Results: We analysed data from 1254 patients with vasculitis and 507 comparators. The vasculitis group was older (median age 64.1 (50.8-74.0) vs 58.1 (45.7-68.8) years; $p<0.0001$) and had shorter duration of symptoms (median 10.6 (7.9-16.4) vs 11.6 (7.8-21.7) months; $p=0.0379$). The median (IQR) number of VDI items was higher in all types of vasculitis vs comparators 1 (0-2) vs 0 (0-1), as well as for each form of vasculitis separately: GPA 1 (0-3) vs 0 (0-2); EGPA 2 (1-4) vs 0 (0-2); MPA 2 (0-3) vs 1 (0-2); PAN 1 (0-2) vs 0 (0-1) with $p< 0.0001$ for all; for TAK 2 (0-2) vs 0 (0-1) ($p<0.0004$); for GCA 0 (0-1) vs 0 (0-1) ($p=0.0054$). On multivariate analysis, average VDI scores were significantly higher in the vasculitides than comparators, except for GCA. Data on the individual damage items which were seen more frequently in each type of vasculitis, in comparison with the corresponding comparators, are presented in Table 2.

Conclusion: Patients with vasculitis accrue more damage in the first 6 months than disease comparators. A focus on reducing this early damage should be a key target of management in these patients.

Table 1. Comparator conditions for each form of vasculitis

	GPA	EGPA	MPA	PAN	GCA	TAK

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Vasculitis Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Immunosuppressive agents have changed the outcome of the systemic vasculitides from invariably fatal to chronic conditions associated with damage as a result of disease, its treatment or comorbidity. The Vasculitis Damage Index (VDI) is a validated and standardized tool to measure damage occurring since the onset of disease.

Methods: We compared patterns of damage amongst patients with 8 forms of primary vasculitis, using data obtained from the ACR/EULAR Diagnosis and Classification Criteria of Vasculitis study (DCVAS). VDI was evaluated at the follow up visit, at least 6 months from diagnosis. Total VDI scores, systems involvement and individual damage items were compared across different types of vasculitis.

Results: The distribution of damage items was measured in 1371 adult patients with giant cell arteritis (GCA, n=453; median age 74 years [Inter Quartile Range 66-79]; Male:Female ratio 153:150), granulomatosis with polyangiitis (GPA; n=395; age 56 [43-65]; M:F 199:196), microscopic polyangiitis (MPA; n=158; age 65 [57-74]; M:F 70:88), eosinophilic granulomatosis with polyangiitis (EGPA; n=106; age 58 [44-65]; M:F 58:48), Takayasu's arteritis (TAK; n=93; age 33 [27-44]; M:F 21:72), IgA vasculitis (IgAV; n=86; age 46 [29-69]; M:F 49:37), Behçet's disease (BD; n=42; age 33 [28-39]; M:F 22:20), and polyarteritis nodosa (PAN; n=39; age 52 [34-61]; M:F 22:17). The median VDI score for all patients was 1.5 [0-11], measured at a mean of. 241±143 days after diagnosis. Levels of damage in different forms of vasculitis were defined as: low (IgAV and GCA, median VDI of 0; range 0-7), intermediate (PAN, GPA and BD, median VDI of 1; range 0-8) or high (TAK and EGPA, median VDI of 2; range 0-11). The most frequent VDI systems involved differed for each of the vasculitides included as follows: GCA: eyes (23%, $p<0.001$) and musculoskeletal (10%, $p=0.82$); GPA: ear, nose and throat (46%, $p<0.001$) and kidneys (22%, $p<0.001$); MPA: kidneys (53%, $p<0.001$) and lungs (25%, $p<0.001$); EGPA: lungs (58%, $P<0.001$) and neurological (57%, $P<0.001$); TAK: peripheral vessels (73%, $p<0.001$) and cardiovascular (27%, $p<0.001$); IgAV: kidneys (17%, $p=0.46$) and cardiovascular (6%, $p=0.21$); BD: skin/mucosa (56%, $p<0.001$) and eyes (21%, $p=0.06$); PAN: neurological (36%, $p<0.001$) and gut (20%, $p<0.001$). The most frequent individual items recorded in VDI per diagnosis are shown in Table 1.

Conclusion: Damage is detected early across the spectrum of systemic vascultides evaluated in this study, suggesting that patients suffer long term consequences of having a diagnosis of vasculitis. The amount and pattern of damage differs between individual diseases. EGPA and TAK are associated with the highest levels of damage; IgAV and GCA have the lowest levels. These patterns could serve as a basis for evaluating the impact of new or existing therapies on outcomes in vasculitis.

Table 1 Most frequent items of damage recorded, six months after diagnosis of vasculitis

The top 3 most frequent VDI items recorded for each disease

	Item	Frequency	P-value compared to all other forms of vasculitis

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Vasculitis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

The chronic primary systemic vasculitides are a group of rare conditions with affected patients subject to a significant burden of morbidity from both the disease itself and its treatment. In adult vasculitides, the Vasculitis Damage Index (VDI) is a validated damage assessment tool and an integral outcome measure. The lack of such a validated index in childhood vasculitis has contributed to the paucity of outcome data in children with vasculitis. The aim of this study was to use a modification of the adult VDI to assess damage accrual in a cohort of children with primary systemic vasculitis recruited to A Registry of Childhood Vasculitis (ARCHiVe), a web-based registry founded in 2007 by the Canadian/US based Childhood Arthritis and Rheumatology Research Alliance (CARRA).

Methods:

A multi-centre cohort study of children enrolled into ARCHiVe was conducted. Children were included if they were followed for at least 12 months and had a PVDI completed.

Results:

A total of 74 children were included in the study. 65% were female. The mean age was 11.8 years (range 2-18). Granulomatosis with polyangiitis (GPA) was the most frequently encountered diagnosis (Table 1). At baseline, the median Paediatric Vasculitis Activity Score (PVAS) was 12 (range 2-31). At 12 months, 39/74 children (52.7%) had accumulated at least one item of damage (PVDI=1 in 18 patients, PVDI=2 in 14, PVDI=3 in 4, PVDI=4 in 1 and PVDI=5 in 2). The most commonly recorded damage items were in the "Other" section (consisting of significant striae [16.2%], chronic cough [5.4%] and vocal cord paralysis [5.4%]), followed by "Renal" due to end stage renal failure (9.5%) and proteinuria (9.5%) and "Pulmonary" due to impaired lung function (9.5%) as shown in Figure 1.

Conclusion:

Within the first year of disease more than 50% of children with systemic vasculitis have accumulated damage. The information gained from this study provides a useful data driven basis for future development and validation of a damage assessment tool in paediatric vasculitis.

Table 1

Diagnosis	No of Patients	Percentage %
Granulomatosis with Polyangiitis (GPA)	43	58.1
Limited Granulomatosis with Polyangiitis	8	10.8
Takayasu Arteritis	7	9.5
Eosinophilic Granulomatosis with Polyangiitis (EGPA)	5	6.8
Microscopic Polyangiitis (MPA)	3	4
Isolated Renal Microscopic Polyangiitis	3	4
Polyarteritis Nodosa	3	4
Unclassified Primary Vasculitis	1	1.4
ANCA positive pauci-immune glomerulonephritis	1	1.4

Session Title: Vasculitis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Granulomatosis with Polyangiitis (GPA) is associated with an increased risk of mortality. However, recent mortality trends in GPA are largely unknown, particularly in the general population. Our objectives were to assess mortality trends among GPA patients between January 1, 1997 and December 31, 2012 in a general population context.

Methods: Using an administrative health database from the province of British-Columbia, Canada (4.7 million), we identified all incident cases of GPA and up to 10 (6 were available) non-GPA controls matched on sex, age, and calendar year of study entry, between 1997 and 2012. All GPA cases required the use of glucocorticoids, immunosuppressives or methotrexate, during the period one-month before and six-months after the date of study entry as part of the case definition. The GPA cohort was then divided in two cohorts based on year of GPA diagnosis (i.e., 1997-2004 and 2005-2012) to evaluate changes in mortality. We calculated hazard ratios (HR) for death using a Cox proportional hazard and the rate differences using an additive hazard model, while additionally adjusting for potential confounders (e.g., Charlson Comorbidity Index, number of outpatient visits, hospitalization, cardiovascular drugs, glucocorticoids and NSAIDs).

Results: The early cohort (1997-2004) GPA patients had a considerable higher mortality rate than the late cohort (2005-2012) (i.e., 150.1 cases vs. 51.1 cases per 1000 person-years), as compared with only a moderate improvement in comparison cohorts between the two periods (24.0 to 15.9 per 1000 person-years). The corresponding absolute mortality rate differences were 88.2 (95% CI 55.1, 121.4) and 7.1 (95%CI -9.6, 23.8) cases per 1000 person years (p-value for interaction <0.001).

The corresponding adjusted HRs for mortality were 3.54 (95% CI, 2.42-5.18) and 1.72 (95% CI, 1.17-2.53), respectively (p for interaction = 0.003)

Conclusion: This population-based study shows that survival of GPA patients has improved over the past decade, suggesting the new treatments and improved management of the disease and its complications may be providing substantial benefits.

Table 1: Incidence Rates and Hazard Ratios (HR) for Associations between GPA and Death According to Cohort

Significance of Interstitial Pneumonitis in Microscopic Polyangiitis

Kensuke Nakanishi and Mitsuyo Kinjo,
Rheumatology, Okinawa Chubu Hospital, Uruma, Japan

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Vasculitis Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Microscopic polyangiitis (MPA) is often associated with lung involvement, including alveolar hemorrhage and interstitial pneumonitis (IP). Clinical characteristics of IP in MPA have not been well described. The aim of this study was to determine the prevalence and clinical course of IP in MPA.

Methods: We retrospectively identified MPA patients at a tertiary medical center in Japan between 2002-2014. MPA patients with positive perinuclear anti-neutrophil cytoplasmic antibody (p-ANCA) who presented with renal involvement, including glomerulonephritis, acute and chronic renal failure, or lung disease such as alveolar hemorrhage or IP were selected. Data were collected on clinical features, medications, radiographic imaging (chest X-ray and computed tomography), and clinical outcome

Results: We identified 39 Japanese patients with MPA (Table). Median age was 69 (16-87); 51% were female; median observation period was 33 months (range 3-158). Among 27/39 (69%) who had IP, IP preceded diagnosis of MPA in 9 (33%), was seen upon diagnosis in 15 (56%), and occurred after diagnosis in 3 (11%). IP was not diagnosed in 33% of patients with MPA, over a median observation period of 74 months (range 45-138). Thirty-seven (95%) patients were treated with steroids or immunosuppressants. Acute exacerbation of IP was seen in 4 (15 %), and no radiographic change in 9 (33%) or minimal worsening of IP without clinical significance in14 (52%) on was found. All-cause mortality or death due to pulmonary complication in MPA did not differ between subjects with or without IP.

Conclusion: IP often precedes other manifestations of MPA. Clinical characteristics and outcomes are similar to those without IP.

Table. Clinical Characteristics of Microscopic Polyangiitis, by Interstitial Pneumonitis status.

Clinical characteristics	Interstitial pneumonitis present	Interstitial pneumonitis absent	P
n	27	12	
Age, years (range)	70 (56-87)	68 (15-86)	0.16
Female (n, %)	14 (52)	6 (50)	1
Observation period, months, median(range)	33 (3-159)	31 (18-77)	0.76
Tobacco (n, %)	15 (56)	8 (67)	0.73
Renal involvement (n, %)	23 (85)	12 (100)	0.29
Fever (n, %)	15 (56)	5 (42)	0.5
Skin involvement (n, %)	1 (4)	3 (25)	0.08
Peripheral neuropathy (n, %)	3 (11)	2 (17)	0.63
Alveolar hemorrhage (n, %)	5 (19)	4 (33)	0.42
Steroids (n, %)	25 (93)	12 (100)	1
Immunosuppressants* (n, %)	17 (63)	6 (50)	0.5
All-cause mortality (n, %)	12 (44)	3 (25)	0.31
Deaths due to pulmonary complication (n, %)	6 (22)	2 (17)	1

Diffuse Alveolar Hemorrhage Secondary to ANCA-Associated Vasculitis: Predictors of Respiratory Failure and Clinical Outcomes

Rodrigo Cartin-Ceba[1], Fernando Fervenza[2], Steven R. Ytterberg[3] and Ulrich Specks[4], [1]Pulmonary and Critical Care Medicine, Mayo Clinic, Rochester, MN, [2]Mayo Clinic, Rochester, MN, [3]Rheumatology Division, Mayo Clinic, Rochester, MN, [4]Division of Pulmonary and Critical Care Medicine, Mayo Clinic College of Medicine, Rochester, MN

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Vasculitis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The interpretation of the literature on diffuse alveolar hemorrhage (DAH) secondary to ANCA-associated vasculitis (AAV) has been complicated by the small size of reported cohorts, variable and unclear definitions of DAH used, and insufficient description of respiratory failure and its predictors. In addition, patients with severe DAH requiring mechanical ventilation were excluded from the only randomized controlled trial that comprised a sizable number of patients with DAH. In a well-defined cohort of patients with DAH secondary to AAV, we sought to identify predictors of respiratory failure and to describe the therapeutic efficacy of plasma exchange (PLEX) and rituximab versus cyclophosphamide in patients with or without respiratory failure.

Methods: Single center historical cohort study of all consecutive patients presenting with DAH secondary to AAV evaluated over a 15 year period. Respiratory failure was defined as the need for mechanical respiratory support. The main outcome was complete remission at 6 months (BVAS/WG=0 and off corticosteroids). Logistic regression models were developed to examine the predictive role of the baseline clinical characteristics for the development of respiratory failure, and also for the role of PLEX and induction of remission therapy on the main outcome. To account for potential unequal distribution of important covariates between groups resulting from the lack of random assignment in this observational study (sicker patients received PLEX), a propensity score analysis was performed to assess the probability of receiving PLEX.

Results: Seventy-three patients with DAH were identified of whom 34 patients developed respiratory failure. Degree of hypoxemia upon initial presentation, higher neutrophil percentage in the bronchoalveolar lavage fluid cell count, and higher C-reactive protein levels were independently associated with the development of respiratory failure. Complete remission at 6 months was achieved in 23 of 32 (72%) patients treated with PLEX versus 32 of 41 (78%) patients treated with no PLEX, p=0.54. After adjustment for important covariates, PLEX therapy was not found to be associated with achieving complete remission at 6 months (OR 0.49, 95% CI 0.12-1.95, p=0.32). Complete remission at 6 months was achieved in 33 of 37 (89%) patients treated with rituximab versus 21 of 31 (68%) patients treated with cyclophosphamide, p=0.02. After adjustment for important covariates, rituximab therapy was independently associated with increased odds of achieving complete remission at 6 months (OR 6.45, 95% CI 1.78-29, p=0.003). There was no difference in long-term survival between patients treated with rituximab compared to those treated with cyclophosphamide.

Conclusion: The most important predictor of respiratory failure in these patients seems to be the degree of hypoxemia upon presentation. A clear benefit of PLEX added to standard remission induction therapy could not be demonstrated. Patients with DAH secondary to AAV, including those requiring mechanical ventilation, achieved complete remission by 6 months at a higher rate with rituximab than with cyclophosphamide.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Vasculitis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Diffuse alveolar haemorrhage (DAH) is a rare and potentially fatal complication of the systemic vasculitides and may present directly to the intensivist as a severe acute respiratory distress syndrome (ARDS) with reported mortality of 12- 60%. Whilst a severe respiratory failure (SRF) therapy strategy incorporating extracorporeal membrane oxygenation (ECMO) improves outcomes in ARDS, use of ECMO in DAH is often considered to be relatively contraindicated due to the requirement for systemic anticoagulation.

Methods:

We present a case series of 4 patients with DAH due to underlying ANCA-associated vasculitides diagnosed and / or managed by a standardised diagnostic pathway and ARDS treatment algorithm in a single, UK SRF centre, between 2012-13. We analysed the Extracorporeal Life Support Organisation (ELSO) database using ICD-9 codes 446.2, 446.21, 446.4, 446.6 and report on the current international experience of DAH and ECMO.

Results:

The case series is described in table 1. Median lung injury score (LIS) was 3.5. Three patients required ECMO (median duration 8 days) and all received immunosuppression. One patient received normal heparin protocol to target APTTr 1.5-2 whilst two patients had 48 hours of ECMO with no heparin followed by sub-therapeutic low dose heparin. ICU survival was 100% and six months survival was also 100%. There were no exacerbations of pulmonary haemorrhage, no new events of extra-pulmonary haemorrhage and no clotting complications.

Gender	Age (years)	Diagnosis	Lung Injury Score	Duration MV before referral (days)	Respiratory support (duration in days)	ECMO complic-ations	Treatment	Predicted ICU mortality (APACHE II)	ICU survival (LOS in days)	6 month survival
Male	73	GPA	3.5	1	VV-ECMO (8)	Nil	PEx, MEP, HD, CYC	25	Yes (17)	Yes
Male	61	GPA	3.5	3	VV-ECMO (8)	Nil	PEx, MEP, CYC	18	Yes (14)	Yes
Female	54	MPA	3.5	1	HFOV, Prone	N/A	MEP, CYC	17	Yes (15)	Yes
Male	46	GPA	3.25	1	VV-ECMO (5)	Nil	PEx, MEP, HD, CYC	20	Yes (21)	Yes

Table 1. MV, mechanical ventilation; LOS, length of stay; GPA, Granulomatosis and Polyangiitis (Wegener's Granulomatosis); MPA, Microscopic Polyangiitis; PEx, Plasma exchange; MEP, methylprednisolone; HD, Continuous veno-venous haemodialysis; CYC, Cyclophosphamide

The ELSO database contains 78 patients (adult, 59; paediatric, 19) with pulmonary vasculitides who received ECMO. 43 had a diagnosis of Granulomatosis and Polyangiitis (GPA), whereas the remaining diagnoses included hypersensitivity angiitis, Goodpasture's syndrome and thrombotic microangiopathy. The median age was 23 years (IQR 16-47). The median duration of ECMO was 190 hours (IQR 146-282) and ICU survival was 82%. Twelve patients (15%) were reported to have thrombotic ECMO circuit complications in the context of likely conservative heparinisation.

