysis and guidelines published between 2008 and January 2014 was undertaken. The level of evidence and degree of recommendation were classified according to the Center for Evidence Based Medicine at Oxford or Jadad scale. Level of agreement was established through a Delphi technique.

Results: Both “strong” and “conditional” recommendations were made. In **hand OA** it is important to educate regarding joint protection

and to provide an exercise regimen that improves muscle strengthening and range of motion (IC). Topical NSAIDs are indicated in mild to moderate pain (IA). Acetaminophen (up to 3 g/day) is recommended as the oral analgesic of first choice (IA). If it is not effective, oral NSAIDs are recommended at the lowest effective dose and for the shortest time possible (IA). The use of chondroitin sulfate is recommended and may be used in the long-term (IA). The use of steroids or intra-articular hyaluronic acid might be considered for OA of the symptomatic TMC joint (IIaB). Surgery could be considered for severe rhizarthrosis in patients with strong pain and/or disability and after conservative treatment has failed (IIBB). For **Hip OA**, patients should be educated on the importance of changes in lifestyle (IB). Strengthening the extensors and abductors improves function and can prepare the patient before a hip implant (IB). In mild to moderate pain, acetaminophen (IB) is recommended. In cases of higher pain, high doses of NSAIDs or selective COX2 inhibitors could be indicated (IB). In patients who do not respond to NSAIDs or inhibitors of COX-2, or do not tolerate them or are contraindicated, weak opioids such as tramadol would be useful (IIbB). Total hip arthroplasty is indicated in patients with high pain, walking difficulty and loss of quality of life (IA). Finally in **Knee OA,** it is important to educate about lifestyle changes (IA). Acetaminophen is recommended up to 3 gr per day for mild pain (IA). For moderate pain, traditional and selective NSAIDs are indicated (IA). Topical NSAIDs may be indicated in patients with gastrointestinal risk (IA). In severe pain, the use of tramadol is recommended (IA).Treatment with chondroitin sulphate has demonstrated symptomatic effect in patients with knee OA and it may delay OA progression (IA). Combined use of glucosamine and chondroitin sulfate is indicated in patients with moderate to severe pain (IB). Benefits of intra-articular hyaluronic acid have been reported (IIaB). Arthroscopy is not beneficial (IIIA).Total knee arthroplasty may be indicated in knee OA (IIaB).

Conclusion:

These recommendations are based on the consensus judgment of clinical experts, informed by available evidence, balancing the benefits and harms of treatments, and incorporating their preferences and values. It is hoped that these recommendations will be useful in the management of OA patients.

Engaging Clinic Staff in Work System Redesign to Adapt a Hypertension Protocol for Rheumatology

Edmond Ramly[1], Diane Lauver[2] and Christie M. Bartels[3], [1]Industrial and Systems Engineering, University of Wisconsin-Madison College of Engineering, Madison, WI, [2]University of Wisconsin-Madison School of Nursing, Madison, WI, [3]Department of Medicine, University of Wisconsin (UW) School of Medicine and Public Health (SMPH), Madison, WI

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Quality Measures and Quality of Care Poster Session (ARHP): Clinical Practice/Patient Care

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Despite routine blood pressure (BP) measurement by clinic staff, we reported that rheumatologists discussed elevated BPs in <1/3 of visits leading to missed opportunities for cardiovascular disease prevention. Staff-driven hypertension protocols in primary care reduce such variation by empowering clinic staff. Our objective was to engage clinic staff in work system redesign to develop and implement a blood pressure protocol adapted to specialty care. We report results of this process under the five work system domains: people, tools, organization, environment, and tasks.

Methods: Our multidisciplinary team engaged clinic staff (medical assistants (MA), nurses (RN), and schedulers) in work system redesign. Three discipline-specific one hour focus groups appraised pre-visit rooming and check-out workflows, our proposed protocol, and electronic health record (EHR) tools. Staff participated in a 45 min group session on BP, and one-on-one 15 min EHR training sessions. We audited fidelity through EHR data and provided monthly individual audit feedback. These brief sessions focused on goal-setting and staff-driven problem-solving. Three later focus groups offered us evaluative feedback and suggestions for improvements. We

also administered a retrospective anonymous 15 item staff questionnaire after pilot testing.

Results: Over 90% (9 MAs, 5 RNs, 4 schedulers) of staff participated in focus groups. Content analysis of the focus groups informed the development and implementation of work system redesign interventions (Table 1). The work system redesign included training (people), protocol and workflows adapted to specialty care (organization, tasks), a customized EHR alert for elevated BP and EHR follow-up order set (technology), and supportive physical cues like a desktop patient brochure linking rheumatologic conditions and heart risk (environment). Four monthly audit feedback sessions with 10 regular MAs or RNs identified barriers and solutions. All staff met progressively higher goals and achievement. In evaluative focus groups staff voiced satisfaction and suggested pragmatic changes including BP re-measurement red cue cards and EHR alert revisions. Questionnaires showed improved BP self-efficacy post intervention.

Conclusion: We engaged rheumatology clinic staff in participatory work system redesign to improve follow up for patients with elevated blood pressure. The collaborative redesign process resulted in successful modification and implementation of a blood pressure protocol for specialty care. Results suggest sound intervention feasibility including improved staff self-efficacy and demonstrate good intervention fidelity including improved BP re-measurement and follow up orders over time.

Table 1. Results of Participatory Work System Redesign

Work System Components	Before Redesign	After Redesign
People	Staff BP self-efficacy: 2.5 of 5	Staff BP self-efficacy: 4 of 5
Organization	No BP follow up policy	Standard protocol supported by staff and leadership
Technology	No prompts for elevated BP	EHR alert & order set for education and follow-up
Environment	No physical cues for BP follow up	Patient brochure, Staff red cue card for re-measuring BPs
Tasks	Re-measurement of elevated BPs: <1%	BP re-measurement: <50%(Q1), > 75% (Q2) BP follow up orders: Peak >20 per month
Staff Assessment:	*"There is no system. I don't ever know what happens." MA*	*"I think it's great. They are right in the moment of, "My blood pressure is high,"... we're capturing them at an important time." RN*

Patients Who Take Many Medications for Their Fibromyalgia Symptoms at the Initial Office Visit Tend to Have a Worse Clinical Course

Robert S. Katz[1], Alexandra Katz Small[1] and Hannah Leavitt[2], [1]Rush University Medical Center, Chicago, IL, [2]Rheumatology Associates S.C., Chicago, IL

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Quality Measures and Quality of Care Poster Session (ARHP): Clinical Practice/Patient Care

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Fibromyalgia syndrome (FMS) patients taking a greater number of medications may identify those with a more challenging clinical course.

Methods: We evaluated patients at their initial rheumatology office visit to determine the number of medications they were taking for pain and other fibromyalgia symptoms, and later outcome based on HAQ scores for functional ability as well as visual analogue scales (VAS) for pain, fatigue, concentration and general health.

Results: The mean number of medications taken for fibromyalgia symptoms was 5.23, range 0-23. The mean number of non-prescription medication such as dietary supplements and over-the-counter drugs was 2.12, with a range of 0-10.

Conclusion: Those patients taking more prescription for their fibromyalgia symptoms at their initial office visit tended to have a worse clinical course, evidenced by higher HAQ scores, poor general health, and more pain and fatigue. Those FMS patients may be more difficult to care for.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is an autoimmune disease which is predominant in female with female to male ration ranging between 2:1 to 3:1. The peak incidence of RA in women coincides with the time of menopause. When there are diminished production of estrogen , progesterone and adrenal androgen.

Aim : To assess the effect of menopause early versus late on the functional status of rheumatoid arthritis patients

Methods: this was retrospective study. Fifty patients with RA diagnosed according to 2010 American College of Rheumatology /European League Against Rheumatism classification criteria for RA from those have been treated at our outpatient clinic, provided that they had developed RA prior to the onset of menopause, all are non smoker and their records are available at our clinic archives. Twenty five of those patients had early onset menopause (<45years) constituted group I, while Group II was the remaining 25 patients with late onset menopause(≥45years).

All patients were subjected to history taking including history of the disease, drug history, gynecological history(age of menarche, age of menopause, parity), detailed musculoskeletal examination, current as well as previous Health Assessment Questionaire (HAQ) obtained from previous records that were taken prior to the onset of menopause to each patient. Current disease activity score 28(DAS28) was conducted to all patients.current Laboratory investigations including 1st hour erythrocyte sedimentation rate (ESR), C-reactive protein

Results: The mean age for group I patients was 51.76±9.21, and for group II 55.24±4.28. No significant difference in between groups regarding demographic data (age of menarche, marriage status, parity, occupation. The mean disease duration for group I was 8.58±7.88 and for group II 9.57±9.75 (p=0.838). Regarding the use of disease modifying antirheumatic drugs(DMARDS) ; 21 patients of group I(84%) and 23 patients (92%) of group II used DMARDS. For group I, the mean HAQ before menopause was 0.31±0.59 and that after menopause was 2.05±0.69(p=0.001). For group II the mean HAQ before menopause was 1.02±1.14 and that after menopause was 1.86±0.87(p=0.01). Before menopause, HAQ was significantly higher for group II (p=0.012) while after menopause there is no significant difference in between groups(p=0.496). After menopause, for those patients using DMARDS with both groups, the mean 1st hour ESR was 60.95±32.02 for group I and 52.74±30.93 for group II(p=0.35), the mean C reactive protein for group I was 64.62±72.75 and for groupII was 16.93±12 (p=0.238). The mean DAS for group I was 7.03±1.04, that of group II was 6.59±1.31(p=0.234)

Conclusion: Menopause significantly impairs the functional status of rheumatoid women whether this menopause is early or late. Early menopause tends to affect the disease activity more. Further studies with larger samples will help to document the impact of menopause on functional impairment as well as disease activity of rheumatoid arthritis

Study limitation: lack of previous laboratory studies and DAS28 prior to menopause limited the accuracy of results regarding menopause and disease activity.

Prevalence of Unassessed and Uncontrolled Cardiovascular Disease Risk Factors Among Rheumatoid Arthritis Patients in an Academic Rheumatology Practice

Darcy S. Majka[1], Eric M. Ruderman[2], Ji Young Lee[3], Elisha Friesema[4] and Stephen D. Persell[4], [1]Rheumatology, Northwestern University Feinberg School of Medicine, Chicago, IL, [2]Medicine, Division of Rheumatology, Northwestern University Feinberg School of Medicine, Chicago, IL, [3]Northwestern University Feinberg School of Medicine, Chicago, IL, [4]General Internal Medicine, Northwestern University Feinberg School of Medicine, chicago, IL

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Cardiovascular disease (CVD) is the leading cause of death in individuals with rheumatoid arthritis (RA). Patients with RA are at 1.5-2.0-fold increased risk of CVD morbidity relative to the general population. Despite the high burden of CVD and recommendations by the European League Against Rheumatism (EULAR) for routine cardiovascular risk assessment and management, it has recently been shown that both rheumatologists and primary care physicians identify and manage cardiovascular risk factors less often in RA patients compared with controls from the general population.

Methods: We queried our electronic health record (EHR) using Structured Query Language and used an accurate RA detection algorithm. We assessed whether patients had established CVD, and collected data for cholesterol, blood pressure, antihypertensive and lipid lowering therapy, and smoking and diabetes status. We calculated CVD risk (symptomatic coronary or cerebrovascular disease) using equations from the 2013 American College of Cardiology (ACC)/American Heart Association (AHA) risk assessment guideline. We identified RA patients with a CVD risk of ≥ 5% because at this level the ACC/AHA guideline recommends statin therapy be considered, and strongly recommends it at a level of ≥ 7.5%. In addition, RA patients with CVD risk estimated at 5% likely have a true level of risk exceeding 7.5% because CVD risk is increased approximately 1.5 fold in RA.

Results: Among 1414 RA patients, 83% were female and mean age was 56 years. Only half of RA patients had all major risk factors assessed (data missing for lipids [49%] and diabetes screening [8%]). Among those potentially eligible for a statin (known CVD or 10-year CVD risk of ≥ 5%), only 47% were treated with a moderate or high intensity statin and 46% were prescribed no statin. Most recent BP was <140/90 for 83% of the cohort. Diabetes and current smoking prevalences were low (9.9% and 5.3% respectively).

Conclusion: In this academic rheumatology practice, we found two major areas for CVD prevention improvement: promotion of complete risk factor assessment and the appropriate use of statins. This study demonstrates that system-based interventions are needed to improve CVD risk factor assessment and management among RA patients in this practice. Such interventions might include both rheumatology and generalist provider education, performance feedback, and point of care decision support tools within the rheumatology practice to improve risk factor measurement and referral for risk factor modification.

Table 1. Atherosclerotic Cardiovascular Disease (ASCVD) Risk Factors and Treatment among Study Site RA Patients*

Characteristic	Entire cohort	Known CVD	ASCVD risk ≥5%	Risk < 5%, with diabetes or LDL ≥ 190	Other

Initiating Statin Medication and Risk of Fatigue in Rheumatoid Arthritis

James S. Andrews[1], Harlan Sayles[2], Kaleb Michaud[3] and Patricia P. Katz[4], [1]Rheumatology, University of California San Francisco, San Francisco, CA, [2]University of Nebraska Medical Center, Omaha, NE, [3]Internal Medicine, University of Nebraska Medical Center, Omaha, NE, [4]Rheumatology, UCSF, SF, CA

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Fatigue is common in Rheumatoid Arthritis (RA) and has a major impact on quality of life. Individuals with RA are also at increased risk of cardiovascular disease and are often prescribed statin medications. Recent data suggest that statins may be associated with increased fatigue symptoms (Golomb, Arch Intern Med, 2012; 172:1180), but the effect of statins on fatigue in RA has not been studied. This study tests whether statin initiation is associated with increased fatigue in RA.

Methods: Data were from the longitudinal National Data Bank for Rheumatic Diseases (NDB), for which participants complete questionnaires every 6 months. RA was physician confirmed. Medication use was self-reported. The primary exposure was first-ever initiation of a statin. Participants were classified as exposed if they 1) began taking a statin, 2) took this statin for at least 1 month, and 3) had never taken any statin in the past. Fatigue severity was measured by Visual Analogue Scale (range 0-10): "How much of a problem has fatigue or tiredness been for you in the past week?" The primary outcome was 6-month change in fatigue severity. We used a new-user nested cohort design. Subjects were analyzed as controls until the 6-month interval in which they initiated statin use, during which they were analyzed as exposed. To exclude prevalent statin users, participants were censored beginning in the 6-month interval after exposure. Generalized estimating equations, with a fixed effect term for 6-month interval and robust standard errors, were used to model the effect of statin initiation on change in fatigue, controlling for age, sex, baseline fatigue severity, depressive symptoms, sleep quality, HAQ score, comorbidities, BMI, and RA Disease Activity Index (RADAI) score. Secondary analysis examined the effect of initiation of "high-potency" statins (atorvastatin, rosuvastatin, and simvastatin) on change in fatigue.

Results: Of the 12,482 participants, 80% were female and the mean ±SD baseline characteristics were: age 63 ±12 years, RADAI score 2.4 ±1.4, fatigue 4.1 ±2.5. 3,617 participants (29%) initiated a statin, of which 91% were "high-potency." Mean 6-month change in fatigue was -0.001 (±0.6) among controls and 0.02 (±2.4) among statin new-users. In adjusted models, new use of a statin was not associated with a significant change in fatigue [(coefficient=0.01; (CI:-0.07,0.10); p=0.8]. Results were similar when analysis was limited to new use of high-potency statins [(coefficient=-0.01; (CI:-0.10, 0.08); p=0.8].

Conclusion: In this large longitudinal cohort of patients with RA, there was strong evidence that new use of a statin is not associated with significant risk of increased fatigue. Because the 95% confidence interval (-0.07, 0.10) includes the null and excludes all clinically meaningful values for change in fatigue, we conclude that new use of a statin does not have a clinically important effect on fatigue (Hoenig, American Statistician, 2001; 55:19). Given the importance of statin medications in reducing cardiovascular risk for individuals with RA, these findings have great clinical relevance.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with inflammatory rheumatisms especially rheumatoid arthritis (RA) have a greater risk of cardiovascular diseases (CVD), infections, chronic respiratory diseases (CRD) and osteoporosis. As recommended by EULAR, rheumatologists start to perform systematic screening of CVD and comorbidities. Moreover, the 2015 EULAR guidelines recommend assessment of asymptomatic atherosclerotic plaques by carotid ultrasound. We aimed to determine the real impact of this strategy.

Methods: A screening was set up in an out-patient daily clinic of Rheumatology. It included 1) cardiovascular evaluation with modified SCORE calculation, supra-aortic trunks and abdominal aorta ultrasound and echocardiography, 2) CRD evaluation with spirometry; 3) osteoporosis with bone mineral density and FRAX calculation, and 4) check-up of vaccine calendar and recommended neoplasia screenings. Three months later, patients were called and the application of recommendation evaluated.

Results: 184 patients including 150 RA patients and 29 spondyloarthritis performed this screening. The mean rheumatism duration was

14±9 years and the mean age was 59±11 years. Unknown uncontrolled hypertension was diagnosed in 14% (n=26); dyslipidemia in 21% (n=38); diabetes in 8% (n=14) of the patients. 26% (n=47) patients were estimated at risk of chronic obstructive pulmonary disease or sleep apnea syndrome and were recommended to perform further explorations. Anti-osteoporosis drugs were prescribed in 11% (n=21) patients. Vaccinations and neoplasia screening updates were proposed for 53% (n=97) and 41% (n=75) patients. Only one clinically significant carotid stenosis requiring therapy was found (0.5%). Mild to moderate stenosis were found in 8/168 patients (4.7%). Abdominal aorta aneuvrysm requiring monitoring were detected in 8/168 patients (4.7%). Patients with detected carotid stenosis or aorta aneuvrym were significantly older (65±9 vs 58±11 years, p=0.01), more often male (58 vs 29%, p=0.01), with higher waist circumference (99±16 vs 92±14 cm, p=0.03) and mSCORE (4.4±3.6 vs 2.1±2.2, p<0.001). A mSCORE ≥4.5 would detect vascular Doppler abnormalities with a 88% sensitivity and a 43% specificity. Abnormal echocardiography was found in 30/184 patients (25 patients with valvular diseases, 3 hypokinesia and 5 left ventricular hypertrophia). Three months after screening, 84 patients were contacted by phone. 6/10 declared to have recommendation for hypertension, 5/8 for diabetes and 6/10 for osteoporosis. 14/29 declared to have performed the recommended CRD explorations, 30/40 the vaccines and 18/36 the neoplasia screenings.

Conclusion: A daily out-patient clinic for comorbidity screening helps to detect chronic diseases such as hypertension, diabetes, dyslipidemia, or osteoporosis requiring treatment in a 1/3 of patients. Chronic respiratory diseases were also detected in 26% patients. 50 to 75% of the recommendations proposed appeared to be applied. Profitability of systematic supra-aortic trunk doppler appears to be low with only 0.5% of clinically significant abnormalities. The use of systematic vascular ultrasonography should probably be limited to a more targeted population such as patients with a mSCORE≥4.5.

Session Time: 9:00AM-11:00AM

Increased risk of thromboembolism among patients with VTE association with Rheumatoid Arthritis

Background/Purpose: Rheumatoid arthritis (RA), is among most common autoimmune conditions manifested by progressive and irreversible joint destruction. Less is known about its hematological aspects.

The aim of this study was to assess whether an association exists between RA and venous thromboembolism (VTE); pulmonary embolism and/or deep vein thrombosis.

Methods: This study was a cross-sectional analysis performed utilizing the database of Clalit Health Services, the largest healthcare provider organization in Israel. All patients diagnosed with RA ['cases'] were compared with age and sex matched controls that did not have RA (by a ratio of 1:5). Data on health-related lifestyles and other comorbidities were collected. χ^2, *t*-tests, and logistic regression .models were used to compare the study groups

Results: This study included 11,782 patients with RA, in all ages, compared to 57,973 controls, which were age, Sex, BMI and (socioeconomic statue matched. The prevalence of VTE in people with RA was increased by a factor of 2.2 (CI 2.03-2.42

in comparison to control group in each category (P< 0.001). This factor contributed more than a history of smoking, increased BMI or older age (Table 1).

Conclusion: Our results significantly demonstrate that RA is associated with increased rates of VTE. Pathogenic mechanisms explaining this association should be explored.

Table 1

		O.R.	p-value	95% C.I.

Session Time: 9:00AM-11:00AM

Background/Purpose: This study evaluated the prevalence and progression of subclinical carotid artery atherosclerosis in active rheumatoid arthritis (RA).

Methods: Carotid arteries of RA patients were scanned using high resolution 3D ultrasound at baseline and 24 weeks for vessel wall volume, intima-media thickness (IMT) and total plaque area, as well as arterial stiffness measured using pulse wave velocity. Variables related to inflammation, lipids and cardiovascular risk were assessed for associations with plaque progression. Of 195 screened patients, 31 met inclusion criteria (66 Swollen joint count (SJC) plus 68 Tender joint count (TJC)^{3}8 OR SJC plus TJC^{3}4 with elevated acute phase reactants) and were enrolled (27 female; mean age 59.3±9.8 years). Patients using lipid lowering drugs and uncontrolled comorbidities were excluded.

Results: Atherosclerotic plaque occurred in 35% and arterial wall hypertrophy (IMT^{3}0.6mm) in 86% of patients. Most (68%) had an atherogenic lipid profile characterized by reduced HDL and/or increased total cholesterol/HDL index, which was adversely affected by disease activity. Stepwise binary logistic regression analysis showed that Framingham risk score (OR=1.155, 95%CI:1.002-1.332, p=0.046) and ESR (OR=1.148, 95%CI:1.015-1.299, p=0.028) predicted plaque most strongly (table). Plaque progression was significantly associated with baseline higher hsCRP, ESR, and heavy smoking, but only hsCRP predicted plaque growth in multivariate regression analysis (p=0.004); and hsCRP was related to higher disease activity (r=0.443, p=0.016), LDL (r=0.544, p=0.007), and

smoking (r=0.384, p=0.04). Figure shows carotid artery plaque with and without progression.

Conclusion:

RA-related inflammation contributed to augmented CV burden in RA and might mediate its effect on atherosclerosis through hsCRP and modulation of the traditional CV risk factors, such as dyslipidemia.

EULAR Recommendations for Cardiovascular Risk Management in Patients with Rheumatoid Arthritis and Other Inflammatory Joint Diseases – 2015 Update

Michael T. Nurmohamed and on behalf of the EULAR task force "EULAR Recommendations for Cardiovascular Risk Management in patients with Rheumatoid Arthritis and other Inflammatory Joint Diseases", Rheumatology, Amsterdam Rheumatology and immunology Center, VU University medical center, Amsterdam, Netherlands

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) (and other inflammatory joint diseases (IJD)) have an increased cardiovascular (CV) risk. In 2009 a EULAR taskforce recommended screening, identification of CV risk factors and cardiovascular risk management (CV-RM) largely based on expert opinion. In view of substantial new evidence, an update appeared timely with the aim of producing a more evidence base set of CV-RM recommendations.

Objectives:To 1) Review the presently available RA-specific cardiovascular risk prediction models and advise about the most appropriate model(s), 2a) Assess whether imaging techniques can improve CV risk prediction models, and b) advise whether routine screening with echocardiography before biologic therapy is initiated is indicated. 3) Give recommendations about lipid assessment, lipid lowering treatment and treatment targets, 4) Give recommendations about life style modifications. 5) Conduct a systematic literature update to determine the CV risk in AS and PsA and 6) Update the recommendation on NSAID/COXIB use in patients with IJD.

Methods: The multidisciplinary steering committee comprised 25 members including patients, rheumatologists, cardiologists, internists, epidemiologists and a health professional, representing 15 European countries. Systematic literature searches were done, evidence was categorized according to standard guidelines. The evidence was discussed and summarised by the experts in the course of a consensus finding and voting process and ultimately 10 evidence based recommendations for CV-RM were formulated.

Results: 1) Validated RA-specific CV-risk models have not yet been published, hence adjustment of general population risk models is still recommended 2) There are some suggestions that (imaging) biomarkers might improve risk prediction models. However, there are practical constraints for implementation. Echocardiographic screening before initiation of biologic treatment is not recommended. 3) Statins are at least as effective and safe in RA patients as in non-RA controls. 4) Exercise should be part of RA management, both to lower CV risk and improve disease outcomes. Counselling for smoking cessation should be considered 5) There is now more evidence for an increased CV-risk in patients with AS and PsA that is comparable to RA. Systemic inflammation enhances CV risk and adequate control of disease activity good control of disease activity is likely to be beneficial. 6) Current evidence does not support a strong association

between NSAID use and CVD in patients with IJD. As in the general population, the use of aspirin for the primary prevention of CV events in patients with IJD is not recommended. Level of agreement for the 10 recommendations varied but was generally high.

Conclusion: The present update confirms and further extends the evidence that the CV-risk in the whole spectrum of IJD is increased. This underscores the need for CV-RM in these patients. As these updated recommendations are based on a pan-European consensus it is hoped that they will facilitate CV-RM in daily clinical practice, ultimately leading to a decreased CV burden in our patients.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Obstructive Sleep Apnea Syndrome (OSA) affects 2-4% of the population and it has been observed in rheumatoid arthritis (RA) patients in up to 30.8%. Besides, OSA has been determined as an independent risk factor for arterial hypertension (AHT) and has been associated with cardiovascular disease and stroke. There is little information in the literature about the relationship between this syndrome and the characteristics of RA, therefore the aim of this study is to investigate the risk of OSA in patients with RA and related factors.

Methods: We conducted a multicenter cross-sectional observational study that included consecutive RA patients (ACR 1987-ACR/EULAR 2010). Socioeconomic status, clinical data and comorbidities were recorded. OSA risk was assessed by the Berlin Sleep Apnea Questionnaire and daytime sleepiness by the Epworth Sleepiness Scale. Visual Analog Scale for pain (VAS pain), RAPID3, DAS28, HAQ-DI and Hospital Anxiety and Depression Scale (HADS A and HADS D) were also assessed. For data analysis descriptive statistics, X^2test, T-Test and binary logistic regression for multivariate analysis were applied, using OSA risk as dependent variable.

Results: Of 168 RA patients, OSA high risk was observed in 71 patients (42%) and daytime sleepiness in 50 patients (29.7%). Patients with high OSA risk showed higher BMI (29 ± 5 vs 26 ± 5, p <0.001), higher disease activity [DAS28 (4.5 ± 1.4 vs 3.7 ± 1.2, p <0.001) and RAPID3 (14 ± 7 vs 10 ± 6, p <0.002)], and worse functional capacity [HAQ (1.3 ± 0.7 vs 0.9 ± 0.7, p <0.01)]. The frequency of AHT was higher among patients with high OSA risk (42% vs 19%, p <0.002), as well as with daytime sleepiness (43% vs 25%, p <0.02), anxiety and depression disorders [HAD-A (9.2±4 vs 6.5 ± 4, p<0.001) and HAD-D (7.5±3 vs 5.4 ± 3, p<0.001)] than the low OSA risk group. In multivariate analysis, the independently variables associated with high OSA risk were BMI (OR 1.14, 95%CI: 1.052-1.235, p = 0.001) and DAS28 (OR 1.13, 95%CI: 1.006-2.459, p = 0.047).

Conclusion:

The risk of OSA was 42% in patients with RA and was associated with BMI and disease activity.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Cardiovascular mortality is increased in rheumatoid arthritis (RA) and RA is an independent risk factor leading to a rapid increase in risk following diagnosis. Reduction of LDL-cholesterol (LDL-c) is essential to decrease CV risk. Between 2005 and 2010, French recommendations were based on the serum level of LDL-c, the target LDL-c depending on the number of risk factors. In 2006, it was recommended to consider RA as an additional cardiovascular risk factor (1). Our objective was to assess every year between 2005 and 2010 the proportion of patients with recent-onset RA achieving LDL-c objectives of national guidelines.

Methods : ESPOIR is a large, French, multicenter cohort of patients with early arthritis of less than 6 months' duration and a high probability of developing RA. 814 patients were included between 2002 and 2005. Repeated cross-sectional analysis for cardiovascular risk factors, LDL and HDL cholesterol levels were performed every year between 2005 and 2010 to determine the proportion of patients achieving the LDL-c goal according to the French guidelines considering RA as an additional risk factor since 2006.

Results : 689 patients were analyzed at the first point (age 49.6 ± 12.2 years, mean symptom duration was 1.83 ± 0.95 years), 77 % were female. At this first point, 495 patients (72 %) fulfilled the ACR criteria for RA. 3 % of the patients were being treated with statins which did not significantly vary during follow-up. The proportion of patients achieving the recommended LDL-c target decreased significantly following the publication of specific RA guidelines in 2006 but did not differ during the next 5 years of follow-up (89.5 % in 2005 ; 84.7 % in 2006 ; 81.5 % in 2007 ; 77.5 % in 2008 ; 80.6 % in 2009, 81.5 % in 2010). More males and more than half of patients with high CV risk did not reach the lipid target. The proportion of patients who did not achieve the LDLc target increased with the number of risk factors accounting for less than 8 % in patients with only one risk factor and for more than 58 % in patients with the highest risk (Table).

Conclusion: Regardless of specific recommendations for management of cardiovascular risk in RA patients and large cholesterol screening, management of dyslipidaemia remained suboptimal in particular among patients at highest risk. It is still unclear whether the expansion of the indications for statin therapy would expand lipid target achievement.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Nitric oxide (NO) has been implicated in immune regulation, inflammation, arthritis and atherosclerosis. Raised levels of nitrite (NO_2) in serum and synovial fluid have been reported in rheumatoid arthritis (RA). However, impaired NO bioavailability is a hallmark of endothelial dysfunction, an early step in atherosclerosis. Premature atherosclerosis is known to exist in RA. Plasma NO_2 has been validated as an excellent measure of NO synthase activity and negatively correlated with CV risk factors in non-RA patients. This study aims to compare the levels of NO_2 in RA and controls, and to evaluate the relationship of NO_2 to traditional cardiovascular (CV) risk factors, subclinical atherosclerosis, and atherosclerosis biomarkers.

Methods: Traditional CV risk factors of smoking (current/ever vs. never), family history of CV disease, obesity, hypertension (HTN), hyperlipidemia, and diabetes were compared between RA subjects and controls using chi-squared or Fisher's exact tests. Carotid ultrasounds were performed with measurement of intima-media thickness (cIMT, using maximum of both sides) and plaque presence (of either side), and serum biomarkers (ICAM-1, VCAM-1, E-selectin, MPO, IL-6, CD40L, and MMP-9) were measured by ELISA in all subjects (78 RA cases and 92 controls). NO_2 was measured by chemiluminescence (39 RA and 50 controls). NO_2 was compared between cases and controls, and between those with and without plaque or individual CV risk factors (both overall and by case status), using t-tests. The relationship between NO_2 and each serum biomarker or cIMT was tested by Pearson correlations. The relationship between number of CV risk factors and NO_2 or each biomarker was tested by Spearman correlations.

Results: All traditional CV risk factors were similar between RA and controls except for HTN, which was higher in RA (44.9%) than controls (24.4%) (p=0.01). Mean ± SD NO_2 levels in RA (0.17 ± 0.08) were similar to levels in controls (0.15 ± 0.09; p=0.35). There were no significant differences in mean NO_2 between those with and without plaque either overall (p=0.86) or in the RA group only (p=0.78). NO_2 levels were not significantly associated with cIMT or any serum biomarker in RA group, but did have significant negative correlations with CD40L in controls (r -0.28, p=0.048) and with MMP9 in overall group (r -0.22, p=0.03). There were no significant differences in mean NO_2 between those with and without each CV risk factor, both overall and in the RA group. In the overall group, number of CV risk factors was slightly positively correlated with NO_2 (r_s 0.20, p=0.06), and significantly positively correlated with cIMT (r_s 0.24, p<0.01) and E-selectin (r_s 0.19, p=0.01), but these were not significant within the RA group. Number of CV risk factors was significantly positively correlated with MPO (r_s0.26, p=0.02) in the RA group.

Conclusion: NO_2 levels in RA are not lower than controls, and were similar in those with or without traditional CV risk factors or plaque.

Number of CV risk factors positively correlated with cIMT and E-selectin in the overall group, but not within RA patients. These findings suggest possible different pathways by which NO and CV risk factors mediate subclinical atherosclerosis in RA versus non-RA persons.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

High density lipoprotein (HDL) cholesterol efflux capacity measures how well HDL particles remove cholesterol from lipid-laden macrophages, such as those found in atherosclerotic plaques. This function of HDL is an important predictor of cardiovascular (CV) risk, independent of traditional risk factors, and is impaired in RA. Apolipoprotein A1 (apoA1) is the component of HDL that mediates cholesterol efflux. Recently developed assays can measure citrullinated apoA1 (cit-apoA1) as well as antibodies against cit-apoA1 (anti-cit-apoA1) in human serum. Our objective was to study whether cit-apoA1 and anti-cit-apoA1 in RA subjects was associated with impaired HDL efflux capacity.

Methods:

We performed this study in a prospective RA cohort based at a large academic center. We focused on a subgroup of subjects who had HDL cholesterol efflux capacity and total apoA1 measured in a previous study. Subjects were included in the subgroup if they experienced a reduction in inflammation between two consecutive years. HDL cholesterol efflux capacity was measured using a cell based assay, and total apoA1 was measured in a clinical laboratory using standardized commercial methods. For the present study, we measured cit-apoA1 and anti-cit-apoA1 at baseline. Cit-apoA1 was measured using ELISA and anti-cit-apoA1 was measured using a multiplex bead assay. To test the association between cit-apoA1 and HDL efflux capacity, we studied cit-apoA1 as a proportion to total apoA1 levels: (cit-apoA1)/(total apoA1). We then constructed a linear regression model to examine the association between the proportion of cit-apoA1 with HDL efflux capacity at baseline, adjusted by age and gender. Additionally, we tested the association between cit-apoA1 with HDL efflux capacity, and total apoA1 with HDL efflux capacity in separate linear regression models. We constructed a linear regression model to study the association between the concentration of anti-cit-apoA1 with HDL efflux capacity at baseline, adjusted by age and gender.

Results:

The 90 subjects in the study had a mean age of 57.4 (SD 12.3), 90% were female, and 77.8% were anti-CCP positive. A higher proportion of cit-apoA1 in the serum was associated with impaired HDL efflux capacity [β=-46.0 (SE 22.0), p=0.039]. While there was no association between the absolute concentration of cit-apoA1 with HDL efflux capacity (p=0.47), a higher level of total apoA1 was associated with better HDL efflux capacity [β=-2.0x10^{-3} (SE 3.0x10^{-4}), p=<0.0001]. We found no significant association between the concentration of anti-cit-apoA1 and HDL efflux capacity [β=-3.0x10^{-4} (SE 2.0x10^{-4}), p=0.136].

Conclusion:

This study suggests that a higher proportion of citrullinated apoA1 is linked with impaired ability of HDL to remove cholesterol from lipid-laden macrophages. Larger studies are needed to further investigate this relationship and its potential impact on cardiovascular risk in RA.

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: African American (AA) patients with rheumatoid arthritis (RA) have worse Health Assessment Questionnaire (HAQ) scores and increased disease activity clinically compared to Caucasian (CAU) RA patients. Serologically, AA RA patients have a higher reported prevalence of antinuclear antibody (ANA) and anti-SSA compared to CAU RA patients in two established unmatched RA cohorts. However, no matched studies have been performed. In addition, RA and Sjogren's Syndrome can co-exist and this joint pathology is associated with worse clinical manifestations and increased ANA and anti-SSA positivity. We hypothesize that the increased disease activity of RA in AAs may be linked to an increased frequency of ANA and anti-SSA antibodies, causing increased disease activity and more severe RA in AA patients.

Methods: Plasma samples were assayed from matched AA and CAU RA patients in the Rheumatoid Arthritis Comparative Effectiveness Research (RACER) cohort at the University of Pittsburgh. Patients were matched for variables including age, gender, disease duration, and RF and Cyclic Citrullinated Peptide (CCP) antibody positivity. ANA testing was performed using Indirect Immunofluorescence and titers of $\geq$ 1:80 were classified as positive. Samples also underwent specific autoantibody testing, including anti-SSA testing, with the Bioplex 2200 Multiplex Bead Assay and titers $\geq$ 1:1.9 were considered positive. Differences in autoantibody prevalence between AA and CAU RA patients were assessed using chi-square and Fisher's exact tests.

Results: AA RA patients (N=94) were matched with CAU RA patients (N=93) for age, BMI, gender, RF positivity, anti-CCP positivity, and disease duration (Table 1). Anti-SSA was significantly more prevalent in the AA RA patients (11.70% vs. 3.23%; p=0.021). AA RA patients also had a higher prevalence of ANA (21.28% vs. 10.75%) and higher prevalences of systemic lupus associated antibodies including anti-RNP, anti-SM/RNP, and anti-chromatin compared to CAU RA patients (Table 2).

Conclusion: The increased disease severity observed in AA RA patients compared to CAU RA patients may be mediated by an increased prevalence of a serologically unique subset of RA patients who are ANA and anti-SSA positive.

Table 1: RACER Demographic Data

	African American (N=94)	Caucasian (N=93)	P-value
Mean Age (years)	60.39	58.72	0.394
Mean BMI (Kg/M2)	31.04	29.54	0.243
Female (%)	93.50%	95.60%	0.747
RF Positive	77.20%	82.80%	0.363
Anti-CCP Positive	75.00%	76.30%	0.864
Mean Disease Duration (Months)	14.00	13.04	0.520

Table 2: Autoantibody prevalence in AA and CAU Patients

	AA % Positive (N=94)	CAU % Positive (N=93)	P-value
ANA (≥1:80)	21.28% (20/94)	10.75% (10/93)	0.095
Anti-SSA	11.70% (11/94)	3.23% (3/93)	0.021
Anti-SSB	4.26% (4/94)	1.08% (1/93)	0.180
Anti-SSA AND/OR Anti-SSB	12.77% (12/94)	4.30% (4/93)	0.021
Anti-Double Stranded DNA	4.26% (4/94)	6.45% (6/93)	0.523

Abstract Number: 1512

Incidence of Co-Morbid Autoimmune Diseases in Patients with Rheumatoid Arthritis

TA Simon[1], H Kawabata[1], JM Esdaile[2], V Moorthy[3] and S Suissa[4], [1]Bristol-Myers Squibb, Hopewell, NJ, [2]Arthritis Research Canada, Vancouver, BC, Canada, [3]Mu Sigma, Northbrook, IL, [4]McGill University, Montreal, QC, Canada
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is one of more than 80 different types of autoimmune diseases, many of which, including RA, share common pathogenic mechanisms, resulting in overlapping syndromes. Some autoimmune diseases, such as lupus and psoriasis, may also occur as a side effect of treatment. The purpose of this study was to quantify the incidence of autoimmune diseases in an RA population. For comparison, a population of patients was identified who had osteoarthritis (OA) and similar health care encounters to the RA population.

Methods: Patients were identified from the US MarketScan® Commercial and Supplemental Medicare databases. Patients with RA were age- and sex-matched 1:5 with a comparison cohort of patients with OA. Patients were required to have ≥180 days of continuous health plan enrollment before the qualifying RA or OA diagnosis between January 1, 2006 and September 30, 2013. Study index date corresponded to the first qualifying RA or OA diagnosis date during the study period. A single International Classification of Diseases, Ninth Revision diagnosis code of an autoimmune disease after the index date was considered an event. Over 28 autoimmune diseases were pre-specified. Patients were followed from their index date until the end of study period, end of enrollment, or occurrence of autoimmune disease, whichever occurred first. For the RA cohort, patients were censored if they developed OA during the follow-up period. Patients with an autoimmune disease in their 6-month baseline period were excluded when calculating incidence rates (IRs) for that specific autoimmune disease during follow-up. IRs with 95% CI for 28 pre-specified autoimmune diseases during the follow-up period were computed for both RA and OA populations.

Results: A total of 208,397 and 1,031,784 patients with RA and OA, respectively, were evaluated. Of the 28 pre-specified autoimmune diseases evaluated, lupus, psoriatic disease, and Sjögren's syndrome occurred most frequently among patients with RA, occurring in 5%, 3%, and 3% of the population, respectively, with corresponding IRs of 29, 19 and 17/1000 person-years. Corresponding IRs for the matched OA population were 2, 6 and 2/1000 person-years for lupus, psoriatic disease, and Sjögren's syndrome, respectively. Chronic urticaria and type 1 diabetes were the most frequently reported autoimmune diseases in the OA population (2% and 1.9%, respectively), with IRs of 8.7 and 8.4/1000 person-years, respectively. The IRs of autoimmune diseases were generally higher among the RA patients than the matched OA patients (except for type 1 diabetes). Selected co-morbid autoimmune diseases in either cohort are shown in the Table. **Conclusion:** Previous work showed that the prevalence of certain autoimmune diseases was greater in RA patients compared to those with OA. These results suggest that some autoimmune diseases occur more frequently among patients with RA than in closely matched patients with OA.

Table. Incidence of selected co-morbid autoimmune diseases in patients with RA or OA (by incidence in RA)								
	RA (N=208,397)				OA (N=1,031,784)			
Autoimmune disease	Patients evaluated (n)	Person-years	Incident events	IR per 1000 person-years (95% CI)	Patients evaluated (n)	Person-years	Incident events	IR per 1000 person-years (95% CI)
Systemic lupus erythematosus	201,443	357,799	10,500	29.35 (28.79, 29.91)	1,027,876	2,356,510	5273	2.24 (2.18, 2.30)

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Hepatitis B virus (HBV) reactivation is a common complication of immunosuppressive treatment in countries with a high prevalence of HBV infection. Biologics – and especially Rituximab – seem to cause this adverse event more commonly than conventional forms of treatment do. However, it is unclear how often patients suffer from HBV reactivation in a low prevalence country like Germany when treated with biologics for rheumatic diseases.

Methods: Using an electronic database (EMIL©; version 4.7.6.19), we were able to digitally search the files of patients treated in our Rheumatology out-patient unit between April 2008 and May 2015 (10.019 patients in total). Patients on immunosuppressive therapy screened for HBV infection have been included in the analysis. Clinical data of all patients are summarized in table 1.

Results: Between April 2008 and May 2015, 1107 patients were treated with biologics in our Rheumatology/Immunology out-patient department, 378 of which received Rituximab at least once. Of the 1107 biologics patients, 59 (5%) tested HBc antibody positive, indicating prior infection with HBV. One patient (1/59) suffered from an active HBV infection (HBs antigen positive). Only 2/59 patients, including the chronically infected patient mentioned above, received prophylactic antiviral treatment. There were no obvious HBV reactivations and no incidents of liver failure due to HBV, although in 2 patients, traces of HBV DNA could newly be detected under treatment with Infliximab in one case, and Rituximab in another case. After antiviral treatment HBV DNA became undetectable again in both cases.

Conclusion: HBV reactivation during antirheumatic therapy with biologics is a relatively rare event in German patients. Whilst both screening for prior or chronic HBV infection and close monitoring of affected patients is mandatory, prophylactic antiviral treatment does not seem to be necessary in every detected case of prior HBV infection.

Table: Clinical data of the patients involved in the current analysis

Total number of patients treated with biologics between April 2008 and May 2015 included in this analysis	**1107**
Number of patients receiving Rituximab at least once (not withstanding other biologic treatment). Reactivation under Rituximab	**378** **1/378**
Rheumatologic diagnosis	Rheumatoid arthritis: **663** Psoriatic arthritis: **113** Spondyloarthritis: **140** Connective Tissue Diseases (CTD)/Myositis: **50** Vasculitis: **54** Other: **87**
Hepatitis Bc antibody positive	**59**
HBs antigen positive	**1**
HBV DNA positive	**3**
Reactivation with Rituximab Reactivation with non-Rituximab treatment	**1/378 (0,3%)** **1/729 (0,1%)**
Antiviral treatment	Preemptive: **2** After increase of HBV DNA: **2**
Liver failure due to HBV infection	**0**

Incidence and Risk Factors of Malignancy in a Cohort of Rheumatoid Arthritis Patients from Singapore

XR Lim[1], LZ Liu[2], X Gao[2], J W L Tan[1], L W Koh[3], TY Lian[1], W Q See[4], KP Leong[1], ET Koh[1] and TTSH RA Study Group, [1]Rheumatology, Allergy and Immunology, Tan Tock Seng Hospital, Singapore, Singapore, [2]Clinical Research and Innovation Office, Tan Tock Seng Hospital, Singapore, Singapore, [3]Department of Rheumatology, Allergy and Immunology, Tan Tock Seng Hospital, Singapore, Singapore, [4]Tan Tock Seng Hospital, singapore, Singapore

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Patients with rheumatoid arthritis (RA) have been shown to have an increased risk of developing malignancies. This study was undertaken to determine the incidence and pattern of malignancy in RA patients and identify risk factors of malignancy among patients with RA.

Methods:

Patients from the TTSH RA Registry were followed up longitudinally and those who developed malignancies from 2001 to 2013 after the onset of RA were identified. Age-standardised rates (ASRs) of various cancers were analyzed and compared with the Singapore Cancer Registry data. Risk factors for developing malignancy, including demographics, disease characteristics and treatment history, were analyzed using Chi-squared test and student's t test.

Results:

Of the 1,134 patients in the registry, 81 patients developed malignancies at a mean interval of 15.1 (SD 9.7) years after the onset of RA. The mean age of the 81 patients was 65.9 (SD 10.8) years, of which 61 (75.31%) were females and 69 (85.19%) were Chinese. There were 70 (86.4%) with solid-organ tumours and 11 (13.6%) haematological malignancies.

The ASR of cancer in RA patients was 310.3 for males and 232.5 for females per 100,000 person-years, compared with 229.3 (95%CI 226.5-232) for males and 218.3 (95%CI 213.8-216.3) for females in the general population. By cancer type, there is an increased risk of lung cancer, lymphoid neoplasms and stomach cancer in RA compared with the general population.

The risks factors for developing malignancy ($p<0.05$) include male gender, non-Indian ethnicity, onset of RA at an older age, untreated RA and higher disease activity.

Conclusion:

The incidence of solid-organ malignancies was higher than hematological malignancies, unlike that in the literature. The overall risk of malignancy is higher in RA patients. Chronic inflammation from RA is associated with increased risk of malignancy.

Table 1

Crude Rates (CR) and Age standardize rates (ASR) of specific cancer types among the general population and rheumatoid arthritis cohort

Gender	Maligancy	Singapore general population (2009-2013)				1106 RA patients (2001-2013)

Accounting for Rheumatoid Arthritis in the Determination of 10 Year Cardiovascular Risk

Rupal Chavda and **Rochella A. Ostrowski**, Rheumatology, Loyola University Medical Center, Maywood, IL
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Patients with rheumatoid arthritis (RA) carry a higher risk for cardiovascular disease (CVD) independent of traditional risk factors. In this study, we set out to determine the proportion of patients in our practice who receive cholesterol screening, and we evaluated the effects of the EULAR (European League Against Rheumatism) risk multiplication factor[1] on the number of RA patients identified as having a high or moderate 10 year risk for CVD.

Methods:

A chart review was performed for adult RA patients evaluated as return visits in the division of Rheumatology at our institution from June 1, 2012 to June 1, 2013. Clinical information was reviewed for CVD or CVD risk equivalents (cerebrovascular accident, peripheral artery disease, diabetes mellitus). The Framingham 10 year risk for CVD was calculated for patients who did not have CVD or CVD risk equivalents. A risk multiplier of 1.5 recommended by the EULAR for patients with 2 risk factors (disease duration > 10 years, seropositivity, or severe extra-articular manifestations) was applied. We evaluated the proportion of patients who received cholesterol screening and the proportion of patients taking statin therapy as indicated by the 10 year risk, for CVD, with and without the EULAR risk multiplication factor.

Results:

Of 520 patients who met inclusion criteria, 364 (70% , 95%CI 66.0-73.9%) received cholesterol screening. The proportion of patients with ≥2 CVD risk factors who had high or moderate risk (>20% or 10-20% 10 year risk respectively) increased from 12.5% to 20% when the EULAR risk multiplication factor was applied (Table 1). Amongst patients with any number of risk factors, the proportion of patients with high or moderate risk increased from 10.3% to 14.6% (Table 2). Of 16 patients with ≥2 risk factors who were not at target for low density lipoprotein (LDL) levels, 11 were not receiving statin therapy. In the larger patient cohort, 31 patients were not at LDL goal, and 23 of these were not on statin therapy.

Conclusion:

Given the increased risk for CVD in RA patients, methods to increase the rate of cholesterol screening should be explored. Additionally, the EULAR multiplication factor serves as a valuable tool when determining the 10 year risk for CVD in RA patients who otherwise may not be identified as requiring lipid lowering therapy.

Quality Improvement in Elderly Patients with Rheumatoid Arthritis: Pharmacotherapy and Identification of Cognitive Dysfunction

Brett Smith[1] and Kenneth S. O'Rourke[2], [1]Section on Rheumatology and Immunology, Wake Forest School of Medicine, Winston-Salem, NC, [2]Section on Rheumatology and Immunology, Wake Forest University School of Medicine, Winston-Salem, NC

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Cognitive impairment (CI) casts a significant burden on individuals, caretakers and the US health care system with an estimated prevalence between 10-20%. While CI is seen in a portion of the general population, it has also been identified in systemic lupus erythematosus, primary Sjogren's syndrome, antiphospholipid syndrome and rheumatoid arthritis (RA). However, no study has specifically evaluated the prevalence of CI in adults with RA over the age of 65. Our goal was to assess the prevalence of CI in a cohort of elderly patients with RA, and to pilot an educational intervention in those affected.

Methods: A cross sectional, survey based study was conducted at a single tertiary center, outpatient rheumatology clinic. Inclusion criteria were >65 years of age and a history of RA by 1987 criteria. Exclusion criteria included overlap syndromes. Thirty patients were consecutively enrolled and underwent our novel rheumatology-specific screening tool, the Rheumatology Mini-Cog (RMC). Those who failed were administered the Mini-cog. Those passing the Mini-cog were presumed not to have CI and administered an educational intervention using the Teach Back method. Those failing the Mini-cog were presumed to have CI and participated in an educational intervention with a family member or friend.

Results: Thirty patients were recruited during routine office visits. The average age was 72.2 years, 83% were Caucasian and 70% were female. Eight of 30 patients (26.7%) were found to have CI. Of those with CI, there was a higher prevalence of erosive disease (57.1% vs 83.3%, p=0.36), longer disease duration (10.2 vs 19.5 years, p=0.01), higher RAPID-3 scores (9.16 vs 12.98, p=0.18), use of multiple DMARDs (22.7% vs 75%, p=0.04) and anti-TNF usage (13.6% vs 50%, p=0.06). There was no difference in frequency of diabetes, hypertension, depression or anti-depressant usage between groups.

Conclusion: Our study suggests the prevalence of CI in RA patients is significantly higher than the general population and may benefit from a one-time screening. The prevalence of CI was also correlated with disease duration and more aggressive disease, suggesting RA is an independent risk factor. While this is the first study to identify CI in older adults with RA, further studies would be warranted to assess the use of validated instruments and potential interventions, if CI is found.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Hypertension is highly prevalent in patients with rheumatoid arthritis (RA). High sodium and low potassium intake are both modifiable determinants of blood pressure in the general population and can be estimated by measuring urinary sodium and potassium excretion. Moreover, a high sodium:potassium ratio is associated with increased risk of high blood pressure. However, little is known about the relationship between sodium and potassium intake and blood pressure in patients with RA. Thus, we examined the hypothesis that sodium and potassium excretion is related to blood pressure and markers of inflammation in patients with RA.

Methods: We studied 166 patients with RA and 92 control subjects frequency-matched for age, sex, and race. First morning urine samples were collected and the concentrations of urine sodium and potassium were measured by flame photometry and 24 hour sodium and potassium excretion were estimated with the Kawasaki formula, a validated method that incorporates age, sex, height, weight, and urine creatinine. Blood pressure was the average of two resting measurements. In patients with RA, sedimentation rate and concentrations of vascular cell adhesion molecule-1, C-reactive protein, interleukin-6 and tumor necrosis factor were measured. Fisher's exact and Wilcoxon's tests were used to compare categorical and continuous variables, respectively. The associations between systolic (SBP), diastolic blood pressures (DBP), and inflammatory markers with estimated 24 hour urinary sodium, potassium, and sodium:potassium intake ratio were tested using Spearman correlations. For the blood pressure analyses, linear regressions were modeled to adjust for age, sex, and race.

Results: Patients with RA and control subjects had a similar mean age (54.2±11.9 vs. 53.2±11.6, p=0.43), were predominantly female (69% vs. 63%, p=0.41) and Caucasian (89% vs. 85%, p=0.44). Patients with RA had higher rates of hypertension (54% vs. 39%, p = 0.03). The estimated 24 hour sodium [median (interquartile range) of 5.1 (3.9-6.6) and 4.9 (4.0-6.5) g/day, respectively, p=0.90] and potassium [2.5 (2.1-3.2) and 2.7 (2.2-3.8) g/day, p=0.08] intake were similar in patients with RA and control subjects. The urinary sodium:potassium ratio was higher in patients with RA than in controls [2.0 (1.6-2.4) and 1.7 (1.5-2.1), p=0.02] but was not associated with blood pressure in either group. Lower potassium (g/day) intake was associated with DBP in patients with RA [β coefficient (95% CI) =-1.79**,** p=0.04], but there was no significant association between the estimated sodium or potassium intake or their ratio with markers of inflammation (all p>0.05).

Conclusion: Patients with RA had significantly lower estimated sodium:potassium intake ratio than control subjects. Higher 24 hour potassium intake was significantly associated with lower DBP in patients with RA. Further studies are needed to evaluate the impact of diets with low sodium and high potassium content on blood pressure in patients with RA.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Pulmonary involvement in rheumatoid arthritis (RA) patients is associated with high morbidity and mortality. Nevertheless, limited data are available regarding such lung complications in the Middle East, especially in the Kingdome of Saudi Arabia. The objective of the current study were to determine the prevalence of pleuropulmonary manifestations and to identify the risk factors predicting lung involvement.

Methods: This was a retrospective study involving 419 RA patients diagnosed at a tertiary center over a 12.5-year period. RA was diagnosed on the 2010 American College of Rheumatology (ACR) criteria. The frequency of pulmonary manifestations were recorded based on combined results from the chest X-rays, pulmonary function tests, and high resolution computed tomography (HRCT) scan on the chest.

Results: The overall frequency of lung involvement in RA was 25.8%. Pneumonia and bronchiectasis were the most common abnormalities (36% and 35% respectively). HRCT scan was more sensitive in detecting of pleuropulmonary abnormalities. . The presence of comorbid illness (OR=3.19, 95% CI: 2.02–5.1), male gender (OR=2.4, 95% CI: 1.3–4.24), and the presence of extra-articular manifestations (OR=2.35, 95% CI: 0.4–4.01) were significantly predicting lung involvement .

Conclusion: Pneumonia and bronchiactasis were the most common abnormalities seen in RA patients in Saudi Arabia. This finding were comparable with other studies.. The presence of comorbidity , male gender and extra-articular manifestation were statistically associated with lung involvement .

Table 1: Demographic and clinical characteristics of 419 RA patients

Safety, Clinical and Immunologic Effectiveness of the Live Zoster Vaccine Administered to Patients Receiving Anti-TNF Biologics

Jeffrey R. Curtis[1,2], Anita Turner[3], Corretta Thomas[4], Stacey Cofield[4], Randall Parks[5], Jennifer H. Ku[6], Ilhem Messaoudi- Powers[7], Keith Wanzeck[1] and Kevin L. Winthrop[8], [1]University of Alabama at Birmingham, Birmingham, AL, [2]Rheumatology & Immunology, University of Alabama-Birmingham, Birmingham, AL, [3]Clinical Immunology and Rheumatology, University of Alabama at Birmingham, Birmingham, AL, [4]School of Public Health, University of Alabama at Birmingham, Birmingham, AL, [5]Rheumatology, University of Alabama at Birmingham, Birmingham, AL, [6]Casey Eye Institute, Oregon Health & Science Univ, Portland, OR, [7]Oregon Health and Sciences University, Portland, OR, [8]Oregon Health & Science University, Portland, OR
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

The live herpes zoster vaccine (ZV) has been shown to be safe and effective in large randomized controlled trials of older adults. It is currently contraindicated in participants receiving immunomodulatory therapies such as biologic agents due to theoretical concerns regarding safety.

Methods:

VERVE is a 2-site, pilot study (n=125 participants) preparatory to a large NIH-funded pragmatic randomized controlled trial (RCT) of 1,000 participants

receiving anti-TNF therapy. Participants must be age >= 50 years, receiving any FDA-approved anti-TNF therapy for rheumatoid arthritis (RA), psoriatic arthritis (PsA) or other spondyloarthritis. Participants were randomized to ZV or blinded placebo. The primary outcome was immunogenicity at 6 weeks; secondary outcomes included clinical safety, tolerability, and long-term clinical effectiveness. For the pilot study, participants must also not have received glucocorticoid therapy within the past month. **Results** of this ongoing trial have not yet been unblinded. Therefore only baseline characteristics at the time of this abstract were available, presented as mean(SD) or %, as applicable.

Results:

A total of 95 participants have been screened for VERVE as of June 2015. Of these, 19 have been randomized (20.0%); 3(3.2%) tested negative on screening varicella ELISA testing and were considered screen failures; 73 (76.8%) have been enrolled and are awaiting randomization. Characteristics of the 19 randomized participants included age 60(7) years, 68.4% women, 73.7% with RA, 15.8% PsA. The most commonly used concomitant DMARD therapies were methotrexate (85.7%) and hydroxychloroquine (7.1%). Concomitant biologics included adalimumab (47.1%), etanercept (23.5%), Infliximab (17.6%), and golimumab (11.8%). The majority of participants had moderate disease activity (42.1%), with mean CDAI of 13.7(10.6). Among the 19 randomized who received ZV or placebo, there were no clinically significant serious adverse events attributable to the vaccine in the 40(16) days of follow-up (5.7 weeks; range 2.3, 9.0).

Conclusion:

Preliminary results from VERVE have shown no immediate safety-related issues when given to patients with autoimmune diseases being actively treated with anti-TNF biologic agents. Ongoing results for the entirety of the pilot study are expected by Nov. 2015 to further characterize the immunogenicity and effectiveness of the vaccine in abti-TNF users.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) treated with biologic agents are at increased risk of infection. Therefore, screening for urinary tract infection (UTI) with urine dipsticks (UD) is often performed as part of monitoring in the daily clinic regardless of UTI symptoms. We examined the prevalence of bacteriuria detected by UD and urine culture (UC), and the value of UD compared to UC in TNFi-treated RA patients. Secondary aims were to assess the reproducibility of UD and the association between UTI symptoms and results of UD and UC.

Methods: Urine samples from 126 adult RA patients treated with TNFi for ³ 6 months were collected according to standard guidelines and tested twice by use of an automated UD test (Clinitek) (one patient had only one UD performed), followed by quantitative UC. Positive UD test was defined as presence of leucocyte esterase and/or nitrite. UC with more than 100,000 CFU/mL was considered positive. True and false positive and negative rates (TPR, FPR, TNR and FNR) and positive and negative predictive values (PPV and NPV) were calculated. Cross-tabulations and X^2-tests were used to analyze the results.

Results: Patient characteristics are shown in Table 1 and urine test results in Table 2 and 3. Only one patient (0.8%) had UTI symptoms (UD negative). 4.8% (n = 6) of the patients had a positive UC. None of these had UTI symptoms and only 50% (n = 3) were UD positive (dipstick 1, 2 or both). In the patients as a whole (n = 126), UD was positive in 23% of the cases but only 10.3% (PPV) of these had a positive UC. The NPV for UD was 96.9% versus 95.2% for UTI symptoms. Duplicate UD results agreed (positive or negative) in 97.6% of the cases indicating high reproducibility.

Conclusion: Less than 5% of RA patients treated with TNFi had a positive UC, none of these had UTI symptoms and UD detected only half of the cases. The PPV for UD was only 10%. The NPV for UD was high, reflecting the low prevalence of positive UC in the study population. The results question the value of general UTI screening with UD and/or UC in the daily clinic.

Table 1. Basic characteristics of 126 RA patients.

Male:female ratio	1:3
Age at diagnosis (yrs), mean/SD (range)	44/14.13 (11.1-76.8)
Time since diagnosis (yrs), mean/SD (range)	15.1/10.7 (1.4-43.9)
Length of treatment with TNFi (yrs), mean/SD (range)	4.5/3.4 (0.1-12.9)
Positive RF and/or anti-CCP, n /%	84/67 (unknown in 7)
Erosive disease, n /%	69/55
Concomitant DMARDs, n /%	102/81
DAS28-CRP, mean/SD (range)	2.64/0.97 (1.2-6.5)

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Rheumatoid Arthritis (RA) patients are more prone to atherosclerosis. Oxidation of Low-density lipoprotein (LDL) is an important event in the development of atherosclerosis, especially of coronary and carotid arteries. We hypothesized that due to increased systemic inflammatory response in RA patients there will be higher subclinical/ clinical morphologic evidence of atherosclerosis in carotid arteries, leading to increased carotid intima media thickness (IMT). Our primary objective was to correlate serum Oxidized LDL level with Carotid IMT in RA patients; secondary objective was to correlate oxidized LDL

with disease activity by DAS 28.

Methods:

This descriptive observational case control study recruited 30 RA patients (1987 ACR criteria) without any comorbidities (diabetes mellitus, hypothyroidism, morbid obesity, dyslipidemia, chronic kidney disease, chronic liver disease, or known atherosclerotic disease) and 30 age and sex matched healthy controls; active smokers and non consenting participants were excluded. After history, examination and routine laboratory investigations, oxidized LDL levels were obtained by ELISA method. Carotid IMT was measured by Doppler ultrasonography (Philips HDI5000): Common carotid IMT (CCIMT), carotid bulb IMT (CBIMT), total carotid IMT (TCIMT), and internal carotid IMT (ICIMT) were measured by trainned radiologist. Means were compared using unpaired "t" test; correlation was measured using Pearson correlation method. SPSS version 19 was used for statistical analysis, and $p<0.05$ was considered significant.

Results:

Mean age of cases and controls was 43.13±13.32 and 42.87±15.03 years respectively; 86.67% (26/30) of all cases were females. DAS 28 score was found to be high among 27 cases in a range of severe disease activity (>5.1), while in 3 cases it was found that disease activity was in moderate range (3.2-5.1). Values of CCIMT, CBIMT, and TCIMT were significantly higher in RA patients ($p<0.05$); ICIMT values was not significantly different from controls. Mean oxidized LDL level was significantly higher in RA patients (9.03±6.12 microgram/ml vs 3.01±2.67 microgram/ml; $P<0.0001$). Pearson correlation test failed to show any correlation between oxidized LDL values and CCIMT, CBIMT, TCIMT, and ICIMT values in both cases and controls (Table 1). Oxidized LDL level was not significantly associated with disease activity (DAS 28) in RA patients.

Table 1:Correlation of oxidized LDL and CIMT in cases

	Ox-LDL	CCIMT	CBIMT	ICIMT	TCIMT
OX-LDLPearson correlation	1	-.115	-.277	-.139	-.203
Sig(2tailed)		.544	.138	.465	.281
CCIMT Pearson correlation	-.115	1	.113	.485	.881
Sig(2tailed)	.544		.551	.007	.000
CBIMT Pearson correlation	-.277	.113	1	.484	.516
Sig(2tailed)	.138	.551		.007	.004
ICIMT Pearson correlation	-.139	.485	.484	1	.775
Sig(2tailed)	.465	.007	.007		.000
TCIMT Pearson correlation	-.203	.881	.516	.775	1
Sig(2tailed)	.281	.000	.004	.000	

Conclusion:

On comparision with the general population, oxidized LDL values as well as carotid IMT values were markedly higher in RA patients, but the correlation was statistically non signifcant. Oxidized LDL values were also not statistically correlated with disease activity (DAS 28). Oxidized LDL can be used as an inflammatory marker in RA patients. This is the first study in RA patient from India and there is need for larger similar studies after these encouraging results.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Cardiovascular diseases, among which atherosclerotic heart disease, are known to be one of the most important mortality and morbidity causes in patients with Rheumatoid Arthritis (RA). Ischemia modified albumin (IMA) is a potential marker that can be used to assess atherosclerosis-related myocardial ischemia. Another frequently used marker for the assessment of atherosclerotic lesions is the carotid intima media thickness (CIMT). To evaluate role that IMA has on atherosclerosis development and its clinical usability in patients with RA, by assessing the values of IMA and CIMT.

Methods: Our prospective study was conducted between June 2012 and March 2013 at the rheumatology department of Meram Medical School. 52 RA patients, diagnosed according to the criteria of the 1987 American College of Rheumatology, and an age- and sex-matched control group of 46 healthy subjects were included in this study.

Results: No significant difference was detected between the groups with respect to age, sex and body mass index. Baseline laboratory characteristics of patients and controls. In the patient's group the IMA and CIMT values were found to be 0.37±0.12 ABSU and 0.80±0.22 mm respectively while in the control group were 0.31±0.11 ABSU and 0.51±0.18 mm respectively. The IMA and CIMT values were significantly higher in the patient's group ($p=0.022$ and $p<0.0001$ respectively). A positive correlation was found between IMA, CIMT and DAS-28 ($p=0.016$ and $p=0.002$ respectively) (Figure 1).

Conclusion: Since the values of IMA were higher in the patient's group compared to control and because of its correlation with CIMT, we suggest the usage of IMA as an early marker of atherosclerosis in RA patients.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Studies have reported that TNF-inhibitors (TNF-Is) are associated with a reduced risk of cardiovascular (CV) events,[1] but data on their effects on traditional CV risk factors in clinical practice are limited. The objective of this analysis was to evaluate mean changes from baseline (CFB) in CV risk factors of blood pressure (BP), lipids, hemoglobin A1c (A1c) and CRP among adult RA patients (pts) prescribed first bDMARDs. A secondary objective was to compare mean CFB in CV risk factors in pts prescribed abatacept (ABA) vs TNF-Is and other non-TNF-Is (excluding ABA). **Methods:** A retrospective analysis was conducted using GE Centricity® data, a nationally representative electronic database of >17 million de-identified medical records. Inclusion criteria were: ≥1 RA diagnosis code (January 2000–February 2014), aged ≥18 yrs at diagnosis, received a prescription for a bDMARD (index bDMARD), no bDMARD prescription during baseline (12 months prior to index bDMARD), ≥1 CV risk factor measured during the baseline period and 1 during follow-up, and receiving index bDMARD during 12-month follow-up. Lab values closest to the 12-month interval in a +/- 6-month window were used to calculate CFB. CFB in CV risk factors were described using mean, variance and SEs. Regression analyses were conducted for CFB in CV risk factors as dependent variables, and baseline covariates of demographics, co-morbidities, treatments to manage CV risk factors and RA treatments as independent variables. Sensitivity analyses were conducted to assess changes in CV risk factors among pts who had treatment changes for BP, lipids and diabetes. **Results:** 17,960 RA pts were included in the analysis. Mean (SD) age: 53.8 (13.5) yrs; 75.6% female; 6.5% had a CV event during baseline. Mean (SE; p-value) CFB were: systolic BP –0.50 mm Hg (0.165; 0.002); diastolic BP –0.28 mm Hg (0.103; 0.006); low-density lipoprotein (LDL) –2.42

mg/dL (0.81; 0.003); high-density lipoprotein (HDL) 0.23 mg/dL (0.27; 0.402); total cholesterol (TC) –1.87 mg/dL (0.83; 0.024); triglycerides –0.23 mg/dL (1.36; 0.864); A1c 0.01% (0.04; 0.767); CRP –0.61 mg/dl (0.099; <0.0001). Most (69%) pts did not have treatment for CV risk factors at baseline or follow-up; within this untreated subgroup, the CFB in CV risk factors were only statistically significant for HDL and CRP. Beta coefficients of the regression analysis for CFB in CV risk factors between pts prescribed ABA vs TNF-Is and ABA vs non-TNF-Is are shown in the Table; none were significant at an alpha level of 0.05.

Conclusion:

Though we observed that CV risk factors of BP, lipids (LDL-cholesterol and TC) and CRP levels were significantly reduced in RA pts prescribed bDMARDs, these reductions (except CRP) are likely driven by treatment for CV risk factors. There were no differences in changes in CV risk factor levels between pts prescribed abatacept and those prescribed TNF-Is or other non-TNF-Is.

First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: We aimed to evaluate the performance of QFT-GIT and T-SPOT.TB assays to predict the risk of latent tuberculosis infection (LTBI) in Japanese rheumatoid arthritis (RA) patients, measured simultaneously total and CD4-positive lymphocytes. When total or CD4-positive lymphocytes are suspected to be low due to aggressive treatment of RA, it remains unclear whether interferon-γ release assays (IGRAs) can be used reliably without increasing indeterminate results, and are affected by peripheral lymphocyte and CD4-positive cell counts

Methods: Because of no gold standard for LTBI, we compared with or without previous pulmonary tuberculosis infection as an alternative diagnosis using chest CT. We defined a history of TB infection (past TB infection group) as chest CT findings with old pulmonary TB infection. As a comparable control (non-TB infection group), we included a group of patients without prior contact with active TB, or old TB infection on chest CT. Sixty-eight patients treated with MTX and/or biologics were divided into two groups: 33 with and 35 without a past TB infection. MTX dose was 9.2 mg in those with a past TB infection and 11.0 mg in those without. Biologics was received 41% in the past TB and 57% in non-TB infection group. Mean total and CD4-positive lymphocyte in the past TB infection group decreased to 1,091/μL and 491/μL, respectively.

Results: The sensitivity and specificity of QFT-GIT for discriminating past TB infection were 21.2% and 100%, respectively. With a lower cutoff of 0.1 IU/mL (gray zone), the sensitivity and specificity of QFT-GIT were 30.3% and 96.9%, respectively. This gray zone of QFT-GIT requires further investigation to estimate the risk of TB. Positive T-SPOT.TB (SFC ≥6) were found in 21.9% in the past TB infection group, and 15.6% had SFC ≥8. With the positive cutoff (SCF ≥6) of T-SPOT.TB, the sensitivity and specificity were 21.9% and 100%. In the past TB infection group, 5 patients had positive QFT-GIT (≥0.35 IU/mL) and T-SPOT.TB (≥6 spots). The results for 4 patients with past TB were negative with T-SPOT.TB, but of these 4 patients, 3 in positive and 1 in the gray zone for QFT-GIT. The overall agreement of two IGRAs was high. Results were indeterminate in 4 (5.9%) of 68 patients, due to 3 patients decrease positive control of QFT-GIT and 1 increased negative control of T-SPOT.TB. QFT-GIT yielded results in 43% with low lymphocyte (<1000/μL) and 47% with low CD4-positive lymphocyte (<500/μL). In both IGRAs, PHA mitogen responses were not different between those treated with or without biologics. The positive rates of QFT-GIT and T-SPOT.TB decreased upon stimulation with TB antigens according to total and CD4-positive lymphocyte counts: this effect was more notable in QFT-GIT than T-SPOT.TB. When total lymphocytes (<1,000/μL) and CD4-positive lymphocytes (<500/μL) were low, the positive rates of QFT-GIT and T-SPOT.TB were low. Even where total and CD4-positive lymphocyte counts were low, the positive rate of QFT-GIT was increased when the gray zone range was included.

Conclusion: Two IGRAs had high specificities, but may falsely identify past TB infection owing to low sensitivities. Despite low total and CD4-positive lymphocyte counts, IGRAs could be utilized without high indeterminate rates.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid Arthritis impacts negatively on quality of life and work productivity. There are virtually no data on the employment status and burden of disease in RA patients from Latin-America (LA). To assess the burden of RA on work productivity and health related quality of life in LA patients.

Methods: Consecutive RA patients attending 20 rheumatology outpatient clinics distributed in Argentina, Brazil, Colombia and Mexico were included and completed the following standard questionnaires: Workplace Activity Limitations Scale (WALS), Work Productivity and Activity Impairment (WPAI), Work Limitations Questionnaire (WLQ), EuroQol (EQ-5D) and Short Form 36 Health Survey (SF-36). Sociodemographic data were also collected.

Results: The study included 309 patients, 90% female, mean age of 43 years (SD 9) and disease duration of 8 years (SD 8). At least 40% of patients reported some difficulty in all workplace activities (WALS), especially "crouching, bending, kneeling or working in awkward positions" (83%) and "lifting, carrying or moving objects" (80%). WPAI showed employment rate of 58%, and mean work time lost in a week of 4.3hs (SD 15.8). For WLQ, physical job demands were affected in 42% of patients followed by time demands in 34%. Mean self-evaluated health status using EQ-5D visual analogue scale (where 0=worst and 100=best health status) was 69 (SD 20), ranging from 63 (SD 22) in Brazil to 75 (SD 21) in Mexico. EQ-5D dimension mostly impaired was pain and discomfort with only 20.3% reporting have no problems in that dimension, while 72% reported have no problems with self-care. SF-36 physical and mental component scores for the total sample were 39 (SD 9.8) and 45(SD 11.4), respectively. Lower values were observed for the physical component in Brazil (34) and the mental component in Argentina and Colombia (44). The table below summarizes these results for each country analyzed.

Conclusion: RA affects both work performance and quality of life in a substantial proportion of patients. Although similar trends were shown among countries, Brazilian patients reported to be more affected in most of evaluated aspects.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Frailty has been defined as "an excess vulnerability to stressors, with reduced ability to maintain or regain homeostasis after a destabilizing event" [1]. Frailty is closely related to body composition and physical functioning, and is associated with increased risk of poor health outcomes including death. Serum inflammation is associated with differences in body composition and physical functioning in the general population and individuals with chronic disease. The ability of serum markers of inflammation to identify increased frailty among individuals with rheumatoid arthritis (RA) is unknown. This study tests whether serum erythrocyte sedimentation rate (ESR) and C-Reactive Protein (CRP) are associated with increased risk of frailty among men and women with RA.

Methods: Participants were individuals in a longitudinal cohort with physician-documented RA. All measures were collected during an in-person research visit. ESR and high sensitivity CRP were assessed from blood samples using standard clinical assays. Individuals with 3 or more of the following physical deficits were classified as frail[1]: 1) body mass index $\leq$ 18.5, 2) low grip strength (adjusted for sex and BMI, measured by handheld dynamometer), 3) severe fatigue (measured by the Fatigue Severity Inventory), 4) slow 4-meter walking speed (adjusted for sex and height), 5) low physical activity (measured by the International Physical Activity Questionnaire). Individuals with 1 or 2 deficits were classified as "pre-frail", and those with no deficits as "robust." [1] Multinomial logistic regression analyses controlling for age, sex, smoking status, RA disease duration, prednisone use, tumor necrosis factor inhibitor use, appendicular lean mass, and pain modeled the effects of ESR and CRP on severity of frailty.

Results: Of the 141 participants, 60% were female; mean age was 58 (±11) years, duration of RA was 19 (±11) years, ESR was 19 (±19) mm/h, and hsCRP was 5 (± 8) mg/L. Sixteen participants (11%) were frail, 86 (61%) pre-frail, 22 (16%) robust, and 17 (12%) were missing grip strength data. In adjusted models, higher ESR was associated with significantly increased risk of frailty (Table 1). Similar trends were observed between CRP and risk of frailty, but did not reach statistical significance in adjusted models.

Conclusion: Frailty and pre-frailty were common in our cohort of individuals with RA, with a greater prevalence than that of geriatric populations. Serum levels of ESR were associated with approximately twice the risk of being frail or pre-frail compared to being robust. CRP demonstrated similar effects on

risk of frailty, though trends did not reach statistical significance. These findings underscore the high burden of frailty among individuals with RA, and they may suggest a clinical role for serum ESR and CRP in identifying individuals with RA at greatest risk of frailty.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with Rheumatoid arthritis (RA) experience declining functional ability, quality of life, employment and work productivity. Such outcomes have been described in homogeneous, mostly Caucasian cohorts. Our objective was to characterize baseline determinants of employment, absenteeism, presenteeism, work productivity loss (WPL), and activity impairment (AI) in Latinos with RA in the US. We further explored longitudinal predictors of both maintenance of employment, as well as of regaining employment over time.

Methods: We assessed 303 Latinos with RA and regular follow up in a single center between 2011 and 2014. Evaluator outcomes- including global disease activity (EGA), swollen and tender joints, sedimentation rate (ESR)- and patient reported outcomes such as global activity (PGA), disability (Health Assessment Questionnaire, HAQ-DI), pain, fatigue, and depression (Patient Health Questionnaire, PHQ9) were recorded at baseline and follow-up visits, at a median of 2 years. A Work Productivity and Activity Impairment (WPAI) questionnaire was completed at both times. Linear and logistic regression models evaluated predictors of outcomes of interest at baseline. Cox regression models assessed survival of employment, regaining employment, and their determinants longitudinally.

Results: At baseline, 77 (25%) patients were employed; they were younger, had lower ESR, prednisone use and numbers of concurrent synthetic disease modifying agents-DMARDs (all <0.05). They also had lower PGA, disability, pain, fatigue, and activity impairment (all <0.05). Higher HAQ-DI, DMARD numbers, and pain negatively associated with employment (table 1). Fatigue and HAQ-DI strongly predicted presenteeism and WPL in those employed, while pain and PGA additionally predicted AI in all. Those remaining employed (68%) had lower depression scores; employment survival was further predicted by decrease in tender joints, fatigue, and EGA. Those gaining employment (11%) were significantly younger, with lower baseline HAQ-DI and greater changes in HAQ-DI (all, p<0.05).

Conclusion: Few Latinos with RA are gainfully employed. HAQ-DI is a durable predictor of baseline employment, work productivity loss and activity impairment; its change- in those unemployed- further determines who regains employment. Patient-reported outcomes such as fatigue, pain, and PGA

significantly and differentially contribute to several aspects of work productivity and activity impairment.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Rheumatoid Arthritis (RA) is associated with low bone mass and increased risk of fragility fractures that are related to patient characteristics, treatments and disease activity.

Trabecular Bone Score (TBS) is a new gray-level texture measurement derived from lumbar spine DXA images, independent of bone mineral density (BMD).

In early RA patients, to quantify TBS and its determinants.

Methods:

From an early RA unit, we selected all the patients who had been prospectively followed from the disease onset according to a predefined protocol, based on a tight control strategy, and had at least a bone densitometry available to calculate TBS. Four patients were excluded because of a body mass index (BMI) greater than 35 kg/m^2, since TBS is not reliable in those cases. The study variables were: 1) Demographics: age, sex, body mass index (BMI); 2) RA history: duration, RF, ACPA; 3) Disease activity: DAS28 and CRP; 4) Disability: HAQ; 5) RA treatment; 6) Spine and proximal femur BMD; and 7) TBS.

Results:

We included 170 patients (116 female) with a mean age of 54 ± 14 years and a BMI of 27 ± 4.5 kg/m^2. Sixty-seven percent of the patients had RF+ and 60% had ACPA + (mean title: 330 ± 524 U/L). At diagnosis, mean DAS28 was 5.77 ± 1.31; CRP was 26 ± 39.3 mg/L; and HAQ, 1.500 ± 0.654.

Mean BMD in lumbar spine was 0.967 ± 0.162 g/cm^2; in femoral neck, 0.779 ± 0.218 g/cm^2; and in total femur was 0.952 ± 0.143 g/cm^2. Forty-nine percent of the patients had a normal BMD, 34% had osteopenia and 17% had osteoporosis, according to WHO diagnostic classification. Mean TBS was 1.345 ± 0.123. Fifty-two percent of the patients had normal bone microarchitecture, 35% had partially degraded microarchitecture and 13% had degraded microarchitecture. Ten-year probability of having a major osteoporotic fracture, calculated by combining TBS and WHO categories according to data of Hans D *et al** and expressed according to the system of the Canadian Association of Radiologists and Osteoporosis Canada (CAROC), was low (< 10%) in 78% of the patients, medium (10-20%) in 16% and high (>20%) in 6%.

In the multivariate analysis, TBS correlated with age (r: -0.50), BMI (r: -0.50), CRP (r: -0.15) and BMD at lumbar spine (r: 0.34). These variables accounted for 51% of the variability of TBS (Regression line: TBS: 1.583 - (0.003 x age) - (0.013 x BMI) + (0.273 x LS BMD)). TBS did not correlate with other study variables.