Conclusion:

In this case series, ECMO offers an excellent survival rate in SRF due to ANCA-associated DAH. ELSO registry data supports our case series and suggests that DAH related to vasculitis should not be considered a contraindication. ECMO should be considered as adjunctive therapy in DAH patients with SRF not responsive to conventional therapy.

Session Title: Vasculitis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

ANCA associated vasculitis (AAV) is known as a systemic vasculitis with unknown etiology. Recently, relationship between AAV and complement have been shown and complement have an important role in the pathogenesis of AAV (1). Regarding clinical feature of AAV, hypocomplementemia is reported to be associated with a poor prognosis in a study with a small number of patients (2). However, the clinical characteristics of AAV with hypocomplementemia still remain unclear. In this study, we tried to show the clinical characteristics of AAV with hypocomplementemia.

Methods:

We retrospectively analyzed patients in Nagasaki University Hospital who were newly diagnosed with AAV from April 2008 to June 2015. We analyzed the baseline variables, laboratory data, clinical symptoms and therapeutic outcomes after treatments including episodes of relapses, initiation of dialysis and death using medical records. All patients were classified as AAV based on the Chapel Hill Consensus Conference (CHCC) criteria and the European Medicines Agency (EMA) algorithm. The patients consist of all types of AAV including eosinophilic granulomatous polyangiitis (EGPA), granulomatous polyangiitis (GPA), microscopic polyangiitis (MPA), and renal limited vasculitis. We defined hypocomplementemia as the state which at least one of each complement 3 (C3), complement 4 (C4), or total complement activity (CH50) was lower than lower limits of normal range of each complements.

Results:

We included 82 patients with AAV (11 EGPA, 14 GPA, 54 MPA and 3 renal limited vasculitis) who were newly diagnosed. The median onset age was 71. Forty eight patients (59%) were female. Median follow up duration was 40 months. Seventeen patients (21%) had hypocomplementemia at diagnosis of AAV. Compared to AAV without hypocomplementemia, AAV with hypocomplementemia had significantly higher rates of occurrences of diffuse alveolar hemorrhage (DAH) (7 (41%) vs 5 (8%), $p<0.01$), thrombotic microangiopathy (TMA) (3 (18%) vs 0 (0%), $p<0.01$) and skin lesions (9 (53%) vs 8 (12%), $p<0.01$). Of 17 patients who had hypocomplementemia, only one patient fulfilled American college of rheumatology revised criteria for classification of systemic lupus erythematosus (SLE) concomitantly. Assessed by life-table analysis using the Kaplan-Meier method, hypocomplementemia at disease onset was associated with a poor prognosis ($p=0.012$).

Conclusion:

Our result suggested that hypocomplementemia in AAV might become risk factor for DAH and TMA. Moreover hypocomplementemia was a poor prognostic factor in AAV in this study. Therefore it is significantly important to pay attention to the levels of complement at the diagnosis of AAV.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Vasculitis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Vasculitis damage index (VDI) is a validated comprehensive damage tool which has been developed as an outcome measure and consists of different types of lung damage items. We aimed to investigate lung damage in AAV by using VDI.

Methods: We analysed 51 patients (25 female) with AAV (40 GPA, 8 MPA, 3 e-GPA) and lung involvement who met ACR criteria and followed-up from a single tertiary center, between 1998-2014. Demographic and clinical features, smoking and exposure history, severe infections (SI) requiring hospitalization, relapse rates and immunsuppressive doses were recorded. Initial BVAS scores and imaging findings were noted. Severe pulmonary infections requiring hospitalization were recorded. Pulmonary function tests (PFT), 6MWT, HRCT and VDI scores were obtained. Correlation analysis was performed for BVAS and VDI scores. VDI scores were compared between the groups stratified in accordance to the presence and recurrence of severe pulmonary infections by Mann-Whitney U test.

Results: Lung involvement was investigated by imaging (X-Ray/HRCT) (100%), histopathology (15%) or bronchoscopy (25%). ANCA positivity was found in 94% (66% C-ANCA/anti-PR3, 34% p-ANCA/anti-MPO). Mean age at diagnosis, time between the first symptom and diagnosis and total follow-up time were 49±13 y (med 51), 4,8±5,8 mo,(med 3) and 66,5±52 mo (med 47), respectively. 28 patients were smokers. Kidney was the most frequently involved organ (78%) with lung. Initial total and lung BVAS were 22±7 (4-38) (med 23) and 4,6±2,8, respectively.The frequency of BVAS items were as follows: Nodules/cavities 80%, infiltration 52%, massive haemoptysis/alveolar haemorrhage 19%, respiratory failure 11%, pleural effusion/pleurisy 5%, endobronchial involvement 3 %. Respiratory failure developed in 11% at presentation. Cumulative total and lung VDI scores were 3,4±2,2 (0-9) (med 3), 0.4±0.8 (0-4) (med 1) respectively. The frequency of VDI lung items were 21% for impaired lung function, 7% for pulmonary fibrosis, 5% for chronic breathlesness, 1% for pulmonary hypertension. AAV patients had 1 (24%), 2 (12%) or 4 (1%) items of VDI. VDI scores of lung items in AAV subgroups were shown in Table-1. One of four patients who suffered from respiratory failure died. Severe pulmonary infections (>1 SI in 33%) were detected in 44%. VDI was higher in patients who suffered from pulmonary infection but, it was statistically insignificant (4.1±.4 vs 3±1.9, p>0.05). The patients with recurrent severe pulmonary infections had significantly high VDI scores when compared to the patients with only one infection (4.8±2.7 vs 3±1.9, p= 0.02). No significant correlation was found between BVAS and VDI scores.

VDI items	GPA n (%)	MPA n (%)	e-GPA n (%)
Pulmonary Hypertension	-	-	1 (2)
Pulmonary Fibrosis	1 (2)	3 (6)	-
Pulmonary Infarct	-	-	-
Pleural Fibrosis	-	-	-
Chronic Asthma	-	-	2 (4)
Chronic Breathlesness	2 (4)	-	1 (2)
Impaired Lung Function	5 (10)	3 (6)	3 (6)

Conclusion: VDI is a useful tool to demonstrate lung damage in AAV. Lung damage has been demonstrated in almost 40% of AAV patients. Recurrent pulmonary infections seem to be an important contributor to the lung damage in AAV.

Evaluation of Thiopurine Metabolites Monitoring in Patients Treated with Azathioprine for Rheumatic Diseases

Aurélie Chapdelaine[1], Maxime Doré[2], Yves Troyanov[3] and Anne-Marie Mansour[1], [1]Internal Medicine, Université de Montréal, Montréal, QC,

Canada, [2]Pharmacy, Université de Montréal, Montréal, QC, Canada, [3]Rheumatology, Université de Montréal, Montréal, QC, Canada
First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Vasculitis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: The thiopurine azathioprine (AZA) is an inactive pro-drug that undergoes complex metabolic transformations leading to the formation of 6-thioguanine nucleotide (6-TGN), the active metabolite, and 6-methylmercaptopurine (6-MMP), an inactive and potentially hepatotoxic metabolite (Figure). Evidence in inflammatory bowel disease (IBD) suggests that there is a weak correlation between the thiopurine dose and the 6-TGN blood concentration. In a subgroup of patients, production of 6-MMP predominates over production of active 6-TGN. This phenomenon is called hypermethylation. These patients are identified as shunters and are known to be thiopurine resistant unless combined with allopurinol. Current data in IBD support the clinical usefulness of 6-TGN and 6-MMP monitoring to improve the effectiveness and the safety profile of thiopurines. There are few data regarding the clinical benefits of thiopurine metabolites monitoring in patients with rheumatic diseases. The aims of the study were to evaluate the thiopurine doses used to treat diseases other than IBD, to estimate the correlation between the thiopurine dose and the 6-TGN blood concentration, to identify shunters and to describe their management.

Methods: Patients were identified using the central laboratory database and data were retrospectively collected. Spearman's correlation coefficient was used to estimate the correlation between the thiopurine dose (mg/kg) and the blood concentration of 6-TGN (pmol/8×10^8 erythrocytes).

Results: Seventy-one patients were included. Twenty-nine patients (41%) received AZA for vasculitis, 26 (37%) for connective tissue disease, 9 (13%) for myositis, and 7 (10%) for various conditions. Correlation between the thiopurine dose (mg/kg) and the blood concentration of 6-TGN has been estimated at the first thiopurine metabolites assay and at the greatest dose of thiopurine. Spearman's correlation coefficients are 0.337 (p=0.004) and 0.270 (p=0.023), respectively. For the subgroup of non-shunters, the correlation was consistent with that observed for the overall patient sample with Spearman's correlation coefficients of 0.319 (p=0,026) and 0.399 (p=0.005), respectively. Twenty-two patients (31%) were identified as shunters and 6 of them developed significant aminotransferase elevations (>1.5 times the normal upper limit). The AZA-allopurinol combination therapy was used in 9 shunters and allowed a shift toward 6-TGN production in 8 of them.

Conclusion: In this retrospective study, the correlation between the thiopurine dose and the 6-TGN blood concentration was weak. Thirty-one percent of the patients were identified as shunters. Consequently, thiopurine metabolites monitoring demonstrated its clinical usefulness and it should be routinely used to guide thiopurine therapy in patients treated for rheumatic diseases.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Vasculitis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: Granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA) and eosinophilic granulomatosis with polyangiitis (EGPA) comprise a group of multisystem diseases of the small blood vessels known as antineutrophil cytoplasm antibody (ANCA)-associated vasculitis (AAV). Inflammation can occur throughout the body and patients demonstrate significant impairments in mental and physical health. Treatment with glucocorticoids, often in high doses and in combination with other immunosuppressive therapy, is the cornerstone of management. However, glucocorticoids have substantial physical and psychological adverse effects.

Methods: Patients with AAV from the UK, USA, and Canada were interviewed about their disease and treatment. Patients were purposively sampled to include the spectrum of diseases, chronicity of disease (diagnosis or flare < 2 years previously or > 2 years), age, sex, and organ involvement. The project steering committee, which included patient-partners, defined a set of neutral, nondirective interview prompts and cues on the patient experience of AAV and its treatment, and any impact on health-related quality of life. Interviews were recorded and transcribed verbatim, anonymised and systematically analysed to establish themes grounded in the data. As themes emerged, a collaborative code book was developed. The final transcript yielded no new codes, indicating data saturation. Earlier transcripts were checked for the emerging new codes. A treatment-related code was used to identify all ideas related to experience of treatment; sub codes within the treatment code related to glucocorticoids were defined, grouped into categories, and then grouped into overarching themes.

Results: Forty-nine interviews were conducted. Individual sub codes related to glucocorticoid therapy were identified and grouped into 3 themes: i) Glucocorticoids are effective at the time of diagnosis and during relapse; withdrawal can potentiate a flare, ii) Glucocorticoids are associated with salient emotional, physical and social effects (depression, anxiety, irritation, weight gain and change in appearance, diabetes mellitus); and iii) Balancing the pros and cons of glucocorticoids (symptom relief versus long-term effects). The interaction between these themes is described in Figure 1.

Conclusion: Patients are generally positive about treatment with glucocorticoids in terms of rapidity of onset and efficacy, but anxious about potential long-term adverse effects and the uncertainty of the weaning process. Psychological effects predominated among adverse effects experienced. The results of this study will inform the development of a disease-specific PRO for AAV and a deeper understanding of the risks and benefits of this extremely common form of treatment.

a Retrospective Analysis of Low Dose Cyclophosphamide Therapy in Systemic Vasculitides

Antigoni Grigoriou[1], Shirish Sangle[2], Chai Ling[2] and David P. D'Cruz[3], [1]Rheumatology, St George's Univeristy Hospitals NHS Foundation Trust, London, United Kingdom, [2]Louise Coote Lupus Unit, Guy's and St Thomas' Hospital, London, UK, London, United Kingdom, [3]Louise Coote Lupus Unit, Guy's and St Thomas' Hospital, London, United Kingdom

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Vasculitis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

The 'Euro-Lupus' low dose cyclophosphamide (CPM) protocol has been validated for use in lupus nephritis patients in randomised controlled trials. A recent controlled study of this protocol by the French vasculitis group has shown favourable results in ANCA positive vasculitis. Our aim is to assess the efficacy and safety of low dose CPM in systemic vasculitides patients.

Methods:

We retrospectively assessed 26 patients with systemic vasculitis at the Louise Coote lupus Unit at Guy's and St Thomas' Hospital who received low dose CPM induction therapy along with corticosteroids during the last 15 years. All patients fulfilled the ACR/Chapel Hill classification criteria for Granulomatosis with Polyangiitis, eosinophilic Granulomatosis with Polyangitis and Microscopic Polyangitis. All patients received 3 pulses of methylprednisolone 500mg and 6 pulses of CPM infusion 500 mg with mesna fortnightly as induction therapy. Subsequently Azathioprine, Methotrexate or Mycofenolate Mofetil were used as remission maintaining agents. Data regarding inflammatory markers Erythrocyte Sedimentation Rate (ESR) and C-reactive protein (CRP), Birmingham Vasculitis Activity Score (BVAS) and Vasculitis Damage Index (VDI) scores were assessed at baseline and after 6, 12, 24, 60, 120 and 180 months. Data on all relapses, organ involvement, duration of remission, corticosteroid requirement, repeat CPM infusions, Rituximab and adverse events were recorded.

Results:

26 patients (13 males, 13 females) were assessed. 22 were Caucasians, 2 mixed ethnicity and 2 Asians. Median age was 54 years. 20 patients had positive ANCA antibodies (15 anti-PR3, 5 anti-MPO). 6 were ANCA negative. The median disease duration prior to induction therapy was 3.12

years. 10 patients had pulmonary involvement (pulmonary hemorrhages, haemoptysis, cavitating lung lesions, nodules), 9 necrotizing crescentic glomerulonephritis, 1 myocarditis, 7 neurological manifestations (raised ICP, occipital masses, mononeuritis multiplex), 3 orbital granulomas, 1 necrotizing scleritis, 2 otitis media with hearing loss and 1 bowel ischaemia. Co-morbidities were antiphospholipid syndrome (2 patients), positive lupus anticoagulant (2), type 2 diabetes mellitus (1), past Tuberculosis (1) and sleep apnoea (1). All patients received tapered doses of oral prednisolone (median dose 30 mg) following the induction regimen.

Median duration of remission was 2.40 years. There was improvement in BVAS, CRP and ESR. 10 patients had relapses over 5 years. 5 patients required repeat CPM pulses for flares and 7 received Rituximab. 12 adverse events were recorded. Renal function remained stable over the years. 1 death has been recorded (See Table)

Conclusion:

Low dose intravenous infusion of CPM in combination with steroids may be effective in achieving remission in systemic vasculitides. This regimen may have fewer adverse events than conventional therapy with high dose CPM.

Table:

Time (1/12=1month)	Pre therapy	6/12	12/12	24/12	60/12	120/12	180/12
BVAS	15.52 (n=23)	4.54 (n=22)	5.42 (n=19)	9.00 (n=9)	4.40 (n=5)	2.00 (n=3)	2.00 (n=2)
ESR (mm/hr)	28.77 (n=22)	18.26 (n=19)	24.52 (n=17)	31.00 (n=6)	9.60 (n=5)	8.50 (n=2)	8.50 (n=2)

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Vasculitis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

To evaluate the long term outcomes, of patients with multi-relapsing Antineutrophil Cytoplasmic Antibody (ANCA) associated Vasculitis (AAV), who received induction therapy with a rituximab regimen upon disease relapse versus a control group who received the standard regimen.

Methods:

We studied patients with biopsy proven AAV, and a history of frequent relapses of the disease, who were treated with a rituximab regimen upon relapsing vasculitis. Rituximab was typically used in combination with the standard regimen for patients with major relapses or with glucocorticoids alone for minor relapses. A control group consisted of patients from the era prior to the initiation of rituximab in the treatment of AAV, was selected, using the following criteria; history of relapse, organ involvement at relapse, treatment with the standard regimen (cyclophosphamide plus glucocorticoids). Patients and controls were also matched for age, gender, and disease duration. Comparisons of outcomes, along with the frequency and severity of adverse events were performed between groups.

Results:

Of 147 patients with biopsy proven AAV and a mean total follow up time of 78.2 months, we identified 18 patients (12.2%), who received induction treatment with rituximab for disease relapse. A control group of equal size was selected. Organ involvement and disease activity were similar between groups at entry. The mean number of relapses per patient was significantly higher in this group for the same period compared to the control group. 13/18 patients in the rituximab group received the standard regimen in addition to rituximab as inductive therapy. Patients in both groups achieved remission in similar rates but patients in the rituximab group showed a significant decline in the number of relapses per patient [median, (range): 2(1-4)] compared to the number of relapses per patient in the period prior to therapy with rituximab [0(0-1), $p<0.001$]. As a result, the subsequent exposure to cyclophopshamide was radically decreased in this group [median, (range): 21.75 grams (4.0-177.0) vs. 3(0.0-10.5), $p<0.0001$].

Conclusion:

In our experience, rituximab was shown efficacious in achievement of long term remission in patients with a history multiple relapsing AAV and allowed us to minimize the ultimate exposure to cyclophosphamide in these patients, avoiding further accumulation of toxicity.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Vasculitis Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose:

Despite recent therapeutic advances in treating ANCA-associated vasculitides (AAVs), some patients relapse or require long-term immunosuppression, leading to significant morbidity and mortality. IVIg represents a therapeutic alternative for AAVs, but its efficacy has been evaluated in only 2 small prospective trials. This study aimed to evaluate IVIg efficacy and safety for AAVs.

Methods:

We conducted a nationwide retrospective study (1990–2014) on patients with AAVs, including granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA) and eosinophilic granulomatosis with polyangiitis (EGPA), who received IVIg immunomodulation (dose >1 g/kg/cycle). Patients given a substitution dose (<1 g/kg/cycle) for hypogammaglobulinemia were excluded.

Results:

Ninety-two patients (mean age: 51 years) with GPA (68%), EGPA (23%) or MPA (9%) received at least 1 IVIg cycle; 72% were ANCA-positive (immunofluorescence assay). IVIg were used as median 3rd-line therapy (range: 1-8), for AAV relapse (83%), the first AAV flare (11%) or dependency on initiated treatments (6%).

The main clinical manifestations at IVIg onset were: ENT (61%), pulmonary (37%), constitutional symptoms (32%), arthralgias (28%), glomerulonephritis (20%), skin (16%), peripheral neuropathy (15%), central nervous system (13%), asthma (12%). The Five-Factor Score (FFS) was 0 (75%), 1 (21%) or 2 (4%). Mean BVAS was 9.4 (range: 0–34).

IVIg was given for a median of 6 (1–156) months (M), combined only with corticosteroids for 21% or with other immunosuppressants/another immunosuppressant for 77%.

IVIg efficacy was assessed for the whole population and a subset of 34 patients with unmodified background therapy; their respective remission rates at M3 and M6 were 49% and 62%, and 44% and 62%, with respective refractory disease rates of 23% and 25%.

Mean BVAS declined from 9.4±6.3 at baseline to 3.0±4.1 at M3, 2.3±4.5 at M6, 1.8±3.6 at M9 and 1.1±2.2 at M12. Similarly, mean CRP and mean prednisone dose also declined during the first year after starting IVIg.

Comparing patients achieving remission (n=43) versus those with only partial responses (n=24) or refractory disease (n=20) at M3, no significant differences were found for age, sex, AAV subtype, FFS, ANCA status or organ involvement at baseline, or IVIg-associated therapeutic regimens. Baseline BVAS was lower for patients who entered remission (7.6±6.8) versus those with partial responses (11.1±4.2, P=0.001) or treatment failures (10.9±6.1, P=0.017).

Adverse events occurred in 33%, among which 12% were serious and led to IVIg discontinuation for 7%.

Conclusion:

The results of this large study showed IVIg's clinical benefit as adjunctive therapy, with an acceptable tolerance profile, supporting its use for patients with refractory or relapsing AAVs.

Session Title: Vasculitis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Plasma exchange (PE) is usually used to treat severe primary systemic necrotizing vasculitides (SNVs) and/or virus-induced vasculitides. Only severe renal insufficiency (serum creatinine (SCR) >500 µmol/l) was validated but long-term outcomes remain poor. In practice, PE may be used in clinical situations without literature input. This study aimed to identify practical PE indications for nonviral SNVs and evaluate short-term and long-term prognoses.

Methods:

This multicenter retrospective study (2005–2014) included PE-treated patients with AAV or nonviral polyarteritis nodosa (PAN) meeting ACR criteria, EMA algorithm and/or Chapel Hill nomenclature. For each indication, analysis of short- and long-term outcomes compared baseline (M0) vs post-PE parameter values.

Results:

Diagnoses of the 152 patients [94 men, 58 women; median age 64 (range 17–89) yr] were: 87 granulomatosis with polyangiitis (GPA), 56 microscopic polyangiitis (MPA), 5 PAN and 4 eosinophilic granulomatosis with polyangiitis (EGPA). ANCA were positive in 142/147 (97%, never PAN): 55% PR3-ANCA+ and 45% MPO-ANCA+.

PE was used for rapidly progressive glomerulonephritis (RPGN) in 126 (83%) [mean SCR 465±257 µmol/l; including <250, 250–500 and >500 µmol/l in one-third each], 64 (42%) alveolar hemorrhage most often RPGN-associated, 23 (15%) with extensive and severe multiple mononeuropathy, usually of acute onset (<4 weeks) and severe motor weakness, and 7 (5%) with extensive skin necrosis. M0 median BVAS was 18. Median (range) PE was 7 (1–12) sessions over a median of 11 (1–43) days.

After median follow-up of 22 (range 1–125) months post-PE onset, 18 (12%) had died, including 11 within M1–6. Renal function of 126 PE-treated RPGN patients improved significantly, as assessed by estimated glomerular filtration rate (eGFR) using MDRD, reaching a plateau between M3 and M6 post-PE onset, and maintaining eGFR through follow-up M24. According to M0-SCR (µmol/l) subgroup, M0-to-M6 eGFR

(ml/min), respectively, rose from 33.3 to 47.3 (P<0.0001) for <250, from 13.5 to 34.7 (P<0.0001) for 250–500, and from 6.9 to 32.9 (P<0.0001) for >500. PE-session numbers were similar for the 3 M0-SCR subgroups, with eGFR improving as that number rose, suggesting a PE dose-dependent effect on eGFR recovery.

PE resolved alveolar hemorrhages in all 64 patients, enabling O_2-therapy or MV discontinuation, after a median of 15 days.

Motor weakness regressed markedly in 23 PE-treated extensive mononeuritis patients. Severe motor-weakness (MRC <3/5) declined from M0 52% to 23%, 19% and 12.5% at M3, M6 and M12 post-PE onset.

End-stage renal disease and/or mortality rates were similar among M0-SCR groups but higher for MPO- than PR3-ANCA+ patients. PE-attributable adverse events occurred in 63%. No one died during PE.

Conclusion:

Our results highlight PE indications for SNVs. Different organ involvements seem to benefit from PE. For RPGN patients, the PE number seemed to correspond to the degree of eGFR recovery. These findings support using PE in conditions less severe than previously validated.

Session Title: Vasculitis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Eosinophilic granulomatosis with polyangiitis (EGPA) is characterized by asthma, blood and tissue eosinophilia, vasculitis-related peripheral neuropathy, glomerulonephritis or skin symptoms. Although peripheral nervous system involvement occurs frequently, usually as multiple mononeuropathy, exceptional central nervous system (CNS) disease, severe and associated with poor prognosis according to the 1996 Five-Factor Score, has been described. This study aimed to describe CNS involvement in EGPA.

Methods: This retrospective, observational, multicenter study included patients with EGPA meeting ACR criteria and/or Chapel Hill definitions, and CNS involvement affecting cranial nerves, brain or spinal cord. We also undertook a systematic literature review.

Results:

We analyzed 26 patients (50% women, mean age 57±15 years) and 62 reported EGPA-CNS cases (52% women, mean age 47±16 years). At EGPA diagnosis, their main manifestations included: asthma in 97%, hypereosinophilia in 98% with median eosinophil count 7500/mm^3, sinonasal abnormalities in 66%, peripheral neuropathy in 55%, pulmonary infiltrates in 52% and biopsy with eosinophilic infiltration in 46%; 41% had cardiac involvement, including myocarditis (27%), pericarditis (16%), endomyocardial fibrosis (8%) and cardiac arrhythmia (2%). 38/71 (55%) were ANCA-positive, with a perinuclear-labeling pattern and/or anti-MPO specificity.

The CNS was involved in 86% at EGPA diagnosis, preceded EGPA in 2%, and occurred during follow-up in 12% after a median of 24 months. The main neurological signs were: 46 (52%) ischemic cerebrovascular lesions, 21 (24%) intracerebral hemorrhage or subarachnoid hemorrhage, 28 (32%) visual acuity loss (15 with retrobulbar optic neuritis, 10 occluded central retinal artery or 4 cortical blindness), and 18 (20%) cranial nerves palsies; 25 patients had ≥1 of these clinical CNS signs.

Patients with visual acuity loss and cranial nerve palsies had similar clinical-biological parameters. In contrast, patients with intracerebral or subarachnoid hemorrhage compared to those with ischemic cerebrovascular lesions were younger (43 vs 52 years), had less frequent myocarditis (10% vs 35%), more frequent peripheral neuropathy (67% vs 41%), glomerulonephritis (29% vs 13%) and ANCA (79% vs 52%); and had higher median eosinophil counts (12850 vs 7500/mm^3).

All patients were treated with corticosteroids, associated with cyclophosphamide in 63%, azathioprine in 4% or methotrexate in 1%. Among the 81 patients with assessable neurological responses, 43% had complete responses without sequelae, 43% had partial responses with long-term sequelae and 14% refractory disease. After a mean follow-up of 36 months, 11 patients died, half of intracerebral hemorrhages.

Conclusion: The main EGPA-CNS manifestations form 4 distinct neurological pictures: ischemic lesions, intracerebral hemorrhages, cranial nerve palsies and optic neuritis- or central retinal artery occlusion-related visual acuity loss. Such manifestation should prompt practitioners to consider an EGPA diagnosis in such conditions. Neurological sequelae were common.

Session Date: Sunday, November 8, 2015

Session Title: Vasculitis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Omalizumab, an anti-IgE monoclonal antibody, has proven efficacy for the treatment of moderate-to-severe and severe-persistent allergic asthma and allergic rhinitis, with a favorable safety profile. Only rare and contrasting results have been reported for eosinophilic granulomatosis with polyangiitis (EGPA).

Methods:

To describe omalizumab efficacy and safety in patients with refractory and/or relapsing EGPA, we conducted a nationwide retrospective study on EGPA patients who had received omalizumab in these situations. Complete response was defined as the absence of asthma and/or sinonasal exacerbations with a prednisone dose ≤7.5 mg/day, and partial response as the absence of exacerbations with a prednisone dose >7.5 mg/day.

Results: Seventeen patients (median age: 45 years) took omalizumab for severe steroid-dependent asthma (88%) and/or sinonasal involvement (18%), always combined with only corticosteroids, (53%) or with adjunction of other immunosuppressive agents/another immunosuppressant (47%). After median follow-up of 22 months, 6 (35%) patients achieved complete responses, 5 (30%) had partial responses and 6 (35%) showed no improvement. Overall median BVAS dropped from 2.5 at baseline to 1 and 0.5 at 6 and 12 months, respectively. Median numbers of exacerbations decreased from 1/month at baseline to 0 at 6 and 12 months, and median forced expiratory volume in 1 second increased from 63% at baseline to 82% and 85% of the average predicted value at 6 and 12 months, respectively. Median prednisone dose decreased from 16 mg/day at baseline to 11 and 9 mg/day at 6 and 12 months, respectively. Eight patients stopped omalizumab, 25% because of remission, 25% for refractory disease or 50% for relapse. Relapses included EGPA-attributable retrobulbar optic neuritis (n=2) and severe asthma attacks (2 others). No other severe adverse events occurred.

Conclusion:

Results of this study suggest that omalizumab provides mild efficacy and corticosteroid-sparing effect in EGPA with asthmatic and/or sinonasal manifestations. Severe flares occurred in a quarter of the patients raising the question of its safety in this setting.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Vasculitis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

Eosinophilic granulomatosis with polyangiitis (EGPA) often presents with persistently active disease requiring chronic glucocorticoid therapy or it may have a relapsing course with partial or no response to traditional immunosuppressive agents. Severe disease frequently responds to cyclophosphamide but its use is limited by the significant toxicity associated with prolonged therapy. The maintenance of disease remission presents a challenge, as patients often require unacceptable doses of glucocorticoids to control asthma or active disease. Rituximab (RTX) is an effective agent used for granulomatosis with polyangiitis (GPA) and microscopic polyangiitis (MPA). Recent retrospective reports have suggested that RTX may also be effective for EGPA. The role of RTX for EGPA is still unclear, including whether repeated courses of RTX may benefit individuals with relapsing disease.

Methods:

We present our experience using RTX for EGPA and present the available worldwide data on RTX for EGPA.

Results:

We identified 56 patients meeting ACR or Revised International Consensus Criteria for EGPA at our institution, 6 of whom received RTX. Five of 6 patients (83%) treated with RTX significantly improved. The remaining patient experienced respiratory distress during the first infusion and did not complete the infusion. These 5 patients had long follow-up (mean 53 months) and received multiple courses of RTX (mean 4.6 courses) for either disease relapse or remission maintenance. We identified 65 cases of EGPA treated with RTX published in the literature with 83-95% response rate using variable outcome measures. These patients received fewer courses of RTX (mean 1.6) and had shorter follow-up (mean 15 months). There were 3 infusion reactions (5%) and 18 infections (28%), 8 of which were severe (12%). Patients from our cohort and from the literature were able to reduce prednisone dose from a mean baseline of 28mg/day to 6.6mg/day and from 18.9mg/day to 8.1mg/day, respectively.

Discussion:

This series provides data on the use of multiple courses of RTX for EGPA. It is also the first series to provide follow-up beyond 3 years for RTX use in EGPA. It is noteworthy that further reductions in prednisone were observed in patients who received repeated courses of RTX as ongoing therapy.

Conclusion:

Although the role of RTX for EGPA is still unclear, a small but growing number of reports suggest that RTX may be an effective treatment option for EGPA that is severe, relapsing or refractory to other medications. Long-term treatment of EGPA using multiple courses of RTX may allow for further reductions in prednisone and thereby reduce associated morbidity. A multicenter prospective trial should be considered to better define both the short-term and long-term efficacy and safety of RTX in patients with EGPA.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Vasculitis Poster I

Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose: To characterize a single centre retrospective case series of patients with orbital inflammatory masses associated with autoimmune diseases including granulomatosis with polyangiitis(GPA)(formerly Wegener's granulomatosis), eosinophilic granulomatosis with polyangiitis(eGPA) or Immunoglobulin G4 related disease(IgG4-RD).

Methods: We identified 30 patients with orbital inflammatory masses on MRI imaging. Clinical and laboratory data was collected from electronic clinical records. Comprehensive Diagnostic Criteria were used for IgG4-RD and Chapel Hill criteria for GPA and eGPA. Statistical analysis was performed by GraphPad software; continuous variables were compared between IgG4-RD and GPA groups using non-parametric Mann-Whitney test and categorical variables were compared by Fisher's exact test.

Results:

The study included 21 Caucasian, 6 Asian and 3 patients of African descent. There were 19 female and 11 male patients. The median age was 44 years(range 29-76).

14 patients were diagnosed with GPA, 11 patients had IgG4-RD, 1 patient with IgG4 lymphoma, 1 with eGPA, 1 unspecified vasculitis, 1 IgA dacryoadenitis, 1 non-specific granuloma.

7/11 patients with IgG4-RD had isolated orbital masses whereas all 14 GPA patients suffered extra-ocular manifestations (p=0.01), usually sino-nasal or pulmonary disease.

11/14 GPA patients had positive ANCA vs 2/11 patients with Ig4-RD (p=0.04). IgG4 levels were elevated pre-treatment in IgG4 RD patients (median 2.46 g/l (range 1.2-23.7)) and dropped to 1.25 g/l (range 0.37-10.4) after therapy(p=0.05); immunoglobulin subclasses were not checked routinely in GPA.

All 11 patients with IgG4-RD underwent diagnostic orbital biopsy vs 3/14 GPA (p=0.0001).

All 30 patients were treated with corticosteroids (used alone in 3/11 IgG4-RD patients). The median number of DMARDs ever used to treat GPA was 3 vs 1 DMARD for IgG4-RD (p=0.001). Rituximab was effectively administered to 10/14 GPA patients vs 3/11 IgG4-RD (p=0.04), is planned for 2 further IgG4-RD patients and approval was refused for 1 case. Surgical debulking was undertaken in 6/11 IgG4-RD vs 1/14 GPA (p=0.02). All 30 patients had subsequent MRI to assess response to therapy.

Conclusion: IgG4-RD is an important differential diagnosis of orbital inflammation, especially if ANCA is negative. Unlike GPA which was associated with extra-ocular manifestations in all patients, IgG4-RD was more likely to present with isolated orbital inflammation and to require biopsy or surgical debulking as the diagnosis was initially uncertain. Treatment with corticosteroids +/- DMARDs was effective, however the majority were left with some chronic visual damage. Serial imaging is useful to document clinical response. Rituximab can specifically deplete autoreactive B lymphocytes producing IgG4 and future systematic studies are required to establish the optimum therapeutic strategy.

Patient Group	Granulomatosis with polyangiitis	IgG4 asociated disease	P value
Number of patients	14	11	
Median age (years)	46	38	0.16
Gender distribution	8 female: 6 male	7 female: 4 male	1
Ethnic distribution	10 Caucasian/3 Asian/1 African	6 Caucasian/ 3 Asian/ 2 African	0.4
ANCA status	11 ANCA+ / 3 ANCA negative	2 ANCA+ /9 ANCA negative	0.04
Bilateral orbital inflammation	4/14	2/11	0.7
Extra-ocular manifestations	14/14	5/11	0.03
Orbital biopsy	3/14	11/11	0.0001
Median number of DMARDs	3 (range 1-5)	1 (range 0-3)	0.001
Rituximab treatment	10/14	3/11	0.04
Surgical debulking	1/14	6/11	0.02
Chronic damage (visual loss, diplopia, orbital pain /swelling)	8/14	5/11	0.7
Improvement of orbital inflammation on MRI	9/14	10/11	0.2

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Vasculitis Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: IgA vasculitis (IgAV, Henoch–Schönlein) is the most common childhood vasculitis in western countries. Population-based studies mainly carried out in Europe over the last 4 decades reported annual incidence rates of 3 to 27 per 100,000 children. The etiology of IgAV remains unclear. Incidence peaks in the colder months suggested an infectious underpinning, although genetic susceptibility and other environmental triggers might also play a role. More epidemiological studies are required to determine potential changes over time in the epidemiological characteristics of IgAV. This study aimed at describing the epidemiological characteristics of childhood IgAV in a large French population.

Methods: Cases were prospectively collected in Val de Marne county, a southeastern suburb of Paris, with 262,124 residents < 15 years old. Children with incident IgAV living in this area from 2012 to 2014 were identified by 4 sources of case notification (emergency departments, pediatrics departments, private practice pediatricians, general practitioners). Diagnoses were verified against the EULAR/PRINTO/PRES criteria. We calculated 95% confidence intervals (95% CIs) for incidence rates under the assumption of a Poisson distribution. Four-source capture–recapture analysis (CRA) was performed using log-linear modeling to estimate the completeness of case finding. Seasonal variations in IgAV incidence were investigated by comparing observed to expected frequencies by chi-square testing.