Conclusion:

Almost half of early RA patients have a deterioration of bone microarchitecture assessed by TBS. In these patients, TBS is very dependent on age, BMI and BMD at lumbar spine. Other disease variables are not related to TBS.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Decreases in circulating neutrophil counts have been observed in adults with rheumatoid arthritis (RA) and children with systemic or polyarticular juvenile idiopathic arthritis treated with the interleukin-6 (IL-6) receptor-α antagonist tocilizumab (TCZ). However, no temporal relationship with risk for infection has been demonstrated to date, and the mechanism of neutrophil count decrease associated with TCZ is unclear. Previous research in RA patients showed that TCZ had no effect on neutrophil function or survival when assessed 4 and 12 weeks after TCZ initiation[1]; however, the effects of TCZ on neutrophil function and survival at the neutrophil nadir (day 4 [D4] after TCZ administration) have not been assessed.

Methods: Healthy male subjects age 18-65 years received a single intravenous dose (blinded to subjects only) of TCZ 8 mg/kg or placebo (PBO) on day 0 (D0). Neutrophil function and survival were assessed ex vivo in isolated polymorphonuclear leukocytes (PMNs) on D0 predose and on D4. Neutrophil apoptosis, phagocytosis, production of reactive oxygen species (ROS), morphology, and surface markers (adhesion molecules CD11b, CD62L, and CD162; CD16) were assessed.

Results: TCZ was administered to 12 subjects and PBO to 6 subjects. Neutrophil count decreased with TCZ but not with PBO. No subjects experienced a drop in their neutrophil count $<1\times10^9$/L. TCZ-treated subjects were divided into 2 groups: PMN high (subjects with ≤50% reduction in D4 neutrophil count relative to baseline, n=5) and PMN low (subjects with >50% reduction in D4 neutrophil count relative to baseline, n=7). Mean neutrophil counts at D4 as percentages of D0 levels were 102% in the PBO group, 72% in the PMN-high group, and 45% in the PMN-low group. The functional capacity of neutrophils was unaffected by the administration of TCZ, as demonstrated by intact respiratory burst activity and intact phagocytosis of heat-killed *S. pneumoniae* at D4 (Table). Survival of neutrophils after 20 hours of culture was unaffected in the TCZ-treated subjects, with apoptosis rates showing no differences between PBO and TCZ groups either under control conditions or in the presence of the prosurvival factors granulocyte macrophage–colony-stimulating factor and tumor necrosis factor-α (Table). Surface markers and neutrophil shape change were also similar among the PBO, PMN-low, and PMN-high groups at D4 in both control and stimulated PMNs (Table). No serious adverse events were reported.

Table. Function and Survival of Neutrophils 4 Days After TCZ Administration

FSC, forward scatter; FITC, fluorescein isothiocyanate; fMLP, *N*-formyl-methionyl-leucyl-phenylalanine; GM-CSF, granulocyte macrophage–colony-stimulating factor; HRP, horseradish peroxidase; PI, propidium iodide; PMN, polymorphonuclear leukocytes; RLU, relative light unit; ROS, reactive oxygen species; TNF-α, tumor necrosis factor-α. Data are means (SE). ROS generation was measured by peak fMLP-stimulated HRP-luminol chemiluminescence. Bacterial phagocytosis was measured by fluorescence of eFluor670-labelled, heat-killed *S. pneumoniae* by flow cytometry. Apoptosis was measured by flow cytometry using annexin V-FITC/PI staining and by assessment of microscopic morphology. Neutrophil surface markers were measured by flow cytometry in control and fMLP-stimulated PMNs. Shape change in control and fMLP-stimulated PMNs was measured by flow cytometry, as median FSC and as percentage shape change, and by microscopic morphology.

Conclusion: IL-6 blockade with TCZ resulted in reduced counts of circulating neutrophils. However, the functional capacity and survival of neutrophils at the D4 nadir were unaffected by TCZ treatment; this may support why, to date, no temporal associations between decreased circulating neutrophil counts and increased risk for infection have been observed.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a risk factor for septic arthritis (SA), and anti-TNF therapy doubles the risk of SA. The purpose of this study was to see whether the frequency and features of SA complicating RA have changed over the last 35 years.

Methods: This retrospective single-center study included the full register of all patients hospitalized at the rheumatology department of Clermont-Ferrand—CHU between 1979 and 2013 for septic arthritis bacteriologically documented by synovial fluid and/or blood culture samples. The periods 1979–2002 (period before biotherapies) and 2003–2013 (last decade in the era of biotherapies) were compared.

Results: Between 1979 and 2013, 64/514 (12.5%) SA presented with a RA—21/153 (13.7%) in the 2003–2013 period and 43/361 (11.9%) in the 1979–2002 period. Over the past decade, median age of SA–RA patients increased (61 *vs* 68 years; $p<0.02$) and predominant gender became males (52% *vs* 40%). The features of the RA remained unchanged: history (18 years (8–29) *vs* 16 (8–25)), rheumatoid factor (95% *vs* 87%), and corticosteroids (91% *vs* 81%) at the same mean dose (10 mg/d). 71% in the period before biotherapies and 63% in the last decade received a DMARD. Over the last decade 24% (*vs* 0; $p<0.003$) of patients received a biologic DMARD: etanercept (n=2), adalimumab (n=1), rituximab (n=1), tocilizumab (n=1). Proportion of polyarticular infection had decreased (9.5% *vs* 37%; $p<0.02$), down to the same level as SA-non-RA cases (8%). Proportion of *S. aureus* infections had stabilized (62% *vs* 74%) in SA-RA patients but was higher than SA-non-RA (47% and 53%). MRSA infections became more frequent in SA-RA (31% *vs* 6%; $p<0.05$) in contrast to SA-non-RA cases (8% *vs* 16%; ns). Gram-negative bacilli infections have tended to become more frequent (19% *vs* 5%; $p=0.08$). Blood cultures less often tested positive (29% *vs* 47%; ns). Mortality rates has fallen slightly (5% *vs* 9%; ns), in contrast to SA-non-RA cases (7% *vs* 6%; ns).

Conclusion: This study brings reassuring findings—in the era of biotherapies, the frequency of septic arthritis complicating rheumatoid arthritis has stabilized, and the most severe septic polyarticular forms are on the decline.

Occurrence of Valvular Heart Disease in Rheumatoid Arthritis: A Population Based Study

Tamanna Khullar[1], John P. Bois[1], Cynthia S. Crowson[2], Megan L. Krause[3] and Rekha Mankad[1], [1]Cardiovascular Diseases, Mayo Clinic, Rochester, MN, [2]Health Sciences Research, Mayo Clinic, Rochester, MN, [3]Rheumatology, Mayo Clinic, Rochester, MN

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) are known to have an increased risk of cardiovascular disease, particularly atherosclerosis and heart failure. However, little is known about the occurrence of valvular heart disease (VHD) in RA. The purpose of our study was to investigate the occurrence of VHD among patients with RA compared to the general population.

Methods: A population based inception cohort of residents of a geographically well-defined area with adult onset RA who met 1987 ACR criteria in 1998-2007 and a comparison cohort of age and sex matched non-RA subjects from the same population base were assembled and followed until death, migration or the present. Echocardiograms were reviewed to determine the occurrence of VHD as defined by the 2014 ACC/AHA guidelines. Cumulative incidence of VHD adjusted for the competing risk of death was estimated.

Results: The study included 379 patients with RA and 379 non-RA subjects (mean age 55.1 [SD 15.2] years, 69% women in both cohorts). Among these cohort of patients, 117 patients with RA and 89 non-RA subjects had at least 1 echocardiogram performed after incidence/index date. The prevalence of VHD was similar in the RA and non-RA cohorts at RA incidence/index date(2% versus 3%; $P=0.82$). The cumulative incidence (± SE) of any valve disease during follow up was higher among patients with RA compared to non-RA subjects(26% ± 2.5% versus 16.9% ± 2.1% at 10 years; $P=0.013$). The

difference persisted after adjustment for age, sex, and calendar year of RA incidence/index date (hazard ratio[HR]:1.49; 95%CI: 1.11,1.99). Among all valve diseases, the cumulative incidence of any grade of mitral regurgitation (MR) (24.6% ± 2.4% versus 15.6% ± 2.0% at 10 years; p=0.015) and tricuspid regurgitation (TR) (23.1% ± 2.4% versus 16.3% ± 2.1%; p=0.045) were significantly higher in patients with RA compared to non-RA subjects. The cumulative incidence of at least moderate MR (4.3% ± 1.2% versus 3.0% ± 0.9%; p=0.95) and at least moderate TR (6.6% ± 1.5% versus 3.7% ± 1.1%; p=0.23) were not significantly different between RA and non-RA. Risk factors for valve disease occurrence in patients with RA included age (HR 2.08 per 10 year increase; 95% CI: 1.79, 2.42), atrial fibrillation (HR 2.67: 95%CI: 1.63, 4.37), stroke (HR 2.45; 95%CI: 1.41, 4.26), coronary heart disease (HR: 2.25; 95%CI: 1.45, 3.49). Joint erosions were associated with reduced risk of valvular disease (HR 0.67, 95% CI 0.45, 0.99). Rheumatoid nodules, joint surgery, elevated ESR in first year of diagnosis, DMARDs, and biologics were not associated with risk of valve disease. Risk factors for at least moderate valve disease included atrial fibrillation and stroke as well as severe extra-articular manifestations (HR 4.22; 95%CI: 1.64, 10.86).

Conclusion: Although VHD has not been considered to be a major cardiac manifestation of RA, our current study has revealed a higher than anticipated incidence of asymptomatic valvular involvement. MR and TR incidence is more common than any other valve diseases.

Age Related Disability in Daily Life Should be Considered in Older Than Sixty-Five-Year-Old Rheumatoid Arthritis Patient

Ichiro Yoshii[1] and Tatsumi Chijiwa[2], [1]Department of Orthopaedic Surgery, Yoshii Hospital, Shimanto, Japan, [2]Rheumatology, Kochi Memorial Hospital, Kochi, Japan

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

In treating rheumatoid arthritis (RA), patient's activity in daily life (ADL) is extremely important factor, because RA is chronic inflammatory disease that leads discomfort or disability in ADL in natural. In RA treatment, patient is usually interviewed and evaluated. Health assessment questionnaire (HAQ) is common index for ADL. In general, HAQ is thought to be influenced by disease activity and structural damage, thus it consists of activity related HAQ (ACT-HAQ) and damage related HAQ (DAM-HAQ). It is widely accepted in rheumatologist. However, HAQ often results in unexpected. It is more frequently seen in elderly patient, that even joint deformity is minimum and disease activity is well controlled. We have been thinking that HAQ is not only with ACT-HAQ and DAM-HAQ, but other factors have affected on HAQ. Aging is candidate for HAQ influencing factor. We have evaluated effect of aging on HAQ.

Methods:

579 RA patients had been treated more than 1 year in our clinic. In these, 257 patients who have been treated consecutively for more than three years had been recruited for analysis in this study. These patients have been consulted in one to three months interval, and have been evaluated their disease activity as twenty-eight joints disease activity score with C-reactive protein (DAS28-CRP), daily activity as HAQ disability index (HAQ-DI), and radiographic evaluation with Sharp/van der Heijde score (SHS) from X-ray pictures of bilateral hands and feet have been taken at first, and mostly one year period. HAQ-DI, DAS28-CRP, SHS, and age at first (@BL), and average value of these indices in follow up (@F) were calculated for every patient, and relationship between HAQ-DI@F, and each of other indices had been evaluated statistically with single regression analysis. Then relationship between HAQ-DI@F and every other index had evaluated with multiple regression analysis.

In additional, patients were classified according to Age@F, whether less than sixty-five (G-Y) or not (G-O). HAQ-DI@F, DAS28-CRP@F, and SHS@F of the two groups were compared statistically with ANOVA. Relationship between age and HAQ@F were statistically evaluated with linear regression analysis for each age group.

Results:

All indices but DAS28-CRP@BL demonstrated significant positive relationship with HAQ-DI@F ($p < 0.0001$) in single regression analysis, and for multiple regression analysis, every index has demonstrated significant positive relationship between HAQ-DI@F.

In ANOVA study, G-O demonstrated significantly higher HAQ-DI in both @BL and @F ($p < 0.0001$), although no significant difference have demonstrated for other indices. Age@F demonstrated significant positive correlation with HAQ@F in G-O ($p < 0.0001$), although in G-Y there have shown no significant correlation.

Conclusion:

These results suggested that HAQ-DI is not consisted only with ACT-HAQ and DAM-HAQ. HAQ@BL has extremely strong influence on HAQ-DI

thereafter, and at the same time, age is also very important factor that determines HAQ-DI. For the reason, elderly patients tend to diminish HAQ-DI reduction by disease activity control. In treating RA, we need to consider patient's age to make optimal results for treatment.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is associated with increased risk of cardiac mortality. With better treatment modalities, some studies suggest that infarction (AMI) mortality in RA has decreased. We aimed to evaluate temporal trends of incidence and mortality of RA in AMI hospitalizations in a nationally representative sample.

Methods: We reviewed Nationwide Inpatient Sample (NIS) data over 10 year period from 2002-2011 for adult AMI hospitalizations as a primary diagnosis with RA as secondary diagnosis using validated ICD9-CM codes. We calculated unadjusted proportions of mortality yearly and used survey logistic regression to calculate adjusted odds ratios (aOR) for hospital mortality and adverse discharge and after stratifying for age (≤50 vs. >50).

Results: We identified a total of 6588743 AMI hospitalizations from 2002-2011 of which 77040 (1.16%) had a diagnosis for RA. The proportion of patients with RA in AMI hospitalizations increased from 0.96% in 2002 to 1.44% in 2011. RA hospitalizations were older (70.4 vs. 67.7 years; p<0.01); more female (62.7% vs. 40%; p<0.01); with a higher proportion of whites (82.3% vs. 77.7%; p<0.01) and a higher Charlson comorbidity index (2 vs. 1.5; p<0.01). The unadjusted mortality rates in RA hospitalizations yearly were similar to hospitalizations without RA. (Figure 1) After adjusting for age, gender, race, Charlson comorbidity index, hospital level characteristics, cardiac procedures, RA hospitalizations had lower odds-ratio for hospital mortality (aOR=0.76; 95% CI= 0.70-0.83; p<0.01) compared to non-RA hospitalizations. However, in hospitalizations ≤50 years, there was no significant difference in the adjusted odds of hospital mortality (aOR=0.68; 95% CI 0.38-1.21; p=0.19) or adverse discharge (adjusted aOR=1.03; 95% CI 0.84-1.28; p=0.73)

Conclusion: The odds of hospital mortality in RA hospitalizations with AMI are lower than non-RA hospitalizations. This is likely related to better disease recognition and risk modification in RA patients. However, the mortality in RA hospitalizations younger than 50 years was similar to non-RA hospitalizations, suggesting an unmet need for better disease and comorbidity management in younger RA patients.

Figure 1. Proportion of Mortality in AMI Hospitalizations Stratified by Rheumatoid Arthritis Status

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Obesity has recently been spotlighted as an important comorbidity in rheumatoid arthritis (RA); not only associated with disease severity but also its development. Despite that the long-term impact of obesity in RA should be studied in longitudinal studies, our aim was to investigate what clinical aspects of obese Korean RA patients would differ from those with normal body mass index (BMI) in a cross-sectional study.

Methods: COMORA is an international (17 countries), cross-sectional study investigating demographics, disease characteristics, and comorbidities (cardiovascular, infections, cancer, gastrointestinal, pulmonary, osteoporosis and psychiatric disorders) in RA patients. The Korean delegation consisting of 11 centers nationwide provided clinical data of total 1050 RA patients. We divided the RA patients into 2 groups (table); those with normal BMI (n= 834) versus (vs.) BMI equal to, or higher than 25 (abnormal BMI, n= 216).

Results: Demographic and medication data between normal vs. abnormal BMI were mostly comparable, but not for age (55.4 vs. 58.5, p= 0.0005) and education level (lower in the abnormal BMI group, p= 0.0072). Additional parameters were compared adjusting age, gender, disease duration, and education level. Disease activity at survey was similar between the 2 groups. Modified HAQ scores were significantly higher in patients with abnormal BMI (p= 0.028), and prevalence of hypertension, dyslipidemia were much higher in the abnormal BMI group, as expected. Additionally, data from the other 16 countries (COMORA-EK) was compared with Korean patients (COMORA-K). Interestingly, abnormal BMI patients in COMORA-EK showed higher disease activity (swollen, tender joint counts, DAS28-ESR, DAS28-CRP), which was not appreciated in COMORA-K.

Conclusion: These data demonstrate that overweight RA patients have worse functional status in general, yet abnormal BMI does not seem to affect disease activity in Korean patients to the degree observed in COMORA-EK.

Table. Selected clinical parameters from COMORA-K and -EK

Parameters	COMORA-K				COMORA-EK			
	Normal BMI (n= 834)	Abnormal BMI (n= 216)	p-value	p-value*	Normal BMI (n= 1710)	Abnormal BMI (n= 1810)	p-value	p-value*
Body mass index	21.4 ± 2.1	27.5 ± 2.4	< 0.001		22.0 ± 2.1	30.2 ± 4.7	< 0.001	
Age, years	55.4 ± 12.4	58.4 ± 11.1	0.0005		56.2 ± 14.3	56.4 ± 12.0	0.6018	
Gender (female %)	83	82	0.6026		82	80	0.0882	
Disease duration	7.0 ± 6.3	6.6 ± 6.2	0.4796		10.1 ± 9.2	9.6 ± 8.6	0.0811

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is characterized by inflammation of the synovial membrane of the diarthrodial joints which include arthrodesis of the middle ear, (incudomalleolar and incudostapedial joints) causing conductive hearing impairment (CHI). Extra-articular involvement may also affect the auditory system targeting the inner ear causing sensorineural hearing impairment (SNHI). The majority of the risk factors for SNHI reported in the literature are related to the cardiovascular system, as the inner ear may be vulnerable to circulatory alterations affecting the labyrinthine artery; however the physiopathology of hearing impairment in RA remains unclear. We decided to evaluate, in a cohort of RA patients without known cardiovascular risk factors, the association of hearing impairment and subclinical atherosclerosis.

Methods: RA patients (according to the ACR classification criteria) with no known traditional cardiovascular risk factors were included. Routine clinical and laboratory assessments for RA patients were included. Pure tone air (125 – 8000 Hz) and bone conduction (250 – 6000 Hz) thresholds were obtained, tympanograms were classified according to Jerger and impedance audiometry was done. SNHI was defined if the average thresholds for at least one of low-, mid-, or high-frequency ranges were ≥25 decibels (dB) hearing level in one or both ears. Carotid Intima-Media Thickness (cIMT) was assessed. Two segments from the common carotid artery (CCA), one from the carotid bifurcation (BF) and two from the internal carotid artery (ICA) were evaluated. Patients were classified according to the cIMT with a cut-off point of 0.6mm.

Results: Forty-one RA patients were included into the study, 39 (95.1%) were female. Mean (SD) age and disease duration were 46.46 (10.20) and 7.05 (7.37) years respectively. Twelve patients (29.2%) had normal audition, 29 (70.8%) had hearing impairment; of them, 28 (68.3%) had SNHI [22 (53.6%) bilateral, 24 (58.5%) left and 26 (63.4%) right], three patients (7.3%) had right CHI and one (2.4%) had left CHI. No significant differences were found between disease activity, rheumatoid factor and anti-CCP among SNHL and normal hearing RA groups. Patients with SNHI had thicker levels of cIMT in the media segment of carotid common artery vs patient with normal hearing (right ear 0.21±0.29 vs 0.02±0.10 mm, $p = 0.007$; left ear 0.20±0.30 vs 0.06±0.18 mm, $p = 0.075$) (Table 1)

Table 1. Type of audition according to the cIMT

	Rigth ear			Left ear		
cIMT (right and left, respectively, mm)	Normal n = 15	SNHI n = 26	*p*	Normal n = 17	SNHI n = 24	*p*
Proximal CCA	0.43 ± 0.29	0.46 ± 0.29	0.740	0.41 ± 0.28	0.50 ± 0.32	0.370
Media CCA	0.02 ± 0.10	0.21 ± 0.29	**0.007**	0.06 ± 0.18	0.20 ± 0.30	0.075
Distal CCA	0.44 ± 0.42	0.61 ± 0.45	0.244	0.45 ± 0.31	0.57 ± 0.39	0.341
Bulb	0.48 ± 0.36	0.51 ± 0.34	0.784	0.54 ± 0.44	0.50 ± 0.41	0.754
Proximal ICA	0.44 ± 0.30	0.46 ± 0.28	0.791	0.49 ± 0.36	0.40 ± 0.30	0.420
Distal ICA	0.34 ± 0.30	0.40 ± 0.38	0.562	0.35 ± 0.34	0.39 ± 0.29	0.704

cIMT, carotid intima media thickness; SNHI, sensorineural hearing impairment; CCA, carotid common artery; variables are expressed as mean ± standard deviation. Statistical significance: $p \leq 0.05$

Conclusion: Thickening of the carotid Intima-Media was associated with SNHI in RA patients. Unknown cardiovascular risk factors may contribute to accelerated atherosclerosis and hearing impairment in RA patients. Further studies are needed to elucidate this association.

Effect of TNF-Alpha Blockade on Body Composition in Inflammatory Rheumatic Disease: Systematic Review with Meta-Analysis

sarah marouen[1], Thomas Barnetche[2], Bernard Combe[3], Jacques Morel[4] and Claire I. Daien[4], [1]Rhumatology Department, Lapeyronie Hospital and Montpellier University, Montpellier, France, [2]Rheumatology Department, Pellegrin University Hospital, BORDEAUX, France, [3]Rheumatology, Hopital Lapeyronie, Montpellier, France, [4]Department of rheumatology, Lapeyronie Hospital and Montpellier University, Montpellier, France
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Patients with chronic inflammatory rheumatic disease have elevated circulating concentrations of TNF-alpha and other pro-inflammatory cytokines that can modify body composition. Metabolic changes are involved in the onset of cardiovascular disease events. We aimed to evaluate the body composition of patients with Rheumatoid Arthritis (RA) or Spondyloarthritis (SpA) and to assess the effect of TNF-alpha inhibitors (TNFi) on body composition, using systematic review with meta-analysis.

Methods:

PubMed, Cochrane Library, and congress abstracts databases were searched for articles published up to February 2015. Search terms were ("body fat distribution" OR "fat mass" OR "lean mass" OR "body mass component" OR "body composition" OR "body fat distribution") AND ("rheumatoid arthritis" OR "spondylarthritis" OR "psoriatic arthritis" OR "spondylitis" OR "ankylosing spondylitis"). We restricted the search to adult subjects and body composition using by Dual Energy X-Ray Absorptiometry (DEXA). TNFi effects on body composition were assessed at 6, 12 and 24 months in a systematic review. A meta-analysis comparing DEXA body composition in patients with RA or SpA versus healthy controls was performed using Revman program with an inverse variance model. Heterogeneity was evaluated with Cochran's Q-test and I^2value P-values less than 0.05 were considered as significant.

Results:

Among the 208 articles reviewed, 16 studies met the inclusion criteria. In RA patients, a significant increase in fat mass (+ 1.85 kg, p = 0.02, n= 328, I^2= 0%), adiposity (+ 1.7 %, p < 0.00001, n= 219, I^2= 0%) and android mass (+ 3.53 kg, p < 0.00001, n= 309, I^2= 74%) and a significant decrease in lean mass (- 3.03 kg, p = 0.01, n= 308, I^2= 70%), were observed. In SpA patients, a significant but modest increase in fat mass (+ 0.69 kg, p = 0.03, n= 143, I^2= 0%) and a significant decrease in lean mass (-3.74 kg, p = 0.03, n= 143, I^2= 28%) was observed. TNFi did not modify body composition at 6 and 12 months, whereas at 24 months TNFi were associated with fat mass increase in RA patients (+ 2.32 kg, p = 0.04, I^2= 32%) and SpA patients (+1.64 kg, p<0.00001, I^2= 0%) and lean mass increase in RA patients (+0.49 kg, p=0.003, I^2= 0%) and in SpA patients (+0.9 kg, p<0.0001, I^2= 0%).

Conclusion:

Only RA patients have a significant increase of fat mass, that could be related to frequent steroids usage by contrast with SpA. Both RA and SpA patients have a significant decrease of lean mass probably explained by chronic inflammation since it was restored 2 years after initiation of TNFi. Increase of fat mass after TNFi may be explained by an increase in ghrelin.

Clinical Analysis of 30 Rheumatoid Arthritis Patients Complicated with Malignant Lymphoma, Especially Methotrexate-Related Lymphoproliferative Disorder

Takuma Tsuzuki Wada[1], Yuji Akiyama[1] and Toshihide Mimura[2], [1]Department of Rheumatology & Applied Immunology, Faculty of Medicine, Saitama

Medical University, Iruma, Japan, [2]Department of Rheumatology and Applied Immunology, Faculty of Medicine, Saitama Medical University, Saitama, Japan

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Recently, methotrexate (MTX) has been considered as the anchor drug in the treatment of rheumatoid arthritis (RA). However, it has been reported that MTX occasionally induced lymphoproliferative disorder (LPD) most of which is malignant lymphoma (ML), especially in Japan. MTX-LPD is one of the "other iatrogenic immunodeficiency-associated lymphoproliferative disorders (OIIA-LPD)" in the WHO classification. A line of evidence suggests that Epstein-Barr virus (EBV) infection may be involved in the pathogenesis of MTX-LPD, however, precise mechanism and the risk factor of MTX-LPD have not been known yet. Although some of MTX-LPD naturally improves by discontinuing MTX, other may need the chemotherapy for fatal ML. Taken together with the several reports showing that RA itself increases the risk of ML, this problem needs to be solved. Thus, we investigated clinical courses of 30 RA patients complicated with ML in our hospital.

Methods: We analyzed clinical characteristics and course of 30 RA patients complicated with ML retrospectively and compared their laboratory data with those from 1260 RA patients without ML in our department.

Results: Characteristics of the thirty patients (23 female); age 62.5±10.0 years, disease duration 9.2±0.6 years. Twenty-one were diagnosed as MTX-LPD. Three patients with MTX-LPD were naturally improved by discontinuing MTX, however, 2 of those patients were relapsed. Twelve patients among 15 patients with MTX-LPD on chemotherapy have continued to be complete remission. One patient died after chemotherapy. The dose of MTX was under 8mg/week in 13 among 15 patients and duration of MTX was under 5 years in 11 among 15 patients. The histological type of MTX-LPD was diffuse large B-cell lymphoma (DLBCL) in 16 patients. The most first-symptom is palpable tumors in 15 (50%) patients. Serum CRP was elevated 2 months before ML onset and LDH was elevated at the time of ML onset. The numbers of lymphocytes, hemoglobin and IgG were significantly lower and those of LDH, CRP and ESR were significantly higher compared with non-ML RA patients.

Conclusion: We clarified clinical characteristics of RA patients complicated with ML. From our study, the summarized clinical characteristics of MTX-LPD were as follows; age of onset; from 50 to 70 years old, MTX-duration; within 5 years when start to receive MTX, histology; DLBCL, and first symptom; palpable tumor. MTX-LPD developed in RApatients in spite of low dose MTX and relapsed patients exist after cessation of MTX. The levels of CRP rather than LDH might be elevated earlier before diagnosis of ML. Furthermore, low lymphocytes and IgG might be the risk factors of ML, including MTX-LPD.

Control of Modifiable Cardiovascular Risk Factors in Rheumatoid Arthritis Patients Compared to Traditional High-Risk Cardiovascular Disease Patients

Brian LaMoreaux[1], Alexa Meara[2] and Wael N. Jarjour[3], [1]Rheumatology, The Ohio State University, Columbus, OH, [2]Internal Medicine/Rheumatology, The Ohio State University, Columbus, OH, [3]Department of Internal Medicine, Division of Immunology and Rheumatology, The Ohio State University Medical Center, Columbus, OH

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic systemic inflammatory autoimmune disease affecting one percent of the population. The main cause of mortality among RA patients is cardiovascular disease (CVD), which occurs on average 10 years earlier than in the general population. Even when traditional risk factors such as hypertension, tobacco use, diabetes, and dyslipidemia are accounted for, there is still an elevated CVD risk associated with having RA that may be partly due to systemic inflammation from RA. Many rheumatologists routinely recommended that primary care providers (PCPs) follow the established guidelines for high risk cardiovascular patients in terms of modifiable CVD risk factors when treating RA patients. In this study we are comparing modifiable risk factor control in RA patients to high risk CVD patients.

Methods: Retrospective data was collected from the year 2013 in rheumatology, internal medicine, family medicine, and cardiovascular medicine clinics. ICD-9 codes were defined for patient selection: 1) RA without other CVD codes as the RA group, and 2) the CVD group which included one or more of myocardial infarction, diabetes, peripheral vascular disease, and coronary atherosclerotic disease without an RA code. Demographics including age and sex

as well as modifiable CVD risk factors including systolic and diastolic blood pressure (BP), body mass index (BMI), smoking status, and lipid panel including total cholesterol, high-density lipoproteins (HDL), low-density lipoproteins (LDL), and triglycerides (TG) were collected. RA patients were then compared to high risk CVD patients in terms of these modifiable risk factors.

Results: The CVD group was on average older, smoked more, and had an equal gender ratio. BMI was lower in the RA group (**Table 1**). Systolic BP was similar in the two groups, though diastolic BP was slightly higher in the RA patients (**Table 1**). As expected, many RA patients had missing cholesterol data presumably because they received screening studies through their primary care provider outside of the university system. However, in the RA patient subgroup with available lipid data, analyses showed that RA patients had significantly higher mean total cholesterol, HDL, and LDL, while CVD patients had higher triglycerides (**Table 1**).

Conclusion: Despite an emerging body of evidence that RA patients should be treated as high risk CVD patients in terms of modifiable CVD risk factors, RA patients in our study had reasonable BP control but did not meet most lipid goals. Opportunities for improvement are numerous, starting with patient and provider education and increasing the frequency of PCP visits. Our future studies will examine the same cohort longitudinally and evaluate the rate of cardiovascular events. We also plan to study PCP attitudes towards RA patients and CVD risk, as well as on CVD risk factor control.

TABLE 1: Modifiable CVD Risk Factors

Category	Rheumatoid Arthritis Patients: Mean (SD)	High-Risk CVD Patients: Mean(SD)	Estimated Difference Ratio (95% Confidence Interval)	p-value
Age	56.7 (13.1)	59.5 (13.5)	-2.81 (-3.53, -2.09)	<0.001
BMI	29.7 (7.5)	33.5 (8.5)	0.89 (0.88, 0.90)	<0.001
Systolic BP	127.2 (17.2)	126.8 (15.8)	1.00 (1, 1.01)	0.491
Diastolic BP	77.2 (9.7)	75.2 (10.2)	1.03 (1.02, 10.4)	<0.001
Total Cholesterol	181.9 (38.1)	167.8 (41.8)	1.09 (1.06, 1.13)	<0.001
HDL	52.5 (14.4)	44.9 (12.7)	1.17 (1.13, 1.21)	<0.001
LDL	105.7 (32)	92.1 (34.4)	1.17 (1.12, 1.24)	<0.001
TG	122.6 (73.6)	153.1 (93)	0.82 (0.76, 0.88)	<0.001

Cardiovascular Risk Management in Rheumatoid Arthritis Patients

Calin Popa[1], Elke.E.A. Arts[1], Inger L. Meek[1], Frank H.J. van den Hoogen[2] and Jaap Fransen[1], [1]Rheumatology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [2]Rheumatology, Sint Maartenskliniek, Nijmegen, Netherlands

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) patients have been previously shown to have a higher cardiovascular (CV) burden as compared to the general population. The CV risk in RA seems still underestimated. We present here the results of a 1.5 year experience of our Department with the CV risk management in RA patients.

Methods: RA patients have been consecutively screened on lipid profile and blood pressure. Other CV risk factors have been also recorded (smoking, CV history, family history of premature atherosclerotic events, weight –BMI, renal function, glucose). Patients fulfilled either the 1987 ACR criteria or the revised ACR-EULAR criteria for the diagnosis of RA. They were visiting the outpatient clinic for their regular controls. The SCORE index has been used to determine their 10-year risk to develop CV event/ death by CV event.

Results: In total, 342 RA patients have been consecutively screened. Among them 181 patients have been tested in primary prevention setting and were further analyzed (Table 1). Forty patients (22%) had hypertension. Thirty-three patients (18%) should have been treated with statins according to their 10-years CV risk as calculated using the algorithms for the general population. This percentage almost tripled (52%) if CBO recommendations for RA patients have been applied. Finally, 17% of the studied group had a high CV risk according to SCORE index for the general population, increasing to 21% according to SCORE-EULAR and to 49% when CBO guidelines recommendations for RA patients have been applied (Table 2).

Conclusion: There is a relative high percentage of RA patients in need for primary prevention measures, yet the use of SCORE-CBO might easily overestimate/exaggerate the risk. Screening for CV risk factors early in the course of disease should be integrated in the standards protocols for RA

management. Applying the “treat to target” strategy together with primary prevention measures might drastically reduce CV burden in RA in the near future.

	Primary prevention (N=181)
Age (years)	56 ± 14
Gender (M:F)	70:111
Disease duration (years)	10 ± 8
Rheumatoid factor (% positive)	73 (%)
BMI (kg/m²)	25 ± 4
Total cholesterol (mmol/l)	5.41 ± 1.03
HDL (mmol/l)	1.38 ± 0.34
TC:HDL	4.11 ± 1.14
Systolic blood pressure (mmHg)	127 ± 16
Diastolic blood pressure (mmHg)	76 ± 10
Smokers (%)	23 (%)

Table 1. Main characteristics of the RA group in which the screening has been applied in the primary prevention setting (mean ± SD); BMI = body mass index; HDL = high-density lipoprotein; TC = total cholesterol;

	SCORE	SCORE-EULAR	SCORE-CBO
Low risk (<10%)	124	113	57
Intermediate risk (10-19)	25	29	36
High risk (>20%)	32	39	88

Table 2. Distribution of CV risk among the 181 RA patients. SCORE-EULAR = SCORE index according to EULAR recommendations (x 1.5 when two of the following factors have been present: rheumatoid factor, disease duration> 10 years, extra-articular manifestations); EULAR-CBO = SCORE according to 2011 CBO guidelines (adding 15 years to current age)

Session Date: Monday, November 9, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a heterogeneous inflammatory disease with various signs and symptoms. Previous studies have shown that RA patients can be sub-grouped based on inflammation, pain, and mental health, but it cannot be readily implemented without extra burden in daily practice. We identified subgroups of RA patients using the American College of Rheumatology (ACR) core data set measures and Multi-Dimensional Health Assessment Questionnaire (MDHAQ) and investigated the clinical significance of the subgroups.

Methods: RA subjects enrolled in the University of Pittsburgh Rheumatoid Arthritis Comparative Effectiveness Registry (RACER) with moderate to high disease activity by Clinical Disease Activity Index (CDAI > 10) were included. Based on previous work, ACR core set measures and sleep, anxiety; depression questions in MDHAQ at the initial visit were included as clustering variables. Remission or mild disease activity (CDAI ≤ 10) was considered as low disease activity (LDA). Time to achieve LDA was calculated for each cluster identified. We used a hierarchical clustering procedure with the Ward method. To examine differences between clusters, we used the Kruskal-Wallis test comparing the factors between each of the clusters.

Results: For the 175 subjects analyzed, subject age was 57.5 ± 13.4 (Mean±SD) years with disease duration of 13.7 ± 13.5 years. Five clusters were identified but the majority of subjects were grouped into cluster 1 (reference cluster). (Table.1) Qualitative comparison showed that 5 clusters can be

grouped into 2 categories (Physical Global Assessment [PhGA] - Patient Global Assessment [PtGA] concordant group [Cluster 1, 2, 3] and PhGA-PtGA discordant group [cluster 3, 4]). Furthermore, they were different in anxiety and depression level. Although cluster 2 and 3 had similar disease activity, cluster 2 had higher anxiety and cluster 3 had higher depression. Similarly, cluster 4 had higher anxiety and cluster 5 had higher depression. Clusters having higher depression (cluster 3 in comparison with cluster 1 and 2, cluster 5 in comparison with cluster 4) had longer time to achieve low disease activity when compared with other similar clusters (Table.2).

Conclusion: This study suggests that discrepancy between patient and physician global assessment, severity of anxiety and depression can be useful to identify and distinguish subgroups of RA patients. Severity of depression may be associated with longer time to achieve low disease activity. Given very small numbers in other clusters except the reference cluster, further analyses will be necessary to confirm these findings.

Table 1. Clinical characteristics of the patients, used as variables to define the clusters

Arterial Vascular Events in Hispanics from Puerto Rico with Rheumatoid Arthritis

Ariana González-Meléndez[1], Ruth Fred-Jimenez[2], Mariangelí Arroyo-Ávila[2], Leyda Díaz-Correa[2], Naydi Pérez-Ríos[3], Noelia Rodríguez-Pérez[2], Grissel Ríos[2] and Luis M. Vilá[2], [1]School of Medicine, Ponce Health Sciences University, Ponce, PR, [2]Department of Medicine, Division of Rheumatology, University of Puerto Rico Medical Sciences Campus, San Juan, PR, [3]Puerto Rico Clinical and Translational Research Consortium, University of Puerto

Rico Medical Sciences Campus, San Juan, PR

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Arterial vascular events have a great impact in the morbidity and mortality of rheumatoid arthritis (RA). Traditional and nontraditional risk factors for arterial vascular events vary widely among different ethnic groups. Few studies have been conducted in Hispanics from the United States. Thus, we determined the factors associated with the occurrence of arterial vascular events in a cohort of Hispanics from Puerto Rico with RA.

Methods: RA patients (per American College of Rheumatology classification criteria) of Puerto Rican ethnicity (self and four grandparents) were studied to determine the demographic features, health-related behaviors, clinical manifestations, disease activity (per disease activity score 28 [DAS28]), comorbid conditions, functional status (per Health Assessment Questionnaire [HAQ]), and pharmacologic profile associated with arterial vascular events. An arterial vascular event was defined as the occurrence of myocardial infarction, angina pectoris, vascular procedure for coronary artery disease, stroke, or peripheral artery disease. Patient characteristics were analyzed by bivariable (chi-square and Student's t tests) and multivariable (logistic regression) analyses.

Results: In total, 405 RA patients were studied. The mean (standard deviation [SD]) age was 56.1 (13.9) years and the mean (SD) disease duration was 15.0 (50.7) years; 87.2% were woman. Forty-three patients (10.6%) had at least one incident arterial vascular event. In the bivariable analyses, patients with arterial vascular events were more likely to be male (23.3% vs. 11.6%, p= 0.031) and older (63.0 [11.1] vs. 55.2 [14.0] years, p<0.001) and to have more extra-articular manifestations (69.8% vs. 48.9%, p=0.010), disease activity (DAS28 score, 4.21 [1.81] vs. 3.61 [1.45], p=0.044), functional disability (HAQ score, 1.40 [0.89] vs. 1.09 [0.78], p=0.017), arterial hypertension (83.7% vs. 51.7%, p<0.001), diabetes mellitus (25.6% vs. 13.8%, p=0.041), dyslipidemia (81.0% vs. 45.3%, p<0.001) and peripheral venous disease (11.6% vs. 3.9%, p=0.040) than those without arterial vascular events. No differences were found for disease duration, smoking, exercise, body mass index, joint deformities, erosive disease, and exposure to nonsteroidal anti-inflammatory drugs, corticosteroids, disease modifying anti-rheumatic drugs and biologic agents. In the multivariable analysis adjusted for gender and age, extra-articular manifestations (OR=2.08, 95% CI 1.03-4.20), functional status (OR=2.52, 95% CI 1.24-5.11), arterial hypertension (OR= 3.43, 95% CI 1.40-8.41), dyslipidemia (OR= 4.48, 95% CI 2.00-10.04) and peripheral venous disease (OR=2.93, 95% CI .96-8.97) retained significance.

Conclusion: This is the first study examining the prevalence and correlates of arterial vascular events in Hispanics from Puerto Rico with RA. Patients with extra-articular manifestations and greater disability as well as those with traditional risk factors for cardiovascular disease were at higher risk. Awareness of these factors may lead to more effective management strategies of patients at risk for arterial vascular events.

Traditional Risk Score Underestimates the Cardiovascular Risk in Rheumatoid Arthritis Patients

Tomas Cazenave[1], Natalia Zamora[1], Gustavo Citera[1,2] and Marcos G. Rosemffet[1], [1]Rheumatology, Instituto de Rehabilitación Psicofísica, Buenos Aires, Argentina, [2]Rheumatology, Instituto de Rehabilitacion Psicofisica, Buenos Aires, Argentina

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: An increased incidence of cardiovascular (CV) mortality has been reported in patients with rheumatoid arthritis (RA). Adequate stratification of the CV risk is an issue of major importance in these patients. ***Objective:***To compare the CV risk estimated by a traditional score with carotid ultrasound (US) assessment in RA patients.

Methods: A cross-sectional study including RA patients without history of CV events was designed. Data collected included clinical and demographic characteristics. All patients were evaluated for traditional CV risk factors. CV risk was stratified according to Framingham Score. Carotid US was performed to assess the presence of subclinical atherosclerosis. The presence of cIMT >0.90 mm and/or carotid plaques (US Carotid Atherosclerosis=UCA) were considered a marker of CV high risk. The association between clinical characteristics and US findings was assessed using univariate and multivariate analysis. ROC curves were developed to estimate cut-off values.

Results: We included 60 patients with RA. Mean age was 54.2±12.3 years, and 78% were female. Mean disease duration was 13±9 years, and mean DAS28 was 3.8±1.17. All patients were receiving DMARDs, 36% biologic treatment and 58% oral steroids (mean dose: 6.22±2.3). Eleven patients (18%)

had hypertension, 16 (26,7%) dyslipidemia and 28 (46%) were exposed to tobacco (pack/year mean:10.8±7.4). The Framingham median score was 6.05 (IQR:3.4-10.2); 45 (75%), 10 (16.7%) and 5 (8.3%) patients were classified as low, moderate and high CV risk, respectively. US assessment detected UCA (plaque and/or cIMT >0.90) in 33 (55%) patients, plaques in 30 (50%), and cIMT >0.90 in 18 (30%). The UCA frequencies observed in the different Framingham categories were: Low: 20/45 (44.4%), Moderate: 8/10 (80%), High: 5/5 (100%). In the univariated analysis the presence of UCA was more frequent in older patients (p<0.0001) and with longer disease duration (p=0.057). After adjusting for multiple confounders age was the only variable that remained associated with UCA. In the ROC analysis the optimal cutoff value for age, that predicts UCA presence was 53.5 years with a sensitivity and specificity of 84.8% and 81.5%, respectively (AUC: 0.89).The UCA prevalence was 84.8% (n = 28) in patients with age ≥53.5 years, compared to only 15.2% (n = 5) in those with age <53.5 years.

Conclusion: More than a half of patients classified in low-moderate risk according to Framingham score presented subclinical atherosclerosis in carotid US assessment. A large majority of patients older than 53.5 years showed high-risk carotid involvement, which may require intensive CV risk management.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis is a chronic, systemic, autoimmune disease affecting 0.5 – 1% of the adult population that leads to a progressive decline in functional status[1]. Psychological distress, including depression, is common among patients with rheumatoid arthritis and a predictor of functional outcome[2]. Resiliency, the presence of effective coping and adaptation when faced with loss, hardship or adversity has been shown to be a protective factor in chronic disease, including autoimmune disorders such as SLE[3]. In this study, we aimed to assess predictors of depressive symptoms in patients with rheumatoid arthritis.

Methods: Twenty-one patients with a diagnosis of rheumatoid arthritis from a single center in Kingston, Ontario were evaluated with a demographics questionnaire, a 9-item self-reported depression scale (Patient Health Questionnaire 9, PHQ-9), a 4-item resilience scale (Brief Resilience Coping Scale, BRCS), as well as a physician administered measure of objective disease activity (DAS-28). Multiple regression analysis was conducted to assess predictors of depressive symptoms.

Results: The sample had low to moderate disease activity ($M = 3.10$, $SD = 1.56$). The mean PHQ-9 score was 4.09 ($SD = 4.03$) and the mean resilience score was 13.86 ($SD = 4.07$). Disease activity ($\beta = .38$) and resilience ($\beta = -.47$) were significant predictors of depressive symptoms, $R^2 = .73$, adjusted $R^2 = .64$, $F(5, 15) = 8.20$, $p < .01$. Disease activity is a positive predictor and resiliency is a negative predictor of depressive symptoms.

Conclusion: Resilience had the greatest regression weight, implicating resilience as an important target for psychological intervention. Assessment of resilience in patients with rheumatoid arthritis may allow for the identification of patients at risk for psychosocial distress and allow for the implementation of targeted therapies to improve functional status.

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Atherosclerotic cardiovascular disease (ASCVD) is the number one cause of death in rheumatoid arthritis (RA) patients. RA itself is an independent risk factor for ASCVD comparable to that of diabetes. Lipid-lowering therapy with statins is one of the most effective drug treatments for primary and secondary ASCVD prevention. The American College of Cardiology/American Heart Association (ACC/AHA) 2013 guidelines on the treatment of blood cholesterol and the Adult Treatment Panel-III (ATP-III) guidelines differ between their strategies for initiating statins in primary prevention. Carotid ultrasound is a non-invasive tool useful for the detection of subclinical atherosclerosis. Presence of carotid plaque (CP) is an indication of lipid-lowering therapy with statins. The objective of the present study is to compare statin treatment recommendation according to ACC/AHA 2013 guidelines, ATP-III guidelines and CP by carotid ultrasound.

Methods:

An observational, cross-sectional study was designed based on a cohort of RA statin-naïve, 40 to 75 year old, Hispanics that attended a referral center. All fulfilled the 1987 ACR and the 2010 ACR/EULAR classification criteria for RA. Exclusion criteria included overlap syndromes, previous ASCVD (myocardial infarction, stroke and peripheral arterial disease), dyslipidemia, pregnancy, and statin use at baseline. CP was evaluated with B-mode ultrasound and defined as focal thickening at least 50% greater than that of the surrounding wall or carotid intima media-thickness ≥1.2 mm. Multiplication of the scales by 1.5 was performed when applicable according to EULAR cardiovascular risk 2008 recommendations.

Results:

A total of 62 patients were included in the analysis. The patients' characteristics are shown in Table 1. The mean age was 56.4 ±9.74 years. Women accounted for 55 (88.7%). Mean disease duration in years was 11.46 ±9.73. Statin therapy was recommended by ATP-III guidelines in 8 (12.9%) cases and by ACC/AHA 2013 guidelines in 23 (37.1%) cases. CP by carotid US was identified in 28 (45.2%) patients. McNemar's test revealed statistical difference in statin therapy recommendation between CP and ATP-III guidelines ($p \leq 0.001$), and ACC/AHA and ATP-III guidelines ($p \leq 0.001$). No difference was noted between CP and ACC/AHA guidelines ($p = 0.332$).

Conclusion:

In this Hispanic cohort of RA patients, statin treatment recommendation varies among CP and ATP-III guidelines, and ACC/AHA and ATP-III guidelines. No difference was found between CP and ACC/AHA 2013 guidelines. The recent ACC/AHA guidelines may offer better risk assessment for early detection of cardiovascular risk in RA but further prospective studies are needed to evaluate it.

Patients' characteristics	
Age (years); mean ± SD	56.40 ± 9.74
Women; n (%)	55 (88.7)
Disease duration (years); mean ± SD	11.46 ± 9.73
Diabetes; n (%)	6 (9.7)
Anti-hypertensive treatment; n (%)	22 (35.5)
Family history of coronary heart disease; n (%)	6 (9.7)
Active smoking; n (%)	16 (25.8)
Positive rheumatoid factor or anti-cyclic citrullinated peptide; n (%)	45 (72.6)
Body mass index; mean ± SD	28.63 ± 5.57
Systolic blood pressure (mmHg); median (Q1-Q3)	120 (116.75-135.25)
Diastolic blood pressure (mmHg); mean ± SD	78.65 ± 13.89
Remission by DAS28 ESR; n (%)	33 (53.2)
LDL cholesterol (mg/dl); mean ± SD	105.41 ± 26.47
HDL cholesterol (mg/dl); mean ± SD	55.17 ± 9.74
Framingham lipids 10-year risk calculator; median (Q1-Q3)	7.86 (4.70-14.06)
ACC/AHA 2013 10-year ASCVD risk Pooled Cohort Equation; median (Q1-Q3)	4.00 (1.60-12.91)
Treatment recommended by ATP-III guidelines; n (%)	8 (12.9)
Treatment recommended by ACC/AHA 2013 guidelines; n (%)	23 (37.1)
Carotid plaque; n (%)	28 (45.2)

Session Date: Monday, November 9, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory disease that leads to progressive joint deformity, destruction, and disability. While smoking is recognized as a strong environmental risk factor for the development of RA, the relationship between smoking and the progression of RA has often been reported to be inconsistent or paradoxical ("the risk factor paradox"). To summarize the relevant data to date, we conducted a systematic review of the literature on the impact of smoking on the risk of RA progression.

Methods: We conducted a mapped search of MEDLINE and EMBASE databases for articles published from database inception to June 2015. Additional articles were retrieved by a hand-search of relevant bibliographies. Our search strategy used a combination of mapped subject headings (i.e., MeSH and Emtree terms) and keywords for unindexed concepts relating to the themes of RA progression and smoking/tobacco use. Full-text articles meeting the following criteria were included in the systematic review: 1) RA patient population; 2) outcome of a change in RA status (e.g., radiologic progression, functional status, or disease severity); 3) original research article; and 4) English language. Studies were excluded if they reported the impact of smoking on the risk of incident RA. Non-human studies, reviews, and case reports/series were additionally excluded.

Results: We identified 685 unique citations with our search strategy. Of these, 28 studies met all inclusion criteria and were included in the systematic review. The main outcomes reported included radiographic progression (e.g., Larsen or Sharp/van der Heijde score) (n=14 studies), disease activity (e.g., DAS) (n=13), treatment response (n=6), functional status and disability (e.g., HAQ) (n=7), achievement of remission (n=2), and total joint replacement (n=1). Overall, smoking did not have a significant impact on RA outcomes and progression, and in some studies (n=4) smoking actually conferred a protective impact **(see Table)**. Only two of 14 studies on radiographic progression reported a hazardous effect, and the impact of smoking on functional status was non-significant in all studies identified. Additionally, there was no significant association between smoking status and achievement of remission.

Conclusion: While smoking is a well-established risk factor for incident RA, findings from the majority of studies identified in this systematic review suggest that it does not confer the same impact on disease progression. Although biological explanations for these counterintuitive results may exist, an enticing methodologic explanation is a type of selection bias known as index event bias. Appropriate methods to correct for this bias should be explored to determine the true impact of smoking on the risk of RA progression.

Table. Summary of Reported Associations between Smoking and RA Progression

Outcome	Protective or Null Association	Hazardous Association
Radiologic progression (n=14)	12	2*
Disease activity (n=13)	11	2
Treatment response (n=6)	5	1
Functional status/disability (n=7)	7	0
Remission (n=2)	2	0
Total joint replacement (n=1)	1	0

*One was based on a cross-sectional analysis of a cohort study

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Cardiovascular disease (CVD) is the leading cause of death among individuals with rheumatoid arthritis (RA). The 2010 EULAR guidelines recommend annual CV risk assessment for all RA patients in accordance with national guidelines[1]. However, CVD risks are not being assessed frequently and systematically in RA patients. We implemented an Electronic Medical Record (EMR)-based clinical decision support intervention at a large tertiary care center and assessed the effects of this intervention on lipid screening among RA patients by treating rheumatologists.

Methods: We developed a self-populated form that was incorporated into each EMR rheumatology visit and contained the following information (Image): 1) dates of the latest assessment of CVD risks (body mass index (BMI), blood pressure, smoking, lipid screening); 2) the latest values for all of the above CVD risks; 3) Framingham risk score calculator. To evaluate the impact of this EMR-based intervention, lipid screening rates among adult RA patients

were compared pre and post implementing this EMR tool. LDL levels were compared for patients seen, pre-intervention, 1/1/2012-6/30/2012 (2012), and post-intervention, 1/1/2014-6/30/2014 (2014). RA patients were identified using a previously validated algorithm requiring two or more visits with the ICD9 code *714.0 (Rheumatoid arthritis),* and at least one prescription for a disease modifying anti-rheumatic medication[2]. The first visit within the study period was defined as the index visit. Wilcoxon-Mann-Whitney tests were used to compare continuous variables, and Pearson's Chi-square tests (or Fisher's exact test when appropriate) were used to compare categorical variables.

Results: 131 and 111 RA patients seen in outpatient rheumatology clinics by rheumatologists in 2012 and 2014, respectively. Sex, race, and ethnicity were similar: 35% vs. 29% were Black, 60% and 64% were Hispanic, 12% and 9% were men. There were no age differences: mean (SD) 58(14) years old in 2012, and 59 (14) years old in 2014. BMI was also similar: mean (SD) 30(7) kg/m^2 in 2012, and 30(6) kg/m^2 in 2014. Lipid screening frequency in the subsequent 6 months was 32% in 2012 and 23% in 2014 (p=0.12). Median (SD) LDL was 96 (30) mg/dl in 2012, and 109 (36) mg/dl in 2014 (p=0.09)

Conclusion: Implementing an EMR based decision support tool did not improve rates of screening for lipid abnormalities among RA patients. Lipid screening rates remained low. Further studies are needed to identify and address barriers to CVD screening in RA among rheumatologists and primary care providers.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Atherosclerotic cardiovascular disease (ASCVD) is the leading cause of death in RA. Management and stratification of ASCVD in RA patients is still a matter of debate. Performance of cardiovascular risk calculators, including Framingham Risk Scores (FRS) BMI and Lipids, Reynolds Risk Scale (RRS) and QRISK2 have shown poor results in RA. The recent ACC/AHA 2013 risk calculator (OMNIBUS) has not been compared against the other scales in RA patients.

Methods:

An observational, cross-sectional, prospective study was designed. Patients with RA that fulfilled ACR/EULAR 2010 classification criteria and attended a reference center were included. Cardiovascular risk was calculated by 5 different scales using the official online calculators. Patients with prior ASCVD, overlap syndromes, out of the predefined age range (40-75 years old) or with missing data were excluded.

Sample size was calculated to determine a 5% difference between scales. Friedman test was used to identify difference between the calculators considering a $p<0.05$ as statistically significant. To determine differences between each algorithm, Wilcoxon signed-rank tests were used and considered significant when $p<0.005$ due to repeated measurement analysis.

Results:

A total of 93 patients were included. Mean age was 56.8±8.8 years old and mean disease duration of 12.84±8.3 years. Women accounted for 86 (92.6%). The population's demographical data is shown in Table 1. Friedman test determined a significant difference between the scales ($p<0.001$). Wilcoxon signed-rank test results are shown in Table 2. RRS estimation was significantly lower than any other calculator ($p<0.001$). FRS BMI gave higher values than the other algorithms ($p<0.001$). OMNIBUS risk was lower than FRS Lipids and QRISK2 ($p<0.001$). There was no difference between QRISK2 and FRS Lipids ($p=0.964$). OMNIBUS gave higher values than RRS ($p<0.001$).

Conclusion:

In our cohort of Hispanics with RA, FRS BMI provided higher risk values than any other scale. There was no difference between FRS Lipids and QRISK2 estimations. OMNIBUS stratified patients lower than FRS Lipids and QRISK2. Prospective information is needed to determine if FRS BMI could represent the best option in RA.

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid Arthritis (RA) patients are at increased risk of developing co-morbid conditions. We designed this study to evaluate the prevalence of comorbidities and their monitoring in Korean RA patients compared with the patients from other countries.

Methods: We analyzed the demographics, disease characteristics, comorbidities and their monitoring states of 1050 RA patients from 11 Korean centers and compared with those of 3520 patients from 16 other countries using COMORA database.

Results:

The prevalence of obese patients was significantly lower and married patients was higher in Korean patients (p<0.0001, both). Disease duration was shorter, uses of prednisolone and NSAIDs were more frequent and the use of biologics was lower in Korean patients (p<0.0001, all). The prevalence of cardiovascular (CV) event was not significantly different between two groups. The prevalence of basocellular skin cancer was significantly lower in Korean patients (p<0.0001).

The proportion of current smoker, patients who have a family history of CV disease, hyperlipidemia and patients with Framingham score >20% were significantly lower, although the prevalence of diabetes was higher in Korean patients (p<0.0001, all).

Annual evaluation of CV risk was less frequently performed in Korean (p=0.0011) although the use of antiplatelet agent was more frequent (p=0.0004). Prostatic and skin cancer monitoring were less frequently performed (p<0.0001) but lung and breast cancer monitoring were more frequently performed (p=0.048 and p<0.0001). Vitamin D supplement was less frequently used (p<0.0001).

When we analyzed the association of GI disease with medication, the risk of GI ulcer was increase with prednisolone (Odds ratio 1.68, 95% CI 1.34-2.09) and NSAIDs (odds ratio 1.44, 95% CI 1.16-1.79) in patients from other countries. The usage of NSAID was protective for the development of colon cancer in RA patients of Korea (odds ratio 0.09, 95% CI 0.01-0.86) and other countries (odds ratio 0.3, 95% CI 0.12-0.75). The usage of biologic agents increased the risk of lymphoma in countries other than Korea (odds ratio 19.08, 95% CI 2.51-145.27).

Conclusion: There are differences in the prevalence of co-morbidities and monitoring states of the risk factors between patients in Korea and the other countries. The prevalence of CV morbidity was similar between two groups although the prevalence of CV risk factors is significantly low in Korean, suggesting more attention to yearly CV risk monitoring is needed. The usage of NSAID was protective for the development of colon cancer in RA patients of Korea and other countries.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) patients have an increased risk of cardiovascular diseases (CVD). The underlying mechanism is partly explained by the inflammation process in both RA and atherosclerosis. Atherosclerosis is an important risk factor for the occurrence of premature coronary heart disease, like myocardial infarction (MI) (1). A higher average level of disease activity in RA patients might cause MI, however this hypothesis was not confirmed (2). Probably, flares are more important than the average level of disease activity as risk factor for CVD in RA. Therefore, the objective was to determine whether the annual flare rate is associated with the occurrence of MI in RA patients.

Methods: We used case-control data from a large Dutch prospective RA cohort, which started in 1985. Medical files of RA patients were used to determine the occurrence of MI events. Patients were defined as cases at the moment they experienced a MI event. Randomly chosen RA controls were matched on disease duration; the time between RA diagnosis and MI event or censoring. Flares were defined as an increase in DAS28>1.2 or >0.6 if DAS28≥3.2. The annual flare rate was calculated as the number of flares divided by disease duration. Other important characteristics of RA and risk factors for CVD were determined at baseline or during follow-up. Characteristics of cases and controls were compared by t-tests or non-parametric Mann-Whitney U. Logistic regression was performed to determine the crude association between the annual flare rate and occurrence of MI. Confounding variables were taken into account using multivariate logistic regression.

Results: The study population consisted of 41 cases and 181 matched controls. Cases were older and more frequently male while also risk factors for CVD were raised in cases, like: significantly higher BMI, total cholesterol, triglyceride, LDL, atherogenic index, incidence of hypertension and, a significantly lower HDL, compared to controls. Other characteristics like smoking status, disease duration, average DAS28, C-reactive protein levels, rheumatoid factor positivity, prevalence of diabetes mellitus, and medication use did not differ significantly between cases and controls. The crude OR of the annual flare rate and the occurrence of MI was 0.78 (95% CI: 0.48; 1.25). The OR adjusted for age, LDL, male gender, cholesterol, hypertension, and HDL was 0.97 (95% CI: 0.58; 1.68).

Conclusion: No significant association was found between annual flare rate and the occurrence of MI in RA patients. This implies that the presence of flares in disease activity does not contribute to the increased CVD risk in RA patients, in contrast to expectations.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid vasculitis is an extra articular manifestation of rheumatoid arthritis (RA), that occurs during the course of long standing disease. It is associated with a poor prognosis

Objectives: To describe the clinical characteristics, incidence, treatment, and outcome of patients diagnosed with rheumatoid vasculitis (RV) at a Rheumatology service of a University hospital during the last 30 years

Methods: Retrospective study (1984-2014). Location: University hospital. Referral area: 850.000 inhabitants. Medical records of patients with diagnosis of RA were reviewed, from the Rheumatology service data base. Inclusion criteria: patients with RV with histopathological confirmation of vasculitis or high suspicion based on clinical or radiological (arteriography) findings (according to Scott and Bacon criteria)

Results: A total of 18 patients were included: 6 (33.3%) females and 12 (66.7%) males, mean age of 10.13 ± 66.5 (49-83 years). The clinical characteristics of patients are listed in Table 1. The most common clinical presentation was skin involvement with palpable purpura and digital ulcers. Other common manifestations were multineuritis and systemic involvement. Heart, eyes, or pulmonary involvements secondary to RV were absent. Laboratory tests at diagnosis of RV, showed an increased of acute phase reactants and anemia. All patients had a positive rheumatoid factor, citrullinated antibodies were determined only in five (27.8%) cases, being positive in all of them.Histological confirmation was possible in 8 (44.4%) cases, in the other 10 (55.6%) cases the diagnosis was made with clinical or radiological findings. Most patients were treated with pulse steroids associated with other immunosuppressive drugs. Seven (38.9%) patients died. Three of them (16.7%) secondary to vasculitis, and 4 (22.2%) of other causes. The incidence of rheumatoid vasculitis has decreased considerably in the last decade. Just 4 cases were diagnosed during the last 10 years

Clinical characteristics		N (%) OR mean (range)
Comorbidities	HTA	9 (50%)
	Diabetes Mellitus	2 (11,1%)
	Smoker	9 (50%)
	Peripheral vascular disease	3 (16.7%)
Characteristics of RA	Disease duration (years)	5,8 ± 5,6 (1-17)
	Rheumatoid nodules	8 (44,4%)
	Radiographic erosions	11 (61,1%)
	Pulmonary involvement	3 (16,7%)
	Renal involvement	1 (5,6%)
Clinical presentation	Cutaneous vasculitis	12 (66,7%)
	Multineuritis	12 (66,7%)
	Mesenteric vasculitis	2 (11,1%)
	Systemic involvement	8 (44,4%)
	Renal involvement	1 (5,6%)
Laboratory	Leukocytosis (>$10x10^{9)}$	9 (50%)
	Anemia (Hb<12g/dl)	9 (50%)
	Thrombocytosis	2 (11,1%)
	ESR	70,76± 28,46 mm3
	C-reactive protein	50,27±56,77 mg/dl
	FR positive	18 (100%)
	ACPA positive	5 (100%)
	ANA positive	4 (22,2%)
	ANCA positive	4 (22,2%)
	Cryoglobulins positives	2 (11,1%)
	Hypocomplementemia	4 (22,2%)
AR treatment previous to the RV	NSAIDs	17 (94,4%)
	Glucocorticoids	16 (88,9%)
	Metotrexate	12 (66,7%)
	Antimalarial	9 (50%)
	D-penicillamine	4 (22,2%)
	Leflunomide	5 (27,8%)
	Gold salts	3 (16,7%)
Treatment of RV	Glucocorticoids	16 (88,9%)
	Cyclophosphamide	10 (55,6%)
	Gammaglobulin	1 (5,6%)
	Azathioprine	1 (5,6%)
	Rituximab	1 (5,6%)
Evolution	Improvement	10 (55,6%)
	Worsening	6 (33,4%)
	Unknown	2 (11,1%)
Recurrence		5 (27,8%)
Death		3 (16,7%)

Conclusion: RV is a rare complication of RA. Cutaneous and neurological involvement is more common. It is more frequent in male smokers with seropositive and nodular RA. Histological diagnosis is difficult. Currently the incidence is decreasing, however mortality is still high

Illness Perceptions in Rheumatoid Arthritis: A Comparison of Canadian and Nigerian Patients

Susan J. Bartlett[1], Olufemi Adelowo[2], Maria Celia Bazan Bardales[3] and **Ines Colmegna**[4], [1]Medicine , Divisions of Clinical Epidemiology, Rheumatology, Respirology, McGill University, Montreal, QC, Canada, [2]Rheumatology, Arthrimed Specialist Clinic, Lagos, Nigeria, [3]Rheumatology, McGill University, Montreal, QC, Canada, [4]McGill University, Montreal, QC, Canada

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Illness perceptions (IP) are the beliefs and expectations that an individual has about medical conditions. IP cluster around five coherent themes and provide a framework for patients to make sense of their symptoms, assess health risk, and direct action and coping. Positive IPs have been associated with higher adherence, better disease outcomes and wellbeing in several chronic diseases while addressing negative or incorrect perceptions has been shown to improve disease outcomes. We explored IP of Canadian and Nigerian RA patients.

Methods: Consecutive RA patients at two academic centers (Montreal and Lagos) completed the Illness Perception Questionnaire–Revised from 2013-14. Sociodemographic (age, sex, and education) and disease characteristics (duration, treatment, CDAI, HAQ) were obtained and compared with t-tests and chi-square, Spearman correlations were calculated between IPQ-R scales and CDAI levels and t-tests and ANOVA were used to compare IPQ scores between countries and across disease activity levels.

Results: 83 Canadian and 30 Nigerian patients completed the survey. While there were no significant differences in the age, sex and education or use of biologics between groups, African participants reported shorter disease duration and had higher CDAI and patient global scores (Table 1). In Canadians, Timeline-Cyclic, Consequences, and Treatment Control were associated with CDAI (rho's=.28 to -.40; p<.05) whereas in Nigerians, Emotional Representations were moderately associated with CDAI (rho=.40; p<.05)(Table 2). Scores on Timeline – Chronic and Illness Coherence were significantly (p<.05) higher in Canadians whereas Treatment Control scores were significantly higher in Nigerians. Beliefs about causes of RA were similar in patients from both countries, although 'chance' or 'other factors' were cited by Nigerians.

Conclusion: Canadians were more likely to view their arthritis symptoms as coherent and chronic whereas Nigerians were more likely to view their RA as controllable through treatments but resulting in greater emotional distress. Understanding illness perceptions, beliefs about aetiology, and expectations about controllability may offer new insight into patient behaviors (e.g., adherence to treatment) that impact long-term outcomes.

Effect of Drug Therapy on Net Cholesterol Efflux Capacity of HDL-Enriched Serum in Rheumatoid Arthritis

Michelle J. Ormseth[1], S. Louis Bridges Jr.[2], Jeffrey R. Curtis[3], Joseph F. Solus[4], Patricia Yancey[5], MacRae F. Linton[6], Sean Davies[6], L Jackson Roberts II[7], Kasey C. Vickers[6], Valentina Kon[6], Sergio Fazio[8], C Michael Stein[6] and TETRAD Investigators, [1]Department of Medicine, Division of Rheumatology, Vanderbilt University, Nashville, TN, [2]Clinical Immunology and Rheumatology, University of Alabama at Birmingham, Birmingham, AL, [3]University of Alabama at Birmingham, Birmingham, AL, [4]Clinical Pharmacology, Vanderbilt University, Nashville, TN, [5]Medicine, Vanderbilt University, Nashville, TN, [6]Vanderbilt University, Nashville, TN, [7]Pharmacology, Vanderbilt University, Nashville, TN, [8]Oregon Health and Science University, Portland, OR
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) have increased coronary heart disease risk. Some RA therapies may modify this risk, but underlying mechanisms are unclear. The cholesterol efflux capacity of HDL (the ability of HDL to remove cholesterol from lipid-laden macrophages) is associated with reduced coronary heart disease risk in non-RA populations. Inflammation can impair the function of HDL. We hypothesized that better control of inflammation with methotrexate, adalimumab and tocilizumab would increase the net cholesterol efflux capacity of HDL-enriched serum in patients with RA.

Methods: A longitudinal multi-center study (Treatment Efficacy and Toxicity in Rheumatoid Arthritis Database and Repository or TETRAD) obtained clinical information and serum samples from 70 patients with RA before and 6 months after starting a new therapy for RA. RA disease activity was measured by DAS28. The study included patients starting methotrexate (n=23), adalimumab (n=22), and tocilizumab (n=25). Net cholesterol efflux capacity of HDL-enriched serum was measured on paired serum samples using THP-1 macrophages and a fluorometric assay for cholesterol measurement. Wilcoxon signed rank tests were used to compare paired continuous data.

Results: DAS28 score decreased significantly in all three groups after treatment (P<0.001). Net cholesterol efflux capacity (mean± SD) was not significantly changed after 6 months of new therapy (baseline, 36.9% units ± 17.3 vs. 6 months, 38.0% units ± 16.9, P=0.58) (Table). Change in cholesterol efflux capacity was modestly associated with change in DAS28 (rho=-0.25, P=0.04) (Figure). Among patients with baseline impaired net cholesterol efflux capacity (efflux capacity below mean), tocilizumab resulted in modest, significant improvement in net cholesterol efflux (baseline, 21.9% units ± 14.7 vs. 6 months, 31.1% units ± 12.8, P=0.02), but this was not observed with methotrexate or adalimumab users or among those with normal baseline efflux capacity (all P>0.05).

Conclusion: The net cholesterol efflux capacity of HDL did not change significantly after 6 months of new RA therapy but was weakly associated with change in disease activity. Among patients with impaired net cholesterol efflux capacity at baseline, there was a modest improvement after treatment with tocilizumab, but not with methotrexate or adalimumab. Further studies are needed to define the relationship between cholesterol efflux capacity and coronary heart disease risk in patients with RA.

Table: Net cholesterol efflux capacity before and after DMARD or biologic therapy

	Baseline	6 Months	Absolute Change	P value
All patients				
All drugs (N=70)	36.9% ± 17.3	38.0% ± 16.9	1.1% ± 16.6	0.58
Methotrexate (N=23)	41.2% ±13.9	38.0% ± 17.5	-3.3% ± 20.2	0.38
Adalimumab (N=22)	36.1% ±16.8	38.5% ± 18.2	2.3% ± 14.6	0.44
Tocilizumab (N=25)	33.7% ± 20.1	37.6% ± 15.8	3.9% ± 14.2	0.23
Patients with impaired baseline net cholesterol efflux

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Disease modifying anti-rheumatic drugs (DMARDs) including methotrexate (MTX) and biologics were ported to attenuate response to a previous 23-prevalent pneumococcal polysaccharide vaccine. Recently, a 13-prevalent pneumococcal conjugate vaccine (PCV13) for adults became easily available but clinical outcome has never been evaluated. Here, we investigated clinical outcomes and associated factors of severe pneumonia after PCV13 administration.

Methods: : We searched patients who received 13-prevalent pneumonoccal vaccine rheumatologic clinic of Cheonan Soonchunhyang university hospital. Severe pneumonia defined as pneumonia requiring in-hospital treatment. We investigated history of severe pneumonia and underlying lung disease including interstitial lung disease (ILD), asthma, chronic obstructive pulmonary disease (COPD) and pneumoconiosis. A total cumulative dose of glucocorticoid and history administration of biologics or DMARDs after PCV13 injection was also investigated. The Chi-Square or Fisher's exact test and Mann-Whiteney test was used assessing association between above mentioned factors and severe pneumonia as appropriate.

Results:

Among a total of 123 patients, female was 82.1 % (101/123) and the mean (standard deviation, SD) follow-up duration was 22.2 (8.0) weeks. The mean (SD) age were age 54.7 ± 14.2 equal or 34 of 123 patients (27.6%) were more than 65 year-old. Thirteen patients had underlying lung disease: ILD= 4, asthma or COPD = 7, bronchiectasis = 6 and pneumoconiosis = 1. One- hundred-four (84.6%), 97 (78.9%), 40 (32.5) and 38 (30.9%) patients were experienced MTX, hydroxycholoroquine, sulfasalazine, and leflunomide respectively. Numbers of patients who had history of biologics use during follow-up duration were as follows: adalimumab 31 (35.2%), etanercept 7 (5.7%), infliximab 10 (8.1%), golimumab 4 (3.3%), tocilizumab 6 (4.9%), and abatacept 5 (4.1%). The mean (SD) of cumulative glucocorticoid dose was 2875.6 (2475.8) of prednisolone. After PCV13, 5.7% (7/123) of patients had severe pneumonia requiring in-hospital treatment during a mean of 22.2 weeks of follow-up. The presence of underlying lung disease ($p = 1.1 \times 10^{-4}$ by Fisher's exact test) and a total cumulative glucocorticoid dose ($p = 0.014$ by Mann-Whitney test) was associated with development of severe pneumonia but age (≥ 65 year-old) or other medication including DMARDs and biologics was not.

Conclusion:

After PCV13 administration, development of severe pneumonia was associated with underlying lung conditions and cumulative glucocorticoid dose but not with age or biologics use.

Geography and the Influence of Comorbidity on the Prevalence of Depression in Patients with Rheumatoid Arthritis,a Study Across Seventeen Countries

Raluca Dumitru[1], Elizabeth M.A. Hensor[2], Ihsane Hmamouchi[3], Paul Emery[2], Maxime Dougados[4] and Maya H. Buch[5], [1]University of Leeds, Leeds Institute of Molecular Medicine and LMBRU, Leeds, United Kingdom, [2]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom, [3]El Ayachi Hospital, Rabat, Morocco, [4]Service de Rhumatologie B, GHU Cochin, F-75014 France, PARIS, France, [5]Division of Rheumatic and Musculoskeletal Disease, University of Leeds, Leeds Institute of Molecular Medicine and LMBRU, Leeds, United Kingdom

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Comorbidities represent a major challenge for patients with rheumatoid arthritis. Depression is one of the most common comorbidities with prevalence up to 38%. Disease activity measures and comorbidities show inconsistent association with depression. There is limited data assessing the prevalence of depression and its association with clinical characteristics in a large cohort, among different countries.

Objectives: Our study aimed to assess the prevalence of depression diagnosis and patient-reported anxiety or depression and their association with 28-disease activity score (DAS28) and comorbidity among 17 different countries, using the COMORA dataset[1] ('Prevalence of Comorbidities in Rheumatoid Arthritis and evaluation of their monitoring: results of an international, cross-sectional study').

Methods: Demographics, clinical characteristics, treatment and comorbidities were recorded for each patient. Multilevel binary logistic regression models were constructed for depression diagnosis (DD) and for patient-reported anxiety or depression (PRAD). An initial null model tested for inter-country differences in prevalence. Unadjusted models were then built for each independent variable (DAS28 and comorbidity). Models were then adjusted for age and sex.

Results: 3674 patients from 17 countries were included [mean (SD) age 56 (13) years; DAS28 3.72 (1.5)]. 30% were diagnosed with at least one comorbidity, 15% with a depression diagnosis and 38% reported anxiety or depression. Moving from a lower to a higher risk country increased the odds of DD and PRAD by a median of 2.5 and 1.76 fold respectively. In unadjusted models, DAS28 and comorbidity count were positively associated with the measures of depression. Adjusting for age and sex, the association between DAS28 and odds of DD showed borderline-significant variation between countries (p=0.053); in the 'average' country there was no association, but the higher a country's mean DAS28, the greater the increase in the odds of DD for each unit of DAS28. The number of comorbidities was positively associated with the odds of DD and the association did not vary between countries. DAS28 and comorbidity count were positively associated with the odds of PRAD and neither of these associations differed significantly by country.

Conclusion: This study confirms that RA patients have a high prevalence of depression and that this varies between countries. Comorbidity is associated with prevalence of depression whilst the association with DAS28 is more variable. These data suggest that country level factors and additional comorbidity play particularly important roles for depression.

The Medication Information-Seeking Behaviors of Rheumatoid Arthritis Patients Who Are Prescribed a New DMARD

Delesha Carpenter[1], Lorie Geryk[2], Courtney Arrindell[3], Beth Jonas[4] and Susan J. Blalock[5], [1]Division of Pharmaceutical Outcomes and Policy, University of North Carolina Eshelman School of Pharmacy, Asheville, NC, [2]Division of Pharmaceutical Outcomes and Policy, University of North Carolina Eshelman School of Pharmacy, Chapel Hill, NC, [3]University of North Carolina at Chapel Hill, Chapel Hill, NC, [4]Thurston Arthritis Research Ct, UNC-Chapel Hill, Chapel Hill, NC, [5]School of Pharmacy, UNC at Chapel Hill, Chapel Hill, NC

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

We present preliminary longitudinal data about the information-seeking behaviors and medication experiences of RA patients who are prescribed a new DMARD.

Methods: We recruited a convenience sample of 32 adult English-speaking RA patients who were prescribed a new self-administered DMARD from one rheumatology clinic in a southeastern state. At the office visit during which the new DMARD was prescribed, patients reported demographic characteristics and satisfaction with DMARD information provided by their rheumatologist (alpha=0.89). Patients then used a 1-week medication diary to document their experiences with side effects. Patients also completed a 1-week and 1-month follow-up telephone interview during which they reported their use of 15 DMARD information sources, whether their DMARD prescription had been filled, and their medication adherence (8-item Morisky Medication Adherence Scale). We calculated descriptive statistics to describe the sources of DMARD information that patients consulted most often. We examined bivariate associations to determine correlates of DMARD information-seeking and ran a linear regression to examine whether information-seeking predicted DMARD adherence at 1-month follow-up. The regression controlled for patient age, gender, race, reading level, disease duration, and whether DMARD side effects had been experienced (yes/no).

Results: Participants were primarily women (91%) and white (70%). The mean age and disease duration were 48.3 (SD=14.1) and 9.4 years (SD=9.4), respectively. Only 3 (10%) of patients were not satisfied with the DMARD information provided by their rheumatologist. Within 1 week of their office visit, 88% of patients had sought DMARD information; most commonly from brochures/pamphlets (57%), medication package inserts (55%), and the Internet (47%). Patients who experienced side effects sought more information ($t_{(26)}$ =2.27, $p<0.05$) and older patients sought less information ($r=-0.42$, $p<0.05$). Between 1-week and 1-month follow-up, 73% of patients sought additional DMARD information. At 1-month follow-up, 10 patients still had not filled their DMARD prescription, primarily due to lack of insurance approval or cost. Patients who sought greater amounts of information were less adherent (beta=-0.78, $p<0.001$).

Conclusion: Most RA patients seek information about their DMARDS. Information-seeking is influenced by demographic characteristics and their experience with side effects. Patients who sought more information were less adherent.

The Impact of Hindfoot Deformity on Disability of Korean Patients with Rheumatoid Arthritis

Hye-Jin Jeong[1], Il Woong Sohn[1], Seung Lee[1], Seung Taek Song[1], Soo-Kyung Cho[2] and Yoon-Kyoung Sung[2], [1]Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea, [2]Department of Rheumatology, Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) commonly involves the hindfoot, but this part is frequently overlooked when caring for patients with multiple joints pain and deformity. For example, disease activity score (DAS)-28 is most widely used assessment tool of disease activity, but the joints in the feet including hind foot are not included in the 28 joint count. Functional disability has been identified as a core outcome measure in RA and it is affected by various factors. However, until now, there have been few studies performed to assess the impact of hindfoot deformity on the functional disability of RA patients. This study aims to evaluate the impact of hindfoot deformities on the functional disability of RA patients.

Methods: In this cross-sectional study, we evaluated about foot deformities using AP and lateral views of simple radiography. The deformities of feet were divided into three parts: the hindfoot, midfoot, and forefoot deformity. We compared the clinical features including HAQ score of RA patients according to the presence of hindfoot deformity, and then performed univariate and multivariable logistic analyses to find the impact of hindfoot deformities on functional disability.

Results: A total of 120 patients (113 females, 7 males) with a mean age of 46.9 years were included in this study. The prevalences of hindfoot, midfoot and forefoot deformities were 33 (27.5%), 41 (34.2%) and 49 (40.8%), respectively. Patients who had hindfoot deformity showed longer disease duration, higher disease activity, higher functional disability, and commonly prescribed with biologic DMARDs comopared with patients without hindfoot deformity. In the univariate analysis, hindfoot deformity showed 4.2 fold increased risk of higher functional disability group (HAQ score $\geq$ 0.5 as a median). After adjusting age, disease duration, disease activity, biologic DMARD use, and other feet deformities, hindfoot deformity showed high odds ratio (OR) but not statistically significant (OR 2.6, 95% CI 0.77-8.57).

Conclusion: The hindfoot deformities might be associated with functional disability of RA patients. Further study with large sample size will be helpful to identify the impact of hindfoot deformity on the functional disability of RA patients.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory disease associated with increased cardiovascular risks. Cathepsin S, a cysteine protease implicated in intracellular and extracellular proteolysis, and its endogenous inhibitor cystatin C has been both associated with increased cardiovascular mortality in general population.

Objective. To assess if serum cathepsin S and cystatin C, two novel markers of cardiovascular disease risk are associated with subclinical carotid atherosclerosis in RA patients.

Methods: Serum cystatin C and cathepsin S levels, ultrasound carotid intima-media thickness (cIMT) and carotid plaques were assessed in a cross-sectional study involving 178 RA patients.Multivariate regression analysis was assessed to study the relationship between cathepsin S and cystatin C serum levels and cardiovascular risk factors and disease related data.