Results: The survey identified 151 incident cases meeting the study criteria, including 79 (52%) boys and 72 (48%) girls with a mean age of 6.7 years (standard deviation: 2.7 years; range 2.2–15.7 years). The overall annual incidence (per 100,000 children) was 19.2 (95% CI: 16.2–22.4), with 19.7 (95% CI: 15.6–24.5) for boys and 18.7 (95% CI: 14.6–23.5) for girls. CRA estimated the completeness of case finding at 61.9% (95% CI: 50.0–81.2). The annual distribution of diagnoses (spring: 29%, summer: 12%, fall: 26%, winter: 33%) significantly deviated from a random distribution ($P<0.01$) and indicated a higher incidence in fall or winter as compared with spring or summer ($P<0.01$). Clinical manifestations at presentation included purpura (100%), urticaria (12%), arthralgias/arthritis (93%), acral edema (72%), abdominal involvement (59%), scrotal edema (13%) and renal involvement (21%). Abdominal manifestations included pain (55%), vomiting (26%), diarrhea (13%), hemorrhage (7%) and intussusception (2%). Renal involvement was mostly mild and diagnosed from findings of proteinuria and hematuria; only 3 children (2%) underwent renal biopsy.

Conclusion: The annual incidence rate of 19.2 per 100,000 children, gender distribution and seasonal variation we observed are in line with data reported from other geographic areas and time periods. In contrast, the small proportion and mild presentation of IgAV-associated renal disease supports the rather benign profile of IgAV at the population level.

Abstract Number: 894

Late-Onset IgA Vasculitis in Adult Patients Exhibits Distinct Clinical Characteristics and Outcomes

Seokchan Hong[1], Soo Min Ahn[1], Doo-Ho Lim[2], Byeongzu Ghang[3], Wook Jang Seo[4], Yong-Gil Kim[1], Chang-Keun Lee[1] and Bin Yoo[2], [1]Division of Rheumatology, Department of Internal Medicine, University of Ulsan College of Medicine, Asan Medical Center, Seoul, South Korea, [2]Division of Rheumatology, Department of Internal Medicine, Department of Rheumatology, University of Ulsan College of Medicine, Asan Medical Center, Seoul, South Korea, [3]Division of Rheumatology, Department of Internal Medicine, Univerisy of Ulsan College of Medicine, Asan Medical Center, Seoul, South Korea, [4]Internal Medicine, Seoul Veterans Hospital, Seoul, South Korea

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Vasculitis Poster I
Session Type: ACR Poster Session A

Session Time: 9:00AM-11:00AM

Background/Purpose:

To determine whether adult IgA vasculitis patients who developed disease at an older age differ from early-onset patients in terms of clinical features and outcomes.

Methods:

All consecutive adult patients who were diagnosed with IgA vasculitis between January 1997 and December 2014 were reviewed retrospectively. Patients who developed the disease at an older age (¡Ã60 years) were compared with those with an earlier onset of disease. Renal insufficiency was defined as an estimated glomerular filtration rate <60 ml/minute.

Results:

In total, 100 adult patients were diagnosed with IgA vasculitis (mean age, 45.61 ¡¾ 17.24 years), of whom 31 (31%) had late-onset disease. Compared to early-onset patients, late-onset patients were less likely to have a preceding upper respiratory tract infection (0/31, 0.0% *vs.* 14/69, 20.3%; p=0.004), and more likely to have renal insufficiency at presentation (14/31, 45.2% *vs.* 7/69, 10.1%; p=0.000). At the last follow-up visit, late-onset patients were more likely to have chronic renal insufficiency, including end-stage renal disease (18/28, 64.3% *vs.* 7/62, 11.3%; p=0.000). Multivariate Cox analysis revealed that late-onset was a significant risk factor for renal insufficiency at follow-up (odds ratio, 12.886, 95% confidence intervals, 3.653–45.457; p=0.000) (Table 1).

Conclusion:

Patients with late-onset IgA vasculitis in adults exhibit distinct clinical features characterized by greater renal involvement and worse renal outcomes. Thus, more intensive treatment might be needed for adult IgA vasculitis patients, in particular those with late-onset disease.

Table 1. Clinical factors that predict the development of chronic renal insufficiency, as measured by multivariate analysis

	OR	95% CI	P-value
Renal insufficiency at presentation[a]	1.947	0.760–4.991	0.165
Proteinuria (>1g/day) at presentation	0.611	0.233–1.601	0.316
Hematuria at presentation[b]	10.854	1.348¡©–87.393	**0.025**
Late-onset disease (¡Ã60 years)	12.886	3.653¡©–45.457	**0.000**

[a]Renal insufficiency was defined as an estimated glomerular filtration rate <60 mL/minute.

[b]Hematuria was defined as ¡Ã10 red blood cells per high-power field in urine analysis.

CI: confidence interval; OR: odds ratio.

Session Title: Vasculitis Poster I
Session Type: ACR Poster Session A
Session Time: 9:00AM-11:00AM

Background/Purpose: Although the prognosis of Henoch-Schönlein purpura (HSP) is usually favorable, relapses are relatively frequent.

Objectives: Our aim was to analyze the frequency, type and risk factors for relapses in a large series of unselected patients with HSP.

Methods: Retrospective study of 417 patients from a single center, diagnosed with HSP according to the criteria proposed by Michel et al. (J Rheumatol 1992; 19: 721-28). Relapse was defined as a new outbreak of HSP in a previously asymptomatic patient (at least for one month). Quantitative variables were expressed as mean ± SD or as median (interquartile range), and compared with the Student t-test or the Mann-Whitney U-test, as appropriate. Dichotomous variables were expressed as percentages and compared by using the chi-square test. The variables associated with HSP relapse in the univariate analysis entered into a stepwise multivariate logistic regression. Statistical analysis was performed using SPSS 15.0.

Results: 417 patients (240 men/177 women) were studied; median age, 7.5 years (IQR [5.3 to 20.1]). 315 (75.5%) were children or young people (≤20 years) and 102 (24.5%) adults. Clinical manifestations (onset/HSP established,%) were: skin lesions (55.9/100), nephropathy (24/41.2), gastrointestinal involvement (13.7/64.5), joint symptoms (9.1/63.1) and fever (6.2/20.4). Corticosteroids were the most frequently used drugs (35%), followed by NSAIDs (14%), and cytotoxic agents (5%).

After a median follow-up of 12 (IQR [2-38]) months, complete recovery was observed in most cases (n=346; 83.2%) and persistent and usually mild nephropathy, in 32 patients (7.7%). Relapses occurred in almost one third of the patients (n=133; 31.9%). Clinical manifestations during relapses were: cutaneous (89.6%); abdominal (27.1%); renal (25.9%) and articular (16.8%). The median number of relapses was 2.4 (IQR [1-3]). The main risk factors for the development of HSP relapse in univariate analysis are shown in the TABLE.

After multivariate analyses the most powerful predictive factors for relapse were joint manifestations at disease onset, gastrointestinal manifestations during the course of the disease, and corticosteroid treatment at the time of the first episode of HSP (TABLE).

TABLE. Univariate and multivariate analyses of the risk of relapses in a series of 417 patients with Henoch-Schönlein Purpura.

Variable	OR (CI 95%)	p
Univariate analysis		
Male gender	1.51 (0,98-2,32)	0,058
Joint manifestations at the beginning	2.60 (1,31-5,15)	0,006
Palpable purpura duration> 7 days	1.89 (1,04-3,42)	0,037
Abdominal pain	1.66 (1,05-2,60)	0,029
Gastrointestinal manifestations	1.60 (1,02-2,50)	0,042
Nephropathy in the course of HSP	1.61 (0,94-2,76)	0,085
Drug-intake	1.61 (1,06-2,45)	0,026
Corticosteroids	1.71 (1,12-2,64)	0,014
Prednisone doses> 30 mg / day	2.61 (1,06-6,41)	0,036
Duration corticosteroids (per month)	1,08 (0,99-1,16)	0,058
Multivariate analysis		
Joint manifestations at the beginning	2.63 (1,.31-5,30)	0,007
Gastrointestinal symptoms in the course	1.66 (1,05-2,62)	0,031
Treatment with corticosteroids	1.65 (1,06-2,55)	0,026

Conclusion: HSP is usually a benign entity but relapses are not uncommon. Patients with articular symptoms at onset or presenting with gastrointestinal manifestations during the course of the disease or those needing corticosteroids to control the initial episode of HSP, are more prone to develop relapses.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: ACR Plenary Session I: Discovery 2015

Session Type: ACR Plenary Session

Session Time: 11:00AM-12:30PM

Background/Purpose: Herpes zoster (HZ) is an opportunistic infection caused by Varicella Zoster Virus (VZV); HZ is observed with increasing frequency in patients on immunosuppressive therapies. HZ is not only a morbid condition but is associated with a variety of complications. Prior literature has suggested that the risk of stroke may increase shortly after an incidence of HZ, but little is known about this association for patients with autoimmune (AI) disease who are at increased risk both for zoster and stroke compared to the general population.

Methods:

Medicare data (2006-2012) was used to identify patients with incident herpes zoster (HZ), defined by at least one ICD9 diagnosis code 053.xx from hospital discharge or outpatient HZ with a prescription for zoster drug within 7 days. Within the preceding 12 months ('baseline'), they also must have had consecutive coverage with Medicare parts A, B, and D and could not have had any diagnosis code or treatment for HZ. They must also have had ankylosing spondylitis (AS), inflammable bowel disease (IBD), psoriasis (PSO), psoriatic arthritis (PSA), or rheumatoid arthritis (RA) based on 2+ diagnoses from physician visits. Patients with prior stroke or the occurrence of HZ and stroke on the same day were excluded.

Follow-up started at the date of HZ diagnosis + 1 day. The outcome of interest was hospitalized ischemic stroke. The hypothesis tested was that the incidence of stroke immediately following HZ was increased compared to the incidence of stroke at later time points. Incidence rate of hospitalized ischemic stroke in risk windows of 6 and 12 months following the HZ event were evaluated. Poisson regression was to compute incidence rate ratios (IRRs) and to control for multiple potential confounders potentially associated with stroke, comparing the 1, 6 and 12 month periods after HZ to subsequent time periods.

Results:

A total of 50,929 patients with autoimmune diseases and incident HZ were eligible for analysis. The crude incidence rate of hospitalized ischemic stroke was 9.8/1000py in the 6 months after HZ, compared to 8.7/1000py in years 2-6. After multivariable adjustment for multiple stroke-related factors, the IRR for the risk in the first year compared to the second was 1.30 (1.05 – 1.61) compared to month 12-18. Examining the shorter risk window of 30 days after HZ, the IRR was 1.50 (1.06 – 2.12) compared to the pooled rate in years 2-6. Age, diabetes, hypertension, atrial fibrillation, prior TIA, and higher glucocorticoid doses were also significantly associated with higher stroke risk.

Conclusion:

In patients with autoimmune diseases, incident herpes zoster was associated with a 50% increase risk for stroke in the subsequent month. These data provide urgency for developing strategies to reduce the risk of VZV in vulnerable immunosuppressed patients.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: ACR Plenary Session I: Discovery 2015

Session Type: ACR Plenary Session

Session Time: 11:00AM-12:30PM

Background/Purpose: Synovitis is common in knees with OA, and is associated with structural progression. Intra-articular corticosteroids are widely used and could reduce knee OA cartilage damage associated with synovitis, but might also have adverse effects on cartilage health and periarticular bone. Our objective was to test the potential for disease modification of synovitic knee OA by triamcinolone hexacetonide (THA) in a clinical trial with comprehensive measurement of effects on cartilage and subchondral bone using MRI and DXA.

Methods: This was a 2-year NIH-funded, randomized, placebo-controlled, double-blind, clinical trial of intra-articular THA (40 mg) versus saline in people with symptomatic OA (KL grade 2 or 3) with ultrasonic evidence of synovitis. Randomization was blocked and stratified by gender and KL grade. We administered the intervention every 12 weeks over 2 years (8 doses). Assessments included WOMAC pain and function at each visit, annual knee MRI (Philips Achieva X-Series 3.0 Tesla using cartilage volume and morphology sequences) and knee/hip DXA scans. We evaluated MRI cartilage damage using a validated quantitative Cartilage Damage Index (primary structural outcome), area of denudation, and a semi-quantitative feature score (fissures, delamination, superficial fibrillation, signal change). We measured bone marrow lesion and synovial fluid volume quantitatively. Readers for quantitative structural measurements had good reliability (ICCs > 0.81). We compared change in outcomes for the groups over the observation period using regression adjusting for randomization stratification factors and malalignment. Skewed outcomes were log-transformed. We did additional repeated measures analyses using random effects mixed models.

Results: Of the 140 participants, 54% were women, 35% were nonwhite; mean BMI was 31.2 Kg/m2. Completion rates were high (≥90%) in both groups. There was no significant difference between groups in mean change in WOMAC pain (THA -2.2, placebo -2.8; p=0.3) or function (THA -7.1, placebo -9.2; p=0.4), chair stand (THA -1.1, placebo -1.6; p=0.8), or walk time (THA -0.5, placebo -0.03; p=0.5). There were also no significant differences in any of the quantitative or semiquantative structural endpoints, except for CDI (greater loss in the THA group; Table), and progression of fibrillation (THA 11%, placebo 24%; p=0.04). Rates of hypertension and hyperglycemia were low (3% overall for each) and did not differ significantly.

Conclusion: Intra-articular corticosteroids administered every 3 months over 2 years appear relatively safe but do not significantly reduce the progression of structural damage or patient outcomes over the long term. The greater rate of loss of cartilage thickness detected by the CDI in the treated group was small in magnitude and of uncertain clinical significance.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: ACR Plenary Session I: Discovery 2015

Session Type: ACR Plenary Session

Session Time: 11:00AM-12:30PM

Background/Purpose: Oral bisphosphonates are the most common osteoporosis treatment, but inconvenient dosing regimens and side effects lead to low adherence. Less frequently dosed bisphosphonates, eg, once yearly zoledronic acid (ZOL), are part of the treatment algorithm for patients who have failed or are intolerant to oral bisphosphonates. Yet there is no evidence that cycling through bisphosphonates offers therapeutic benefit.

Denosumab (DMAb) has shown bone mineral density (BMD) increases in subjects previously treated with oral bisphosphonates, in contrast to ZOL (McClung et al. *Bone* 2007). This study evaluated DMAb compared with ZOL in postmenopausal women with osteoporosis previously treated with oral bisphosphonates.

Methods: This was a 12-month, multicenter, randomized, double-blind, double-dummy study in postmenopausal women aged ≥ 55 years who had received oral bisphosphonates for ≥ 2 years; had a BMD T-score ≤ –2.5 at the lumbar spine, total hip, or femoral neck; and a serum C-telopeptide of type 1 collagen (sCTX) ≤ 0.5 ng/mL. Subjects were randomized 1:1 to DMAb 60 mg every 6 months (Q6M) + placebo (intravenous [IV] once yearly) or ZOL 5 mg IV once yearly + placebo (subcutaneous Q6M) for 12 months, and received calcium and vitamin D daily. Endpoints included percentage change from baseline in BMD at the lumbar spine (primary endpoint), total hip, femoral neck, and 1/3 radius at month 12. sCTX and procollagen type 1 N-terminal propeptide (P1NP) were measured post baseline in a subset of subjects. Safety was also assessed.

Results: A total of 643 subjects were randomized (321 DMAb; 322 ZOL). Mean (SD) age was 69 (7) years, mean (SD) lumbar spine BMD T-score was –2.7 (0.8), and mean (SD) duration of prior oral bisphosphonates use was 6.3 (3.8) years. BMD change from baseline at month 12 was significantly greater with DMAb compared with ZOL at the lumbar spine (3.2% vs 1.1%; $p < 0.0001$; Figure) and all other measured skeletal sites (Figure). Median decrease from baseline was greater with DMAb compared with ZOL for sCTX at months 1 (–78% vs –68%), 6 (–63% vs –22%), and 12 (–63% vs 2%; all $p < 0.01$), and for P1NP at months 6 (–48% vs –30%) and 12 (–50% vs 4%; both $p < 0.01$). Overall and serious adverse events were similar between groups. There were no cases of osteonecrosis of the jaw, hypocalcemia, or delayed fracture healing. Three events consistent with the definition of atypical femoral fracture were observed (2 DMAb; 1 ZOL).

Conclusion: In postmenopausal women with osteoporosis previously treated with oral bisphosphonates, DMAb treatment increased BMD at all measured skeletal sites and reduced bone remodeling more than ZOL. No new safety risks were identified.

Session Title: ACR Plenary Session I: Discovery 2015

Session Type: ACR Plenary Session

Session Time: 11:00AM-12:30PM

Background/Purpose:

We describe a new autoinflammatory syndrome caused by high penetrance heterozygous germline mutations in the NFκB regulatory protein TNFAIP3 (A20) in six unrelated families with early onset systemic inflammation. The syndrome resembles Behçet's disease (BD), which is typically considered a polygenic disorder with onset in early adulthood. Previously, low-penetrance common variants of *TNFAIP3* have been associated with a number of autoimmune and inflammatory diseases in multiple GWAS studies.

Methods:

We performed whole-exome and candidate gene sequencing in the patients and their unaffected family members. Targeted sequencing of *TNFAIP3* was performed in 384 Turkish and 384 Japanese patients with BD that were used for GWAS. We used overexpression experiments in 293T cells and Jurkat cells to establish the causality of candidate variants. Patient samples were analyzed using immunoblotting, immunohistochemistry, flow cytometry, real-time PCR, and cytokine profiling.

Results:

We identified 5 high-penetrance dominantly inherited frameshift and nonsense *TNFAIP3* mutations in 11 patients from 5 families who presented with early-onset systemic inflammation, arthralgia/arthritis, oral and genital ulcers, and ocular inflammation. Targeted sequencing of *TNFAIP3* identified one patient from the GWAS cohort with a novel frameshift mutation. None of the mutations have been reported in any public database. Expression of wild type (WT) A20 was reduced in patients' PBMCs and fibroblasts. A20 is a potent inhibitor of the NFκB signaling pathway. Over-expressed mutant proteins failed to suppress TNF-induced NFκB activity in comparison to WT A20, while co-transfection with the WT A20 normalized the NFκB activity. A20 restricts cellular activation by cleaving K63-linked ubiquitin chains (Ub) from target substrates such as NEMO, RIP1, and TRAF6. Cells transfected with A20 mutants showed a marked defect in the deubiquitination of each of these target molecules. This defect was partially rescued by co-transfection with wild-type A20, mimicking the situation in the patients. These experiments suggest haploinsufficiency as a likely mechanism of disease.