Results: Mean cIMT was 0.670 ± 0.143 mm, and 66 patients (37%) had carotid plaques in the carotid ultrasound assessment. Both cystatin C and cathepsin S were significantly associated with hypertension, diabetes and dyslipidemia. Cathepsin S was inversely related with male gender whereas cystatin was strongly associated with age. Regarding RA related data; cathepsin S was associated with disease duration and cystatin C was positively related with higher levels of ESR. Neither positive rheumatoid factor nor prednisone use were associated with cystatin C or cathepsin S. A trend for lower levels of cystatin C was observed in patients undergoing anti-TNF-alpha therapy (*log* beta coef. -0.20 (-0.44-0.04), p=0.09). An association between disease activity scores with higher levels of cystatin C, but not with cathepsin S, was found. Cystatin C levels were associated with cIMT in the subgroup of patients included in the higher quartile of cIMT (OR 1.31, 95%CI [1.00-1.72], p=0.04) after adjusting for traditional cardiovascular risk factors, age and sex. An association between serum cystatin C levels and carotid plaques was also found in the univariate analysis (OR 1.37, 95%CI [1.06-1.76], p=0.02). However, this significant association was lost after adjusting for traditional cardiovascular risk factors and age. Cathepsin S was not associated with cIMT or carotid plaques.

Conclusion: High cystatin C serum levels identify a subgroup of RA patients with a high risk of subclinical atherosclerotic disease.

Session Date: Monday, November 9, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

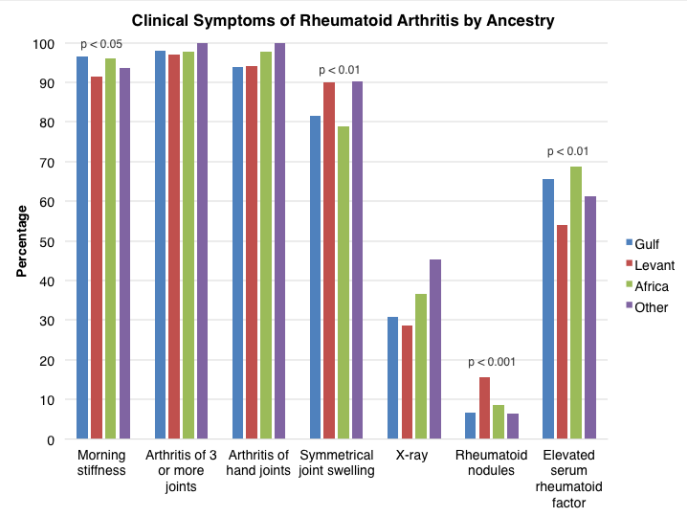
Data on the clinical and genetic characteristics of Arab patients with Rheumatoid Arthritis (RA) is limited. Our aim is to report on the clinical manifestations of the first 844 patients recruited into "The Genetics of Rheumatoid Arthritis in some Arab States (GRASS) study".

Methods:

GRASS is a multicenter case-control study that aims to study the clinical and genetic characteristics of patients of Arab ancestry. Subjects were recruited from 5 centers in Jordan, Kingdom of Saudi Arabia (KSA), Lebanon, Qatar and the United Arab Emirates (UAE). To be eligible for enrollment, subjects had to be 1) of Arab ancestry by self-report, 2) be > 18 years of age. Cases had to be diagnosed as per the 1987 ACR RA criteria. Controls were eligible if they did not have RA or autoimmune disease. Ancestry, demographic, lifestyle, clinical and treatment data was collected via an on-line questionnaire by interviewing the subjects and retrieving information form the medical records. Ancestry was classified into 3 categories as Gulf, Levant or North Africa, when 3 or more grandparents were from the same region. Subjects, which did not fall under those categories for ancestry, were classified as "Other". Data were analyzed using Pearson Chi Square and Fisher's Exact tests.

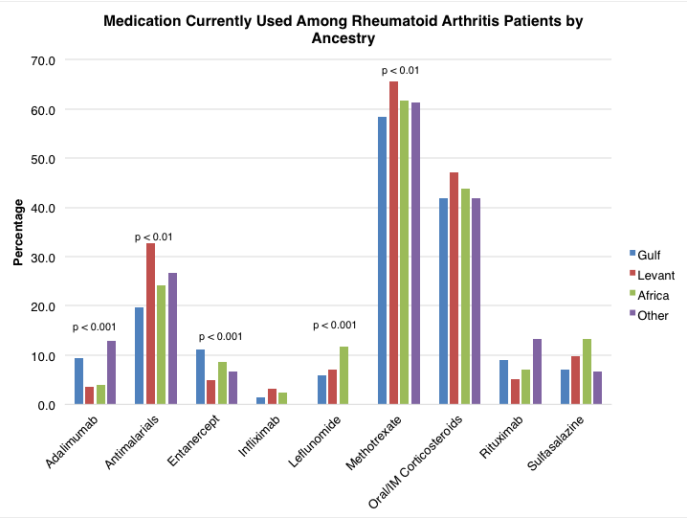
Results:

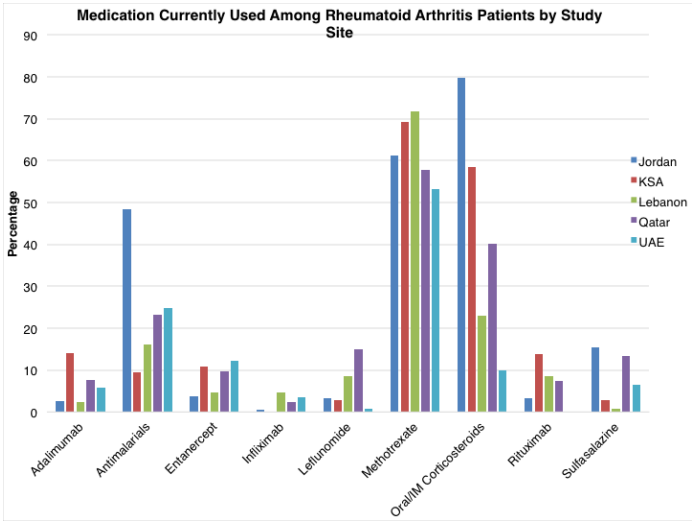
A total of 844 cases, 718 (85.1%) women and 126 men (14.9%) (F/M: 6/1), were enrolled from June 2012 to April 2015. The most common age range of diagnosis for both genders was 30-49(not significant when stratified by study site or ancestry, p>0.05).



The rates of CCP positive, RF positive, CCP/RF positive and seronegative cases differed based on ancestry (p<0.01, excludes the UAE). CCP/RF positive cases were the most common for all ancestries, with The Gulf (174,62.4%) and North Africa (63,62.4%) showing an equal rate of CCP/RF positive cases followed by "Other" (14, 50.0%) and the Levant (48.3). The Levant (77, 26.2%) and "Other" (7, 25.0%) showed a higher rate of seronegative cases than the Gulf (38, 13.6%) and North Africa (15, 14.9%).

Medication use:





Conclusion:

The clinical characteristics of RA and its medical management differ between Arabs of different ancestries found in the Arab region. These differences must be further explored in the context of genetic factors and the influence of GDP on medication use.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The well-known positive effect of pregnancy on improving Rheumatoid Arthritis (RA) disease activity suggests that hormonal changes may play a role in disease pathogenesis and raises a concern that anti-estrogen therapy (AET) including Aromatase Inhibitors [AI] and selective estrogen receptor modulators [**SERMs**] may have an adverse effect on RA. AI can cause musculoskeletal symptoms including AI induced arthritis. Recent observations by our group suggest an increased incidence of RA among patients using either AI or SERMs (1). We intended to examine the effect of AET on disease activity in patients with established RA.

Methods: We searched the electronic medical records in 2 medical centers for patients with the diagnoses of both breast cancer and RA. Of 435 charts reviewed, we identified 40 who had validated RA diagnosis, used SERMs or AI for breast cancer and had appropriate rheumatology evaluation. Data collected included age, BMI, smoking, RA disease duration, clinical status, serology and medication use. The primary outcome measure was worsening of disease within 6 months of AET initiation compared to the most recent evaluation prior to AET, using 2 visits before and 2 after AET. Worsening was defined as an increase in swollen & tender joint count, patient and/or physician global assessment, or documented flare/worsening by rheumatologist assessment, including the need to discontinue AET or modify RA therapy. Worsening could not be attributed to changes or discontinuation of RA therapy. We also reviewed patients who developed RA following initiation of AET.

Results: Thirty eight patients were analyzed. Mean age was 59 years and median duration of RA prior to cancer diagnosis was 8.2 years. AETs used included tamoxifen (6), anastrazole (23) and other AI (9). RA clinical status prior to AET initiation was classified as complete remission (25%), stable (55%) and active (20%), 76.7% were seropositive. Seven patients developed new onset seropositive RA with a mean of 12 months (1-24 months) following initiation of AI (5 patients) and tamoxifen (2). RA worsened in 18 out of 31 patients (58%) after initiating AET, primarily after AI (16/18 patients). On comparing patients who worsened to those who did not (table 1), worsening group was significantly more likely to be younger and seropositive, while age and BMI did not differ between groups. Eighty three percent of patients who were not on DMARDs or biologics worsened while the patients who were maintained on biologics did not.

Table 1: Comparison of Patients with and without RA worsening

Factor	Total (N=31)	Worsening Yes (N=18)	Worsening No (N=13)	p-value
Disease status				0.61[d]
. Remission	8(25.8)	6(33.3)	2(15.4)	
. Stable/Mild	17(54.8)	9(50.0)	8(61.5)	
. Active	6(19.4)	3(16.7)	3(23.1)	
smoking				0.48[d]
• **yes**	10(32.3)	5(27.8)	5(38.5)	
• **No**	21(67.7)	13(72.2)	8(61.5)	
seropositive				***0.025[d]***
. Yes	23(76.7)	16(94.1)	7(53.8)	
. No	7(23.3)	1(5.9)	6(46.2)	
chemotherapy				0.40[d]
. Yes	7(24.1)	3(17.6)	4(33.3)	
. No	22(75.9)	14(82.4)	8(66.7)	
No RA meds or prednisone only				***0.023[c]***
. RA Meds	19(61.3)	8(44.4)	11(84.6)	
. Prednisone or None	12(38.7)	10(55.6)	2(15.4)	
DMARD				0.47[c]
. No DMARD	19(61.3)	12(66.7)	7(53.8)	
. DMARD	12(38.7)	6(33.3)	6(46.2)	
On biologics				***0.023[d]***
. No Biologics	27(87.1)	18(100.0)	9(69.2)	
. Biologics	4(12.9)	0(0.0)	4(30.8)	
Patient Age(Years)	59.2±17.0	54.7±19.0	65.3±11.7	0.085[a]
Disease duration(Years)	7.1±8.5	7.6±10.2	6.3±4.9	0.71[a]
BMI	29.6±8.6	28.0±7.1	31.8±10.3	0.23[a]

Values presented as Mean ± SD, Median [P25, P75], Median (min, max) or N (column %).

p-values: a=ANOVA, b=Kruskal-Wallis test, c=Pearson's chi-square test, d=Fisher's Exact test.

Conclusion: Our study includes the largest reported number of new onset RA cases following the initiation of AET, Our data suggest that use of AET may worsen RA in patients with established disease, especially in those who are not on DMARDs or biologic therapy.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Osteoporosis is more frequently observed in patients with rheumatoid arthritis (RA) than in general population. Bisphosphonate (BP), which suppresses bone resorption by inhibiting osteoclast activation, has been most commonly used for treatment of osteoporosis. Previous studies demonstrated that anti-TNF therapy has a beneficial effect on bone loss possibly through anti-inflammatory effects as well as its inhibitory effects on osteoclast activation. However, there have been few studies assessing the role of TNF blocker for osteoporosis in RA patients under concomitant treatment with BP. Therefore, we performed a retrospective longitudinal study to investigate the changes in bone loss in RA patients received BP with or without TNF blockers.

Methods:

The study cohort consisted of 107 RA patients who were diagnosed with osteoporosis and treated with BP, at a tertiary referral center from Jan. 2005 to Dec. 2013. The areal bone mineral density (BMD) (g/cm^2) of the lumbar spine, femur neck, trochanter and total femur was measured by dual-energy X-ray absorptiometry. Follow-up BMD was obtained at 1.22 ± 0.36 years after initial acquisition of BMD. The rate of change in the BMD was expressed as the annualized percentage change of BMD between initial measurement and subsequent measurement.

Results:

Among RA patients receiving BP with (n = 19) and without TNF blockers (n = 88), 19 (100.0 %) and 80 (90.9 %) were women, respectively. The mean ages at initial BMD for these subjects were 67.4 ± 10.3 years (range, 46 - 84 years) and 66.1 ± 8.3 years (range, 43 - 83 years), respectively (P = 0.569). There was no significant difference in baseline clinical characteristics including laboratory data, baseline BMD and dose of corticosteroid between the two groups. With BP Treatment, follow-up BMD was significantly increased at the area of lumbar spine in RA patients regardless of concomitant use of TNF blockers. Further, there were no statistical significant differences in annualized BMD changes between RA patients receiving BP with or without TNF blockers, although there was a numerical difference in the BMD changes between the two groups (Table 1).

Conclusion:

In RA patients with osteoporosis receiving BP, there was a no significant additional effect of TNF blockers for bone loss. Therefore, administration of BP is still important in treatment of osteoporosis in patients with RA, even in those who were taking TNF blockers.

Table 1. Comparison of mean annualized changes of BMD between patients with and without TNF-blockers

Annualized BMD changes (%/yr)	With TNF blockers (n = 19)	Without TNF blockers (n = 88)	p value
Lumbar spine	4.11 ± 7.2	2.61 ± 7.9	0.450
Neck of femur	2.61 ± 8.5	0.63 ± 7.9	0.328
Trochanter	3.45 ± 17.4	-0.53 ± 9.8	0.173
Total of femur	2.54 ± 10.2	-0.30 ± 5.9	0.103

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Inflammatory ocular disease (IOD) has traditionally been regarded as a severe extra-articular manifestation of rheumatoid arthritis (RA) with high mortality. This study aims to evaluate episcleritis (EP) and scleritis (SC) among a recent large single-institution cohort of patients with RA to determine clinical correlates, outcomes and risk factors.

Methods: A retrospective review was performed to assemble a cohort of patients with EP and SC among RA patients evaluated between 1/1/1996-12/31/2013. All cases met the 1987 ACR criteria for RA. Cases were compared to age- and sex-matched comparators with RA without IOD to identify risk factors. Chi-square and rank sum tests were used to compare characteristics between groups. Kaplan-Meier methods were used to analyze outcomes.

Results: We identified 56 patients (75% female, 92% white, mean age 60 y) with IOD (23 EP, 33 SC). Median follow up was 6.6 y (IQR 4.6 – 13.1) for EP and 3.1 y (IQR 1.3-5.9) for SC. One third had bilateral eye involvement (74 eyes). Majority had seropositive, erosive RA with a median duration of 10.8 y (IQR 3.9-22.2). Although clinical presentation was similar, with conjunctival injection noted in majority, eye pain and headache were more common with SC. Markers of inflammation were elevated in 7/15 SC and 6/15 EP.

EP was primarily treated with topical therapy but SC required systemic therapy (Table) and immunosuppressive agents. SC patients experienced greater loss of visual acuity during disease course (mean 0.3 vs 0.1 logMAR, p = 0.002). At 1 year, the cumulative incidence (CI) of resolution was 65% for EP vs 30% for SC (HR 0.61, p = 0.11) and CI of a new episode of IOD was 10% for EP vs 31% for SC (HR 2.71, p=0.14).

The 56 patients with IOD were compared to 54 age, sex and disease duration matched subjects with RA but without IOD (median disease duration 10.8 y vs. 9.9 y, p = 0.54; median follow up 5.9 y (IQR 2.7-10.4) for IOD patients and 4.3 y (IQR 1.7-10.9) for comparators). Cases had a higher prevalence of severe extra-articular manifestation (ExRA) (Malmo criteria) (25% vs 4%, p = 0.002) and dry eye syndrome (43% vs 19%, p = 0.007). Ten year survival was 76% for IOD vs 69% for non-IOD subjects (HR 0.49: 95% CI: 0.21-1.16, p = 0.10). Patients with SC had a somewhat higher mortality than EP (HR 3.96, 95%CI 0.79-19.75, p=0.094). The incidence of cardiovascular events in 5-years follow up was similar among cases and non-IOD subjects (13% vs 12%, p = 0.933), while new ExRA were more frequent in cases (41% vs 8%, p = 0.006).

Conclusion: Severe ExRA and dry eye syndrome are associated with increased risk of developing SC and EP in patients with RA. SC and EP further predispose to developing additional ExRA, increasing the burden of disease. In contrast to older literature, survival among IOD patients is now at least as good as in those without IOD, perhaps due to modern RA treatment strategies or secular disease trends.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Previous studies showed that obesity in patients with rheumatoid arthritis (RA) is associated with higher disease activity. Beyond obesity, cardiometabolic disturbances may impact the prognosis of RA. We aimed to evaluate the impact of cardio-metabolic clustering (CMC) and of its components at the time of RA diagnosis on disease activity and radiographic progression through the 3 first years of evolution.

Methods: 494 patients from the French early arthritis cohort ESPOIR, fulfilling the ACR/EULAR 2010 criteria and with data available for CMC assessment, were included. CMC was defined as ≥ 2 abnormalities among low levels of HDL cholesterol, elevated levels of triglycerides, blood pressure ≥130/85 mmHg, elevated glycemia and insulin-resistance (Wildman RP et al. Arch Intern Med. 2008;168(15):1617-1624.). Patients were split into 4 categories: non-obese with or without (w/o) CMC and obese patients (BMI≥30 kg/m²) w/o CMC. Baseline characteristics were compared using Chi² and Kruskal Wallis tests. The evolution of DAS28-ESR and total Sharp score at 6 months, 1, 2 and 3 years was compared between the different groups using univariate and multivariate mixed models. Multivariate mixed models including CMC components were used to assess parameters associated with outcomes. Multivariate models including obesity, age, gender, rheumatoid factor or ACPA positivity, CRP (for DAS28 model) and DAS28 (for total Sharp model) were used to assess independent associations between HDL, glycemia and RA outcomes.

Results: 192 and 229 non-obese patients respectively with and without CMC and 55 and 18 obese patients respectively with and without CMC were included. At baseline, age, gender, rheumatoid factor positivity and DAS28 were significantly different between the 4 groups. In univariate mixed models, DAS28 and HAQ evolution during the 3 first years were significantly different between the 4 groups ($p<0.001$), with higher values in obese patients and in patients with CMC. CMC was associated with higher DAS28 and HAQ through the 3 years in non-obese patients ($p=0.003$ and $p<0.001$), but not in obese patients. CMC was also associated with a higher total Sharp score only in non-obese patients ($p=0.02$). In a multivariate model, the only components of CMC associated with outcomes were HDL cholesterol level and glycemia. Low HDL cholesterol level at baseline was an independent predictor of DAS28 during the 3 first years after multiple adjustment ($p=0.003$). Similarly, hyperglycemia at baseline was associated with a higher total Sharp score ($p=0.035$).

Conclusion: In early RA, low HDL cholesterol level and hyperglycemia are independently associated with subsequent higher DAS28 and more severe radiographic progression, respectively. Beyond cardiovascular complications, systematic screening of the CMC in RA patients will help to delineate more accurately disease prognosis.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Low body mass index (BMI) predicts adverse outcomes in rheumatoid arthritis (RA), in part due to weight loss among patients with severe disease and comorbid illness. Weight loss is a strong predictor of adverse long-term outcomes including death. We examined how common therapies

influence short-term changes in BMI in a large database of patients with RA.

Methods: We used 3 administrative VA database sources: the Corporate Data Warehouse (CDW), the Decision Support System (DSS) National Pharmacy Extract, and the Pharmacy Benefits Management (PBM) database. Among patients with at least one diagnosis code for RA, algorithms integrated sources to define unique dispensing episodes of methotrexate, prednisone, leflunomide, and Tumor Necrosis Factor inhibitors (TNFi). The closest values for CRP and BMI within 30 days of the treatment start date were used as baseline values. CRP and BMI values 90, 180, and 365 days from the treatment start date (+/- 30 days) were recorded. Important weight loss was defined as a decrease in BMI of more than 1 kg/m^2. Regression models evaluated changes in BMI at 6-months among treatments compared to methotrexate adjusting for potential confounders such as demographics, seropositivity, CRP, 6-month change in CRP, disease duration, current smoking, and comorbid conditions, including the Rheumatology Disease Comorbidity Index (RDCI). Matched weighting on propensity was utilized adjust for confounding by indication. Sensitivity analyses considered dual use of other RA therapies.

Results: There were 45,264 unique incident treatment courses in 31,175 patients with available BMI data. There were differences in patient characteristics between those receiving different treatments. Prednisone-treated patients had more weight gain, while those receiving leflunomide had substantially greater weight loss ($p<0.001$) (Figure). In multivariable models there was more weight loss among leflunomide users compared to methotrexate [β: -0.40 (-0.45, -0.35) $p<0.001$] and more weight gain among prednisone users [β: 0.072 (0.042, 0.10) $p<0.001$] while no differences were observed with TNFi. There was a greater risk of weight loss for leflunomide after adjustment [OR 1.73 (1.55, 1.79) $p<0.001$]. Associations between therapies and weight change were not attenuated with propensity-adjustment or in sensitivity analyses. Predictors of weight loss included older age, greater CRP, no improvement in CRP, greater BMI, current smoking, disease duration, RDCI, lung disease, and malignancy. Weight loss was associated with drug discontinuation at 6 months and death at 3 years.

Conclusion: Patients initiating leflunomide are marginally (75%) more likely to lose a clinically significant amount of weight compared to those who start other therapies after adjusting for confounding factors. Prednisone use is independently associated with modest weight gain.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Rheumatoid arthritis (RA) is associated with an increased rate of cardiovascular (CV) disease. Systemic inflammation has been implicated as a key factor behind CV comorbidity in RA. The objective of this study was to investigate the impact of disease activity and inflammation over the first two years on the risk of subsequent CV events in patients with early RA.

Methods:

An inception cohort of patients with early RA (symptom duration <12 months), recruited in 1995-2005 from a defined area, was investigated. Patients were followed according to a structured program, with follow-up visit at 6, 12 and 24 months after inclusion. The clinical examinations were performed by the same rheumatologist. Those included in the study were managed according to usual care, with no pre-specified protocol for anti-rheumatic treatment or CV prevention. Patients with a 24-month visit in 1998 or later were included in the present analysis. Data on CV events (hospitalization or out-patient visit due to coronary artery disease, cerebrovascular disease or peripheral artery disease) during the period 1998-2011, based on diagnostic codes, were retrieved from a regional health care register. Traditional CV risk factors were investigated in a structured review of the medical records. Cox regression models were used to assess associations between the area under the curve (AUC) for disease activity parameters over the first two years, and CV events occurring later during the disease course. Furthermore, the impact of disease activity parameters at the 2-year follow-up were assessed in separate models. Since the assay for CRP was modified to a high-sensitivity analysis during the study period, the AUC for CRP could not be calculated. CRP was therefore modelled as a dichotomized variable (above vs. below the 75th percentile at 2 years).

Results:

A total of 207 patients with early RA (70 % women, mean age 62 years) were followed from the 24-month visit to the first CV event, migration from the region, death or Dec 31, 2011. CV events occurred in 54 patients during the follow-up. A high disease activity over the first two years (defined as AUC for DAS28 above the median) was associated with a significantly increased risk of CV events (age-sex adjusted hazard ratio (HR) 2.03; 95 % confidence interval (CI) 1.15-3.60). In separate analyses, it was demonstrated that patients with CRP at two years within the highest quartile (>11 mg/l) had a significantly higher risk of CV events compared to those with lower CRP values (age-sex adjusted HR 1.82; 95 % CI 1.04-3.17). Results were similar in models adjusted for smoking, hypertension and diabetes in addition to age and sex (multivariate adjusted HRs for DAS28-AUC above the median: 2.05 (95% CI 1.13-3.73); for CRP>11 mg/l: 1.90 (95% CI 1.06-3.42)).

Conclusion:

A high disease activity during the first two years after RA diagnosis and a high CRP at the two-year follow-up were both associated with a doubled risk of CV events. These findings suggest that patients with persistently active RA are at particularly increased risk, and highlight the importance of disease control for CV prevention in patients with early RA.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is associated with increased risk of cardiovascular disease (CVD). Disease severity, including extra-articular rheumatoid arthritis (ExRA) manifestations, has previously been demonstrated to be a major risk factor for CVD. With improved treatment possibilities, it is important to assess potential changes in the effect of disease severity measures on development of CVD in patients with RA. The aim of this study was to investigate the impact of patient reported outcome measures (PROMs) and severe ExRA on the risk of CVD in a community based sample of patients with RA.

Methods:

A dynamic community based cohort of patients with RA (n=1977) was studied. Information on CVD events was obtained from a regional health care register. Clinical records were reviewed from January 1, 1998 to December 31, 2011, and cases with severe ExRA (i.e. pericarditis, pleuritis, vasculitis, interstitial lung disease, neuropathy, episcleritis/scleritis, Felty's syndrome and glomerulonephritis), classified according to predefined criteria, were identified. The impact of time dependent incident severe ExRA on CVD was examined in Cox regression models. Questionnaires including the Health Assessment Questionnaire (HAQ) and visual analogue scales (VAS) for current pain and global health were sent to the patients in 1997, 2002, 2005 and 2009. The impact of baseline PROMs, based on the first available questionnaire for each patient, on the risk of CVD was examined in Cox regression models.

Results:

There were 1436 (72.6%) women and 541 (27.6%) men in the study cohort. At the start of follow-up the mean age was 59.9 years and the median disease duration was 5.0 years. During the follow-up, 619 patients had at least one CVD event. There were 387 cases with coronary artery disease (CAD), 221 with cerebrovascular disease and 185 with peripheral artery disease (PAD). Seventy-two patients with a previous history of severe ExRA were excluded. Incident severe ExRA (n=121) did not predict CVD overall [age and sex adjusted HR 0.99; 95% CI 0.70-1.39], CAD, cerebrovascular disease or PAD. In a sensitivity analysis, episcleritis and pleuritis (n=34), which may be regarded as milder ExRA manifestations, were excluded. Severe ExRA was still not associated with a significantly increased risk of CVD (age-sex adjusted HR 1.21; 95 % CI 0.85-1.71), although there was a borderline association with PAD (age-sex adjusted HR 1.68; 0.99-2.84). Greater disability, measured by HAQ at baseline, was predictive of CVD [age and sex adjusted HR (per SD) 1.13, 95% CI 1.03-1.25]. There was a positive association between HAQ and CAD as well as PAD, but not with cerebrovascular disease. Similar patterns were seen in models including VAS for current pain and global health, which were both predictive of CVD overall, CAD and PAD, but not of cerebrovascular events.

Conclusion: Severe ExRA did not predict cardiovascular disease in this cohort of patients with RA. Potential explanations for this discrepancy from previous studies include differences in case selection and improved management of ExRA over time. Disease severity, measured by PROMs, predicted the occurrence of CVD, with the exception of cerebrovascular disease.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Previous studies combining immunosuppressive biologics have shown an increased risk of infections. Few studies have examined the risk of infection with concurrent use of the anti-osteoporosis agent, denosumab (DMAb), a human monoclonal antibody, and an immunosuppressive biologic used to treat rheumatoid arthritis (RA). In this study we examined the occurrence of serious and opportunistic infections in two RA populations: patients treated concurrently with DMAb and an immunosuppressive biologic, and patients treated with only an immunosuppressive biologic.

Methods: We reviewed a select group of RA patients from two rheumatology practices in Hamilton, Ontario, Canada, between the study period of July 01, 2010 and July 31, 2014. Patients were included if they were ≥ 18 years of age with RA, registered in the treatment center ≥ 3 months before and after the index date, and received ≥ 1 injection/infusion or filled a prescription for an immunosuppressive biologic therapy for RA. Patients were excluded if they had HIV or AIDS, were receiving cancer treatment or immunosuppressive therapies for conditions other than RA, or were living in a nursing home. We examined two RA patient groups: those who had used DMAb and an immunosuppressive biologic concomitantly in the study period (concurrent group) and those who had used an immunosuppressive biologic alone in the study period (biologic-alone group). The concurrent group was assigned an index date derived from their initial DMAb injection. A frequency-matching technique utilizing the index date of the concurrent group was used to select the index date of the biologic-alone group. Serious infection was defined as resulting in hospitalization or an ER visit with use of IV antibiotics, associated with the primary diagnosis of infection. Instances of serious or opportunistic infections were recorded. The observational period for infections was between the index date and July 31, 2014 or loss to follow-up, whichever came first. As this was not a comparative study, each group was analyzed separately.

Results: A total of 218 patients met eligibility criteria for the study (N = 109 concurrent group; N = 109 biologic-alone group). Descriptive statistics for both groups are provided in Table 1. Three events of serious infection occurred in three patients in the concurrent group (three cases of pneumonia resulting in hospitalization), and three events of serious infection occurred in three patients in the biologic-alone group (two cases of pneumonia and one upper respiratory tract infection, all resulting in hospitalization). In both groups, all patients recovered and there were no instances of opportunistic infections or death.

Conclusion: RA patients may require treatment for bone loss due to intrinsic disease, steroid use, and advancing age. This study demonstrates a low occurrence of serious infections in biologically-treated RA patients, including patients with concurrent DMAb use.

Table 1: Participant Characteristics* of the Concurrent (Denosumab + Biologic) Group and Biologic-alone Group

Characteristic	Concurrent Group N = 109	Biologic-alone Group N = 109

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Cardiovascular diseases are important contributors to the excess of overall morbidity and mortality in patients with rheumatoid arthritis (RA). The aim of this study is to investigate the effects of RA on cardiac remodeling in patients with acute coronary syndrome (ACS)

Methods: Sixty-one patients with ACS complicated with RA and 55 age- and sex-matched patients with ACS having no RA (controls) were enrolled; General parameters and cardiovascular risk factors were compared in 2 groups. Echocardiogram measurements were used to determine the changes of cardiac morphology and function.

Results: Mean value of BMI in patients of ACS+RA group (27.50±3.53) was significantly higher than that of the controls (24.84±2.36) (P<0.05). No difference was observed in the levels of serum TG, TC and LDL-C, but HDL levels were significantly lower in ACS+RA patients (0.91±0.20 mmol/L) than that in controls(1.10±0.23mmol/L) (P<0.05). Serum HCY (17.27±4.71 mmol/L) ,CRP levels(9.84±5.50 mg/L) and ESR (28.35±15.87 mm/1h) were significantly higher in patients in the ACS+RA group than controls (13.16±4.23 mmol/L,P<0.05), (4.21±3.25 mg/L, P<0.01), (9.33±3.88 mm/1h, P<0.01) respectively. The BNP levels in patients of ACS+RA group (386.31±225.88 pg/ml) was significantly higher than the control group (258.43±136.97 pg/ml),(P<0.05). Rate of left ventricular (LV)hypertrophy (50.8%), and LV diastolic dysfunction (E/A<1) (96.7%) were significantly higher in the ACS+RA group(29.1%, *P*<0.05), (61.6%),(*P*<0.01). While the LV ejection fraction % were significantly lower (54.86±12.12% Vs 63.83±5.61%), (*P*<0.05). Incidence of tricuspid regurgitation (45.9%) and pulmonary valve regurgitation (9.8%) were significantly higher in ACS patients complicated with RA than that in control (12.7%, *P*<0.01) (0%*P*<0.05). Comparison of aortic and mitral regurgitation between the two groups had no statistical significance.

Conclusion: with ACS complicated with RA are more likely to be afflicted with left ventricular remodeling, reduction of systolic and diastolic functions, and cardiac valve impairment.

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: To investigate the efficacy and safety of rituximab (RTX) in the the management of progressive rheumatoid arthritis related interstitial lung disease (RA-ILD).

Methods: An open observational study was performed in patients with progressive RA-ILD (evidence of clinical and functional decline) and inadequate articular response (DAS28 > 3.2) despite treatment with glucocorticoids and synthetic DMARDs.

The following main efficacy variables were evaluated at the end of follow-up: *1)* the improvement of joint counts measured by DAS28-ESR and *2)* the evolution of pulmonary function tests (PFT) according to definitions from the American Thoracic Society, including *a) improvement:* if an increase in FVC ≥ 10% or DLCO ≥ 15% is observed; *b) stabilization:* if changes in FVC are less than 10% or 15% in DLCO; and *c) worsening:* if FVC decreases ≥ 10% or DLCO ≥ 15%.

Results: Thus far, 13 patients have been included (seven women) with a mean age (± SD) of 53 ± 13 years (range, 35-74). All patients were ACPA positive.

The time of evolution (median) was 24 months (range, 8-168) for RA and seven months (range 1-16) for RA-ILD. Regarding tissue specificity, 10 (77%) cases corresponded to NSIP and three to UIP.

Once RA-ILD was diagnosed, patients with NSIP received prednisone treatment at a dose of 0.75-1 mg/kg, whereas patients with UIP were treated with prednisone at a dose of 10-15 mg/day and N-acetylcysteine at a dose of 1800 mg/day. In addition, methotrexate was substituted for leflunomide in eight patients, azathioprine in three, and salazopyrin in two.

At the start of RTX treatment (dose: 1 g on days 1 and 15, repeating the cycle after six months depending on the response), the mean DAS28 value was 5.5 ± 1.1, baseline FCV (%) was 75 ± 15, and baseline DLCO (%) was 55.5 ± 21.

At the end of an 11-month (median, range 6-111) follow-up period, the mean DAS28-ESR score decreased to 3 ± 1.3 (% improvement: -45.45%; range, -62 to -24%). In seven patients (54%), remission of the joint disease (DAS28 < 2.6) was achieved, and in six patients, there was low activity (DAS28 ≤ 3.2). The evolution of PFT values is shown in the following table:

	FVC	**DLCO**	**Postreatment high resolution computed tomography (HRCT)** **(N=8)**
Improvement	5	1	1
Stabilization	8	11	7
Worsening	0	1	0

Considering the total sample, FCV improvement (FCV after treatment: 87 ± 18; 16% improvement) and DLCO stabilization (DLCO after treatment: 59.3 ± 22; 6.8% improvement) were achieved. The number of RTX cycles administered (mean ± SD) was 3.25 ±1.5 (range, 1-6).

The frequency of adverse effects was low, occurring in only one patient (8%) who developed pulmonary aspergillosis at five months of treatment, forcing a temporary suspension of treatment.

Conclusion: In our experience, RTX is a relatively safe and effective drug for the treatment of patients with active symptomatic RA-ILD and an insufficient articular response despite treatment with glucocorticoids and synthetic DMARDs. In this subgroup of patients RTX administration achieved remission/low activity of clinical joints and, at a minimum, PFT were stabilized.

End Stage Renal Disease (ESRD) in Patients with Rheumatoid Arthritis

Sunita Paudyal[1], Monique Bethel[2], Frances Yang[1], Alyce Oliver[1], Michael Skelton[1], Christopher Rice[1], Brian Le[3], Shilpa Brown[1], Stanley Nahman[1] and Laura Carbone[4], [1]Georgia Regents University, Augusta, GA, [2]Internal Medicine, Georgia Regents University, Augusta, GA, [3]Medicine, Georgia Regents University, Augusta, GA, [4]Rheumatology, Georgia Regents University, Augusta, GA

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Substantial progress has been made in the treatment of rheumatoid arthritis (RA) and life expectancy has increased. As the population of patients with RA continues to age, they may be more likely to suffer from diseases of aging, including ESRD. However, the characteristics of patients with RA and ESRD, treatment patterns for RA in the setting of ESRD and the impact of RA on mortality in ESRD have not been previously been examined. The purpose of this study was to determine the prevalence of ESRD and reasons for dialysis in RA, treatment modalities for RA in the setting of ESRD and five year cardiovascular mortality in patients with RA and ESRD compared to those with ESRD without RA.

Methods:

Retrospective cohort study of adult ESRD patients with RA without HIV in the United States Renal Data System (USRDS) beginning in calendar year 2011. Medicare Part D beneficiary data was used to determine filled prescriptions for medications that might be used to treat RA including corticosteroids, DMARDs and biologics. Cox proportional hazard models were estimated to determine five year cardiovascular-related mortality in patients with RA compared to all others with ESRD without RA.

Results:

There were 28,589 patients with RA and ESRD in 2011. Based on population estimates of the frequency of RA in adults in the United States, approximately 2% of adult patients with RA have ESRD. Patients with ESRD and RA are more likely to be female, to have hypertension, diabetes, atrial fibrillation and cardiovascular events ($p<0.01$ for all) than those with ESRD without RA. Hypertensive renal disease (30%) and type II diabetes (25%) are the most common causes of ESRD in RA; amyloidosis, vasculitis and analgesic nephropathy are uncommon, accounting for less than 5% of all cases. More than half of ESRD patients with RA had a filled prescription for a medication for RA treatment; most commonly prednisone (42% of all prescriptions). Ten percent of all filled prescriptions were for hydroxychloroquine; 2.63% for leflunomide and 1.39% for sulfasalazine. Biologics were a rare class of filled prescription therapies (etanercept 1.59%;adalimumab 1.07%; golimumab, infliximab, anakinra and abatacept each comprised <1% of total filled prescriptions in this population). After adjustment for covariates, compared to patients without RA with ESRD, five year cardiovascular mortality in patients with RA and ESRD was significantly increased (HR 1.42 (95%CI 1.38-1.47).

Conclusion:

ESRD is infrequent in patients with RA but has a significant impact on cardiovascular mortality. Similar to the general ESRD population, hypertension and diabetes mellitus are the most common causes of dialysis. Prednisone and hydroxychloroquine are the most frequent prescriptions filled that could be used to treat RA; use of biologics appears uncommon in this population. Further prospective studies of the impact of ESRD on outcomes in RA and optimal treatments for RA in the setting of ESRD are needed.

Abstract Number: 1571

How Substantive Is Heart Rate Variability As a Predictor of Anti-TNF Treatment Outcome for Inflammatory Arthritis?

Andrew Holman[1] and Edmund Ng[2], [1]Inmedix, Normandy Park, WA, [2]Statistical Thinking, Seattle, WA
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II

Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

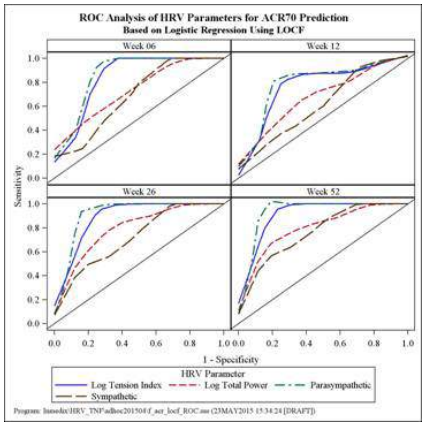
As rheumatologists search for new targets to improve immunosuppressive outcomes, the autonomic nervous system (ANS) as a co-factor in autoimmune disease expression has gained interest. At ACR 2014, heart rate variability (HRV), an accepted assessment of ANS state, was described as a biomarker in SLE. At ACR 2008, HRV predicted biologic treatment outcome for inflammatory arthritis in a 52-week, double-blind, prospective study[1]. But, how worthy is HRV as a metric with pathophysiologic and even therapeutic impact?

Methods:

An in depth, *post hoc* analysis of the clinical study that established proprietary HRV (Omegawave Ltd, Espoo, Finland) as a predictor of biologic treatment outcome for inflammatory arthritis was conducted.[1] To further evaluate the performance of HRV measures in predicting ACR outcomes, receiver operating characteristic (ROC) analysis have been carried out. Area under the ROC curve (AUC) was calculated and the ROC curve was plotted for each of the HRV measures. Youden index was used to find the optimal cutoff at which the sensitivity and specificity were maximized. Relative risk (RR) of the ACR response at the optimal cutoff was also calculated.

Results:

Thirty-three patients (25 rheumatoid and 8 psoriatic arthritis by ACR criteria) were included in the analysis.[1] All HRV measures (parasympathetic, sympathetic, tension index, total power) achieved better prediction with increasing duration of anti-TNF therapy as measured by the AUC. The HRV measures provided moderate to high AUC values at week 26 and week 52 for ACR20/50/70 (range: 0.631 to 0.926). ROC AUC (95% CI) was most optimal for parasympathetic and log tension index to predict ACR70 response at 52 weeks at 0.926 (0.834, 1.000) and 0.918 (0.824, 1.000), respectively. At the optimal cutoff, sensitivity and specificity for the parasympathetic HRV measure to predict ACR70 at 52 weeks were 100% and 88.5%, respectively, and for the tension index, 100.0% and 84.6%, respectively. RR for all HRV measures at optimal cutoffs for ACR20/50/70 at 26 and 52 weeks ranged from 2.23 to infinity (all p-values < 0.05). Patients with parasympathetic > the optimal cutoff (0.17) were 16 times (RR 95% CI: 2.22 to 115.14) more likely to achieve ACR70 at 52 weeks than patients with parasympathetic ≤ the optimal cutoff (p-value < 0.001).



Conclusion:

Expanded statistical analyses of the referenced study further supports HRV as substantively impactful of prediction of anti-TNF biologic treatment outcome of inflammatory arthritis. These findings may encourage study in other diseases, with non-anti-TNF immunosuppressive regimens; expand elucidation of ANS immunomodulatory mechanisms that impact autoimmune disease expression and treatment response; and target the ANS as a prolific source of new therapeutics able to enhance immunosuppressive regimens.

Session Time: 9:00AM-11:00AM

Background/Purpose: Chylomicrons, with apolipoprotein (apo) B48 as a structural protein, induce leukocyte and complement activation and contribute to atherosclerosis. ApoB48 is higher in conditions associated with a higher degree of systemic inflammation and apoB48 helps to identify patients at increased cardiovascular risk. There are no data available on apoB48 levels in rheumatoid arthritis (RA) in relation to atherosclerosis. Since classical risk factors do not predict the cardiovascular risk well in RA, search for novel markers of risk is relevant. The objective of this study was to investigate the levels of apoB48 in RA patients compared to patients with coronary artery disease (CAD) and its association with metabolic and other lipid parameters, carotid intima media thickness (cIMT) and the estimated cardiovascular risk.

Methods: RA patients, without the presence of clinical cardiovascular disease or diabetes mellitus and participating in the FRANCIS study, were included. Also subjects with CAD (CAD+) and without RA were included. Blood samples were collected after an overnight fast and a complete lipid profile, including total plasma apoB and apoB48 (ELISA) were measured. cIMT was measured using ultrasound.

Results: 328 Patients with RA and 56 CAD+ patients were included. RA patients were younger (53±11 vs. 68±11 yrs; P<0.001), more often female (68% vs. 34%; P<0.001) and had lower remnant cholesterol (remnant-C) concentrations (0.52±0.26 vs. 0.75±34 mmol/l; P<0.001) and triglycerides (1.25±0.88 vs. 1.83±1.12 mmol/l; P<0.001) compared to CAD+ patients. Median apoB48 was significantly higher in RA patients compared to CAD+ patients (8.6 [IQR 5.2-12.5] vs. 7.1 [IQR 4.9-10.4] mg/L; P=0.026). In RA apoB48 correlated positively with triglycerides (r=0.616; P<0.001), remnant-C (r=0.479; P<0.001), LDL-cholesterol (r=0.123; P=0.03) and the cardiovascular risk score according to the SCORE model (r=0,141; P=0.011). No significant correlation between apoB48 and cIMT (r=0.103; P=0.07), BMI (r=0.014; P=0.81), systolic blood pressure (r=0.095; P=0.09), glucose (r=0.106; p=0.06)and RA DAS28 (-0.32; P=0.58) was found.

Conclusion: In RA apoB48 is associated with an increased cardiovascular risk score and may contribute to the increased atherogenesis of RA. Since apoB48 in RA was higher compared to CAD+ patients, despite lower triglycerides and remnant-C, chylomicron remnant clearance may be impaired in RA.

Plasma Pentraxin 3 Concentration Is Associated with Progression of Radiographic Joint Damage but Not with Carotid Atherosclerosis in Female Patients with Rheumatoid Arthritis: Results from a 3-Year Prospective Study

Yu Asanuma[1], Yuki Shimada[2], Yoshimi Aizaki[1], Kazuhiro Yokota[1], Noritsune Kouzu[3], Yoshitake Takebayashi[4], Hisashi Noma[4], Shinichi Kawai[5] and Toshihide Mimura[2], [1]Department of Rheumatology and Applied Immunology, Faculty of Medicine, Saitama Medical University, Saitama, Japan, [2]Saitama Medical University, Saitama, Japan, [3]Kouzu Orthopaedic Clinic, Chiba, Japan, [4]The Institute of Statistical Mathematics, Tokyo, Japan, [5]Div of Rheum/dept of Int Med, Toho Uni Sch of Med, Tokyo, Japan

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Pentraxin 3 (PTX3) plays an important role in inflammation, immunity, and atherosclerosis. Plasma PTX3 level is recognized as a marker that responds to local inflammation. PTX3 stimulates osteoclastogenesis by increasing osteoblast RANKL production in vitro. PTX3 is strongly expressed in human

atherosclerotic plaque, and plasma PTX3 concentration increases in patients with atherosclerotic cardiovascular disease such as unstable angina pectoris and myocardial infarction. Rheumatoid arthritis (RA) is a chronic inflammatory disorder, which is known to develop joint damage and atherosclerosis. We examined the hypotheses that the PTX3 concentrations are elevated in patients with RA and are associated with 3-year progression of joint destruction and subclinical atherosclerosis.

Methods: Plasma PTX3 concentrations were measured in 72 female patients with RA and 80 healthy control. The patients were also evaluated with respect to their clinical characteristics, joint damage, atherosclerosis and medications. Radiographs of the hands and feet were evaluated using the van der Heijde modified Sharp scoring method at baseline and at 3 years in patients with RA. We also performed carotid ultrasonography to measure subclinical atherosclerosis at the two time points in RA patients. Among female patients with RA, we investigated whether plasma PTX3 levels were associated with the progression of joint destruction and carotid intima media thickness (IMT), a surrogate marker of atherosclerosis during 3 years of follow-up.

Results:

Plasma PTX3 levels were significantly higher in female patients with RA (4.05±2.91 ng/mL) compared to healthy females (1.61±1.05 ng/mL) (Wilcoxon's rank sum test: P<0.001). Follow-up imaging of articular radiographs and carotid ultrasonography were not obtained from 10 and 8 patients, respectively. Progression of joint damage was observed in 72.6% out of 62 patients during 3 years. Incident plaque was observed in 45% patients (40 out of 64) without baseline plaque. IMT progression was detected in 34 (53%) out of 64 patients. By multivariate analysis using multiple linear regression model for the RA patients, baseline plasma PTX3 levels were significantly associated with total Sharp score (P=0.004), erosion score (P=0.002) and joint space narrowing score (P=0.031) after 3 years follow-up with adjustment for baseline score of joint damage, age, BMI, rheumatoid factor, DAS28-ESR4, postmenopausal, use of biologics. Besides, PTX3 did not predict 3-year carotid artery IMT progression nor incident plaque in RA.

Conclusion: Female patients with RA have increased concentrations of PTX3 compared with control subjects. PTX3 was significantly associated with radiographic progression of joint damage but not with carotid atherosclerosis in RA.

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Mortality from cardiovascular (CV) and respiratory causes is increased in rheumatoid arthritis (RA). Predictive serologic biomarkers of these events are lacking. Previously, we have shown anti-malondialdehyde-acetaldehyde (MAA) antibodies to be associated with disease severity in RA. Anti-MAA antibodies also predict coronary artery disease in the general population and are a marker of smoking and alcohol exposure in the lung. The potential of anti-MAA antibodies as biomarkers of CV and respiratory mortality in RA was assessed in conjunction with serum cytokines / chemokines (CK) and anti-citrullinated protein antibodies (ACPA).

Methods: Male participants in the Veterans Affairs RA registry were followed from enrollment until death or December 2013. Using banked serum from enrollment, anti-MAA antibodies were measured with ELISA, CKs were measured using a bead-based multiplex assay, and ACPAs were measured using multiplex antigen array. CK and ACPA scores were calculated from individual CKs and ACPAs. Vital status and cause of death were determined through the National Death Index. Associations with cause-specific mortality were examined using multivariable competing-risks regression adjusting for age, race, smoking status, body mass index, comorbidity, visit frequency, nodules, RF concentration, enrollment DAS-28, baseline DMARDs and prednisone use.

Biomarkers were analyzed as log transformed continuous variables and ordinal categorical variables by quartile.

Results: There were 1,552 patients included with 321 all-cause, 100 CV, and 50 respiratory deaths occurring over 5,940 patient-years of follow-up. Patients were older (mean 65 ± 10 years), had established disease (median 8.6 years), were seropositive for RF (81%) or anti-CCP antibody (79%), and had frequent smoking history (83% current or former). Associations with cause-specific mortality are shown in Table 1. IgA and IgM anti-MAA antibodies were associated with respiratory mortality. There was a trend towards an association between both respiratory and CV mortality with increasing IgA anti-MAA antibody quartiles. An inverse association of ACPA score with respiratory mortality was observed, though this did not reach statistical significance.

Table 1. Associations of Serum Anti-MAA Antibodies, Cytokines, and ACPAs with CV and Respiratory Mortality in RA.

	All-Cause	Cardiovascular	Respiratory
	Hazard Ratio (95% Confidence Interval) P trend Across Quartiles		
IgA anti-MAA	**1.13 (1.02-1.24) P = 0.019** **P trend < 0.001**	1.01 (0.78-1.32) P = 0.92 P trend = 0.062	**1.20 (1.02-1.42) P = 0.029** P trend = 0.055
IgM anti-MAA	1.05 (0.95-1.15) P = 0.36 P trend = 0.31	1.00 (0.85-1.19) P = 0.97 P trend = 0.46	**1.18 (1.00-1.38) P = 0.05** P trend = 0.43
IgG anti-MAA	0.98 (0.95-1.02) P = 0.33 P trend = 0.51	0.95 (0.71-1.25) P = 0.70 P trend = 0.61	0.93 (0.76-1.15) P = 0.52 P trend = 0.50
Cytokine score	**1.21 (1.08-1.36) P = 0.001** **P trend = 0.012**	1.05 (0.91-1.21) P = 0.49 P trend = 0.96	1.00 (0.67-1.48) P = 0.99 P trend = 0.51
ACPA score	0.98 (0.90-1.06) P = 0.59 P trend = 0.57	0.97 (0.89-1.05) P = 0.38 P trend = 0.48	0.87 (0.75-1.01) P = 0.06 P trend = 0.14
Abbreviations: MAA, malondialdehyde-acetaldehyde; ACPA, anti-citrullinated protein antibody.			

Conclusion: Serum IgA and IgM anti-MAA antibodies predict respiratory mortality in RA independent of disease activity and smoking status, showing promise as a potential biomarker. Further studies are needed to identify the MAA modified peptides driving these antibody responses and to investigate if the observed association is more closely related to smoking-related lung disease (i.e. COPD) or RA-related lung disease (i.e. ILD).

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Mortality is increased in Rheumatoid arthritis (RA) patients mainly due to cardiovascular (CV) disease; however the biologic mechanisms are unknown. Increased CV risk in RA is attributed to both traditional risk factors and systemic inflammation. CV risk scores, even after modification as recommended by EULAR, underestimate risk in RA and thus there is a need to develop a better means of risk stratification. Murine collagen induced arthritis (mCIA) is associated with vascular dysfunction, characterised by reduced vascular constriction to 5-hydroxytryptamine (5-HT). This study was undertaken to characterise the relationship between VCAM-1, which is induced in proatherosclerotic conditions in the general population, and vascular dysfunction in mCIA and CV risk in RA patients.

Methods:

mCIA was induced in DBA/1 mice. Severity of arthritis was assessed by arthritis index score. Constriction responses to 5-HT were used to assess vascular function in isolated sections of thoracic aorta. Serum VCAM-1 was measured with ELISA.

Serum VCAM-1, IL-6, ESR and CRP were measured with ELISA in RA patients (182 patients, F:M 4:1, mean age 60 years (range 21-89), mean disease duration 11.4 ± 11 years). CV risk was calculated using the Framingham risk calculator and the QRISK2 algorithm. The latter includes RA as an independent CV risk factor.

Results:

In mCIA VCAM-1 levels (mean 1500ug/mL, range 929-2528) correlated with arthritis index score (r=0.43, p=0.03) and negatively correlated with maximal aortic contraction (r =-0.35, p<0.05) (Figure1).

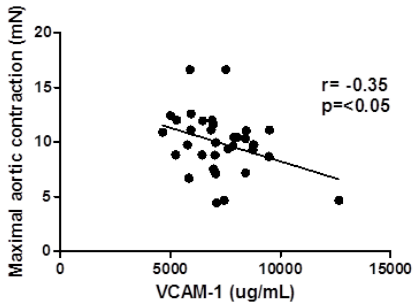

Figure 1. VCAM-1 is negatively correlated with maximal aortic contraction in mCIA in DBA-1 mice

In patients with RA, VCAM-1 was significantly higher in those with a Framingham CV risk score >10% over 10 years (1200ng/mL ± 547) compared to those with <10% risk (937ng/mL ± 570, p=0.02). Similarly the respective VCAM-1 levels using the QRISK2 were 1179ng/mL ± 583 versus 949ng/mL ± 564, p<0.05. VCAM-1 was positively correlated with IL-6 levels (R=0.24, p= 0.008), DAS28 (r=0.25, p= 0.03) and age (r=0.26, p= 0.002). There was no statistically significant correlation between VCAM-1 level and disease duration, statin use, BMI, cholesterol, systolic BP, gender or smoking.

One of the major differences between QRISK2 and Framingham is inclusion of RA as an independent risk factor in the former. QRISK2 and Framingham CV risk scores were correlated moderately (r=0.7, p<0.0001). Multivariate analysis using backward stepwise multiple regression, found that VCAM-1 (p=0.002) was a statistically significant independent predictor of QRISK2 score when added to Framingham and increased R^2 from 0.6 to 0.62.

Conclusion:

VCAM-1 levels correlate not only with disease activity and vascular dysfunction in mCIA but also disease activity and CV risk in RA. VCAM-1 is a potential biomarker for CV disease in RA warrants further investigation.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Immunogenicity of pneumococcal and influenza vaccine in patients with rheumatoid arthritis (RA) have been assessed in many studies. However, the humoral immune response of hepatitis B vaccination in RA patients is not clearly known. This study aims to assess the humoral immune response of hepatitis B vaccination in RA patients receiving conventional synthetic and biological disease modifying anti-rheumatic drugs (csDMARDs and bDMARDs).

Methods:

Forty-five patients with RA (study group), 33 patients received only csDMARDs and 12 patients received both csDMARDs and bDMARDs, and 9 healthy age- and sex-matched subjects (control group) were enrolled in this prospective open-label single-center study. All patients had negative results for hepatitis B surface antigen, hepatitis B core antibody, and hepatitis B surface antibody (anti-HBs) on screening. All subjects received 20 µg of recombinant hepatitis B vaccine (Euvax B®) at weeks 0, 4, and 24. Blood samples were collected 8 weeks after receipt of the third vaccine dose to test for anti-HBs. The responder and high responder were defined as anti-HBs levels of ≥ 10 mIU/ml and ≥ 100 mIU/ml, respectively. Treatment related adverse events reported by patients or observed by physician were collected at every visit. The study was approved by the ethic committee and institutional review board.

Results:

Eight weeks after vaccination, the number of responder significantly lower in study group than control group (64% vs 100%, $p = 0.04$) (Table). In the study group, older age and rituximab use were significantly associated with hepatitis B vaccine non-response ($p = 0.04$ and $p = 0.02$, respectively), while disease duration, disease activity, comorbidities, and the use of prednisolone, methotrexate, etanercept, or infliximab were not associated with hepatitis B vaccine non-response. In subgroup analyses, RA patients receiving csDMARDs tended to has lower number of responder compared with control group (70% vs 100%, $p = 0.09$). However, the number of high responder was significantly lower in patients receiving csDMARDs compared with control group (52% vs 100%, $p = 0.01$). In RA patients receiving bDMARDs, the number of responder and high responder were significantly lower compared with control group (50% vs 100%, $p = 0.02$, 42% vs 100%, $p = 0.01$). No serious adverse event was observed, but one patient (2%) experienced flare of arthritis.

Conclusion:

In RA patients receiving csDMARDs and bDMARDs, older age and rituximab use associated with impaired humoral immune response to hepatitis B vaccine. Further studies are required to confirm these findings in larger numbers of subjects.

Table Proportions of responders and high responders in rheumatoid arthritis patients receiving conventional synthetic and biological disease modifying anti-rheumatic drugs compared with healthy subjects

	Healthy subjects	All RA patients	RA receiving csDMARDs	RA receiving bDMARDs
	(n = 9)	**(n = 45)**	**(n = 33)**	**(n = 12)**
Responder (anti-HBs ≥ 10 mIU/ml), %	100%	64% ($p = 0.04$)	70% ($p = 0.09$)	50% ($p = 0.02$)
High responder (anti-HBs ≥ 100 mIU/ml), %	100%	49% ($p = 0.01$)	52% ($p = 0.01$)	42% ($p = 0.01$)

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) outcomes have improved substantially due to the development of new drug therapies, but also due to emphasis on early aggressive MTX therapy. Although MTX monotherapy is highly effective in approximately one-third of patients, a majority require additional treatment to achieve optimal disease control. Despite growing evidence suggesting a link between periodontitis (PD) and RA pathogenesis there are limited investigations examining whether PD impacts treatment response. This study explores the relationship between PD, smoking, and treatment response to MTX in early RA.

Methods: This is a 16-week, open-label prospective study of RA patients with active disease defined as ≥ 4 swollen and tender joints. Patients completed a questionnaire at enrollment that included items detailing their history of PD: 1. Have you been told you have periodontal disease? 2. Have you required deep cleaning or scaling? 3. Have you been seen by a periodontist? At the initial visit, patients were started on MTX 15 mg weekly. Repeat evaluation at 8 weeks was performed; if patients were not in remission as defined by a DAS28- ESR < 2.6, MTX was increased to 20 mg weekly for the remainder of the study. The primary outcome of this analysis was achievement of low disease activity, defined as a DAS-28 < 3.2 at week 16. For this pilot study, associations of patient factors with treatment response were examined using unadjusted-logistic regression.

Results: Eighty-five RA patients have completed the study and were included in this analysis; 89% were Caucasian and 75% were women. After 16 weeks, 43 (51%) patients achieved a DAS-28 < 3.2. Factors associated with better MTX response included male gender (OR 4.4; 95% CI 1.4-13.8) and prior evaluation by a periodontist (OR 4.0; 95% CI 1.3-13.4) (Table). There was no association of MTX treatment response with other factors examined including age, disease duration, and known PD risk factors including smoking or diabetes. There was no association of "known PD" or "a requirement of deep cleaning" with treatment response.

Conclusion: Results of this pilot study suggest a potential correlation between periodontal disease evaluation and RA treatment response with those reporting prior care from a periodontist being more than 4-times as likely to achieve low disease activity with MTX use. These preliminary findings suggest that PD treatment could be an important component in a comprehensive approach to treating early RA with MTX. Further information is required to confirm these results in a larger patient population and to evaluate if the timing of PD treatment or whether specific oral pathogens or other factors that may be affected by periodontal disease alter MTX response.

Baseline Patient Characteristics and Associations with Achieving Low Disease Activity (n = 90)

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Approximately 30% of adults diagnosed with interstitial lung disease (ILD) have an underlying established autoimmune disease. Based on the strong links between autoimmunity and ILD, we performed the current study to determine whether serum rheumatoid factor (RF) IgM and IgA and anti-cyclic citrullinated peptide antibody (anti-CCP) were associated with subclinical ILD in a population-based cohort.

Methods: MESA is a multi-center, prospective cohort study of 6814 men and women aged 45-84 when recruited in 2000-2002 (exam 1) from 6 US sites. RF and anti-CCP were measured via ELISA at exam 1. Cardiac CT scans were performed at exam 1. Participants returned for 4 subsequent exams, the most recent in 2010-2012. High attenuation areas (HAAs) were assessed on exam 1 cardiac CTs and defined as the volume of lung with a CT attenuation value between -600 and -250 Hounsfield units. 2430 full lung CT scans performed from 2010-2012 were each visually inspected by 1 expert radiologist for the presence or absence of ILD and the following interstitial lung abnormalities (ILAs) affecting >5% of any lung zone in a non-dependent fashion: ground glass abnormalities, reticular abnormalities, diffuse centrilobular nodularity, nonemphysematous cysts, honeycombing, and traction bronchiectasis. RF IgM and IgA and anti-CCP were modeled as the independent continuous variables of interest in linear or Poisson regression models, with HAA and ILA as the dependent variables, adjusting for demographics, anthropometrics, site, smoking, and CT parameters.

Results: RF was measured and HAA quantified in 6736 participants at exam 1; anti-CCP was measured in 6728. Median age was 62 (IQR 53-70). 53% were female, 39% white, 27% African American, 12% Chinese American, and 22% Hispanic. 14% were current smokers; 45% were never smokers. In fully adjusted models, HAA increased by 0.49% per doubling of RF IgM (95% CI 0.11 to 0.86%, p-value = 0.01) and by 0.94% per doubling of RF IgA (95% CI 0.49 to 1.39%, p-value < 0.001). In fully adjusted models, the prevalence of ILA increased by 10% per log unit change in RF IgM (PR 1.10, 95% CI 0.997 to 1.22, p-value = 0.057) and by 17% per log unit change in RF IgA (PR 1.17, 95% CI 1.04 to 1.30, p-value = 0.006). There was no significant association between anti-CCP and HAA or ILA. Among ever smokers, in fully adjusted models, the prevalence of ILA increased by 21% per each natural log unit increase of RF IgM (PR 1.21, 95% CI 1.07 to 1.36), by 21% per each natural log unit increase of RF IgA (PR 1.21, 95% CI 1.08 to 1.36), and by 19% per each log unit increase of anti-CCP (PR 1.19, 95% CI 1.03 to 1.37). Among never smokers, there was no statistically significant association between RF IgM, RF IgA, or anti-CCP and the prevalence of ILA.

Conclusion: In this large population-based multi-ethnic study, we found significant associations between serum levels of RF IgM and RF IgA and subclinical ILD. Moreover, smoking modified the associations of RF and anti-CCP with subclinical ILD. Our findings suggest that RA-related autoimmunity may contribute to the development of ILD in a community-based population sample.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II

Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a multi-organ inflammatory disorder associated with high cardiovascular morbidity and mortality. Cardiac involvements are typically clinically silent, only manifesting as heart failure after an extended subclinical phase. Myocardial abnormalities may arise from a number of distinct processes, including myocardial inflammation and/or myocardial fibrosis, any of which may be active in RA. We aimed to assess cardiac involvements using a cardiac magnetic resonance imaging (CMR) approach and to determine its association with disease characteristics and N-terminal pro-brain natriuretic peptide (NT-proBNP) level in RA patients without cardiac symptoms.

Methods: Consecutive RA patients without cardiac symptoms were enrolled. RA patients with no history and/or clinical findings of systemic and pulmonary hypertension, coronary artery disease, valvular heart disease, atrial fibrillation, diabetes mellitus, and dyslipidemia underwent CMR. RA patients received conventional synthetic disease-modifying antirheumatic drugs (csDMARDs) or biologic DMARDs (bDMARDs). Late gadolinium enhancement (LGE) was obtained for the assessment of myocardial fibrosis. Using Black-Blood T2-weighted image (T2-WI), myocardial inflammation could be assessed. We evaluated the prevalence of CMR abnormalities, and investigated possible associations of CMR abnormalities with RA disease characteristics, and NT-proBNP level.

Results: Sixty patients (mean age, 55.2 ± 1.3 years; 85% female) were enrolled. Thirty RA patients received csDMARDs [25, methotrexate (MTX) (8.7±2.1mg); 5, other drugs)] and 30 RA patients received bDMARDs [15, infliximab 3 mg/kg; 15, tocilizumab 8 mg/kg plus methotrexate (8.6±1.4 mg)]. Twenty RA patients (33%) demonstrated myocardial abnormalities. High intensity on T2-WI was seen in seven RA patients (11%). LGE was found in 19 RA patients (32%), six of whom also demonstrated high intensity on T2-WI. Simplified Disease Activity Index (SDAI) scores were significantly higher in LGE-positive compared to LGE-negative (p=0.011). LGE was significantly associated with high NT-proBNP and SDAI (p=0.005, p=0.018, respectively). The use of bDMARDs was significantly associated with LGE-negative findings (p=0.0017). Other RA characteristics such as disease duration, autoantibody status, and cardiovascular risk factors were not significantly associated with myocardial abnormalities. After adjusting for confounding by age, RA duration, rheumatoid factor and bDMARDs, the association of LGE with SDAI remained significant (p=0.023), in which the SDAI scores were, on average, 10.9 units higher in LGE-positive than in LGE-negative. Receiver operating characteristic analysis showed NT-proBNP reliably detected myocardial abnormalities (area under the curve 0.856; 95% confidence interval, 0.833–0.904).

Conclusion: Subclinical myocardial abnormalities are common in RA patients without cardiac symptoms, associated with SDAI and NT-proBNP level. NT-proBNP level reliably detected the presence of cardiac involvements appeares to be useful markers to risk stratify RA patients.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: High levels of rheumatoid arthritis (RA) disease activity have been associated with abnormal function of circulating high density lipoproteins (HDL) and increased cardiovascular risk. Oxidative modifications to the HDL particle by enzymes such as myeloperoxidase (MPO) occur in atherosclerotic plaques of non-RA patients and adversely affect HDL function. In the current work, we evaluated the oxidant environment and anti-oxidant function of HDL in synovial fluid (SF) from RA patients compared to patients with non-inflammatory arthritis (NIA).

Methods: HDL was isolated from synovial fluid of 10 RA patients and 11 NIA patients by dextran bead precipitation. HDL's anti-oxidant function was measured by a cell free assay as described previously (*A&R* 2009; 60(10): 2870-9). MPO and paraoxonase 1 (PON1) activity (using both paraoxonase and arylesterase assays), were measured in SF by previously published assays with minor modifications (*ARD* 2012 Jul;71(7):1157-62, *A&R* 2012; 64(6):1828-37). Oxidation products of arachidonic acid and linoleic acid including 5 hydroxyeicosatetraenoic acid (HETE), 12-HETE, 15-HETE, 9-hydroxyoctadecadienoic acid (HODE) and 13-HODE were measured in synovial fluid by mass spectrometry as described previously with minor modifications (*Drug Metab Lett.* 2010; 4(3): 139-48). Total and HDL cholesterol (HDL-C) levels in SF were determined by standard methods.

Results: HDL in SF from RA patients had significantly worse anti-inflammatory, anti-oxidant function as measured by a higher mean HDL inflammatory index (HII) compared to SF HDL from patients with NIA (see table). RA SF had significantly higher MPO activity and higher levels of 15-HETE which were most strongly correlated with SF macrophage cell counts (r values= 0.7 and 0.6 respectively, p values <0.05) and showed trends for correlations with the HII (r = 0.5 and 0.3 respectively, p values =0.2). Higher levels of total cholesterol, HDL-C, and PON1 activity were noted in RA SF compared to NIA SF (see table).

Conclusion: HDL is increased in RA SF and is pro-inflammatory and pro-oxidant compared to HDL from NIA SF. These findings suggest a potential mechanism by which circulating HDL in active RA patients lose their protective capacity by exposure to the pro-oxidant joint milieu, linking high RA disease activity to abnormal HDL function, and potentially increased CV risk.

Cardiac Involvement in Patients with Amyloid a Amyloidosis Due to Rheumatoid Arthritis

Daisuke Kobayashi[1], Satoshi Ito[1], Yoko Wada[2], Akira Murasawa[1], Ichiei Narita[2] and Kiyoshi Nakazono[1], [1]Niigata Rheumatic Center, Shibata, Japan, [2]Department of Clinical Nephrology and Rheumatology, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Rheumatoid arthritis (RA) is one of the major causes of amyloid A (AA) amyloidosis, the major organs affected being the kidneys and gastrointestinal (GI) tract. Although cardiac amyloidosis is the principal cause of death in patients with amyloid L (AL) amyloidosis, significant cardiac involvement in AA amyloidosis is thought to be rare. On the other hand, the survival rate of hemodialysis patients with AA amyloidosis associated with RA has been shown to be low, and our previous study revealed that cardiac failure accounted for more than half of the mortality in these patients. Here we attempted to clarify the nature of cardiac involvement in patients with RA-associated AA amyloidosis and its clinical significance.

Methods:

Forty-seven RA patients (7 males, 40 females) with AA amyloidosis who were followed up at our hospital and Niigata University Hospital between 2001 and 2014 were enrolled. All of the patients fulfilled the 2010 ACR/EULAR classification criteria for RA, had undergone biposy of the GI tract (n=41), myocardium (n=2), kidney (n=2), or abdominal fat (n=2), and had been confirmed to have reactive AA amyloidosis by histopathological examination. The patients' background data and echocardiographic features were analyzed retrospectively. Data indicated are median values [range].

Results:

The median age of the 47 patients was 68 [48-89] years, the mean period between RA onset and echocardiographic examination was 25 [2-43] years, and

the mean period between the onset of AA amyloidosis and echocardiographic examination was 1723 [0-7682] days. Echocardiography showed that the median left ventricular (LV) posterior wall thickness was 10.9 [6.0-16.6] mm, with an interventricular septal thickness of 11.0 [5.5-17.0] mm, and an ejection fraction (EF) of 70.0% [32.3-85.4%]. Twenty-seven patients with a LV wall thickness of >11.0 mm were assigned to a LV hypertrophy (LVH+) group, and their clinical features were compared to the remainder (LVH- group; n=20). The Mann-Whitney U test demonstrated no significant differences between the LVH+ and LVH- groups at the baseline in terms of patient age (68 [48-89] years vs. 68 [50-86] years; p=0.829), duration of RA (27[4-41] years vs. 23[2-43] years; p=0.59), and DAS28(3)-CRP (2.73[1.15-5.36] vs. 3.23 [1.42-6.87]; p=0.09). Patients in the LVH+ group had a higher systolic blood pressure (137.4 [116-170] vs. 128.1 [116-170] mmHg in the normal group, p=0.024), a lower echocardiogram EF (68.1% [32.3-85.0%] vs 72.5% [59.6-79.3%]; p=0.03), and a lower estimated glomerular filtration rate (eGFR) (38.7 [13.0-98.8] ml/min/1.73 m^2 vs. 62.8 [19.2-126.4] ml/min/1.73 m^2; p=0.003). Fatalities in the LVH group (n=27) vs. normal group (n=20) were 13 vs. 1 at three years. Log rank test revealed that an older age (>65 years; p=0.073), lower eGFR (<40 ml/min/1.73 m^2; p=0.027), and LVH+ (p=0.002) were associated with higher mortality at 3 years after echocardiography. The Cox hazard regression model indicated LVH+ as an independent risk factor (hazard ratio = 12.4; 95% CI 1.62 – 94.8; p = 0.016).

Conclusion:

Thickening of the LV wall is a notable cardiac feature of patients with AA amyloidosis and is strongly suspected to contribute to a poor prognosis.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Body mass index (BMI) is a predictor of long-term outcome in rheumatoid arthritis and has been associated with joint damage. Our objective was to examine the association between changes in body mass and joint damage in a cohort of rheumatoid arthritis patients.

Methods:

From 1996 to 2009, we recruited 1328 consecutive patients who met the 1987 criteria for RA from private and public rheumatology practices in San Antonio, Texas. All patients participated in a comprehensive baseline evaluation of their clinical and psychosocial characteristics conducted by a physician and trained research assistants and yearly follow up evaluations in which we assessed clinical and laboratory features.

We included the following variables in the analysis: age of RA onset, duration of RA, sex, ethnicity, DAS28 ESR, smoking and current use of steroids. Joint damage was measured using a radiograph of the hands, scored according to Sharp technique. Body mass was measured using the height and weight, expressed as Kg/M^2.

Statistical Analysis:

We used cross-sectional time- series, generalized estimating equation regression models including all follow up visits to estimate independent associations between variables and body mass change over time.

Results:

We studied 1328 patients (347 male, 981 female) who participated in 3609 evaluations during a period of 8338 person- years. During this time body mass was lost at a rate of 0 .26 Kg/M2 per 5 years ($p<0.0001$). The body mass of patients in the lowest joint damage tertile remained stable, with a rate of change of -0.011 Kg/M2 per 5-years. By comparison, patients in the highest damage quartile lost body mass at a rate of 0.29 Kg/M^2 per 5 years ($p<.0001$). Other variables independently associated with lower BMI were age of RA onset, smoking, and non-Hispanic White ethnicity. Current use of steroids and the DAS28ESR were not associated with changes in BMI or the risk of weight loss independent of other factors. When we divided the sample into tertiles according with the sharp score, the association with body mass displayed a dose-response pattern, with higher sharp scores associated with lower body mass (Table 1).

Table 1. Rate of body mass loss according to the sharp score

Sharp Score	Rate of body mas loss (Kg/M^2) per 5 year(95% CI)	p-value
0 - 23	-0.011 (-0.17, 0.20)	Ref
24 - 85	-0.23 (-0.39, -0.069)	**<0.005**
86 - 471	-0.29 (-0.44, -0.14)	**<0.0001**

Conclusion:

Joint damage was associated with loss of body mass in this RA cohort, with the greatest loss observed among patients with the most severe joint damage. Active smoking, age of onset of RA, duration of RA and white ethnicity were also associated with greater loss of body mass over time. This provides evidence of the systemic effects of joint inflammation.

Identifying Risk Factors for Progression of Rheumatoid Arthritis-Associated Interstitial Lung Disease

Yashaar Chaichian[1], Dina Bassiri[2], Imre Noth[3], Mary Strek[3], Tammy Utset[1] and Rekha Vij[3], [1]Medicine, Section of Rheumatology, University of Chicago Medical Center, Chicago, IL, [2]Statistical & Applied Research, ACT, Inc., Iowa City, IA, [3]Medicine, Section of Pulmonary/Critical Care, University of Chicago Medical Center, Chicago, IL

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Interstitial lung disease (ILD) is recognized as a frequent extra-articular manifestation of rheumatoid arthritis (RA) associated with significant morbidity and mortality. Nevertheless, risk factors predicting progression of pulmonary disease in RA-ILD are poorly understood. Specifically, no studies to date have examined whether race/ethnicity or cyclic citrullinated peptide (CCP) antibodies are associated with a progressive disease course. In addition, the frequency of parallel lung and joint activity in patients with RA-ILD is unknown. We assessed the aforementioned clinical factors, along with others, for their association with progressive RA-ILD. We secondarily examined how often pulmonary activity parallels RA joint activity.

Methods:

We performed a retrospective observational study of 47 adults with RA-ILD who met ACR 1987 classification criteria for RA and had typical interstitial abnormalities on chest CT not due to other causes. Progressive RA-ILD was defined as a decrease in forced vital capacity of >10% predicted or diffusing capacity for carbon monoxide of >15% predicted on a minimum of two successive pulmonary function tests (PFTs) ≥8 weeks apart. Parallel ILD and joint activity required concordant worsening in PFTs and evidence of joint disease flare over a three month period. Fisher's exact test and logistic regression were used to compare categorical variables of interest, while an unpaired t-test and logistic regression were used for continuous variables.

Results:

Thirty six patients (77%) had progressive RA-ILD; 11 patients (23%) had stable RA-ILD. On bivariate analysis, high-titer rheumatoid factor (RF) was significantly associated with progressive RA-ILD (p=0.0394). There was also a trend toward association in African Americans (p=0.0912), as well as in patients with high-titer CCP antibodies (p=0.0973) and history of tobacco abuse (p=0.0933). Multivariate analysis using regular logistic regression with overall model fit of p <0.05 suggested statistically significant association with high-titer RF (p=0.0378), and a trend toward association with ILD progression in African Americans (p=0.0514) and in those with a smoking history (p=0.0820). Exact logistic regression, however, revealed only a trend toward association between presence of high-titer RF and progressive RA-ILD (p=0.0936). Twenty eight patients had serial rheumatology assessments coinciding with PFTs: 9 patients (32%) had parallel ILD and joint activity. None of the factors associated with RA-ILD disease progression were significantly associated with parallel or non-parallel ILD and joint activity.

Conclusion:

RA-ILD patients with high-titer RF in particular, as well as those who are African American or have a history of tobacco abuse may be at higher risk for progressive lung disease and warrant close monitoring. In contrast, multivariate analysis suggests that high-titer CCP antibodies do not appear to be associated with disease progression. As most RA-ILD patients did not have parallel ILD and joint activity, different factors may contribute to pulmonary and articular disease flares.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic systemic inflammatory disease involving articular and extra-articular systems, including cardiovascular (CVS), respiratory, as well as hematologic systems, etc. Among extra-articular manifestations, CVS disease is a leading cause of morbidity and mortality in the recent years. Patients with RA also have increased risk of metabolic syndrome (MS), compared to general population**.** Chronic systemic inflammation from both RA and MS could promote endothelial dysfunction and atherosclerotic plaques development leading to increase in CVS risk. Our objective was to investigate the association between MS and disease activity in patients with RA.

Methods: Siriraj Rheumatoid Arthritis registry is a prospective cohort study establishing since May 2011. A total of 267 patients who had complete data in February 2015 were included in these analyses. All clinical and laboratory data related to disease activity, functional status, and parameters of MS according to the 2001 National Cholesterol Education Program Adult Treatment Panel III (NCEP ATP III) were collected. For cumulative disease activity, time-adjusted mean (TAM) of disease activity score (DAS) 28 was calculated. The TAM of DAS28 is the area under a curve (AUC) of DAS28 plotted against time, divided by the total length of time from first to last measurement. Univariate and backward stepwise multivariate analyses were performed to identify factors associated with MS.

Results: Most (88%) were female with the mean age ± standard deviation of 59 ± 11.1 years old. MS was found in 43 patients (16%). High blood pressure was the most prevalent components of MS in both RA with MS and non-MS. Patients with MS had a significantly lower proportion of patients with remission (time adjusted mean of disease activity score 28 or DAS28 < 2.6) than those with non-MS (2.3% vs. 16.5%, p = 0.02). Multiple logistic regression analysis identified 4 independent factors associated with MS including age [odds ratio (OR) 1.01, 95% confidence interval (CI) (0.98 to 1.05)], body mass index [OR 1.2, 95% CI 1.1 to 1.3], educational level ≤ 12 years [OR 5.92, 95% CI 1.47 to 23.83], and disease remission [OR 0.11, 95% CI 0.01 to 0.93]. This model correctly predicted 84% of cases.

Conclusion: Disease activity of RA, body mass index, and educational level are associated with metabolic syndrome in patients with RA

Table Odds ratios for the presence of metabolic syndrome in patients with rheumatoid arthritis

	Univariate analysis			Multivariate analysis

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The guidelines for the management of rheumatoid arthritis (RA) recommend an annual influenza vaccine and a pneumonia vaccination (EULAR, 2011), prior to starting disease-modifying anti-rheumatic drug (DMARD) therapy. It is not clear how well these guidelines are adhered to in the UK. This study aimed to measure the extent to which patients with RA are vaccinated in the UK, and to determine the timing of the vaccinations in relation to starting DMARD therapy.

Methods: This was a retrospective cohort study using data from the Clinical Practice Research Datalink (CPRD). An inception cohort of adult patients, diagnosed with RA and prescribed DMARD therapy during follow-up (1st January 2000 – 31st December 2013) were identified. Vaccination status was considered as follows: 1) Influenza: The influenza season was estimated to start on 1st September each year and all patients were considered unvaccinated at this point. Patients were considered vaccinated if they received an influenza vaccine between 1st September and 31st August the following year. 2) Pneumonia: Following vaccination patients were considered vaccinated for the rest of follow-up. For both influenza and pneumonia vaccines, descriptive statistics show i) the proportion having at least one vaccination, ii) the observed and expected use and iii) the proportion of first vaccinations occurring prior to DMARD therapy initiation. Patients were stratified by age 65 at the start of follow-up, given differences in vaccination guidelines for the general population.

Results: There were 17877 patients with RA identified who were treated with DMARD therapy during follow-up (median follow-up 5.1 years).

Age below 65 years (N=11391): 8309 (73%) patients had received at least one influenza vaccination, of whom 3021 (36%) were vaccinated prior to starting DMARD therapy. Of those expected to have up to 5 vaccinations, 20% - 30% received all expected vaccinations. There were 4960 (44%) patients who had received at least one pneumonia vaccination, of whom 1269 (26%) were vaccinated prior to starting DMARD therapy.

Age 65 years and over (N=6486): 5858 (90%) patients received at least one influenza vaccination, of whom 4590 (78%) were vaccinated prior to starting DMARD therapy. Of those expected to have up to 5 vaccinations, 55%-75% received all expected vaccinations. There were 4026 (62%) patients who received at least one pneumonia vaccination, of whom 2498 (62%) received a vaccination prior to starting DMARD therapy (Table 1).

Conclusion: One in five patients received no influenza vaccine and 1 in 2 patients received no pneumonia vaccine over 5 years of follow-up. Of those vaccinated, only half of patients were vaccinated prior to initiating DMARD therapy. In a five year period, only 1 in 3 patients received regular annual influenza vaccines. There remains significant scope to improve the uptake of vaccinations in patients with RA.

Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Obesity is recognized as a systemic, low-grade inflammatory state and the adipose tissue as an endocrine organ releasing pro-inflammatory cytokines. On the other hand, obesity is one of the potentially preventable risk factors for rheumatoid arthritis (RA) being associated with RA onset, disease severity and poor response to therapy (1,2). The aim was to evaluate whether in obese RA patients with a low-moderate disease activity, a weight loss obtained with a controlled nutritional intervention may lead to an improvement of disease activity and to reduce the need of increasing therapeutic regimens, without modifying RA treatment during the study period.

Methods: 63 consecutive obese RA patients (BMI>30 Kg/m2), not in disease remission and with a low-moderate disease activity (1.6<DAS<3.7), in stable therapy with conventional DMARDs (cDMARDs) and/or biological DMARDs (bDMARDs) for at least 12 weeks, were enrolled. All patients underwent a scheduled dietetic regimen under a Nutritionist guide, aimed at a weight loss >5% of the baseline weight at the 6thmonths (T6) of follow-up, maintaining unchanged the RA therapy. Patients were evaluated by the Rheumatologist and the Nutritionist every 2 months and at each visit clinical and laboratory data and the ACR/EULAR core data set was registered. Disease activity was evaluated by the Disease Activity Score on 44 joints (DAS) and the Simplified Disease Activity Index (SDAI).

Results: Of the 63 RA patients reaching the 6thmonth FU (82.8% female, age 56.5±12.5 years, disease duration 8.1±8.1 years, 66.9% seropositive, baseline DAS 2.8±0.7, baseline BMI 35.3±4.3), 35 (55.5%) were under cDMARDs-only therapy and 28 (44.5%) under bDMARDs therapy+/- cDMARDs.

At T6, the mean reduction of body weight was 6.7±4.7 Kg (7.3±6.0% of baseline body weight, p<0.01 vs T0) and that of DAS was 0.8±1.0 (DAS T6: 2.0±0.7, p<0.01 vs DAS T0).

Dividing patients according to the percentage of weight loss at T6, the 40 (63.5%) RA patients reaching a weight reduction >5% of the baseline body weight obtained higher rates of DAS remission than patients with a weight reduction <5% (DAS remission at T6: 35.0% vs 9.1%, respectively, p=0.03), as well as of SDAI remission (34.2% vs 4.8%, p=0.01).

The difference was even more significant considering a weight reduction >10%, with a DAS remission at T6 of 55.6% in RA patients reaching >10% of weight reduction with respect to 13.6% in patients not reaching this outcome (p<0.01), and a SDAI remission at T6 of 62.5% and 9.3%, respectively (p<0.01). Results were similar between patients under cDMARDs-only and bDMARDs treatment.

Conclusion: A weight loss obtained with a controlled diet in obese still active RA patients can allow to obtain a better disease control without changing the treatment of RA, and in particular a weight loss >10% permits to reach disease remission in a significant percentage of patients, therefore reducing the need of an increase/modification of therapy. The effects of weight loss based on a nutritional intervention, and so applicable at the population level, on the RA disease course appears to be crucial in terms of potential clinical and pharmacoeconomics perspectives.

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Comorbidities have an important impact on outcomes in chronic diseases. A new and simple to compute index, the Rheumatic Disease Comorbidity Index (RDCI), has recently been proposed in addition to existing indices. Evidence on its performance in relation to functional status and health-related quality of life compared to other known indices is scarce.

Medical Dictionary for Regulatory Activities (MedDRA) is a clinically validated international medical terminology dictionary used by regulatory authorities and by researchers to code comorbidities and adverse events. However, no simple algorithm is as yet available to convert MedDRA classification into existing comorbidity indices.

Objective of this study was o develop algorithms to calculate the RDCI, Charlson-Deyo index (CDI) and Functional comorbidity index (FCI) from MedDRA, and to test in patients with RA how MedDRA-derived indices predict function (HAQ) and health-related quality of life (based on SF-36).

Methods:

First, two researchers coded the conditions listed in MedDRA classification into the categories of each index. Next, using data from patients with RA from the Norwegian NOR-DMARD study (2000-2012), we tested predictive values of the RDCI, CDI, and FCI for physical function (HAQ) and Physical and Mental Component Summary measures (PCS and MCS) from SF-36. Outcomes (HAQ, MCS and PCS) were modeled at baseline and over time. Two models were constructed for each outcome: a bare model (age and gender) and a clinical model (including also DAS28). Generalised estimating equations (GEE) (outcome over time) and linear regression models (outcome at baseline) were fitted and model fit measures (the quasi likelihood under the independence model criterion (QIC) for GEE and R-square for linear regression) were compared. We examined which of the three indices provided the best model fit to draw conclusions about the comparative performance of the indices: the lower the QIC or the higher the R-square, the better the model fit.

Results:

Data from 4,080 patients were analysed (28.4% male, mean age 56 yrs, mean DAS28 at baseline 4.9). RDCI (mean 0.6, range 0-6) and FCI (mean 0.40, range 0-6) performed comparably well in predicting the three outcomes considered. CDI (mean 0.24, range 0-7) performed worst on all outcomes HAQ, SF-36 PCS and MCS. Of note, the comorbidities had almost no influence on SF-36 MCS (Table).

Table. Comparison of model fit statistics (QIC and R-square values) between models with RDCI, CDI and FCI (independent variables, separate models) and HAQ and physical and mental components of the SF-36 as an outcome

	QIC model fit for generalized mixed models*

HAQ	3.23%	2.57%	3.50%	28.30%	27.95%	28.47%
PCS	5.15%	3.90%	5.36%	23.78%	22.94%	23.92%
MCS	0.96%	0.79%	1.00%	3.15%	3.04%	3.18%

*n=3842-4006

best model fit | worst model fit

Conclusion:

We have shown that the MedDRA classification, which is widely used in registries and clinical trials can be used to compute currently used comorbidity indices. The new RDCI performed comparably well with FCI on HAQ and the SF-36 (both physical and mental components). CDI performed worst on all outcomes explored, but it needs to be reminded the CDI was developed to predict mortality and not functioning.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Fragility fractures represent one of the serious extra-articular manifestations of rheumatoid arthritis (RA). The aim of this study was to investigate whether fracture incidence differs between patients with early RA and the general population.

Methods:

The patients were recruited from the BARFOT (Better Anti-Rheumatic FarmacO Therapy) cohort, which is a Swedish multicentre observational study of patients with early RA (disease duration ≤ 12 months at inclusion). All patients fulfilled the 1987 American College of Rheumatology classification criteria and were included between 1992 and 2006. Each patient was matched by sex, age and residential area (at the date of inclusion into the BARFOT) with 4 population controls. Controls without diagnosed RA were randomly selected from the general population using data from the Swedish Central Statistics Office. Incidental fractures were identified through the Swedish Inpatients Register, the Swedish Outpatients Register and the Swedish Cause of Death Register until December 2013. In this study, fractures of wrist, upper arm and hip were considered, as these locations of fractures are supposed to be typical for fragility fractures and can be accurately defined through the registries. The first fracture and total number of all fragility fractures throughout the study period were considered. Fracture incidence rates were calculated and Kaplan-Meier analysis was used to compare the time to the first fracture and rate of fracture occurrence among RA patients and in matched population controls. Analysis were performed for the total study population and also stratified by inclusion period; 1992-1999 and 2000-2006.

Results:

During a mean (SD) follow-up period of 14 (3.9) years 617 of 2751 (22.4%) patients with RA and 1898 of 11004 (17.2%) of controls experienced a fracture ($p < 0.001$). Compared with controls, patients with RA had an increased risk of fractures in upper arm, OR (95% CI) 1.43 (1.12-1.83); $p=0.005$, hip, OR 1.45 (1.23-1.72); $p<0.001$, and other fractures, OR 2.72 (1.57-3.28); $p<0.001$), but not in wrist, OR 1.04 (0.85-1.26); $p=0.714$. Except for wrist fractures, the number of fractures/1000 person-years was significantly increased in RA-patients (upper arm 2.9 vs. 1.9; hip 6.7 vs. 4.8; other 2.5 vs. 1.4). In total population and in the groups stratified by inclusion periods, the mean times to the first fracture in upper arm, hip and fragility fractures of other locations were shorter in patients than in controls.

Conclusion:

In this study we observed an increased risk of fragility fractures in patients with early RA compared with matched population controls. Further studies are needed to explain the increased fracture risk in patients with RA.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Rheumatoid arthritis (RA) is a polyarticular autoimmune inflammatory disease characterized for pain, joint edema and functional limitation. Some items in evaluation could be affected by other medical conditions. Hand osteoarthritis can coexist with RA but its effect is unknown. The aim of our study was to describe the impact of hand osteoarthritis on rheumatoid arthritis pain, disease activity and health status.

Methods:

We performed a descriptive and transversal study comparing patients with RA with and without hand osteoarthritis. A total of 41 patients per group were calculated to find a difference of 20mm in visual analogue scale (VAS) of pain. Demographic characteristics were registered as well as disease characteristics, treatment, disease activity, patient and physician global assessment, function disability (HAQ-DI score) and quality of life; quality of sleep, depression and anxiety diagnosis were also analyzed.

Results:

We included 83 patient; 42 RA patients with hand OA and 41 without; demographic characteristics were similar but patients with OA were older than controls (63,5 ± 11,6 vs 55,7 ± 10,8; p=0.002). Comorbities were more prevalent among patients with osteoarthritis. (Table 1). Characteristics of the disease (RA) were similar among the groups (Table 2); there were no differences on treatment strategies (methotrexate monotherapy, steroids and biologic use); although NSAID use was more frequent among patients with hand osteoarthritis (92.6% vs 78.5%) it was not significant. Depression and anxiety prevalence were similar but self-reported quality of sleep was poorer in patients with OA. Patients with OA reported more intensity of pain, resulted in worse global assessment (patient and physician reported), higher activity (DAS 28, SDAI and CDAI), showed more disability but interestingly, reported similar quality of life scores (Table 3). Patients without hand OA were more probable to achieve remission compared with patients with this condition [OR 4,09 (IC 95% 1,2 - 13,46)].

Conclusion:

Although it might be regarded as a benign condition, osteoarthritis of the hand exerts a great impact over patients with rheumatoid arthritis, affecting the possibility of achieving response to treatment.

Rheumatoid Arthritis-Related Interstitial Lung Disease (RA-ILD): Methotrexate and the Extension of Lung Disease Are Associated to Prognosis

Jorge Rojas-Serrano[1], Denisse Herrera-Bringas[2], Renzo Perez-Dorame[3], Mayra Mejia[2] and Heidegger Mateos-Toledo[4], [1]Interstitial Lung Diseases Unit, Instituto Nacional de Enfermedades Respiratorias, Mexico City, Mexico, [2]Interstitial Lung Diseases Unit, Insituto Nacional de Enfermedades Respiratorias, Mexico, Mexico, [3]Intertitial Lung Disease Unit, Instituto Nacional de Enfermedades Respiratorias, Mexico, Mexico, [4]Interstitial Lung Diseases Unit, Instituto Nacional de Enfermedades Respiratorias, Mexico, Mexico

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Interstitial lung disease (ILD) is a severe rheumatoid arthritis manifestation with a median survival of 2.6 years. Worst survival has been associated to usual interstitial pneumonia (UIP)-like patterns in high-resolution lung CT (HRCT) scans. To date, no formal recommendations to treat RA-ILD exist. Moreover, the use of methotrexate in RA-ILD is controversial. Our aim was to evaluate prognostic factors in a RA-ILD cohort, including extension of lung disease and methotrexate with their association to survival.

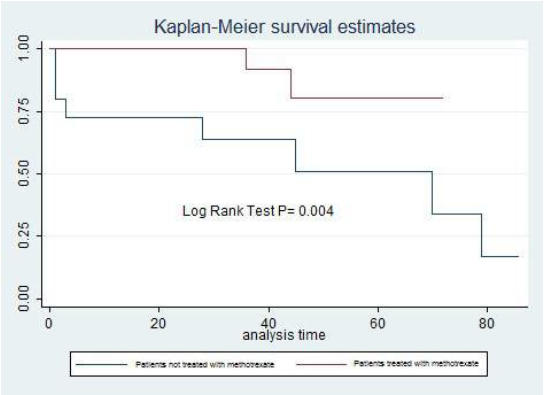
Methods:

RA patients (ACR 87 or ACR/EULAR 2010 criteria) with ILD were included. At the baseline, pulmonary function tests were realized and a high-resolution chest tomography was obtained. A radiologist evaluated the ILD tomographic pattern and the extension of lung disease with the Kazerooni index for lung inflammation and fibrosis. The survival function was estimated and Cox regression was used to evaluate factors associated to prognosis.

Results:

68 patients were included, mostly females (85%) with a median age of 58 years old, (IQR: 53-66). UIP tomographic pattern was present in 18 patients (27%), non-specific interstitial pneumonia (NSIP) pattern in 20 (29.85%), nevertheless, there was considerable overlapping of tomographic patters with mixed pattern (combination of two ILD tomographic patterns) in 25 of the patients (37%). There was no difference in survival according to the HRCT pattern of the patients. Variables associated to mortality were the extension of lung fibrosis according to the Kazerooni index (HR: 2.53, 95% CI: 1.16 – 5.51, p = 0.02) and the extension of lung inflammation (ground glass Kazerooni score) (HR: 4.03, 95% CI: 1.56- 10.39, p = 0.004). Treatment with methotrexate was associated to survival (figure) (HR: 0.13, 95% CI: 0.02 – 0.64, p =0.012). A multivariable Cox regression analysis including methotrexate treatment, extension of lung inflammation and extension of lung disease is shown in table.

Variable	HR	95% CI	P
Methotrexate treatment during follow up	0.16	0.02 – 0.99	0.049
Kazerooni ground glass score (lung inflammation)	4.24	1.53 – 11.72	0.005
Kazerooni fibrosis score (lung fibrosis)	1.84	0.65 – 5.2	0.25



Conclusion:

Methotrexate treatment during follow up was associated with survival. The extension of lung disease and not the tomographic pattern is associated to mortality.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Adipokines exert pleiotropic actions, including immunoregulatory and matrix degrading effects. There is evidence of adipokine involvement in the pathogenesis of cardiovascular (CV) disease as well as inflammatory rheumatic disease (IRD). It is well known, in the general population, that increased circulating leptin is associated with CV risk while adiponectin has a cardioprotective effect. Altered circulating adiponectin and leptin levels may contribute to the accelerated atherosclerosis in IRD. The aim of this study was to compare plasma levels of leptin and adiponectin in coronary artery disease (CAD) patients with and without rheumatoid arthritis (RA), patients with RA without CAD and healthy controls (HC).

Methods: Leptin and adiponectin were measured in plasma by ELISA in four groups of patients from the Feiring Heart Biopsy Study: 1) RA patients referred to coronary artery bypass grafting (CABG) (CAD+RA group, n=22); 2) Patients without RA, referred to CABG (CAD non-RA group, n=52); 3) RA patients without CAD (RA non-CAD group, n=17); and 4) HC (n=29).

Results: Adiponectin was significantly lower in CAD+RA than in RA without CAD (Figure 1A). The mean leptin was significantly lower in HC than in CAD non-RA, CAD+RA and RA without CAD (Figure 1B). Leptin/adiponectin-ratio was significantly lower in HC than in CAD non-RA and CAD+RA (Figure 1C). In linear regression analyses, CAD was related to lower adiponectin levels, and this relationship was independent of age, sex, RA, triglycerides, HDL and ESR (Table 1). CAD was associated with higher leptin and leptin/adiponectin-ratio, and these associations were independent of age, sex and RA (Table 2 and 3). There were no significant associations between adiponectin, leptin or leptin/adiponectin-ratio and RA disease activity score 28 (DAS28).

Image/graph:

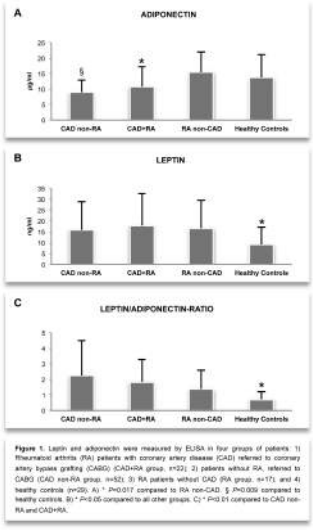

Table 1. Clinical Predictors of Adiponectin Level

	Model I			Model II		
	β	95% CI	P	β	95% CI	P
CAD	-0.424	-0.282, -0.126	<0.001	-0.237	-0.209, -0.022	0.018

Female	0.434	0.138, 0.274	<0.001	0.369	0.103, 0.254	<0.001
Triglycerides	-	-	-	-0.053	-0.081, 0.043	0.545
HDL	-	-	-	0.323	0.063, 0.281	0.002
ESR	-	-	-	-0.018	-0.003, 0.002	0.539

CI = confidence interval; CAD = coronary artery disease; RA = rheumatoid arthritis; HDL = high density lipoprotein; ESR = erythrocyte sedimentation rate

Table 2. Clinical Predictors of Leptin Level

	β	95% CI	P
CAD	0.223	0.041, 0.326	0.012
RA	0.080	-0.051, 0.108	0.297
Age	0.091	-0.003, 0.010	0.266
Female	0.526	0.300, 0.551	<0.001

CI = confidence interval; CAD = coronary artery disease; RA = rheumatoid arthritis

Table 3. Clinical Predictors of Leptin/adiponectin-ratio

	β	95% CI	P
CAD	0.424	0.210, 0.562	<0.001
RA	0.033	-0.129, 0.182	0.700
Age	-0.080	-0.011, 0.005	0.410
Female	0.239	0.096, 0.370	0.007

CI = confidence interval; CAD = coronary artery disease; RA = rheumatoid arthritis

Figure 1. Leptin and adiponectin were measured by ELISA in four groups of patients: 1) Rheumatoid arthritis (RA) patients with coronary artery disease (CAD) referred to coronary artery bypass grafting (CABG) (CAD+RA group, n=22); 2) patients without RA, referred to CABG (CAD non-RA group, n=52); 3) RA patients without CAD (RA group, n=17); and 4) healthy controls (n=29). A) * P=0.017 compared to RA non-CAD. § P=0.009 compared to healthy controls. B) * P<0.05 compared to all other groups. C) * P=0.01 compared to CAD non-RA and CAD+RA.

Conclusion: CAD was related to higher circulating levels of leptin and leptin/adiponectin ratio, but to lower circulating levels of adiponectin. The

relationship between adiponectin and CAD was independent of age, sex, triglycerides, HDL and ESR. As previously described for non-RA patients, increased circulating adiponectin may also provide a cardioprotective effect in RA patients.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) have an excess risk of cardiovascular disease (CVD). There is a clear female to male preponderance of RA. In the general population it is well documented that females have their CVD diagnosed at a later stage compared to males. We therefore evaluated if CVD risk prediction and CVD event rates differed between females and males with RA, and if adjustments for traditional and RA specific risk factors were of importance regarding sex differences in CVD event rates.

Methods: RA cohorts from 13 rheumatology centers were compared. Data on CVD risk factors and RA characteristics were collected at baseline for each cohort; CVD outcomes (myocardial infarction, angina, revascularization, CVD death, stroke and peripheral vascular disease) were collected using standardized definitions. Standardized incidence ratios (SIR) (observed/expected CVD event) were calculated with respect to sex using the following risk calculators FRS, SCORE, ACC/AHA and QRISK II. The CVD-free survival between the sexes was compared using adjusted Kaplan-Meier plots.

Results: 5638 patients with RA and no prior CVD were included (mean age: 55.3 [SD: 14.0] years, 76% female). During a mean follow-up of 5.8 (SD: 4.4) years, 437 patients developed CVD events. Male patients had a significantly higher burden of traditional CVD risk factors, including increased blood pressure, higher total cholesterol and were more frequently smokers ($p<0.001$ for all). Female RA patients used more anti-rheumatic medication, both synthetic and biologic disease modifying anti-rheumatic drugs ($p<0.001$). Erythrocyte sedimentation rate was higher in females, while C-reactive protein (CRP) levels were highest in males ($p<0.001$ for both). SIRs (95% CI) using the various CVD risk calculators were for females and males: FRS: 1.02 (0.80, 1.31) and 0.86 (0.67, 1.12) ($p=0.19$), SCORE: 0.34 (0.17, 0.67) and 0.25 (0.11, 0.58) ($p=0.98$), ACC/AHA: 0.72 (0.50, 1.04) and 0.56 (0.36, 0.88) ($p=0.74$) and QRISKII 0.61 (0.47, 0.79) and 0.52 (0.35, 0.79) ($p=0.42$). The 10 year CVD-free survival differed significantly between the sexes, both when adjusting for a) age, b) age and CVD risk factors and c) age, CVD risk factors and RA disease characteristics (Females [mean %±SD] 88.3±0.3, males 79.4±0.4), $p<0.001$ for all (Figure 1).

Conclusion:

In a large international cohort of patients with RA, there was no sex difference in the ability of the various risk calculators to predict CVD. However, the FRS seems to predict CVD risk more accurately compared to the other risk calculators in both sexes. CVD-free survival was significantly higher in females, even after adjustments for both traditional and RA specific risk factors.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Telomeres protect against DNA damage and shorten with each cell division; their length may be a marker of cardiovascular and overall biological aging. Patients with rheumatoid arthritis (RA) have accelerated cardiovascular disease resulting in early mortality. The relationship between telomere length and atherosclerosis in RA is not known. We examined the hypothesis that reduced telomere length is associated with increased coronary atherosclerosis in RA.

Methods: We performed a cross-sectional study in 145 patients with RA and 87 control subjects frequency matched for age, race and sex. Coronary artery calcium score, a measure of coronary atherosclerosis, was determined by non-contrast cardiac computed tomography. Telomere length was measured from DNA extracted from whole blood, using real-time quantitative polymerase chain reaction and expressed as the ratio of telomeric repeats to a single-copy gene (T/S ratio). The associations between telomere length and coronary artery calcium score and disease activity (DAS28) were assessed with Spearman correlation, proportional odds logistic regression, and linear regression adjusting for age, race and sex in patients with RA.

Results: Telomere length was significantly inversely correlated with age in patients with RA (rho=-0.37, P<0.001) and control subjects (rho=-0.39, P=0.001). Among patients with RA, for every interquartile range (IQR) decrease in telomere length (T/S ratio), the odds of higher coronary artery calcium score increased by 38% (95% CI: 4, 60%), after adjusting for age, race and sex (P adjusted= 0.03) (Figure). Telomere length was not associated with DAS28 (P adjusted= 0.17). Telomere length was not significantly different in patients with RA (median [IQR]: 1.02 units [0.9, 1.11 units]) compared to control subjects (1.05 units [0.95, 1.17 units]; P= 0.10).

Conclusion: Telomere length is inversely associated with coronary artery calcium score independent of age, race and sex in patients with RA.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Citrullinated proteins have been found in atherosclerotic plaques. However, contradictory results currently exist regarding the association of anti-citrullinated peptide antibodies (ACPAs) with coronary artery disease in RA patients. Our objective was to test this association in two different cohorts of RA patients without known cardiovascular disease (CVD).

Methods: One-hundred and ninety-five patients underwent cardiac multi-detector row computed tomography for coronary artery calcium (CAC) measurement and concurrent serum testing of a panel of 17 specific ACPAs using a custom Bio-Plex bead array. With a high ACPA level defined as ≥ 75th percentile, the association of each ACPA and CAC was tested. A second independent validation cohort of 75 RA patients without CVD was investigated assessing the association of CAC with an expanded panel of 30 ACPAs. CVD risk factors and RA characteristics were adjusted for.

Results: In cohort 1, the mean age was 59 ±9, with 51% of the patients being females, 85% self-identified as white, 65% were RF or anti-CCP positive, and had a median disease duration of 9years (4-17). In cohort 2, the mean age was 54±13, predominantly females (85%), only 37% were white, 79% were RF or anti-CCP positive, and had a median disease duration of 7years (3-17). In both studies, the DAS28 CRP score was in the moderate range, and about 40% were hypertensive. Cohort 2 study subjects were more likely to have diabetes (13% vs. 7%), and fewer were smokers (7% vs. 12%). In cohort 1, no association between ACPA reactivity and CAC was found. In cohort 2, high levels of ACPAs targeting citrullinated vimentin and the citrullinated vimentin58-77 were associated with higher levels of CAC (p=0.05 and p=0.04, respectively) in univariable linear regression models. However, when adjusted for potential confounders, this association lost statistical significance (p=0.11 and p=0.12, respectively) (Figure 1).

Conclusion: Higher levels of the ACPAs tested in our panel were not significantly associated with CAC in two cohorts of RA patients without known CVD. However, it is conceivable that other as yet unidentified citrullinated vascular proteins could be targets for APCAs.

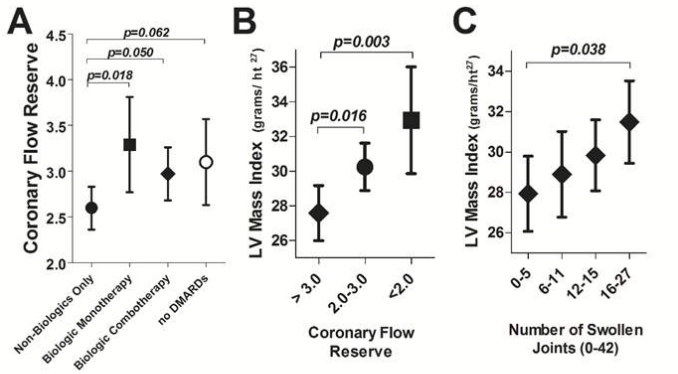
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Myocardial microvascular dysfunction may precede or coexist with coronary atherosclerosis and heart failure, two conditions over-represented in RA. Coronary flow reserve (CFR) offers an indirect index of myocardial microvascular function. We investigated indicators of CFR and its association with cardiac structure and function in RA.

Methods: RA patients without known cardiovascular disease underwent ^{13}N-ammonia cardiac positron emission tomography (PET) vasodilator myocardial perfusion imaging to evaluate myocardial ischemia and CFR. Global myocardial blood flow (MBF) was quantified at rest and during peak hyperemia with CFR=peak stress MBF/rest MBF, Participants also underwent 3-D echocardiography to assess left ventricular (LV) mass, volumes, and systolic and diastolic function. Mass and volume measures were indexed to height. Generalized linear models were used to explore the associations of patient characteristics with CFR, and measures of LV structure and function.

Results: A total of 76 RA patients [mean age=54 yrs; 80% Female; 43% and 36% non-Hispanic White and Hispanic, respectively; Median RA duration=7.1 yrs; 70% RF or anti-CCP positive; mean DAS28=3.6; 39% treated with biologics] were analyzed. Mean ± SD CFR was 2.9 ± 0.8, and 12% had a CFR<2.0 (an established abnormal threshold). After adjustment, male sex, IL-6, and non-biologic DMARD use were significantly and inversely associated with CFR, while biologic use was associated positively. On average, CFR was lower by 0.18 units for every log unit higher IL-6 (p=0.022). Adjusting for sex and IL-6, RA patients treated with only non-biologics had significantly lower CFR compared with those treated with any biologics or no DMARDs (Fig 1.a). Associations were maintained after adjusting for coronary macrovascular disease [i.e. coronary artery calcification (CAC)]. CFR was not associated with diabetes, smoking, prednisone use, or lipids in adjusted models. Adjusting for relevant demographic and CVD risk factors, CFR<2.0 was associated with a 5.4 unit higher LV mass index (p=0.003; Fig 1.b), the equivalent of 60 mm Hg higher systolic blood pressure (SBP). In the same model, each swollen joint, on average, was associated with a 0.16 unit higher LV mass index (p=0.038), equivalent to almost 2 mm Hg higher SBP, per joint (Fig 1.c). Lower CFR was also significantly associated with higher LV end-diastolic and systolic volumes, but there was no significant association with ejection fraction or measures of diastolic dysfunction.

Conclusion: Higher IL-6 and non-treatment with biologics were among the strongest indicators of lower CFR, which, along with higher swollen joint counts, was associated with higher LV mass. These data suggest that articular and systemic inflammation may contribute to the microvascular and myocardial structural changes in RA that are known to precede heart failure.



Means and 95% confidence intervals are depicted. Panel A is adjusted for age and IL-6, which were the only other relevant covariates retained in multivariable modeling. Panels B and C are adjusted for age, systolic blood pressure, rheumatoid factor, swollen joint count, myocardial flourodeoxyglucose uptake, and coronary flow reserve.

Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

The leading cause of death in RA is atherosclerotic cardiovascular disease (ASCVD). Traditional risk factors do not explain the increased cardiovascular risk (CVR), which appears to be linked to inflammatory pathways. Several CVR calculators have been developed for the general population. The most widely used are the Framingham Lipids (FRS Lipids), Framingham BMI (FRS BMI), ACC/AHA 2013 cardiovascular risk calculator (OMNIBUS) and QRISK2 calculator. FRS has shown to underestimate and QRISK2 to overestimate CVR. Carotid artery evaluation by ultrasound is a useful tool for the detection of subclinical atherosclerosis. Carotid plaque (CP) presence significantly increases the risk of ASCVD, mainly stroke and myocardial infarction.

Methods:

A cross-sectional study was designed. Patients with RA were prospectively and consecutively recruited. All fulfilled the ACR/EULAR 2010 classification criteria. Presence of prior ASCVD, overlap syndromes and patients younger than 40 or older than 75 were excluded. A certified radiologist performed the carotid ultrasound. CP was defined as focal thickening of at least 50% greater than that of the surrounding wall or carotid intima media-thickness ≥ 1.2 mm. CVR by 4 different algorithms was calculated online in the official sites. Diagnostic performance was calculated using receiver operating characteristics (ROC curves). Area under the curve (AUC) values greater than .5 with $p<0.05$ were considered statistically significant.

Results:

A total of 97 patients were included. The demographical characteristics are shown in table 1. CP was present in 40 patients (41.2%). Patients with CP were categorized as low-risk by FRS Lipids in 60%, QRISK2 IN 50%, OMNIBUS in 50% and FRS BMI in 42.5% of cases. ROC curves showed poor AUC values, with no significant difference between them ($p>0.05$). The best cut-off point for OMNIBUS was 2.05%, 5% for FRS Lipids, 4.95% for FRS BMI and a 2.9% for QRISK2 (Table2).

Conclusion:

CVR calculators are poor diagnostic tools for CP detection. There is no difference between the ROC curves for the different CVR algorithms in RA. Most of the patients with CP are stratified as low-risk patients by current algorithms.

Table 2. ROC curves and Diagnostic performances

CVR Scale	AUC ± Standard error	P value	Suggested Cut-off value	Sensitivity	Specificity	Negative predictive value
OMNIBUS	.690 ± .053	.001	2.05%	.900	.473	.871
FRS Lipids	.681 ± .054	.002	5%	.900	.386	.846
FRS BMI	.671 ± .055	.004	4.95%	.900	.350	.833

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose : Previous studies in rheumatoid arthritis (RA) have shown that patient socioeconomic status (SES) impacts patient prognosis. We hypothesized that public vs. private healthcare coverage would be a surrogate of low SES. The aim of this analysis was to assess the association between patient health insurance coverage and disease parameters with emphasis on functional activity in RA patients initiating treatment with anti-TNF agents in Canadian routine clinical practice.

Methods : BioTRAC is an ongoing, prospective registry of patients initiating treatment for RA, ankylosing spondylitis, or psoriatic arthritis with infliximab (IFX) or golimumab (GLM). Eligible people for this analysis included RA patients treated with IFX who were enrolled since 2002 or with GLM enrolled since 2010. Independent predictors of HAQ were identified using generalized linear models.

Results: A total of 1144 patients were included of whom 598 (52.3%) had public insurance. Patients with public insurance were older (59.7 vs. 51.8 years; P<0.001), had longer disease duration (9.3 vs. 7.5 years; P=0.029), and were more likely to be from British Columbia (81.2% vs. 18.8%) and Manitoba (68.8% vs. 31.3%) but less likely to be from the Maritimes (30.6% vs. 69.4%) (P<0.001). With respect to disease activity, patients with public insurance had higher CDAI (37.3 vs. 30.3; P<0.001), DAS28 (6.0 vs. 5.2; P<0.001), swollen joint count (11.0 vs. 8.5; P<0.001), tender joint count (12.8 vs. 10.3; P<0.001), patient global (62.1 vs. 55.5; P<0.001), and HAQ (1.74 vs. 1.36; P<0.001).

Multivariate analysis adjusting for age (P=0.028), gender (P<0.001), anti-TNF agent (P=0.227), and CDAI (P<0.001) showed that private insurance type was a significant independent predictor of lower HAQ (1.28 vs. 1.52; P<0.001). Furthermore, rheumatology practice was also identified as a significant predictor of HAQ (P=0.027; Figure 1).

Conclusion: The results of this analysis suggest that, upon adjusting for patient demographics and disease activity, significant variation exists in the HAQ score based on the type of health insurance coverage and the rheumatology practice which may reflect differences inherent to the patient SES or to the manner of administration of the HAQ instrument.

Session Date: Monday, November 9, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Studies on obesity and the risk for development of rheumatoid arthritis (RA) have shown diverse results. In this study we evaluated the association between obesity and subsequent risk for development of RA.

Methods:

In The Västerbotten Interventional Program (VIP) or/and The WHO project Multinational MONItoring of Trends and Determinants of CArdiovascular Disease (MONICA) 1985-2013 individuals with RA (according to the ACR/ARA 1987 Classification criteria, with year of onset of symptoms 1989-2013) were identified (cases, n=557), and data from the latest visit antedating onset of RA symptoms were retrieved. From the same population-based, prospective cohorts 1671 controls, matched for age, sex, cohort, inclusion year, cohort and area of inhabitance (rural/urban) were randomly selected. Prospectively collected data on body mass index (BMI; weight/lenght^2), smoking habits, and educational level was used in calculations of odds ratio; OR (95% confidence interval) in conditional logistical regression assessing associations between obesity and the risk for development of RA. Missing variables were handled by multiple imputation (smoking 2.2%, BMI 0.6%, and education 1.6%).

Results:

The cases (mean age at RA symptom onset 58 SD 11 years, 68% women) had been included in the cohorts (MONICA n=50, VIP n=507) at a mean of 6.2 SD 4.7 years before the onset of symptoms of RA. Obesity (BMI≥30) was associated with an increased risk for RA development, OR 1.5 (1.1-2.0), compared to those with normal weight (BMI 18.5-25). The association was observed in both sexes (Table 1). Stratifying the patients on age at onset of symptoms of RA the association between obesity and the risk of RA was only observed in the quartile with disease debut at 50 years of age, or earlier, OR for obesity vs. normal weight 1.9 (1.03-3.5) (Figure 1).

Table 1. Conditional logistic regression models with case-controls sets matched for age, sex, area of inhabitance, cohort and year of visit in the cohort, assessing odds ratios for the risk for development of RA associated with categories based on body mass index

		Cases (n=557)	Controls (n=1,671)	OR1 (95% CI)	OR2 (95% CI)
All	Under- or normal weight	228 (41%)	778 (47%)	Reference	Reference
	Overweight	229 (41%)	655 (40%)	1.21 (0.97–1.50)	1.23 (0.98–1.55)

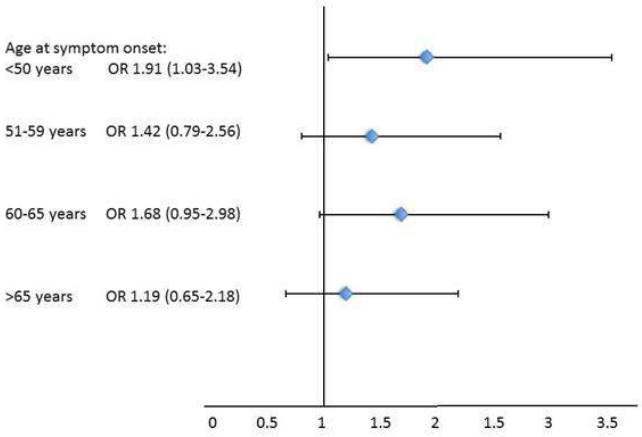
OR1 = Unadjusted model. OR2 = Model adjusted for smoking and educational level.

Figure 1. Odds ratios for the association between obesity and risk of development of RA in subgroups based on age at onset of symptoms of RA.



Conclusion:

Obesity was associated with a moderately increased risk for subsequent development of RA. The association was observed in both men and women, but mainly in patients with early onset of RA.

Clinical Characteristics of Interstitial Lung Disease (ILD) in Rheumatoid Arthritis (RA) Patients in High Resolutional CT (HRCT) and Titer of Anti Citrullinated Peptide Antibodies (anti-CCP2)

Masaomi Yamasaki, Rheumatology, Shin-Yokohama Arthritis and Rheumatology Clinic, Yokohama, Japan
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

To investigate clinical characteristics of interstitial lung disease (ILD) in rheumatoid arthritis (RA) patients. And to analyze whether high resolutional CT (HRCT) and anti citrullinated peptide antibodies (anti-CCP2) can predict the outcome of ILD in RA.

Methods:

405 patients with RA were treated at our hospital and followed up at least one year as newly onset RA. All patients were performed chest radiological examinations at the initial presentation. The HRCT findings which include (1) ground glass opacity, (2) air-space consolidation, linear opacity including (3) septal line and (4) non-septal line, (5) honeycomb lung, (6) traction bronchiectasis, (7)pleural irregularity, and (8)pleural effusion were scored as the CT scoring system. The extent of involvement of each abnormality was assessed independently for each of the three zones of each lung. The HRCT extent score was represented the sum of the score of each lung. HRCT parameters which include the extension score and the clinical features which include anti-CCP2 at the initial presentation were retrospectively analyzed.

Results:

189 out of 405 patients had abnormal chest radiological findings which included bronchiectasis, bronchitis and ILD (46.7%). 93 (28 male (40.0%), 67 female (22.7%)) out of 405 patients showed ILD at initial presentation (23.0%). 6 out of 93 patients had shortness of breath and showed a rapidly progressive ILD (6.5%). In HRCT findings, ILD in these 6 cases were widely spread at the initial presentation. The rest of 87 patients showed no progression of ILD and asymptomatic (=subclinical ILD). However there were no difference in the HRCT findings which include nonseptal linear attenuation, ground-glass attenuation and air space consolidation between rapidly progressive ILD group and asymptomatic group, rapidly progressive ILD group showed more higher degree in honeycombing (p=0.00018) and extensive ILD (p=0.0068). Higher anti-CCP2 titers were found in higher extensive score of ILD (p=0.0214). Prognosis of the rapidly progressive ILD was variable. The rapidly progressive ILD are treated with immunosuppressive agent

which include high dose steroid, cyclophosphamide, azathioprine, cyclosporineA (CsA) and Mycophenolate Mofetil(MMF) for ILD. 2 patients treated with CsA , one with MMF and one with tacrolimus showed improving of ILD on HRCT. But in other 2 patients were resistant to these immunosuppressive agents.

Conclusion:

HRCT findings focused on the extension score at the initial presentation is a useful predictor of the outcome of ILD in RA. Anti-CCP2 is one of the related factor of the extension score. This study suggests that RA patients with preexisting honeycombing lung and extensive ILD must be aware of rapidly progressive ILD which need immunosuppressant.

Pulmonary Manifestations in Early Rheumatoid Arthritis: A 6 Month Follow up Study

Gudrun Reynisdottir[1], Helga Olsen[2], Johan Grunewald[2], Magnus Skold[2], Anders Eklund[3] and **Anca I Catrina**[4], [1]Rheumatology Unit, Department of Medicine, Karolinska University Hospital and Karolinska Institutet, Stockholm, Sweden, [2]Department of Medicine, Division of Respiratory Medicine, Karolinska University Hospital, Karolinska Institute, Stockholm, Sweden, [3]Division of Respiratory Medicine, Karolinska University Hospital, Karolinska Institute, Stockholm, Sweden, [4]Unit of Rheumatology, Department of Medicine Solna, Karolinska University Hospital, Karolinska Institutet, Stockholm, Sweden

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Pulmonary manifestations are common in rheumatoid arthritis (RA). However, limited information is available concerning the early development of such manifestations in newly diagnosed patients. In this study we present the six months follow up data of a previously published study, documenting the pulmonary response to standard disease modifying anti rheumatic drug (DMARD) treatment in patients with early RA.

Methods:

A total of 143 patients with newly diagnosed RA were recruited via the Early Arthritis Clinic (Karolinska University Hospital in Stockholm, Sweden). Patient characteristics were recorded at baseline, and high resolution computed tomography (HRCT) and spirometry were performed at inclusion and after six months of treatment.

Results: HRCT at baseline demonstrated parenchymal abnormalities in 54% of patients and/or airway changes in 66% of patients. Pulmonary fibrosis was evident in twelve patients. At 6 months follow up, no obvious changes were observed with the exception of radiographic progression of pulmonary fibrosis in one third of patients (four of 12 patients). Furthermore, an additional three patients developed new radiographic changes suggestive of early interstitial lung disease. Spirometry was abnormal in 62% of patients at inclusion, with a reduced DLco and/or airways obstruction being the most common findings (occurring in 52% and 32%, respectively). At follow up, the forced expiratory volume in one second (FEV1) had decreased by a mean of 70 ml in all patients. The reduction was numerically larger in current smokers compared to never smokers (150 ml versus 30 ml), but was independent of antibody status.

Conclusion:

RA patients frequently exhibit pulmonary HRCT changes and signs of airway inflammation, already at the early stages of the disease, not obviously related to methotrexate treatment and smoking. Pre-clinical interstitial lung disease (ILD) is prevalent and may be progressive.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Whether glucose metabolism is abnormal in patients affected by inflammatory arthritis is controversial. In the present study, we aimed to evaluate glucose metabolism in a cohort of rheumatic patients with respect to matched controls.

Methods:

We prospectively recruited patients affected by inflammatory arthritis followed-up at our Immunorheumatology Unit. We selected two sex-age and BMI matched controls from a cohort of patients who underwent an Oral Glucose Tolerance Test (OGTT) in our Metabolic Unit. Rheumatologic diagnosis were based on ACR/EULAR 2010 classification criteria for Rheumatoid Arthritis (RA), CASPAR criteria for Psoriatic Arthritis (PsA) and ASAS Criteria for Spondyloarthritis (SpA).

Results:

The study population includes 97 cases (F=68, 70.1%) affected by RA (N=53, 54.6%), PsA, (N=35, 36.1%) or other SpA, (N=9, 9.3%) and 194 matched controls. Cases and controls were similar with regard to age, BMI, waist circumference (WC) and rate of arterial hypertension. We could not detect any difference between case and controls in glucose and insulin plasma concentration neither at baseline nor after OGTT. HOMA was similar in the two groups as well as Glycated haemoglobin (HbA1C).

In the group of cases C-Reactive Protein (CRP) was directly related to: plasma glucose at baseline (G0; p=0.0005); plasma glucose after OGTT (G120; p=0.0002); insulin plasma concentration after OGTT (I120'; p=0.006); HbA1C (p=0.02). Erythrocyte sedimentation rate (ESR) was directly related to: G0 (p=0.02); G120; p=0.002; HbA1C (p=0.03).

We then focused our attention on RA patients. According to DAS28-ESR, 33 patients were in remission, while 18 showed a residual disease activity. CRP was still correlated to G0, G120 and HbA1C even in patients with a DAS28<2.6; anyway in a multivariate regression model the only independent predictor of all these variables was BMI. In fact patients with a pathological BMI had also a significantly higher CRP (0.33 [0.15-0.60]) than people with a normal BMI (0.16 [0.06-0.43]); p=0.04. In patients with residual disease activity DAS28 was linked to I0 (p=0.034, as well as ESR (p=0.004); ESR was also directly related to HOMA (p=0.002). in multivariate regression model ESR was a predictor of HOMA (p=0.003), as well as BMI and WC, independently by cumulative steroid dose.

Conclusion:

In patients with rheumatic disease, glucose metabolism is not different from general population if remission has been achieved. However, among patients with residual activity ESR is a strong predictor of insulin resistance, suggesting that the inflammatory state induced by the rheumatic condition may represent a factor in the development of an altered glucose metabolism.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Insulin resistance (IR) is increased and β-cell function impaired in rheumatoid arthritis (RA). The aim of this study was to evaluate whether treatment with tocilizumab (TCZ) results in attenuation of IR and improvement of β-cell function.

Methods: The study population included 31 RA pts, (mean age 53.5±11.1 yrs, RA duration 7.1±6.5 yrs, all on disease modifying antirheumatic drugs, 77.4% on steroids (8.0±2.9 mg)), without diabetes, cardiovascular diseases, and previous treatment with biologic drugs. Disease activity was assessed using mDAS28-SE and mHAQ. Insulin resistance was calculated using the updated-computer Homeostasis Model Assessment (HOMA2-IR), with an algorithm to determine insulin sensitivity (%S) and β cell function (%B) from fasting plasma glucose and specific insulin, or C peptide concentrations. We used C peptide to calculate β cell function, as a marker of secretion, and proinsulin as indicator of β cell dysfunction. Serum specific insulin was measured by a sensitive ELISA and the values were logarithmically transformed (coefficient of variation 42-55%). Association between baseline HOMA2-IR, demographics, disease-related factors, and inflammation markers (SE, hsCRP IL-6) was evaluated using linear regression. Changes in HOMA2-IR, HOMA2%-B, HOMA2%-IS and proinsulin concentration during TCZ therapy were assessed using a general linear method.

Results: Baseline logHOMA2-IR was associated with body mass index, triglycerides concentration and mHAQ (β-coefficients [95% CI]: 2.64 [0.003,0.023; p=0.013], 2.79 [0.074, 0.500;p=0.010], and 2.082 [0.005, 0.572;p=0.046], respectively) but not with DAS28-SE, RF or anti CCP positivity, IL-6 level, ESR, CRP, or steroids. After 12 weeks of TCZ treatment, HOMA-IR was reduced and HOMA2%-IS was improved but did not change after 24 weeks of treatment although parameters of disease activity (DAS28-SE, mHAQ), and inflammation markers (ESR value) continued to decrease. Improvement of %IS did not follow better β cell function assessed by HOMA2%-B. Importantly, proinsulin concentration was significantly reduced after 12 weeks of TCZ, without changes further on (Table 1).

Conclusion: These data support hypothesis that inflammation and disease activity could not fully elucidate the presence of IR and β cell dysfunction in RA pts and that β cell dysfunction is at least in part independent of IR.

Table 1. Changes in disease activity, inflammation markers, HOMA2-IR, HOMA2%-B, HOMA2%-IS and proinsulin concentration after 12 and 24 weeks of TCZ therapy in 31 RA pts without diabetes and cardiovascular diseases.

Session Title: Rheumatoid Arthritis - Clinical Aspects Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Among patients with rheumatoid arthritis and hepatitis C virus (HCV) infection, the impact of biologic and nonbiologic DMARD therapy on hepatotoxicity has received limited study.

Methods: Using 1997-2011 national data from the US Veteran's Health Administration, we identified a cohort of 38,433 rheumatologist-diagnosed RA patients. Eligible patients had HCV infection (defined by detectable HCV RNA) and subsequently initiated a new biologic (infliximab, adalimumab, etanercept; rituximab) or nonbiologic (hydroxychloroquine, sulfasalazine, methotrexate, leflunomide) DMARD that they had never been on previously. Patients were required to have a baseline ALT <66 IU/mL and quantifiable HCV RNA within 90 days prior to starting biologic/DMARD therapy (defined as "index date") as well as ALT and HCV RNA measurement within 1 year after index date. Patients with HIV and hematologic malignancy were excluded. Patients could contribute more than one treatment episode provided they switched to a new biologic/DMARD they had not previously used, or switched to a previously used biologic/DMARD they had not used in the past year. The primary outcome of interest was hepatotoxicity, defined as ALT elevation ≥100 IU/L (corresponding to 3x ULN for women and 2.5x ULN for men) or increase in HCV RNA by one log, and was examined within the first year of biologic/DMARD use. Current exposure was defined as-treated based on day supply (injection biologics) or usual dosing intervals (infused biologics*).***Results*** were reported as the cumulative incidence of patients achieving pre-defined hepatotoxicity at 3, 6 and 12-months post-biologic exposure.

Results:

RA patients with HCV (n=748) were identified and contributed 1097 biologic/DMARD treatment episodes. Mean age was 59.8 years and 77.3% were male. Nearly half of biologic users (47.4%) were also prescribed methotrexate and/or leflunomide. Overall, ALT elevations were uncommon, with 37 hepatotoxicity events (ALT ≥100 IU/L or HCV RNA increase by one log) occurring within 12 months (3.4%). Treatment episodes with biologics demonstrated increased frequency of hepatotoxicity (ALT ≥100 IU/L or HCV RNA increase by one log) than nonbiologics (4.8% vs 2.3%, p=0.028). Most hepatotoxicity events occurred within 6 months of DMARD initiation (29/37, 78%).

Table: Cumulative hepatotoxicity events among RA patients with HCV within 12 months of initiating biologic/nonbiologic DMARDs

		Cumulative Hepatotoxicity Events		
Drug	Number exposed	3-months	6-months	12-months
ADA	180	3(1.7%)	7(3.9%)	8(4.4%)
ETA	179	4(2.2%)	7(3.9%)	10 (5.6%)
INF	48	0(0%)	2(4.2%)	2(4.2%)
RIT	28	1(3.6%)	1(3.6%)	1 (3.6%)
ABA	22	0(0%)	1(4.6%)	1(4.6%)
LEF	91	1(1.1%)	2(2.2%)	2(2.2%)
MTX	156	0(0%)	4(2.6%)	6(3.9%)
HCQ	272	2(0.7%)	2(0.7%%)	4(1.5%)
SSZ	121	3(2.5%)	3(2.5%)	3(2.5%)
Total	1097	14(1.3%)	29(2.6%)	37(3.4%)

ADA=adalimumab; ETA=etanercept; INF=infliximab; RIT=rituximab, ABA=abatacept;

LEF=leflunomide; MTX=methotrexate; SSZ-HCQ=sulfasalazine/hydroxychloroquine

Conclusion: In US Veterans with HCV and RA receiving biologic and nonbiologic DMARDs, the frequency of treatment-related hepatotoxicity (ALT ≥100 IU/L) was low, with a higher frequency observed in treatment episodes with current biologic use. The majority of hepatotoxicity events occurred within 6 months after biologic/DMARD initiation.

Cardiovascular Disease in a Large Incident Cohort of Early Inflammatory Arthritis

Background/Purpose: Rheumatoid Arthritis (RA) is associated with an increased risk of cardiovascular disease (CVD). The aim of this study is to determine the incidence and predictors of CVD in Early Inflammatory Arthritis (EIA) from the Canadian early arthritis cohort (CATCH).

Methods: CATCH is a multicentre, prospective inception cohort of patients with EIA. Cardiovascular disease (CVD) was defined as an acute coronary syndrome, percutaneous or surgical intervention for coronary artery disease, stroke, transient ischemic attack, peripheral vascular disease requiring surgical intervention or death secondary to CVD. Pre-existing diagnoses of CVD, risk factors and medications for CVD were collected at baseline by physician. Incident CVD events and cardiac medications after study enrollment were self-reported by patients. Stepwise logistic regression was used to identify predictors for CVD.

Results: 2652 patients were enrolled in the study with a mean follow-up of 3.4 (SD 2.1) years. At baseline, 180 (7%) had pre-existing CVD. During the course of follow-up there were 62 new CVD events in 57 subjects. There were a total of 6 deaths (1 secondary to CVD). The incidence rate of CVD for years 1, 2, 3, 4 and 5 of the study, respectively were: 2.3, 4.4, 15.4, 10.4, 10.8 per 1000 person-years. Patients with new CVD events were older, more likely male and have higher rates of traditional CVD risk factors (Table 1). Arthritis-related factors were not significantly associated with the risk of CVD. Independent predictors of CVD were male gender (OR 1.8 (95% CI: 1.0-3.0), dyslipidemia (OR 1.8 (95% CI: 1.1-3.2)), hypertension (OR 2.7 (95% CI: 1.6-4.6)) and the use of non-steroidal anti-inflammatories (NSAIDs) (OR 3.2 (95% CI: 1.8-5.6). Less than 25% of subjects with a CVD diagnosis reported taking aspirin or cholesterol-lowering drugs during the follow-up period.

Conclusion: The rate of CVD events in patients with EIA was higher later in the disease course. CVD appears to be under-treated and is independently associated with traditional CVD risk factors and the use of NSAIDs.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: RA patients have a 2-fold increased risk of developing coronary artery disease (CAD) regardless of traditional risk factors. Atherosclerosis, the underlying process in CAD, is a chronic maladaptive inflammatory response, and macrophages play a critical role in its progression through cytokine and chemokine secretion, production of tissue-injurious enzymes and amplification of adaptive immune responses. Here, we have examined macrophages in RA and CAD, with the goal to identify disease-specific and shared molecular pathways swaying such myeloid cells towards pathogenic inflammation.

Methods: Patients with RA who fulfilled 2010 ACR/EULAR RA Classification Criteria, CAD patients with a history of at least one myocardial infarction (>3 months post event), and healthy controls were enrolled. Monocytes isolated from peripheral blood were differentiated into macrophages with macrophage colony stimulating factor. To recapitulate an inflammatory tissue environment, macrophages were stimulated with IFN-γ and lipopolysaccharide. Gene expression profiles were analyzed by quantitative RT-PCR. Intracellular cytokines were measured by flow cytometry. Intracellular reactive oxygen species (ROS) were quantified using CellROX. The oxidant superoxide was scavenged using the superoxide dismutase mimetic, Tempol.

Results: Compared to healthy macrophages, RA and CAD macrophages shared the enhanced expression of the oxidative stress response gene, NAD(P)H:quinone oxidoreductase 1 (NQO1). Measurements with redox-sensitive probes confirmed an oversupply of reactive oxidant species. Also, RA and CAD macrophages were programmed to produce higher levels of the chemokine CCL18, which promotes T cell recruitment and is highly expressed in the atherosclerotic plaque. Scavenging of ROS with Tempol suppressed CCL18 production, implicating oxidant species in regulating the chemokine secretion profile. Depriving macrophages of glucose had profound implications on both ROS production and the gene expression pattern. Specifically, reducing glycolytic flux by treatment with 2-deoxy-glucose restored the expression of the negative regulators Krüppel-like factor (KLF)2 and KLF4, which inhibit inflammatory effector functions.

Conclusion: Enhanced glucose metabolism acts as an upstream regulator of inflammatory macrophage functions. ROS, produced in excess by glucose-addicted macrophages, influence the chemokine production pattern, specifically CCL18, a predominant chemokine in atherosclerotic plaque. Patients with RA and CAD share common features in macrophage differentiation towards hyperinflammtory effector cells. Such macrophages may contribute to the acceleration of CAD in RA patients.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Production of anti-CCP autoantibodies, the hallmark of rheumatoid arthritis (RA), is dependent on T cell help, positioning T cells into a pinnacle position in the breakdown of self-tolerance. Such RA T cells have features of premature senescence and age-inappropriately erode their telomeric sequences. It has been speculated that senescence and telomere erosion result from increased proliferative pressure, but the underlying mechanism is not understood. To explore why RA T cells lose telomeric sequences, we have analyzed the structure and function of telomere-residing proteins in CD4 T cells, focusing on DNA repair molecules involved in telomeric maintenance.

Methods: Naïve $CD4^+CD45RA^+$ T cells were purified from anti-CCP^+ RA patients and age-matched controls and stimulated by T cell receptor triggering. The length and structural intactness of the telomeric cap of individual telomeres was examined by fluorescence-in-situ-hybridization in metaphase nuclei. DNA repair molecules were mapped to the telomere by multicolor confocal microscopy, utilizing the shelterin protein TRF2 as a telomere-specific marker. To investigate the function of individual DNA damage proteins in telomere protection, we employed siRNA knockdown technology.

Results: Metaphase nuclei from RA T cells consistently had structurally damaged telomeres. Almost 70% of nuclei had structural abnormalities, including telomere fragility products, end apposition, telomere fusion and signal free ends ($p=0.001$ compared to age-matched controls). Confocal analysis demonstrated that the protein complexes recruited to duplicating telomeres were significantly different in RA and control T cells, with RA telomeres lacking the MRN complex ($p=0.002$). Knockdown of the MRN component MRE11 in healthy T cells promptly produced telomeric damage, quantified by the telomeric localization of the damage-sensing protein 53BP1 ($p=0.0001$). Also, forced MRE11 loss rapidly induced T cell senescence, as demonstrated by the induction of the cyclin-dependent kinase inhibitor 2A ($p=0.01$) and the cell surface marker CD57 ($p=0.04$).

Conclusion: Telomeres in RA T cells are not only shortened, but are structurally damaged. The protein complex surrounding RA telomeres lacks the repair molecule MRE11, and knockdown of MRE11 in healthy T cells promptly reproduces the telomere damage phenotype of RA T cells. MRE11 loss is mechanistically linked to T cell senescence. Telomeric erosion and premature senescence in RA T cells results from insufficiencies in the DNA repair machinery.

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic disease leading to joint destruction. Although many studies have addressed correlates associated with the speed of joint destruction, less attention has been paid to the distribution of joint destruction in RA. Here, we divided hand bone destruction into fingers and non-fingers in patients with RA and analyzed which factor is associated with finger joint destruction.

Methods: We recruited a total of 1,215 Japanese subjects with RA as two different sets. We assessed the degree of joint destruction by total sharp score (TSS). TSS of fingers and non-fingers were used as a dependent variable and a covariate, respectively. Age, sex, disease duration, smoking, C-reactive protein, RA treatment, positivity and levels of anti-citrullinated peptide antibody (ACPA) and rheumatoid factor (RF) were used as candidates of correlates. We assessed overall effect in meta-analysis. We further tested findings in Japanese subjects for their associations in 157 Dutch RA patients in the BeSt study in which treatment regimens were strictly specified. The association was also analyzed between finger TSS and HLA-DRB1 alleles or genetic risk scores based on haplotypes of amino acid residues associated with RA susceptibility. We also extended the analyses to TSS in the foot joints.

Results: Unsurprisingly, disease duration was associated with finger TSS ($p \leq 0.00037$). RF positivity and levels showed significant associations with finger TSS after adjusting for covariates ($p=0.0022$ and 8.1×10^{-7}, respectively). These associations were true to time-averaged finger TSS. We observed association between RF positivity and finger TSS in the BeSt study ($p=0.049$). We did not find associations between finger TSS and positivity or levels of ACPA. ACPA(-)RF(+) subjects were found to explain the difference between RF and ACPA. No associations of HLA-DRB1 alleles or genetic risk scores were observed. RF positivity and levels also showed a significant association with foot TSS or combination of foot and finger TSS.

Conclusion: RF positivity and levels are associated with finger joint destruction independently from non-finger joint destruction and covariates. Our findings might suggest different mechanisms between joint destruction of finger and non-finger joints in RA.

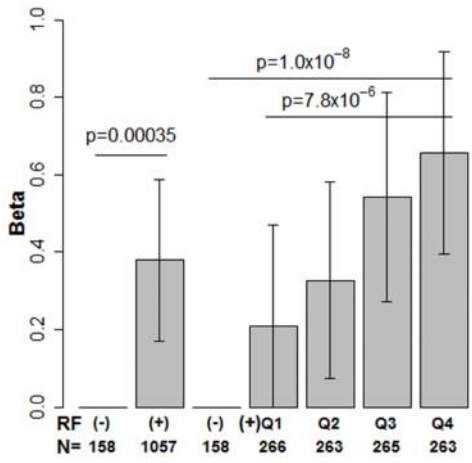

Figure. Associations between finger TSS and positivity or levels of rheumatoid factor.

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Several *vitamin D receptor* (*VDR)* polymorphisms have been associated with cardiovascular (CV) and autoimmune diseases. Carotid plaques are surrogate markers of severe atherosclerotic disease. Rheumatoid arthritis (RA) is a chronic inflammatory autoimmune disease associated with an increased risk of CV death, mainly due to a process of accelerated atherogenesis. Patients with RA have increased frequency of carotid plaques when compared with the general population. The aim of the present study was to determine the potential association of TaqI (rs731236), ApaI (rs7975232), BsmI (rs1544410) and FokI (rs2228570) *VDR* polymorphisms with carotid plaques in patients with RA.

Methods: A total of 591 RA patients from Northern Spain who met the 1987 American College of Rheumatology (ACR) and the 2010 ACR/European League Against Rheumatism criteria for RA were genotyped for rs731236, rs7975232, rs1544410 and rs2228570 *VDR* polymorphisms by TaqMan genotyping assays. In addition, the presence of carotid plaques was evaluated in these patients by carotid ultrasound technology.

Results: RA patients carrying *VDR* rs7975232 CC genotype had a decreased risk of carotid plaques, after adjustment for sex, age and traditional CV risk factors (p=0.014, OR=0.46, 95% CI: [0.24-0.85]). This effect was also found in patients who carried the mutant *VDR* rs7975232 C allele, after adjustment for potential confounder factors (p=0.018, OR=0.70, 95% CI: [0.52-0.94]). Although no association between rs731236, rs1544410 and rs2228570 *VDR* polymorphisms and presence of carotid plaques was observed, RA patients who carried the GATG haplotype (which harbors the A allele of rs7975232) had an increased risk of carotid plaques, after adjustment for sex, age and traditional CV risk factors (p=0.003, OR=2.20, 95% CI: [1.30-3.73]).

Conclusion: Our results show a protective effect of the *VDR* rs7975232 allele C on the risk of severe atherosclerosis in patients with RA.

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster II
Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a polygenic disease associated with accelerated atherosclerosis and increased cardiovascular (CV) mortality. Recent studies have identified the *ZHX2* rs11781551 polymorphism as the most relevant genetic variant associated with carotid intima-media thickness (cIMT) values and *LEPR* rs4420065, *GCKR* rs1260326 and *ASCL1* rs10745954 as polymorphisms related to C-reactive protein levels in non-rheumatic Caucasians individuals. Accordingly, we evaluated the potential relationship between these 4 polymorphisms and subclinical atherosclerosis (assessed by cIMT and presence/absence of carotid plaques) and CV disease in RA.

Methods: 2,298 Spanish RA patients were genotyped for these 4 polymorphisms by TaqMan assays. Subclinical atherosclerosis was evaluated in 907 of these patients by carotid ultrasound.

Results: No statistically significant differences were found when each polymorphism was assessed according to cIMT values and presence/absence of carotid plaques in RA after adjustment the results for potential confounders. Moreover, no significant differences were obtained when RA patients were stratified according to the presence/absence of CV disease after adjustment for potential confounders.

Conclusion: Our results do not confirm an association between *ZHX2* rs11781551, *LEPR r*s4420065*, GCKR* rs1260326 and *ASCL1* rs10745954 and subclinical atherosclerosis and CV disease in RA.

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Aberrant DNA methylation patterns have previously been associated with rheumatoid arthritis (RA) [MIM 180300]. Our study aimed to determine whether differentially methylated CpGs in synovium-derived fibroblast-like synoviocytes (FLS) of RA patients were also differentially methylated in peripheral blood samples.

Methods:

DNA methylation was measured by generating 371 genome-wide DNA methylation profiles for 63 RA cases (all satisfied the ACR classification criteria, 57 were seropositive), and 31 controls using Illumina HumanMethylation450 (450k) BeadChips. Cells from peripheral blood were FACS-sorted and CD14+ monocytes, CD19+ B cells, CD4+ memory T cells, and CD4+ naive T cells were assayed for each individual. One-tailed Wilcoxon rank sum tests were used to analyze case-control differences in the FLS candidates within these four cell types. Receiver operating characteristic (ROC) curve analysis was employed to test the predictive power of a hypermethylation score based on the differentially methylated sites we observed.

Results:

Of the 5,532 hypermethylated FLS candidates, 1,056 (19%) were hypermethylated in CD4+ naive T cells of our RA cases compared to controls (FDR $q<0.05$). No other CpG candidates achieved significance in the other cell types. A hypermethylation score was calculated based on these results and had an area under the curve (AUC) of 0.73 when predicting RA case status. This hypermethylation score was compared to having the HLA-DRB1 shared epitope (SE) (yes/no) and a continuous genetic risk score consisting of 43 non-HLA SNPs (Yarwood 2013 and Eyre 2012). The SE model had an AUC of 0.66 (0.56-0.77), and the genetic risk score had an AUC of 0.51 (0.38-0.63). A combined model of shared epitope, GRS and the methylation score had an AUC of 0.78, which was the best predictive model. Both methylation score and SE remained significant ($p<0.05$) when included in a multivariable logistic model of methylation score, SE and genetic risk score, with RA case-status as the outcome. Although the methylation score had a greater AUC than the SE (0.73 versus 0.66), the SE had a larger odds ratio in the multivariable logistic regression model (5.31 versus 1.06).

Conclusion:

Our results suggest that measurement of DNA methylation in CD4+ naive T cells of peripheral blood may have diagnostic or prognostic value and represents one of the first steps towards precision medicine in RA.

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Peripheral blood gene expression profiling has been used to identify gene signatures which reflect a variety of pathologic conditions. The CorusCAD¨ test is a peripheral blood gene expression test incorporating age, sex, and gene expression into an algorithm which assesses obstructive CAD (coronary artery disease) likelihood in non-diabetic patients without inflammatory diseases. Our objective was to evaluate the validity of the CorusCAD¨ expression profile with CAD in persons with rheumatoid arthritis (RA), a chronic inflammatory condition.

Methods:

Twenty RA-non RA, case-control matched pairs of individuals with a range of known CAD were identified in a large cardiac catheterization cohort, CATHGEN. Rheumatoid arthritis patients were identified using ICD9 codes, and diagnosis was confirmed by chart review. Controls, without RA, were matched by sex, age, race, number of diseased coronary vessels, and BMI. Persons with type 2 diabetes were excluded. Gene expression levels of 23 CAD-associated genes composing the CorusCAD¨ score were used to determine the age, sex, gene expression scores (ASGES). ASGES were compared in RA and controls using a matched pair analytic approach (paired t-test).

Results:

In persons with RA, the range of CorusCAD¨ ASGES scores was similar for those with and without RA. Independent of CAD, persons with RA had higher Corus ASGES scores than matched controls ($P<0.04$). Specifically, RA contributed to a 10% increase in CorusCAD¨ ASGES when controlling for CAD using the matched design. RA was associated with higher expression levels for 6 of the 23 genes ($P<0.05$ for all, not adjusted for multiple comparisons): S100 calcium binding protein A12; interleukin-18 receptor accessory protein; caspase 5; S100 calcium binding protein A8; aquaporin 9; and cluster of differentiation (CD)79b. All except aquaporin 9 are associated with higher expression in CAD.

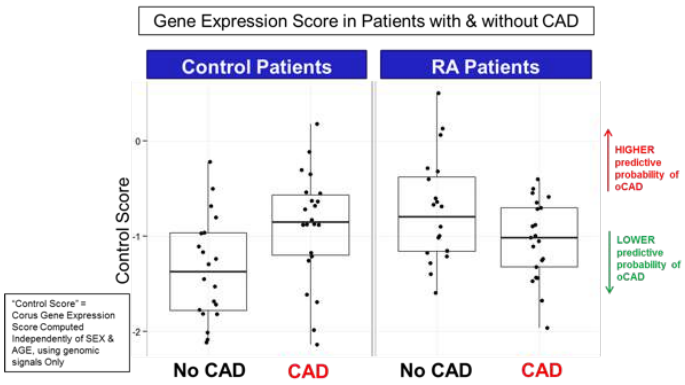

Figure 1. Corus gene expression scores (GES) are higher in RA patients compared to matched controls. GES was not able to differentiate oCAD in RA patients. (Figure contains results from the original 40 pairs, and not the selected subset with RA confirmed by chart review. However, the inability to distinguish oCAD remained when using only the confirmed RA subset.) oCAD = obstructive coronary artery disease

Conclusion:

Across a range of known coronary disease severity, RA is associated with increased expression of CAD-associated genes; among these are two genes associated with neutrophil activation, S100A8 and S100A12. Both are associated with RA disease activity in published studies. Further work on the mechanism and consequences of gene activation for these genes is indicated.

Session Date: Monday, November 9, 2015

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Lung diseases (LD) are common extra-articular manifestations in rheumatoid arthritis (RA). Recent studies have shown the association of RA-LD with anti-citrullinated protein antibodies. The peptidylarginine deiminase (PADI) mediates post-translational deimination of peptidylarginine to a non-standard amino acid peptidylcitrulline.

The aim of the present study was to investigate whether the single nucleotide polymorphisms (SNPs) of *PADI4* are associated with RA-LD.

Methods:

Blood samples and clinical data were collected from 116 consecutive RA patients who satisfied the 1987 American College of Rheumatology classification criteria. RA-LD was diagnosed using high-resolution computed tomography of the chest and a pulmonary function test. All of the patients were genotyped for SNPs of *PADI4* and HLA-DRB1 alleles. The independent *t*-test or Mann-Whitney test for continuous variables, the chi-square test or Fisher's exact test for categorical variables, and multivariate logistic regression analysis to assess genetic susceptibility to RA-LD were performed.

Results:

Of the 103 RA patients, 8 (7.8%) had interstitial lung disease (ILD) and 33 (32.0%) had small airway disease (AD). High titers of ACPA (≥80 U/mL; p=0.022) and RF (≥ULN×3; p=0.008) were significantly associated with susceptibility to RA-LD. The minor allele homozygote of padi4_92 was susceptible to RA-large AD (OR = 3.11 , 95% CI = 1.29-7.48). The recessive genotypes of padi4_89 (OR = 3.69, 95% CI = 1.14-11.95) and padi4_104 (OR = 3.47, 95% CI = 1.10-11.00) were susceptible to large AD. HLA-DRB1 *0405 was protective against the development of RA-AD (OR = 0.32, 95% CI = 0.11-0.98). The combination of any HLA-DRB1 *04 alleles except the *0405 and padi4_92 GG+ presented a synergistic effect on the development of

RA-large AD (OR = 17.73, 95% CI = 2.22-141.63).

Conclusion:

This study demonstrates the association of SNPs of *PADI4*and HLA-DRB1 alleles with susceptibility to RA-LD.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Methotrexate (MTX) is the most frequently used DMARD in the treatment of rheumatoid arthritis (RA). There are known links between the use of MTX and accelerated development of rheumatoid nodules in RA, although the mechanisms are unclear. Little is known of the potential for an anti-folate mode of action by MTX within nodule tissue. Previous studies indicate that adenosine release and genetic factors may be important to nodule development. However, the potential for these mechanisms to operate within nodules is unknown. The objective of this study was to determine whether MTX affects the expression of genes encoding adenosine receptors, MTX transporters and metabolising enzymes within subcutaneous rheumatoid nodules.

Methods: Subcutaneous nodule tissues (n=23) were obtained following elective surgery from 21 patients with RA, including 16 nodules from 15 patients receiving MTX and 7 nodules from 6 patients without MTX therapy. Plasma levels for 15 cytokines were measured in paired bloods from 12 patients using Bio-Plex Pro human Th17 assays (BioRad). Quantitative real-time PCR assays (Applied Biosystems) were used to determine the expression of SLC19A1, ABCB1, ABCC1, ABCG2, GGH, FPGS, MTR, MTRR and TYMS, ADORs A1, A2A, A2B, and A3 genes within each nodule. Differences in normalised gene expression between groups was determined by Mann Whitney U tests and Spearman correlations between gene expression used to establish gene connectivity.

Results: All genes examined were expressed in all 23 nodule tissues. Amongst all genes, only the expression of MTR, encoding 5-methyltetrahydrofolate-homocysteine methyl transferase, was affected by MTX therapy, with reduced MTR expression in nodules from patients on MTX therapy, compared to those not receiving MTX (1.682ng vs 3.625ng respectively; p=0.023). The potential for gene co-regulation and connectivity was determined based on gene expression correlations. Greatest connectivity was established for TYMS, where expression significantly correlated, positively with GGH and FPGS and negatively with ADORA1, ABCG2 and MTR expression. MTX therapy impacted on this connectivity maintaining especially the TYMS with MTR and ADDORA1 negative correlations. Finally we found no evidence for an effect from interleukin (IL)-23, IL-6, TNFalpha or IFNgamma in plasma on gene expression within nodules.

Conclusion: The genes responsible for MTX transport, metabolism and mode of action are expressed in subcutaneous rheumatoid nodules. Amongst the genes investigated, MTX therapy impacts only on MTR gene expression, which is significantly reduced in nodules by MTX therapy. Plasma levels of key cytokines driving RA have no impact on nodule gene expression. Our data demonstrate the potential for MTX to exert its anti-inflammatory effects witin

nodules; that MTX influences connectivity between gene expresion in nodules; and suggest that, through MTR expression, DNA methylation might be an underlying mechanism important to the formation of this extraarticular inflammatory lesion.

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Leukocyte immunoglobulin-like receptor A3 (LILRA3) is a putatively secreted protein belongs to the leukocyte immunoglobulin-like receptor (LILR) family. Based on our research that LILRA3 is a novel genetic risk for rheumatoid arthritis (RA) in Chinese Han population , we undertake this study to investigate the role of LILRA3 on synovium inflammation in RA patients.

Methods: i) The expression of LILRA3 in serum and synovial fluid from patients with RA ,OA, and health controls were measured by using ELISA. ii) Fibroblast-like synoviocytes (FLSs) from RA patients were stimulated with different concentration of recombinant LILRA3 protein in the presence or absence of tumour necrosis factor (TNF)-α and interleukin (IL)-1β. iii) FLSs from patients with RA were transfected with LILRA3 plasmid or control vector and 24 hours later were treated with TNF-α and IL-1β co-culture. The expression of inflammatory mediators, including IL-6,IL-8, MMP-1and MMP-3 was measured by q-PCR array and ELISA. MARKinse signaling pathway activation levels were detected by Western Blotting method. One-way analysis of variance was used to detect the differences between the group means.

Results: Compared with health controls, the expression of LILRA3 in RA and OA serum was high and LILRA3 was specifically express in synovial fluid with RA patients. We demonstrated that LILRA3 can promote the secretion of inflammatory factors independently or synergy with TNF-α and IL-1β both in vitro and in a transfect system. Furthermore, we proved that LILRA3 can promoted synovium inflammation through the activation of the signaling pathways, particularly the ERK and JNK pathways.

Conclusion:

Our data demonstrate that LILRA3 is a potent new pro-inflammatory factor in RA. LILRA3 can aggravates synovium inflammation through MARKinse signaling pathway. These findings may give us some clues for the study on the pathogenesis of RA.

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

A recent study has suggested that the excess cardiovascular (CV) risk observed in patients with rheumatoid arthritis (RA) could be partially explained by immune-complexes of antibodies against citrullinated proteins that locally promote and perpetuate inflammation and progression of atherosclerotic plaques (1). Our aim has been to replicate one of the observations supporting this hypothesis: association between anti-citrullinated fibrinogen (citFib) and subclinical atherosclerosis.

Methods:

Three surrogate markers of atherosclerosis were assessed in 124 patients with RA, with no previous history of CV events: carotid intima-media thickness (cIMT) and carotid plaques assessed by carotid ultrasonography (US), and coronary artery calcification score (CACS) performed by multi-detector computed tomography (MDCT) scan. We analyzed the relationship of these three markers of subclinical atherosclerosis with the presence and levels of autoantibodies, including anti-citFib, anti-CCP2 and RF.

Results:

CV risk based on gender, age, cholesterol, systolic blood pressure and smoking status was low or moderate for most patients, and only 17 patients showed ≥ 5 % risk of fatal events in 10 years according with classical risk factors. In contrast, most patients (81.4 %) showed at least one sign of subclinical aterosclerosis: carotid plaques were present in 69.4 % of the patients, moderate to high CACS in 21.0 %, and cIMT > 0.9 mm in 15.6 %. None of these surrogate markers of atherosclerosis showed a significant association with anti-citFib antibodies (either against the whole protein present in 33.9 % of the patients, or against an immunodominant peptide present in 23.4 %) or with anti-CCP2 (60.7 %) or RF (58.1 %) in this series of patients with RA. In addition, no significant association was observed when the patients were analyzed according to sex, seropositive status RA or combined atherosclerosis surrogate markers.

Conclusion:

Our results do not support a relationship between anti-citFib antibodies and subclinical atherosclerosis in RA questioning the claim that these antibodies have a role in the increased risk of CV disease observed in patients with RA.

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

We previously described that sensitivity to TRAIL-induced apoptosis varied in rheumatoid arthritis (RA) fibroblasts-like-synoviocytes (FLS) from one patient to another, and was inversly correlated with disease severity. Therefore, we screened for genes differentially expressed in RA FLS sensitive and resistant to TRAIL induced apoptosis.

Methods:

The sensitivity of RAFLS was defined based on the percentage of TRAIL-induced apoptosis: 0-10% for resistant RAFLS (RAFLS-R) and above 25% for sensitive RAFLS (RAFLS-S). We performed transcriptomic comparison using microarray to compare sensitive (n=6) and resistant RAFLS (n=6). Differential expression was validated using quantitative PCR (q-RTPCR) and we examined the implication of identified candidates in the regulation of apoptosis using siRNA .

Results:

Microarray analysis revealed 10 functional genes differentially expressed according to TRAIL sensitivity. These factors are implicated in different functions, such as the respiratory chain (ND3), the transport of lipids (OSBP2, PLTP), the regulation of signalling linked to extracellular factors (SULF2, GALNT1, SIAE) or the regulation of gene expression (TET2 and LARP6). We confirmed differential expression for GALNT1 ($p<0.05$) and LARP6 ($p<0.05$) by q-RTPCR, with an overexpression of LARP6 in RAFLS-R and of GALNT1 in RAFLS-S, while SULF2 also tended to be overexpressed in RAFLS-S ($p=0.1$). LARP6 protein was also significantly overexpressed in RAFLS-R (n=6) compared to RAFLS-S (n=7) ($p<0.05$). Using siRNA extinction, we demonstrated the implication of GALNT1, SULF2 and LARP6 in the control of TRAIL induced responses since the siRNA which target GALNT-1, SULF-2 significantly decreased ($p<0.05$, n=7) while siRNA targeting LARP6 significantly increased TRAIL-induced apoptosis of RAFLS ($p<0.01$, n=10).

DISCUSSION: Concurring with the demonstration of the importance of glycosylation in the regulation of TRAIL sensitivity in cancer cells line , we demonstrated that GALNT1 and SULF2 are factors participating in TRAIL-induced apoptosis in FLS. We also did the first demonstration that LARP6 participate to the resistance against TRAIL-induced apoptosis.

Conclusion: To conclude, we described several new potential targets controlling TRAIL induced cell death in RAFLS. These results are of particular interest since GALNT1 and LARP6 have been implicated in the regulation of cell death or in cancer and may represent interesting targets to induce apoptosis of RAFLS.

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Inhibitor of DNA-binding 1 (Id1) is a nuclear transcription factor actively transcribed in endothelial progenitor cells and in cells that exhibit hyperproliferative responses such as synovial fibroblasts. Previously, we identified Id1 as an angiogenic factor expressed in rheumatoid arthritis (RA) synovial tissues (STs) and upregulated in RA synovial fluids (SFs). Although it is a relatively small protein of approximately 16 kDA, Id1 contains 10 modifiable arginines. As a variety of citrullinated proteins is known to bind to anti-citrullinated protein antibodies (ACPAs), we investigated citrullinated Id1 (citId1) as a potential autoantigen in RA.

Methods: RA SFs were immunodepleted of Id1 and measured by ELISA using anti-modified citrulline (AMC) antibody for total citrullinated antigens pre and post Id1 depletion. Id1 was also immunoprecipitated from homogenized RA STs and analyzed by Western blot (WB) using anti-human Id1 or AMC antibodies. CitId1 was prepared *in vitro* from recombinant human (rh) Id1 by incubation with rh peptidyl arginine deiminase 4 (PAD4); noncitrullinated Id1 (noncitId1) was prepared identically without rhPAD4. To confirm the citrullination sites, citId1 and noncitId1 were analyzed using liquid chromatography-tandem mass spectrometry (LC-MS/MS). To test the presence of ACPAs to citId1, normal (NL) and RA patient peripheral blood (PB) sera immunodepleted of rheumatoid factor (RF) were analyzed using immunodot blot (IDB). CitId1 and noncitId1 were dotted onto nitrocellulose membranes, blocked, and incubated in the patient sera. Bovine serum albumin (BSA) and citBSA were used as antigen controls; anti-human Id1 antibody and rh IgG were used as sera controls. Epithelial-derived neutrophil-activating peptide-78 (ENA-78/CXCL5) and citENA-78/CXCL5 were similarly tested for autoantigenicity.