Stimulated patients' cells showed increased phosphorylation of IKKα/β, increased degradation of IκBα, and increased nuclear translocation of p65. Patients' PBMCs displayed weak association of A20 with the TNFR complex and a defect in the deubiquitination of A20 target molecules. Patient cells had a sustained higher K63-ubiquitinaton level of NEMO and RIP1 and accumulated high-molecular weight Ub-aggregates. These results indicate that inefficient deubiquitination of A20 target proteins might explain a higher NFκB signaling activity in mutant cells. Levels of IL-1β, TNF-α, IP-10, IL-17, and IL-9 were substantially increased in patients' serum and in the supernatants of stimulated PBMCs relative to healthy controls. Patients' cells showed constitutive activation of the NLRP3 inflammasome. Initial experience with agents targeting pro-inflammatory cytokines has been encouraging.

Conclusion:

This study provides the first example of the effects of germline high-penetrance heterozygous truncating mutations in the *TNFAIP3* gene.

Session Date: Sunday, November 8, 2015

Session Title: ACR Plenary Session I: Discovery 2015

Session Type: ACR Plenary Session

Session Time: 11:00AM-12:30PM

Background/Purpose: Systemic sclerosis (SSc), is a chronic autoimmune disorder of the connective tissue. There is an unmet need to define precise immune correlates involved in SSc pathogenesis. The interplay between the tissue microenvironment such as the skin and the periphery in potentiating an inflammatory response remains to be elucidated. This knowledge gap is a major impediment for development of therapeutic interventions.

Methods: Our Immunomics platform integrates highly multiplexed technologies with the objective of identifying unique immune signatures that cluster meaningfully at the single-cell level. 1) Gene expression studies using Nanostring - Human dermal fibroblasts stimulated with culture supernatants of blood and skin derived DNA Topoisomerase I (Topo I, an autoantigen relevant in SSc) specific T cell lines (TCLs) 2) Mass spectrometry (CyTOF) analysis of peripheral blood using 35+ phenotypic and intracellular markers. 3) Next-gen, RNA-seq analysis of the the whole transcriptome, including TCR usage of Topo I specific TCLs. Using this approach, we interrogated samples from SSc subjects stratified (according to modified Rodnan skin score, MRSS) as patients with ILD (n=13), No ILD (n=13) and compared to healthy controls (n=8). The dense data sets generated from these high throughput measurements were analysed using computational tools such as Automatic Classification of Cellular Expression by Nonlinear Stochastic Embedding (ACCENSE), Principal Component Analysis (PCA) and Ingenuity Pathway Analysis (IPA).

Results: Skin derived Topo I specific TCLs expressed significantly higher amounts of IL-17A and IL-13 (p value $< .001$) compared to blood derived Topo I specific TCLs. Nanostring gene expression studies revealed that IL-1a, IL-1β, IL-6, IL-8, IL-11, CCL2, CXCL2, CXCL10, CSF3 and TNFSF14 were significantly (p value $< .05$) in the human dermal fibroblasts stimulated with culture supernatants from skin-derived TCLs. Gene expression was also confirmed at the protein level using Enzyme linked immunosorbent assay (ELISA). IPA gene ontology studies annotated IL-17A as a top upstream regulator of these genes. CyTOF analysis showed that CD4+CD45RO+CD161+CCR4+CCR6+ Th17 cells were increased (p value $< .03$) in SSc subjects with No ILD compared to patients with ILD and healthy controls. Finally, unique clonotypes of Topo I specific CD4+ T cells could be identified.

Conclusion: We have defined an Immunome in SSc that circumscribes an altered frequency of Th17 cell subset in patients with ILD as compared to No ILD. IL-17A was identified as the top regulator of genes upregulated by Topo I specific T cells in human dermal fibroblasts. Interestingly, cytokines encoded by some of these genes such as IL-1a, IL-1β, IL-6 and IL-11 are known to be involved in Th17 polarisation. We hypothesise that skin homing Topo I specific T cells secreting IL-17A upregulates inflammatory cytokines in SSc skin, perpetuating inflammation and polarizing a cutaneous Th17 response. These results annotate an interplay between the skin microenvironment and the periphery in shaping the Immunome relevant in SSc pathogenesis

Session Date: Sunday, November 8, 2015

Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: In rheumatoid arthritis (RA), inappropriate recruitment of T-cells into the joint contributes to disease pathogenesis and joint destruction. We examined the ability of adiponectin to regulate the migration of T-cells.

Methods: Peripheral blood lymphocytes were isolated from healthy donors and from patients with newly presenting RA fulfilling the 1987 ACR criteria at the time of initial assessment. Lymphocyte migration across TNFα+IFNγ stimulated endothelial cells was assessed *ex vivo* using phase-contrast microscopy. *In vivo*, lymphocyte migration was assessed in a model of zymosan-driven peritoneal inflammation.

Results: Adiponectin inhibited the migration of human lymphocytes across inflamed endothelium in a dose dependent manner. This effect was lost when B-cells were absent, but could be regained by the addition of supernatants from adiponectin-stimulated B-cells. Mass spectrometry identified the adiponectin induced B-cell-derived agent as a small peptide, subsequently named PEPITEM. *In vitro*, PEPITEM blocks T-cell migration by stimulating endothelial cells to release sphingosine-1-phosphate, a known regulator of T-cell migration. In zymosan-induced peritonitis, T-cell recruitment was significantly increased in B-cell deficient animals compared to wild-type controls, and this was ameliorated by treatment with synthetic PEPITEM. B-cells isolated from patients with RA expressed lower levels of adiponectin receptors compared to healthy controls and were unable to respond to adiponectin. Consequently, T-cells from patients with RA were released from the inhibitory effects of adiponectin on transmigration. Excitingly the full effect of adiponectin was rescued by the therapeutic use of exogenous PEPITEM.

Conclusion: We have identified a novel endogenous peptide (PEPITEM) mediated pathway that suppresses T-cell recruitment across inflamed endothelium, which is dysfunctional in patients with RA. Thus, deregulation of the adiponectin-PEPITEM axis during early development and/or progression of disease could directly contribute to pathology in RA. Re-establishing PEPITEM function to "turn off" pathological recruitment of T-cells represents a novel and potentially powerful approach to treating patients with early rheumatoid arthritis.

Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Inhibitor of DNA binding 1 (Id1) is a nuclear protein containing a basic helix-loop-helix (bHLH) domain that regulates cell growth by selective binding and prevention of gene transcription. We have shown that Id1 exhibits pleiotropic activity, is highly expressed in rheumatoid arthritis (RA) synovial tissues (STs) and effusions, and is primarily fibroblast derived. Soluble Id1 acts as a potent inducer of angiogenesis and may contribute to vasculogenesis and angiogenesis by independent mechanisms. This suggests that fibroblast-like synoviocytes (FLS) produce Id1, which induces blood vessel growth after release from FLS through an unknown mechanism.

Methods: Histologic analysis of RA STs and K/BxN mice ankles was conducted to reveal the cell types expressing Id1 in these tissues and how Id1 expression correlates with disease severity. FLS from RA, osteoarthritis (OA), and normal (NL) STs were plated and cell supernatants were measured for Id1 expression by ELISA. Supernatants were subjected to ultracentrifugation to isolate and purify exosomes. Nanoparticle Tracking Analysis was used to quantify the size and concentration of particles within the exosome fractions. Whole and lysed (0.5% Triton X-100) exosome fractions were then measured for Id1. For signal transduction analysis, human dermal microvascular endothelial cells (HMVECs), endothelial progenitor cells, and FLS were plated and stimulated with human Id1 to assess the kinetics of protein phosphorylation. Finally, we confirmed the effects of Id1 signaling on angiogenesis using silencing RNA (siRNA) to inhibit HMVEC signaling pathways in the mouse Matrigel plug assay. Further studies of Id1 as a secreted factor included electroporation of RA FLS with a clustered regularly interspaced short palindromic repeats (CRISPR)/Cas9 plasmid with a guideRNA targeting the Id1 gene. Successful expression of this plasmid will cause error-prone nonhomologous end joining (NHEJ) repair at the start codon of the Id1 gene, likely causing a nonsense mutation, resulting in an Id1 knockout cell.

Results: Histologic analysis revealed that Id1 expression correlated well with disease severity in RA STs and in K/BxN mouse ankles. We confirmed that >70% of particles in the exosome fraction of RA FLS supernatants were between 25-135 nm in diameter, which is the expected size of exosomes. We found that >80% of the Id1 released by RA FLS was encapsulated within these exosomes. Cell signaling assays showed the JNK pathway was consistently upregulated by Id1 in the cell types tested. Furthermore, we showed that inhibiting HMVEC associated JNK with siRNA reversed Id1 induced vessel formation in Matrigel plugs. Finally, we confirmed Cas9 mediated NHEJ at the start codon of the Id1 gene via Sanger sequencing and T7 endonuclease activity. These Id1 knockout FLS showed a 40% decrease in cell proliferation compared to sham transfected cells.

Conclusion: Id1 is a pleotropic molecule that has significant effects on angiogenesis, vasculogenesis, and FLS proliferation. Our data shows that Id1 is not only an important nuclear protein, but that it is also released from FLS, primarily in exosomes, thus expanding its role in the orchestration of inflammatory lesions through trans-cellular effects.

Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

CGEN-15001 is an Fc fusion protein composed of the extracellular domain of a novel B7-like protein. Therapeutic CGEN-15001 treatment is effective in collagen induced arthritis and potentially re-establishes immune tolerance. This is supported by long lasting efficacy in autoimmune disease models, and by establishment of tolerance to donor graft in a bone marrow transplantation model. CGEN-15001 inhibits T cell activation and induces Th1/Th17 to Th2 shift, IL-10 secretion and regulatory T cell (Treg) differentiation.

As Tregs have key role in tolerance, their involvement in the effects of CGEN-15001 was studied in the EAE (experimental autoimmune encephalomyelitis) model of multiple sclerosis by blocking IL-10 or TGFβ which play critical roles in Treg differentiation, or upon transient Treg inactivation by anti-CD25.

The therapeutic potential of CGEN-15001 for RA was studied in co-cultures of cytokine activated T cells (TcK) and macrophages (Mϕ) from RA patients and healthy donors. Such co-cultures mimic the interaction of cells in RA synovium that lead to aberrant cytokine production and provide a translational tool to evaluate potential therapies.

Methods:

CD4+ T cells and monocytes were isolated from healthy donors or RA patients' blood and cultured for 6 days with TNFα, IL-6 and IL-15 to induce TcK or with M-CSF to induce Mϕ differentiation, respectively. Autologous TcK and Mϕ were co-cultured in the presence of CGEN-15001 or controls for 24hrs. Cytokines were evaluated by luminex.

EAE was induced in SJL mice primed with $PLP_{139-151}$ in CFA. Mice were treated from onset of remission, 3 times/week for 2 weeks. Anti-IL-10 or anti-TGFβ were injected concomitantly with CGEN-15001. Alternatively, 2 injections of anti-CD25 were given 2 days before treatment with CGEN-15001 or 2 weeks after last treatment. Disease severity was followed.

Results:

In synovial-like Mϕ: TcK co-cultures, CGEN-15001 abrogated secretion of pro-inflammatory cytokines including TNFα, IL-17, IFNγ, GM-CSF, RANTES and MIP-1α. Similarly, inhibition in TNFα secretion was observed in co-cultures from RA patients' cells.

In EAE, durable remission was induced by a short course of therapeutic treatment. This effect was abrogated by concomitant treatment with anti-TGFb or anti-IL-10, demonstrating a central role for Treg supporting pathways in the therapeutic effects of CGEN-15001. Transient inactivation of Tregs by anti-CD25 before CGEN-15001 treatment did not affect the durable remission achieved by CGEN-15001, however, administration of anti-CD25 2 weeks after the last treatment resulted in transient disease relapse, suggesting that Treg functionality is crucial for the durable effects of CGEN-15001, while at early stages Th1/Th17 to Th2 skew may control the disease.

Conclusion:

The anti-inflammatory activity of CGEN-15001 in a translational assay mimicking RA synovium supports its therapeutic potential in RA. The long remission maintained by active Tregs in the EAE model supports a novel mechanism of re-establishing tolerance to autoantigens. Therefore, these results support the therapeutic potential of CGEN-15001 to reduce inflammation and maintain long-term remission in autoimmune diseases and RA in particular.

Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

Neuropsychiatric lupus (NPSLE) is a common disease manifestation in lupus patients; however, the underlying mechanisms are not fully understood. TWEAK is a cytokine member of the TNF superfamily; the TWEAK receptor, Fn14, is inducibly expressed in the central nervous system (CNS) in endothelial cells, astrocytes, microglia, and neurons. Previously, we had found that Fn14 knockout MRL/lpr lupus mice have

significantly attenuated neuropsychiatric manifestations. To establish whether this improvement in disease is secondary to inhibition of TWEAK-Fn14 signaling within the CNS rather than in the periphery, and determine whether TWEAK-mediated neuropsychiatric effects are strain dependent, we performed short term intra-cerebroventricular injections (ICV) of Fc-TWEAK to C57Bl6/J (B6) mice.

Methods:

ICV injection of Fc-TWEAK (2 µg, n=12) or isotype control (P1.17, 2 µg, n=11) was conducted twice a week in B6 mice at 8 weeks of age for a total of 5 injections, according to the following stereotaxic coordinates: anteroposterior: -0.34 mm, mediolateral: -1.0 mm; dorsal ventricular: 2mm. Three days after the last injection, neurobehavioral tests including open field, object placement, object recognition, anhedonia, and forced swim were performed, after which the mice were sacrificed. To evaluate whether ICV administration of Fc-TWEAK modulates changes in blood brain barrier (BBB) integrity, extravascular fibronectin, aquaporin-4, and iNOS expression were evaluated by Western blot, immunofluorescence staining and qRT-PCR, respectively. Complement activation was assessed by measuring the expression of C3 by qRT-PCR and Western blot. TUNEL staining was employed to analyze for apoptosis in brain cells.

Results:

We found that Fc-TWEAK injected non-autoimmune mice developed significant depressive-like behavior and cognitive dysfunction (impaired spatial memory). Inflammatory mediators associated with lupus brain disease, including MCP-1, C3, and iNOS, were significantly elevated in the brains of Fc-TWEAK treated mice. Furthermore, Fc-TWEAK directly increased BBB permeability, as demonstrated by increased fibronectin deposition and reduced aquaporin-4 expression in the brain of Fc-TWEAK treated mice. Finally, mice injected with Fc-TWEAK exhibited increased apoptotic cell death in the cortex and hippocampus.

Conclusion:

TWEAK can contribute to lupus-associated neurobehavioral deficits including depression and cognitive deficits by acting within the CNS to enhance production of inflammatory mediators, promote permeability of the BBB, and induce apoptosis in resident brain cells. Our study provides further support that the TWEAK/Fn14 signaling pathway may be a potential therapeutic target for neuropsychiatric manifestations in SLE.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic autoimmune disorder characterized by monocyte (MN) infiltration into the synovium. Citrullination is a post-translational modification of arginine to citrulline mediated by peptidyl arginine deiminase (PAD). Previously, we have shown that citrullination converts epithelial-derived neutrophil-activating peptide 78 (ENA-78/CXCL5) from a neutrophil recruiter to a MN recruiter. In this study, we investigated the signaling pathways involved in MN recruitment by citrullinated ENA-78/CXCL5 (citENA-78/CXCL5).

Methods: Recombinant human (rh) ENA-78/CXCL5 was citrullinated by incubation with rhPAD enzyme. To confirm the citrullination sites, citENA-78/CXCL5 was analyzed using liquid chromatography-tandem mass spectrometry (LC-MS/MS). To determine the signaling pathways involved, MN chemotaxis assay was performed with citENA-78/CXCL5 in modified Boyden chambers with chemical signaling inhibitors. MNs were also transfected with JNK silencing RNA (siRNA). Three mutants (R45K, R48K and R45/48K) of rhENA-78/CXCL5 were generated by transmutation of arginines to lysines and were used in MN chemotaxis assays. To assess citENA-78/CXCL5-induced MN migration *in vivo*, a mouse subcutaneous air pouch model was used. The exudates from the air pouch were collected after 24 hours and immunofluorescence was

performed to detect MNs/macrophages using anti-F4/80 antibody. MNs were stimulated with citENA-78/CXCL5 for 15 minutes and Western blots were performed to evaluate phosphorylation of signaling molecules. We also assessed the crosstalk between the signaling pathways after incubating with chemical signaling inhibitors before citENA-78/CXCL5 stimulation.

Results: LC-MS/MS analysis confirmed citrullination of citENA-78/CXCL5. CitENA-78/CXCL5-induced MN migration was significantly reduced by JNK and NFκB inhibitors, but not by inhibitors of Src, p38, and Erk1/2. JNK siRNA-transfected MNs displayed decreased citENA-78/CXCL5-induced MN migration compared to control transfected MNs. CitR45K and citR48K mutations significantly reduced MN chemotaxis, suggesting that citENA-78/CXCL5-induced MN migration is dependent, at least partially, on both citrulline residues. The mouse air pouch model showed marked MN recruitment in response to citENA-78/CXCL5 compared to the controls, suggesting that citENA-78/CXCL5 increases MN ingress *in vivo*. CitENA-78/CXCL5-stimulated MNs showed increased expression of phosphorylated-JNK and phosphorylated-NFκB (p-NFκB) which was inhibited by signaling inhibitors. Moreover, a JNK inhibitor reduced the level of p-NFκB, suggesting that JNK is upstream of NFκB in citENA-78/CXCL5-stimulated MNs.