Results: ELISA analysis of RA SFs showed that the levels of total citrullinated antigens were significantly reduced upon immunodepletion of Id1. WB analysis of immunoprecipitated Id1 from homogenized RA STs showed that a significant portion of the total Id1 was in the modified form. LC-MS/MS analysis provided 97% sequence coverage for citId1, identifying 9 of the 10 total arginines, and 77% sequence coverage for noncitId1, identifying 7 arginines. Of the 9 identified arginines in citId1, citrullination sites were localized specifically at R33, R44, R52, R75, R87, and R121. Of the 7 identified

arginines in noncitId1, R87 was identified to be citrullinated, showing that at least one arginine is natively citrullinated in Id1. IDB analysis of mouse anti-human Id1 antibody (previously used in immunodepletion and immunoprecipitation) showed positive signals from both citId1 and noncitId1, suggesting that this binding epitope was not modified by citrullination. IDB analysis of the patient sera showed robust signals for citId1, and weak but significant signals for citENA-78/CXCL5, from multiple RA patient PB sera, displaying a four-fold increase in average reactivity for citId1 as compared to NL patient PB sera.

Conclusion: We show for the first time the presence of ACPAs with specificity to citId1 in RA patient PB sera, and propose citId1 as a novel autoantigen candidate in RA.

The Protective Effect of HLA-DRB1*13 Alleles during Specific Phases in the Development of ACPA-Positive RA

J. van Heemst[1], A.H. Hensvold[2], X. Jiang[2], H. van Steenbergen[1], L. Klareskog[2], T. W. J. Huizinga[1], A.H.M. van der Helm- van Mil[1], A.I. Catrina[2], René E. M. Toes[1], K. SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: HLA-DRB1*13 alleles are associated with protection from anti-citrullinated protein antibody (ACPA-)positive rheumatoid arthritis (RA). It is however unknown at which phase of disease development (seroconversion, ACPA maturation, disease onset or outcome) these alleles are most important. We therefore examined the effect of HLA-DRB1*13 on: ACPA-presence (:systemic autoimmunity associated with RA) in individuals with and without RA, on ACPA characteristics and on clinical outcome measures.

Methods: The effect of HLA-DRB1*13 on ACPA-presence in subjects with or without RA was assessed in the Swedish twin registry (n=10748). ACPA characteristics were studied in ACPA-positive RA patients from the Swedish Epidemiological Investigation of RA (EIRA, n=1224) and the Dutch Leiden Early Arthritis Clinic (EAC, n=441). Disease activity at inclusion and disease outcome (DMARD-free sustained remission and radiographic progression) was assessed in RA patients from the EAC.

Results: HLA-DRB1*13 is associated with protection from ACPA-positive RA (prevalence 16% versus 28% in ACPA-negative RA), but not with significant protection from ACPA in individuals without RA (prevalence: 22%, p-value 0.09). HLA-DRB1*13 is associated with lower ACPA-levels (EIRA: 447 U/ml versus 691 U/ml, p-value: 0,0002) and decreased citrullinated epitope recognition (EIRA: $p< 0.0001$). No association between HLA-DRB1*13 and disease activity or outcome was found.

Conclusion: These data indicate that HLA-DRB1*13 mainly affects the onset of ACPA-positive RA in ACPA-positive non-RA individuals. In RA, HLA-DRB1*13 influences ACPA characteristics, but not the disease course. This implies that therapeutic strategies aimed at emulating the HLA-DBR1*13 protective effect may be most effective in ACPA-positive healthy individuals at risk for RA.

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Trans-ethnic analyses have found similarities and differences in genetic influences on RA susceptibility among Caucasians and Asians, making both validation and novel gene association studies important in the less well studied African-American (AA) population.

Methods: 535 ACPA-positive AA RA cases and 1,506 AA controls were genotyped using Illumina Omni 1M and 1S arrays. Associated and suggestive loci were defined as variants within 100kB on either side of lead SNPs identified by Okada et al [Nature 506:376 (2014)] with a p-value of $<10^{-8}$, or $< 10^{-5}$, respectively. In addition to traditional association analyses, we used the novel technique, Probabilistic Identification of Causal SNPs (PICS) [Farh et al. Nature 518:337 (2015)], to identify candidate causal SNPs. We used a binomial test to assess whether SNPs with association p-values (using two thresholds: $p<0.01$ and $p<0.001$) in AA RA were enriched for PICS identified in 21 autoimmune diseases as provided by Farh et al.

Results: The association of HLA-DRB1 and PRKCQ was confirmed through the chip data, as was the absence of association of PTPN22, with RA in AA. We found a peak of association at 5p15.31 with the most strongly associated SNP being rs13169313 ($p = 4.87*10^{-8}$, OR=1.44, nearest gene, MTRR). Initial analysis of this locus seems to implicate ancestral African haplotypes, not Caucasian haplotypes. Figure 1 shows a LocusZoom plot of this region. There was significant enrichment of association of autoimmune disease PICS SNPs among SNPs associated with RA at p-value < 0.01 ($p=1.55*10^{-11}$) and at p-value < 0.001 ($p=5.9*10^{-5}$, binomial test).

Conclusion: This analysis confirms gene and variant-level associations of HLA-DRB1 and PRKCQ with RA in AA and shows association with 5p15.31. The marked enrichment of PICS SNPs with low association p-values in our cohort suggests pleiotropy between autoimmune diseases and susceptibility to RA in AA.

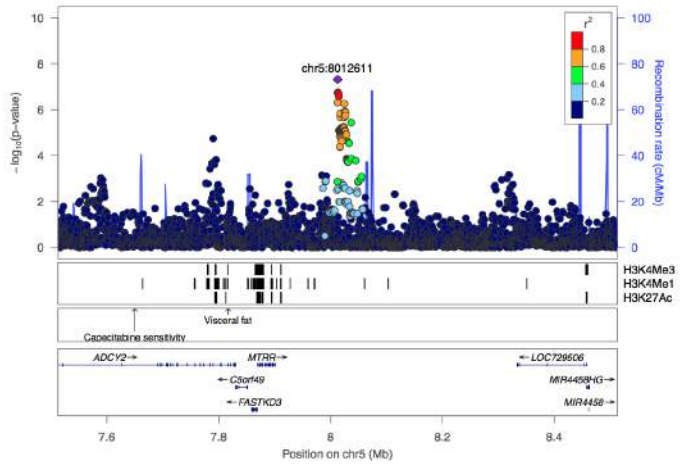

Figure 1 – LocusZoom plot of this region. Here, colored dots refer to linkage to the lead SNP assuming West African LD patterns. The correlation between association p-values and LD to the lead SNP is substantially weaker if European LD is assumed.

Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Epigenetic modifications have been previously associated with rheumatoid arthritis (RA [MIM 180300]). This study aimed to determine whether differential DNA methylation in peripheral blood samples is associated with disease activity among RA patients.

Methods: Peripheral blood samples were taken from 59 RA patients in the University of California, San Francisco RA cohort (all satisfied ACR classification criteria; 53 were seropositive; 41 had evidence of erosive disease). Cells were FACS-sorted into 4 immune cell subsets (CD14+ monocytes, CD19+ B cells, CD4+ memory T cells, CD4+ naïve T cells) per individual, and 233 epigenome-wide DNA methylation profiles were generated using Illumina HumanMethylation450 BeadChips. Patients were also evaluated with the Clinical Disease Activity Index (CDAI) and divided into 2 categories based on cutoffs recommended by the American College of Rheumatology: remission (CDAI<2.8, n=14), and active disease (CDAI≥2.8, n=45). One-tailed Wilcoxon rank sum tests were used to evaluate methylation differences between the two patient categories for candidate CpG sites previously found to be differentially methylated in fibroblast-like synoviocytes derived from RA patients compared to osteoarthritis patients or normal controls.

Results: Of the 13,938 candidate loci, 1 CpG (cg05439368, upstream of *TRIM69*) was significantly hypermethylated and 1 CpG (cg07135032, in *LMX1A*) was significantly hypomethylated in CD4+ memory T cells (FDR q<0.05). No other CpG candidates achieved significance in the other cell types. CpGs within 1500 bp of *TRIM69* were subsequently evaluated, and a block of 6 CpGs (including cg05439368) in the promoter region of *TRIM69* was hypermethylated (p<0.05) in both the CD4+ memory and CD4+ naïve T cell subsets, suggesting that dysregulation of *TRIM69* expression in CD4+ T cells may be associated with RA disease activity. *TRIM69* has been reported to directly interact with a number of toll-like receptors (TLRs), a family of proteins involved in the innate immune response to microbial agents.

Conclusion: Our results identify a potential biological mechanism underlying disease activity in RA cases. This study is the first to report methylation differences associated with RA CDAI scores.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a complex autoimmune condition affecting 0.5-1% of populations worldwide and having a significant heritable component. A major endophenotype within RA is erosive joint damage, which is associated with autoantibodies and is manifested by bony erosions and joint space narrowing. In this study we seek to uncover influences on RA severity using the Immunochip custom array in order to both validate established loci of RA severity and discover novel contributing loci.

Methods: Genotyping was performed on the Immunochip custom array, which was designed for the interrogation of autoimmune phenotypes. In addition, hand and foot radiographs from 548 African American RA patients were available for this study. The total radiographic score ranged from 0 to 140, and we separated these patients into two groups, those having an erosion score of 0 (n=235) and those having an erosion score greater than 0 (n=313). After standard quality control measures for genotype missingness, Hardy-Weinberg equilibrium, etc., logistic regression was carried out while controlling for disease duration, proportion of European admixture, sex, Body Mass Index (BMI), smoking status, DMARD or Biologic use, and number of HLA-DRB1 risk alleles as covariates. We also fitted zero-inflated negative binomial models using total radiographic score as count data. We defined statistical significance at $p=3.1*10^{-6}$based on an Neff of 16,154 calculated using Plink.

Results: rs1466576 reached Immunochip-wide statistical significance (OR=2.19, $p = 1.81*10^{-6}$, nearest gene, *PCBD1*). *CTLA4* also showed suggestive evidence of association with radiographic severity, and the lead SNP was rs73055463, OR=0.39, $p=1.47*10^{-5}$) in CTLA4, an established risk locus in rheumatoid arthritis. Finally, rs506746 (in NALCN, near ITGBL1) was associated with RA severity ($p=9.93*10^{-7}$) using zero-inflated negative binomial

model).

Conclusion: This is the first study to evaluate the genetic contribution to radiographic severity in African Americans with RA. Using the Immunochip we found that PCBD1, NALCN/ITGBL1, and CTLA4 are associated with radiographic severity in African Americans with RA. These findings, while preliminary, may help extend knowledge of the genetic basis of radiographic damage in RA among African Americans, an understudied population in RA research.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Joint damage manifested by bony erosions and joint space narrowing is a major contributor to the morbidity and mortality of RA. Reports in Caucasians (EA) indicate that as much as 58% of radiographic severity of RA may be heritable, but little is known about the heritability of this phenotype, especially in African Americans (AA).

Methods: 175 AA RA patients with longstanding ACPA-positive RA that never progressed to radiographic damage, and 264 autoantibody-positive AA RA patients with radiographic joint damage were genotyped using Illumina Omni 1M and 1S arrays. Whole genome sequence (WGS) data (Complete Genomics) was obtained on a subset of 62 autoantibody-positive AA RA patients (31 with radiographic damage, 31 without damage). DMARD/biologic use, disease duration, sex, smoking status, and the top 10 principal components were included as covariates. We sought variants associated with radiographic damage using a genome-wide significance threshold of $p < 10\text{-}8$. Using our WGS data, we analyzed 126 loci for association with damage: 101 loci associated with susceptibility in EA and 25 loci previously reported to be associated with radiographic severity of RA among EA. We conducted covariate-controlled gene based testing ($\alpha = 4*10\text{-}4$) on these loci using SKAT-O and then conducted immune cell enhancer burden tests ($\alpha = 1.6*10\text{-}5$) in these regions.

Results: We did not detect any associations of SNP variants with damage at a genome wide level of significance with Illumina 1M/1S data; the most strongly associated variant with radiographic damage was rs4743949 (chr9:92722181, $p = 5.76*10\text{-}7$, OR= 0.60) located in an enhancer region nearest mir4290, a non-coding RNA, and about 800kB 5' of Syk. Gene burden testing of WGS data revealed loci having an enrichment of variants that have previously associated with radiographic severity of RA. 3 of the 25 gene burden tests showed evidence of association; these were ILF3 ($1.31*10\text{-}4$, gene based burden test), ATG5 ($7.27*10\text{-}7$, T-cell enhancer region), and CXCR5 ($p=1.28*10\text{-}5$, B-cell enhancer region). We did not detect association of radiographic severity with the HLA-DRB1 locus in either single variant or burden testing.

Conclusion: Consistent with recent reports, variation in enhancer regions, many of which are T-cell enhancers, were associated with damage. For example, the enhancer region of ATG5, a gene important for T and B cell lymphocyte development and required for appropriate processing of antigens for presentation by MHC class II, was significantly associated. The HLA region was not found to be associated with RA severity in this study, possibly because the whole cohort is ACPA positive. Appropriate parsing of NGS data may elucidate associated loci that are missed using array-based GWA studies.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a common autoimmune disease characterized by systemic inflammation. Although the understanding of the pathogenesis is incomplete, there is substantial evidence that an increased Th17 cell response plays an important role in the disease onset. Further attempts to understand the RA pathogenesis recently raised interest in elucidating cell specific epigenetic modifications. In the current study we investigated genome-wide DNA methylation patterns in Th1 and Th17 cells from RA patients.

Methods: Early treatment-naive RA patients (n=6) were included into the study. For control gender- and age-matched healthy controls (n=6, HC) were analyzed. CD4 memory T cells were separated from the peripheral blood using magnetic beads. After overnight stimulation with anti-CD3/CD28 sorting of Th1 and Th17 cells was performed by FACS based on cytokine secretion assay for IL-17 and IFNγ. Subsequently, DNA was isolated, bisulfite-converted and amplified. Epigenome-wide association analysis was performed using the Infinium HumanMethylation 450 Bead Chip Kit assessing more than 480,000 CpG positions. Data were normalized using an algorithm in R software and further analyzed based on an established pipeline.

Results: Comparative analysis of methylation status of Th17 cells from RA patients and HC revealed 853 differentially methylated CpGs located mostly in transcription factor encoding genes such as NFATC1 and TBX2 or in genes for cytokines/cytokine receptors such as LTB and IL4R. Comparison of methylation status of Th1 cells from RA patients and HC identified 1209 differentially methylated CpGs. Interestingly, the most prominent differences were found in several Th17-characteristic genes such as CCL20, IL17R, and IL1R or in LTBD1 and NFATC2 genes. Analysis of Th1 and Th17 cell methylation regardless of whether from RA patients or HC yielded 664 differentially methylated CpGs. Remarkably, methylation differences were found in transcription factor encoding genes such as RUNX3 and TBX21, and in chemokine and cytokine genes such as IL17A, CCL1, CCL20, CXCL14, CXCR5 and XCL2.

Conclusion: Thus, the identified differences were primarily localized in genes encoding cytokines/ chemokines or transcription factors indicating that transcriptional programs leading to different soluble mediator profile might contribute to Th17 prone autoimmune reaction in RA. These data might therefore identify epigenetic patterns associated with the unrestricted Th17 response in RA and might delineate an epigenetic mechanism contributing to disease pathogenesis.

Background/Purpose: Monocytes play a key role in the pathogenesis of the cardiovascular disease (CVD). Three monocyte subsets have been described based on their CD14 and CD16 profile, with different actions in the vascular pathology. The distribution of these monocytes subsets and their epigenetic profile associated with CVD in rheumatoid arthritis (RA) remain unravelled. **Objectives:** 1) to functionally characterize the monocytes subsets in RA patients and analyze their role in the endothelial dysfunction, altered oxidative status and proinflammatory/prothrombotic profile associated to RA. 2) to evaluate the role of anti-CCPs

Methods:

Thirty RA patients and 15 healthy donors were included. Endothelial function was measured through post occlusive hyperaemia using Laser-Doppler. Carotid intima media thickness (CIMT) was used as atherosclerosis marker. The monocyte subsets were characterized by flow cytometry and isolated by

immuno-magnetic selection. Proinflammatory cytokines, peroxides levels and cellular activation markers were analyzed. NanoString nCounter miRNA Expression Array was used to profile 800 microRNAs in isolated CD14+ and CD16+ monocytes. PCR array gene expression was used to analyze the expression of 84 genes related to atherosclerosis. In vitro treatment of T lymphocytes with supernatants of CD14+ or CD16+ precultured cells with or without IgG anti-CCPs was performed.

Results:

CD16+ monocytes were significantly extended in RA patients. These subsets had increased protein and gene expression of proinflammatory cytokines, markers of atherosclerosis and peroxide levels. Isolated CD14+ healthy monocytes treated with IgG anti-CCPs showed increased CD16 and decreased CD14 gene expression after 48 h. Supernatant from CD16+ monocytes treated with IgGs anti-CCPs induced a significant increased expression of inflammatory molecules in T lymphocytes compared to CD14+ or untreated CD16+ supernatants or IgG anti-CCPs directly added to lymphocytes. miRNA expression profiling showed that 38 miRNAs were significantly altered (³2 fold) in CD14+ RA monocytes compared to CD16+ RA monocytes. Functional classification of those miRNAs showed a preponderance of targets mRNAs involved in the pathological process of RA such as inflammatory state, immune response and CVD. .

RA patients had impaired endothelial function, with a reduced perfusion value after ischemia. Increased CD16+ monocytes and reduced CD14+ cells percentage were associated with a pathologic CIMT. Clinical parameters strongly correlated with endothelial dysfunction, decreased percentage of CD14+ monocytes and increased number of CD16+ subsets.

Conclusion:

1) RA patients exhibit an increased number of CD16+ monocytes, which display a specific atherogenic and inflammatory pattern directly associated to the autoimmune profile, the progression of the disease and the altered microvascular function. This atherogenic profile might be associated with an altered epigenetic pattern, and seems to be modulated, at least partially, by anti-CCPs. That data suggest that CD16+ subpopulation might play a key role in the CVD pathogenesis associated with RA.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Macrophages play a key role in the pathogenesis of the rheumatoid arthritis (RA). Under certain stimulus conditions these cells are able to switch their phenotypes to M1 or M2 states, which are characterized by different inflammatory and tissue repair properties. Thus, M1 macrophages are predominantly recruited in inflammatory states and associated with tisular damage. An imbalance in the M1/M2 proportion has been reported in the synovium of RA patients. The molecular mechanisms undertaken this phenotypic switching in RA are not completely defined. In addition, the role of anti-CCPs antibodies in the switch of macrophage polarization has not been studied yet.

Objectives: To analyze the role of anti-CCPs in the polarization state, inflammatory process and the insulin signalling of macrophages

Methods:

M0 macrophages were differentiated from the monocytic cell line THP-1 and primary healthy monocytes. These macrophages were treated with different concentrations of IgGs isolated from healthy donors or RA patients having high levels of anti-CCPs and non-rheumatoid factor for 96 hours. Cells were collected every 24 hours of treatment. In order to analyze the response to insulin, the macrophages were treated with insulin (100 nM) for 10, 20 and 30 min before collecting the cells. The characterization of the polarization states M1 and M2 was performed through flow cytometry and the mRNA expression levels of M1 markers (HLA-DR, iNOS, IL1b, TNFa e IL-23) and M2 (CD206, Arg e IL-10). Moreover, the JNK expression and phosphorylation was analyzed. Finally, the response to insulin was studied through the mRNA expression of AKT and IRS-1 and the protein expression and phosphorylation of

AKT (a key molecule mediating insulin signalling).

Results:

Flow cytometry studies showed that macrophages treated with IgGs anti-CCPs had higher protein expression of M1 markers such as HLA-DR and iNOS and reduced expression of CD206, M2 marker, compared with macrophages treated with IgGs isolated from healthy donors. In addition, IgGs anti-CCPs increased the mRNA expression levels of TNFa, IL1b and IL-23, molecules associated to M1 state, and reduced expression of IL-10, mainly expressed by M2 macrophages. After treatment with IgGs anti-CCPs, macrophages showed significantly lower AKT phosphorylation induced by insulin compared to the macrophages treated with normal IgGs. Moreover, anti-CCPs reduced the expression of AKT and IRS-1. This reduction was accompanied with an increase in the JNK phosphorylation, main molecule initiating the process of inflammation. These effects were significant after 24 hours treatment with 100 ug/ml doses of anti-CCPs.

Conclusion:

1) Anti-CCPs antibodies act as inductors of M1 polarization state, promoting an imbalance of M1/M2 proportion which has been associated with a chronic inflammatory profile and joint damage in RA. 2) These antibodies also produce a defect in the insulin signalling of macrophages, by reducing the response to insulin, suggesting its possible implication in the insulin resistance and the development of the metabolic syndrome related to RA.

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Val and Leu at *HLA-DRB1* position 11 have been reported to be associated with radiographic progression in Caucasians with RA, independent of shared epitope status but not independent of ACPA status. In this study we examined the role of Val at position 11 in radiographic severity of RA in African Americans.

Methods:

DNA samples were directly sequenced for *HLA-DRB1* and then aligned to call four digit resolution genotypes from seropositive (either RF or ACPA positive) RA patients from the Consortium for the Longitudinal Evaluation of African Americans with Rheumatoid Arthritis (CLEAR) Registry. Radiographic severity was defined as total Sharp/van der Heijde scores of hands/feet at study entry (mean (SD) disease duration 7.7 (9.4) years). Base models of van der Heijde modified total Sharp scores (N = 527) were fit using a negative binomial regression conditional on the covariates, sex, disease duration, BMI, local European ancestry at *HLA-DRB1* (estimated using HAPMIX), and smoking. A second series of models were fit that included the covariates of the base model plus the presence of amino acid residues at 29 selected positions from 9 through 86. A third model was fit that included the base model's covariates plus the presence of 21 four digit alleles with appreciable frequency in the patient sample. Significance tests were performed by log likelihood ratio tests of the full and base models.

Results:

From the base model, disease duration (P < 2.0E-16) was positively associated, and local ancestry was negatively associated (P = 0.032) with radiographic severity. Four digit alleles were significantly associated with radiographic severity (χ^2 = 41, DF = 21, P = 0.0056), but substitutions of residues at amino acid positions were not, after multiple testing correction. Val 11 was not associated with radiographic severity (P value = 0.55), but the study was well-powered (0.85) to detect the OR previously reported in Caucasians (1.75). *HLA-DRB1* *04:01, *09:01, *13:03, and *16:02 were significantly associated with radiographic severity in this study.

Conclusion:

In African Americans with seropositive RA, *HLA-DRB1* alleles, but not Val 11, are associated with radiographic severity. Local European ancestry was negatively associated with radiographic damage, but did not modify the associations of the alleles with radiographic severity (χ^2 = 27, DF=21, P = 0.17). These findings have implications on the mechanisms of radiographic damage in RA.

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Intense synovial fibroblast (SF) hyperplasia contributes to the chronic inflammation and osteoarticular destruction that characterizes rheumatoid arthritis (RA)**.** Hypoxia-inducible factor 1α (HIF-1α) plays a pivotal role in the metabolic adaptation of SF in hypoxic inflamed joints. The purpose of this study was to analyze the impact of HIF-1α knockdown on metabolic regulation and cell survival of rheumatoid arthritis SF (RASF).

Methods: HIF-1α was silenced using lentiviral vectors or siRNA duplexes transfer strategies. Cell viability upon HIF-1α silencing was analyzed by Alamar Blue assay in SF lines from RA, osteoarthritic or healthy synovium and LC5 lung fibroblasts. To analyze the effect of HIF-1α silencing on RASF *in vivo*, RASF were engrafted into an air pouch in NOD *scid gamma* (NSG) mice and siRNA duplexes (siHIF-1α or control, 9 mice per group) were administered locally. After 11 days mice were sacrificed, pouch membranes dissected and analyzed by immunoperoxidase labeling to quantify the number of human nuclei per pouch wall area. Proteomic analysis was performed in silenced HIF-1α RASF by iTRAQ labelling, and expression of identified glycolytic enzymes as GAPDH, TPI1 and ENO1 was confirmed by western blot. Energy metabolism was analyzed in silenced RASF and LC5 cells by measuring oxygen consumption rate (OCR) with a XF24 Extracellular Flux Analyzer (Seahorse Bioscience, Billerica, MA, USA), and lactate production by Lactate colorimetric assay kit II (Biovision, Milpitas, CA, USA).

Results: HIF-1α silencing induced cell death in cultured SF regardless of their origen but not in LC5 cells. The number of RASF engrafted into the air pouch was significantly reduced in HIF-1α compared to control siRNA injected mice (205±174 vs 393±237 nuclei/mm^2, p=0.04 Mann-Whitney U-test). iTRAQ analysis identified 321 proteins in HIF-1α silenced and control RASF, down-regulated proteins included several glycolytic enzymes but only GAPDH expression was significantly decreased in siHIF-1α transduced compared to non-silenced RASF (ratio GAPDH/β-actin 0.54±0.28 vs 0.85±0.18, p=0.004 Wilcoxon test). The oligomycin sensitive respiratory rate (OSR) as indicator of oxidative phosphorylation was significantly reduced in RASF compared to LC5 (14.1±3.5 vs 62.2±8.8 pmol O_2/min/5000 cells, p<0.0001 Mann-Whitney U-test). Lactate production was significantly higher in RASF compared to LC5 (26.6±12.6 vs 12.2±1.9 nmol/mg/hour, p=0.003 Mann-Whitney U-test), and was reduced by HIF-1α silencing. Treatment of RASF with the GAPDH inhibitor 3-bromopyruvate (3BrP) also induced cell death in cultured RASF.

Conclusion: Our data show that RASF metabolism is mainly glycolytic and demonstrate that the regulatory role of HIF-1α in the glycolytic metabolism is critical for SF survival. In addition, local targeting of HIF-1α may provide a feasible strategy to reduce the pathogenic contribution of SF to chronic arthritis.

Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Epigenetic changes including histone modification play an important role in development of rheumatoid arthritis (RA). Histone deacetylase inhibitor (HDACi) increases transcription of numerous genes by rendering chromatin state more accessible for transcription factor and RNA-polymerase, leading to anti-proliferative and anti-inflammatory effects. In addition, direct change in acetylation state of cellular proteins may alter cellular function.

This study was aimed to investigate the effects of CKD-H059, a novel HDAC-6 inhibitor, on regulatory T (Treg) cells and fibroblast-like-synoviocytes (FLS) of RA patients in vitro and on development of arthritis in vivo.

Methods: Regulatory T cells (iTreg) were induced from naïve CD4+ T cells of RA patients. CSFE labeled effector T cells (Teff) from healthy subjects were co-cultured with iTreg in the increasing concentrations of CKD-H059 and Teff proliferation was analyzed by flow cytometry. After 24 hour activation with IL-1β in the increasing concentrations of CKD-H059, proliferation and IL-6 production of RA-FLS were assessed. Cytoplasmic acetylation of α-tubulin in the activated RA-FLS was visualized by confocal microscopy. Adjuvant-induced arthritis (AIA) was induced in mice that were treated with oral CKD-H059 (3, 10, 30, 50, 100 mg/kg) and the severity of arthritis was assessed on 9, 13, and 16 days.

Results: In the presence of CKD-H059, iTreg efficiently inhibited the proliferation of Teff in a dose dependent manner. CKD-H059 induced acetylation of α-tubulin in cytoskeleton with subsequent cell morphology change (i.e. from long spindle form into round flat cells) and inhibited cell proliferation and production of pro-inflammatory cytokine IL-6. In AIA mice, oral CKD-H059 was able to prevent the development of clinical arthritis in a dose-dependent manner.

Conclusion: The novel HDAC6 inhibitor CKD-H059 inhibits the inflammatory response in T cells and FLS of RA in vitro and ameliorates arthritis severity in vivo. Therefore, CKD-H059 might offer a novel treatment option for RA.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Golimumab (GOL) has shown its efficacy and safety in various randomized clinical trials with accurately selected patients. Data from daily clinical practice in Germany are still lacking.

To gather data from German patients with a known moderate to severe inflammatory rheumatic disease (RA, PsA, AS) treated with GOL sc in daily clinical practice. The aim of this non-interventional, prospective, multicenter study was to show the safety, effectiveness, socio- and health economic parameters, and quality of life reported by patients in a real-life setting.

Methods:

1,598 patients with RA, AS or PsA at 168 German study sites were enrolled in GO-NICE. The study explored days of sick leave, ability to work, hospitalizations, data of quality of life and clinical effectiveness by DAS28, PsARC and BASDAI as well as safety of GOL 50 mg sc therapy. This 3rd interim analysis evaluates all patients treated for at least 12 months or more until 31st March 2014.

Results:

A total of 1,218 patients met the criteria for the 3rd interim analysis.

RA (n=401, 33%): The mean age was 54.9 years, 26.9% were male. The DAS28 was initially at 5.0 and dropped within 24 months to 3.0. After 3 months of therapy, 35.8% of patients were in remission (DAS28 <2.6), after 24 months 42.4%. 46.1% of the RA patients worked full or part-time at baseline (BL).

PsA (n=408, 33.6%): The mean age was 50.4 yrs, 46.3% were male. 159 patients had a nail involvement (39%), 86 dactylitis (21.1%) and 57 enthesitis (14%). 52.3% of PsA-patients had a good response (mod. PsARC) after 3 months with increase to 67.8% at 24 month. 55.0% of PsA-patients worked fully or part-time al BL.

AS (n=407, 33.5%): The mean age was 42.9 years, 67.1% were male. The most common extra-articular manifestations were iritis (16%), enthesitis (13.8%), CED (6.1%) and dactylitis (3.9%). The mean BASDAI score (1-10) decreased from 5.1 (month 0) to 2.3 (24 months). 69.9% of AS patients were employed fully or part-time at BL.

Days of absenteeism from work dropped in RA patients from 16.0 to 8.2 (-48.8%) in PsA from 10.0 to 3.2 (-68.0%) and AS from 14.4 to 4.1 days (-71.7%) within the past six months. The disease impact on quality of work within past 6 months, determined by 0 (no impact) to 10 (very severe impact) decreased within the 24 months treatment from 5.0 to 2.4 (RA-) from 4.7 to 2.2 (PsA-) and from 4.0 to 2.2 (AS-patients). The proportion of patients who required hospitalization decreased from 11.4% to 1.2%, physiotherapy from 24.4% to 10.7%, and massage treatment from 11.3% to 3.4% within the first year of treatment. An improvement of the quality of life (EQ-5D-3L) was seen in all three patient groups in all five domains after 6 months and was maintained over the time.

After 24 months, 80% of the rheumatologists rated the treatment course of as "successful", 10-15% as" partially successful", and less than 5% as "unsuccessful".

The safety profile of GOL was consistent with that observed in other studies of GOL.

Conclusion:

GOL sc once monthly is an effective treatment in patients with RA, PsA and AS in a real-life setting in Germany. It shows remarkable improvements in health economic and patient-reported quality of life parameters. No new safety signals were detected.

Progressive Destruction of Large Joints in Patients with Rheumatoid Arthritis Treated with Biologic Agents

Arata Nakajima[1], Masato Sonobe[2] and Koichi Nakagawa[2], [1]Orthopaedics, Toho University Sakura Medical Center, Sakura, Japan, [2]Toho University Sakura Medical Center, Sakura, Japan

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Many clinical trials have revealed that biologic agents inhibit destruction of small joints, however, there have been a few reports demonstrating their inhibitory effects on destruction of large joins. In this study, we investigated progressive destruction of large joints in patients with

rheumatoid arthritis (RA) treated with biologic agents and determined risk factor(s) associated with progressive destruction.

Methods: We assessed a total of 273 large joints in upper and lower extremities including the shoulder, elbow, hip, knee and ankle of 67 patients. Prior to the treatment with biologic agents, X-rays for tender and/or swollen large joints in individuals were taken, and the follow-up X-rays were taken at least once between 11 and 36 months (mean 18.6) after the initial examinations. At the time of follow-up, progressive destruction was defined when at least one of the following changes was detected: 1) progressive Larsen grade (LG), 2) increase in bone erosion and/or appearance of new bone erosion, and 3) progressive joint space narrowing.

Results: Progressive destruction was seen in 14 patients (20.9%) and 17 joints (7.2%). To determine factors associated with the progressive destruction, we first performed a univariate analysis regarding variables including height, body weight, age, disease duration, CRP, DAS28, stage, LG, MTX dose, PSL dose, and X-ray intervals between the initial and the follow-up time. As shown in Table 1, LG alone was statistically significant (P<0.01). Next, the variables with a P value of <0.1 in the univariate analysis, which included LG, stage and CRP, were subject to a multivariate logistic regression analysis. As a result, LG alone was extracted as a risk factor associated with progressive destruction (odds ratio: 2.28, 95%CI: 1.19-4.36). The cutoff value of LG that discriminated progression from non-progression by the ROC curve was determined to be 2.5 (sensitivity: 0.529, specificity: 0.805), suggesting that progressive destruction of large joints is expected to be increased when LG is 3 or higher (Figure 1).

Conclusion: These results suggest that progressive destruction of large joints cannot be stopped completely even under the tight control using biologic agents. Furthermore, results of the ROC curve indicate that the bone damage of large joints should not be advanced to LG-3. Since the risk factor(s) of progressive destruction are associated with the extent of individual joint damage but not with patients' disease characteristics, regular X-ray examinations for large joints are indispensable.

Table 1. Univariate analyses for the disease characteristics of patients with progression and non-progression in destruction of large joints.

Variables	Progression (N=17)	Non-progression (N=256)	P
Height (cm)	152.3±7.0	154.8±6.0	0.165
Body weight (kg)	53.7±9.5	52.7±9.9	0.696
Age (y)	62.9±11.1	60.9±12.8	0.770
Disease duration (y)	15.1±13.6	11.8±11.2	0.305
CRP	4.51±4.89	2.87±3.52	0.079
DAS28-ESR	4.91±1.09	4.71±1.31	0.716

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: After more than a decade using biological agents (BA), is widely known their efficacy in the treatment of Rheumatoid Arthritis (RA) and their relationship with Adverse Drug reaction (ADR). We know that drugs metabolism changes with age and, thus, the AE but we have no concrete information about AE with BA in these patients in real life. The purpose of our study was to describe the incidence and characteristics of moderate and severe ADR to BA in a cohort of elderly patients with RA.

Methods: Observational longitudinal study from 1999 to 2013 was conducted. RA patients followed in outpatient clinic at Hospital Clinico San Carlos, which started BA treatment after 65 years of age, were included. Primary outcome: discontinuation due to an ADR (moderate: suspension of the drug regardless of the impact; severe: suspension and hospitalization or death) related to BA (Etanercept (ETN); Infliximab (INF); Adalimumab (ADA); Rituximab (RTX); and other BA [Golimumab, Certolizumab, Abatacept and Tozilizumab]). Co variables: sociodemographic, clinical and therapy. Incidence rates of discontinuation due to ADR (IR) per 100 patient-years were estimated using survival techniques with their respective 95% confidence interval [95% CI]. Comparison between BA ADR discontinuation rates and other associated factors were run by Cox regression models.

Results: We included 286 courses of BA therapy in 146 patients (604 patient-years). Of these, 78% were women with a mean age at diagnosis of 66.5 ± 7 years and a median time to the start of the first BA of 6 ± 4 years. ADA (27.3%), followed by INF (22.4%), ETN (21.3%), and RTX (19.2%) were the most frequently used. Treatment was suspended due to ADRs in 111 cases (IR: 18.3 [15.2 -22.1]), 56% of them were severe (IR: 10.3 [8-13.2), with 16 deaths during the study period (IR: 2.6 [1.6-4.2]. The retention rate for discontinuation due to ADR was 71%, 50%, 35% and 20% for the first, third, fifth and tenth year. The most frequent cause for ADR was infection (50.5%; IR: 9.3 [7.1-12]). The crude IR of discontinuation was lower for ETN (IR for all ADRs: 14.5 [9-23.3]; IR for severe: 5.1 [2.3-11.4]) compared to TNF- antagonists and RTX. In the multivariate analysis for all ADRs after adjusting by calendar time, age and sex: a) for all ADRs: INF was the BA with the highest risk of ADR development, compared to ETN. No other BAs comparisons achieved statistical signification. Concomitant triple therapy with DMARDs, corticoids, functional loss, and specific comorbidities were other independent factors found; b) for severe ADRs: INF achieved the highest risk of ADR development, compared to ETN, ADA and RTX. ETN also had lower risk compared to RTX. Age of the patient, concomitant corticoids, and specific comorbidities were also associated.

Conclusion: After 5 years of treatment, two thirds of the patients over 65 years have discontinuated BA due to ADRs, mainly related to infections. 18.4 % and 10.3% patient * year discontinued BAs due to all ADR and severe ADRs respectively. The mortality rate in our study was 2.7%. We have found differences in discontinuation rates among BA due to ADRs, being Infliximab the BA with the highest risk. We have also found other clinical factors that modify their survival due to ADRs.

Do RA Susceptibility Loci Predict Response to Methotrexate As First DMARD in Early RA?

Thomas Frisell[1], Saedis Saevarsdottir[2,3] and Johan Askling[1,4], [1]Clinical Epidemiology Unit, Department of Medicine, Karolinska Institutet, Stockholm, Sweden, [2]Rheumatology Unit, Karolinska University Hospital, Karolinska Institutet, Stockholm, Sweden, [3]Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden, [4]Rheumatology Unit, Karolinska University Hospital, Stockholm, Sweden

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Improved means to predict which RA patients will respond to methotrexate monotherapy, the preferred first line therapy in early RA, would allow patients to more quickly receive effective treatment, possibly preventing irreversible joint damage. Among the more than 100 risk loci so far identified as risk factors for RA, many tag genes in pathways targeted by current therapies and/or that are involved in general inflammatory response. Thus, it would not be unexpected if alleles influencing RA risk also have an effect on RA treatment response.

Methods: We linked recent onset RA patients from the EIRA study (genotyped with the Illumina Immunochip array) to prospectively recorded data on

treatment and clinical characteristics in the nationwide Swedish Rheumatology register (SRQ). The cohort was defined as those who started methotrexate monotherapy as first DMARD treatment 2000-2012 (n=1390), and had at least one return visit with recorded DAS28 within 2-8 months after treatment start (92%, N=1278).Based on previous meta-GWAS data on risk factors for RA development, we identified 76 risk loci tagged by SNPs on the Immunochip (R^2>0.6), and calculated a risk score by weighting alleles by their published log-odds, standardizing the sum against an RA-free population. The association of RA risk score, individual SNPs, and the shared epitope alleles, with DAS28-based EULAR response at the evaluation visit closest to 3 months after initiation, was estimated using logistic regression models.

Results: With respect to RA risk, the genetic risk score was a stronger predictor of onset of ACPA+ than ACPA- RA (odds ratio per stdev increase: 2.2 vs 1.2). With respect to response to methotrexate, the number of SNPs associated to EULAR response in individual analyses was not higher than expected by chance (3/76 SNPs had p<0.05 in ACPA+, 2/76 in ACPA-), and there was no association of the genetic risk score to methotrexate response in RA overall, nor in ACPA+ (Table). Higher genetic risk score was, however, associated with borderline significantly better response to methotrexate in ACPA- RA (odds ratio [95%CI]: 1.27 [1.01-1.60]).

Conclusion: We found no association between identified RA susceptibility loci and response to methotrexate monotherapy in RA overall nor in the ACPA-positive subgroup. The borderline increased EULAR response with higher genetic risk score among ACPA- RA patients may reflect individuals within this subset with a “correct” diagnosis of RA, and hence more likely to respond to this therapy.

Table. Odds ratios and 95% confidence intervals for Good/Moderate vs No EULAR response after 3 months of methotrexate monotherapy in 1278 early RA patients

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor for the treatment of RA. This analysis assessed if patients achieving Clinical Disease Activity Index (CDAI) remission (REM) or low disease activity (LDA) at Month 6 had less radiographic progression and improved patient-reported outcomes (PROs) at Month 24 and compared results between tofacitinib and MTX.

Methods: ORAL Start (NCT01039688) and ORAL Scan (NCT00847613) were Phase 3 randomized, controlled trials (RCTs) in MTX therapeutically-naïve and MTX-inadequate response (IR) patients with RA, respectively, who received tofacitinib 5 or 10 mg twice daily (BID) monotherapy vs MTX monotherapy or tofacitinib 5 or 10 mg BID + MTX vs placebo + MTX, respectively. This was an observed analysis of patients with radiographs at Months 6, 12, and 24, excluding placebo-treated patients in ORAL Scan. Patients were assigned to subpopulations according to CDAI responses at Month 6: REM (CDAI ≤2.8); LDA (CDAI >2.8 to ≤10); or incomplete-responders (CDAI >10). Outcomes included the proportion of patients with no radiographic progression (change in modified Total Sharp Score [mTSS] ≤0) and/or HAQ-Disability Index (HAQ-DI) <0.5 (defined as normative) at Month 24, and mean changes from baseline in mTSS and HAQ-DI.

Results: In ORAL Start, 250, 269, and 98 patients received tofacitinib 5 mg BID, tofacitinib 10 mg BID, and MTX, respectively. In ORAL Scan, 193 and 201 patients received tofacitinib 5 and 10 mg BID, respectively. Baseline demographics were generally similar between subpopulations within each RCT; however, incomplete-responders generally had higher baseline disease activity. In both ORAL Start and Scan, patients in REM or LDA with tofacitinib at Month 6 were more likely to be non-progressors and achieve normative HAQ-DI scores at Month 24 (Table). Tofacitinib-treated patients in REM at Month

6 generally had better HAQ-DI scores at Month 24 than LDA patients. In ORAL Start at Month 6, a higher proportion of tofacitinib- than MTX-treated patients were in REM or LDA (Table). CDAI incomplete-responders receiving tofacitinib had improved HAQ-DI scores and less radiographic progression compared with MTX. Overall, more patients receiving tofacitinib than MTX in REM or LDA were non-progressors and achieved HAQ-DI scores <0.5.

Conclusion: More MTX-naïve or MTX-IR tofacitinib-treated patients achieving CDAI REM or LDA at Month 6 were radiographic non-progressors with normative HAQ-DI scores at Month 24, compared to CDAI incomplete-responders. In ORAL Start, more tofacitinib than MTX-treated MTX-naïve patients achieved CDAI REM or LDA at Month 6 with better PROs and radiographic outcomes at Month 24.

The Effects of Glucocorticoids on the Efficacy of Tofacitinib As Monotherapy and in Combination Therapy with Nonbiologic Dmards: An Analysis of Data from Six Phase 3 Studies

Roy Fleischmann[1], Christina Charles-Schoeman[2], Gerd Burmester[3], Cristiano Zerbini[4], Peter Nash[5], Kenneth Kwok[6], Koshika Soma[7], Alan Mendelsohn[8] and Eustratios Bananis[8], [1]Metroplex Clinical Research Center, Dallas, TX, [2]University of California, Los Angeles, CA, [3]Department of Rheumatology and Clinical Immunology, Charité - Universitätsmedizin Berlin, Berlin, Germany, [4]Centro Paulista de Investigação Clinica, São Paulo, Brazil, [5]Nambour Hospital, Sunshine Coast and Department of Medicine, University of Queensland, Queensland, Australia, [6]Pfizer Inc, New York, NY, [7]Pfizer Inc, Groton, CT, [8]Pfizer Inc, Collegeville, PA

Session Date: Monday, November 9, 2015

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor for the treatment of RA. Patients with RA often receive concomitant treatment with glucocorticoids (GCs) to control inflammatory symptoms. Therefore, the objective of this analysis was to determine whether the presence or absence of oral GCs has an effect on the efficacy of tofacitinib as monotherapy or in combination with nonbiologic DMARDs, within the RA program.

Methods: Tofacitinib efficacy data were analyzed from six Phase 3 (P3) studies. Data were pooled from four P3 studies in which patients with inadequate response (IR) to MTX, biologic/nonbiologic DMARDs, or TNF inhibitors (TNFi) received tofacitinib in combination with MTX or other nonbiologic DMARDs. Data from two P3 tofacitinib monotherapy studies, ORAL Solo (in DMARD-IR patients) and ORAL Start (in MTX-naïve patients), were analyzed separately. In the P3 tofacitinib clinical program, patients receiving GCs (≤10 mg/day of prednisone or equivalent) prior to enrollment were required to remain on a stable dose throughout the study. The following efficacy endpoints were assessed for patients receiving tofacitinib 5 or 10 mg twice daily, placebo +/- DMARDs or +/- MTX (comparator arms), +/- concomitant GCs: ACR response criteria (ACR20, ACR50, ACR70), Clinical Disease Activity Index (CDAI), disease activity score in 28 joints using the ESR (DAS28-4 [ESR]), and HAQ-disability index (HAQ-DI).

Results: In total, 3200 tofacitinib-treated patients were included in this analysis. 279 (57%) and 354 (46%) tofacitinib-treated patients in the P3 monotherapy studies ORAL Solo and ORAL Start were using concomitant GCs, respectively, as were 1129 (58%) tofacitinib-treated patients in the pooled P3 combination studies. Within each study, baseline demography and disease characteristics were similar regardless of concomitant GC use. The efficacy of

tofacitinib, placebo +/- DMARDs or MTX, +/- concomitant GCs at 3 months is presented in the Table. Tofacitinib-treated patients had significantly greater treatment responses compared with the comparator arms for almost all efficacy endpoints. Similar responses were observed with tofacitinib regardless of concomitant GC use.

Conclusion: Tofacitinib was more effective than placebo +/- DMARDs or MTX as monotherapy and combination therapy. As expected, the efficacy of tofacitinib was similar in patients receiving and not receiving concomitant GCs as these patients had active disease in spite of their background GCs. A randomized clinical trial in GC-naïve patients with RA is needed to determine the effect of the addition of GCs on the efficacy of tofacitinib.

Table: Efficacy of tofacitinib as monotherapy or combination therapy with or without GCs at 3 months

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Tocilizumab (TCZ) is a IL-6 receptor blockade, administered intravenously every 4 weeks and efficiently inhibits IL-6/STAT3 signaling pathway. We have previously reported the usefulness of adjusting the dosing interval based on the disease activity of rheumatoid arthritis (RA). We herein hypothesized that strength of IL-6/STAT3 signaling could differ in each patient. Accurate measurement strategy of inhibitory strength of IL-6/STAT3 signal in RA patients who administered TCZ, has not been currently established. So, we assessed IL-6 induced phosphorylated-STAT3 (pSTAT3) in RA patients treated with TCZ and achieved low disease activity.

Methods: Whole blood was collected from RA patients in low disease activity (LDA; CDAI <=□10) treated with intravenous TCZ (8mg/kg) every 3 weeks (3w group; n=10), 4 weeks (4w group; n=10), 5 weeks (5w group; n=10) or with methotrexate (mean dose: 9.0 mg/week, range: 4-14 mg/week) (control group, n=10). Recombinant human (rh) IL-6 (0, 0.1, 1, 10, 100 ng/ml) was exogenously added to whole blood and proportion of pSTAT3 positive CD4+ T cells (% in CD4+ T cell) was measured by Phosflow cytometric analysis (BD, USA). Serum IL-6 and soluble IL-6 receptor (sIL-6R) were measured by ELISA, expression of membrane IL-6R (mIL-6R, CD126) and gp130 (CD130) on CD4+T cell were analyzed by flow cytometry.

Results: Proportion of pSTAT3 positive CD4+ T cells increased in a dose dependent manner of exogenous rhIL-6 in each treatment group. Although, all patients were in LDA, %pSTAT3 was significantly increased in control group (mean: 58.6%) from the lowest concentration (0.1 ng/ml) of rhIL-6 compared to TCZ treated patients (mean: 0.0%, 0.0%, 12.2% in 3w, 4w, 5w group respectively). %pSTAT3 showed significant increase from low concentration (1 ng/ml) of rhIL-6 in 5w group (mean: 27.4%), while 4w group showed complete inhibition of pSTAT3 (mean: 0.0%). On the other hand, stimulation with 10, 100 ng/ml of rhIL-6 resulted in significantly suppressed pSTAT3 in 3w group (mean: 0.0%, 3.1%) compared to 4w group (mean: 5.6%, 29.2%). Serum IL-6 level was significantly higher in TCZ group than control group, and 3w and 4w group exhibited significantly higher IL-6 level compared to 5w group. Although sIL-6R concentration and mIL-6R expression were upregulated in TCZ group compared to control group, no significant difference were observed among 3w, 4w, 5w group. Meanwhile, gp130 level expression did not differ among each treatment group.

Conclusion: Our study demonstrated that IL-6 stimulated-pSTAT3 detection assay is a useful method to assess the inhibitory strength of IL-6/STAT3 signaling in RA patients treated with TCZ. Our results also suggested that further alteration of dosing interval of TCZ could be possible in certain RA patients, with our new method. Measurement of pSTAT3 in RA patients treated with TCZ could be a promising strategy to optimize treatment.

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Efficacy and safety of certolizumab pegol (CZP) treatment in combination with optimized-dose MTX in Japanese MTX-naïve early rheumatoid arthritis (RA) patients (pts) with poor prognostic factors has previously been reported.[1] Here we report 2-year data from the C-OPERA study, investigating maintenance of clinical effect after discontinuing CZP treatment in an observational post-treatment period while continuing MTX treatment.

Methods: MTX-naïve pts with early RA (defined as ≤12 months from onset of persistent symptoms) fulfilling the 2010 ACR/EULAR classification criteria and poor prognostic factors were eligible to enter C-OPERA; a multicenter, double-blind (DB), randomized study (NCT01451203). Pts were randomized to CZP+MTX (n=159) or placebo (PBO)+MTX (n=157) with oral MTX escalated up to 16 mg by Week (Wk) 8 (optimized dose), if tolerated. After completing 52-wk DB period, CZP (n=108) or PBO (n=71) was discontinued and pts continued with MTX monotherapy up to Wk104 in 52-wk post CZP-treatment period. Pts who were in DAS(ESR) ≥3.2 for two consecutive visits (4 wks) or longer after Wk24 could receive rescue treatment with CZP and

were excluded from the post-CZP treatment period. Full analysis set (FAS) population was analyzed. Last observation carried forward (LOCF) imputation was used for missing data for clinical remission, whereas linear extrapolation was employed to estimate mTSS in patients who withdrew before Wk104.

Results: In CZP+MTX→MTX group, SDAI remission rate was decreased over the initial 16 weeks from 57.9% to 44.9% after CZP discontinuation. However, the rate remained stable thereafter, with higher rate of SDAI remission compared with PBO+MTX→MTX up to Wk104 (41.5% vs 29.3%; p=0.026 [Figure A]). Similar trend was observed in DAS28(ESR) and Boolean remission. Pts retreated with CZP due to flare after CZP discontinuation (n=28) showed rapid clinical improvement after CZP retreatment. The CZP+MTX→MTX group showed significantly less radiographic progression at Wk104 (mean change from baseline (CFB) in mTSS: 0.66±5.38 vs 3.01±9.66; p=0.001 [Figure B]) with higher non-radiographic progression rate (CFB in mTSS≤0.5) (84.2% vs 67.5%; p<0.001). Incidence of overall adverse events was similar between groups, with no new or unexpected safety signals.

Conclusion: The clinical benefit of initial 1-year CZP treatment in MTX-naïve early RA patients was still observed after discontinuing CZP for an additional 1 year while continuing optimized MTX monotherapy.

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The purpose of this study was to describe the treatment patterns in biologic naïve initiators of TNF-inhibitors (TNFi) based on their disease activity over a 1-year follow-up period from a national cohort of patients with rheumatoid arthritis (RA).

Methods: Using data from the Corrona registry, biologic naïve RA patients were identified between 1/1/2006 and 8/31/2013 who had initiated their first TNFi (the index date) after any prior use of ≥1 conventional disease modifying anti-rheumatic drug (cDMARD). The patients were categorized into disease activity strata defined by the lowest level of disease activity reached using the Clinical Disease Activity Index (CDAI) across all visits reported while on TNFi therapy in Corrona during the 1 year follow-up period including the index date. The mutually exclusive strata are as follows: sustained remission - attained remission (CDAI ≤2.8) on at least 2 consecutive visits; remission - attained remission on at least one visit; sustained LDA - remission was never attained on any visits, but reached low disease activity (LDA; 2.8< CDAI ≤10) on at least 2 consecutive visits; LDA - attained LDA; and moderate/high disease activity (MDA/HDA) (CDAI>10) - never achieved remission or LDA on any visit. Patients were compared on demographics, RA disease characteristics, and treatment patterns. Comparisons across these disease activity strata were performed with one-way ANOVA for continuous variables and chi-square test for categorical variables.

Results: There were 1931 RA patients who met inclusion criteria of whom 15% achieved sustained remission (n=286), 22% remission (n=426), 14% sustained LDA (n=271), 23% LDA (n=436) and 27% MDA/HDA (n=512). The groups differed in terms of demographics (Table 1). Those with higher levels of disease activity (MDA/HDA) were older at disease onset, had higher baseline levels of disease activity and greater functional impairment based on the modified Health Assessment Questionnaire (mHAQ). There were significant differences between the groups in terms of combination therapy (Table 1). Higher disease activity was associated with less use of methotrexate (MTX) based combination therapy (e.g, more use of TNFi monotherapy or combination therapy with a non- MTX cDMARD). Switching to another TNFi occurred in 14% of the population, 6.5 to 8.4 months after initiation, on average. At the study conclusion, 331 (17%) had discontinued TNFi therapy with 99% switching to a non-TNFi biologic. Those with higher levels of disease activity switched more frequently to both another TNFi or to a non-TNFi biologic.

Conclusion: Majority of patients (63%) did not achieve remission or sustained remission. Those in the lower disease activity strata were more likely to have been prescribed a TNFi with MTX as compared to MTX monotherapy or in combination with a non-MTX cDMARD, while those with higher disease activity were more likely to have been switched to another biologic.

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

In established rheumatoid arthritis (RA), a lack of response to treatment with certolizumab pegol (CZP) at early timepoints is associated with a low probability of achieving future target responses.[1] The phase 3 C-EARLY study (NCT01519791) assessed efficacy and safety of CZP in inducing and maintaining a sustained clinical response and inhibiting radiographic damage in DMARD-naïve patients (pts) with active, severe, progressive RA with poor prognostic factors in comparison to MTX alone. Here, we examine the association between response to CZP+MTX in this pt population at an early visit (improvement/lack of improvement from baseline [BL] in DAS28[ESR] at Week [Wk] 12) and remission at Wk52.

Methods:

This multicenter, double-blind, randomized study enrolled pts who were DMARD-naïve with active, severe, progressive RA (<1 year since diagnosis at BL, fulfilling 2010 ACR/EULAR criteria: ≥4 swollen and ≥4 tender joints; DAS28[ESR]≥3.2; CRP≥10 mg/L and/or ESR≥ 28 mm/hr, rheumatoid factor/ACPA positive). 879 pts were randomized 3:1 to CZP (400 mg at Wks 0, 2 and 4, then 200 mg every 2 wks to Wk52+MTX; n=660) or PBO+MTX Q2W (n=219).

MTX was initiated at 10 mg/wk and increased to 25 mg/wk by Wk8, maximum tolerated dose per patient (optimized dose) was maintained to Wk52. Predictability analyses consisted of positive predictive value (PPV; probability of achieving Wk52 remission after achieving a Wk12 response) and negative predictive value (NPV; probability of failing to achieve Wk52 remission after failing to achieve a Wk12 response). Remission was defined as DAS28(ESR)<2.6; Wk12 responses analyzed were change from BL in DAS28(ESR) ≥0.6 and ≥1.2. Observed data were utilized for Wk12 responses; missing Wk52 values were imputed using non-responder imputation.

Results:

At Wk52, 42.6% CZP+MTX pts vs 26.8% PBO+MTX pts achieved remission (DAS28[ESR] <2.6) (Table A). NPV of early responses was high (Table B): CZP+MTX-treated pts who did not achieve DAS28(ESR) improvements from BL ≥0.6 or ≥1.2 points at Wk12 had a high probability of not being in remission at Wk52; 92% and 93% respectively. Pts who did achieve an improvement from BL in DAS28(ESR) of ≥0.6 and ≥1.2 at Wk12 had 45% and 49% chance of Wk52 remission (Table B), respectively.

Conclusion:

DMARD-naïve pts with active, severe and progressive RA who failed to achieve DAS28(ESR) improvements at Wk12 after treatment with CZP+MTX were unlikely to be in remission at Wk52. These findings in DMARD-naïve pts are consistent with earlier reports in pts with established disease.

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Treatment options delivering sustained efficacy when given as monotherapy in RA are limited.[1] Tofacitinib is an oral Janus kinase inhibitor for the treatment of RA. Tofacitinib monotherapy demonstrated efficacy in adult patients (pts) with RA in two index studies (ORAL Solo[2] and Start[3]). Open-label, long-term extension (LTE) studies enrolled pts to evaluate safety and efficacy of tofacitinib monotherapy and combination therapy. Here we present data up to Month (Mo) 84 for safety and Mo 60 for efficacy for pts who stayed on tofacitinib monotherapy in LTE studies.

Methods: Data were pooled from two tofacitinib LTE studies (NCT00413699 [ongoing; database unlocked as of Apr 2014 data cut-off] and NCT00661661). Pts from Phase (P) 1/2/3 tofacitinib index studies received tofacitinib 5 or 10 mg twice daily (BID) as monotherapy or with background csDMARD in LTE. For tofacitinib and permitted concomitant RA medications, dose adjustments were allowed for inadequate efficacy or safety reasons. In this analysis, pts were assigned to tofacitinib 5 or 10 mg BID groups based on average total daily dose in LTE (<15 mg/day or ≥15 mg/day, respectively). Monotherapy was defined as those pts who received tofacitinib without other DMARDs (except antimalarials) throughout the LTE. Baseline (BL) values were those of the index studies for pts enrolling in LTE within 14 days of index study; for all others, BL was start of LTE. Safety was evaluated up to Mo 84 and efficacy to Mo 60 due to limited sample size.

Results: 1808 pts initiated LTE on tofacitinib monotherapy; 1638 (91%) stayed on monotherapy throughout LTE (504 on 5 mg BID; 1134 on 10 mg BID). For pts staying on monotherapy, mean (max) treatment duration was 1157 (2522) and 788 (2104) days for 5 and 10 mg, respectively. Efficacy responses for tofacitinib monotherapy were stable up to Mo 60 (Table 1). In 5 and 10 mg groups, 68% and 88% of pts, respectively, stayed on initial dose throughout LTE. Proportion of pts staying on steroids decreased from 56% to 39% and 41% to 23%, respectively, from baseline to Mo 60. Rates of discontinuation due to lack of efficacy and adverse events (AE), and of serious infection and malignancies (excluding non-melanoma skin cancer) were low (Table 2).

Conclusion: In this analysis of pts receiving tofacitinib monotherapy in LTE studies, over 90% of pts stayed on monotherapy, most did not have tofacitinib dose adjustments or add a DMARD, and efficacy was sustained over 60 months, with low rates of discontinuations due to lack of efficacy or AEs.

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor for the treatment of rheumatoid arthritis (RA). ORAL Scan was a 2-year, randomized, Phase 3, clinical trial that evaluated tofacitinib therapy with background methotrexate (MTX) in patients (pts) with RA and an inadequate response (IR) to MTX.[1] In this analysis, the effect of MTX dose on tofacitinib efficacy in pts from ORAL Scan was studied.

Methods: In ORAL Scan, MTX-IR pts with RA were randomized 4:4:1:1 to tofacitinib 5 mg twice daily (BID), tofacitinib 10 mg BID, or placebo with advancement to 5 mg BID or to 10 mg BID at Month 3 or Month 6, in combination with background MTX. MTX dose was stable throughout the study and was categorized as Low (≤12.5 mg/week), Medium (>12.5 to <17.5 mg/week), or High (≥17.5 mg/week). Endpoints evaluated at Month 6 included ACR response rates, proportion of pts achieving low disease activity measured by Clinical Disease Activity Index (CDAI ≤10), CDAI defined remission rate (CDAI ≤2.8), proportion of pts achieving an improvement ≥0.5 in Health Assessment Questionnaire-Disability Index (HAQ-DI), and least squares mean change from baseline in HAQ-DI, Disease Activity Score (DAS28-4[ESR]), and CDAI. Binary variables were evaluated with non-responder imputation, and continuous variables were analyzed using a longitudinal model. Regression analyses were conducted to evaluate efficacy responses by MTX dose group and other covariates.

Results: 797 pts were randomized and treated (tofacitinib 5 mg BID, n=321; tofacitinib 10 mg BID, n=316; placebo, n=160). 242 pts were included in the Low MTX (9 mg mean) dose group, 333 in the Medium MTX (15 mg mean) dose group, and 222 in the High MTX (21 mg mean) dose group. Baseline demographics and disease characteristics were similar across MTX dose groups, though weight, BMI, glucocorticoid (GC) use, and CDAI were higher in the High MTX dose group. At Month 6, greater efficacy was seen with tofacitinib compared to placebo for all endpoints across the 3 MTX dose groups (Table). Efficacy for placebo-treated pts was generally numerically greater in the Medium and High MTX dose groups than in the Low MTX dose group. Efficacy with tofacitinib appeared similar regardless of MTX dose group. Regression analyses demonstrated a lack of effect of BMI, GC use and MTX dose groups on efficacy assessments.

Conclusion: In this post-hoc analysis, clinical efficacy of tofacitinib at Month 6 was greater than placebo, and appeared similar regardless of MTX dose, as in these pts, tofacitinib was added to patients that had an inadequate response to MTX. Higher MTX doses did not appear to result in additional efficacy to tofacitinib than lower doses. A randomized clinical trial is needed in which different doses of MTX are added to tofacitinib in MTX-naïve pts in order to examine the effect of MTX dose on tofacitinib efficacy.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Seropositivity for rheumatoid factors and anti-citrullinated (Cit) protein antibodies (ACPA) are the strongest predictor for clinical response to rituximab (RTX) in rheumatoid arthritis (RA). ACPAs are routinely detected using cyclic Cit peptides (CCP). However, the wide variety of non-cross reactive epitopes recognized by ACPA may explain why fluctuations in anti-CCP antibodies are not a reliable measure of response to therapies. We therefore investigated the kinetics of individual IgG- and IgA-ACPA in relation to clinical improvement (during B cell depletion) and recurrence of symptoms following RTX using multiplex antigen array.

Methods:

16 patients with active RA (DAS28 ≥ 5.1; median duration 20 years) undergoing initial cycles of RTX were included. All achieved B cell depletion in the peripheral blood (<5 cells/µl) and clinically responded (ΔDAS28≥1.2) within 5 months (median=3). Follow-up to re-treatment or relapse was 4-13 months. IgG and IgA antibodies binding to a custom, bead-based, antigen array comprising CCP and 29 RA-associated Cit-antigens and 22 corresponding native antigens, based on those in inflamed synovium, was assessed using mean fluorescence intensity (MFI). To compensate for number of binding sites per antigen, MFI were Z-normalized in serial studies, with Z score >1 'positive'. Spearman's Rank, T-tests used for data analysis.

Results:

Pre-RTX, IgG- and IgA-binding (MFI) to Cit antigens were strongly correlated (R^2=0.75; p<0.0001) but MFI of IgA-Cit were approximately 10 fold lower. Mean % change in ACPA from baseline to clinical improvement (during depletion phase), was significantly greater for IgA-Cit (-43%) than IgG-Cit (-21%) (p=0.003), largely due to 24% (16/65) of IgG-Cit antibodies, but only 3/47 IgA-Cit, showing a transient increase following RTX. Amongst IgG- and IgA-Cit antibodies that fell following RTX, some increased prior to relapse (n=28 and 27 respectively) whereas others continued to fall (n=21 and 17). In those rising to relapse after an initial fall, 13/21 different Cit antigens recognized by IgG also bound IgA. Although putative 'new' specificities (baseline Z score ≤1; relapse Z score >1) were recognized by 9 IgG- and 10 IgA-Cit, most (7 IgG; 6 IgA) were detectable at low levels before RTX. Cit-fibrinogen derived targets were consistently detected in all different ACPA patterns post-RTX, but no particular specificities were identified.

Conclusion:

After RTX, ACPA showed a variety of profiles, presumably due to the ability of RTX to deplete or modify the function of different parent B cell clones. Some IgG-Cit (rarely IgA-Cit) rose after RTX, despite peripheral B cell depletion, suggesting that IgG-B cells were more resistant, or that the half-lives of IgG or IgA plasma cells vary. Location within protective niches in tissues may also aid survival. Expansion of pre-existing memory B cells appeared to accompany disease resumption after RTX with levels of many autoantibody specificities present pre-RTX rising with B cell reconstitution or impending relapse. Dissection of the ACPA response using multiplex bead array revealed diverse kinetics of ACPA-committed B cells which could be exploited for more efficient B cell directed therapies.

Session Date: Monday, November 9, 2015

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Previously published rheumatoid arthritis (RA) trials in which TNFi-MTX and triple therapy (MTX + hydroxychloroquine + sulfasalazine) were included as treatment arms in MTX inadequate responder (MTX-IR) patients did not convincingly demonstrate superiority for TNFi-MTX. This could be due to trials being underpowered to detect true differences.[1,2]The objective of this study was to estimate the efficacy and radiographic benefits of TNFi-MTX vs. triple therapy in MTX-IRs by conducting a systematic review and network meta-analysis. This is an important, clinically relevant question in MTX-IRs.

Methods: Medline, EMBASE, and the Cochrane Library were searched for randomized controlled trials that used either TNFi-MTX or triple therapy as one of the treatment arms in MTX-IRs with RA. The primary endpoint for this analysis was ACR70 at 6 months. Other endpoints included ACR20, ACR50, DAS28 LDA, DAS28 remission, EULAR good response, and no radiographic progression; and changes in DAS28 score, joint erosion, joint space narrowing, and various versions of Sharp scores from baseline. Endpoints were analyzed at 3 months, 6 months, 1 year, and 2 years from baseline when feasible. Data from direct and indirect comparisons between TNFi-MTX and triple therapy were pooled and quantitatively analyzed using fixed and random effects Bayesian models (FEM and REM) in WinBUGS version 1.4.3. Relative treatment effects were generated as odds ratio [OR] (OR>1 indicated a benefit towards triple therapy) for dichotomous endpoints and mean differences (D<0 indicated a benefit towards triple therapy) for continuous endpoints.

Results: A total of 39 studies met the study eligibility criteria, corresponding to 12,749 randomized patients. MTX-IRs were significantly less likely to achieve ACR70 with triple therapy than with TNFi-MTX at 6 months in both fixed effects models (FEM) (OR=0.35, 95% Credible Interval [CrI]: 0.19,

0.64) and random effects models (REM) (OR=0.36, 95% CrI: 0.16, 0.80). All endpoints except for DAS28 score change from baseline showed a statistically significant benefit of TNFi-MTX relative to triple therapy in FEM but not REM at some point within the 2 years of evaluation from baseline. Across the 27 analyzable endpoint-time scenarios evaluated, 26 numerically favored TNFi-MTX in both FEM and REM.

Conclusion: In this network meta-analysis of MTX-IR patients, triple therapy had a 65% significantly lower odds than TNFi-MTX in achieving an ACR70 at 6 months. The benefits of TNFi-MTX over triple therapy were shown across clinical and radiographic endpoints in the MTX-IR population, supporting the use of biological therapy in this setting.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor for the treatment of RA. A modified-release (MR) formulation has been designed to enable once daily (QD) dosing and achieve a comparable clinical profile to the approved 5 mg twice daily (BID) immediate-release formulation (IR). Two key clinical pharmacology studies have been conducted to evaluate pharmacokinetic (PK) performance of the MR formulation.

Methods: Two randomized, open-label, cross-over, Phase 1 studies were conducted in healthy volunteers (HV). HV were randomly assigned 1:1 to one of two treatment sequences in each study. In study A (Pfizer study A3921212), HV were given tofacitinib MR 11 mg QD or tofacitinib IR 5 mg BID under both single- and multiple-dose conditions to assess relative bioavailability (BA) of the MR formulation compared with the IR formulation. Duration of multiple-dose phase was 5 days. In study B (NCT0208475, Pfizer study A3921180) tofacitinib MR 11 mg single dose was given under fed and fasted conditions to

evaluate the impact of a high-fat meal on BA. HV were aged 18-55 years, with body mass index 17.5 30.5 kg/m^2, total body weight >50 kg, and no evidence of active or latent tuberculosis infection.

Results: In study A (N=24), MR and IR achieved maximum plasma concentration (C_{max}) at 4 hours and 0.5 hours post-dose, respectively; mean terminal half-life ($t_{1/2}$) was 5.9 and 3.2 hours, respectively. Area under the plasma-concentration time profile (AUC) and C_{max} after both single- and multiple-dose administrations were equivalent between MR and IR (Table 1); minimum plasma concentration was 29% lower for the MR formulation. In study B (N=24), maximum plasma concentrations were achieved 1 hour later in the presence of food. Mean $t_{1/2}$ was 4.4 and 5.5 hours, under fed and fasted conditions, respectively. AUC was essentially the same under fed and fasted conditions (Table 2). C_{max} increased by 27% under fed conditions (Table 2), and peak concentrations were achieved 1 hour later in the presence of food. Tofacitinib MR, under fasted and fed conditions, was well tolerated in both studies. Most reported adverse events (AEs) were mild and related to study treatment; AEs were similar in frequency and type for tofacitinib MR and IR.

Conclusion: The tofacitinib MR formulation given QD has equivalent AUC and C_{max} to the IR formulation given BID; C_{min} for MR is ~29% lower. Food does not impact the BA of tofacitinib from the MR formulation. Tofacitinib was well tolerated in both studies.

Routine Assessment of Patient Index Data 3 (RAPID3)-Defined Remission Is As Stringent As ACR/EULAR Boolean-Defined Remission in a Clinical Trial of Patients with Early Rheumatoid Arthritis Treated with Abatacept

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Routine Assessment of Patient Index Data 3 (RAPID3) comprises the three patient-reported ACR RA Core Data Set measures: function (HAQ-DI), pain and patient global estimate of status (10-cm visual analog scale). These can be scored in <10 seconds, making RAPID3 suitable for use in routine clinical practice where it provides quantitative data to supplement qualitative assessments. Significant correlations between RAPID3 scores and DAS28 (CRP) and CDAI have been reported previously.[1,2] In this analysis, we examined time to first RAPID3 remission compared with time to first remission, as defined by other disease activity measures (DAS28 [CRP], CDAI, SDAI, Boolean). **Methods:** We performed *post hoc* analyses of data from AVERT, a Phase IIIb, randomized, active-controlled trial of 24 months, with a 12-month, double-blind treatment period, in which patients were randomized 1:1:1 to subcutaneous abatacept (ABA) + MTX, ABA monotherapy or MTX alone.[3] RAPID3 scores were calculated at baseline and 3-monthly intervals thereafter, up to 12 months. Definitions of remission were RAPID3 ≤3 (scale of 0–30), DAS28 (CRP) <2.6, CDAI ≤2.8, SDAI ≤3.3 and Boolean: TJC28 ≤1, SJC28 ≤1, patient global assessment of disease activity (0–10 cm) ≤1 and high-sensitivity CRP ≤1 mg/dL. Proportions of patients in RAPID3, DAS28 (CRP), CDAI, SDAI and ACR/EULAR Boolean remission at each time point were calculated. Proportions at 3, 6, 9 and 12 months were compared using cross-tabulation analysis. Agreement between RAPID3 disease activity states and those of other measures were assessed using kappa statistics. Time to first RAPID3 remission was compared with time to first remission, as defined by other disease activity measures (DAS28, CDAI, SDAI, Boolean) using Kaplan–Meier plots. **Results:** Among the total AVERT population, the percentages of patients in remission according to each measure at Month 12 were: RAPID3, 29.3%; Boolean, 28.8%; SDAI, 32.2%; CDAI, 33.6%; and DAS28 (CRP), 50.1%. For each treatment arm, good agreement was observed between RAPID3 and Boolean, SDAI and CDAI remission at Month 12 (0.45–0.67); these kappa correlations were higher than those with DAS28 (CRP) (0.19–0.48). The patterns of time to RAPID3 remission were most similar to Boolean and show that ABA + MTX and ABA monotherapy lead to a faster onset of remission than MTX alone (Figure).

Conclusion: RAPID3-defined remission may be as stringent as ACR/EULAR Boolean-defined remission and agrees well with SDAI and CDAI remission criteria. RAPID3 may be used in clinical trials in addition to routine clinical care in early RA. In agreement with other remission criteria, abatacept results in a high rate of RAPID3-defined remission in early RA, with a faster time to remission than MTX.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor for the treatment of rheumatoid arthritis (RA). We report tofacitinib safety, tolerability, and clinical response over 84 months (mo), and radiographic data over 12 mo, in long-term extension (LTE) studies.

Methods: Data were pooled from two open-label studies (NCT00413699 [ongoing; database unlocked at March 2015 data-cut] and NCT00661661 [completed]) of patients (pts) with RA who completed randomized Phase (P)1, P2, or P3 tofacitinib studies. Pts received tofacitinib 5 or 10 mg BID as monotherapy or with background DMARDs; data from both doses ±background DMARDs were pooled. Baseline (BL) was that of P1/P2/P3 studies for pts enrolling ≤14 days after last dose, and start of LTE study for all other pts. For radiographic data, BL was last P1/P2/P3 study value. Primary endpoints: AEs and laboratory safety. Confirmed data are reported for decreased hemoglobin (Hgb), neutrophil and lymphocyte counts, and increases >50% from BL in creatinine. Secondary endpoints: ACR responses, DAS28-4(ESR), HAQ DI, and modified total Sharp score (mTSS). Safety data were included over 96 mo and efficacy data up to Mo 84 (n≤30 post-Mo 84).

Results: 4,867 pts were treated (mean [max] duration: 1,107 [2,895] days). BL data were from index studies for 90.9% of pts. Total tofacitinib exposure was 14,926 pt-years (py); 79.2% of pts maintained initial dose. In total, 2,132 pts (43.8%) discontinued (AEs: 1,051 [21.6%]; insufficient clinical response: 153 [3.1%]). Most common AE classes: infections and infestations (67.6%), musculoskeletal/connective tissue disorders (37.3%), and GI disorders (32.4%). Most common AEs: nasopharyngitis (18.1%), upper respiratory tract infection (16.2%), bronchitis (11.7%), and urinary tract infection (11.5%). Serious AEs occurred in 26.8% of pts (incidence rate [IR] 9.7/100 py [95% CI 9.2, 10.2]), and serious infection events (SIEs) in 8.4% of pts (IR 2.8/100 py [95% CI 2.5, 3.0]). Malignancies excluding NMSC were reported in 3.0% of pts (IR 1.0/100 py [95% CI 0.8, 1.1]). IRs for SIEs and malignancies through Mo 96 did not increase vs reported data through Mo 84.[1] Decreased Hgb (>30% decrease from BL/Hgb <8 g/dL) occurred in 6.8% of pts. Increased aminotransferases (>3 × ULN) occurred in 5.4% (ALT) and 3.1% (AST) of pts. Moderate to severe neutropenia (absolute neutrophil count [ANC] 0.5–1.5 × $10^3/mm^3$) was noted in 1.5% of pts; there were no confirmed cases of ANC <0.5 × $10^3/mm^3$. Confirmed absolute lymphocyte counts <0.5 × $10^3/mm^3$ occurred in 1.3% of pts. Increases >50% from BL in creatinine were seen in 2.4% of pts. ACR20, ACR50, and ACR70 response rates were sustained from Mo 1 (73.8%, 49.8%, and 29.3%) to Mo 84 (79.4%, 66.7%, and 46.0%). Mean DAS28 4(ESR) was 6.29 at BL, 3.74 at Mo 1, and 3.20 at Mo 84. Mean HAQ-DI score was 1.42 at BL, 0.81 at Mo 1, and 0.78 at Mo 84. Radiographic data were available for 1,099 pts. Mean mTSS was 24.0 at BL (last index value), 25.1 at Mo 6, and 24.3 at Mo 12. Mean change from BL in mTSS was 0.3 at Mo 6 and 0.2 at Mo 12.

Conclusion: Consistent safety and sustained efficacy over 84 mo was seen in pts with RA receiving tofacitinib 5 or 10 mg BID in LTE studies. Changes in mTSS were minimal at Mo 12 in LTE studies.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Baseline factors influencing the use of tocilizumab (TCZ) in monotherapy (Mono) instead of combination with DMARDs (Combo) in real-life practice in RA patients (pts) as described previously in the ACT-Solo study were: no MTX over the past 2 years, past-history of severe infection, age ≥ 65 years and an increased DAS28[1]. Drug retention rate, efficacy and tolerance of TCZ at M12 with a focus on Mono and Combo are described here.

Methods: Prospective, multicenter, longitudinal, non-interventional 12-month study in RA pts requiring TCZ according to their physician. *Treatment:* TCZ as prescribed in real life. *Primary endpoint*[1]: Baseline factors influencing the use of TCZ in Mono or Combo. *Secondary endpoints*: drug retention rate, premature withdrawals, safety and efficacy. *Data collected*: pts characteristics at baseline and after TCZ initiation, monthly disease activity components, RA treatments. *Statistical analysis*: Efficacy population was pts fulfilling inclusion and non-inclusion criteria and with ≥1 TCZ infusion. Safety population was all pts with ≥1 TCZ infusion.

Results: 608 pts were recruited of whom 603 were analysed for safety and 577 (Total) for other endpoints. At baseline: mean age 57±13 years, 454 (79%) females, at least 1 co-morbidity: 409 (71%), mean RA duration: 11±9 years, RF or ACPA positive: 478 (86%), erosive disease: 435 (77 %), mean DAS28:

5.2±1.3. Past RA treatments included DMARDs + biologics in 75%, only DMARDs in 24%. MTX was previously prescribed in 95% of pts and in 71% within the last 2 years. TCZ Mono was initiated in 228 (40%) pts and TCZ Combo in 349 (60%) pts of whom 80% received MTX (mean 16±5mg/w). Steroids (GCs) were used in 386 (67%) pts (mean 10±7mg/d). 337 pts completed M12 visit. 194 pts withdrew for: AE 53 pts, inefficacy 88, patiens wish 12, lost to follow-up 23, other 18. At M12, drug retention rate was 69% in Total, 67% in Mono, 71% in Combo. Mean number of TCZ infusions was 9.4±4.1; mean time between infusions was 31.8 ±12.6 days. 29% of the pts experienced at least 1 discontinuation, 25% and 33% in Mono and Combo groups respectively. DMARD was added in 20 Mono and definitely stopped in 25 Combo pts. 170 (50%) pts remained on GCs, 66 (51%) in Mono group and 104 (50%) in Combo group. At M12, mean DAS28 in Total, Mono and Combo were 2.4±1.3, 2.4±1.3 and 2.3±1.2 respectively. DAS28 remission was 35% in Total, 35% and 36% in Mono and Combo respectively (p=0.83). Using propensity score, no effect of Mono was observed on drug retention HR= 1.194 [0.852,1.673], p=0.30 ; DAS remission OR= 1.111 [0.773,1.597], p=0.57; or GCs use OR= 0.880 [0.558,1.387], p=0.58 at M12. No new safety signal was reported. 325 (54%) patients had at least one AE, 74 (12%) had at least one serious AE with no differences between Mono and Combo.

Conclusion: At 12 months, drug retention rate was 69% in pts receiving TCZ in real life. In Total group mean DAS28 decreased from 5.2±1.3 to 2.35±1.26. No new safety signal occurred. Propensity scores showed no differences between Mono and Combo for drug retention, DAS remission or use of steroids. Safety was comparable in both groups.

This study was conducted thanks to an unrestricted grant from Roche Chugai France.

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Etoricoxib, a selective cyclooxygenase-2 (COX-2) inhibitor, provides symptom modification in RA patients. Previous dose-ranging studies in RA demonstrated the clinical efficacy of etoricoxib 90 mg vs placebo (PBO). In these studies, etoricoxib 60 mg demonstrated some clinically meaningful treatment effects, therefore the current study further evaluated the efficacy of etoricoxib 60 mg and 90 mg in RA.

Methods:

This was a 2-part, double-blind, PBO controlled study in RA. Part I (6 weeks) assessed the efficacy of etoricoxib 60 mg and 90 mg vs PBO. Part II (6 weeks) evaluated whether subjects with inadequate pain relief on etoricoxib 60 mg in Part I benefitted from increasing to etoricoxib 90 mg in Part II. Patients were ≥18 years of age, with a diagnosis of RA ≥6 months prior to screening and prior clinical response to NSAIDs. Patients were required to have a disease flare after NSAID washout prior to randomization. Eligible patients were randomized to one of four treatment groups: PBO in Part I; etoricoxib 60 mg in Part I & II; etoricoxib 60 mg in Part I followed by 90 mg in Part II; or etoricoxib 90 mg in Part I in a 2:7:7:8 ratio, respectively. Primary endpoints were Disease Activity Score evaluating 28 joints and C reactive protein level (DAS28-CRP) index and Patient Global Assessment of Pain (PGAP) score (0-100 mm VAS) after 6 weeks of treatment in Part I. Safety and tolerability measures included independent adjudication of all thrombotic cardiovascular and serious upper GI AEs.

Results:

In total, 1404 patients were randomized; 83.5% were female; the mean age was 53.8 years, 75.4% were Caucasian, 1228 patients completed Part I and 713 patients continued to Part II. Both 60 mg and 90 mg etoricoxib were superior to PBO for the treatment of RA on both primary efficacy endpoints: change from baseline DAS28-CRP score (Table 1A) and change from baseline PGAP score (Table 1B). For DAS28-CRP, there was no significant treatment difference between etoricoxib 90 mg and 60 mg (Table 1A). Etoricoxib 90 mg demonstrated a small, but statistically significant decrease in baseline PGAP score as compared to 60 mg (Table 1B). In Part II, inadequate pain responders did not experience a significant decrease in PGAP score after increasing the etoricoxib dose from 60 mg to 90 mg compared to inadequate pain responders who stayed on 60 mg (Table 1C). In both etoricoxib 90 mg and 60 mg groups, the incidence of SAEs and drug-related AEs were similar between the two treatment groups.

Conclusion:

Both etoricoxib 90 mg and 60 mg are superior to PBO in relieving the symptoms of RA. Etoricoxib 90 mg vs 60 mg resulted in a statistically significant, though small, improvement in PGAP score, but not DAS28-CRP. Dose escalation from 60 mg to 90 mg in pain inadequate responders did not significantly improve efficacy. Both etoricoxib 90 mg and 60 mg were well tolerated and no new safety signals were identified.

A:Part I: DAS 28-CRP index time-weighted average change from baseline over 6 weeks

Treatment	N	LS Mean change†	Between etoricoxib and placebo		Between etoricoxib doses	
			Difference in LS mean† change† (95% CI)	p-value†	Difference in LS mean† change† (95% CI)	p-value†
Placebo	103	-1.10				
Etoricoxib 60 mg	732	-1.39	-0.29 (-0.49, -0.09)	0.004		
Etoricoxib 90 mg	426	-1.37	-0.27 (-0.48, -0.06)	0.034	0.02 (-0.10, 0.14)	0.730

B: Part I Patient Global Assessment of Pain (VAS) time weighted average change from baseline over 6 weeks

Treatment	N	LS Mean change†	Between etoricoxib and placebo		Between etoricoxib doses	
			Difference in LS mean† change† (95% CI)	p-value†	Difference in LS mean† change† (95% CI)	p-value†
Placebo	108	-20.26				
Etoricoxib 60 mg	751	-28.25	-7.99 (-11.85, -4.13)	<0.001		
Etoricoxib 90 mg	430	-30.96	-10.70 (-14.74, -6.66)	<0.001	-2.71 (-4.98, -0.45)	0.019

C: Part II: Average Change from Week 6 at Weeks 10 and 12 in Patient Global Assessment of Pain (VAS) Among Pain Inadequate Responders From Part I (Modified Intention-to-Treat Population)

Treatment	N	LS Mean (95% CI)	Difference in LS Mean (80% CI)	p-Value†
Etoricoxib 60 mg/60 mg	188	-11.96 (-14.96, -8.97)		
Etoricoxib 90 mg/90 mg	187	-10.35 (-13.32, -7.39)	1.61 (-0.49, 3.71)	0.327

†The LS means and p-values were derived from the analysis of covariance model with terms for treatment, biologics use, and baseline value as a covariate. Comparisons to placebo were based on Tukey-Ciminera-Heyse trend test with a step-down procedure

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: It has been shown that the balance between Th17 cells and regulatory T (Treg) cells plays an important role for the development of autoimmune diseases including rheumatoid arthritis (RA). Th17 cells secrete IL-17 and generally promote autoimmunity, whereas Treg cells interact with a various cells and regulate autoimmunity and inflammation. Recent studies showed that the treatment with abatacept (ABT) or tocilizumab (TCZ) affected the population of Th17 cells and Treg cells in patients with RA. Although not unanimously approved, several reports showed that Treg cells are decreased by ABT and increased by TCZ, and that Th17 cells are decreased by TCZ. To further investigate the effect of ABT and TCZ on the skewing of T cells, we analyzed the expression of master regulators of helper T cell lineages, in patients with RA treated with ABT or TCZ.

Methods: Ten patients treated with ABT and 9 patients treated with TCZ were enrolled. All patients met the 2010 ACR/EULAR classification criteria. Total RNA was extracted from peripheral blood cells at baseline, and after 12 weeks and 24 weeks of therapy. The expression levels of T-bet, GATA3, Foxp3 and Ror-γt were measured by real-time PCR using Light Cycler 480. Because of different T cell counts in each sample, relative expression levels were expressed as the ratios of two genes (T-bet/GATA3, Foxp3/GATA3, Foxp3/T-bet, Foxp3/Ror-γt, Ror-γt/T-bet, Ror-γt/GATA3). And the changes in these ratios (the ratios at baseline were defined as 1.00) were determined. This study was approved by the local ethics committee, and written informed consent was obtained from all patients.

Results: In patients treated with ABT, the mean DAS28CRP was 3.92 before treatment, and 5 patients achieved remission or low disease activity, whereas in patients treated with TCZ, the mean CDAI was 14.7 before treatment, and 8 patients achieved remission. The Foxp3/Ror-γt ratio was decreased after ABT therapy (0.67 ± 0.16 (0.33 to 0.91) at 24 weeks, p=0.0034), but was increased after TCZ therapy (2.00 ± 1.03 (0.63 to 3.47) at 24 weeks, p=0.0035).

In addition, the Ror-γt/GATA3 ratio was decreased after TCZ therapy (0.78 ± 0.39 (0.29 to 1.70) at 24 weeks, p=0.0029). Except for these, no significant skewing was observed. No significant relationships between clinical response to the treatment and the changes in the ratios were detected.

Conclusion: The treatment with TCZ or ABT differently affected the balance of Foxp3/Ror-γt expression in the peripheral blood of patients with RA.

Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Olokizumab (OKZ) is a humanized anti-interleukin-6 monoclonal antibody in development for moderate-to-severe rheumatoid arthritis (RA) treatment. OKZ efficacy and safety were assessed in the 12-week (wk) randomized controlled trials (RCTs) RA0056 (NCT01242488) and RA0083 (NCT01463059), which enrolled Western and Asian RA patients respectively, who had failed previous anti-TNF therapy. OKZ significantly reduced disease activity vs placebo (PBO).[1] Here we report results from the open-label extension (OLE) studies of these RCTs, RA0057 (NCT01296711) and RA0089 (NCT01533714).

Methods:

In the RCTs, RA pts on MTX who had failed anti-TNF therapy were recruited from Belgium, the US and the UK (RA0056), and Japan, Korea and Taiwan (RA0083). Pts received PBO, subcutaneous (sc) OKZ 60/120/240 mg every 2 weeks (Q2W) or 4 weeks (Q4W) (240 mg Q2W in RA0056 only), or (in RA0056 only) intravenous tocilizumab (TCZ) 8 mg/kg Q2W. Completers were eligible for the OLEs, in which all pts received sc OKZ 120 mg Q2W + MTX (RA0057: 12.5–25.0 mg/wk to Wk 12, after which dose could be reduced; RA0089: 6-16 mg/wk in Japan, 7.5-20 mg/wk in Korea and Taiwan). Pts with ongoing serious adverse events (SAEs) were excluded.

The primary objective of both studies was to assess long-term safety of OKZ; secondary objectives were to assess long-term efficacy by change from OLE baseline (BL) in Disease Activity Score 28 C-reactive protein (DAS28[CRP]) (4-variable). RA0057 was planned to run for 5 years, RA0089 to marketing application approval. Both OLEs were prematurely terminated when the drug was partnered: data are available to Wk90 in RA0057 and Wk89 in RA0089. Pts receiving ≥6 months' OL treatment are considered completers. Data are reported for the full analysis set (all pts who received ≥1 dose of OKZ with ≥1 efficacy measurement in the OLE).

Results:

198 pts completed RA0056; 190 (114 OKZ, 40 PBO, 36 TCZ) enrolled in RA0057. 105 pts completed RA0083; 103 (79 OKZ, 24 PBO) enrolled in RA0089. 67 (35.3%) pts completed RA0057 (median [min–max] exposure: 51 [0–98] wks); 82 (79.6%) pts completed RA0089 (median [min–max] exposure: 40 [0–76] wks) (Table).

Treatment-emergent (TE) AEs occurred in 180 (94.7%) and 91 (88.3%) pts in RA0057 and RA0089 respectively; TEAEs and serious TEAEs are summarized in the Table.

Efficacy measures continued to improve in the OLEs, most notably, as expected, in PBO pts switching to OKZ. Disease activity in each treatment group was as follows: Wk48 mean DAS28[CRP] change from BL in RA0057: PBO: -1.76, OKZ:-0.60, TCZ: -0.43; in RA0089: PBO: -1.70, OKZ:-0.68. Data past Wk48 were not interpreted due to low pt numbers.

Conclusion:

OKZ was well-tolerated, with an expected safety profile for this class of agent. Reductions in disease activity were sustained to Wk48. These results support the development of OKZ for the treatment of moderate-to-severe RA in Western and Asian pts.

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Disease remission is the current treatment goal for patients (pts) with early RA (eRA). Initiation of an anti-TNF agent ± methotrexate (MTX) is recommended for pts with severe eRA of poor prognosis.[1] Data from 2 phase 3 clinical trials, FUNCTION[2] and AMBITION,[3] have shown the efficacy of tocilizumab (TCZ) in eRA pts, and TCZ was recently approved in the Europe Union for the treatment of severe, active, progressive RA in MTX-naive pts.[4] Data from the 2 phase 3 trials on TCZ and MTX as monotherapy in eRA pts are presented.

Methods: In FUNCTION, MTX-naive pts with active RA of ≤2 years' duration received intravenous (IV) TCZ 8 mg/kg (TCZ8) + oral MTX, IV TCZ8 monotherapy, IV TCZ 4 mg/kg + oral MTX, or oral MTX monotherapy. In AMBITION, pts with moderate to severe RA who were MTX naive or had not received MTX for ≥6 months received IV TCZ8 or oral MTX as monotherapy. Twenty-four-week data are included from FUNCTION pts who received TCZ8 or MTX monotherapy and from AMBITION pts with RA of ≤2 years' duration (exploratory subanalysis). Key efficacy end points are remission rates based on Disease Activity Score using 28 joints (DAS28-erythrocyte sedimentation rate [ESR] <2.6), American College of Rheumatology (ACR) response, and physical function assessed by Health Assessment Questionnaire–Disability Index (HAQ-DI) at week 24.

Results: Included were 241 AMBITION pts (mean RA duration, 0.7 years) and 579 FUNCTION pts (mean RA duration, 0.4-0.5 years). Baseline characteristics were similar across pt groups analyzed except that all FUNCTION pts were MTX naive and had low previous rates of DMARD use, whereas 89.2% of the AMBITION eRA subpopulation were MTX naive and had greater previous rates of DMARD use (Table 1). Across both studies, greater proportions of pts receiving TCZ8 than receiving MTX achieved DAS28-ESR remission (Table 2). The difference between arms was statistically significant in FUNCTION, and the weighted difference in response for TCZ8 compared with MTX was 22.4% in AMBITION, which is similar to the corresponding value in FUNCTION (Table 2). In both studies, ACR response rates were similar or numerically greater with TCZ8 than with MTX, and change from baseline in HAQ-DI score was numerically higher with TCZ8 than with MTX (Table 2). Safety of TCZ8 in the eRA population in FUNCTION and AMBITION was consistent with the known safety profile of TCZ.

Table 1. Baseline Characteristics (ITT population)

	FUNCTION		AMBITION Early RA Subpopulation[a]	
	MTX n = 287	TCZ8 n = 292	MTX n = 125	TCZ8 N = 116
Age, years, mean (SD)	49.6 (13.0)	49.9 (13.2)	49.3 (13.2)	48.1 (14.8)
Female, n (%)	229 (80)	219 (75)	94 (75)	89 (77)

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose : The current treatment paradigm in rheumatoid arthritis (RA) is to attempt to decrease, when clinically feasible, concomitant use of OGCs after their use as part of the initial therapeutic approach. This study examined OGC-sparing effects of tocilizumab (TCZ) and RA biologics used second-line (BDM2) in RA patients (pts) treated with combination therapies and monotherapies.

Methods: This was a retrospective cohort study performed using the Truven MarketScan administrative claims database. RA pts were identified as those with an RA diagnosis (ICD-9-CM: 714.xx excluding 714.3x) followed by confirmatory RA diagnosis in 7-365 days or confirmatory DMARD procedure or prescription any time after the initial RA diagnosis. Pts had to be ≥18 y at the time of RA index date and continuously enrolled around the RA index date. Pts were then split into 2 treatment groups: TCZ treated and BDM2 treated, not including TCZ. Cohort demographic characteristics and treatment history were analyzed. OGC use and dosing were investigated during several time frames with respect to index therapy initiation. OGC doses were calculated using a prednisone-equivalent dose for each medication. A multilevel random coefficient model was used to test for statistically significant OGC-sparing effects of TCZ compared with BDM2 over time while adjusting for baseline OGC use, comorbidities, and demographics.

Results: The analysis population comprised 10,402 pts (2604 in TCZ initiator cohort, 8209 in BDM2 comparator cohort). Mean age at RA diagnosis was similar between the cohorts (51.0 vs 51.2 y). More women were observed in the TCZ cohort (81.2% vs 77.1%). Mean baseline Charlson Comorbidity Index (CCI) scores and individual comorbidities were higher in the TCZ cohort (2.6 vs 2.3). Mean baseline cumulative OGC dose was higher for TCZ than BDM2 (1988 mg vs 1616 mg). In multivariate results, there was a significant reduction in OGC use in both cohorts over time (b=0.177 mg/d; $p<0.000$). There was a significant time × cohort interaction such that the TCZ cohort had an additional reduction of 0.167 mg/d ($p<0.0001$). In the TCZ cohort, mean OGC dose decreased over time from 4.6 mg/d in months 1-3 to 1.2 mg/d in months 27-30, a 74% reduction. In the BDM2 cohort, mean OGC use decreased from 3.3 mg/d to 1.4 mg/d, a 58% reduction in the same period. Factors significantly associated with greater OGC use over time included baseline comorbidities as measured by the CCI (b=0.85, $p<0.0001$), female sex (b=0.99, $p<0.000$), and baseline OGC dose (b=0.78 mg/d, $p<0.0001$). Similar results were observed when we restricted the analysis to pts on monotherapy though the sample size was smaller.

Conclusion: In this large cohort of RA pts, initiators of TCZ had greater mean starting and cumulative baseline OGC doses and higher mean CCIs than initiators of other RA biologics previously treated with bDMARDs, implying that historically they might have been more difficult to treat. We found statistically significant OGC-sparing effects in RA pts treated with TCZ and BDM2. TCZ use was associated with significantly quicker and relatively more pronounced taper of OGC than BDM2. The clinical implications of such OGC-sparing effects warrant further investigation.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Whilst methotrexate (MTX) is the first-line treatment of rheumatoid arthritis (RA), response is not universal. Rates of adherence reported in the literature range from 59% to 107% and non-adherence is associated with poor treatment response. There is no gold standard measurement of adherence and currently no biochemical test of MTX levels in blood samples is available to objectively assess adherence. The aim, therefore, was i) to develop a liquid chromatography-selected reaction monitoring mass spectrometry (HPLC-SRM-MS) method to measure the concentrations of both MTX and its major metabolite 7-OH-MTX in plasma; ii) to apply the assay to a cohort of patients with RA undergoing MTX therapy and iii) to develop a population pharmacokinetic model to explore the relationship of MTX ingestion with ability to detect the analytes over time.

Methods:

A HPLC-SRM-MS method to detect MTX and 7-OH-MTX was developed according to the European Medicines Agency guidelines. RA patients (n=20) using oral MTX were admitted for 24 hours and on 2 subsequent days within 7 days of MTX administration. Nine blood samples were taken during the study period to measure MTX and 7-OH-MTX levels in plasma. All samples were analysed in triplicate, and the data were used to develop a population pharmacokinetic model. Effects of covariates (body weight and serum creatinine levels) on the model parameters were tested. Finally, simulations were performed to predict the proportion of patients with detectable concentrations of both MTX and 7-OH-MTX over time.

Results:

Twenty RA patients (65% female) completed the study with median (IQR) age of 66 (56-70) years, serum creatinine 72 (68-79) umol/l and weight 77 (68-84) kg. MTX dose ranged from 7.5 to 25mg. The lower limit of quantification for MTX and 7-OH-MTX was 0.5 and 0.75nM respectively. The model that best described the plasma concentration-time data was a two-compartment model with a first-order absorption process for MTX, and one linked compartment for 7-OH-MTX. Bodyweight was included as a covariate. The effect of serum creatinine levels on the systemic clearance of MTX was negligible. Inter-subject variability could be estimated for all parameters and appeared to be highest for the absorption parameter. The simulations suggest that after administration of 15 mg of MTX, approximately 70% of patients will have detectable MTX plasma concentrations 144 hours (6 days) post-dose (figure 1) but that the optimal time for testing would be within 60 hours (10% undetectable).

Conclusion:

A HPLC-SRM-MS assay to measure MTX and 7-OH-MTX levels in patients on low dose MTX has been developed. A population pharmacokinetic model of plasma MTX and 7-OH-MTX levels can be used as a qualitative tool to evaluate patients' adherence to treatment.

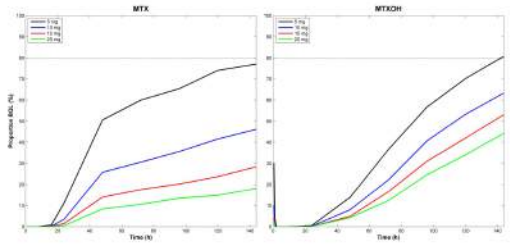

Figure 1. Simulated (n=1000) expected proportion of subjects with undetectable MTX/7-OH-MTX levels over time after administration of different oral MTX doses.

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: There is a growing emphasis on treating patients to a target level of low disease activity (LDA) or remission to order to improve outcomes associated with rheumatoid arthritis (RA). Our objective was to examine trends in the achievement of LDA over the past decade among RA patients initiating their first biologic agent.

Methods: Using the Corrona registry, we identified new initiators of biologic therapy in distinct periods of calendar time over the last decade (2002-2004, 2005-2007, 2008-2010, 2011-2013) with moderate or high disease activity at the time of the initiation based on the Clinical Disease Activity Index (CDAI >10), and a follow-up CDAI measured at 1 year (+/- 3 months). The primary outcome was achievement of LDA (CDAI ≤ 10) at 12 months with the secondary outcome being change in CDAI. Trends over time between the groups were examined using Chi square tests or Kruskal Wallis test as appropriate. Multivariable linear and logistic regression models were performed to model the association between time period and the outcome of interest.

Results: We identified 2,597 biologic initiators who met inclusion criteria (2002-2004: 238; 2005-2007: 569; 2008-2010: 640; 2011-2013: 1150). The majority of patients were female (70-78%) with a mean age of 57-58. Patients in the later time periods were more often nonwhite (Groups 1-4: 15% vs. 14% vs. 20% vs. 19%; p=0.02), had a greater body mass index (Groups 1-4: 27.7 vs. 28.8 vs. 27.8 vs. 29.2, p=0.0005), fewer years of RA disease duration (Groups 1-4: 7 vs. 5 vs. 3 vs. 3, p<0.0001), and less concomitant prednisone use (Groups 1-4: 40% vs. 33% vs. 33% vs. 30%, p=0.03). Unadjusted rates of LDA increased over time with 44% in 2002-2004 to 51% in 2011-2013 (Table 1). Adjustment for baseline disease characteristics revealed an increased likelihood of LDA in the later time periods (2008-2010 and 2011-2013). The unadjusted mean improvement in CDAI ranged from 12.2 to 13.6, which exceeds the minimally clinically important difference. There was a greater reduction in CDAI over the successive time periods, although not significant. In the adjusted models, those treated in 2008-2010 had a greater decrease in CDAI as compared to those treated in 2002-2004.

Conclusion: Using the U.S. Corrona registry, the proportion of RA patients achieving LDA when initiating a biologic in moderate or high disease activity has increased over time. Since 2005 treatment with biologics has resulted in >50% of patients reaching LDA by 12 months. Additional investigation is needed to understand the factors contributing to the trend in improved disease control, such as availability of new therapeutic agents, more treatment accelerations by providers and greater acceptance of medications by patients, in order to inform efforts to further increase the proportion of patients who achieve LDA.

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Several published randomized head-to-head trials in rheumatoid arthritis (RA) have compared TNFi-MTX with triple therapy (MTX + hydroxychloroquine + sulfasalazine) in MTX-naive patients (MTX-Ns) where most were designed as non-inferiority studies.[1]Pooled analyses of multiple trials through network meta-analysis may improve the precision of point estimates and allow more accurate interpretation of results with more power to determine between-groups differences. Thus, the objective of this study was to estimate the efficacy and radiographic benefits of TNFi-MTX vs. triple therapy in MTX-Ns by conducting a systematic review and network meta-analysis.

Methods: Medline, EMBASE, and the Cochrane Library were searched for randomized controlled trials that used either TNFi-MTX or triple therapy as one of the treatment arms in MTX-Ns with RA. The primary endpoint for this analysis was ACR70 at 6 months. Other endpoints included ACR20, ACR50, DAS28 LDA, DAS28 remission, EULAR good response, and no radiographic progression; and changes in DAS28, joint erosion, joint space narrowing, and various versions of Sharp scores from baseline. Endpoints were analyzed at 3 months, 6 months, 1 year, and 2 years from baseline when feasible. Data from direct and indirect comparisons between TNFi-MTX and triple therapy were pooled and quantitatively analyzed using fixed and random effects Bayesian models (FEM and REM) in WinBUGS version 1.4.3. Relative treatment effects were generated as odds ratio [OR] (OR>1 indicated a benefit towards triple therapy) for dichotomous endpoints and mean differences (D<0 indicated a benefit towards triple therapy) for continuous endpoints.

Results: A total of 21 studies met the study eligibility criteria, corresponding to 8,118 randomized patients. MTX-Ns were not statistically different in achieving ACR70 with triple therapy than with TNFi-MTX at 6 months in both the FEM (OR=0.76, 95% credible interval [CrI]: 0.36, 1.50) and REM (OR=0.77, 95% CrI: 0.31, 1.76). The following endpoints showed a statistically significant benefit in FEM but not REM: ACR70 at two years (FEM: OR=0.44, 95%CrI: 0.22, 0.82; REM: OR=0.43, 95% CrI: 0.14, 1.28), and proportion with no radiographic progression (FEM: =0.48, 95%CrI: 0.25, 0.90; REM: OR=0.47, 95%CrI: 0.15, 1.41). Across the 15 analyzable endpoint-time scenarios evaluated, 11 numerically favored TNFi-MTX in both FEM and REM.

Conclusion: In this network meta-analysis of MTX-N patients, most endpoints numerically favored TNFi-MTX but with no statistically significant differences between triple therapy and TNFi-MTX. At the group level the two treatment strategies appear similar.

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Monotherapy accounts for approximately 30% of biologic disease-modifying anti-rheumatic drug (DMARD) use in RA (Emery P et al. Ann Rheum Dis 2013;72:1897-904). A validated algorithm can assess effectiveness of these drugs from claims data (Curtis JR et al. Arthritis Res Ther. 2011;13:R155). The objective of this study was to apply the algorithm to evaluate effectiveness of monotherapy in patients initiating TNFi and non-TNFi biologics.

Methods: Optum claims data (January 2009-February 2014) were analyzed. The index date was the date of the first claim for a biologic DMARD or tofacitinib after the patient was enrolled for ≥6 months. Inclusion criteria were age ≥18 years at index, RA diagnosis (ICD-9-CM 714.0x) pre-index or the first 30 days post-index, and monotherapy (no conventional DMARD for 120 days post-index). Key exclusion criteria were a previous claim for the index drug during the pre-index period, use of a biologic for a non-RA indication (eg, psoriasis), or <12 months of continuous enrollment with medical and pharmacy benefits after the index date ("post-index period"). Consistent with the validated algorithm, RA was considered effectively treated if the patient met all 6 criteria post-index: (1) high adherence (infusions per labeling or medication possession ratio ≥80% for other medications); (2) no increase in biologic dose; (3) no biologic switch; (4) no new non-biologic DMARD; (5) no new/increased oral glucocorticoid; and (6) <2 glucocorticoid injections >90 days after the index date.

Results: New monotherapy was initiated in 2,147 RA patients: IV TNFi (n=246), IV non-TNFi (n=266), SC TNFi (n=1,595), SC non-TNFi (n=36), or tofacitinib (n=4). Mean age was 52.9 years (SD, 13.4), 77.0% were female, and 81.0% were commercially insured. Achievement of all 6 effectiveness criteria was not different between new non-TNFi monotherapy and new TNFi monotherapy (20.9% vs 20.8%, p=0.947); patients initiating TNFi monotherapy were more likely to increase their index biologic dose (Table). Patients initiating IV non-TNFi monotherapy were more likely to achieve all 6 effectiveness criteria (21.4% vs 10.6%, p<0.001); patients initiating IV TNFi monotherapy were more likely to have high adherence and more likely to increase their biologic dose (Table). Small sample sizes for SC non TNFi or tofacitinib limited interpretation of their effectiveness.

Conclusion: Application of the claims-based algorithm considered non-TNFi monotherapy initiation to have similar (all non-TNFi) or better (IV non-TNFi) effectiveness compared with TNFi monotherapy initiation in RA.

Table. Achievement of claims-based RA effectiveness algorithm criteria, TNFi vs non-TNFi				
Algorithm Criterion	Total		Intravenous	
	TNFi (n=1841)	Non-TNFi (n=306)	TNFi (n=246)	Non-TNFi (n=266)
High adherence	31.7%	30.4%	43.9%	30.5%*
No increase in biologic dose	91.0%	97.1%*	52.9%	96.6%*
No new non-biologic DMARD	87.5%	86.9%	88.6%	86.8%
No biologic switch	82.1%	81.7%	84.6%	83.5%
No new/increased oral glucocorticoid	85.5%	84.3%	87.8%	85.0%
<2 intra-articular injections	92.7%	92.2%	91.5%	92.5%
Effective (met all 6 criteria)	20.8%	20.9%	10.6%	21.4%*
*p < 0.001 for TNFi vs non-TNFi. DMARD = disease-modifying anti-rheumatic drug; TNFi = tumor necrosis factor inhibitor.

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: CD4+ T-cell depletion after a first cycle of rituximab (RTX) in patients with rheumatoid arthritis (RA) was previously reported by our group (Mélet J et al. Arthritis Rheum 2013). This effect was not observed in non-responders. The aim of the study was to describe CD4+ T-cell changes over multiple, repeated cycles of RTX (two infusions of 1000 mg each, 2 weeks apart) and their potential relationship with disease activity.

Methods: Patients who started RTX for treatment of RA in our centre between July 2007 and July 2013 were included and studied retrospectively until November 2014. Disease activity was assessed by disease activity score on 28 joints (DAS28) and peripheral blood CD4+ T-cell counts were measured by flow cytometry. In each cycle, pre-treatment, post-treatment and re-treatment CD4+ T-cell counts were compared using Wilcoxon's matched-pairs signed rank test.

Results: In each cycle, the mean CD4+ T-cell count was systematically above the normal range prior to the first and second infusions. The improved clinical response observed with the repeated RTX treatment was associated with normalisation of the mean CD4+ T-cell count in each cycle, this effect being slightly additive. Post-RTX CD4+ T-cell counts were sometimes below 300/mm^3. B-cell counts usually remained low when patients were re-treated. Conversely, RTX-induced CD4+ T-cell depletion was temporary and was followed by an almost complete recovery of the pre-treatment count. Additionally, all of the non-responders to cycle 1 demonstrated only a small decrease or even an increase in CD4+ T-cells in this first cycle; of the non-responders to cycle 1 who were subsequently re-treated, those who had high depletion (i.e.>33%) in the second cycle were more likely to be responders than others (11 of 11 versus 11 of 21). Interestingly, 80 % of these patients became responders and had greater CD4+ depletion in cycle 2 than in cycle 1.

Conclusion: Repeated post-treatment CD4+ T-cell depletion occur over successive cycles of RTX in RA patients. These results suggest that CD4+ T-cell variations induced by RTX are more closely related to changes in disease activity than B-cell variations. Monitoring circulating CD4+ T-cells might be helpful for clinicians when assessing disease activity and also for consequent evaluation of treatment efficacy or for the determination of re-treatment intervals in RTX-treated RA patients.

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: In patients with early RA, autoantibodies, elevated MMP-3, and acute phase proteins are prognostic biomarkers of joint damage and disease activity. However, the ability to identify patients most likely to have progressive disease is limited in those with established RA.

The MOBILITY study (NCT01061736) included MTX inadequate responder (MTX-IR) RA patients. Two doses of sarilumab (SAR) studied (200 mg every 2 wks [q2w] and 150 mg q2w) + MTX significantly reduced radiographic joint damage compared with placebo (Pbo) + MTX, including modified total Sharp score (mTSS), erosion score (ES), and joint space narrowing (JSN). Mean change from baseline in mTSS at wk 52 was 0.90 and 0.25 for SAR 150 mg and 200 mg + MTX, respectively, and 2.78 for Pbo + MTX (P<0.0001 vs Pbo). The most common treatment-emergent adverse events with SAR included infections, neutropenia, injection site reactions, and increased transaminases. SAR 200 mg + MTX also significantly decreased levels of bone erosion and joint inflammation markers such as receptor-activated NFκB ligand (RANKL), MMP-3, and MMP-cleaved fragments of collagen types 1 and 3 (C1M and C3M) relative to Pbo + MTX.[1] The objective of this study was to evaluate the prognostic utility of proteins involved in bone resorption and joint inflammation in patients treated with Pbo + MTX from the MOBILITY study.

Methods: Serum markers were measured at baseline and posttreatment in patients receiving Pbo + MTX (n=128) or subcutaneous SAR 200 mg q2w + MTX (n=131). For baseline analysis, both treatment groups were included; for posttreatment analysis, only Pbo + MTX patients were analyzed. Spearman ranked correlations (rho) were calculated between baseline markers and baseline radiographic scores (x-ray) or DAS28-CRP for both treatment groups. Correlations between baseline biomarkers and change from baseline in x-ray scores at wk 52 or DAS28-CRP at wk 24 were calculated for the Pbo + MTX group. No adjustment for multiplicity was performed.

Results: Correlations were observed between baseline MMP-3 levels and baseline x-ray scores as well as wk 52 change from baseline in mTSS and ES (Table). Baseline C1M was associated with wk 52 JSN progression. Baseline C1M and C3M correlated with baseline DAS28-CRP (rho = 0.36 and 0.199, respectively; P<0.01). No significant correlations were identified between baseline levels of RANKL, osteoprotegerin, OC, or CTX-1 with baseline clinical scores.

	Clinical parameter	Spearman rho
Baseline MMP-3	Baseline mTSS	0.206*
	Baseline JSN	0.206*
All patients (N=258)[a]	Baseline ES	0.198†
	Baseline DAS28-CRP	0.213*
Baseline MMP-3	Dwk 52 mTSS	0.193†
	Dwk 52 JSN	0.111NS
Pbo + MTX (n=128)	Dwk 52 ES	0.180†
	Dwk 24 DAS28-CRP	-0.117NS

ES, erosion score; JSN, joint space narrowing; mTSS, modified total Sharp score; NS, not significant.

Rho = Spearman ranked correlation; unadjusted P values. *P<0.001. †P<0.05. NS= P>0.05. [a]For 1 patient, baseline MMP-3 value was missing.

Conclusion: Analysis of markers described in the literature as prognostic of structural damage and disease activity in MTX-IR patients showed correlation in MOBILITY patients. These data suggest that multivariate analysis of markers may be necessary to identify increased risk of joint destruction and elevated disease activity in patients with established RA.

Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Rheumatoid factor (RF) is considered an important factor in diagnosing rheumatoid arthritis (RA). The association between the treatment efficacy of biological agents and RF status (negative or positive) is unclear; therefore, in the present study, we elucidated whether pretreatment RF examination outcomes affect the efficacy of first biological treatment in RA.

Methods:

The records of relevant patients with RA were derived from Tsurumai Biologics Communication Registry (TBCR) where the department of Nagoya University and 20 affiliated hospitals in Japan are enrolled. The relevant data of a total of 707 patients with RA who met the 2010 ACR–EULAR classification criteria for RA were recorded with regard to both pre- and post-biological treatment DAS28ESR; the RF status was divided into negative (0–15 U/ml) or positive (>15 U/ml). RF-negative patients (n = 118) and RF-positive patients (n = 589) were compared with regard to the effect of the RF status on biological treatment. Only bio-naïve patients were included in this study, and those who received second or latter biological treatment were excluded. We analyzed the relevant data using the analysis of covariance method (ANCOVA), with pretreatment DAS28ESR as the covariate.

Results:

The demographic characteristics of each group at baseline are presented in Table 1. Pretreatment DAS28ESR was significantly associated with DAS28ESR improvement, with a higher pretreatment DAS28ESR corresponding to larger DAS28ESR improvement ($p < 0.01$; Figure 1). Pretreatment DAS28ESR was 5.07 in RF-negative patients and 5.34 in RF-positive patients, with DAS28ESR improvement of 2.25 and 2.09, respectively. Compensating each DAS28ESR according to pretreatment value using ANCOVA, DAS28ESR improvement was 2.40 in RF-negative patients and 2.06 in RF-positive patients, respectively, and the difference was significant ($p < 0.05$; Table 2).

Conclusion:

The RF status significantly affected DAS28ESR improvement in the first biological treatment. Additionally, the efficacy of the first biological treatment in RF-positive patients was inferior to that in RF-negative patients with RA.

Session Date: Monday, November 9, 2015

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: It is recommended that all patients receiving MTX also receive at least 5mg/week of folic acid in an effort to reduce occurrence of MTX associated adverse effects. Previous research has suggested that supplemental folic acid has no detrimental effects on control of RA. However, we have shown that patients with higher red blood cell (RBC) folate have more active RA compared to those with lower RBC folate concentrations. The aim of this study was to determine whether reducing the amount of supplemental folic acid patients receive improves disease control in RA patients receiving MTX

Methods: A randomized double blind controlled trial of the effect of reducing folic acid supplementation was undertaken in patients with RA as defined by ARA 1987 criteria. Patients were on MTX for at least 3 months at a stable dose for at least one month. All patients had active disease as defined by DAS28≥3.2 or required a change in therapy as determined by the treating clinician. Patients were randomized to receive supplemental folic acid 5mg/week (high dose or 0.8mg/week low dose. Patients were seen at weeks 4, 8, 16 and 24. Disease activity, full blood count, liver function tests, RBC folate and RBC methotrexate polyglutamates (MTXPGs) were collected at each visit along with reports of adverse events.

Results: Forty patients were recruited. Demographics are outlined in the table. The mean (SD) change in RBC folate between baseline and 24 weeks was +87.9 (57.4) nmol/l in the high dose group and -113.3 (65.7) nmol/l in the low dose group ($p<0.05$). There was no significant difference in the change in DAS28CRP between the high and low dose groups at 24 weeks (-0.14 (SEM 0.30) vs -0.31 (0.37) respectively ($p=0.72$)). One patient in the high dose group and one in the low dose group had a transient reduction in neutrophils (1.7 and $1.5x10^9$/l respectively). Three patients in the low dose and one in the higher dose group had an increase in ALT (all <1.5x upper limit normal). One patient in the low dose group had an increase in AST (<1.5x upper limit normal).

There was no relationship between change in RBC folate and change in DAS28 irrespective of randomisation ($r=0.05$, $p=0.80$). There was no significant association between change in RBC folate and change in RBC MTX polyglutamate concentrations ($p>0.05$ for all).

Conclusion: We have shown that a reduction in RBC folate resulting from a reduction in oral supplemental folic acid was not associated with a change in RA disease activity and there was no change in RBC methotrexate polyglutamate concentrations or adverse effects. The relatively low DAS28 at entry may have made it difficult for a difference to be observed.

Demographics	High dose	Low dose

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Dose reduction of biological therapy in patients with chronic arthritis (CA) with good clinical response is a common pattern in clinical practice. However, most published studies are based on cross-sectional data in small groups of patients. We analyse the evolution of CA patients receiving low doses of biologics and the predictive factors associated with maintaining reduced doses of biological therapy

Methods: Prospective, observational study that analysed the evolution of 153 patients treated with standard or reduced doses of biologics with a two-year follow up. Variables analysed: age, sex, diagnosis, disease duration, previous treatment (sDMARD, bDMARD), current bDMARD and dosage, duration of biological treatment. In patients on reduced doses: concomitant therapy (sDMARD, steroids), ESR and CRP were collected. In rheumatoid arthritis (RA) patients, autoantibody status, erosions, and DAS-28 score were analysed. A logistic regression model was used to identify factors associated with maintaining the reduced dose after 2 years. The confidence interval of the area under the ROC curve was estimated by bootstrap technique to internally validate the predictive capacity of the model

Results: 153 patients were included between June and November 2011: 82 RA, 29 ankylosing spondylitis (AS), 20 psoriatic arthritis (PsA) and 22 with other diagnoses: 70 patients (45.7%) were on reduced doses of biologics. This cohort was followed prospectively for 2 years until November 2013. Of the 153 patients initially included, 142 remained on biologics after 2 years and 11 discontinued (6 on lower doses and 5 on standard doses: 3 due to adverse events (malignancies), 2 to pregnancies, 2 to prolonged remission, 1 to death and 3 lost to follow-up). After 2 years of follow-up, 56 patients remained on low-dose biological therapy (39.4%) and 8 (5.6%) required an increase in the dose to the standard regimen. By contrast, 19 patients receiving the standard dose were on reduced doses at 2 years. 75 (52.8%) patients were on a reduced dose after 2 years follow up. In patients (37 RA, 13 PsA) in whom DAS-28 was analysed (mean ± SD), 17.9% (8 AR, 2 PsA) had low disease activity (2.8 ± 0.2) and 71.4% (29 AR 11, PsA) were in remission (1.9 ± 0.5). Univariate analysis showed that patients who remained on a reduced dose after 2 years had less use of concomitant steroids in 2011 [9% vs 45% ($p < 0.0001$)] and lower ESR [8 ± 6 vs 2.9 ± 1.5 ($p < 0.0001$)], CRP [0.1 ± 0.2 vs 0.3 ± 1.1 ($p < 0.0001$)], and DAS-28 [2.3 ± 0.3 vs 2.9 ± 1.5 ($p < 0.0001$)] in 2011. Multivariate analysis showed that lower use of concomitant steroids in 2011 in all patients [adjusted odds ratio (AOR) = 0.15, 95% CI 0.05 to 0.52, p = 0.0026] was independently associated with the maintenance of reduced doses. In RA patients, a lower DAS-28 in 2011 was also a predictor of maintaining reduced doses [AOR = 0.24, 95% CI 0.10 to 0.59, p= 0.0018]. The area under the ROC curve was 85.5% [95% (74.2% -91.5%]

Conclusion: In our cohort, 87.5% of patients receiving reduced doses in 2011 remained on them after 2 years of follow up. Factors associated with the maintenance of a clinical response with reduced biological doses in the multivariate model were lower previous use of steroids and a lower DAS-28 score

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Innate immunity is implicated in RA pathogenesis and is likely mediated via TLR pathways, with anti-citrullinated protein antibodies (ACPA) serving as key triggers**.** NI-0101 is the first monoclonal antibody (mAb) that blocks TLR4 signaling independently of ligand type (i.e., exogenous/endogenous) and concentration. The objectives of the study were 1) To investigate NI-0101 ability to block TLR4-mediated inflammatory cytokine production induced by endogenous TLR4 ligands using RA patient samples; 2) To evaluate the effect of TLR4 blockade on arthritis progression in RA mouse model; 3) To determine preliminary tolerability, safety, pharmacokinetic (PK)/pharmacodynamic (PD) profiles after single administrations of different NI-0101 doses to Healthy Volunteers (HV).

Methods: Monocytes obtained from HV or RA patients were stimulated with citrullinated protein immune complexes (cP-IC) or synovial fluids (SF) of RA patients in the presence and absence of NI-0101. The correlation of TLR4 blockade with level of endogenous TLR4 ligands in paired SF and serum was assessed. In parallel, the anti-mouse TLR4 surrogate mAb, 5E3, was tested in a collagen induced arthritis (CIA) murine model of RA. Finally, a PK/PD guided single ascending dose Phase 1 study was conducted in 73 HV, in the presence of *in vivo* and *ex vivo* challenges with the TLR4 ligand, lipopolysaccharide (LPS).

Results: *In vitro*, NI-0101 efficiently blocked monocyte TLR4 activation by cP-IC and SF from sub-populations of RA patients. This inhibition correlated with the presence of anti-citrullinated protein antibodies and citrullinated fibrinogen immune complexes in the SF and matching sera (Figure 1A). Administration of 5E3 inhibited arthritis progression in the CIA mouse model (Figure 1B). NI-0101 was administered up to a single dose of 15 mg/kg in the Phase 1 study in HV and showed no safety concerns. The predictable PK profile was biphasic, similar to other therapeutic IgG targeting cell surface receptors. NI-0101 administration inhibited *ex vivo* and *in vivo* LPS-induced cytokine release (complete inhibition from a dose of 1 mg/kg) (Figure 1C), as well as prevented CRP increase and occurrence of flu-like symptoms following LPS administration to HV. NI-0101 PK/PD profiles allowed, through modeling and simulation of multiple administration of NI-0101, to identify an appropriate dose range to be tested in Phase 2 trials.

Conclusion: NI-0101 blocks TLR4 activation induced by TLR4 ligands (cP-IC) present in SF and serum in a subgroup of RA patients and *in vivo* LPS challenges in HV. NI-0101 safety and PK/PD profiles in HV allow initiation of Phase 2 development. Taken together, these data strongly support the potential of TLR4 as a valid therapeutic target in RA, and provide an opportunity to evaluate specific endogenous TLR4 ligands as biomarkers of NI-0101 treatment response in Phase 2 trials.

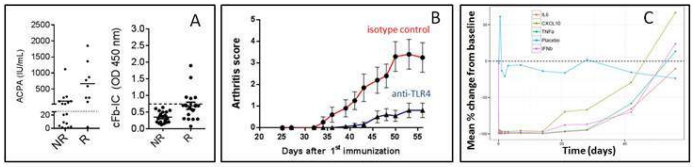

Figure 1: TLR4 blockade by NI-0101 (anti-human mAb) or 5E3 (anti-mouse mAb) correlates, *in vitro*, with serum ACPA levels and immune complexes (A), prevents disease progression in mice (B) and inhibits cytokine release induced by LPS in HV (C). A: Correlation of *in vitro* RA monocyte response to NI-0101 (measured by IL-6 inhibition after RASF stimulation; NR: no response (absence of inhibition), R: response (inhibition)) with ACPA levels in serum matching SF samples and with cFb-IC in RASF samples. B: Arthritis score in CIA mouse model in presence of isotype control or 5E3. C: Mean percentage change from baseline of cytokine levels induced by LPS after administration of a single dose of 1 mg/kg of NI-0101 in HV; line designated 'placebo': IL-6 data of the placebo group.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Presently the goals of rheumatoid arthritis (RA) therapy are to control symptoms, to prevent joint damage and disability. Attaining long-term clinical remission or at least low disease activity (LDA) is mandatory to reach these goals. Treat-to-target (T2T) protocols have been shown to be feasible and superior to non-protocolled care in treating early RA patients in daily clinical practice. However, not all patients may equally benefit from these treatment protocols. Not reaching remission or loss of remission results in periods of moderate to high disease activity in which signs and symptoms impair the health status of patients. Moreover, longer periods of moderate to high disease activity probably affect long term outcome. The objective of the present study was to identify the proportion of RA patients not receiving optimal long-term clinical benefit from T2T therapy.

Methods: Data were used from patients with early RA included in the DREAM remission induction cohort between January 2006 till June 2010. Patients were treated according to a step-up strategy aiming at remission, which consisted of methotrexate, followed by the addition of sulfasalazine and subsequently exchange of sulfasalazine with a TNFi in case of persistent disease activity. Patients were evaluated at the outpatient clinic at baseline and every 3 months thereafter. ESR-DAS28 was used to assess if patients were in LDA (DAS28 ≤3.2) or remission (DAS28 <2.6) at every visit. T2T therapy is considered not fully effective in case the patient's disease activity is moderate to high over a period of ≥ 6 months.

Results: Five-year follow-up data were available from 229 patients (63.3% female, mean age 57.7 years). Between 1 and 5 years after disease onset and start of T2T treatment, the mean DAS28 scores over time remained stable and below the cutoff for remission (Figure). In this period however, 67 (29.3%) patients experienced at least one episode of ≥ 6 months with low, moderate or high disease activity (DAS28> 2,6). Moreover, 34 (14.8%) patients experienced at least one episode of ≥ 6 months with moderate or high disease activity (DAS28> 3,2).

Conclusion: At the population level, T2T therapy in early RA results in stable low disease activity. However, even in this very well managed population, a relevant proportion of patients is not always in remission. This suggests an unmet need that deserves additional study to further improve RA management.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Filgotinib is an oral, selective Janus kinase 1 (JAK1) inhibitor combining clinical efficacy and a rapid onset of action with a good safety profile in patients with rheumatoid arthritis (RA). While people of any age can be affected by RA, the disease is common in the elderly. Age-related processes may have an impact on drug metabolism and pharmacokinetics (PK), among others from an age-related decline in enzymes activity and glomerular filtration rate (GFR). Given that metabolism followed by renal excretion is the main routes of elimination for filgotinib and its active metabolite, the impact of age as well as renal impairment on PK and safety of filgotinib was studied./Assess the PK, tolerability and safety of filgotinib in elderly subjects and in subjects with various degrees of renal impairment.

Methods: The effect of age on filgotinib PK was assessed in a single-center Phase 1 study with two groups (N=10 per group) of healthy elderly subjects (65-74 years and ≥75 years) and one group of younger healthy subjects (40-50 years). In a second single-center Phase 1 study, subjects with mild (GFR: 60-89 mL/min/1.73m²; n=6), moderate (GFR: 30-59 mL/min/1.73m²; n=6) and severe (GFR: 15-29 mL/min/1.73m²; n=3) renal impairment and one group with normal renal function (GFR: ≥ 90 mL/min/1.73m²; n=9) were included to investigate the effect of renal impairment on filgotinib PK. In both studies, male and female subjects received once daily 100 mg filgotinib orally for 10 days. The PK of filgotinib and its main metabolite were evaluated. Standard safety assessments were performed throughout the studies.

Results: At steady state, filgotinib plasma exposure was moderately increased (1.4-fold) in the oldest subjects (≥75y) compared to younger subjects. Neither the apparent terminal elimination half-life nor the amounts of filgotinib excreted unchanged in urine were impacted by the age. An exposure increase was also observed for its main metabolite, suggesting no impact of age on filgotinib' drug metabolism. Renal clearance of filgotinib and its main active metabolite decreased with the degree of renal impairment leading to 1.5- and 2.7-fold increase in exposure in subjects with severe renal impairment, respectively. Filgotinib was generally safe and well tolerated in elderly and in subjects with renal impairment. There were no deaths or serious adverse events reported. Most of the treatment emergent adverse advents (TEAEs) were mild. Safety profiles in elderly and in subjects with renal impairment were similar to young heathy subjects.

Conclusion: Higher age and mild to moderate impairment of renal function has a limited impact on the PK of filgotinib. In severe renal impairment, the exposure to filgotinib's active metabolite is elevated, consistent with its renal elimination pathway. This was not associated with safety signals in these Phase 1 studies.

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Tocilizumab (TCZ) represents an efficacious alternative for patients with rheumatoid arthritis (RA) with an inadequate clinical response to biological or non-biological disease-modifying anrirheumatic drugs (DMARDs). Previous data support the use of TCZ in monotherapy but there are limited data on its efficacy compared to TCZ + MTX (methotrexate).

Methods:

The study was designed as a phase III, randomized, double-blind, parallel-group (1:1), multicentre clinical trial. During the first part of the study all patients with active RA and previous inadequate response to MTX were treated with combined TCZ 8 mg/Kg i.v. every 4 weeks + oral MTX for 16 weeks and then all which showed a low activity (DAS28 ≤ 3.2) were randomized (1:1) to either TCZ + MTX or TCZ + placebo with a follow-up of 28 weeks. Secondary endpoints included clinical response after 28 weeks, improvement of general status and quality of life. Safety assessment was also assessed and included adverse events, serious adverse events, and change in laboratory parameters. Sample size was calculated in 79 patients per group in order to detect a minimum disease activity score (DAS28) clinically relevant difference of 0.5 (standard deviation 1.1) with 80% power and two-sided 5% alpha level. Statistical analysis was performed with SAS v9.2, and included analysis of covariance for the primary endpoint (with week 16 DAS28 as a covariate), and descriptive parameters for secondary endpoints, with an intention to treat approach. Safety cumulative incidences were estimated using Kaplan-Meier methods. (ClinicalTrials.gov Identifier: NCT01399697.)

Results:

The first part of the study included 263 RA patients with previous inadequate response to MTX (DAS28 5.6 ± 1.2). Of those, 165 patients showed low disease activity (LDA) at 16 weeks (DAS ≤ 3.2) and were randomized to TCZ + MTX (n=83) or TCZ + placebo (n=82). DAS28 from week 16 to week 28 did not change significantly in both groups (from 1.77 to 1.87 with TCZ + MTX, and from 1.96 to 1.98 with TCZ + placebo, ANOVA, p=0.89). Remission rates (DAS28<2.6) at week 28 were similar in both groups TCZ + MTX and TCZ monotherapy (82.3% and 75.9% respectively, p=0.33), and similar to those at week 16 in both groups (84.0% and 72.0% respectively). No statistically significant differences were observed in any of the secondary variables. The incidence of adverse events after week 16 was similar in both groups. Hypertransaminasemia was the most frequently adverse event reported in both groups (9.6% and 4.9%, respectively)

Conclusion:

Switching from TCZ + MTX to TCZ monotherapy in patients with LDA is not followed by any clinical change, either in the efficacy or the safety profiles. Therefore, the TCZ monotherapy could be an efficacious and safe alternative for those patients not suitable to receive MTX in combination.

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Guidelines support the use of combination conventional synthetic Disease-Modifying Antirheumatic Drugs (csDMARDs), switching csDMARDs and/or use of biologic DMARDs (bDMARDs) treatment in active rheumatoid arthritis (RA) after use of methotrexate (MTX).

The purpose of this study was to determine treatment practices after use of MTX in patients with RA who were on either monotherapy or combination csDMARDs in a large observational cohort (OBRI) in order to determine contemporary practice where use of bDMARDs from government coverage is restricted to active RA (+RF and/or +ACPA) or erosions, SJC≥5 with MTX failure, combination failure (triple csDMARDs: MTX + hydroxychloroquine + sulfasalazine) or use of leflunomide. **Methods:** Patients enrolled in the Ontario Best Practices Research Initiative (OBRI) with documented MTX failure defined as discontinuation due to side effect, primary / secondary failure, or patient / physician decision were included. Demographics and disease parameters at MTX failure were compared between monotherapy failures, double therapy (Rx) failures, and triple Rx failures. **Results:** A total of 313 patients with MTX failure were included with a mean (SD) age of 58.8 (13.2) years and disease duration of 6.7 (8.2) years. Of these, 102 (32.6%) were on MTX monotherapy, 156 (49.8%) were on double (MTX +1 csDMARD) Rx, and 55 (17.6%) were on triple or more (MTX + multiple csDMARDs) Rx, respectively, at the time of MTX failure. At the time of MTX failure disease duration was significantly higher in patients failing monotherapy and double Rx as compared to triple Rx (7.5 vs. 6.8 vs. 4.5 years, respectively; P=0.003). Figure 1 shows the disposition of patients who transitioned to csDMARD monotherapy, csDMARD combination Rx or bDMARDs treatment. Patients receiving monotherapy were more apt to have switches to other monotherapy whereas those on combination Rx received more combination csDMARDs and bDMARDs combination Rx. **Conclusion:** There are inherent differences in the selection of subsequent treatment regimen between patients failing MTX monotherapy vs. MTX combination therapy. Overall, the results of the current analysis suggest the use of a sequential treatment intensification strategy in routine clinical practice in Ontario. **Figure 1: Treatment Profile after MTX Failure by Type of MTX Failure**

Session Date: Monday, November 9, 2015

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Throughout evolution mutations in mitochondrial DNA (mtDNA) have accumulated sequentially subdividing the human population into different haplogroups classificed from A-Z. Specific mtDNA haplogroups have been associated with the development of several conditions such as Alzheimer and Parkinsons diseases. RA is a chronic auto-inflammatory disorder in which the pathogenesis is not fully understood. We analyzed the distribution of mtDNA haplogroups in a cohort of patients with RA defined by disease activity, presence of rheumatoid factor, and biological or conventional treatment.

We compared the distribution of mtDNA haplogroups in the RA-cohort with two historical control groups from the background population.

Methods:

Two-hundred nineteen consecutive patients with RA had mtDNA, isolated, sequenced and haplogroups were identified from blood samples. Patients were diagnosed according to the American College of Rheumatology (ACR)/European league against Rheumatism (EULAR) criteria. Demographic and clinical data (rheumatoid factor status, erosions, disease activity score 28-joints (DAS-28), biological/synthetic anti-rheumatic treatments were retrieved from the Danish nationwide database (DANBIO). Logistic regression analyses were performed to test for associations.

Results:

One-hundred eighty-four patients were eligible for analysis (29 were excluded due to rare non-European haplogroups, 6 had unknown haplogroups). Haplogroup frequencies were as follows: H (n= 88, 47.8%), U (n= 37, 20.1%), T (n= 22, 12.0%), J (n= 16, 8.7%), K (n= 11, 5.9%), HV (n= 6, 3.3%) and V (n= 4, 2.2%). In the overall RA-cohort the distribution of individual haplotypes was identical to the background population. None of the haplogroups were significantly associated with gender, anti-CCP, IgM RF or DAS-28. Macrohaplogroup HV was associated with administration of biological treatment (OR = 2.13; 95% Confidence Interval (CI): 1.13 - 4.07; p = 0.020). However, we found a trend towards fewer erosions in patients with haplogroup HV (OR = 0.54, 95% CI: 0.29 - 1.00, p = 0.051).

Conclusion:

The distribution of mtDNA haplogroups in the RA-cohort did not differ from the background population. However, there was a significant overrepresentation of individuals with haplogroup HV (OR 2.13) among patients undergoing biological treatment. When patients were grouped according to presence of radiographic erosion there was a trend pointing in the opposite direction. Erosive patients were less likely to belong to haplogroup HV (OR 0.54). When subjects were stratified according to DAS-28 level there were no significant associations with a certain haplogroup. We have shown that in a randomly selected cohort of patients with RA the HV mtDNA haplogroup may be overrepresented in a subgroup of patients, but no clear association with respect to diseases severity was observed.

Clinical Parameters and B Cell Subsets As Biomarkers of Response to Tocilizumab in Rheumatoid Arthritis

Anna Laura Fedele, Barbara Tolusso, Elisa Gremese, Silvia Canestri, Clara Di Mario, Marcin Nowik and Gianfranco Ferraccioli, Division of Rheumatology, Institute of Rheumatology, Catholic University of the Sacred Heart, Rome, Italy

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Tocilizumab (TCZ) is an effective treatment for Rheumatoid Arthritis (RA) and it is a modifier of B cell subsets in vivo, inducing changes in the distribution of B-cell subpopulations[1-3]. Our purpose was to define whether the combination of clinical parameters and B cell subset analysis at baseline could help to identify the best responders to TCZ, and to examine whether changes after 3 months could predict the occurrence of response to therapy over time.

Methods: 63 RA patients not responder to previous cDMARDs and/or bDMARDS were studied, of which: A) 17 (27.0%) with an early RA (ERA), treated according to a tight control strategy and B) 46 (73.0%) with a long-standing disease (LSRA). All patients were treated with TCZ at a dose of 8 mg/Kg every 4 weeks. At baseline, and every 3 months, demographic and immunological data and the ACR/EULAR core data set were recorded. At each visit, clinical improvement and remission were evaluated according to ACR/EULAR criteria[4]. At baseline and every 3 months peripheral blood samples were collected and analyzed by flow-cytometry for the distribution of circulating B-cell subsets using IgD-CD27 classification[5].

Results: In the whole RA cohort, 16.4% and 17.6% of patients treated with TCZ, reached the ACR/EULAR remission (SDAI≤3.3) at 6th and 12thmonths of follow-up (FU), respectively.

The percentage of ACR/EULAR remission after 3, 6 and 12 months of TCZ therapy was higher in male patients compared to female subjects ($p<0.05$), in ERA compared to LSRA patients ($p<0.05$), and in subjects with baseline moderate disease activity (SDAI≤26) compared to patients with a high disease activity ($p<0.05$). Moreover, a lower percentage of RA patients already treated with bDMARDS reached remission over time compared to cDMARDs treated subjects ($p<0.05$). Autoantibody seropositivity or BMI did not influence the outcome over time.

A decrease of the percentage of post-switched (IgD-CD27+; *p=0.001*) and double negative (IgD-CD27-; *p=0.004*) memory B cells occurred after 12 months of treatment with TCZ, together with an increase of the percentage of naïve (IgD+CD27-; *p=0.05*) B cells.

A higher percentage of reduction of double negative memory B cells at 3 months of TCZ treatment was observed in RA patients reaching remission (SDAI≤3.3) at 6 months compared to patients not achieving this target (*p=0.02*).

At the multivariate analysis, a disease duration less than 12 months [OR (95%CI): 24.1 (1.7-341.8)], a moderate disease activity (SDAI≤26) at baseline [OR (95%CI): 18.5 (1.4-250)] and a higher reduction of double negative B cells at 3 months of FU [OR (95%CI): 1.05 (1.001-1.1)] arose as significant independent predictors of ACR/EULAR remission (SDAI≤3.3) at 6thmonth of TCZ treatment.

Conclusion: In our cohort of TCZ-treated RA patients, being male, having a disease duration less than 12 months and a moderate disease activity at baseline represent the best clinical matrix to predict remission at 6 months. Furthermore, a significant reduction of DN memory B cells at the 3th month of FU has emerged as an early biomarker of remission at the 6thmonth of treatment.

Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Patterns of relapse in the Rheumatoid Arthritis cohort treated with Rituximab at University College London

Background/Purpose: Two patterns of relapse were defined in the first studies of Rituximab (RTX) therapy in patients with Rheumatoid Arthritis (RA): either occurring coincident with B-cell return (concordant relapse – C-R) or 'delayed' occurring months after B-cell return (discordant relapse - D-R), with around 50% of patients belonging to each subgroup in the first 24 patients studied. Later clinical observations showed a greater frequency of C-R pattern. Our study analyzed the current frequency of patients showing a concordant/discordant pattern of relapse after their first cycle of RTX.

Methods: Retrospective observational study of the RA cohort treated with RTX at University College Hospital, selecting patients with a good response to the 1st cycle of RTX and analyzing the pattern of relapse after that cycle. All patients fulfilled the 1987 revised ACR criteria and had severe disease activity (DAS28 > 5.1). Data were collected on demographics, previous and concomitant therapy, months to repopulation and months to relapse. B cell depletion was confirmed by CD19 determination of <5/microl of the total lymphocyte population. B cell repopulation was considered when B cells were again detectable in peripheral blood (CD19 count >5/microl of the total lymphocyte population). Patients with a poor response to the therapy, or treated with a second cycle because of persistent disease activity were taken out of the analysis.

Results: 271 patients have received RTX at our unit between 1998 and 2012. Total patient-years follow up was 886.05 and total number of cycles administered was 910. We selected 168 patients with a good response after 1 cycle of RTX and followed up at least until their first relapse, which occurred 4 to 67 months after the first cycle. Mean time to repopulation was 7.3 months (range 3-20 months) and mean time to relapse was 10.4 months (range 3-67 months). Patients were then divided in two patterns of relapse, that is C-R if relapse occurred less than 3 months after repopulation was first documented, and D-R if it occurred more than 3 months after such repopulation. Seventy % (118 patients) were C-R, with a mean time to repopulation of 7.1 months (range 4-20 months) and a mean time to relapse of 7.7 months (range 4-20 months); Thirty % (50 patients) were D-R, with a mean time to repopulation of 7.8 months (range 3-20 months) and a mean time to relapse of 17.4 months (range 6-67 months).

Conclusion: there are two clear patterns of relapse after repopulation in patients with RA treated with RTX, with a higher frequency of concordant patients. In one third of the patients a discordant pattern of relapse has been identified. The decision of when to retreat RA patients with RTX should be made for each patient individually, taking into account the patterns of relapse described. This will possibly decrease the risk of adverse events and reduce costs for each therapy.

Characteristics	n = 168 patients
Mean age (range)	56 years (range 18-85)
Female no (%)	132 (78%)
Mean years of disease (range)	15 years (range 1-56)
Rheumatoid factor-positive, no (%)	154 (91 %)
Anti-CCP positive, no (%)	137 (81 %)
Previous methotrexate/ other DMARDS, no (%)	157 (93 %) / 153 (91 %)
Mean no (range) previous DMARDs (including methotrexate)	3 (0-6)
Previous TNF inhibitor, no (%); mean no (range)	110 (65 %); 1,24 (0-3)
Concomitant oral steroids, no (%)	47 (28 %)
Concomitant methotrexate/ other DMARDS, no(%)	71 (42 %) / 42 (25 %)
Concomitant cyclophosphamide no (%)	25 (15 %)

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Survivin is an oncological biomarker. In rheumatoid arthritis (RA), elevated serum *survivin* is common and has been used to predict disease onset and progressive joint damage. We investigated the predictive capacity of *survivin* for response to various antirheumatic treatments in patients with early RA.

Methods:

Survivin levels in serum were measured using ELISA in 302 patients enrolled in the Swedish pharmacotherapy (SWEFOT) trial at baseline and at 3, 12, and 24 months of follow-up. *Survivin* levels >0.45 ng/mL were considered positive. After methotrexate (MTX) monotherapy for 3 months, responders (DAS28≤3.2) remained on MTX, while non-responders were randomized to triple therapy (MTX+sulfasalazine+hydroxychloroquine) or anti-TNF (MTX+infliximab). The core-set outcomes (i.e. DAS28, HAQ, pain & global VAS) were evaluated at 3, 12, and 24 months in relation to *survivin* status.

Results:

Over one-third of all patients (n=114) were *survivin*-positive at baseline. S*urvivin*-positive ever-smokers (51/71 vs. 64/112, OR 1.91 [95% CI 1.01-3.62], p=0.045) and *survivin*-negative patients who converted to positive over 24 months (13/161 vs. 2/100, OR 4.30 [0.95, 19.49], p=0.037) responded seldom to MTX.

At 3 months, *survivin*-positive patients among MTX responders who converted to negative (n=11) had greater reductions in DAS28, HAQ and global VAS vs. those who remained positive (n=28). A delay in improvement from functional disability was shown among the patients who remained positive, as the HAQ value was already higher despite MTX response. At 12 months, *survivin*-positive MTX responders who continued monotherapy had a higher risk of disease re-activation compared to *survivin*-negative patients (12/36 vs. 7/52, OR 3.21 [1.12-9.24], p=0.032) and deteriorated in HAQ over 24 months.

Among *survivin*-positive patients on triple therapy, converting to negative (n=19) was associated with a lower DAS28 at 12 months (2.34 vs. 4.12, p=0.046) and a higher frequency of low disease activity (DAS≤3.2, 86% vs. 37%, p=0.056) at 24 months vs. converting to positive (n=7). Lower pain (p=0.048) and global VAS (p=0.015) at 12 months was also found compared to the same subgroup, which was not observed among anti-TNF – where no differences in core-set outcomes were observed between the *survivin* groups. The patients on triple therapy who converted to negative attained a lower DAS28 at 12 months compared to those on anti-TNF (2.34 vs. 3.43, p=0.045). *Survivin*-positive patients on anti-TNF had a higher risk to have active disease at 24 months compared to those on triple therapy (DAS28>3.2, 16/29 vs. 9/32, OR 3.15 [1.09-9.10], p=0.037; DAS28, 3.50 vs. 2.37, p=0.020).

Conclusion:

S*urvivin*-positive patients who initially respond to MTX monotherapy have worse long-term outcomes than *survivin*-negative patients, and conversion from positive to negative is associated with a good response to conventional disease-modifying antirheumatic drugs. For *survivin*-positive patients with early RA who fail MTX, triple therapy is associated with a better likelihood for response than anti-TNF therapy.

Rapidity of Therapeutic Response of Biologics Compared to Methotrexate Monotherapy in Early RA: A Network Meta-Analysis

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Rapidity of onset of therapeutic efficacy may be critically important in the management of early RA and may reduce long-term impact of the disease. Traditional DMARDs have slow onset, potentially losing an opportunity to mitigate damage. Information on the trajectory of response to biologics relative to DMARDs in early RA could be important in making treatment decisions and influencing payer decisions. We therefore performed a network meta-analysis comparing biologics and tofacitinib to MTX in early RA, specifically evaluating treatment responses at early time points.

Methods: Medline, EMBASE, Web of Science, and Cochrane Database were searched from inception through June 1, 2015. We included all randomized controlled trials involving early RA patients that reported extractable data for disease activity score (DAS) remission, and ACR50, and compared a biologic/tofacitinib with/without MTX to MTX. Odds ratios were calculated for all DAS remission and ACR 50 outcomes reported at the following time points: 2, 4, 8, 12, 16, and 24 weeks. Network meta-analysis was performed using a Bayesian hierarchical random effects model for mixed multiple treatment comparisons.

Results: We included 18 studies involving 8658 patients with early RA. The mean age of the patients ranged from 48 to 55 years, and the mean disease

duration ranged from 2 to 43 months. 83% were biologic naïve and 78% were MTX naïve (Table 1). Biologic + MTX combination therapy worked more quickly than MTX achieving better ACR50 and DAS remission rates even at week 2 (Table 2). Although the therapeutic trajectories converge over time, they remain significantly different for up to 6 months. Tofacitinib monotherapy emerged as the best treatment option at almost all the time points with odds ratios for DAS remission compared to MTX monotherapy ranging from 18.97 (95% Credible interval 1.68, 354.32) at 4 weeks to 3.42 (1.64, 8.26) at 24 weeks, and ACR50 ranging from 7.53 (1.35, 44.96) at 4 weeks to 3.54 (1.65, 7.85) at 24 weeks.

Conclusion: Biologics combined with MTX, or tofacitinib alone, both result in faster onset of efficacy than MTX alone for early RA. Onset of efficacy is evident as early as 2 weeks, with superiority over MTX that persists for as long as six months. Our findings suggest that early introduction of biologics could produce rapid and sustained suppression of inflammatory disease, preserving function and reducing joint damage. Consideration should be given to whether the health economics favor introduction of biologics/tofacitinib earlier in the treatment pathway.

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: There is strong pre-clinical validation for Bruton's Tyrosine Kinase (BTK) as a therapeutic target for autoimmune diseases based on multiple animal models. Principia discovered a potent, selective inhibitor of BTK that forms a reversible covalent bond to a cysteine residue (Cys481) which results in prolonged residence time. We characterized the potency, selectivity and durability of target binding of PRN1008 in addition to testing its efficacy in an animal model of arthritis. Furthermore the safety, tolerability and PK/PD profile of PRN1008 was tested in a phase 1 clinical trial to assess its potential as a treatment for RA.

Methods: PRN1008 was tested for potency, durability and selectivity in biochemical and cell-based functional assays. The in vivo efficacy of PRN1008 was tested in a rat model of collagen-induced arthritis

rheumatoid arthritis.

was tested in a rat model of collagen-induced arthritis (CIA). The first-in-human study consisted of two randomized, double-blind, placebo-controlled parts: Part A, 5 SAD cohorts (50-1200 mg) and Part B, 4 MAD cohorts with 10 days treatment (300mg and 600mg QD, 300mg and 450mg BID). Safety was assessed clinically and by ECG, vital sign and laboratory measurements. PRN1008 pharmacodynamic coverage was assessed by BTK occupancy; Pharmacokinetic/pharmacodynamic analysis was performed to characterize the relationship between BTK occupancy and PRN1008 PK.

Results: PRN1008 is very potent against BTK (IC50 = 1.3 ± 0.5 nM) and highly selective when tested against a broad panel of kinases. Cysteine targeting by PRN1008 results in a slow off-rate demonstrated by retention of 79 ± 2% of binding to BTK in PBMC 18 hours after washout in vitro. The covalent cysteine binding was completely reversible after denaturation of the target. Human B cell proliferation and activation (CD69 expression) were inhibited by PRN1008 with IC50 of 5 ± 2.4 nM and 123 ± 38 nM, respectively. Dose dependent efficacy in rat CIA was observed at trough BTK occupancies of 16 ± 3.6% to 79 ± 4.2%. PRN1008 was safe and well-tolerated in both parts of the human study without changes in vital signs, ECG or laboratory measurements. In humans dosed with PRN1008, BTK maximal occupancy was 90 ± 6% (mean ± SD) and 93 ± 2% at four hours on day 1 and day 10, respectively. BTK maximal occupancy at trough (12 or 24 hours) on day 10 ranged from 59 ± 11 to 80 ± 6%, when plasma PRN1008 was essentially cleared, demonstrating an extended PD effect. PK/PD analyses revealed that maximum occupancy was exposure-dependent; the rate of occupancy loss tended to be faster in subjects who did not achieve > 90% occupancy at 4h. Intersubject variability in occupancy was very low, particularly in subjects whose plasma exposures resulted in >90% occupancy at 4 hrs.

Conclusion: PRN1008 is a potent, selective and reversible covalent inhibitor of BTK with extended PD effects in vivo. PRN1008 was safe and well tolerated after single and 10 day dosing in humans. Dosing to achieve > 90% occupancy after a dose results in consistent and prolonged target occupancy. BTK target coverage with a daily dose of ≥300mg reached therapeutic levels based on translational studies in a rat model of arthritis. These data support continued development of PRN1008 as a therapeutic agent for rheumatoid arthritis.

Session Date: Monday, November 9, 2015

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Interleukin-6 (IL-6) is a pleiotropic cytokine known for its proinflammatory functions. In rheumatoid arthritis (RA), increased concentrations of IL-6 may stimulate leukocyte recruitment to the joint and promote osteoclast maturation and activation, contributing to joint damage. Sirukumab is a human anti-IL-6 monoclonal antibody under development for RA treatment. This study was sponsored by Janssen in collaboration with GSK.

Methods:

The primary objective of this study was to assess the safety of sirukumab monotherapy in Japanese subjects with moderate to severe RA. The study consisted of a 52-week double-blind treatment phase and a 16-week post-treatment phase. In total, 122 subjects were randomized 1:1 to sirukumab 50mg every 4 weeks (q4) or sirukumab 100mg every 2 weeks (q2). No disease-modifying anti-rheumatic drugs (DMARDs) were permitted until Week 24.

Results:

Of the 122 subjects randomized in the 50mg q4 group and the 100mg q2 group, respectively: 77.0% and 70.5% were female; mean weights were 55.0 and 56.8 kg; mean disease durations were 7.60 and 7.95 years; and 14 and 10 subjects had experienced treatment with previous biologics (Table 1).

Safety: In 122 treated subjects, 56 subjects in the 50mg q4 group and 58 subjects in the 100mg q2 group experienced at least 1 adverse event (AE); there was no marked difference between the 2 groups. In addition, 9 subjects in the 50mg q4 group and 5 subjects in the 100mg q2 group discontinued the study agent due to AEs; 23 subjects in the 50mg q4 group and 24 subjects in the 100mg q2 group experienced injection site reactions, and 1 subject discontinued due to it. There were no deaths, major adverse cardiac events, or serious gastrointestinal perforations. Serious AEs (SAEs) were observed in 4 subjects in the 50mg q4 group and 5 subjects in the 100mg q2 group (Table 2). SAEs of “osteomyelitis”, “borderline serous tumor of ovary”, and “acute sinusitis” were mild or moderate, and considered reasonably related to the study drug.

Efficacy: At Week 24, the proportions of ACR20/50/70 responses were 73.8/49.2/24.6% in the 50mg q4 group and 82.0/63.9/36.1% in the 100mg q2 group. ACR responses were generally maintained through Week 52.

Conclusion:

Sirukumab 50mg q4 and 100mg q2 monotherapy dose regimens for 52 weeks were well tolerated in Japanese RA patients. The proportions of AEs in both groups were similar and there were no dose-dependent safety issues. The proportions of ACR 20/50/70 responses at Week 24 in the 100mg q2 group were numerically higher than those in the 50mg q4 group; however, the number of subjects was too limited to make conclusions about dose response.

Table 1: Demographics and Baseline Characteristics

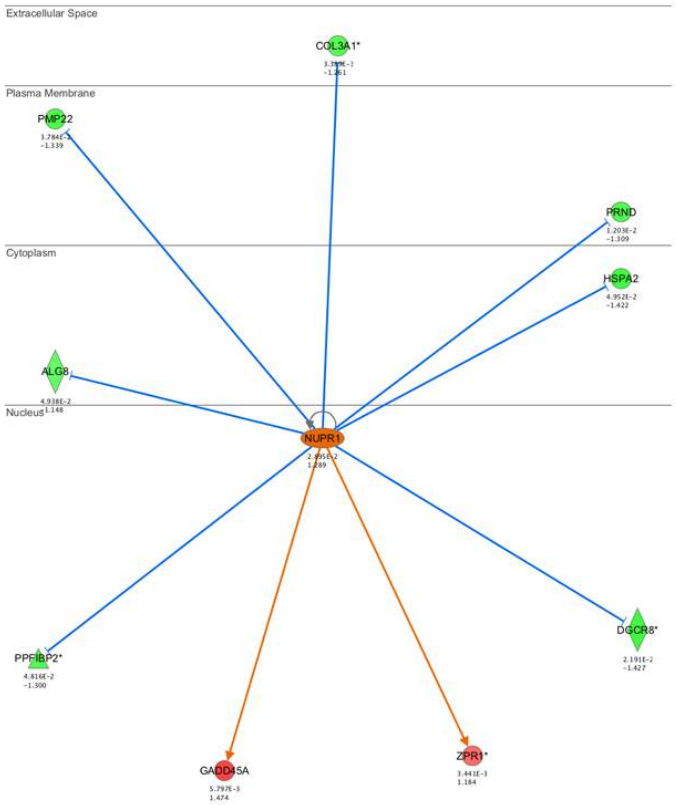
SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: The cause of accelerated atherosclerosis in rheumatoid arthritis (RA) is still unclear and appears to be multifactorial. Besides the traditional risk factors, also RA-specific risk factors play a role. Notably, vascular inflammation in the vascular adventitia may be a crucial factor. Elucidating the pathomechanism of cardiovascular (CV) disease in RA is essential in order to provide optimal CV prevention and treatment. Examination of vascular specimens may provide important clues for such an endeavor. The purpose of the study was to compare the gene expression profile in the aortic adventitia in coronary artery disease (CAD) patients with and without RA.

Methods: Total RNA was isolated from biopsies of the adventitia of the ascending aorta removed during coronary artery bypass grafting in patients with (n=8) and without (n=8) RA. The gene expression profile was determined using Affymetrix microarray. The CEL files were imported into the Partek Genomics Suite software, and differentially expressed genes were identified by one-way ANOVA (p<0.05; FC>1.1).

Results: Non-supervised hierarchical clustering analyses showed that the gene expression profiles clustered into two groups. A total of 15586 transcripts were identified, of which 201 were differentially expressed between the groups (p<0.05). Upstream analysis demonstrated activation of the stress-induced nuclear protein transcriptional regulator 1 (NUPR1) in RA patients (z-score: 3.0). Nine target molecules of NUPR1 were identified, including the endothelial dysfunction-related growth arrest and DNA-damage-inducible alpha (GADD45A), which was up-regulated in RA patients (p=0.006; FC=1.474) (Figure 1).



Conclusion: NUPR1 is a known key player in the cellular stress response. Our results indicate that the increased CV risk in RA might be related to activation of NUPR1, with downstream activation of GADD45A, which in turn promotes endothelial dysfunction. Interestingly, NUPR1 has also been linked to heart failure, and GADD45A to immune senescence, autoimmunity and inflammation, and to endothelial dysfunction. In theory, factors of the NUPR1 pathway might be a target for novel therapy.

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

The prediction of a stable treatment for rheumatoid arthritis (RA) is one of the targets of clinical research in rheumatology. However, only few biomarkers were successfully described as predictors of retention in therapy with biological agents. The aim of this paper was to investigate whether T-cell characterization might be used as predictor of abatacept (ABA) treatment continuation.

Methods:

Data are expressed as median (10^{th}-90^{th}percentile), if not otherwise specified. Seventy-one consecutive RA patients treated with ABA were prospectively

followed (female: 80%; age: 54 (40-71) years; disease duration: 7 (1-19) years; rheumatoid factor positivity: 81%; anti-cyclic citrullinated peptide (ACPA) positivity: 83%; DAS-28 (CRP): 5.1 (3.9-6.5); number of previous disease-modifying antirheumatic drugs: 3 (1-5); numbers of previous biological treatments: 2 (0-3), ABA as first line biological treatment: n=17).

T-cell characterization was performed by multi-color flow-cytometry (Navios, Beckman-Coulter).

Results:

At the end of our investigation, 28 patients discontinued ABA after 8 (4-16) months (18 for inefficacy; 5 for adverse events; 5 for other reasons) and 43 patients were still in therapy after 31 (13-62) months. In patients that maintained the treatment we observed: a lower proportion of smokers (25.6% vs 51.9%; p=0.03); a not significant lower proportion of ACPA positivity (76% vs 89.5%; p=0.13); a higher proportion of CD8+ terminally differentiated effector memory (TDEM) T-cells at baseline (38.7 (20.7-55.9) vs 22.0 (7.8-39.2) % of CD8+ T-cells; p=0.002). Other demographic, clinical and laboratory parameters were not different. Logistic multivariate analysis showed that only the proportion of CD8+TDEM T-cells was an independent predictive factor of high retention rate (OR (95% IC)=6.2 (1.2 to 30.8), p=0.026).

The ROC analysis showed a significant performance of this biomarker for prediction of persistence in therapy (using a cut-off of 30.6%: AUC: 0.760+0.07; p=0.002). patients with a high proportion of CD8+TDEM had a higher probability of continuing the treatment for a longer period of time (Mantel-Cox test: p<0.01). The positive and the negative predictive value of this test for treatment continuation were 83.3% and 65.0% respectively.

Conclusion:

T-cell characterization for identification of TDEM CD8+ T-cells might be a useful test to predict persistence in therapy with ABA. It can be speculated that a high TDEM CD8+ T cell percentage might be a marker of previous repeated T-cell activation, identifying a subset of patients in which the CD28 costimulation blockade with ABA may be particularly efficacious.

Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

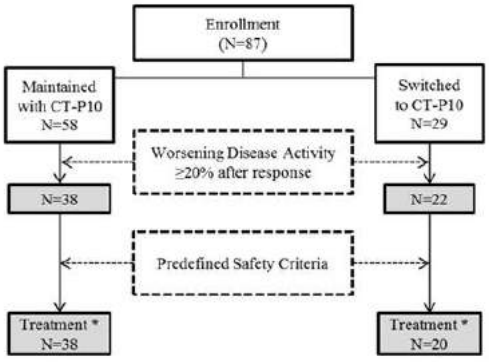
Background/Purpose: Pharmacokinetic (PK) equivalence and similarity of clinical efficacy, safety and immunogenicity up to week 24 were demonstrated between CT-P10, a biosimilar candidate for innovator rituximab (RTX), and RTX groups in patients with rheumatoid arthritis (RA) [1].

The objective of this open-label study was to confirm efficacy and safety of switched CT P10 from RTX in RA patients (NCT01873443).