Conclusion: We found that citENA-78/CXCL5 induces MN migration via JNK and NFκB signaling pathways. MN chemotaxis induced by citENA-78/CXCL5 is partially dependent on both citrulline residues. CitENA-78/CXCL5 plays an important role in MN migration *in vivo* in the air pouch inflammatory model. Our data suggest that citENA-78/CXCL5 induces JNK and NFκB signaling pathways with JNK upstream of NFκB. Targeting citENA-78/CXCL5 and its signaling pathways may be a novel approach to treat MN-dependent diseases.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: The IL-36 family of cytokines comprises three agonists, IL-36α, IL-36β and IL-36g, an antagonist IL-36Ra, as well as IL-38, another potential IL-36 inhibitor. IL-36 agonists are highly expressed in skin and are involved in the pathogenesis of psoriasis while antagonists limit uncontrolled inflammation. The expression and role of IL-36 cytokines in other chronic inflammatory diseases is currently debated. In this study, we compared the expression profile of IL-36 cytokines in psoriasis, RA and Crohn's disease (CD).

Methods: Skin, joint and colon inflammation was induced in mice according to standard protocols. Skin, synovial and colonic biopsies from patients respectively with psoriasis (n=15), RA (n=21) or CD (n=16) were collected with corresponding control samples. Synovial fluids from patients with RA (n=30) or osteoarthritis (n=29) were also collected. These samples were analyzed for cytokine expression by RT-qPCR, ELISA, multiparametric Luminex assays, immunohistochemistry and confocal microscopy. The cell sources of IL-36 cytokines were confirmed in cell cultures after stimulation with inflammatory cytokines and TLR agonists by RT-qPCR.

Results: During imiquimod-induced mouse skin inflammation and in human psoriasis, expression of IL-36α, g and IL-36Ra, but not IL-36β and IL-38, was induced and correlated with Th17 cytokines (IL-17A, IL-22, IL-23, CCL20), IL-1β, Oncostatin M, IFNg and IL-8. In mice with collagen-induced arthritis and in the synovium of patients with RA, IL-36α, β, g, IL-36Ra and IL-38 were all elevated and correlated with IL-1β, myeloid cytokines such as CCL3, CCL4 and MCSF, but not with Th17 cytokines, TNFα or IL-6. In mice with dextran sulfate sodium-induced colitis and in patients with CD, only IL-36α, g and IL-38 were induced at a relatively low level. Only a minor subgroup of patients with RA (17-29%) or CD (25%) had an elevated IL-36 agonists/antagonists ratio, versus 93% of patients with psoriasis. By IHC and in cell cultures, the different IL-36 cytokines were produced at different levels by human keratinocytes, $CD68^+$ inflammatory macrophages, dendritic/Langerhans cells, and $CD79\alpha^+$ plasmocytes. Endothelial cells and $CD55^+$ fibroblasts could also participate, but enterocytes were poor producers.

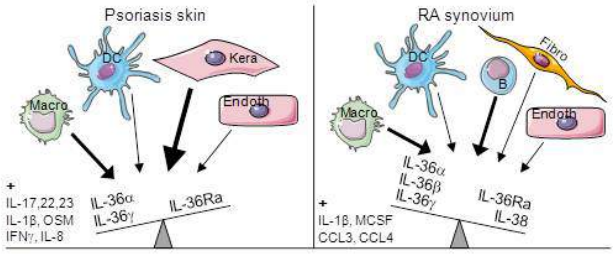

Figure: Proposed model for the distinct expression of IL-36 cytokines in psoriasis versus RA.

Conclusion : Expression of the different IL-36 cytokines is differently regulated and their cell sources are distinct. This helps to explain the different expression profiles observed in three chronic inflammatory diseases and why only a minor subgroup of RA and CD patients have an elevated IL-36 agonists/antagonists ratio. Additional studies are necessary to better identify these patients and to investigate whether they would benefit from IL-36 neutralization.

Session Date: Sunday, November 8, 2015

Session Title: Epidemiology and Public Health I: RA Comorbidities and Mortality

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: There is little data on the 20 year outcome of patients with inflammatory polyarthritis (IP). Hence the aim of this study was to describe patients with IP over long term follow up, including disease activity, disability and surgery.

Methods: Adults, aged ≥16 with ≥2 swollen joints for ≥4 weeks, recruited from 1990-1994 to the Norfolk Arthritis Register (NOAR) were included in this study. Baseline assessments included demographics, 51 swollen / tender joint counts and HAQ. RF, ACPA and CRP were measured from stored blood samples taken every 5 years; DAS28-CRP scores were calculated. Patients were re-assessed at years 1-3, 5, 7, 10, 15 and 20 years and self-report major orthopaedic surgeries data were also collected at these visits. Differences in the progression of disability over time based on gender and other baseline characteristics were assessed using a random effects model. The association between demographics, disability and disease activity and risk of first surgery was assessed using the Cox proportional hazard model. Censoring occurred when patients left the cohort. Mortality rates were calculated, using 15th December 2014 as censor date.

Results: Of 1022 patients (60.1% met the 2010 ACR RA criteria) included at baseline, 354 (34.6%) completed 20 years follow-up. 404 (39.5%) died during follow up (mortality rate: 22.6 / 1000 patient years). At baseline, median (IQR) swollen / tender joint counts were 6 (2-13) / 7 (3-16), and HAQ was 0.8 (0.3-1.4). After baseline, median joint counts improved and remained low (see table). The median HAQ (IQR) score dropped to 0.5 (0.0 -1.3) after 1 year before increasing to 0.9 (0.3-1.6) at 10 years and 1.0 (0.3-1.8) at 20 years. Median DAS28-CRP showed a similar trend. In total, 237 (23.2%) patients underwent at least 1 major joint surgery. The probabilities of patients completing 10 / 20 years of follow-up without surgery were 0.84 and 0.70 respectively. Higher age at onset (HR 1.01; 95% CI 1.00-1.02 per year), baseline HAQ (HR 1.35; 95% CI 1.03 -1.78) and baseline CRP level (HR 1.01; 95% CI 1.00-1.01 per mg/l) were associated with an increased risk of first surgery. The median (IQR) number of surgeries per patient was 2 (1-3). Men were older than women at baseline (mean 55.7 vs 55.2 years, p = 0.0012) whilst women had worse median HAQ scores (0.9 vs 0.5, p<0.0001) and more swollen (7 vs 4, p<0.0001) and tender joints (8 vs 6, p=0.0016).Women had higher HAQ scores than men over 20 year follow up (β coef. 0.007; p<0.001) using a random effects model.

Conclusion: Over 20 years patients' disease activity was well controlled. Median disability rose progressively but slowly after 5 years. Higher baseline HAQ and disease activity scores were associated with joint surgery during follow-up.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Epidemiology and Public Health I: RA Comorbidities and Mortality

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Smoking is a major preventable cause of death and cessation is recommended for the general population. However, it is unclear whether being diagnosis with RA affects smoking cessation and whether continuing to smoke contributes to the excess mortality of RA. We aimed to describe smoking behavior changes after RA diagnosis and to evaluate the effect of smoking on mortality after RA diagnosis.

Methods: We investigated smoking and mortality among women diagnosed with RA during follow-up in the Nurses' Health Study (NHS). The NHS is composed of 121,700 women aged 30-55 years at baseline in 1976 and followed with biennial questionnaires. RA diagnosis was validated by medical record review according to the 1987 ACR criteria by two rheumatologists who identified the date of RA diagnosis. Smoking status and intensity (never, current, or past; cigarettes/day) were reported biennially during follow-up and cumulative smoking pack-years were calculated for each follow-up cycle. We categorized smoking at each follow-up cycle as occurring before or after the date of RA diagnosis. Deaths were identified by the National Death Index up to 2012. Cox regression models estimated HRs for all-cause mortality according to smoking pack-years after RA diagnosis, adjusting for sociodemographic, behavioral, and clinical factors.

Results: We analyzed 923 women diagnosed with RA during follow-up in the NHS with detailed prospective data available on smoking before and after RA diagnosis. There were 288 deaths in 16,111 person-years of follow-up. At RA diagnosis, mean age was 59.5 (SD 9.9) years, 52% were obese, and 60% consumed alcohol. In the cycle prior to RA diagnosis, 36% were never smokers, 43% were past smokers, and 21% were current smokers. Among current smokers just prior to RA diagnosis, 16% immediately quit smoking after RA diagnosis and maintained cessation, 21% continued to smoke throughout follow-up, 49% continued smoking for at least two cycles after RA but quit later, and 1% quit smoking after RA diagnosis then started smoking again later. Compared to never smokers after RA diagnosis, women who smoked >5 pack-years after RA diagnosis had significantly increased mortality (HR 2.69, 95% CI 1.33-5.46, **Table**) after adjustment for age, smoking pack-years prior to RA diagnosis, and other confounders. When analyzing only ever smokers at RA diagnosis, smoking >5 pack-years remained significantly associated with mortality compared to those who never smoked after RA diagnosis (HR 4.35, 95% CI 1.81-10.44).

Conclusion: Despite the known harmful effects of smoking in chronic diseases, only 16% of smokers quit after diagnosis with RA and maintained smoking cessation during follow-up. Smoking >5 pack-years after RA diagnosis was associated with increased mortality, independent of smoking before RA diagnosis. Interventions promoting cessation of smoking for patients newly diagnosed with RA may diminish the excess mortality of RA.

Table. Hazard ratios for all-cause mortality by cumulative smoking after RA diagnosis during 36 years of prospective follow-up in the Nurses' Health Study, 1976-2012.

Cumulative smoking after RA diagnosis, N=923	Deaths/Person-years	Incidence (per 100,000)	Age and pre-RA smoking adjusted HR (95% CI)*	Multivariable HR (95% CI)**
Never/past/current smoker before RA and never smoker after RA diagnosis	184/12,307	1,529	1.00 (Ref)	1.00 (Ref)
>0-5 pack-years after RA diagnosis	44/2,070	2,126	1.49 (0.85-2.60)	1.42 (0.71-2.82)
>5 pack-years after RA diagnosis	60/1,734	3,460	2.98 (1.70-5.22)	2.69 (1.33-5.46)
Subgroup analysis: Cumulative smoking after RA diagnosis among ever smokers, N=590	Deaths/Person-years	Incidence (per 100,000)	Age and pre-RA smoking adjusted HR (95% CI)*	Multivariable HR (95% CI)**
Past/current smoker before RA and never smoker after RA diagnosis	113/6,172	1,831	1.00 (Ref)	1.00 (Ref)
>0-5 pack-years after RA diagnosis	44/2,070	2,126	1.50 (0.80-2.81)	1.68 (0.74-3.82)
>5 pack-years after RA diagnosis	60/1,734	3,460	3.88 (2.01-7.45)	4.35 (1.81-10.44)

*Adjusted for age, questionnaire period, and cumulative smoking prior to RA diagnosis (never, >0-10, >10-20, >20 pack-years)

**Additionally adjusted for median family income (<$40K, ≥$40K), body mass index category (underweight/normal, overweight, or obese), postmenopausal hormone (PMH) use (premenopausal or postmenopausal/never PMH use, postmenopausal/ever PMH use), physical activity (continuous METs-hours/week), alcohol consumption (0, >0-<5, ≥5 g/d), Alternate Healthy Eating Index without alcohol component (tertiles), cardiovascular disease, and aspirin use.

Session Title: Epidemiology and Public Health I: RA Comorbidities and Mortality

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Results from several small studies support the potential blood pressure lowering effect of tumor necrosis factor (TNF)-a inhibitors in rheumatoid arthritis (RA) patients. Yet, no study has compared the effect of TNF-a inhibitors with non-biologic disease-modifying

anti-rheumatic drugs (nbDMARDs) on the development of incident hypertension in a population-based cohort of RA patients. Therefore, the objective of this study was to compare the risk of incident hypertension between initiators of TNF-α inhibitors and initiators of nbDMARDs in a cohort of RA patients taking methotrexate monotherapy who are free from cardiovascular diseases or hypertension.

Methods: We conducted a cohort study using insurance claims data (2001-2012) from the US. We identified initiators of either TNF-α inhibitors or nbDMARDs. Subsequent exposure to these agents was measured monthly in a time-varying manner. The outcome of interest was incident hypertension, defined by a diagnosis and a prescription for an anti-hypertensive drug. Marginal structural models (MSM) estimated hazard ratios (HR) adjusted for both baseline and time-varying confounders. To validate the primary analysis examining TNF-α inhibitors and hypertension association, we designed a verification analysis to evaluate a known association between leflunomide and hypertension using similar methodology.

Results: We identified 4,822 initiations of TNF-α inhibitors and 2,400 of nbDMARDs. Crude incidence rates of hypertension per 1,000 person-years of follow-up were 36.1 (95%CI 31.8-40.7) for the TNF-α inhibitor group and 41.2 (95%CI 33.0-50.8) for the nbDMARDs. The crude HR of TNF-α inhibitors versus nbDMARDs for the risk of incident hypertension was 0.85 (95%CI 0.67-1.09). After adjusting for both baseline and time-varying covariates in MSM, the HR was 1.01 (95%CI 0.78-1.31). In the verification analysis, the adjusted HR of incident hypertension was 2.33 (95% CI 1.75-3.09) in leflunomide initiators compared with methotrexate initiators.

Conclusion: Treatment with TNF-α inhibitors was not associated with a reduced risk of incident hypertension compared with nbDMARDs in RA patients.

Table: Incidence rates and relative risks of hypertension in initiators of TNF-alpha inhibitors compared to the initiators of non-biologic DMARDs for RA

	nbDMARDs	TNF-α inhibitors
Hypertension Events	88	258
Follow-up (person-years)	2137	7155
Crude incidence rates/1000 person-years (95% CI)	41.2 (33.0-50.8)	36.1 (31.8-40.7)
Unadjusted HR	1	0.85 (0.67-1.09)
Adjusted HR for only time-fixed covariates*	1	0.94 (0.74-1.25)
Adjusted HR for time-fixed and time-varying covariates using IPTW† in MSM**	1	1.01 (0.78-1.31)

Abbreviations: CI- Confidence interval, HR- Hazard ratio, IPTW- Inverse probability treatment weights, MSM- Marginal structural models, nbDMARDs- non biologic disease modifying anti-rheumatic drugs, TNF- tumor necrosis factor

*Time-fixed covariates (measured at initiation of either TNF-inhibitor of non-biologic DMARDs): gender, diabetes, hyperlipidemia, lipid-lowering agent use, anti-diabetic medication use, obesity, smoking, combined comorbidity score.

**Time-varying covariates (updated monthly post-initiation of either TNF-inhibitor of non-biologic DMARDs): use of NSAIDs, injectable steroids, cumulative dose of oral steroids, methotrexate use, leflunomide or cyclosporine use, other non-TNF biologic use, hospitalizations, emergency room visits, office visits, and number of distinct drugs, and age (updated every year in the study).

† IPTW were truncated at the 1st percentile (0.53) and 99th percentile (1.85). Mean (SD) of the weights were 0.97 (0.19) after truncation.

Session Date: Sunday, November 8, 2015

Session Title: Epidemiology and Public Health I: RA Comorbidities and Mortality

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Studies among unselected patients with rheumatoid arthritis (RA) suggest increased risks of both ischemic and non-ischemic heart failure (HF). Since the risk of these two subtypes of HF have not been assessed simultaneously within the same cohort of RA-subjects, let alone in relation to time before/after RA diagnosis, the objectives of this study were to assess the relative risk (RR) of HF by subtype and to determine RR in different time periods since RA onset, in one and the same cohort.

Methods: We identified all subjects above 18 years of age with incident RA within the *Swedish Rheumatology Quality register (SRQ)*. All RA subjects were matched with up to 10 general population comparator subjects based on sex, age, and area of residency. The date of diagnosis was defined as the index-date; comparators received the same index-date as their corresponding RA patient. Ischemic HF was defined on the basis of ICD codes from linkage to the nationwide Patient Register as i) a diagnosis of any HF after a diagnosis of IHD or ii) a main diagnosis of ischemic HF, and was investigated in all subjects free of any HF at the index-date. Non-ischemic HF was defined as a diagnosis of HF in individuals without prior IHD-diagnosis, and was assessed in all subjects free of HF at index date and free of IHD by the date of the HF outcome. Study subjects were followed from the index-date until Dec 31st 2012 and censored at death, first migration, IHD and ischemic HF (when the outcome was non-ischemic HF), and HF (without antedating IHD) when the outcome was ischemic HF. Crude rates were calculated and presented as numbers of events per 1,000 person-years. As a measure of the RR of HF, hazard ratios (HRs) were obtained using cox regression models, and odds ratios were calculated using logistic regression as a measure of RR prior to the index-date.

Results: In total**,** 15,572 RA subjects and 132,018 comparators were free of HF at the index-date, and 14,581 RA subjects and 12,4406 comparators were free of both HF and/or IHD at index date. During follow-up 566 (6.7/1000 person-years) RA subjects and 3413 (4.5/1000 person-years) comparators developed a first non-ischemic HF, corresponding to a 40% risk increase for the RA subjects (HR 1.43 [95% CI 1.30-1.56]). 259 (2.9/1000 person years) RA subjects and 1,254 (1.6/1000 person-years) comparators developed ischemic HF during the follow-up, translating into an 80% risk increase for the RA subjects (HR 1.77 [95% CI 1.55-2.03]). For both HF subtypes, stratification by sex did not reveal any differences between sexes, HRs were higher for RF-positive compared to RF-negative patients. For both subtypes, the RR went from null prior to the index-date to increased risks soon after start of follow-up.

Conclusion: RA is associated with an increased risk of both ischemic and non-ischemic HF. Differences in when and how, in relation to RA onset the risks develop may suggest that several mechanisms mediate HF risks in RA.

Figure 1. The relative risk of subtypes of HF within different time periods since RA onset.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Epidemiology and Public Health I: RA Comorbidities and Mortality

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Suboptimal use of secondary preventive pharmacotherapies after acute coronary syndrome (ACS) in patients with rheumatoid arthritis (RA) has been suggested to contribute to an increased risk of deaths and recurrent events following ACS. The objectives of this study were therefore to investigate whether (i) use of secondary preventive pharmacotherapies, (ii) long term mortality risk and (iii) risk of recurrent ACS after incident ACS differ in patients with prevalent RA and compared to general population comparators.