Methods : A total of 87 patients, who completed up to 72 weeks of the phase I randomized controlled trial (NCT01534884), entered into the open-label extension study for maximum of 56 weeks: 58 and 29 patients were recruited from CT-P10 and RTX groups, respectively, in the controlled study. Thirty

eight (65.5%) and 20 (69.0%) patients in each group received CT-P10 treatment according to DAS28 and the predefined safety criteria during this open-label study (Figure 1). Among 29 patients who did not receive CT-P10 treatment during the study, disease activity was well controlled until the end of study in 20 and 7 patients from the CT P10 and RTX groups, respectively. Two patients in RTX group did not receive CT-P10 treatment due to safety reason. Efficacy and safety assessments were monitored throughout the study.

Figure 1 Patient Disposition



* Last course of treatment was allowed until week 80 of entire study period (controlled study + open-label study)
Note: Number of patients who omitted an additional course of treatment due to stable disease activity/ safety: CT-P10, 20/0; RTX, 7/2

Results : The DAS28-CRP and ESR improvement at Week 24 after the last CT-P10 infusion were similar in the 2 treatment groups; -2.2 for both groups in DAS28-CRP (p=0.9474) and -2.7 for maintained CT-P10 group and -2.4 for switched CT-P10 group in DAS28-ESR (p=0.5687).

The proportion of patients experienced at least one adverse event (AE) or serious AE was comparable between maintained and switched CT-P10 groups. Infusion related reactions were reported in 1 patient in each treatment group (Table 1).

No deaths, malignancy or AEs leading to permanent study drug discontinuation were reported during the study.

Table 1 Efficacy by DAS28 Changes

	Maintained CT-P10 Group	Switched CT-P10 Group
DAS28-CRP, Mean ± SD (n)		
Baseline	5.9 ± 0.90 (38)	5.8 ± 0.72 (18)
Changes at Week 24 after 1st Course	-2.2 ±1.15 (33)	-2.2 ± 1.16 (16)
DAS28-ESR, Mean ± SD (n)		
Baseline	6.8 ±0.83 (38)	6.5 ±0.80 (18)
Changes at Week 24 after 1st Course	-2.7 ±1.17 (34)	-2.4 ±1.33 (16)

RTX, innovator rituximab; DAS28, disease activity score in 28 joints; CRP, C-reactive protein; ESR, erythrocyte sedimentation rate; SD, standard deviation

Table 2 Safety Summary

	Maintained CT-P10 Group N=38	Switched CT-P10 Group N=20	Total N=58
Number of Patients (%) with at Least One			
AE	9 (23.7)	4 (20.0)	13 (22.4)
Serious AE	1 (2.6)	1 (5.0)	2 (3.4)
Infusion-related reaction	1 (2.6)	1 (5.0)	2 (3.4)
Infection	3 (7.9)	2 (10.0)	5 (8.6)
Malignancy	0	0	0
Discontinuation due to AEs	0	0	0

RTX, innovator rituximab; AE, adverse events

Conclusion : Switched CT-P10 from RTX demonstrated comparable efficacy and safety profiles compared to those of maintained CT-P10. Maintained CT-P10 was also well tolerated and effective up to 2 years in RA patients.

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Biologic disease-modifying anti-rheumatic drugs (DMARDs) in combination with conventional DMARDs provide patients with severe rheumatoid arthritis (RA) and an inadequate response to conventional DMARDs with treatment options. A previously published systematic review/network meta-analysis (NMA)[1] comparing the relative efficacy of biologic DMARDS was updated to take account of new clinical evidence for current and recently licensed treatments with alternative modes of administration, i.e. subcutaneous (SC) versus intravenous (IV).

Methods: The systematic review undertaken in April 2011 was updated in November 2014. Literature searches were conducted in MEDLINE, EMBASE and the Cochrane Library, in addition to hand searches of conference proceedings and reference lists. A Bayesian NMA, which estimates the relative effectiveness of treatments whilst preserving the randomized comparisons within each trial, was conducted in WinBUGS using a random-effects logit-link model fitted to the binomial trial data namely the count of patients reaching American College of Rheumatology (ACR) scores 20/50/70 at follow-up.

Results: In addition to the 13,647 citations originally identified[1], 7,328 citations were identified in the update, of which 18,337 were excluded after screening the title/abstract. After reviewing 2,638 full-text papers, 43 studies enrolling over 15,000 patients and reporting ACR outcomes between 12 and 30 weeks were identified for inclusion in the meta-analysis. The following nine biologic DMARDs/ conventional DMARD combinations were included in the evidence network: abatacept IV (5 randomized controlled trials (RCTs), n=1,484); abatacept SC (3 RCTs, n=1,113); adalimumab (8 RCTs, n=1,112); certolizumab pegol (4 RCTs, n=802); etanercept (8 RCTs, n=881); golimumab (4 RCTs, n=345); infliximab (7 RCTs, n=1,122); tocilizumab IV (8 RCTs, n=2,545); tocilizumab SC (1 RCT, n=631).

The table below presents the NMA results for ACR20/50/70 outcomes for combination treatments of interest.

TABLE		
Treatment	**Median OR vs. cDMARD (95% CrI)**	**% patients achieving ACR20/50/70 (95% CrI)**
ACR20		
Conventional DMARD	-	28.5% (25.0%, 32.4%)
Abatacept 10mg/kg/4 weeks IV + cDMARD	3.11 (2.06, 4.62)*	55.4% (44.2%, 65.7%)
Abatacept 125mg/week SC + cDMARD	3.50 (2.04, 6.23)*	58.3% (44.1%, 71.7%)
Adalimumab 40mg/2 weeks + cDMARD	3.22 (2.30, 4.53)*	56.3% (46.8%, 65.5%)
Certolizumab pegol 200mg/2 weeks + cDMARD	9.23 (5.78, 14.69)*	78.6% (69.2%, 85.9%)
Etanercept 2x25mg/week + cDMARD	9.39 (5.02, 17.98)*	79.0% (66.1%, 88.0%)
Golimumab 50mg/4 weeks + cDMARD	3.79 (2.35, 6.04)*	60.2% (47.7%, 71.4%)
Infliximab 3mg/kg/8 weeks + cDMARD	3.18 (2.23, 4.50)*	56.0% (46.2%, 65.3%)
Tocilizumab 162mg/week SC + cDMARD	4.18 (1.98, 9.22)*	62.5% (43.8%, 79.0%)
Tocilizumab 8mg/kg/4 weeks IV + cDMARD	4.63 (3.31, 6.64)*	64.9% (55.9%, 73.4%)
ACR50		
Conventional DMARD	-	12.6% (10.3%, 15.2%)
Abatacept 10mg/kg/4 weeks IV + cDMARD	3.58 (2.23, 5.90)*	33.9% (23.3%, 47.0%)
Abatacept 125mg/week SC + cDMARD	3.86 (2.06, 7.37)*	35.7% (22.2%, 52.4%)
Adalimumab 40mg/2 weeks + cDMARD	3.71 (2.49, 5.57)*	34.8% (25.3%, 45.9%)
Certolizumab pegol 200mg/2 weeks + cDMARD	6.86 (3.97, 12.03)*	49.7% (35.3%, 64.3%)
Etanercept 2x25mg/week + cDMARD	11.24 (4.96, 26.87)*	61.7% (40.9%, 79.9%)
Golimumab 50mg/4 weeks + cDMARD	4.63 (2.41, 9.24)*	40.0% (24.9%, 57.8%)
Infliximab 3mg/kg/8 weeks + cDMARD	3.68 (2.42, 5.74)*	34.6% (24.8%, 46.4%)
Tocilizumab 162mg/week SC + cDMARD	5.27 (2.09, 13.43)*	43.0% (22.7%, 66.4%)
Tocilizumab 8mg/kg/4 weeks IV + cDMARD	5.47 (3.58, 8.50)*	44.1% (32.7%, 56.3%)
ACR70		
Conventional DMARD	-	4.2% (3.1%, 5.7%)
Abatacept 10mg/kg/4 weeks IV+ cDMARD	3.65 (2.34, 6.13)*	13.8% (8.5%, 22.7%)
Abatacept 125mg/week SC + cDMARD	4.08 (2.36, 7.75)*	15.2% (8.7%, 26.7%)
Adalimumab 40mg/2 weeks + cDMARD	4.39 (2.84, 6.97)*	16.1% (10.1%, 25.2%)
Certolizumab pegol 200mg/2 weeks + cDMARD	13.66 (6.68, 33.64)*	37.4% (21.5%, 60.8%)
Etanercept 2x25mg/week + cDMARD	19.66 (5.31, 139.3)*	46.3% (18.2%, 86.3%)
Golimumab 50mg/4 weeks + cDMARD	5.51 (2.60, 12.65)*	19.5% (9.6%, 37.3%)
Infliximab 3mg/kg/8 weeks + cDMARD	3.63 (2.359, 5.88)*	13.7% (8.5%, 22.1%)
Tocilizumab 162mg/week SC + cDMARD	6.24 (2.63, 14.29)*	21.5% (9.9%, 39.8%)
Tocilizumab 8mg/kg/4 weeks IV + cDMARD	7.28 (4.53, 11.73)*	24.2% (15.2%, 36.4%)
Abbreviations: CrI, credible interval (Bayesian equivalent of a confidence interval); IV, intravenous; OR, odds ratio; SC, subcutaneous; *significant		

difference based on the 95% CrI

Conclusion: Based on the meta-analysis of the studies that met the inclusion criteria for this review, all biologic DMARDs in combination with conventional DMARDs were significantly more effective than conventional DMARDs alone in improving ACR 20/50/70 outcomes in patients with severe RA and an inadequate response to conventional DMARDs.

Etanercept in combination with conventional DMARDs was the most effective biologic DMARD combination in terms of ACR 20/50/70 response.

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The current treatment for patients with rheumatoid arthritis (RA) consists of biological drugs, often in combination with methotrexate. However, some patients fail to respond to biological therapy in one or multiple joints. We are therefore aiming to develop a gene therapy for local treatment of affected joints. By using disease-inducible promoters to drive expression, the joints will only produce biological drugs during a disease flare.

Methods: Microarrays on joint tissue of 20 RA patients and 7 patients without joint disease were analyzed to find genes that are upregulated in the joint during active disease.

The promoter of the *CXCL10* gene was isolated from human cDNA and cloned into a lentiviral vector containing the firefly luciferase reporter gene. THP-1 cells were transduced with the lentiviral constructs and stimulated for 6 hours with pro-inflammatory stimuli, 64 RA patient sera and 63 control sera to determine the inducibility of the promoters. The luciferase reporter gene was replaced by IL-10 and the expression of recombinant IL-10 was measured under control of the *CXCL10*promoter. The production of TNFα, IL-1β, IL-8 and MCP-1 by lipopolysaccharide (LPS) stimulated synovial cells were measured by multiplex ELISA assay.

Results: The microarrays showed a 10-fold upregulation of *CXCL10*, an interferon inducible gene known to be expressed by many cell types. Primary cells obtained from patient synovium were transduced with the *CXCL10*-luciferase reporter vector and stimulated with pro-inflammatory lipopolysaccharide (LPS) or with TNFα. This resulted in a 3.3- and 2.3-fold upregulation of the luciferase signal respectively. The *CXCL10* promoter was also activated by serum from RA patients and could significantly distinguish between RA serum and healthy donor serum (P=0.017). The *CXCL10* promoter in THP-1 monocytes showed a 33.7-fold upregulation after 8h stimulation with TNFα. The promoter activity declined after 96h, but was re-inducible by a second TNFα-stimulation. This shows the temporal responsiveness of the *CXCL10*promoter to inflammatory signals and the vigilant state under basal conditions. For therapeutic testing, the luciferase reporter gene was replaced by the anti-inflammatory Interleukin-10 (IL-10) gene. RA synovial cells transduced with the CXCL10-IL10 lentivirus produced significantly less pro-inflammatory cytokines (TNFα, IL-1β, IL-8 and MCP-1) after LPS stimulation compared to control virus. This was observed in multiple patients. These results show the functionality of the CXCL10-IL10 lentivirus in the desired synovial target cells.

Conclusion: Our CXCL10 regulated IL-10 gene construct shows good responsiveness to inflammatory stimuli and inhibits inflammatory cytokine production by RA synovial cells. CXCL10-regulated IL10 overexpression can thus provide inflammation-inducible local gene therapy suitable for joints with persistent RA that are refractory to treatment.

Does the Level of Disease Control Achieved with Biologics Influence Overall Costs for Health Care and Work Loss in RA?

Jonas K Eriksson[1], Martin Neovius[2], Johan Askling[3] and ARTIS study group, [1]Clinical Epidemiology Unit, Dept of Medicine, Karolinska Institutet, Stockholm, Sweden, [2]Clinical Epidemiology Unit, Karolinska Institutet, Stockholm, Sweden, [3]Rheumatology Unit, Rheumatology Unit, Karolinska University Hospital, Stockholm, Sweden

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Numerous studies have modeled whether biologic drugs are good value for money in the treatment of RA, in terms of reducing health care use and work loss to a higher extent than when using alternative therapeutic options. However, whereas several studies have estimated costs in RA and in relation to therapies, few studies have investigated cost trajectories in relation to the clinical response to such therapies. The aim of this study was therefore to estimate the societal monthly costs related to work loss, health care use, and prescription drug use over 2 years in relation to the level of disease activity control achieved after start of biologic therapy.

Methods:

RA patients ≥18y with a treatment period of ≥3 months with a first ever biologic drug between 2006 through 2010 were identified from the Swedish Rheumatology Quality Register (including the Swedish Biologics Register ARTIS). Based on start DAS28 and the lowest registered DAS28 during visits 3 to 12 months after biologic start, patients were categorized as EULAR good, moderate and no responders.

Data on work loss, health care use, drug use, and mortality were retrieved from nationwide registers. Patients were followed from 12 months before the DAS28 evaluation until first of 24 months of follow-up, death, emigration, or Dec 31, 2012. As a general population benchmark we used five sex-, age-, and county-matched comparators per RA patient.

Results:

A total of 3788 patients with RA who started their first biologic therapy in 2006 through 2010 were identified (mean age, 56.7y; 75% women; mean disease duration, 10.2y). Of these, 1950 (51%) patients achieved and were categorized as EULAR good response (55.1y; 72%; 10.0y), 1208 (32%) achieved moderate response (59.0y; 79%; 10.6y), and 630 (17%) patients never reached any EULAR response (57.2y; 77%; 10.1y).

The mean monthly cost at 24 months after DAS28 evaluation was lower in working age patients with good response (n=1249) compared to patients with moderate or no response (n=1052; $2837 vs $3799; adjusted mean difference [95% CI], -$242 [-503; -$15]; **Figure**). The lower monthly cost in patients with good response was mainly driven by reduced work loss costs.

In patients ≥65y, the mean monthly health care cost was similar across the response groups.

Conclusion:

Working age RA patients who achieve a good level of disease control during the year after start of biologic therapy have lower monthly costs as compared to patients with moderate or no response. However, the monthly cost in those who achieved good disease control was still around 3 times higher compared to the general population 2 years after biologic therapy initiation.

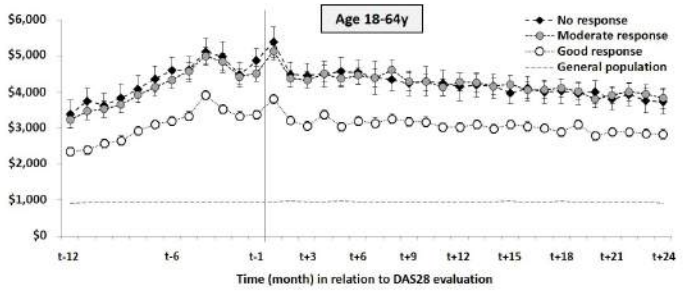

Figure Trajectories of costs for hospital care, drugs and lost work days, stratified by EULAR good, moderate and no response in working age patients with RA and their matched general population comparators

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is an autoimmune disease driven by chronic inflammation, upheld by sustained recruitment and infiltration of leucocytes, especially macrophages. Mavrilimumab is a fully human monoclonal antibody targeting the granulocyte-macrophage colony-stimulating factor receptor-α. Mavrilimumab suppresses the effect of granulocytes and monocytes/macrophages, in RA. Serologic biomarkers can also be used to assess efficacy. The serum neo-epitope biomarker, citrullinated and MMP-degraded vimentin (VICM), is a marker of inflammation. We investigated whether the biomarker VICM is biomarker of activated macrophages, and whether mavrilimumab modulates serum concentrations of VICM in RA patients.

Methods: *In- vitro* experiments were carried out on peripheral mononuclear cells (PBMCs). Isolated monocytes were differentiated by incubating with M-CSF for 5 days prior to any treatment, and were cultured as a monolayer on plastic. Cells were treated either with lipopolysaccharide (LPS), LPS + calcium chloride (CaCl), or only CaCl as control. Treatment of LPS was 100ng/ml, and CaCl was 0.22µg/mL. Conditioned medium were collected at Days 1, 5, and 8, and stored for ELISA analysis. The *in-vitro* studies was repeated 4 times and analyzed by Kruskal-Wallis analysis. Serum samples were from the Phase IIb RCT (NCT01706926) of RA patients (n=140) receiving either placebo or 150-mg every-other-week dosages of mavri, in combination with methotrexate, for 169 days. VICM was measured at Days 0 and 169. Spearman's correlations were carried out to investigate the association between disease activity (DAS28 and mTSS) and serum concentrations of VICM, and changes in VICM concentrations after mavrilimumab treatment compared to placebo.

Results: The *in-vitro* data indicated that the release of VICM was significantly greater in supernatants from activated macrophages (LPS+CaCl treated) at Days 5 and 8 ($p<0.01$), compared with controls (Fig. 1A), indicating that VICM is a biomarker of activated macrophages. Mavrilimumab significantly inhibited VICM serum concentrations (30%) in patients receiving 150 mg every other week compared with placebo at Day 169 ($p<0.05$) (Fig. 1B), as well as suppressed the presence of CD14 positives cells by approximately 12%. In addition, VICM correlated significantly with DAS28 ($r=0.13$, $p<0.05$), mTSS ($r=0.15$, $p<0.01$) and CRP ($r=0.26$, $p<0.01$) at baseline. Patients with mTSS>23.5 had significantly elevated VICM serum concentrations compared with patients with mTSS<23.5 at baseline ($p<0.01$).

Conclusion: The data indicate that VICM is biomarker of activated macrophages by revealing i) the direct release of VICM from activated macrophages *in vitro,* and ii) a significant suppression upon treatment with the mavrilimumab. These data support further development of mavrilimumab and other drugs targeting macrophages in RA.

Selective JAK1 Inhibition with Filgotinib (GLPG0634) Decreases Plasma Markers of

Inflammation and Joint Damage in Patients with Rheumatoid Arthritis

René Galien[1], Annegret Van der Aa[2], Roland Blanque[1], Sophie Darquenne[1], Pille Harrison[2] and Chantal Tasset[2], [1]Galapagos SASU, Romainville, France, [2]Galapagos NV, Mechelen, Belgium

Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Among the 4 Janus kinase (JAK) family members, JAK1 often has a dominant role in the intracellular signaling for cytokines involved in auto-immune and inflammatory diseases, such as rheumatoid arthritis (RA). We therefore hypothesized that inhibiting JAK1 only would provide an efficacious treatment for RA, and may avoid potential side effects associated with inhibition of other JAKs. Filgotinib (GLPG0634) displays a strong selectivity for inhibition of JAK1 over JAK2, JAK3 and TYK2. In phase 2a clinical trials, filgotinib rapidly improved signs and symptoms of RA with good tolerability and safety. The data reported here present the changes in serum pharmacodynamic markers observed in RA patients after 4 weeks of treatment with filgotinib.

Methods:

RA patients (n=91) with insufficient response to MTX were randomized to receive placebo or 30, 75, 150, or 300 mg filgotinib once-daily orally for 4 weeks as add-on to MTX in a double-blind phase 2a study. Blood was sampled pre-dose and on the last day of treatment. Concentrations of the biomarkers chitinase-3 L1 (CHI3L1)/YKL-40 and SAA were quantified using an ELISA assay from R&D Systems. All other biomarker concentrations were evaluated at Myriad RBM Inc. using the InflammationMAP© assay. For each parameter, data are reported in percentage relative to the baseline value of each individual.

Results:

After 4 weeks of treatment with filgotinib, levels of the acute phase proteins CRP and haptoglobin dose-dependently decreased in RA patients. IL-18 and SAA, two markers of inflammation, and sTNFR2 whose expression is increased in RA patients, also displayed a significant decrease. The plasma concentration of ICAM-1 and VCAM-1, both known to play a major role in the adhesion and recruitment of leukocytes, was also decreased. The concentration of the metalloprotease MMP3, involved in tissue remodelling and induced in inflammation, decreased following treatment with 150 and 300 mg QD. Both CHI3L1 and VEGF, whose expressions are controlled by JAK1-activating gp130 receptors and STAT transcription factors, were decreased at all doses of filgotinib.

TREATMENT	CRP	Haptoglobin	IL-18	SAA	sTNFR2	ICAM-1	VCAM-1	MMP3	CHI3L1	VEGF
PLACEBO	94 +/- 15	101 +/- 15	1034 +/- 4	88 +/- 14	94 +/- 4	97 +/- 6	99 +/- 3	92 +/- 10	120 +/- 5	138 +/- 23
75 mg	72 +/- 13	91 +/- 7	96 +/- 5	86 +/- 20	111 +/- 10	97 +/- 3	110 +/- 6	116 +/- 20	76 +/- 9 ***	106 +/-5

300mg	22 +/- 5 ***	50 +/- 6 **	82 +/- 3 **	38 +/- 8 *	79 +/- 4 *	79 +/- 3 *	89 +/- 2	54 +/- 6 *	56 +/-8 ***	97 +/- 8 *

Percent change from baseline in biomarkers after 4 weeks of filgotinib treatment (Mean +/- SEM - Kruskal – Wallis + Dunn's post hoc tests *: $p<0.05$; **: $p<0.01$; ***: $p<0.001$, compared to baseline)

Conclusion:

Within 4 weeks of treatment with the JAK1-selective inhibitor filgotinib in RA patients, plasma markers of inflammation and joint damage significantly decreased. Markers linked to JAK1-dependent signalling were also significantly impacted. Overall, together with the previously reported clinical efficacy of filgotinib, these results support that inhibition of JAK1 is sufficient to correct inflammation in RA patients, and may offer a treatment strategy that avoids side effects associated with inhibition of other JAKs.

4-Week Treatment of Rheumatoid Arthritis Patients with the JAK1-Selective Inhibitor Filgotinib (GLPG0634) Changes Lipid Profile with a Preferential Increase in HDL

René Galien[1], Pille Harrison[2], Reginald Brys[2], Annegret Van der Aa[2], Gerben van 't Klooster[2] and Chantal Tasset[2], [1]Galapagos SASU, Romainville,

France, [2]Galapagos NV, Mechelen, Belgium

Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Patients with active rheumatoid arthritis (RA) present low levels of lipids - total cholesterol (TC), low density lipoprotein-cholesterol (LDL-c), high density lipoprotein-cholesterol (HDL-c) and triglycerides (TG) - and yet are at a higher risk of cardiovascular disease. RA therapies may modulate lipid levels, presumably because of their anti-inflammatory effects, but some treatments preferentially increase LDL-c, thereby worsening the atherogenic index. We previously reported that 4-week treatment with the JAK1 selective inhibitor filgotinib (GLPG0634), showed a different profile with little effect on LDL-c and a dose-dependent increase in HDL-c. The current study further characterizes the lipid profile of RA patients after filgotinib treatment.

Methods:

RA patients (n=91) with insufficient response to MTX were randomized to receive placebo or 30, 75, 150 or 300 mg filgotinib once-daily orally for 4 weeks as add-on to MTX in a double-blind phase 2a study. Blood was sampled pre-dose and on the last day of treatment. Plasma PCSK9, ApoC-II, ApoC-III, SAA, and CETP concentrations were measured using ELISA kits. Plasma CETP and LCAT activities were determined using a commercial assay from Roar Biomedical. Plasma cholesterol (total and non-HDL-cholesterol), HDL-c, TG, ApoA-I and ApoB were measured using assays available from Diasys. CETP expression in white blood cells (WBC) was measured using qPCR.

Results:

HDL-c increased after treatment with 75, 150 and 300 mg of filgotinib, whereas TC and non-HDL-c increased in plasma only with 300mg dose, compared to baseline.

TREATMENT	TC	non-HDL-c	HDL-c	TC/HDL-c
PLACEBO	110 +/- 7	110 +/- 8	116 +/- 10	98 +/- 5
30 mg	126 +/- 16	131 +/- 20	107 +/- 5	119 +/- 14
75 mg	105 +/- 5	103 +/- 7	114 +/- 4 ***	93 +/- 4
150 mg	99 +/- 5	96 +/- 5	111 +/- 5 *	90 +/- 4 **
300mg	119 +/- 3 ***	113 +/- 3 ***	146 +/- 7 ***	85 +/- 5 ***

Percent change from baseline in biomarkers after 4 weeks of filgotinib treatment (Mean +/- SEM – T-test *: p<0.05; **: p<0.01; ***: p<0.001, compared to baseline)

TC/HDL-c ratio (atherogenic index) decreased after 4 weeks of filgotinib treatment . Plasma concentrations of ApoA-I, ApoB, ApoC-II and ApoC-III also indicated a preferential increase in HDL-c over LDL-c, with an increase in ApoA-I, ApoC-II and ApoC-III and no change in ApoB concentrations, resulting in a decrease in ApoB/ApoA-I ratio. CETP gene expression in circulating WBC as well as protein concentration and enzyme activity in plasma decreased after treatment. LCAT activity and paraoxonase-1 (PON-1) levels increased with filgotinib treatment. There was no change in plasma concentration of PCSK9.

Conclusion:

These early data show that 4 weeks of treatment with filgotinib changed the lipid profile in RA patients, with a preferential increase in HDL-c. As a consequence, the atherogenic index in RA patients improved with doses of 150 and 300 mg once daily. This correlated with changes in HDL-c proteins and enzymes involved in HDL-c homeostasis such as ApoA-1, PON-1, LCAT and CETP, but not in those linked to LDL-c (ApoB, PCSK9). Further longer-term studies are needed to confirm these findings and their cardiovascular relevance.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: We reported that nuclear factor of activated T-cells 5 (NFAT5), originally identified as an osmo-protective transcription factor, has a critical role in the pathogenesis of rheumatoid arthritis (RA). In the present study, we investigated to discover a small molecule to specifically inhibit pro-inflammatory activity of NFAT5.

Methods: We screened small molecules (>150,000) to effectively suppress biosynthesis of nitric oxide (NO), a sensitive end-product of NFAT5 in RAW 264.7 macrophages using high-throughput drug screening. Fluorescence-activated cell sorting (FACS) analysis was performed to confirm a direct NFAT5 inhibitory activity of the candidate chemicals using RAW 264.7 macrophages transfected stably with a novel NFAT5-specific GFP reporter under lipopolysaccharide (LPS) stimulation. Expression of NFAT5 and its target genes was confirmed by quantitative RT-PCR, western blot, ELSIA, and NO assay. *In vivo*effect was tested in adjuvant-induced arthritis (AIA) and collagen-induced arthritis (CIA) mice models.

Results: NFAT5 regulated the production of NO and IL-6 by RAW 264.7 macrophages under LPS stimulation. Among the screened small molecules, filtered were 198 candidate chemicals that strongly inhibited the NO production (IC50 < 1 μM). After testing direct NFAT5 inhibitory activity and *in vitro* cytotoxicity, KRN2 and its oral derivative with high serum stability (KRN5) were finally selected. These compounds did not affect NFAT1-4, NF-κB, p38 MAP kinase and CREB activity, excluding the potential off-target effect of the candidate molecules. We further found out the inhibitory mechanism of KRN2 in regulating NF-κB binding capacity on the NF-κB binding site in the promoter region of NFAT5. Interestingly, these compounds inhibited LPS-induced IL-6, TNF-α, GM-CSF, iNOS, nitric oxide production in RAW 264.7 macrophages, while they did not affect *AR* and *SMIT*mRNA expression involved in osmo-protection and cellular homeostasis. Effectively, KRN2 and KRN5 alleviated disease severity of arthritis and oral administration of KRN5 successfully prevented the development of arthritis in experimental mice models.

Conclusion: We identified selective inhibitors of NFAT5 (KRN2 and KRN5) that potently inhibited the production of pro-inflammatory mediators in macrophages and effectively suppressed the development of experimental arthritis. These compounds could be a good candidate for treating the chronic inflammatory arthritis.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Rheumatoid Arthritis - Small Molecules, Biologics and Gene Therapy Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

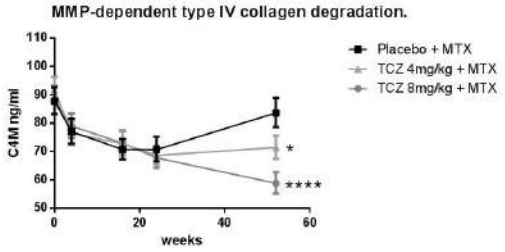
Background/Purpose: It is well documented that epithelium turnover is markedly increased in the affected joints of rheumatoid arthritis (RA). This causes disruption of the well organized supramolecular architectures of the basal lamina composed of a network of collagen IV and other components such as laminins, nidogens or perlecan. The aim of this study was to 1) investigate the circulating levels of MMP-degraded collagen type IV fragments in RA and 2) if TCZ may reduce the epithelial turnover of the RA pathogenesis.

Methods: The LITHE biomarker study (n =682) was a phase III double-blind, placebo (PBO)-controlled, parallel group study of 4- and 8-mg/kg TCZ in combination with methotrexate (MTX). The biomarker C4M, a competitive ELISA assay evaluating fragments of type IV collagen, was tested in serum from baseline and week 4, 16, 24, and 52. A dose-dependent effect was investigated and the differences between groups were evaluated by Mann-Whitney test. Early response was evaluated at week 16 as 7-20% improvement in swollen/tender joint counts; and ACR50 was evaluated at week 52.

Results: All of the 3 patient groups experienced a decrease of C4M from baseline to week 16 of roughly 20%. At this point there were no significant differences between the C4M levels of the placebo group compared to treatment groups. This level seemed to be stabile from week 16-24 for all of the 3

groups. Interestingly, from week 24-52 C4M in the placebo group significantly increased ($p<0.0001$) from a geometric mean of 70.7ng/ml to 83.6ng/ml. The C4M level of the patient group receiving TCZ 4mg/kg was steady with a geometric mean of 68.6 at week 24 and 71.4 at week 52. Patients in the TCZ 8mg/kg had a significant decrease ($p=0.0017$) from a geometric mean of 67.8 to 58.8 from week 24-52.There was a significant difference in C4M level between placebo and treatment groups at week 52 ($p<0.05$).

Conclusion: The differences of C4M between the 3 treatment groups at week 52, indicate a dose-dependent reduction of epithelial degradation as an effect of treatment over time. Furthermore, the decrease of C4M from baseline to week 16 in all of the 3 treatment groups, suggests that MTX has an additional effect on top of that of TCZ.



Evaluation of biomarker levels at baseline, week 4, 16, 24 and 52. Differences between Placebo and TCZ 4mg/kg or TCZ 8mg/kg were evaluated by mean of Mann-Whitney tests. *$p<0.05$, ** $p<0.01$, ***$p<0.001$, ****$p<0.0001$. *Error bars are illustrated as geometric mean + 95% CI.*

Session Date: Monday, November 9, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

In psoriatic arthritis (PsA), misdirected inflammation and therapeutic use of immunosuppressants causes global immune compromise. Similar immunocompromised states, as in rheumatoid arthritis and psoriasis patients, have resulted in an increased risk of malignancy. The aim of our study was to compare the development of malignancy in patients with PsA to comparators without PsA.

Methods:

A geographically well-defined population based cohort of 217 patients diagnosed with PsA was identified by individual medical record review. Cases were classified according to the ClASsification Criteria for Psoriatic ARthritis (CASPAR) criteria. Medical records of 217 PsA cases and a comparison cohort of 271 age and sex matched subjects from the same source population were evaluated retrospectively for cancer occurrence. Patients in both cohorts were followed until death, migration from the geographic area or 12/31/2014. Malignancy information was retrieved from the institutional Cancer Registry data to determine prevalence of most major malignancy types. Information concerning non-melanoma skin cancer incidence was collected manually. Cumulative incidence of malignancy adjusted for competing risk of death was used for malignancy incidence analysis. Cohort comparisons were performed using Gray's test.

Results:

The PsA and non-PsA cohorts (mean age at incidence/index date: 44.0 [SD: 14.2] years; 60% male in both cohorts) were followed on average 15.3 (SD 9.4) and 15.9 (SD 8.6) years, respectively. Prior to PsA incidence/index date, 8 patients with PsA and 15 non-PsA subjects had malignancies ($p=0.20$). During

follow-up, a total of 28 malignancies were detected in the patients with PsA (cumulative incidence at 10 years after PsA incidence: 9.3% [SE 2.2%}), and 41 malignancies were diagnosed in the comparator subjects, representing no statistical difference in malignancy incidence (cumulative incidence at 10 years after index date: 9.4% [SE 2.2%], p=0.21). The relative risk of most individual malignancies was not statistically increased in the PsA cohort compared to the non-PsA cohort. There were more non-melanoma skin cancers in the PsA cohort (n=23 compared to 14 in the comparator cohort) although the difference did not reaching statistical significance (p= 0.09).

Conclusion:

The risk of cancer in this population based cohort of patients with PsA is not increased compared to the general population. This finding is consistent with several other studies employing other methodologies. There were numerically more non-melanoma skin cancers in the PsA cohort, which may be related to the generally increased risk of these cancers seen in psoriasis. We suggest that patients with PsA should be routinely screened for occurrence of these skin cancers.

Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is present in about 30% of cutaneous psoriasis (PsO) patients. Both PsO and PsA are frequently associated to comorbidities that have important implications in the global approach of the psoriatic disease. In PsO, metabolic syndrome (MetS) is associated with disease severity and in PsA the relationship with MetS is likely linked to the underlying chronic inflammatory process. Although MetS is common in PsA, there are no data regarding its prevalence and association with disease activity in brazilian patients. Therefore our objectives were to evaluate the prevalence of MetS, associated comorbidities and correlate findings with some parameters of disease activity in a cohort of Brazilian patients with PsA from a single tertiary center.

Methods: One hundred and one PsA patients regularly followed-up at our outpatient rheumatology clinic during the period of October 2013 to April 2014 were evaluated. All patients were assessed for obesity by measurement of body mass index, functional impairment by HAQ, physical activity practice and the presence of comorbidities including arterial hypertension, diabetes, dyslipidemia, MetS and non-alcoholic fatty liver disease (NAFLD) by abdominal ultrasound. The NCEP-ACT III criteria were used to identify subjects with MetS while DAS 28, BASDAI and ASDAS to evaluate PsA disease activity. Student's t-test, Chi-square and Fisher's exact tests were performed for statistical analyses and P values ≤ 0.05 were considered significant.

Results: Gender proportion was similar with 49 males (48.5%) and 52 females (51.5%), mean age = 54.8+-13yrs (range 26-85yrs) and mean disease duration = 14.4+-8.1yrs (range 04-44yrs). Only 25% PsA patients had normal weight and 75% were overweight. The majority were sedentary (74%), in one third of them (28%) due to joint pain though not associated to worse HAQ score (p=0.7). Half patients (50/101=49.5%) had MetS, with comparable frequencies in both genders and regardless of types of cutaneous PsO involvement. Overall prevalence of arterial hypertension was 49%, dyslipidemia 58%, diabetes 22%, obesity 31% and NAFLD 62%, significantly higher in patients with MetS in comparison to those without MetS (76%vs.23%; 68%vs.27%; 40%vs.4%; 52%vs.9%; 83%vs.22% respectively) (p=0.001). Interestingly, the prevalence of MetS was lower in axial PsA subjects compared to those without axial manifestation (28%vs.49%, p=0.03), and no difference was observed among other PsA subtypes (p>0.05). Further analysis of patients with vs. without MetS revealed that those with MetS used less non-steroidal anti-inflammatory drugs (NSAIDs) (52%vs.74%, p= 0.019), less leflunomide (6%vs.20%, p=0.041) and had higher DAS 28 scores (3.1vs.2.8, p=0.025). Mean HAQ scores were for patients with and without MetS [(0.8 (0.5-2.3) vs. 1(0-3)p=0.4]

Conclusion: The considerable prevalence of MetS in patients with PsA associated to peripheral joint disease activity strengthens a common inflammatory pathway for both conditions. Early disease management including specific therapy allied to lifestyle changes and weight loss, not only to reduce comorbidities, but also to improve disease control, is mandatory.

Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

To evaluate the clinical courses and associated factors of hip arthritis in patients with ankylosing spondylitis (AS).

Methods:

In this retrospective analysis, we evaluated 488 AS patients at a single tertiary hospital. Among the patients with hip arthritis in AS, radiographic hip arthritis was assessed using the Bath Ankylosing Spondylitis Radiology Hip Index (BASRI-h), and the average of the hip joint space width (interbone distance) at three distinct sites between the acetabulum and femoral head was recorded at baseline and the last visit at the outpatient clinic.

Results:

Among 488 patients with AS, 60 (12.3%) patients had hip arthritis. Body mass index (BMI) and erythrocyte sedimentation rate (ESR) were associated with hip involvement (OR 1.11, 95% CI 1.03 to 1.20, p = 0.005 and OR 1.01, 95% CI 1.00 to 1.02, p = 0.004, respectively). Long disease duration and advanced axial disease were associated with severe hip involvement (3≥BASRI-h) at baseline. BASRI-h and interbone distance did not change significantly in patients with hip involvement during the follow-up period of 81.4 ± 35.7 months. Five patients had hip joint replacement surgery during follow-up period. The BMI and initial BASRI-h were associated with joint replacement surgery (OR 1.29, 95% CI 1.01 to 1.65, p = 0.044 and OR 4.90, 95% CI 1.05 to 22.78, p = 0.043, respectively).

Conclusion:

Most of the patients with hip arthritis in AS showed no significant radiographic progression during the follow-up period. BMI was associated with hip arthritis in patients with AS.

Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The aim of this study was to investigate carotid intima-media thickness (IMT) in patients with psoriatic arthritis (PsA) and compare it with those in patients with systemic lupus erythematosus (SLE) and healthy controls (HC).

Patients and Methods: Non-diabetic patients with PsA and age and body mass index (BMI) matched patients with SLE were included. Bilateral carotid IMTs were evaluated by using B-mode ultrasonography in PsA patients and compared with those in controls.

Results: There were 42 PsA patients (30 female, 12 male; mean age: 45.36 ± 8.9 years) who fulfilled CASPAR criteria and 38 patients (37 female, 1 male; 41.2± 13.0 years) who fulfilled the 1982 revised ACR criteria for SLE. Thirthy healthy hospital workers (27 female, 3 male; mean age 41.2 ± 6.8 years) were recruited as HC. The frequency of hiperlipidemia was found to be significantly higher in patients with PsA than SLE patients and HC ($p<0.001$) but hypertension was more common in SLE patients ($p=0.002$). The averaged carotid IMT was found to be higher in PsA patients in comparison with the SLE patients and HC ($p<0.001$).

Conclusion: This study showed that carotid IMT measurements were higher in PsA patients than SLE patients and HC.

Table 1. B-mode ultrasonography results in the study subjects

	Averaged CCA IMT (mm)	Right CCA IMT (mm)	Left CCA IMT (mm)
PsA patients (n:42)	0.76 ± 0.15*	0.72 ± 0.12*	0.79 ± 0.18*
SLE patients (n:38)	0.58 ± 0.11	0.56 ± 0.12	0.60 ± 0.12
Healthy controls (n:30)	0.57 ± 0.12	0.55 ± 0.12	0.59 ± 0.15

Data are mean ± SD (*$p<0.001$ for PsA patients vs SLE patients and healthy controls). CCA: common carotid artery

Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: In the last two decades, tumor necrosis factor alpha (TNFα) inhibitors have been approved for use, and recommended as part of clinical treatment guidelines for people with ankylosing spondylitis (AS) who fail non-steroidal anti-inflammatory drugs and physiotherapy. Contemporary data on US hospitalization rates, costs and length of stay in the TNFα era have not been examined. We sought to determine rates of hospitalization, length of stay and hospitalization costs for patients with AS over the past two decades.

Methods: Using the Nationwide Inpatient Sample (NIS), we evaluated trends in hospitalizations for AS between 1993 and 2012. We describe rates of hospitalization and hospital charges among US residents hospitalized with a principal diagnosis of AS using ICD-9 codes from the NIS. Analyses were performed using NIS sampling weights to obtain US national estimates.

Results: Rates of hospitalization for AS as a principal diagnosis decreased from 0.4/100,000 to 0.2/100,000 over the study period, and mean length of stay also decreased from 8.9 days to 5.7 days (**Table** and **Figure**). However, mean hospitalization charges increased from $40,855 to $94,047, after adjustment for inflation to 2012 US dollars using the Consumer Price Index. The numbers of in-hospital deaths were too low for meaningful comparisons over time.

Conclusion: Rates of hospitalizations for AS and mean length of stay has decreased in AS, providing a benchmark for the perceived improvement in AS care, which may be related to use of biologics. However, hospitalization charges for AS have more than doubled from 1993 to 2012. The reasons for the drastic increase in hospitalization charges warrant further investigation.

Table. Hospitalization rates, mean length of stay and mean hospitalization charges for US residents hospitalized with a principal diagnosis of ankylosing spondylitis between 1993 and 2013 in the Nationwide Inpatient Sample.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

To study the effect of the presence of fibromyalgia (FMS) on common clinical disease activity indices in patients with psoriatic arthritis (PsA).

Methods:

Seventy –three consecutive outpatients with PsA (mean age 51.7 years old;

42 females, 57.5 %) were enrolled in a prospective cross-sectional study.

Patients were evaluated for the presence of fibromyalgia according to the ACR criteria. In parallel, they all underwent a clinical evaluation of diseases activity as well as application of patient reported outcomes questionnaires including HAQ, BASDAI, and DLQI. Disease activity was evaluated using the Composite Psoriatic Disease Activity Index (CPDAI), Minimal Disease Activity (MDA) and Disease Activity index for Psoriatic Arthritis (DAPSA) scores.

Results:

The overall prevalence of FMS was 17.8% (13 patients), with a significant higher prevalence of female gender (12 patients, 92.3%, P = 0.005). CPDAI and DAPSA scores were significantly higher in patients with PsA and FMS (9.23 ± 1.92; 27.53 ± 19.23) than in patients with PsA alone (4.25 ± 3.14; 12.82 ± 12.71; P < 0.001; P = 0.003). None of the patients with FMS complied with the criteria of MDA, whereas twenty-six PsA-only patients complied with it (43.3%, P = 0.003). HAQ, BASDAI and LEI scores were significantly worse in patients with PsA and associated FMS (Table 1).

Conclusion:

FMS is related to worse scores on the CPDAI, DAPSA, MDA, HAQ, BASDAI and LEI in patients with PsA. The presence of FMS distorts our clinical understanding of the abovementioned indices, thus, it should be taken into consideration in the treatment algorithm in order to avoid unnecessary upgrading of treatment.

Table 1.

Indices	PsA (n = 60)	PsA and FMS (n = 13, 17.8%)	Pv
CPDAI ± SD	4.25 ± 3.14	9.23 ± 1.92	< 0.001
DAPSA ± SD	12.82 ± 12.7	27.53 ± 19.23	0.003
MDA (%)	26 (43.3%)	0	0.003
HAQ median	0.25 (0-1)	1.75 (1.07-2.37)	<0.001
BASDAI±SD	2.87± 2.35	7.18±1.73	<0.001
LEI median	0 (0-1)	3 (2-4)	<0.001
PASI	2.1 (0-1)	3 (2-4)	0.22

Fibromyalgia in Spondyloarthritis: Impact on Disease Activity Assessment

Jean Wach, Marie-Claude Letroublon and **Jacques G Tebib**, Rheumatology, Hospices Civils de Lyon, Centre Hospitalier Lyon-Sud, Pierre-Bénite, France
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Spondyloarthritis (SpA) is the second most frequent inflammatory rheumatic disease, which main manifestations are spinal pain and peripheral arthritis or enthesitis. Fibromyalgia (FM), a diffuse painful syndrome that may be associated with SpA, shares a number of common symptoms such as pain, fatigue and sleep disturbance. Still, its influence on SpA disease activity assessment, mainly dependant on patient-based outcome measures, has been poorly studied.

Methods:

This monocentric cross-sectional study included consecutive patients with SpA (according to the Assessment of SpondyloArthritis international Society (ASAS) classification criteria) from one of the authors clinics (JGT) between March 2010 and May 2011. FM was diagnosed according to the 1990 ACR

classification criteria. A controlled population of FM without SpA was included. Patients characteristics, BASDAI, ASDAS-CRP, BASFI, BASMI, SF-36 were compared.

Results:

The study included 103 SpA patients (table 1). Eighteen patients (17.5%) presented a concomitant FM, including 12 out of 81 axial SpA (14.8%) and 6 out of 22 peripheral SpA (27.3%). Demographics were not different except for sex, with a female predominance in FM group (66.7% VS 29.4%; p=0.0056), more important in peripheral forms (100% VS 43.7%; p=0.0461). In the whole population, BASDAI was higher in FM patients, whereas ASDAS-CRP was not significantly different (table 2). Still, median ASDAS-CRP corresponded to high disease activity in SpA-FM patients compared to moderate activity in non-FM patients. In the axial SpA subgroup, there was no difference in the functional index BASFI (median (IQR): axial SpA-FM (n=10) 1.4 (2.7); axial SpA without FM (n=65) 0.9 (2.5); p=0.2921) and in the metrological index BASMI (median (IQR): axial SpA-FM (n=12) 1.5 (1.8); axial SpA without FM (n=64) 1.5 (3.8); p=0.3526). Number of painful joints was higher in SpA-FM patients (n=102; median (IQR): 2.8 (4.5) VS 0 (1); p<0.0001) while number of swelling joints was not. Quality of life assessed by SF-36 was not different between non-FM (n=82) and FM patients (n=15), except for the health concept "physical health" which was lower in SpA-FM patients (median (IQR): 70 (45) VS 85 (25); p=0.0156). Comparison of the 18 SpA-FM with 18 FM control patients showed no difference in demographic characteristics, BASDAI or ASDAS-CRP.

Conclusion:

FM is frequently associated with SpA, especially in peripheral forms. Disease activity measured by BASDAI and to a lesser extent ASDAS-CRP may be overestimated in SpA-FM patients and then could lead to inappropriate treatment escalation.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Fibromyalgia (FM) can be present concomitantly in patients with Ankylosing Spondylitis (AS). It may overestimate the evaluation of disease activity, resulting in more intensive treatment. The Objective of this study was to evaluate the influence of the concomitant presence of FM in the evaluation of patients with AS.

Methods:

Consecutive patients with AS (1984 New York criteria), were included. The presence of concomitant FM was assessed by both 1990 and 2010 ACR criteria. Data regarding sociodemographic characteristics (age, sex), disease duration, treatment, disease activity (BASDAI, ASDAS-ESR, SASDAS, global patient VAS), funcional capacity (BASFI), quality of life (ASQoL), enthesitis (MASES), tender and swollen 44/46 joint count, CRP and ESR, Fibromyalgia Impact Questionnaire (FIQ) was assessed. Categorical data was expressed in frequency and percentage and compared by chi2 or Fisher exact test, continuous data was expressed as median and interquartile range (IQR), and compared by Mann-Whitney-U-Test or Student's T-Test. Multivariate analysis was performed taking activity indexes as dependent variables, adjusting for confounders. A $p < 0.05$ value was considered as significant.

Results:

50 patients were included, 44 (88%) male, median age 40 years (IQR 31-52), disease duration 9.1 years (IQR 2-20), 40 (80%) were treated with NSAIDs, 21 (42%) with TNF alpha blockers. Median BASDAI, ASDAS-ESR and SASDAS were 5.2 (IQR 1.8-6.9), 2.4 (IQR 1.7-3.6) and 19.4 (IQR 6.9-29.1) respectively. FM was present in 12 patients (24%), 7 (14%) and 6 (12%) fulfilled 2010 and 1990 criteria respectively, leaving only one patient overlapping both criteria. In the univariate analysis patients with FM had significantly higher values of disease activity scores, BASFI, ASQoL, FIQ, MASES, tender joints, patient's VAS, number of fibrositic points, but similar ESR, CPR and swollen joint count. All the patients with FM were at the high or very high activity groups according to ASDAS-ESR / SASDAS. In the multivariate analysis, the presence of FM remained significantly associated with higher MASES and poorer ASQoL, but had lost influence in disease activity indexes (BASDAI, ASDAS-ESR nor SADAS).

Conclusion:

In our cohort of patients with AS enthesis evaluation by MASES and quality of life were significantly influenced by the presence of FM, but it had no impact on disease activity assessment. In the evaluation of the enthesis it should be taken in account the coexistence of FM and AS in order to use more specific tools to evaluate them.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: To describe the rates of serious infections in psoriasis patients with psoriatic arthritis(PsA) from PSOLAR.

Methods: PSOLAR is an international, disease-based, observational study in which patients eligible for, or receiving conventional systemic and biologic agents for the treatment of psoriasis are followed prospectively. The characteristics and cumulative incidence rates of serious infections, occurring within 91 days of biologic administration, for patients who reported PsA,including a subset with PsA confirmed by a joint-specialist are summarized. Cohorts were defined as and attribution was based on treatment exposure in the following order (regardless of sequence and duration): (1) ustekinumab(UST) (2) other sponsor biologic (primarily infliximab[IFX]) (3) non-sponsor biologic (primarily adalimumab/etanercept[ADA/ETN]), and (4) non-biologic therapies(NB) (including immunodulators [eg MTX, cyclosporine], phototherapy, and topical therapy). Exposure to any therapy higher in the order precluded inclusion in the lower cohorts. Multivariate analyses using Cox hazard regression were used to identify predictors of time to first serious infection (using exposure within 91 days for biologics [compared to no biologic use] and for immunomodulators [compared to no immunomodulator use]).

Results: As of Aug 23, 2014, PSOLAR was fully enrolled with 12093 patients (40388 total patient-years [PY] of follow-up).Number of patients with reported PsA was overall 4316: 1489 UST, 776 IFX, 1680 ADA/ETN, 371 NB; of these patients, 1719 had confirmed PsA (664 UST, 356 IFX, 576 ADA/ETN, 123 NB). Baseline demographics and medical history were generally balanced across cohorts and were comparable to confirmed PsA subset; however, in overall PsA sub-group, more patients in NB cohort were >=65yrs of age(UST 9.9%, IFX 13.9%, ADA/ETN 12.5% , NB 25.6%)and had a medical history of cancer (UST 3.3%, IFX 3.5%, ADA/ETN 3.9%, NB 8.4%).In the overall PsA subgroup (15 029 PY of follow-up), rates of serious infections per 100 PY were: UST 1.12, IFX 3.36, ADA/ETN 2.49, and NB 2.20. Among the confirmed PsA subset, rates per 100 PY were: UST 1.06, IFX 2.83, ADA/ETN 2.58, NB 1.63. In the overall PsA sub-group, increasing age, male gender, current/prior smoking, history of significant infection, diabetes, and use of biologics (other than UST as a combined group) were associated with increased risk for serious infection; no increased risk was observed with UST and immunomodulators. In patients with confirmed PsA, diabetes, history of significant infection, more severe skin psoriasis, and use of biologics other than UST (as a combined group) were significantly associated with increased infection risk; UST and immunomodulators were not associated. Inherent bias with respect to observational data may apply. Variability in size and clinical features was noted among treatment groups.Incidence rates are not adjusted for differences. Individual biologics beyond UST were not evaluated individually in statistical analyses.

Conclusion: Results suggest a higher risk of serious infections with biologics (as a combined group), other than UST, in comparison with no biologic usage; increased risk was not observed with UST or immunomodulators.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Ankylosing spondylitis (AS) is associated with increased risk of concomitant cardiac disease, such as valvular regurgitation, conduction disturbances and decreased ventricular function (1). However, contemporary data are not available. Therefore, we investigated the prevalence of cardiac manifestations in AS patients between 50 and 75 years old.

Methods:

We performed a cross sectional study in randomly selected AS patients between 50 and 75 years old. Patients were screened for cardiac disease using standard transthoracic echocardiography (TTE) that included two-dimensional, three-dimensional and M-mode echocardiography, spectral Doppler, color Doppler and tissue Doppler imaging. Systolic left ventricular (LV) dysfunction was defined as an ejection fraction <50%. Diastolic LV dysfunction (DD) was graded into three categories: mild (grade I), pseudonormal (grade II) and restrictive (grade III). Valvular parameters and aortic diameters were evaluated according to the current echocardiographic guidelines.

Results:

One-hundred-ten AS patients (27 females, 25%) with a mean age of 60±7 years and a mean disease duration of 21±12 years were included. 24 patients (22%) had a history of CV disease, including stroke (n=2), myocardial infarction (n=4), rhythm disorders (n=8), other (n=4) or a combination (n=6).

Seven patients (6%) had systolic LV dysfunction. Of 107 patients diastolic LV function could be determined: 32% had DD grade I, 19% DD grade II and 0% DD grade III.

In patients without a history of CV disease, a new cardiac abnormality was found on TTE in 20 (18%) which required treatment or follow-up by a cardiologist: ventricular dysfunction (n=3), aortic (root) dilatation (n=10), valvular regurgitation (n=5), rhythm disorders (n=1), or a combination (n=1).

Conclusion:

In patients with a long duration of AS without a history of cardiac disease or symptoms, there is a high prevalence of cardiac manifestations, with high prevalences of LV dysfunction, valvular disease and aortic (root) dilatation. This high prevalence might ultimately translate into increased CV morbidity and mortality. The potential clinical impact and effect on CV mortality remains to be determined.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Describe characteristics and incidence rates of all-cause mortality and malignancies (excluding NMSC) in psoriasis pts with psoriatic arthritis (PsA) from PSOLAR.

Methods: PSOLAR is an international, disease-based, observational study in which pts eligible for, or receiving conventional systemic and biologic agents for psoriasis are followed prospectively. Characteristics and safety for pts who reported PsA, including a narrower subset with PsA confirmed by a joint-specialist,are summarized. Cohorts were defined as and attribution was based on treatment exposure prior to/during registry, in the following order (regardless of sequence and duration): (1)ustekinumab(UST) (2)other sponsor biologic(primarily infliximab[IFX]) (3)non-sponsor biologic(primarily adalimumab/etanercept [ADA/ETN]), and (4)non-biologic therapies(NB) (including immunomodulators [eg.MTX, CsA], phototherapy, and topical therapy). Exposure to any therapy higher in the order precluded inclusion in the lower cohorts. Multivariate analyses using Cox hazard regression were used to identify predictors of time to first malignancy and mortality [compared to no biologic use] and for immunomodulators [compared to no immunomodulator use].

Results: As of Aug 23, 2014,PSOLAR is fully enrolled with 12093 pts (40388 total pt-years [PY] of follow-up). Number of pts with reported PsA overall was 4316: 1489 UST, 776 IFX, 1680 ADA/ETN, 371 NB; of these pts, 1719 had confirmed PsA (664 UST, 356 IFX, 576 ADA/ETN, 123 NB). Baseline demographics and medical history were generally balanced across cohorts; however, in overall PsA sub-group, more pts in the NB cohort were >=65yrs of age (UST 9.9%, IFX 13.9%, ADA/ETN 12.5%, NB 25.6%) and had a medical history of cancer (UST 3.3%, IFX 3.5%, ADA/ETN 3.9%, NB 8.4%). In the overall PsA subgroup, cumulative incidence rates per 100PY for all-cause mortality were UST 0.28, IFX 0.30, ADA/ETN 0.52, NB 0.70; age, obesity, history of cardiovascular disease(CVD), history of diabetes and smoking were predictors of time to mortality. Cumulative incidence rates per 100PY for malignancy were UST 0.57, IFX 0.67, ADA/ETN 0.64, and NB 1.01; age and history of malignancy were predictors of time to first malignancy. Biologic and immunomodulator use were not predictors for mortality or malignancy. Among the confirmed PsA subset, cumulative incidence rates per 100PY for all-cause mortality UST 0.21, IFX 0.36, ADA/ETN 0.38, NB 0.25 and for malignancy UST 0.52, IFX 0.54, ADA/ETN 1.02, NB 1.25. Inherent bias with observational data may apply. Variability in size and clinical features was noted among groups. Incidence rates are not adjusted for differences(adjustment for key factors are included in statistical analyses). Small numbers of pts in the confirmed PsA subset precluded assessment of risk factors.

Conclusion: Unadjusted rates of all-cause mortality and malignancies for biologics were generally comparable among both PsA subsets. Advanced age, history of malignancy were predictors of time to first malignancy and age, obesity, CVD history, diabetes history and smoking were predictors for time to mortality based on overall PsA subset; biologics and immunomodulators were not predictors for mortality or malignancy.

Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Fatigue is one of the essential patient reported outcome almost all inflammatory rheumatic diseases. However, fatigue may be affected from multidimensional factors such as psychological (i.e. depression), physiologic (i.e. anemia) or both. In the clinical practice, active fatigue state may be proceed during remission according to other measures. Objective of this study was to assess frequency of active fatigue level at spondyloarthritis patients during ASAS partial remission.

Methods: Hacettepe University Rheumatology Biologic Registry (HUR-BIO) is a single center biological registry since 2005. HUR-BIO includes 933 ankylosing spondylitis (AS) and 143 axial spondyloarthritis (AxSpA) patients under anti-TNF drugs. After September 2012, we regularly collected outcome measures such as Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), BASDAI 2, 5 and 6. questions, Bath Ankylosing Spondylitis Functional Index (BASFI), CRP, 100mm visual analog scales (VAS) for patient global assessment (PtGA), fatigue and pain every 6 months. Assessment of SpondyloArthritis International Society (ASAS) partial remission was defined as less than 20/100 mm of BASFI, back pain, morning stiffness and PtGA. Active fatigue level was defined as more than 40/100 mm.

Results: Overall, 716 patients (602 AS and 114 AxSpA) were assessed between September 2012 and January 2015 and 452 (63.1%) of patients were male. Mean age was 40.3±11.3 years old, mean disease duration was 8.9±7.1 years and mean symptom duration was 13.2±8.8 years. Initial biological drugs were etanercept 249 (34.8%), infliximab 208 (29.1%), adalimumab 197 (27.5%) and golimumab 62 (8.6%). Fatigue assessed at 1762 times from 716 patients over time. Active fatigue level detected at 663 of those 1762 (37.6%) visits. During this period, ASAS partial remission was detected 489 of 1697 assessment (28.8%). Active fatigue level found 30 of those 489 (6.1%) patients who were ASAS partial remission.

Conclusion: In the routine practice, active fatigue level present at about 38% of spondyloarthritis patients despite biological treatment. Almost six percent of patients with ASAS partial remission were still active fatigue levels. Unfortunately, we did not evaluate possible causes of fatigue other than rheumatic diseases. Comprehensive psychologic and physiologic evaluation should be performed in these certain part of spondyloarthritis patients. Physicians should be keep in mind that fatigue may be continue otherwise clinical remission.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: SCORE tables underestimate the Cardiovascular Risk (CVR) for patients with Rheumatoid Arthritis (RA) and EULAR recommends multiplying by 1.5 the CVR obtained from them in RA patients. A concern exists that CVR in Psoriatic Arthritis (PsA) might be underestimated. Several studies show that the carotid intima-media thickness (CIMT) and the presence of cholesterol plaques (CP) detected with Ultrasound (US) are significantly associated with CVR. Our objectives were to assess the CVR profile in PsA patients using the SCORE/European recommendations and to study the presence of subclinical CV disease by US techniques. **Methods:** Ongoing transversal descriptive study of PsA patients from a Rheumatology Unit. Variables: Age, gender, psoriasis and PsA duration, PsA type and therapy; classic CVR factors (BMI, hypertension, dyslipidaemia, smoking, diabetes); prevalent personal and familiar CV events (coronary, cerebrovascular and thromboembolic events, sudden death). The probability of fatal atherosclerotic CV events over a 10 year period was calculated (Spanish SCORE chart/European recommendations). Then all patients underwent bilateral US carotid study (GE LOGIQ S7 Expert US Equipment). The common CIMT (average and maximum) measured in both common carotids using an automatized lecture of the distal intima-media wall in a surface of 1.39 cm or 300 points, 1 cm caudal to the carotid bulb. Plaques defined according to the Mannheim consensus. Statistical analysis: Descriptive, univariate (t-Test and Chi2) and multivariate analyses (ANOVA) were performed. **Results:** 72 PsA patients were included: mean age 57±11.2 years (53% male). 3 patients had a prevalent CV event. Clinical characteristics summarized in Table 1. Risk levels before/after the US study summarized in table 2. In the US study, 25 patients had pathological IMT thickness or atheroma plaques (35.21%), The final CVR was upgraded due to the US in 23 patients (31.9%). Patients with peripheral PsA had significantly higher CIMT than the other forms of PsA (p=0.03). None of the other variables were associated with CIMT nor with the presence of plaques. A positive association between HBP and CIMT was found (p=0.001, CI 95% -0.19,-0.05) on multivariate analyses. The 3 patients with CV events had significantly higher CIMT (p=0.08, CI 95%= -0.31, -0.09) and all had plaques (p=0.04). **Conclusion:** In this sample, a substantial proportion of patients with PsA are at a very high risk of a fatal CV event. The SCORE/European classification seems to underestimate the CV risk, as 31.9% of the patients were upgraded to a higher risk after the US study.

Obstructive Sleep Apnea and Fatigue in Inflammatory Arthritis Patients Taking TNF-Inhibitors

Brian Breviu[1], Tawnie Braaten[1], Daniel Clegg[2] and Jessica Walsh[3], [1]Department of Internal Medicine, Salt Lake City Veteran Affairs and University of Utah Medical Centers, Salt Lake City, UT, [2]Rheumatology, Salt Lake City Veteran Affairs and University of Utah Medical Centers, Salt Lake City, UT, [3]Rheumatology, Salt Lake City Veterans Affairs, Salt Lake City, UT

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Fatigue improves with TNF-inhibition (TNF-i) in people with inflammatory arthritis (IA), but the mechanistic relationships between TNF-i and fatigue are not well understood. Since Obstructive Sleep Apnea (OSA) is a common cause of fatigue in IA patients and TNF-i alters inflammatory pathways that contribute to both IA and OSA, we hypothesized that TNF-i would improve fatigue by altering OSA. Our aim was to explore the relationship between TNF-i, OSA, and fatigue in IA patients.

Methods: Consecutive rheumatology clinic patients who anticipated starting a TNF-inhibitor for IA were screened for OSA with the STOP-Bang questionnaire. Participants with positive screens completed questionnaires and a 2-night ApneaLink home sleep study, before TNF-i and again 2 to 3 weeks after their first dose. Sleep studies were analyzed by both an automated ApneaLink scoring system and a sleep specialist. OSA parameters and fatigue were compared before and after initiation of TNF-i, with adjustment for change in arthritis severity (patient global assessment of arthritis). OSA was assessed with the Apnea Hypopnea Index (AHI) and percent time below 90% oxygen saturation (%time<90%). Fatigue was measured with the Functional Severity Scale (FSS) and Functional Outcome of Sleep Questionnaire (FOSQ).

Results: Eighteen participants completed the pre- and post-TNF-i sleep studies and questionnaires. The mean age was 54 years and 72% were male (Table 1). TNF-i was not associated with improvements in AHI or %time<90%, after adjustment for change in arthritis severity (Table 2). There were non-significant improvements in fatigue.

Conclusion: OSA parameters did not improve within 2-3 weeks of initiating TNF-i, suggesting that fatigue improvements were not driven by OSA changes. The limitations of this proof of concept study include the small sample size and the short time of TNF-i. Additional research is required to understand how TNF-i influences fatigue in IA patients.

Table 1: Baseline demographics and disease characteristics

Variables	Number or Mean (% or SD)
Male	13 (72.2)
Age	54.4 ± 14.5
Body Mass Index	30.6 ± 7.1
Inflammatory Arthritis Subtype	
Axial spondyloarthritis	4 (22.2)
Psoriatic Arthritis	10 (55.6)
Rheumatoid Arthritis	3 (16.7)
Enteropathic Arthritis	1 (5.6)
Alcohol Use	4 (22.2)
Sleep Medication Use*	6 (33.3)
TNF-inhibitor	
Etanercept	4 (22.2)
Adalimumab	10 (55.6)
Infliximab	4 (22.2)

*Sleep medications included trazodone, zolpidem, melatonin, alprazolam

Table 2: Obstructive sleep apnea parameters & fatigue before & after initiation of TNF-inhibition

	Before TNF-i (Mean ± SD)	2-3 weeks after TNF-i (Mean ± SD)	Unadjusted p value	Adjusted p value*
AHI	12.5 ± 8.5	13.1 ± 10.3	0.18	0.97
% time<90%	29.5 ± 30.2	35.4 ± 36.3	0.22	0.18
FSS**	43.1 ± 15.6	41.3 ± 13.5	0.40	0.08
FOSQ***	11.4± 3.8	11.8 ± 3.5	0.79	0.09

*Adjusted for change in patient global assessment of arthritis severity

**FSS= Fatigue Severity Scale: Higher values represent increased fatigue

***FOSQ = Functional Outcome of Sleep Questionnaire: Higher values represent decreased fatigue

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Patients with Ankylosing Spondylitis (AS) have previously been considered an otherwise healthy patient population. However, emerging evidence suggests AS is an independent risk factor for developing cardiovascular (CV) disease. Due to the predominantly young age of AS patients, screening for other traditional CV risk factors is often not performed. The AS Registry of Ireland (ASRI) was established in 2013. The objectives of ASRI are to provide descriptive epidemiological data on the AS population in Ireland and to establish a registry for potential future studies of genetics, aetiology and therapeutics. The purpose of this study was to evaluate the prevalence of traditional CV risk factors in a well characterised AS patient cohort.

Methods:

A standardised detailed clinical assessment is performed on each patient and entered in a web-based database. Disease activity is assessed by Bath AS Disease Activity Index (BASDAI), function by the Bath AS Functional Index (BASFI) and Health Assessment Questionnaire (HAQ) and quality of life by AS Quality of Life (ASQoL). Structured interviews provide patient-reported data, which include the presence of traditional CV risk factors, other comorbidities and employment status. Statistical analysis is performed using SPSS.

Results:

As of June 2015, 340 patients are enrolled in ASRI: 79.7% males, mean age 47.6 (SD 12.6). The mean disease duration is 21.6 years (SD 12), with an average delay to diagnosis of 8.9 years (SD 8.5). Mean BASDAI is 3.9 (SD 2.4), BASFI 3.8 (SD 2.6), HAQ 0.56 (SD 0.52) and ASQoL 6.27 (SD 5.4). 46.5% of the cohort is engaged in full-time employment. 44.2% of those who are unemployed or in part-time employment only, cite AS as the causative reason. Co-morbidities are listed in table 1, the most prevalent being hypertension (25.9%), hyperlipidaemia (20.9%), smoking (current smoker 27.4%; ex-smoker 32.1%) and depression (13.5%). Patients are significantly more likely to have a higher BASDAI if they are a smoker ($p<0.05$) or have depression ($P<0.001$), with a trend towards higher disease activity in those with hypertension ($p=0.06$). Higher BASFI scores are associated with hypertension, osteoporosis, diabetes and hyperlipidaemia ($p<0.05$). Peptic ulcer disease is associated with a trend towards higher BASDAI ($p=0.09$) and BASFI ($p=0.05$).

Conclusion:

Despite their relatively young age, there is a high prevalence of traditional CV risk factors in this patient cohort, in particular hypertension, hyperlipidaemia and smoking. The presence of co-morbidities is associated with higher disease activity and functional impairment in this patient cohort. With increasing focus on AS as an independent risk factor for CV disease, quality improvement initiatives are needed to improve the recognition of traditional CV risk factors among AS patients.

Table 1: Prevalence of comorbidities

Co-morbidity	Prevalence (%)
Ex-smoker	32.1
Current smoker	27.4
Hypertension	25.9
Hyperlipidaemia	20.9
Peptic ulcer disease	9.1
Osteoporosis	7.4
Diabetes mellitus	5.6
Ischaemic heart disease	3.2
Cancer	3.2
Cerebrovascular disease	1.8

Obesity and Pediatric Psoriatic Arthritis

Cynthia Manos[1], Timothy Brandon[2], Rui Xiao[3], Jon M. Burnham[4] and Pamela F. Weiss[1], [1]Rheumatology, Children's Hospital of Philadelphia, Philadelphia, PA, [2]Pediatrics, Children's Hospital of Philadelphia, Philadelphia, PA, [3]Department of Pediatrics, Division of Biostatistics, Children's Hospital of Philadelphia, Philadelphia, PA, [4]Pediatric Rheumatology, Children's Hospital of Philadelphia, Philadelphia, PA
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Studies in adults have shown a significant association between obesity and psoriatic arthritis. The association of obesity with pediatric psoriatic arthritis is unknown. We aimed to evaluate the prevalence of obesity in a pediatric psoriatic arthritis cohort.

Methods: We conducted a retrospective cross-sectional study of children with psoriatic arthritis evaluated at a single center between 6/2010 and 9/2014. The cohort consisted of children with an ICD-9-CM code of 696.0 "Psoriatic arthritis" given at diagnosis or a subsequent follow-up visit. Age- and sex-specific Z-scores for weight, height, and body mass index (BMI) were calculated based on the 2000 CDC Growth data. Overweight or obese was defined as a BMI greater than or equal to the 85th and 95thpercentile, respectively. Differences in clinical and demographic characteristics who were overweight and not overweight were assessed using Wilcoxon rank sum test, t-test or chi-squared test, as appropriate. The association of age, sex, active joint count, and presence of psoriasis with being overweight was tested using univariate logistic regression. The reference population consisted of 909 healthy participants recruited from general pediatric clinics in the surrounding community for multiple studies done by the Nutrition and Growth laboratory at our institution.

Results: During the study period 48 children with psoriatic arthritis were evaluated. 34 (71%) were female and 17 (35.4%) had a first-degree relative with psoriasis. 29 (60.4%) and 19 (39.6%) of children had psoriasis or dactylitis at diagnosis, respectively. 3 (6.3%) and 5 (10.4%) of the children with psoriatic arthritis were overweight or obese, respectively. Mean BMI z-scores for children with psoriatic arthritis and the reference group were 0.40 (SD 0.96) and 0.36 (SD 1.01), respectively. In comparison to the reference population the proportion of children with psoriatic arthritis who were overweight was not statistically different (0.30 versus 0.17; p=0.06). Comparison of demographics and clinical features between those children with psoriatic arthritis who were overweight and not overweight are shown in the Table. In univariate logistic regression, female sex was associated with significantly decreased odds of being overweight (Odds ratio: 0.17, 95% CI: 0.03 to 0.87). Age, disease duration, psoriasis, dactylitis, and active joint count at diagnosis were not significantly associated with being overweight.

Conclusion: 17% of our psoriatic arthritis cohort was overweight or obese. Female sex was associated with decreased odds of being overweight. The lack of association of obesity with pediatric psoriatic arthritis may be secondary to our limited sample size or may be reflective of true differences in pediatric and adult disease.

Table. Comparison of demographic and clinical features of children who were not overweight and those who were overweight or obese

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Accelerated atherosclerosis and increased cardiovascular morbidity and mortality have been associated with ankylosing spondylitis (AS). Noninvasive angiological methods have been developped to evaluate endothelial and vascular dysfunction which is correlated with future development of atherosclerosis. The objectives were to determinate the presence or not of a subclinical vascular dysfunction in AS and if treatments could have an effect on it. A systematic review was done.

Methods:

Studies evaluating subclinical atherosclerosis and vascular function in AS were identified using Pubmed, (Ovid, EMBASE). Search terms included "ankylosing spondylitis" AND (endothelial OR vascular OR intima media thickness (IMT) OR Flow mediated dilatation (FMD) OR pulse wave velocity (PWV) OR atherosclerosis). This identified 353 results after limiting to French and English. The final selection identified 29 articles.

Results:

Overall, 1529 AS patients were included representing 38 studies: 8 studies about endothelial function, 198 AS patients and 130 healthy control (HC); 20 studies about carotid IMT, 900 AS and 644 HC; 10 studies about arterial rigidity, 431 AS and 285 HC. In cross-sectional studies, 4/6 indicated endothelial dysfunction in AS versus HC, 9/18 indicated increased cIMT and 3/5 increased arterial rigidity. About ED, 3 open label studies noted positive effect of TNFα blockers and spironolactone on FMD and rosuvastatin improved FMD in a placebo controlled study after 24 weeks. TNFα blockers seems not to improve neither cIMT (2 studies) nor arterial rigidity (5 studies). Exercise alone has improved arterial rigidity in 15 patients after 12 weeks.

Conclusion:

Whereas early and accelerated atherosclerosis is patent in AS, presence of subclinical atherosclerotic lesions is controversial in the literature especially concerning cIMT and arterial stiffness. This is reinforced by the lack of TNF blockers efficacy. Conversely it seems that endothelial dysfunction is present and reversible after treatment with TNF blockers, statin and spironolactone. These results are consistent to treat AS patients with early effective treatment to prevent the risk of CV morbidity and mortality.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Total hip replacement (THR) surgery is a reliable therapeutic intervention for patients with severe hip involvement. The aim of our study was to determine the long term outcome and associated risk factors of THR in patients with Ankylosing Spondylitis (AS).

Methods: Patients ≥ 18 years with AxSpA diagnosis according to ASAS or NY criteria of ESPAXIA cohort were included. Demographic data, disease duration, comorbidities and current treatment were collected. Pain, patient global assessment (VAS), disease activity (BASDAI), functional capacity (BASFI), enthesitis (MASES), axial mobility (BASMI) and radiological damage (mSASSS) were assessed. THR data included: date of each total hip arthroplasty (right, left), surgery complications and revision. Actual hip pain by VAS and Steimbroker functional class (FC I-IV). Patients were asked to determine the level of pain previous to the surgery (VAS). Hips functional capacity was evaluated by Merle d´Aubigné and Postel method. Pelvis x rays were taken to determine: presence of periprosthesic osteolysis of the femoral and acetabular components, fracture, luxation and heterotopic ossification (HO) according to Brooker´s classification. Statistical analysis: T test, Mann Whitney, $Chi^2$and Fisher test. Multiple logistic regression analysis to explore risk factors associated to THR.

Results: 190 patients were evaluated and 25 (13,15%) underwent THR. 16 patients were included in the analysis (2 died and 7 lost follow-up). Nine (56,2%) had bilateral THR. Fifteen (93,8%) were male, median age of 45 years (IQR 35-44), median disease duration 28,5 years (IQR 18-35,2). 11 (68,8%) were *HLA-B27*positive . The median time of THR's evolution was 12,5 years (IQR 8.7-16.7). 25 prosthesis were evaluated (14 right y 11 left). 48% were cemented and 54% were non cemented. 3 (12%) prosthesis had surgery complications, 3 (12%) had revision surgery. A relief of pain was observed after THR surgery median pain (VAS) previous surgery 10 cm (IQR 9.7-10) vs 0 cm (IQR 0-1.2). There was also improvement after the surgery in FC: 6 (24%) class II, 16 (64%) class III y 3 (12%) class IV and at the moment of evaluation 15 (60%) class II y 10 (40%) class III. Merle d`Aubigné and Postel method median value 15,2 (IQR 13,5-17). We evaluated 22 THR x rays. 11 (50%) prosthesis had acetabular osteolysis, 3 (13,6%) subluxation and 1 peri-prosthesis fracture. 15/17 hips (88,2 %) had femoral osteolysis. 15 had heterotopic ossification, (4 grade I, 4 II, 6 III y 1 IV). THR was associated with longer disease duration (27,1 ± 10,6 vs 19,6 ± 13,4 years, p= 0,03), younger age at the beginning of symptoms (17,4 ±7,6 vs 26,2 ±11,9 years, p= 0,0001), minor MASES (0,6 ±1,2 vs 1,6 ±2,3 p= 0,007) and more frequency of biologic treatment (50% vs 23,6%, p=0,03). In the multivariate analysis, the only variable independently associated with THR was younger age at the beginning of symptoms [β 0,91 (IC95% 0,85-0,97) p=0,001].

Conclusion: A substantial relief in pain and improvement of functional capacity were seen in AS patients who underwent THR . Younger age at disease onset was the only predictor associated to THR.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriatic Arthritis (PsA) is an inflammatory arthritis affecting peripheral and axial joints in patients with psoriasis. The disease process in PsA comprises of complex bone involvement. A preliminary review of studies evaluating Osteoporosis in PsA provides inconsistent and conflicting results. The aim of this this study was to analyze Bone Mineral Density (BMD) in patients with (PsA), as well as to investigate its possible associations with measures of disease activity and functional capacity.

Methods: Consecutive Patients from PsA Clinic underwent BMD scan of spine L1-L4 and left Femoral Neck using Hologic Discovery A – 84248 model between March and May of 2015. BMD was expressed as g/cm2, Z-score and T-score. The percentage of patients with T-score ≤ -2.5 SD (WHO osteoporosis definition) and with Z-score ≤ -1.0 SD was calculated. Disease activity measures included: tender, swollen and damaged joint counts, patient and physician global assessment, presence of enthesitis, nail involvement and Psoriasis Area Severity Index (PASI) score. Laboratory tests included inflammatory markers ESR and CRP. Health Assessment Questionnaire (HAQ) and Short Form 36 Health Survey were used to assess functional status. Patients' clinical, laboratory and radiological data were extracted from PsA program computer database. Statistical analysis included descriptive statistics, linear regression models and logistic regression models controlling for age.

Results: Total of 61 patients [38 males (mean age 56.57 ± 10.19 years) and 23 females (mean age 53.95 ± 10.76)] years were studied. According to WHO definition, spinal osteoporosis was found in 3% of patients and femoral neck osteoporosis in 5% of patients. Spinal osteopenia was found in 28% of patients and femoral neck osteopenia in 39%.

Disease activity measures of the recruited patients [mean (SD) or proportion] at the time of BMD assessment included: tender joint count 3.8 (7.7), swollen joint count 0.7 (1.7), clinically damaged joint count 9.1 (12.3), patient global 2.6 (0.9), physician global 1.8 (0.7), presence of enthesitis 7 (12%), nail involvement 10 (16%), ESR 14.8 (10.8), CRP 5.2 (3.3), HAQ 0.5 (0.4), Short Form -36 PCS 39.5 (10.4) and Short Form-36 MCS 50.1(12.5).

None of the clinical or laboratory features were associated with bone density either using linear regression with bone density in g/cm^{2}measured by the BMD as outcome, or with logistic regression using low versus normal bone density as outcome.

Conclusion: In our cohort of PsA patients, prevalence of osteoporosis was not increased. BMD was not associated with disease activity or functional status.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Adipose tissue and adipokines are linked to inflammation. The relationship of obesity to rheumatologic disease activity is complex and recent studies demonstrate a connection (1-3). Our objective was to assess association of disease activity with obesity in rheumatoid arthritis (RA), ankylosing spondylitis (AS) and psoriatic arthritis (PsA) in a single center biological registry.

Methods: Hacettepe University Rheumatology Biological database is a single center registry, including 1015 RA, 814 AS and 203 PsA patients on biologics. Collected data include demographics, 28 tender/swollen joint counts, 100mm visual analog scale (VAS) for patient global assessment (PtGA), fatigue, pain, ESR, CRP, health assessment questionnaire (HAQ), Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankylosing Spondylitis Functional Index (BASFI), PsAID-12 and DAS-28. BMI was recorded before anti-TNF treatments. BMI≥30 was defined as obesity. We used the following cut-offs to dichotomize groups: DAS28>3.2, BASDAI>4, BASFI>4, PSAID>4, HAQ>0.5, SJC≥1, TJC≥1, for PtGA/BASDAI/BASFI/Fatigue/Pain>40 mm, ESR and CRP>ULN.

Results: There were 655 RA (79.1%F), 624 AS (33.5% F) and 161 PsA (65.8%F), patients. Mean(SD) age was 52.8 (12.5) 41.8 (11.4) and 44.8 (11.8) years. Mean(SD) disease duration was 11.5 (8.0), 10.1(7.5) and 10.3(7.3) years. In RA, AS and PsA mean(SD) BMI was 29.1 (5.9), 27.2 (5.4), 28.7 (6.1); and %BMI>30 were 40.2, 24.5 and 37.3. Disease activity groups by BMI categories are shown in Table.

Conclusion: In these cross sectional view, obese RA (DAS-28, all PROs, acute phase reactants) and PsA (BASDAI, PsAID, pain) patients had more active state, however obesity did not influence on activity of AS patients. Functional impairment of obese patients may be related mechanical effect of weight rather than disease activity. For each disease, different influence of BMI on disease activities need to assess at other biological registries.

Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Estimate the prevalence of Obesity (O) and Metabolic Syndrome (MS) in AxSpA and evaluate its association with sociodemographic and clinical variables.