Methods: Using the Swedish national patient register, patients with prevalent RA and matched general population comparators with incident ACS between 2007 and 2010 were identified. After the ACS, information on dispensed secondary preventive drugs (antiplatelets, β-blockers, statins and RAS-blockers) was retrieved from the prescribed drug register and analyzed during 4 consecutive time periods the year following the ACS. Information on deaths and recurrent ACS was also retrieved and analyzed at 1 year and complete follow-up period, until the end of 2011, using cox regression models stepwise adjusted for preexisting comorbidities and ACS-type.

Results*:* 1135 (0.9%) of the RA-patients and 3184 (0.5%) of the comparators were listed with an incident ACS between 2007 and 2010 and remained eligible for analysis as exposed cases (RA-cases) and unexposed cases (Population-cases) . Among cases diagnosed with transmural myocardial infarction (MI), there were no differences in dispensed drugs within any of the time periods studied. Among RA-cases diagnosed with subendocardial and unspecific MI, the proportion dispensed antiplatelets were lower compared to population-cases within the first two time periods studied, but during the last two time periods these discrepancies disappeared. RA-cases had higher case-fatality rates the year following the ACS and during the complete follow-up period. The relative mortality risk was increased by 60% at 1 year (HR1.59 [95% CI 1.39-1.82]) and 70% during the complete follow-up period (HR 1.73 [95% CI 1.55-1.93]). RA-cases also had higher recurrence rates at 1 year and during the complete follow-up period, corresponding to an increased relative risk of approx. 30% (1 year HR 1.35 [95% CI 1.09-1.68]; Follow-up HR 1.34 [95% CI 1.12-1.60]), which remained stable after adjusting for previous comorbidities and infarct-type.

Conclusion: Despite similar usage of secondary preventive pharmacotherapies, patients with prevalent RA suffer increased risk of recurrent events and death after ACS compared to general population comparators.

Session Title: Fibromyalgia: Insights Into Diagnostic Criteria and Symptom Epidemiology

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: The American College of Rheumatology (ACR) 2010 preliminary criteria for the diagnosis of fibromyalgia requires ascertainment of pain extent and symptoms by physicians. The 2011 ÒsurveyÓ or ÒresearchÓ criteria modified the 2010 requirements by ascertaining criteria items entirely by patient self-report. Various concerns have been raised about potential problems with validity and reliability of the 2011 criteria. We used previously unreported patient data collected simultaneously from 514 patients in the ACR 2010 criteria study to compare physician based (MD) (2010) and patient based (PT) (2011) criteria.

Methods: From the 2010 study, we used data collected separately by physicians and patients for the widespread pain index (WPI), the symptom severity scale (SS), polysymptomatic distress scale (PSD) scale, and for fibromyalgia diagnosis using 2010 and 2011 study rules. A physician tender point count and determination of fibromyalgia by 1990 ACR criteria was also evaluated.

Results: The tender point count was strongly associated with the MD PSD scale (r=0.779) and PT PSD scale (r=0.702). Similar associations were noted with the MD WPI (r=0.751) and PT WPI (r=0.672). The area under the receiver operating curve (ROC) between tender point count and MD and PT diagnosis of fibromyalgia was 0.893 and 0.855. The MD and PT diagnostic agreement was substantial (83.4%, kappa = 0.67. PSD scores differed slightly: 12.3 (SD 7.7) for MD and 12.8 (SD 7.8) by PT, a difference of 0.42 units (p=0.213). The Bland-Altman 95% limits of agreement (LOA) for PSD was -8.5 and 7.7, with a standard error of the measurement of 2.9, and bias of -0.42 (Figure 1) [N.B. We will actually use Figure 2, below, for this ACR abstract].

Conclusion: MD and PT diagnosis and criteria items were strongly associated with tender points. Overall, there was good agreement in MD (2010) and PT (2011) fibromyalgia diagnosis and other measures. The low bias scores indicate consistent results for the physician and patient measures, but the large values for LOA indicate many widely discordant pairs. FM diagnostic agreement is greatest at high and low values of PSD, but becomes more uncertain as the 12-13 border line for diagnosis approaches There is acceptable agreement in diagnosis and PSD for research, but insufficient agreement for clinical decisions and diagnosis. If questionnaires are used to obtain clinical data for patient diagnosis, we recommend adjudication of symptom data by patient and physicians, as recommended by the 2010 ACR criteria.

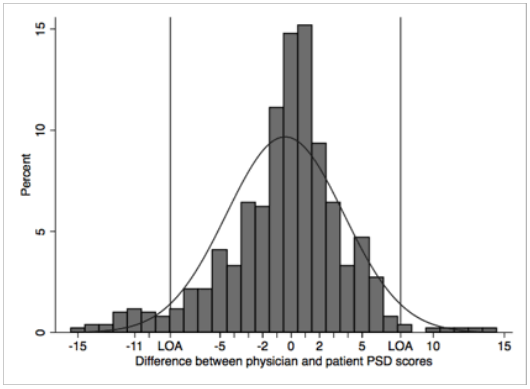

Figure 1. Bland-Altman 95% Limits of Agreement (LOA) histogram. Mean difference (bias) is -0.42, Although PSD difference is close to 0, lack of agreement at individual physician-patient level is evident.

When Fibromyalgia Criteria Misclassify

Frederick Wolfe[1] and Winfried Häuser[2], [1]National Data Bank, Wichita, KS, [2]Department of Psychosomatic Medicine and Psychotherapy, Technische Universität München, Munich, Germany

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Fibromyalgia: Insights Into Diagnostic Criteria and Symptom Epidemiology

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose : The 2010 American College of Rheumatology (ACR) preliminary criteria for the diagnosis of fibromyalgia (FM2010) and its extension for clinical research by patient self-report questionnaire (FM2011) broke with previous 1990 criteria (ACR1990) by eliminating tender points, but also by eliminating the requirement that pain be widespread (4 quadrant + axial) (WSP). By changing the definition of fibromyalgia (FM), the 2010 and 2011 criteria created an expected and natural discordance with the 1990 criteria. In addition, some researchers indicated that elimination of WSP could lead to misclassification by including cases that did not have generalized pain (ACR1990 regions = 5) into the FM definition; and thereby introducing bias favoring psychological symptoms. In the ACR 2010 criteria paper, WSP was absent in 6%-7% of those with FM.

Methods: From 17,385 mixed rheumatic disease patients, we studied 4,964 (28.6%) who satisfied FM2011 criteria, and we evaluated the presence of WSP, and widespread pain index (WPI) scores (0-19) and the Symptom severity scales (SSS) (0-12). FM is diagnosed when (WPI ≥7 AND SS ≥5) OR (WPI 3–6 AND SS ≥9). We also calculated the number of painful regions (0-5: 4 quadrants + axial) from ACR1990. We determined the proportion of patients meeting FM2011 criteria who did not meet the ACR1990 widespread pain definition

Results: Among patients FM2011 (+) 6.6% did not have WSP. 3.5% those FM2011 (+) who had WPI <7did not have WSP. As shown in Table 1, 93.4% of FM2011 (+) had 5 ACR1990 painful regions; 5,3% had 4, and only 1.3% had <4. For the 0-19 WPI, 7% had scores between 4 and 6. Overall, those not meeting the ACR1990 definition, and those perhaps appropriately (regions = 4) not meeting the criteria, were few.

Conclusion: FM criteria may be used 1) for differential diagnosis in which fibromyalgia is the best clinical diagnosis to explain a patient's symptoms; or 2) for concomitant diagnosis in which the several illness are identified, one of which is fibromyalgia. FM2010 and FM2011 were designed for optimal diagnosis in the setting of usual rheumatic disease presentation and usual clinic prevalence. When used in settings where non-WSP and regional or psychiatric diagnoses are substantially increased, FM criteria will "misclassify" persons. This occurs because there is no reliable gold standard fibromyalgia definition. The solution to this type of misclassification is to use the most appropriate clinical diagnosis (e.g., regional arm pain or rheumatoid arthritis) and indicate the patient also satisfied fibromyalgia criteria. In a general or rheumatic disease clinic setting few people will meet FM2011 criteria without WSP, but most will also have many painful regions.

Table 1. Relation between Widespread Pain index and Widespread Pain Regions (ACR1990) and Fibromyalgia Criteria Status

Widespread Pain Index (WPI)	FM2011 (-)	FM2011 (+)	Widespread Pain Regions	FM2011 (-)	FM2011 (+)

Session Date: Sunday, November 8, 2015

Session Title: Fibromyalgia: Insights Into Diagnostic Criteria and Symptom Epidemiology

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: The 1990 criteria for fibromyalgia (FM) remain the only set approved by the American College of Rheumatology (ACR). They require that pain be both widespread (i.e. occurs in contralateral body quadrants and in the axial skeleton) and have been present for three months. Subsequent preliminary ACR criteria in 2010 and modification for self-report require only that the pain be multi-site. As part of the Analgesic, Anesthetic, and Addiction Clinical Trial Translations, Innovations, Opportunities, and Networks (ACTTION) initiative developing a new taxonomy for pain conditions, we have investigated whether associations with features are stronger in persons with chronic widespread pain (CWP) compared to multi-site pain (MSP).

Methods: We have used four population-based studies conducted in the UK: 1958 Birth Cohort study, EpiFunD, SHAMA and WHeSt. In all studies participants were asked "Have you experienced pain in the past month lasting at least a day" - those responding positively shaded the site(s) of pain on 4-view body manikins and indicated if pain had been present for ≥ 3 months. Manikins were coded for pain at 35 individual sites. We determined the number of pain sites indicated and whether subjects met the ACR 1990 criteria definition of CWP. Information was collected across at least two studies on each of: fatigue (Chalder Fatigue or SF-36 vitality scale), Sleep (Sleep Problem Scale or 2010 modified preliminary ACR criteria question) and mood (General Health Questionnaire, Hospital Anxiety and Depression Scale, PROMIS). Relationships with pain reporting were determined by logistic regression, specifically comparing amongst those with MSP, persons with and without CWP.

Results:

There were a total of 28,789 subjects across studies (mean age 42-55 years; males 43-52% [WHeSt was conducted only in females]). Prevalence of CWP, across studies was 12-17%, and in each study the equivalent prevalence was obtained by defining multi-site pain (MSP) as ≥8 sites. Amongst persons with MSP, the proportion also with CWP varied between 62-72%. Those with CWP were more likely to report sleep problems (SHAMA: $OR_{CWP\ vs.\ no\ CWP}$2.99, 95% CI 1.66-5.38; EpiFunD: 2.26, 1.69-3.02), have depression/high levels of distress (1958 Birth cohort: 1.51, 1.15-1.98; WHeSt 3.00, 95% CI 1.42-6.31; EpiFunD 1.99, 1.32-2.98) and be more likely to report fatigue (SHAMA: OR 2.85, 95% CI 1.54-5.26; WHeSt: 1.23, 0.80-1.88).

Conclusion:

We have found that a definition of MSP as at least 8 (of 35) pain sites consistently results in a similar population prevalence to that of CWP, and that the defined groups are similar but not the same. The results suggest that amongst persons with MSP, those with CWP are significantly more likely to exhibit features typical of fibromyalgia.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Fibromyalgia: Insights Into Diagnostic Criteria and Symptom Epidemiology

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Diagnosing FM is difficult because there is no specific laboratory test to confirm the disorder. Billing practices dictate that physicians assign ICD-9-CM (Corresponding International Classification of Diseases, Ninth Revision, Clinical Modification) codes based on the procedure for which they use to treat patients. Since FM pain encompasses many regions of the body and associated problems, physicians

commonly do not assign 729.1. Instead, patients may receive an ICD-9-CM code based on a procedure performed for pain relief, or some other diagnosis commonly associated with a symptom of FM. One of the objectives of this study was to develop a method to identify FM patients who do not meet the inclusion criteria of the 729.1 diagnosis assigned at least twice in a span greater than 12 months apart.

Methods: The FM predictive model was developed using different techniques. Among the 9,758 patients, there were 183,540 patient touch points, defined as a distinct time for which information could be obtained from the patient (Physician Health Assessment (PHA) questionnaire, office visits, medication prescriptions, and surgeries). Over 150 possible predictors were entered into a random forest as a second step for variable reduction. In place of the FM ICD-9-CM code, patients were required to have some type of procedure or visit within the same time frame. A logistic regression model identified the four predictors: musculoskeletal procedures, total unique medications, total unique diagnoses, and days between touch points. The model was validated by using *10*-fold cross validation. Propensity score 1:1 matching based on gender, age, length of treatment, and physician was then used to identify a control group of non-malignant chronic pain but without FM group. A two-sample *t*-test was used to assess differences between cases and controls for patient variables including total number of procedures, diagnoses, medications, and days between touch points.

Results: There were 15 diagnoses highly associated with FM that were distinguished by moderate to large effect sizes (Cohen's $d > 0.5$). The diagnoses included chronic pain syndrome, latex allergy, muscle spasm, fasciitis, cervicalgia, thoracic pain, shoulder pain, rheumatoid arthritis, cervical disorders, cystitis, cervical degeneration, anxiety, joint pain, lumbago, and cervical radiculitis. There was a significant association between FM patients and the region where they receive procedures. Specifically, FM patients are more than four times as likely to receive a procedure in the shoulder (3.55, 5.67) or neck (3.50, 5.02) as non-malignant chronic pain patients. Overall, FM patients are more likely to receive more procedures encompassing six of the seven regions used for analysis: shoulder, neck, arm, chest, knee, thoracic area (all $p < 0.05$).

Conclusion: The predictive model allows a larger selection of FM patients and, by doing so, may assist in accurately targeting more patients for appropriate treatment. This project gives new insights into the diagnosis, co-morbidities, and treatments associated with FM patients in a pain management setting.

Session Date: Sunday, November 8, 2015

Session Title: Fibromyalgia: Insights Into Diagnostic Criteria and Symptom Epidemiology

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Chronic widespread pain (CWP), one of the hallmarks of fibromyalgia, is not uncommon in adolescents and it has previously been shown that adolescents with pain often become young adults with pain. CWP often co-varies with anxiety, depression, and stress symptoms in adults, but the knowledge regarding this is small in youth and young adults.

The aim was to study the associations between CWP, anxiety, depression and stress in adolescents attending first year of high school.

Methods: A computerized questionnaire to 296 adolescents attending Swedish high school, with validated questions regarding presence and distribution of pain (Epipain mannequin), stress symptoms (ELO question), anxiety and depression (Hospital Anxiety and Depression Scale – HADS), and health related quality of life (HRQL as measured by EQ5D). Pain was considered chronic when persistent for more than three months, and the subgroup CWP was defined according to the 1990 ACR criteria for fibromyalgia. Statistical analyses in SPSS v21 with comparison of means by Student's t-test and proportions by chi2-test or Fischer's exact test.

Results: 257 (87%) out of 296 eligible students, mean (SD) age 16.1 (0.7) and 65.8% girls, responded to the questionnaire. Prevalence of chronic pain was 20.8% and that of the subgroup CWP was 4.7%, without any gender differences (boys 18.2% vs girls 22.2%; p=0.224, and 3.4% vs 5.4%; p=0.692). High level (4 or 5 on a 5 point scale) of stress symptoms were less common in boys (16.0% vs 28.2%; p=0.015), as

was possible or probable anxiety (17.1% vs 44.4%; p<0.001), but not depression (10.3% vs 12.5%; p=0.764). Students with high level of stress reported CWP five times more often than those with less stress (30.4% vs 5.8%; p=0.001). Students with probable anxiety reported CWP ten times more often than students with no anxiety (17.6% vs 1.8%; p=0.001), and CWP was also more common, but not statistically significant, in students with probable depression (20.0% vs 3.1%; p=0.163). Those reporting CWP had significantly lower HRQL (0.58 vs 0.87; p=0.038) than students with no chronic pain.

Conclusion: The high prevalence of chronic pain and the strong associations between CWP and reports of stress and anxiety in adolescents highlights that a multifactorial background to chronic pain must be considered early in life. An apparent lower score in EQ5D also indicates that the presence of CWP has an marked impact on HRQL also in adolescents.

Session Title: Fibromyalgia: Insights Into Diagnostic Criteria and Symptom Epidemiology

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

In the last decade, interest in fibromyalgia (FM) has increased with the publication of revised diagnostic criteria and clinical guidelines. The 2010 and revised 2011 ACR criteria emphasized the polysymptomatic nature of FM. National FM guidelines (Germany, Canada & Israel) showcased the importance of sustained functionality, multimodal therapy ideally targeting the primary symptom/s and cautioned the likely modest effect for most drug treatments. Whether recommendations influenced clinical care remains speculative. We examined the profile and clinical care of FM Canadian patients in two time periods to assess the effect of this paradigm change.

Methods:

FM patients followed prospectively at a Montreal university based tertiary care pain clinic from 2005 to 2013 were recruited. Disease severity was measured with pain visual analog scale (VAS), patient global assessment (PGA), McGill Pain Questionnaire (MPQ), Pain Disability Index (PDI), Pain Catastrophizing Scale (PCS), Fibromyalgia Impact Questionnaire (FIQ), Health Assessment Questionnaire (HAQ) and Arthritis Impact Measurement Scales (AIMS) the latter including anxiety and depression subscales. Differences between enrolment period groups (2005-08 vs 2009-13) were assessed for statistical significance with the chi-square test for categorical variables and the independent-samples t-test for continuous variables.