Methods: We included patients ≥18 yrs diagnosed with AxSpA (ASAS criteria and/or NY criteria) belonging to ESPAXIA cohort. Socio-demographic data (age, sex, occupation, education), disease characteristics (disease duration, extra-articular manifestations, comorbidities, current treatment) and cardiovascular risk factors (smoking, hypertension, diabetes, dyslipidemia and sedentary) were collected. Physical examination was performed: height (cm), weight (Kg), abdominal circumference (cm), blood pressure (average of two measures), swollen joint count (44), enthesitis (MASES index). BMI was calculated. Patients were classified according to WHO in Normal: BMI 18.5-24.9; Overweight: BMI ≥25; and Obesity: BMI ≥30 (grade I: BMI 30-34.9, II: BMI 35-39.9 and III: BMI ≥40). The MS was evaluated according to NCEP ATP III and ALAD (Latin American Diabetes Association). Radiographs of cervical spine, lumbar spine and sacroiliac joints were evaluated by a blinded observer using mSASSS index (ICC ≥ 0.90). Glucose, lipid analysis, ESR and CRP were tested. All patients completed self-reported questionnaires BASDI, BASFI and ASQoL. *Statistical analysis:* Univariate and multivariate analysis were performed to evaluate association of MS and O with socio-demographic and clinical variables.

Results: 187 patients were included, 74.2% were male with median age of 45 yrs and median disease duration of 18.5 yrs. Median weight was 77.5 kg, median height 169 cm and median BMI was 26.67 (23.7-29.44). 33.7% had normal BMI, 42.8% overweight and 23.5% obesity (65% grade I, 20.5% grade II, 13.6% grade III). Obese patients had longer disease duration (24.5 ± 14.55 vs 16.8 ± 12.8 yrs, p=0.01), were older (51.7±13 7 vs 41.3±13.8 yrs, p=0.001), had worse functional capacity (BASFI 4.9±2.8 vs 3.5±2.5 p=0.02) and poorer quality of life (ASQoL 8.3±4.7 vs 3.5±2.5 p=0.02) compared to patients with normal BMI. In multivariate analysis adjusting for age and disease duration only male sex was associated with obesity. 117 patients had complete data to evaluate MS. 73.5% were male, with median disease duration of 19.5 yrs. 28 patients met criteria of MS by ATP III and 27 by ALAD. Patients with MS were older (55.7±9.6 vs 43.1±12 yrs, p=0.0001), had longer disease duration (24.6 ± 10.3 vs 18.5 ± 12.2 yrs, p = 0.01), higher frequency of cardiovascular complications (60.7% vs 34.8% p=0.02), hepatobiliary diseases (39.3% vs 19.1% p=0.04) and alcohol consumption (21.4% vs 5.6%, p=0.02). They also had higher radiological damage (mSASSS 42.9 ± 2.8 vs 23.1 ± 25.7 p=0.02), which remained significant after adjusting for disease duration. The presence of MS did not have influence on other disease variables.

Conclusion: 23.5% of our AxSpA patients were obese and 23% fullfilled MS criteria. Obesity was higher in men and those patients with MS had higher radiological damage.

Acute Anterior Uveitis in Ankylosing Spondylitis: Association with Inflammatory Bowel Disease and Psoriasis Independent of HLA-B27

Ahmed Omar[1], Tristan Boyd[2], Ismail Sari[1], Arane Thavaneswaran[3], Renise Ayearst[1], Robert D Inman[4] and Nigil Haroon[1], [1]Rheumatology, Toronto Western Hospital, University of Toronto, Toronto, ON, Canada, [2]Rheumatology, University of California San Diego, La Jolla, CA, [3]Rheumatology, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, [4]Immunlogy and Institute of Medical Science, Toronto Western Hospital, University of Toronto, Toronto, ON, Canada

Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Acute anterior uveitis (AAU) is the most common extra-articular manifestation in patients with ankylosing spondylitis (AS), developing in 20-30% of these patients during the course of their disease.

Our aim was to study the characteristics and risk factors associated with AAU in our cohort of AS patients.

Methods: From our longitudinal observational cohort, 716 patients with AS (meeting modified New York Criteria) and at least 2 years follow up were included and who were followed from January 2006 to November 2013. Patients with (AAU+) and without (AAU-) uveitis were compared. Uveitis flare rates were calculated per year. T-test, Chi-squared tests and logistic regression were used where appropriate.

Results: Of the 716 patients, 225 (31.4%) had a reported diagnosis of AAU at their baseline clinic visit. Patients with AAU+ were older compared to the AAU- group (mean age of 42.6 vs 37.9 years; p< 0.001). AAU started after the onset of back pain in the majority of patients with only 10.5% of patients reporting onset of AAU before onset of AS related back pain. Patients with AAU had higher HLA-B27 (B27) prevalence (91.8% vs 82.1%, p<0.05). In the multivariate analysis (MVA), AAU was independently associated with age, B27, psoriasis, IBD and elevated CRP. B27 (OR=2.66 [95% CI=1.44-4.9]), psoriasis (OR=2.36 [95% CI=1.41-3.97]) and IBD (OR=2.25 [95% CI=1.27-4]) are the strongest independent predictors of AAU. Within the AS/IBD group (n=86), 43% of these patients had a history of AAU, of which 81% were B27 positive.

In patients with AAU , there was a trend towards more peripheral arthritis and enthesitis. The BASMI score was higher in patients with AAU (3.3 vs 2.7, P<0.05), however there was no association found on MVA. There was no significant difference found between the two groups in terms of BASDAI score,

hypertension, diabetes, previous history of myocardial infarctions and smoking history.

There was no difference found between NSAID use at baseline (66.1% vs. 66.5%, p=0.90). Patients with AAU were more frequently treated with DMARDs (26% vs. 16.5%, p<0.01). Sulfasalazine was used more frequently in the AAU+ group (14.2% vs. 7.9%, p<0.01). Use of biologics was similar at baseline (22.2% vs. 18.4%, p=0.23).

Conclusion: In our cohort of AS patients, an increased frequency of HLA-B27 was seen in AAU+ AS. AAU+ AS is associated with psoriasis and IBD. The psoriasis and IBD association is independent of HLA-B27, suggesting an interaction of other genetic as well as environmental factors. At baseline DMARD use was associated with AAU, likely reflecting the association with peripheral joint disease.

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The prevalence of osteoporotic vertebral fractures (VF) in psoriatic arthritis (PsA) is not known. We aim to determine the prevalence and factors associated with non-traumatic radiographic VF in patients with PsA.

Methods: The most recent digital plain radiographs of the thoracic and lumbar spine as well as demographic, clinical, laboratory and imaging information on a large cohort of patients diagnosed with PsA, satisfying CASPAR classification criteria, were retrieved from a database. Fractures were diagnosed by quantitative morphometric assessment (QMA) on lateral spinal radiographs of lumbar and thoracic spine (T6-L4) that was previously demonstrated to have high inter- and intra-assessor reliability. Covariates including demographic features, measures of disease activity, body mass index and pharmacologic treatment, particularly OP-causing treatments like corticosteroids and methotrexate were investigated as factors associated with VF in PsA using descriptive statistics and logistic regression.

Results:

Data on 450 patients [191 (42%) females, mean age at the time of x-ray 54.4 ±13.6 years, mean PsA duration 18±11.9 years] were retrieved from the database. Only 24 (5.3%) patients (1 fracture-13, 2 fractures-9, >2 fractures-2) were diagnosed with VF. Univariate logistic regression analyses revealed that age (OR 1.08, 95% CI [1.04, 1.12], p value <0.0001), duration of psoriasis (OR 1.03, 95% CI [1.004, 1.062], p=0.027), PsA duration (OR 1.05, 95% CI [1.02, 1.09], p=0.002) and therapy with bisphosphonates (OR 4.92, 95% CI [1.29, 18.76], p=0.02) were associated with increased odds of the presence of VF, whereas race, sex, menopausal status, smoking, BMI, damaged joint count, presence of DISH, axial disease, enthesitis, dactylitis, time-averaged ESR, therapy with topical or systemic corticosteroids, NSAIDs, and methotrexate, HAQ and SF36 physical and mental component summary scores were not. Therapy with biologic agents showed a trend towards less odds of the presence of VF (OR 0.42, 95% CI [0.17, 1.02] p=0.056). Multivariate logistic regression analysis with backward elimination with age, sex, psoriasis and PsA duration, and therapy with bisphosphonates and biologics in the model revealed that only age (OR 1.08, 95% CI [1.04,1.12], P<0.0001) was independently associated with VF in PsA.

Conclusion: Prevalence of VF is low in PsA. PsA related variables are not associated with the presence of VF in patients with PsA.

Comorbidity Burden and Medication Use Among Patients with Psoriatic Arthritis in the US

Joseph F. Merola[1], Simeng Han[2], Jipan Xie[2], Huaying Song[2], Vivian Herrera[3], Jin Wei[2], Eric Q. Wu[2] and Jacqueline B. Palmer[3], [1]Brigham and Women's Hospital, Boston, MA, [2]Analysis Group, Inc., Boston, MA, [3]Novartis Pharmaceuticals Corporation, East Hanover, NJ

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Psoriatic arthritis (PsA) is a chronic inflammatory disease that is associated with various comorbidities. This study aimed to assess the comorbidity burden and medication use among PsA patients as compared to matched controls who did not have PsA or psoriasis (PsO).

Methods:

Adults (18-64 years) with ≥2 claims for PsA diagnosis (ICD-9-CM: 696.0) that are ≥30 days apart were selected from the Truven Health MarketScan claims database (07/2009-06/2014) and constituted the case group. The index date was a randomly selected calendar date after the first claim for PsA. Cases were required to have ≥ 12 months continuous eligibility after the index date (the study period). Controls free of PsA and PsO (ICD-9-CM code: 696.0 and 696.1) in the entire claims history were assigned the same index date and study period as the matched cases. All selected patients were further required to have ≥12 months before the index date (washout period), which was used to confirm that controls were free of PsA and PsO. Cases and controls were matched 1:1 on age as of the index date, gender, and geographic region. Patient demographics as of the index date, comorbidities (including both PsA-associated and non-PsA-associated comorbidities), and medication use during the study period were compared between cases and controls. Wilcoxon signed rank tests were used to compare continuous variables and McNemar's tests were used to compare binary variables. Bonferroni correction was used to adjust for multiple comparisons.

Results:

A total of 35,061 matched pairs were included in this study with a mean age of 49.11±10.20 years and 47.27% were male. In general, PsA patients had significant higher rates of non-PsA-associated comorbidities compared to the controls, most notably, chronic pulmonary disease (22.70% vs. 14.50%, p<0.0001), liver disease [excluding fatty liver] (12.78% vs. 5.48%, p<0.0001) and co-prevalent rheumatic disease (6.25% vs. 0.98%, p<0.0001). PsA patients also had higher rates of PsA-associated comorbidities, notably, psychiatric diseases including anxiety (17.34% vs. 12.04%) and depression (21.71% vs. 13.14%), inflammatory eye disease including uveitis (2.41% vs. 0.64%) and scleritis (0.89% vs. 0.27%), inflammatory bowel disease [Crohn's disease or ulcerative colitis] (2.70% vs. 1.08%), celiac disease (0.75% vs. 0.30%) and gout (6.93% vs. 2.88%) (all p<0.0001). PsA patients had significantly higher rates of all-cause medication use (96.64%) and larger number of unique medications filled (12.04) than controls (78.95% and 5.59 respectively). Significant differences were also seen in the mean number of unique medications filled between PsA patients and controls for non-PsA-related medications (9.74 vs. 5.20), antidepressants (0.58 vs. 0.31), antidiabetics (0.28 vs. 0.18) and cardiovascular agents (1.53 vs. 1.05) (all p<0.0001).

Conclusion:

PsA patients had a significantly higher comorbidity burden compared to matched subjects without PsA or PsO. PsA patients also incurred significantly more medication use overall and related to these comorbid conditions. This study represents a unique look at the comorbidity burden and prevalence among a large US PsA population.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Depression is a known comorbidity of ankylosing spondylitis (AS) with over one-third of AS patients affected and increased depression-rate ratio compared to the general population. Predictors of depression in AS have not been comprehensively reported. The purpose of this study is to examine the baseline demographic and clinical predictors of depression in addition to depression severity over time in AS. The baseline predictors of depression in AS were also studied over time on depression severity.

Methods:

Using the Center for Epidemiological Studies Depression (CES-D) Scale for depression severity, 622 patients who met modified New York criteria for AS and were followed at least two years were studied from the Prospective Study of Outcomes in Ankylosing Spondylitis cohort. Univariable/multivariable longitudinal analyses using mixed effect negative binomial regression models were conducted to assess the clinical/demographic features associated with CES-D score accounting for correlation of repeated CES-D measures over time.

Results:

The cohort was 73% male and 81% of patients were white, having a mean age 42.4 years (SD= 13.8). The mean disease duration at baseline was 17.5 years (SD±13.1). The median CES-D score at baseline was 9 (IQR= [5, 17]). In the univariable longitudinal model, independent factors positively associated with a higher CES-D score included: smoking , have multiple comorbidities, Hispanic ethnicity, greater reported pain, disease activity (by the Bath Ankylosing Spondylitis Disease Activity Index), functional impairment (by the Bath Ankylosing Spondylitis Functional Index), elevated CRP, NSAID use, DMARD use, anti-depressants use, narcotic use, and self-reported depression. Inversely associated factors included: marital status (married), exercise and TNF –α inhibitor use. Baseline radiographic severity did not have any statistically associations with CES-D scores. In multivariable analysis (Table 1), positive correlations with current smoking, functional impairment, disease activity, greater pain perception, usage of DMARDS and narcotic pain analgesics and self-reported depression. Inverse associations were found with being married, exercising > 120 minutes per week, and, curiously, greater baseline radiographic severity (as measured by the Bath Ankylosing Spondylitis Radiographic Index).

Conclusion:

This study identifies demographic and clinical factors that predict longitudinal depression severity and demonstrates potentially modifiable targets to treat depression in AS patients.

Table 1. Multivariable Associations of Selected Variables on Longitudinal CES-D Score

Variable	Rate Ratio (95% CI)	P Value
Male	1.02 (0.9,1.16)	0.717
Married	0.86 (0.77,0.96)	0.006
Age ≥40	1.11 (0.99,1.25)	0.083
working pay	0.98 (0.87,1.09)	0.669
Exercise ≥120min/week	0.91 (0.86,0.97)	0.003
currently smoking	1.25 (1.08,1.45)	0.003
BASFI ≥40	1.16 (1.07,1.25)	0.0003
BASDAI ≥40	1.35 (1.27,1.44)	<0.0001
BASRI baseline≥6	0.83 (0.73,0.94)	0.0034
depression	1.38 (1.19,1.6)	<.0001
pain scale ≥50	1.21 (1.13,1.3)	<.0001
Patient Global Assessment of Disease Activity≥23	1.5 (1.34,1.69)	<.0001
CRP abnormal	1.00 (0.94,1.07)	0.891
anti-depressant use	1.09 (0.97,1.22)	0.130
NSAID use	1.01 (0.95,1.07)	0.801
DMARD use	1.14 (1.04,1.25)	0.005
Narcotics use	1.17 (1.07,1.28)	0.0004
Hypnotics use	1.11 (0.94,1.31)	0.230
TNF –α inhibitor use	1.00 (0.93,1.08)	0.9636

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is associated with increased cardiovascular risk (CV)[i]. Several studies associate low levels of 25-hydroxivitamin D (25OHD) with a greater prevalence of CV risk[ii]. Carotid ultrasound is a useful method to detect subclinical CV disease[iii]. To estimate CV risk and contrast it to presence of subclinical atherosclerosis in patients with PsA. To determine the relation between 25OHD deficit and presence of subclinical vascular damage.

Methods: Cross-sectional study included patients with PsA and peripheral joint affection of over one year evolution meeting CASPAR criteria. Demographic (sex, age, IMT), clinical (classic CV risk factors, previous CV incidents) and analytical data (liver and kidney function, calcium, phosphorus, 25OHD and PTH, total cholesterol and HDL) were recorded. CV risk was estimated with SCORE stratification table for low risk countries such as Spain. Ultrasound study was performed with Esaote MyLab xv70, 7-12 mHz linear transducer. An automated program assessed the IMT through radiofrequency (Quality intima media thickness in real time [QIMT]). Measurements were taken at the bilateral common carotid artery, and presence of atheroma plaque in the extra-cranial carotid artery was recorded following the Manheim consensus. Statistical analysis done with SPSS 17.0 program.

Results: 90 patients comprised the study, 24 of which were excluded due to high CV risk (prior CV event, glomerular filtration rate <60mg/dL, and/or Type I or II diabetes with target organ injury). Mean age was 53±11 years and most patients were women (58%), 30% were smokers, 29% were obese (mean BMI: 27±5). Mean DAS28 was 2.3±0.8 and mean HAQ was 0.5±0.7. Mean 25OHD levels were 27.56±12.8ng/dl, and PTH 54±23pg/ml. 61% of patients had vitamin D insufficiency (<30ng/ml) and 30.3% deficiency (<20ng/ml). 42%(28) of patients had low CVR estimated by SCORE (0), 49%(32) medium risk (SCORE ≥1 y<5), and 1.5% (1) high or very high risk (SCORE≥5). Mean IMT was 0.71±0.14mm and 9% exhibited IMT>0,9mm. Atheroma plaque was found in 34%. 34% of patients exhibited a pathological ultrasound (plaque and/or pathological IMT). We didn't observe any association between DAS28 or HAQ and pathologic findings in carotid evaluation. Based on these results, 25% of patients with Low and 45% of patients with Medium SCORE should be reclassified as High Risk.

RISK LEVEL	IMT > 0,9mm	Presence of atheroma plaque	Pathological ultrasound
LOW	2/28 (7.1%)	7/28 (25%)	7/28 (25%)
MEDIUM	5/32 (15.6%)	14/31 (45.2%)	14/31 (45.2%)
HIGH or VERY HIGH	0/0 (0%)	0/1 (0%)	0/1 (0%)

No association was observed between 25OHD levels or densitometric findings and DAS28, HAQ, presence of atheroma plaque or IMT.

Conclusion: We proved that SCORE underestimated CV risk in patients with PsA and that carotid ultrasound allows to re-stratify such risk. Patients with atheroma plaque or pathological IMT do not show lower levels of 25OHD than those without these vascular changes.

Enthesitis in Psoriatic Arthritis: Incidence, Prevalence and Characteristics

Ari Polachek[1], Suzanne Li[2], Vinod Chandran[1] and Dafna Gladman[1], [1]Rheumatology, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, [2]University of Toronto, Toronto Western Hospital, Toronto, ON, Canada
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II
Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Enthesitis reflects inflammation at the insertion of tendons and ligaments into bone and is a well-known component of psoriatic arthritis (PsA). It is part of the stem requirements of the CASPAR (Classification Criteria for Psoriatic Arthritis) criteria. However, little is known about the characteristics of enthesitis in patients with PsA.

The aim of this study was to evaluate the incidence, prevalence, and characteristics of enthesitis in patients with PsA.

Methods:

The study population included patients with PsA who were followed at 6 month interval according to a standard protocol from January 2008 to December 2014. Enthesitis was defined as the presence of at least one painful entheseal site of the 18 entheseal insertion locations of the SPARCC (Spondyloarthritis Research Consortium of Canada) enthesitis index. Descriptive statistics are provided. Incidence calculated per patient-year of follow-up.

Results:

Of 803 patients who were evaluated during this period 281 had enthesitis on at least one visit, with a prevalence of 35%. 192 patients developed enthesitis during the course of follow-up, with an annual incidence of 0.9%. Among the 281 patients with enthesitis the mean (SD) age at enthesitis diagnosis was 49 years (± 12.7) and PsA duration was 11.4 years (± 11.3). At the time of enthesitis the BMI was 30 (± 6.4), mean number of actively inflamed joints was 9.5 (±11.1) and 52 (19%) patients had dactylitis. The mean psoriasis area severity index (PASI) score was 4 (±5.7) and the mean modified nail psoriasis severity index (mNAPSI) score was 6.1 (± 9.9). 31 (11%) patients had a diagnosis of concomitant osteoarthritis, 33 (12%) diabetes mellitus and 42 (15%) fibromyalgia. 81 (31%) patients had elevated ESR, 115 (41%) patients had elevated CRP and 14% were positive for HLA-B*27. The X-ray evaluation revealed plantar spurs in 143 (53%) patients, Achilles spurs in 99 (37%) and sacroiliitis in 116 (42%). The treatment at diagnosis included NSAIDS in 205 (73%) patients, DMARDS in 154 (55%) and biologics drugs in 95 (34%).

Most of the patients had 1 or 2 (110 and 99 patients, respectively) tender entheseal sites. The 3 most common tender entheseal sites were: Achilles tendons, plantar fascia and, lateral epicondyles (24.2%, 20.8% and 17.2%, respectively).

Conclusion:

Clinical enthesitis is common, occurring in 35% of PsA patients. Usually it appears in only 1 or a few sites simultaneously and the most symptomatic locations are Achilles tendons, plantar fascia and lateral epicondyles.

Enthesitis in Psoriatic Arthritis – Disease Association and Risk Factors

Ari Polachek[1], Suzanne Li[2], Vinod Chandran[1] and Dafna Gladman[1], [1]Rheumatology, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, [2]University of Toronto, Toronto Western Hospital, Toronto, ON, Canada
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Psoriatic arthritis (PsA) is a heterogeneous disease presenting with musculoskeletal and extra-articular manifestation. Enthesitis is a well-known component of PsA. However, little is known about the disease association and risk factors of clinical enthesitis in patients with PsA.

Aim: To evaluate the disease association and risk factors of clinical enthesitis in patients with PsA.

Methods:

The study population included patients with PsA who were followed at 6 months interval according to a standard protocol from January 2008 to December 2014. Enthesitis was defined as the presence of at least one painful entheseal site of the 18 entheseal insertion locations of the SPARCC (Spondyloarthritis Research Consortium of Canada) enthesitis index. Logistic regression was used to analyze baseline characteristics associated with enthesitis and a Cox regression analysis was used to identify predictors for the development of enthesitis in those without enthesitis at baseline.

Results:

Of 803 patients who were seen during this period 281 (35%) had clinical enthesitis on at least one visit, while 522 (65%) did not. The enthesitis group was

significantly younger at baseline and was younger at psoriasis diagnosis. The mean active joint count as well as the presence of tenosynovitis were significantly higher in the enthesitis group. The damaged joint count and the mean Steinbrocker score were significantly lower in the enthesitis group. Fibromyalgia was more prevalent in the enthesitis group. Quality of life and function were significantly poorer in the enthesitis group. The enthesitis group used significantly more NSAIDS. Multivariate logistic regression analysis showed that the following variables were independently associated with the presence of enthesitis: younger age (OR 0.98, p=0.03), higher mean active joints (OR 1.06, p<0.0001), less damaged joints (OR 0.97, p=0.01), presence of tenosynovitis (OR 2.75, p=0.0008) and NSAIDS use (OR 1.6, p=0.01). 128 (16%) patients were diagnosed with new clinical enthesitis during follow-up. Predictive factors for development of enthesitis are shown in the table 1.

able 1: Multivariate cox regression analysis risk factors for enthesitis in PsA patients

Variable	Hazard Ratio	Lower C.I	Higher C.I	P-value
Age at baseline	**0.98**	**0.97**	**0.99**	**0.007**
Age at psoriasis diagnosis	0.99	0.98	1.004	0.2
Gender	1.01	0.8	1.3	0.92
BMI	1.02	0.99	1.04	0.1
Active joint count	**1.02**	**1.007**	**1.03**	**0.003**
Presence of tenosynovitis	**2.1**	**1.45**	**3.01**	**<0.0001**
Damaged joint counts	**0.97**	**0.95**	**0.99**	**0.003**
Steinbrocker score	0.99	0.98	1.02	0.9
PASI	1.009	0.99	1.03	0.4
Presence of nail lesions	1.09	0.82	1.44	0.5
Presence of sacroiliitis	1.06	0.8	1.4	0.7
Presence of fibromyalgia	1.2	0.82	1.8	0.3
HAQ	**1.5**	**1.2**	**1.8**	**0.0009**
NSAIDS use	1.3	0.96	1.74	0.08

Conclusion: PsA patients with enthesitis are younger, have higher active joint counts, more tenosynovitis, less damage and worse quality of life. The same variables are predictive of developing enthesitis during the course of PsA.

Development of a Novel SI Joint CT Score for Diagnosis of Axial Spondylitis

Jonathan Chan[1,2], Ismail Sari[3,4], David Salonen[5], Robert D Inman[6] and Nigil Haroon[7], [1]Rheumatology, Spondylitis program, Toronto Western Hospital, University of Toronto, Toronto, ON, Canada, [2]Rheumatology, University of British Columbia, Vancouver, BC, Canada, [3]Rheumatology, Toronto Western Hospital, University of Toronto, Toronto, ON, Canada, [4]Rheumatology, Dokuz Eylul University School Of Medicine, Department Of Internal Medicine, Division Of Rheumatology, Izmir, Turkey, [5]Department of Medical Imaging, University Health Network, Toronto, ON, Canada, [6]Immunlogy and Institute of Medical Science, Toronto Western Hospital, University of Toronto, Toronto, ON, Canada, [7]Rheumatology, Toronto Western Hospital, Toronto, ON, Canada
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: The diagnosis of ankylosing spondylitis (AS) is based on pelvic radiographs plagued by poor sensitivity, specificity, and reproducibility. Many AS patients, particularly those with inflammatory bowel disease (IBD), may have CT scans performed for other clinical indications and sacroiliitis may be incidentally noted. Though the modified New York (mNY) criteria have never been validated in CT imaging, previous studies have used a radiologist's adaptation of the criteria as a gold standard for diagnosing sacroiliitis.

Our objective is to develop a validated scoring system for sacroiliitis on CT that can ground future studies in prevalence and pathogenesis.

Methods: Patients from the Toronto AS clinic meeting mNY criteria for AS who had CT scans of the abdomen/pelvis were matched to controls by age and gender. Control patients had their charts reviewed to ensure they had no history of spondylitis, colitis, uveitis, or psoriasis. A training exercise involving 10 CT scans (5 AS and 5 controls) was conducted to identify candidate features and to optimize reliability. A derivation cohort of 24 CT scans (12 AS and 12 controls) was used to test these features. Finally, 2 blinded readers performed a validation study on 68 CT scans (34 AS and 34 controls).

SI joints were divided into left and right as well as iliac and sacral segments for a total for 4 segments. The maximum number of erosions seen on a single slice was counted for each segment. The sum of these values gave a total erosion score. Sclerosis was only measured on the slice with the longest synovial length. Inter- and intra-observer values, sensitivity, specificity, and likelihood ratios (LR) were calculated for variables that correlated with AS. Combinations of variables were trialed to maximize sensitivity and specificity.

Results: Features with the highest +LR included ankylosis, number of erosions, iliac sclerosis >0.5cm, and sacral sclerosis >0.3cm. Inter-reader reliability for these variables were 1.0 for ankylosis, 0.99 for number of iliac erosions, 0.99 for number of sacral erosions, 0.58 for iliac sclerosis, and 0.39 for sacral sclerosis. Fig 1A demonstrates the ROC curves for the total erosion number as well as the increasing depth of sclerosis. A total erosion number of ≥3 erosions was found to have the highest sensitivity and specificity for AS. Fig 1B demonstrates the ROC curves for combinations of ankylosis, sclerosis, and erosions for diagnosing AS. Sclerosis was defined as either >0.5cm of iliac or >0.3cm of sacral sclerosis >1cm in length. The presence of >1cm of ankylosis or ≥3 total erosions resulted in a sensitivity of 91% and specificity of 91%. The addition of >0.5cm of iliac sclerosis or >0.3cm of sacral sclerosis marginally increased the sensitivity to 94% but decreased specificity to 86%.

Conclusion: It is proposed that the presence of ankylosis >1cm or ≥3 total erosions has the greatest diagnostic utility for AS.

Fat Metaplasia on Sacroiliac Joint Magnetic Resonance Imaging at Baseline Is Associated with Spinal Radiographic Progression in Patients with Axial Spondyloarthritis

Kwi Young Kang[1], In Je Kim[2], Yeon Sik Hong[3], Sung-Hwan Park[4] and Ji Hyeon Ju[5], [1]#505, Banpo-dong, Seocho-gu, Division of Rheumatology, Department of Internal Medicine, Catholic University of Korea, Seoul, South Korea, [2]Division of Rheumatology, Department of Internal Medicine, Ewha Womans University School of Medicine, Seoul, South Korea, [3]catholic University of Korea, Incheon, South Korea, [4]Kangnam St Mary's Hospital, Seoul, South Korea, [5]Division of Rheumatology, Department of Internal Medicine, College of Medicine, The Catholic University of Korea, Seoul, South Korea

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: To study the relationship between inflammatory and structural lesions in the sacroiliac joints (SIJs) on MRI and spinal progression observed on conventional radiographs in patients with axial spondyloarthritis (axSpA).

Methods: One hundred and ten patients who fulfilled the ASAS axSpA criteria were enrolled. All underwent SIJ MRI at baseline and lumbar spine radiographs at baseline and after 2 years. Inflammatory and structural lesions on SIJ MRI were scored using the SPondyloArthritis Research Consortium of Canada (SPARCC) method. Spinal radiographs were scored using the Stoke AS Spinal Score (SASSS). Multivariate logistic regression analysis was performed to identify predictors of spinal progression.

Results: Among the 110 patients, 25 (23%) showed significant radiographic progression (change of SASSS≥2) over 2 years. There was no change in the SASSS over 2 years according to the type of inflammatory lesion. Patients with fat metaplasia or ankyloses on baseline MRI showed a significantly higher SASSS at 2 years than those without ($p<0.001$). According to univariate logistic regression analysis, age at diagnosis, HLA-B27 positivity, the presence of fat metaplasia, erosion, and ankyloses on SIJ MRI, increased baseline CRP levels, and the presence of syndesmophytes at baseline were associated with spinal progression over 2 years. Multivariate analysis identified syndesmophytes and severe fat metaplasia on baseline SIJ MRI as predictive of spinal radiographic progression (OR, 7.92 and 8.25, respectively).

Conclusion: Inflammatory lesions in the SIJs on baseline MRI were not associated with spinal radiographic progression. However, fat metaplasia at baseline was significantly associated with spinal progression after 2 years.

Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Axial SpondyloArthritis (axSpA) is a heterogeneous disease. The likelihood of diagnosis varies depending upon the specific findings that are present. However, it is debated whether additional examinations (i.e. HLA-B27 testing and imaging of the sacro-iliac joints (SIJ)) should be performed in patients with a low suspicion of axSpA: i.e. negative findings on medical history, physical examination, CRP/ESR measurement. By this study we aim to investigate if HLA-B27 testing and imaging of the SIJ is useful in young patients with back pain and maximally 1 SpA feature.

Methods: The SPACE cohort includes patients with chronic back pain (≥3 months ≤2 years, onset <45 years) recruited from 6 participating centres across Europe. All patients underwent full diagnostic work-up: MRI and x-rays SIJ, HLA-B27 testing and assessment of all other SpA-features. Patients were classified according to the ASAS axSpA-criteria.

Results: In this analysis, 133 patients from 4 participating centres were included. Of the 38/133 (28.6%) patients with 0 SpA-features; 4/38 (10.5%) were classified according to the ASAS-axSpA criteria after additional investigations (imaging arm only: 2MRI+/mNY+, 1MRI+/mNY-, 1MRI-/mNY+). Of the 95/133 (71.4%) patients with 1 SpA-feature; 22/95 (23.2%) patients fulfilled the ASAS-axSpA criteria (imaging arm only: 3MRI+/mNY+, 15MRI+/mNY-, 4MRI-/mNY+). Those patients presented the following features: 7 IBP, 5 IBD, 4 positive family history for SpA, 3 good response to NSAIDs, 2 raised CRP/ESR, 1 enthesitis.

Conclusion: In patients with CBP and 0 or 1 SpA-feature after medical history, physical examination and CRP/ESR measurement, subsequent HLA-B27 testing and imaging led to fulfilment of the axSpA-criteria in 11% and 23% respectively. Therefore in these patients, the disease cannot be ruled out without additional imaging and/or HLA-B27 testing.

Table 1: classification and diagnosis of patients with 0 and 1 SpA-feature after HLA-B27 and SIJ-imaging

No. of SpA-features	HLA B27 status	Imaging status	ASAS axSpa YES	Rheum Spa YES	ASAS axSpA NO	Rheum SpA NO

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: To date, although several have been proposed, there are no validated remission criteria in psoriatic arthritis (PsA). Validated criteria for minimal disease activity (MDA) in PsA have been established. This study aimed to compare sensivity and specificity of different potential remission criteria to identify patients in remission as defined by musculoskeletal ultrasound (US).

Methods: In this cross sectional study PsA patients were consecutively recruited from an outpatient clinic. All the patients fulfilled the CASPAR criteria for PsA. The following potential remission criteria were assessed: **(1)** Disease Activity Index for Psoriatic Arthritis (DAPSA) ≤3.3, **(2)** Composite Psoriasis Disease Activity Index (CPDAI) <2, **(3)** Psoriatic ArthritiS Disease Activity Score (PASDAS) <2.4 **(4)** Boolean's definition of remission modified for PsA, meeting all of the following criteria: 68 tender joints (TJC68) ≤1, 66 swollen joints (SJC66)≤1, Maastricht Ankylosing Spondylitis Enthesitis Score (MASES) ≤1, dactylitis count ≤1, evaluator's global assessment (EGA) ≤1 (0-10 scale), patient's global assessment (PGA) ≤1 (0-10 scale), C-reactive protein ≤1mg/dl **(5)** MDA, meeting 5 of the 7 following criteria: TJC68 ≤1, SJC66 ≤1, Psoriasis Area Severity Index (PASI) ≤1, patient's pain ≤15 (0-100 scale), PGA ≤20 (0-100 scale), Modified Health Assessment Questionnaire (MHAQ) ≤0.5 and MASES ≤1. US evaluation was performed on 68 joints, 15 tendons and 29 entheses if clinical findings indicating inflammation. Mandatory US evaluation was performed on 34 joints, 15 tendons and 10 entheses. US remission was defined as power Doppler (PD) score=0 in all joints, entheses and tendons. Chi-Square test or Fishers exact test (as appropriate) was used to calculate proportions. The odds ratio (OR) within the 95% confidence interval was calculated using the 2 x 2 table. A value of p<0,05 was accepted as statistically significant.

Results: A total of 141 PsA patients were included. Mean (SD) age was 52,4 (10,2) years, mean disease duration 9,5 (6,6) years and 72% were females. Median (range) TJC68 was 6 (0-55), SJC66 0 (0-6), MASES 2 (0-13). Mean (SD) EGA was 14,8 (12,3), PGA 36,3 (24,4), DAPSA 18,3 (14,1), CPDAI 6,2 (2,7) and PASDAS 3,1 (0,4). Overall, US remission was achieved by 70 (49,6%) patients. Sensivity and specificity of clinical criteria to identify patients in US remission are displayed in the table.

	Sensivity (%)	Specificity (%)	OR (95% CI)	p
MDA (n=32)	30.0	84.3	2.3 (1.0-5.2)	**0.048**
DAPSA≤3.3 (n=14)	15.7	95.8	4.2 (1.1-15.9)	**0.025**
CPDAI>2 (n=12)	13.0	95.7	3.4 (0.9-13.0)	0.066
PASDAS<2.4 (n=11)	8.6	93.0	1.2 (0.4-4.3)	0.748
Boolean's for PsA (n=8)	10.0	98.6	7.8 (0.9-65.0)	**0.033**

Conclusion: MDA, DAPSA and Boolean's PsA remission criteria had some utility as regards identifying PsA patients in US remission. Off note, while the specificity of these criteria was good, the sensivity was quite poor.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Due to the high prevalence of PsA among patients with PsO,[1] rheumatologists and dermatologists should recognize early signs and symptoms of joint involvement among patients with PsO without diagnosed PsA.[2,3]This analysis sought to evaluate the prevalence of joint symptoms and frequency of joint exams for patients with plaque PsO without PsA in the US.

Methods: This analysis was based on US data from the Adelphi 2011 and 2013 Psoriasis Disease Specific Programme, a cross-sectional survey of 91 dermatologists and their patients with PsO. Patients with suspected or confirmed PsA were excluded from the analysis. Joint symptoms were reported separately from both patients and physicians. Joint exams were reported by physicians and included tender joint count, swollen joint count, rheumatoid factor, immunoglobin A and immunoglobin M tests. Clinical and health-related quality of life (HRQoL) parameters were compared between 2 groups: patients with physician-reported joint symptoms without joint exams, and patients without physician-reported joint symptoms or who had a joint exam. Similar comparisons were made using patient rather than physician-reported joint symptoms. T-tests or Mann-Whitney U tests for numerical variables and chi-square tests or Fisher's exact tests for categorical variables were applied.

Results: A total of 1,002 patients were included in the analysis (mean age 45.7±15.7 [SD], 54.8% male). Overall, only 4.3% received joint exams. Physician-reported joint symptoms were less frequent than patient-reported joint symptoms (8.5% vs. 25.4%). Among those with physician-reported and patient-reported joint symptoms, 79.0% and 90.7% of patients did not receive a joint exam, respectively. Only 6.7% of the entire sample had physician-reported symptoms but no joint exams, while 22.9% had patient-reported symptoms but no joint exams. Compared with patients without physician-reported joint symptoms or who had a joint exam, patients with physician-reported joint symptoms but no joint exams had significantly poorer EuroQoL-5D (3L) (EQ-5D) utility scores (0.83 vs. 0.91), greater activity impairment (21.4% vs. 14.9%) as measured by the Work Productivity and Activity Impairment questionnaire (WPAI), and more severe psoriasis (Body Surface Area: 14.1% vs. 9.7%) (all $p<0.05$). Compared with patients who did not self-report symptoms or who had a joint exam, patients who self-reported symptoms but had no joints exams had significantly poorer EQ-5D utility scores (0.87 vs. 0.91) and greater activity impairment (19.3% vs. 14.0%) as measured by the WPAI (both $p<0.05$).

Conclusion: In the US, over three quarters of PsO patients without a diagnosis of PsA did not receive a joint exam when the patient or patients' physician reported joint symptoms. Early diagnostic actions such as referral to a rheumatologist or joint exams could increase recognition of PsA, leading to earlier diagnosis and appropriate treatment.

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Magnetic resonance imaging of sacroiliac joints (MRI-SI) and HLA-B27 testing are important tools in the diagnosis of spondyloarthritis (SpA). The aim of the study was to evaluate the patient´s characteristics associated with the clinical decision to request MRI-SI and/or HLA-B27 in daily practice

Methods: A cohort of patients referred to a specialised rheumatology outpatient clinic in a national referral centre was used. Data related to age, gender, number of initial symptom at presentation (arthritis and/or enthesitis and/or back pain and/or buttock pain), disease duration, infection history, past and currently present SpA features (chronic back pain, inflammatory back pain (IBP), asymmetric oligoarthritis, enthesitis (heel pain), dactylitis, buttock pain, uveitis, psoriasis and inflammatory bowel disease) were collected from the clinical record. BASDAI and ASDAS were calculated. Patients with the clinical diagnosis of SpA according to the rheumatologist were included. Information on MRI-SI and HLA-B27 was available only for those patients for whom the rheumatologists decided to order these tests. Characteristics associated with ordering MRI-SI or HLA-B27 separately were identified with univariable analyses. Variables with a p-value <0.05 and data available over 80% of cases were entered in the (backward) multivariable analysis. Colinearity and interactions were checked and relevant interactions were excluded A multivariable logistic regression analysis was used to evaluate factors related with the decision to perform MRI-SI and/or HLA-B27 and odds ratios (95% CI) were calculated

Results: In total, 581 patients with SpA were included, 72% were men, with a mean age of 34.6±12.1 years, age at symptom onset of 28,0±10.3 years and disease duration of 7.3±9.7 years. Disease activity was calculated separately for axial and peripheral SpA and was rather high for both: BASDAI: 5.4 (2.4) and ASDAS-ESR: 3 (0.9). For axial SpA ASDAS-CRP was 2.6 (0.8) and for peripheral SpA was 2.3 (0.9). Of these patients, 24% (n=137) had MRI-SI and 77% (n=441) had HLA-B27 testing ordered. Predictive factors for ordering a MRI-SI were IBP (OR=1.81), enthesitis (OR=1.57) and the number of initial symptoms at presentation (OR=1.27). Predictive factors of HLA-B27 testing were the number of initial symptoms at presentation (OR=1.45) and uveitis (OR=3.19) Table1

Conclusion: IBP, enthesitis, and the number of symptoms at presentation were independently associated with ordering an MRI-SI. The number of symptoms at presentation and to some extent uveitis were associated with the request of HLA-B27. This study provides insight in characteristics that prompt rheumatologists to order complementary imaging or HLA-B27 testing in the diagnostic work-up of patients with SpA

Table 1. Association of SpA disease characteristics that independently prompt to ordering MRI-SI and HLA-B27. Results from a multivariable logistic regression model.

	MRI-SI ordered		**HLA-B27 ordered**

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

It has been shown that nail involvement in psoriasis is associated with systemic enthesopathy. The association of enthesopathy and nail disease at distal interphalangeal (DIP) joints in psoriasis (PsO) and psoriatic arthritis (PsA) has not been studied until now. Our purpose was to analyze the association of nail involvement and extensor tendon enthesopathy at DIP level in patients with PsO and PsA.

Methods:

Consecutive patients with PsO or PsA were included. Patients with DIP osteoarthrtitis were excluded. Patients were seen by trained rheumatologists and dermatologists, for diagnosis and the Psoriasis Area and Severity Index (PASI), and the modify Nail Psoriasis Severity Index (mNAPSI) were calculated. Ultrasound (US) examinations included the second to fourth extensor tendon insertions at DIP joints bilaterally. The Outcome Measures in Rheumatoid Arthritis (OMERACT) definition of enthesopathy was adopted. Prevalence with 95% confidence intervals of enthesopathy was calculated for PsO and PsA with and without nail involvement and compared. The relationship between nail involvement and enthesopathy was also analyzed at fingers level.

Results:

One hundred and ten patients were included (table 1). US showed extensor tendon enthesopathy (ETE) in at least one DIP joint in 9 patients with PsO (17%; 95% CI: 8-29 %) and in 18 with PsA (32 %; 95%CI: 20-46%) (p=0.059). Among patients with PsO, 20% (95%CI: 7-41%) and 14% (95% CI:4-32%) of those with and without clinical nail involvement showed ETE on US examination, respectively (p=0.542). Among PsA patients, the prevalence of ETE was 30% (95% CI: 15-49%) for patients with clinical nail involvement and 35 % (95% CI: 17-56%) for those without nail involvement, respectively (p=0.712). On logistic regression analysis, the diagnosis of PsA (OR: 3.3; 95% CI: 1.1-9.8; p=0.032), but not nail involvement (OR: 1.1 (95% CI: 0.42-3); p=0.824 was associated with ETE, while the use of DMARDs was protective (OR: 0.33; 95% CI: 0.11-0.99; p=0.0481). Table 2 shows the relationship between ETE and clinical nail involvement at fingers level.

Table 1. Patients' characteristics

Features	PsO (n= 54)	PsA (n=56)
Females, n (%)	26 (53)	28 (46)
Mean disease duration, yrs (SD)	10.4 (8)	4.9 (6)
Nail involvement, n (%)	25 (46.3)	30 (54)
Mean PASI (SD)	4.3 (5)	3.4 (5.4)
Mean mNAPSI (SD)	6.7 (10.4)	9.3 (12.4)
Treated with DMARDs, n (%)	14 (26)	39 (70)
Treated with TNFi, n (%)	3 (6)	12 (21)

Table 2. Association between extensor tendon enthesopathy and nail involvment at fingers level

	Psoriasis Patients (n=54)		Psoriatic Arthritis Patients (n=56)		All Patients (n=110)	
	Nails with clinical involvement (n= 93)	Normal nails (n=339)	Nails with clinical involvement (n=143)	Normal nails (n=305)	Nails with clinical involvement (n=236)	Normal Nails (n=644)
Number of fingers with Extensor tendon enthesopathy (%)	57 (61)	57 (17)	86 (60)	67 (22)	143 (60)	124 (19)
OR (95% CI)	7.8 (4.6-13.4)	p<0.0001	5.4 (3.4-8.4)	p<0.0001	6.5 (4.6-9.1)	P<0.0001

Conclusion: Extensor tendon enthesopathy at DIP joints was more frequent in PsA than in PsO. No association was found between nail involvement and extensor tendon enthesopathy at patients' level. There was a significant increased prevalence of extensor tendon enthesopathy in fingers with involved nails both in PsO and PsA. These features might support the nail-entheseal pathogenesis theory at DIP level.

Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: There is growing interest in the management of early axial spondyloarthritis and intervention with disease-modifying agents while disease is still confined to the sacroiliac joints (SIJ). Assessment of structural lesions of the SIJ on MRI may be a helpful tool to monitor disease progression but requires evidence that change in such lesions can be reliably detected and the type of calibration necessary to achieve this. We aimed to assess reliability of detection of structural lesions in the SIJ on MRI and the impact of calibration using either a standardized web-based training module or a set of DICOM-based reference MRI scans.

Methods: In this international multicenter study, 5 readers without exposure to the application of scoring methods specifically for structural lesions in the SIJ reviewed either a web-based training module (n=3) that included standardized definitions for and examples of erosion, fat metaplasia, backfill, and ankylosis, or a set of DICOM-based reference MRI scans (n=2). Both calibration methods included instructions for the scoring of lesions according to the Spondyloarthritis Research Consortium of Canada SIJ Structural Score (SSS) on 5 consecutive semi-coronal slices through the SIJ using a binary method based on presence/absence of the lesion in SIJ quadrants (erosion, fat metaplasia (range 0-40)) or SIJ halves (backfill, ankylosis range (0-20)). Baseline and 2-year T1-weighted (T1W) scans from 30 patients with axial SpA blinded to patient characteristics, short-tau inversion recovery (STIR) scan, and time point, were scored and data entered directly online using a web-based schematic of the SIJ. Interobserver reliability for status and change scores was calculated by intra-class correlation coefficient (ICC) and comparisons made with pre-specified expert readers (n=3).

Results: Mean (SD) reduction in SSS erosion score was significantly greater for expert readers (-1.62 (4.05)) and for DICOM-trained readers (-1.40 (3.42)) than for web-based module trained readers (-0.47 (1.56)). Mean (SD) increase in SSS backfill score was significantly greater for expert readers (0.82 (3.87)) than for web-based module trained readers (-0.07 (1.67)). ICC differed between groups mainly for 2-year change in erosion and backfill. Although reliability was superior for DICOM-trained readers, substantial reliability with expert readers was attainable following training with the web-based module (Table).

Conclusion: Structural lesions in the SIJ on MRI are often heterogeneous in appearance and their evolution may not be reliably detected without the more rigorous approach to calibration using DICOM scans.

Table. Interobserver ICC

Session Date: Monday, November 9, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Fat metaplasia in the bone marrow is an indicator of disease progression in spondyloarthropathy (SpA). This study aimed to evaluate the bone marrow fat content in patients with SpA using advanced magnetic resonance imaging (MRI) techniques to measure the proton density fat-fraction and identify fat-fraction changes according to disease progression.

Methods: A total of 129 patients with SpA who underwent a pelvis MRI at Hanyang University Hospital for Rheumatic Diseases from September 2014 to March 2015 were retrospectively evaluated. Quantitative fatty infiltration was assessed on the fat-signal fraction maps using the Dixon technique. Fat fractions were quantified after measuring the signal intensity within the region of interest (ROI) over the periarticular bone marrow where there was no contamination from the bony cortex or joint spaces. The ROIs were drawn at each of two sites of the right and left ilium. MRI was used to examine the fat fraction at inflammatory regions (inflammatory fat) and noninflammatory regions (noninflammatory fat) in the bone marrow. Clinical characteristics and the correlation between the sacroiliac (SI) joint grades and fat fractions were evaluated.

Results: Patients had a mean age of 32.2 ± 11.6 years, and 84 were male (65%). Mean symptom duration was 4.2 ± 6.0 years, and 84 out of 116 patients (72.4%) had tested positive for HLA-B27. Mean right and left SI joint grades on the radiograph were 1.7 ± 1.3 and 1.8 ± 1.3, respectively. Mean fractions of inflammatory fat were 82.6% ± 9.8% and 82.0% ± 11.1% (right) and 82.4% ± 10.2% and 82.2% ± 10.3% (left), while the mean fractions of noninflammatory fat were 51.1% ± 9.6% and 53.2% ± 9.6% (right) and 52.8% ± 9.5 % and 53.4% ± 11.0% (left). A significant correlation was found between right and left inflammatory fat fractions and right ($p = 0.003$ and $p = 0.005$) and left ($p = 0.000$ and $p = 0.000$) SI joint grades on the radiographs, respectively (Spearman correlation analysis), although no correlation was found between the total noninflammatory fat fraction and each SI joint grade on the radiographs (Figure 1). A significant correlation was also found between inflammatory fat fractions and modified Stoke Ankylosing Spondylitis Spinal Score.

Conclusion: The inflammatory fat fraction of the bone marrow increased in SpA patients who showed severe radiographic SI joint changes. Quantitative MRI assessment of the fat fraction may represent another useful imaging technique to evaluate the progression of SpA.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Ankylosing spondylitis (AS) is a chronic inflammatory disease that primarily affects the axial skeleton. New bone formation resulting in syndesmophytes can lead to spinal ankylosis and associated disability and poor functional outcomes. Conventional X-rays represent the gold-standard for the assessment of the radiographic damage. In this study, we evaluated a cohort of AS patients to identify factors associated with radiographic progression.

Methods: AS patients (satisfying the modified New York criteria) who had a full set of baseline and follow-up x-rays at a minimum interval of 2 years were included in the study. Two readers scored the X-rays independently. In discordant cases, radiographs were evaluated by an arbitrator. Radiographic damage was assessed by the modified Stoke Ankylosing Spondylitis Spinal Score (mSASSS). Progression was defined as ≥2 mSASSS change between two time points. Clinical variables at baseline were derived from the database and included disease duration, B27 status, demographics, smoking, BASDAI, BASFI, BASMI, SF-36-PCS, -MCS, and ASQoL.

Results: There were 288 patients with a total of 822 x-rays. The mean age and disease duration were 38.7±13.6 and 15.9±10.8 years respectively. 77.1% of the patients were male and 78% were B27 positive. The mean interval between first and last x ray (ΔTime) was 55.9±23.8 months. Total mSASSS change (ΔTotal) was 2.84±6.03 for the cohort overall. The mean mSASSS change/year (ΔYear) was 0.67±1.3 unit. 47.9% of the total patients had damage at baseline as defined as an mSASSS score ≥2. The reliability between the observers regarding lumbar, cervical and total mSASSS scores were 0.97, 0.94 and 0.94 respectively. Overall, 40.6% of the patients progressed during the period of observation. Comparison of progressors *vs*non-progressors revealed that age, disease duration, smoking history, baseline radiological damage and baseline BASMI were significantly higher in the patients who progressed ($p<0.005$). Logistic regression analysis showed that smoking and baseline radiological damage independently predicted the radiographic progression with an odds ratio of 2.8 and 22.8 respectively. In addition to baseline mSASSS, degree of sacroiliitis at baseline was associated with radiographic progression.

Conclusion: AS Patients who are smokers and have baseline changes in SI joints or spine are more likely to demonstrate radiographic progression.

What Is the Clinical Utility of MR Imaging in the Management of Nr-Axspa Patients?

Ismail Sari[1], Ahmed Omar[1], Jonathan Chan[2], Mohamed Bedaiwi[1], Renise Ayearst[1], Nigil Haroon[1] and Robert D Inman[3], [1]Rheumatology, Toronto Western Hospital, University of Toronto, Toronto, ON, Canada, [2]Rheumatology, Spondylitis program, Toronto Western Hospital, University of Toronto, Toronto, ON, Canada, [3]Immunlogy and Institute of Medical Science, Toronto Western Hospital, University of Toronto, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The ASAS classification criteria have provided new insights in the classification of axial spondyloarthropathy (axSpA). MR imaging (MRI) is an intrinsic component of the imaging arm of the classification criteria for non-radiographic (nr)-axSpA. The scheme classifies these patients by the imaging arm if the MRI is positive or by the clinical arm if such MRI evidence is lacking. The current algorithm does not address the clinical utility of MRI in patients who meet the clinical criteria, in which B27 is mandatory. The main aim of our study was to compare clinical features and outcomes of nr-axSpA patients stratified into MRI-Pos, MRI-Neg, and MRI-ND (not done) subsets. The study provided the opportunity to define clinical commonalities and differences between these three subsets, and to address the added value of MRI in the management of nr-axSpA.

Methods: Patients who met the criteria for nr-axSpA by the imaging arm or the clinical arm were included. Patients who met the NY criteria for AS were excluded. X-rays and MRIs were scored by two rheumatologists, blinded to clinical diagnosis. Discordant results were settled by a third reader. Patients classified as nr-axSpA were further stratified into the imaging or clinical arms. The clinical arm was further stratified into MRI-Neg and MRI-ND groups. Clinical characteristics were then obtained for each group from the clinical database.

Results: There were 107 patients fulfilling ASAS criteria for nr-axSpA. The median age of the patients was 35.2 (18-64) years, 51.4% were male and 85% were B27+. There were 37 patients in the imaging arm and 70 patients in the clinical arm. The intraclass correlation coefficient of the readers for right and left SIJ were 0.75 and 0.73 respectively. The kappa value of the readers for MR classification was 0.74. Age, sex distribution and disease duration were similar between the three groups (Table 1). Extra-articular features, acute phase reactants, BASDAI and BASMI were also comparable between the three groups. There were 45 (42.1%) patients who were treated with TNF inhibitors. Subgroup analysis of the patients who received TNFi treatment showed that biological treatment utilization, biologic switch frequencies, and rates of biologic non-response were similar between the three groups.

Conclusion: The clinical profiles of nr-axSpA patients with and without MRI confirmation are comparable, including response to biologic therapy. This suggests that there is a degree of homogeneity in the nr-axSpA cohort when patients are classified on clinical grounds alone. Including B27 as a mandatory inclusion criterion likely underlies this homogeneity, and does so to a greater extent than imaging studies.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Previous studies assessing the prevalence of sacroiliitis in patients with inflammatory bowel disease (IBD) using CT scans have relied on the general impression of a radiologist. These estimates have ranged between 30-45%; however, only a small proportion of these patients were symptomatic and only patients who had symptoms suggestive of spondylitis had an increased frequency of HLA-B27. To date, the prevalence of sacroiliitis in IBD patients using a standardized CT scoring system is not known.

Our aim is to determine the prevalence of sacroiliitis in patients with IBD using a validated standardized CT scoring system and to compare this prevalence to that in a non-IBD control population.

Methods:

Patients with IBD were recruited from one gastroenterology clinic and control patients were recruited from a urology clinic. The chart of each control patient was reviewed to ensure there was no history of back pain, spondylitis, psoriasis, colitis, or uveitis. Two blinded readers scored the CT scans using two diagnostic models: **Model 1:** ankylosis or ≥3 erosions; **Model 2:**ankylosis, ≥3 erosions, ≥0.5cm of iliac sclerosis, or ≥0.3cm of sacral sclerosis. These models have been developed and validated in our previous study to have a sensitivity of 91% and 94% and a specificity of 91% and 86% respectively. We also noted the presence of lumbar spine syndesmophytes and whether the reporting radiologist had noted sacroiliitis in their reporting.

Results:

The percent of patients who fulfilled the various models for sacroilitis are presented in Table 1.

Table 1: Prevalence of sacroiliitis according to each model

	Model 1	Model 2
Control (n=108)	5.6%	13%
Crohn's disease (n=233)	15%	17.2%
Ulcerative colitis (n=83)	16.9%	21.7%

There was no significant difference in prevalence of sacroiliitis between patients with CD and UC with a Chi^2test= 0.725. There was a significant difference in the number of erosions between control and IBD patients but no difference in rate of ankylosis or sclerosis.

Amongst the 49 CT scan positive patients, radiologist comments were reported on 39 images and sacroiliitis was noted in 16 cases. Only 5 of these 49 patients had been referred to the spondylitis clinic. Amongst the 267 CT scan negative patients, radiologist comments were reported on 184 images and 5 definite and 4 possible cases of sacroiliitis were noted.

Conclusion: Using a standardized CT scoring system, the prevalence of sacroiliitis in IBD patients is 16% with no difference between CD and UC patients. This indicates a 3-fold increase in prevalence over non-IBD controls. Despite a growing awareness of the high prevalence of sacroiliitis in patients with IBD, a significant proportion of patients have never been referred to a rheumatologist. Finally, there may be a small proportion of asymptomatic patients who have changes in their sacroiliac joints suggestive of sacroiliitis, though this is of uncertain clinical significance.

Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: There is a well-documented association between inflammatory bowel disease (IBD) and ankylosing spondylitis (AS). The hallmark feature of AS is the presence of sacroiliitis that has traditionally been diagnosed using an AP view of the pelvis on X-ray. Many IBD patients receive supine and erect abdominal X-rays in the management of their bowel disease and it is not known whether these films can be used in the diagnosis of AS.

Many experts agree that CT scan is a superior imaging modality for the diagnosis of sacroiliitis though until recently there was no definition of what constituted a positive CT. Recently we have described a standardized scoring system for the diagnosis of sacroiliitis which is anchored in the modified New

York criteria (mNY). To date, there has not been a study assessing the diagnostic utility of abdominal X-rays for the diagnosis of spondyloarthritis in IBD patients.

We aim to compare the reproducibility and test characteristics of abdominal X-rays in detecting CT-positive sacroiliitis in a IBD cohort.

Methods: In a previous study, we identified IBD patients who had a CT scan of their abdomen/pelvis from one IBD clinic. CT scans were read by 2 blinded readers and 49 patients were identified as having sacroiliitis according to a recently validated scoring system. Of these 49 patients, 33 were found to have abdominal X-rays done within 1 year of their CT scan.

The 33 patients included in the study were matched by age, gender, and IBD subtype to control IBD patients (n=33). X-rays were randomized and read by two experienced blinded readers according to modified New York grade. Discordant results were settled by a third reader. Patients were classified as having diagnostic or non-diagnostic SI joints and inter-reader reliability as well as the prevalence of specific features of sacroiliitis was determined.

Results: The median age for IBD patients was 35 years (range 17-75) and 64% were male. Within the CT positive group, 21/33 (64%) were scored as having diagnostic X-rays according to mNY grading system. Amongst the CT-negative control group, X-rays identified sacroiliitis in 3/33 (9%) patients. Inter-reader reliability for diagnosis of sacroiliitis using X-rays was good (κ=0.659) which was similar to that found with CT scan (κ=0.697). Cramér's V correlation between the two imaging modalities revealed an r=0.647. Chi squared test was used to compare the two nominal variables and showed a p value <0.0001. Fig 1 shows the distribution of SI joint grade according to CT scan result.

Conclusion: Abdominal X-ray and CT scan have a similar inter-reader reproducibility for the diagnosis of sacroiliitis. Abdominal X-ray is able to detect the majority of patients with CT-positive sacroiliitis; however, 36% of CT-positive patients would not have been identified. These results need to be further correlated with clinical context to confirm a diagnosis of spondyloarthritis.

Fig 1: Distribution of SI joint grade according to CT scan results

Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: There is growing recognition of the importance of structural lesions of the sacroiliac joints (SIJ) on MRI to the diagnostic evaluation of axial spondyloarthritis (axSpA) but it is unclear to what degree current definitions for such lesions and methods for evaluation of the SIJ allow reliable assessment between different centers and readers. We aimed to assess reliability of evaluation of structural SIJ lesions on MRI without conducting

calibration exercises between readers at two centers, readers at one center being internally calibrated and having extensive experience in evaluation of structural lesions in the SIJ.

Methods: All readers simultaneously evaluated T1-weighted and short tau inversion recovery (STIR) scans from 9 patients with non-specific back pain and 23 with axial SpA from 2 centers (Leiden=12, Edmonton=20). All readers were internally calibrated, and readers in one center have extensive experience in evaluation of structural lesions in the SIJ. Scans were read blinded to patient characteristics, diagnosis, and scan origin, and data entered directly online using a web-based schematic of the SIJ. Bone marrow edema (BME) and structural lesions (erosion, fat metaplasia, sclerosis, ankylosis) were scored on consecutive semi-coronal slices through the SIJ using a binary method based on presence/absence of the lesion in SIJ quadrants except for ankylosis, which was assessed according to SIJ halves. Slices were selected according to the methodology used in the Spondyloarthritis Research Consortium of Canada (SPARCC) MRI SIJ inflammation scoring method. Interobserver reliability was calculated by intra-class correlation coefficient (ICC) and comparisons made with pre-specified expert readers.

Results: Mean (SD) scores for BME, erosion, fat metaplasia, sclerosis, and ankylosis were 5.3 (7.1), 6.1 (5.5), 6.5 (7.5), 2.5 (3.4), 0.3 (1.2) with significantly higher scores being recorded for BME, erosion, and fat metaplasia by expert readers. Mean (range) for sensitivity/specificity for expert clinician diagnosis of SpA was 0.85 (0.75-0.91)/0.88 (0.79-1.00), sensitivity of expert readers being higher (0.90 vs 0.81) though specificity was lower (0.85 vs 0.92). Interobserver reliability for structural lesions was comparable between groups of readers and approached the reliability of BME for erosion, and fat metaplasia (Table). Reliability for sclerosis and ankylosis varied although few cases demonstrated significant involvement with these lesions.

Conclusion: The presence and extent of erosion and fat metaplasia can be reliably assessed by simultaneous evaluation of T1W and STIR scans even without calibration between readers and seems promising for diagnostic evaluation. Evaluation of ankylosis and sclerosis, on the other hand, requires further study in cohorts that have more cases with these lesions.

Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Psoriatic arthritis mutilans (PsAM) is the most severe form of Psoriatic arthritis (PsA). Research on PsAM has been hampered by the lack of an accepted disease definition and a consensus on radiographic assessment. We recently performed a systematic review of the literature and conducted a survey of members of the Group for Research and Assessment of Psoriasis and PsA (GRAPPA) to identify radiographic features associated with PsAM. Based on the results of these studies, joint erosion of the entire articular surfaces on both sides of the joint, bone resorption leading to bone shortening, pencil-in-cup deformity, ankylosis, and subluxation were deemed to be PsAM manifestations. Thus, the aim of this study was to determine the reliability of assessing PsAM features on plain radiographs.

Methods: The radiographs of 35 PsA patients who have one of the five features in at least one joint of the hands or feet were retrieved and duplicated to generate 70 sets of images. Three rheumatologists, blinded to diagnosis, independently evaluated the radiographs for the five PsAM features in random order. A total of 42 joints, including wrists, all joints of the hand, all metatarsophalangeal joints and the interphalangeal joints of the first toes, were evaluated for each set of images. Inter- and Intra-observer reliability of the five features (joint erosion of the entire articular surfaces on both sides, bone resorption, pencil-in-cup change, ankylosis, and subluxation) in each joint were determined using the kappa statistic with standard errors calculated to accommodate an association between joints within patients.

Results: Moderate inter-rater agreement was observed for radiographic assessment of PsAM when the five PsAM features were considered as separate categories (kappa 0.63). The kappa improved to 0.83 when the PsAM features were grouped together as one category, indicating excellent inter-rater reliability in identifying severe joint damage. However, the specific agreement for each of the five PsAM features ranged from poor to moderate. Specifically, the assessment of joint erosion involving entire articular surfaces on both sides of the joint and bone resorption showed a kappa of 0.22 and 0.17, respectively whereas pencil-in-cup change, ankylosis and subluxation showed a kappa of 0.59, 0.76 and 0.52, respectively. Intra-rater reliability is excellent with an overall kappa ranging from 0.81 - 0.83. Based on these results, a revised evaluation protocol, where subluxation was removed and bone resorption and joint erosion were combined into one category as severe osteolysis, was applied to the analysis. The assessment of severe osteolysis showed an improved kappa of 0.54, and the kappa for overall inter-rater agreement in PsAM assessment increased to 0.72 with the revised protocol.

Conclusion: These results indicate that there is moderate agreement in radiographic assessment of severe joint damage associated with PsAM. However, the agreement for specific features such as severe joint erosion and bone resorption was poor. The new definitions of the PsAM features and the revised evaluation protocol showed promising result in improving the feature-specific and overall agreement in radiographic assessment of PsAM.

MRI Vertebral Corner Inflammation Followed By Fat Deposition Is the Strongest Contributor to the Development of New Bone at the Same Vertebral Corner: A Multi-Level Longitudinal Analysis in Patients with Ankylosing Spondylitis

Pedro Machado[1], Xenofon Baraliakos[2], Désirée van der Heijde[3], Juergen Braun[2] and Robert Landewé[4], [1]Rheumatology, Leiden University Medical Center, Leiden, Netherlands, [2]Rheumazentrum Ruhrgebiet, Herne, Germany, [3]Dept. of Rheumatology, Leiden University Medical Center, Leiden, Netherlands, [4]Division of Clinical Immunology and Rheumatology, Academic Medical Center / University of Amsterdam, Amsterdam, Netherlands

Session Date: Monday, November 9, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Syndesmophyte formation in ankylosing spondylitis (AS) is still insufficiently understood. Previous studies have suggested an association between MRI vertebral corner inflammation (VCI) and vertebral corner fat deposition (VCFD) and the subsequent development of radiographic syndesmophytes (SYN). Our aim was to investigate the relationship between MRI inflammation and fat deposition at a VE and the development of a SYN at the same VE.

Methods: A random 80% sample of the ASSERT database was used for this analysis. ASSERT was a 24-week (wk) RCT comparing infliximab monotherapy and placebo in patients with active AS, with an open extension until 102wks with all patients on infliximab. Spinal MRIs (T1-weighted and STIR images) at baseline, 24wks and 102wks were assessed by 2 readers independently who scored each VE for the presence or absence of VCI and VCFD. Spinal X-rays (baseline and 102wks) were scored by 2 different readers independently using the mSASSS. Data were analysed at the VE level in the 24 VEs assessed by the mSASSS (anterior VEs of the cervical and lumbar spine), using a multi-level approach to adjust for within-patient correlation and MRI reader (GEE for binomial outcomes). Particular emphasis was on a sequence analysis, which aimed at the specific sequence VCI→VCFD→SYN. The following variables were considered potential covariates and adjusted for when appropriate: treatment, gender, presence of SYN/ankylosis at baseline (patient level), HLA-B27, baseline- and time-averaged BASDAI/ASDAS/CRP, age, BMI and disease duration. Readers were unaware of the patient's identity, their treatment, the scores of the other imaging modality, and the true time-order of the images (fully unbiased scores).

Results: After excluding VEs with SYN or ankylosis at baseline and non-evaluable VEs, data from 3079 to 3363 MRI and X-ray paired case-definitions, belonging to up to 177 patients, were analysed. The presence of VCI (adjusted (ad)OR=1.98-1.93) as well as the presence of VCFD (adOR=1.59-2.32) at any time point (TP) was significantly associated with the development of a new SYN. The strength of the association increased by combining VCI and VCFD, both when analysing VEs with VCI and VCFD present across any of the three TP (simultaneously or not) (adOR=2.29-2.73) and also when analysing

only newly developed VCFD preceded by inflammation in the same VE at a previous TP (adOR=2.45-3.01) (sequence analysis, VCI→VCFD→SYN). The complete absence of both VCI and VCFD across the three TP was protective for the development of a new SYN (aOR= 0.45-0.62) (Table). However, a large proportion of SYN developed in VEs without MRI inflammation or fat degeneration at any of the three TP (42-66%, depending on the combination of MRI- and X-ray reader).

Conclusion: Both VCI and VCFD contribute to the development of a new SYN in AS, especially if VCI precedes VCFD. But this typical sequence only partially explains the development of new SYN in AS.

Table. Multivariable GEE results (adjOR; 95% CI) for the outcome SYN formation according to X-ray reader 1 (R1) or/and reader 2 (R1)					
Variables	**SYN formation according to R1 or R2**

Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Diffusion weighted imaging (DWI) is an MRI protocol which assesses the random Brownian motion of water molecules in the tissue imaged; this motion is restricted in inflamed tissue. Previous studies have suggested that this approach may have diagnostic potential in AS. We sought to test the diagnostic capacity of DWI, and to assess its potential an objective measure of treatment response to TNF-inhibition, in AS.

Methods: Three cohorts were studied: 1. 18 AS patients with BASDAI>4 and ESR>25 and/or CRP>10 meeting the modified New York Criteria for AS; 2. 20 cases with non-radiographic axial SpA as defined by the ASAS criteria, and 3. 20 non-AS patients with chronic low back pain >3 months duration aged >18 years but <45 years. Group 1 patients were studied immediately prior to and following 14 weeks of treatment with adalimumab 40mg s/c fortnightly. All Group 2 patients met the imaging arm of the ASAS criteria and 13 also met the clinical criteria. Ten Group 3 patients met the ASAS clinical criteria, but none met the imaging criteria, and all were assessed as having non-inflammatory back disease clinically. Patients were assessed by DWI (right and left iliac ADC measures corrected for sacral background measure), BASDAI, BASFI, BASMI, ASDAS-CRP, CRP and ESR. Patients on corticosteroids were excluded, and NSAID and analgesic medications were kept stable during the follow-up study of Group 1 patients.

Results: At baseline BASDAI, BASFI, BASMI, ASDAS-CRP, CRP and ESR levels were increased in Group 1 patients, but similar between Group 2 and 3 patients (CRP levels were increased in Group 2 vs 3 patients). Post treatment Group 1 patients had lower BASDAI, BASFI, ASDAS-CRP, and similar BASMI, CRP and ESR levels, compared with either Group 2 or 3 patients. ROC curve analysis showed that none of these measures individually discriminated between Group 1 and 2 patients vs non-inflammatory controls (AUC values 51-74%). In contrast DWI ADC values showed good discriminatory performance (AUC 86%, $P<10^{-5}$, sensitivity 88%, specificity 81%). The AUC for G2 vs G3 was similarly high (90%, $P<10^{-5}$, sensitivity 90%, specificity 85%). DWI ADC scores correlated poorly with other disease activity measures (correlation coefficients -0.27 to +0.36, overall dataset). Comparing patients pre and post adalimumab treatment, BASDAI, BASFI, ASDAS-CRP, ASDAS-ESR, CRP and ESR had high discriminatory performance (AUC 99%, 81%, 99%, 97%, 95% and 88% respectively). DWI ADC values were significantly lower post adalimumab treatment (0.45±0.433 pre, 0.154±0.23 post, P=0.022), but had only modest discriminating capacity (AUC 64%).

Conclusion: DWI imaging is informative for diagnosis of AS and non-radiographic axial spondyloarthritis, but has only moderate utility in assessment of disease activity or treatment response.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Ankylosing Spondylitis (AS) is debilitating disease affecting the axial skeleton which is often difficult to diagnose in early stages. Magnetic Resonance Imaging (MRI) is a valuable tool in detecting early inflammatory lesions of the spine and monitoring treatment effects. The longitudinal relationship between changes in MRI inflammation and measures of clinical disease activity remains uncertain. The aim of this study was to describe the predictors of change in spinal inflammation and the association with change in clinical outcomes.

Methods:

129 participants [mean age (years) 41 (17-72); 64 % male] were studied at baseline and 2 years. MRI of the spine and sacroiliac (SI) joints were performed at the baseline and follow-up visits. Images were scored, using the Spondyloarthritis Research Consortium of Canada (SPARCC) 6–discovertebral unit (6-DVU) and SPARCC method for the SI joints. Radiographs were used to assess structural damage at the cervical/lumbar spine and SI joints. Disease activity was assessed using ESR measurements, Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and Bath AS disease activity index or by the AS disease activity score (ASDAS). Functional limitations and disability were assessed using the Bath Ankylosing Spondylitis Functional Index (BASFI) and the Health Assessment Questionnaire (HAQ) respectively.

Results:

Table 1 describes the characteristics of the participants split by the mean spinal MRI score at the baseline visit. A higher spinal MRI score was significantly associated with older age, male gender, higher BMI, higher BASMI, BASDAI and BASFI scores, and a more advanced disease at the SI joint.

Only higher mean BASDAI ($p=0.025$) and HAQ ($p=0.024$) scores significantly predicted an increase in spinal MRI scores over 2 years (data not shown).

Table 2 describes the association between change in spinal MRI score and change in clinical outcomes over 2 years. Increases in BASDAI, BASFI and ASDAS scores, but not BASMI, were independently associated with an increase in the severity of the spinal MRI scores.

Conclusion:

In summary, only high BASDAI and HAQ scores predicted an increase in MRI spinal inflammation over 2 years. Increase in MRI spinal inflammation in turn, was independently associated with worsening clinical outcomes such as BASDAI, BASFI and ASDAS. These results suggest that MRI spinal inflammation mirrors clinical outcomes over 2 years.

Table 1: Baseline characteristics of participants split by mean spine MRI score*

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Impaired function and spinal mobility in patients with ankylosing spondylitis (AS) can be caused by both spinal inflammation and new bone formation. Anti-TNF therapy has been shown to reduce inflammation but the influence on radiographic progression is less clear. The aim of the study was to investigate the impact of long-term (up to 10 years) anti-TNF therapy on function and spinal mobility in relation to radiographic progression in the spine in patients with AS.

Methods:

Altogether 60 patients with AS from two long-term trials with TNF blockers (43 on infliximab and 17 on etanercept) were included in this analysis based on availability of spinal x-rays performed at baseline and at least at one following time-point (year 2, 4, 6, 8, 10) during the follow-up. Spinal radiographs (cervical and lumbar spine lateral views) were scored according to the modified Stoke Ankylosing Spondylitis Spine Score (mSASSS) system by two readers (DP and AF) not blinded for the time point. The functional status was assessed by means of the Bath Ankylosing Spondylitis Functional Index (BASFI), spinal mobility – by the Bath Ankylosing Spondylitis Metrology Index (BASMI, 0-10), and clinical disease activity - by the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI).

Results:

Patients treated with infliximab and etanercept had similar baseline characteristics with regards of age, gender, HLA-B27 status, symptom duration, disease activity and baseline structural damage that allowed pooling of the data. After the BASFI, BASMI, and BASDAI had initially improved significantly in response to anti-TNF therapy these two outcome parameters remained remarkably stable at low levels over 10 years in those patients who remained on the drug over time despite the observed mean increase of the mSASSS by 6 points. The cumulative probability plots (figure) demonstrate no increase of BASFI and BASMI with increasing mSASSS. In the multivariate analysis, there was no association between mSASSS change and BASFI change, while there was some impact of the mSASSS change on BASMI change over time (table). BASDAI demonstrated a strong association with functional status and, to a lesser extent, with spinal mobility.

Conclusion:

Functional status in patients with advanced AS remained stable during long-term anti-TNF therapy despite radiographic progression. Under these conditions, the BASFI course correlated strongly with BASDAI but not with the mSASSS. This might indicate that a good control of inflammation is able to overweight the negative effect of structural damage in the spine on the functional status in AS.

Figure: Cumulative probability plots of BASFI (A) and BASMI (B) changes from baseline in relation to radiographic spinal progression over 10 years of follow up

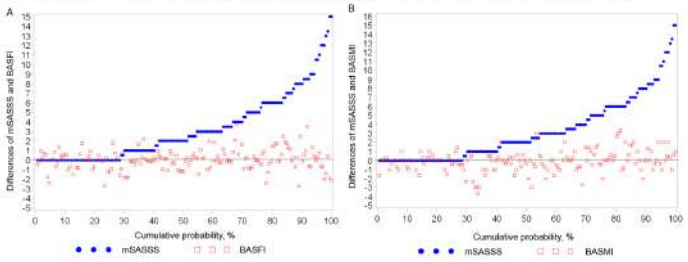

Table: Impact of radiographic spinal progression and disease activity on functional status and spinal mobility in AS under long-term anti-TNF treatment

	BASFI change from baseline (week 12)		BASMI change from baseline (week 12)	
	ß (95% CI)	p	ß (95% CI)	p
mSASSS change from baseline	0.0 (-0.04 to 0.03)	0.95	0.05 (0.01 to 0.09)	0.020
BASDAI	0.50 (0.39 to 0.61)	<0.001	0.11 (0.00 to 0.22)	0.055

ß – regression coefficients from the generalised linear mixed model analysis

Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: In ankylosing spondylitis (AS), syndesmophyte formation and ankylosis of the vertebral bodies are characteristic radiographic changes that are evaluated during follow-up. However, the facet joints are also involved in the disease process. Our aim was to investigate the prevalence and incidence of radiographic facet joint involvement in comparison to damage of vertebral bodies in the cervical spine of AS patients treated with TNF-α inhibitors. Second, to explore the association of facet joint involvement with patient characteristics and clinical outcome.

Methods: Consecutive patients from the Groningen Leeuwarden AS (GLAS) cohort who started treatment with TNF-α inhibitors because of active disease were included. Available lateral radiographs of the cervical spine at baseline and after 4 years of follow-up were scored by two trained and independent readers blinded to patient characteristics and time sequence. Facet joints of C2-C3 up to C6-C7 were scored according to the method of de Vlam *et al.* (0: normal, 1: joint space narrowing or erosion, 2: partial blurring or ankylosis, 3: complete blurring or ankylosis). Definite damage and progression of facet joints was defined as the presence and development of partial/complete blurring or ankylosis (score ≥2) in ≥1 facet joint, respectively. The modified Stoke AS Spine Score (mSASSS) was used to assess radiographic damage of the vertebral bodies. Definite damage and progression was defined as the presence and development of ≥1 (bridging) syndesmophyte, respectively.

Results: Of 108 included patients, 76% were male, mean age was 43±11 years, median symptom duration 17 years (range 1-50), 84% were HLA-B27 positive, mean BASDAI was 5.9±1.7, and mean ASDAS 3.8±0.8.

At baseline, 28 (26%) patients had definite damage of facet joints with on average 3 facet joints involved. Fifty-nine (55%) patients had definite damage of vertebral bodies. Damage of facet joints exclusively occurred in 5 (5%) patients. Patients with damage of facet joints were more frequently male, older, had longer symptom duration, more frequently a history of psoriasis, larger occiput-to-wall distance, and higher mSASSS of the cervical spine (all $p<0.05$).

After 4 years of follow-up, 13 (12%) patients showed definite progression of facet joints and 28 (26%) showed definite progression of vertebral bodies. Progression of facet joints without progression of vertebral bodies was seen in 8 (7%) patients.

Conclusion: In this observational cohort of AS patients with active disease, 26% had radiographic damage of facet joints whereas 55% had damage of vertebral bodies. Damage of facet joints was associated with male gender and more advanced disease. During 4 years of TNF-α blocking therapy, 12% showed definite progression of facet joints. More than half of these patients did not show progression of vertebral bodies.

Session Date: Monday, November 9, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Comorbidities and Treatment Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Assessing radiographic progression in ankylosing spondylitis (AS) is challenging. The results regarding the effect of tumor necrosis factor-alpha (TNF-α) blocking therapy on spinal radiographic progression are difficult to interpret due to methodological limitations. Our aim was to evaluate spinal radiographic progression over 2 to 8 years of follow-up in a large cohort of AS patients treated with TNF-α inhibitors.

Methods: Consecutive patients from the Groningen Leeuwarden AS (GLAS) cohort who started treatment with TNF-α inhibitors because of active disease were included. Available lateral cervical and lumbar radiographs at baseline and after at least one follow-up visit at 2, 4, 6, or 8 years were scored in chronological time order by two trained and independent readers using the modified Stoke AS Spine Score (mSASSS). Descriptive statistics for 0-2, 0-4, 0-6, 0-8 years and generalized estimating equations (GEE) for complete cases over 8 years were used to evaluate spinal radiographic progression.

Results: In total, 193 GLAS patients were included; 69% were male, mean age was 42 ± 11 years, median symptom duration was 15 years (range 1-53), 78% were HLA-B27 positive, and median baseline mSASSS was 2.5 (range 0-68).

The mean spinal radiographic progression ranged from 1.7 ± 2.8 over the first 2 years to 7.0 ± 5.3 over 8 years of follow-up (Table 1). GEE analysis of complete cases over 8 years (n=19) revealed that the logarithmic time model had the best fit for the data. This model showed a deflection in mSASSS over time; the estimated progression rate was 2.3, 1.4, 1.0 and 0.8 during 0-2, 2-4, 4-6, and 6-8 years, respectively.

Conclusion: This observational study showed overall slow spinal radiographic progression in AS patients treated with TNF-α inhibitors. In a limited number of patients, complete case analysis indicated a deflection in spinal radiographic progression during 8 years of follow-up.