Results:

Table 1 presents the profile of 248 FM patients stratified by enrolment period: 147 patients in 2005-08 and 101 patients in 2009-13. The mean ± SD age of patients was 47.9 ± 10.3 years (2005-08 vs 2009-13: 49.3 ± 9.71 vs 45.9 ± 10.94; p=0.012). The majority (91.1%) of patients were female (p=0.179). Mean ± SD disease duration was 10.8 ± 9.80 years (p=0.851). Significant between-group differences (2005-08 vs 2009-13) of mean ± SD scores were observed for PDI (36.1 ± 15.10 vs 40.0 ± 13.21; p=0.036), FIQ (65.1 ± 18.24 vs 69.8 ± 14.18; p=0.029) and AIMS depression (5.1 ± 1.64 vs 4.5 ± 2.05; p=0.005). Statistical trends were observed in regard to medication use: 2005-08 patients used more analgesics (24.5% vs 15.8%; p=0.114) and NSAIDs (26.5% vs 17.8%, p=0.126) but less antiepileptics (27.9% vs 38.6%, p=0.097). Exercise activity was more prevalent among 2009-13 patients (23.8% vs 39.6%; p=0.011). The 2009-13 group had lower disability rates (39.5% vs 18.8%; p=0.001), higher employment rates in manual and service areas (37.2% vs 16.3%) and lower rates in health care or educational areas (31.9% vs 58.1%) (p<0.001).

Conclusion: FM patient profile changes in the past decade may have been informed by recent guidelines. Despite similar pain durations at presentation and generally greater symptom severity, FM management has trended away from traditional analgesic medication use. Maintained

function with more patients employed and participating in exercise activity reflects the evolving concept of FM care.

Table 1 Clinical Features of FM Patients According to Enrolment Period

Parameter	Enrolment Period		P-value	Total
	2005 - 2008	2009 - 2013		
Age, years, mean ± SD	49.3 ± 9.71	45.9 ± 10.94	**0.012**	47.9 ± 10.3

Session Title: Health Services Research I: Digital Health and Patient, Provider Factors in Rheumatic Disease

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Systemic lupus erythematosus (SLE) can be difficult to study given the relatively low prevalence of the disease. While we are now collecting a multitude of data in the electronic health record (EHR) that can be used to answer important research questions, there are no validated algorithms for SLE case-identification. In this study, we aimed to establish an algorithm to identify individuals with SLE from an EHR. We compared algorithms using structured terminologies for SLE with those based on novel machine learning (ML) algorithms that are capable of analyzing clinical free text in conjunction with structured data.

Methods: We created a data repository of "possible SLE" by extracting structured EHR data and clinical notes for patients who either had a relevant ICD-9 code OR positive dsDNA or Smith antibodies OR a mention of "SLE" or "lupus" in the text of clinical notes. We identified 18,357 individuals meeting this criteria, and selected 300 patients for review: 150 randomly and 150 enriched for positive serologies (to capture enough true SLE for ML). Via chart review performed by domain experts, we identified definite SLE cases as patients with ≥4 documented American College of Rheumatology (ACR) criteria. Next, we calculated the test characteristics for various definitions of SLE using only structured data. Finally, we compared this to a series of supervised ML algorithms based on support vector machines (SVMs) which used text features extracted from clinical notes in addition to structured fields. All SVM algorithms were trained and validated using 10-fold cross-validation.

Results: 121 of 300 patients reviewed met ACR criteria for SLE. The test characteristics of both the structured and supervised ML algorithms are shown in the Table. While a single ICD-9 code for 710.0 was near 100% sensitive for a diagnosis of SLE, additional criteria including a SLE-related medication and any positive serology increased the specificity with minimal loss in sensitivity (94%). ML algorithms slightly outperformed traditional definitions. The text features extracted from clinical notes that were strong predictors of SLE are graphically represented in the Figure.

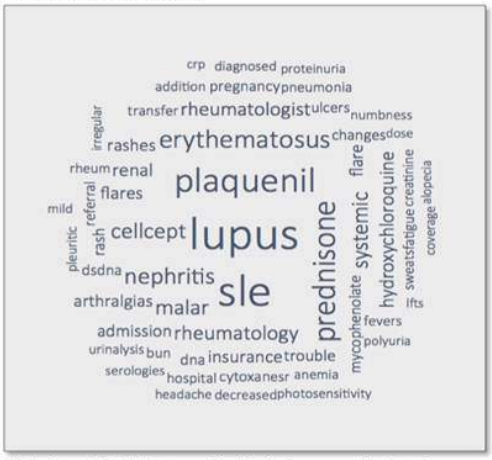
Conclusion: In an EHR-based data repository, a single ICD-9 710.0 was highly sensitive for SLE. ML algorithms processed a multitude of structured and unstructured EHR data, allowing increased specificity with minimal loss in sensitivity. These findings should be validated in other cohorts to lay the foundation for multi-institutional lupus research and creation of large national registries.

Table. Performance of traditional structured definitions and supervised machine learning algorithms in case identification of SLE in the electronic health record.

Structured Definitions				Supervised Machine Learning			
	Recall (Sensitivity)	Specificity	Precision (PPV)		Recall (Sensitivity)	Specificity	Precision (PPV)
Single ICD-9 710.0	1.00	0.72	0.71	All ICD-9 codes and counts[1]	1.00	0.72	0.71
Single ICD-9 710.0 + any lupus medication	0.97	0.80	0.77	All ICD-9 codes and counts + clinical notes[2]	0.98	0.76	0.74
Single ICD-9 710.0 + any lupus medication + any positive lupus serology	0.94	0.82	0.78	All ICD-9 codes and counts + clinical notes + all serologic data[3] + all medication data	0.99	0.84	0.78
				All ICD-9 codes and counts + clinical notes + all serologic data + all medication data + demographics[4]	0.90	0.94	0.82

[1]Supervised machine learning (ML) algorithms included all available ICD-9 codes for patients as well as counts and locations in the medical record in which they were found (clinical encounters, problem lists, medication orders, etc.).
[2]All free text data from clinical notes associated with a patient's medical record were included in the ML algorithm.
[3]Serologic data included ANA and antibodies to dsDNA, Smith, RNP, SSA and SSB.
[4]Demographic information included age, gender, race/ethnicity, insurance status, and employment status.

Figure. Word cloud of text data-elements that predict of a diagnosis of lupus in clinical notes extracted from the electronic health record.



*Text elements listed above were identified using our machine learning algorithms with the addition of penalization to restrict the predictor set so that it included only the most relevant text features. Size is directly proportional to weights identified by these algorithms.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Health Services Research I: Digital Health and Patient, Provider Factors in Rheumatic Disease
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: SLE patients face many challenges due to lupus, including pain, fatigue, managing medications and appointments, and emotional impact. Patients employ various strategies to manage these challenges. mHealth offers the opportunity to improve self-management and self-efficacy and could prove effective in helping SLE patients manage their disease. Patient input is critical to the development of an SLE-specific mHealth tool; our aim was to explore patient preferences and interest related to development of an mHealth app for SLE patients.

Methods: Subjects ≥15 years old who met ACR SLE criteria were recruited from a diverse patient population at a large, urban SLE referral center. A standardized focus group methodology was developed by an expert panel of rheumatologists and social workers. Focus group sessions, moderated by clinical social workers trained in this methodology, were audio recorded, transcribed, and analyzed using NVivo in an iterative process to develop thematic categories. Questions explored challenges due to SLE, current coping strategies, how an SLE app could help with disease self-management, app format and design, and priorities for app content.

Results: 57 subjects participated in 8 focus groups. Participants were mostly female (84%), well-educated (68% had at least some college education), and 46% self-identified as belonging to a minority group. Mean SLEDAI was 3.7 (range 0-10) and mean SLICC-DI was 1.3 (range 0-7). Subjects identified physical manifestations (pain, fatigue, hair loss, change in weight), emotional/psychological issues (stress, frustration, unpredictability of disease, depression), and medications (adherence issues, pill burden) as current challenges in managing lupus; scheduling, exercise, sleep, relaxation, and social networking helped to manage those challenges. Regarding how the app could help, six key themes emerged

(Table): 1) track symptoms, 2) manage medications, 3) manage appointments, 4) communicate with providers, 5) nutrition and exercise tips, and 6) manage emotional/psychological issues. Ease of use, simplicity, and customizability were deemed critical to uptake of the app; finger pain, Raynaud's, denial/avoidance of illness, and technological complexity were identified as potential deterrents to use. 98% of participants said they would use an app to help manage lupus.

Conclusion: Participants were overwhelmingly interested in an mHeatlh app designed to help manage SLE and identified challenges an app could help them manage. These patient-generated themes can be used in platform development and assessment of a lupus-specific mHealth app.

How an App Can Help: Emerging Themes	Selected Illustrative Quotes
1. Track symptoms	[You could record] symptoms for the day, because sometimes when I go to the doctor I don't remember certain symptoms I had during the month and if I have a place to write that down, like how I was feeling certain days, I think it would help.
2. Manage medications	It would be great if you could put in your meds and your doses and time of day and it alerted you like, "Okay, it's time to take something." And then also… we'd get to the doctor and they say, "What have you been taking?" It's like, there.
3. Manage appointments	There are many different aspects of planning…The appointment reminder might be two days before the appointment, because I find that if I don't write it down, I will forget… I need time to process a day or two before.
4. Communicate with providers	Sometimes when we're at the appointment, we sometimes forget what was wrong at that moment, so when [the doctors] ask us a question, we're just like, "Oh, no, no, everything is fine…" and then you leave and remember, "Ok, I should have said this and I should have said that!"
5. Nutrition and exercise recommendations	So…we see what we're getting in terms of diet and what we're eating, how it affects the symptoms, that could be helpful, and it would help everybody.
6. Resources to manage emotional/psychological issues	The initial diagnosis can be very traumatic and I think if you have an app that can guide you through processing those emotions as well as learning how to accept help and communicating effectively what the illness does to you, I think it would be a helpful app.

Session Date: Sunday, November 8, 2015

Session Title: Health Services Research I: Digital Health and Patient, Provider Factors in Rheumatic Disease

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Prior research has shown that persons with SLE in poverty have fewer physician visits for SLE and receive lower technical quality of care. The current study evaluates the impact of poverty at baseline on longitudinal change in SLE outcomes, including disease activity, accumulated damage, and overall physical health.

Methods: We analyzed data from the UCSF Lupus Outcomes Study, a national sample of persons with SLE interviewed annually using a structured telephone survey. The annual survey collects data to assess whether individuals are ≤ 125% of the Federal poverty level (POV) as well as validated self-reported batteries of disease activity, the Systemic Lupus Activity Questionnaire (SLAQ); accumulated damage, the Brief Index of Lupus Damage (BILD); and the SF36 physical health component (PCS). We used linear regression to analyze the impact of POV in the 2012-2013 LOS annual wave on change in SLAQ, BILD, and PCS between 2012-2013 and 2014-2015. Models were adjusted for age, gender, race/ethnicity, level of educational attainment; disease duration; number of physician visits; kind of health care (public and private managed care or fee-for-service), specialty of physicians for SLE, and quality of care (pass rate of ≥ 85% on technical quality of care indicators vs. not and summary of ratings of interactions with providers and health systems).

Results: 524 persons with SLE responded to the annual LOS interviews in both 2012-2013 and 2014-2015 who had no missing values on variables in analysis; 10 with missing values were omitted from analysis. Mean age was 53.0 ± 12.5 yrs., mean duration was 20.1 ± 8.5 yrs., 36.6% were non-whites, and 12.6% met study definition of POV. In 2012-2013, mean SLAQ was 10.7 ± 7.0; BILD 2.9 ± 2.6; and PCS 39.3 ± 12.1. By 2014-2015, mean change in SLAQ was -0.27 ± 4.21; in BILD was 0.44 ± 0.75; and in PCS was -0.65 ± 7.22. Table 1 shows the unadjusted and adjusted values of the outcome measures by POV and indicates that poverty is associated with increased levels of BILD, but not SLAQ or PCS.

Conclusion: Poverty is associated with an increase in accumulated damage in SLE over two years, an effect only partially explained by sociodemographic and disease characteristics, number of physician visits, and kind, quantity, and quality of health care. Reducing the impact of poverty on damage will require increased attention to factors outside of health care as well as on-going improvements in treatment.

Table 1. Impact of Poverty Status on Change in Disease Activity (SLAQ), Damage (BILD), and Physical Health Status (PCS)

	Change in SLAQ*			Change in BILD**			Change in PCS***		
	Not Poor	Poor	Diff (95% CI)	Not Poor	Poor	Diff (95% CI)	Not Poor	Poor	Diff (95% CI)
Unadjusted	-0.24	-0.50	0.26 (-0.83, 1.36)	0.40	0.73	-0.33 (-0.52,- 0.14)	-0.62	-0.90	0.29 (-1.58, 2.16)
Adjusted‡	-0.98	-1.14	0.16 (-1.05, 1.37)	0.41	0.65	-0.24 (-0.45, -0.04)	0.64	-0. 01	0.65 (-1.40 , 2.70)

* SLAQ scored 0-47, higher scores indicate greater level of disease activity; positive change scores represent more disease activity.

** BILD scored 0-18, higher scores indicate greater level of accumulated damage; positive change scores represent more damage.

*** PCS scored 0-100, higher scores indicate better physical health status; negative change scores represent declining physical health status.

‡ Models adjusted for age, gender, race/ethnicity, educational attainment, disease duration, # MD visits in past year, kind of health care, specialty of SLE physicians, technical quality of care pass rate, and ratings of interactions with health systems and providers.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Health Services Research I: Digital Health and Patient, Provider Factors in Rheumatic Disease

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

Assessment of disease activity is a critical step in the management of patients with juvenile idiopathic arthritis (JIA). The American College of Rheumatology provisional criteria for clinical inactive disease (CID) are a widely accepted measure of disease activity for JIA. The aim of this study is to determine the frequency at which patients are fully assessed for disease activity using the Pediatric Rheumatology Care and Outcomes Improvement Network (PR-COIN) registry and to identify which component of disease activity is most often not evaluated. We also aim to identify patient and institutional factors associated with assessment of CID.

Methods:

Visits between January 2011 and February 2015 were evaluated for assessment of CID. Full assessment of CID was considered to have been performed if all components of CID were completed. (Table 1) The number of visits with full assessment of CID was calculated as a percentage of the total number of visits. The principal investigator of each PR-COIN site completed a survey regarding institutional characteristics. Hierarchical mixed model logistic regression was used to model full assessment of CID using patient and institutional factors.

Results:

There were 11,249 patient visits; 2,261 visits were excluded due to missing data. Assessment of CID occurred at 47% of patient visits. The component of CID most commonly not evaluated was assessment for uveitis. (Figure 1) Male gender, a positive ANA, and younger age were associated with full assessment of CID. Patients with systemic JIA, RF+ polyarticular JIA, and enthesitis related arthritis were more likely to have been fully assessed for CID. Having a full time coordinator was associated with better performance than having no coordinator. (Table 2)

Conclusion:

Evaluation of CID in patients with JIA does not occur consistently. Assessment for uveitis drives this low performance rate. While younger patients and patients with a positive ANA were more likely to be fully assessed, patients with JIA subtypes at highest risk for uveitis were the least likely to have been assessed for CID and to have had appropriate uveitis screening.

Table 1. Quality Measures Used to Determine Performance of Assessment of CID
1. A full joint count should be done at every visit.
2. A Physician's Global Assessment (PGA) of disease activity should be done at every visit.
3. Either the American Academy of Pediatrics (AAP) or modified Heiligenhaus guidelines for eye examinations should be followed for patients with any category of JIA. Documentation of compliance with the guidelines should be performed at every visit at least 3 months apart.
4. Duration of morning stiffness should be assessed at every visit.
5. The presence of active systemic arthritis features should be assessed at every visit for patients with systemic JIA.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Health Services Research I: Digital Health and Patient, Provider Factors in Rheumatic Disease

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Physicians often encounter patients who are treated with immunosuppressive agents and must consider the risk of infection that the medications may pose. We explored physician perceptions of the infectious risk of commonly used immunosuppressive therapies, hypothesizing that they vary by specialty and level of experience.

Methods: All physicians in seven departments at a single tertiary care institution were asked to complete a web-based survey. Data regarding medical specialty, level of experience, years of experience post medical school, frequency of prescribing immunosuppressant medications, and comfort level with issues related to immunosuppressant medications were collected. Respondents were asked to rate medications from 0 to 100 on their perception of the one-year risk of infection attributable to that medication if used as monotherapy. To facilitate comparisons, scores were divided into three groups, with 0 to 33 labeled low risk, 34 to 66 medium risk, and 67 to 100 high risk. Experienced physicians were defined as those with five years of experience post medical school who also reported that they prescribed immunosuppressant medications sometimes or frequently.

Results: The survey was distributed to 634 physicians; 197 physicians completed the survey. There was a significant difference in the median rating between specialties for 8 of 15 medications (Table 1). Compared to less experienced providers, the experienced providers (n=43) generally rated hydroxychloroquine, dapsone, and anti-TNF therapy lower in terms of infection risk (Figure 1). In contrast, 66% of experienced physicians compared to 52% of less experienced physicians rated prednisone 10-20 mg as medium or high risk. The majority of less experienced physicians (55%) identified anti-TNF therapy as high risk, while experienced physician perceptions were split nearly evenly among low (32%), medium (32%), and high risk (37%).

Conclusion: There is wide variability in physician perception of the infectious risk of many immunosuppressive medications by specialty and level of experience. Among experienced physicians who prescribe these agents, level of concern about commonly used therapies such as anti-TNF therapy range broadly. Less experienced physicians may perceive a lower risk of intermediate doses of prednisone and a higher risk of dapsone and hydroxychloroquine compared to more experienced physicians. Resources to better define and communicate the risks of immunosuppressive medications would facilitate better care of patients who require these drugs.

Table 1: Physician Reported Median Scores of Risk of Infection Using a 0 to 100 Visual Analogue Scale

	Derm n=41	EM n=25	FM n=11	ID n=19	IM (O) n=19	IM (I) n=60	Rheum n=22	p value*
Prednisone < 10mg	22	15	16	16	15	18	18	0.91
Prednisone 10-20mg	40	20	44	38	29	35	40	0.53

Patient and Provider Factors in Optimal Gout Management

Brian Coburn[1], Kayli Bendlin[2], Harlan Sayles[1] and Ted R. Mikuls[1], [1]Omaha VA Medical Center and University of Nebraska Medical Center, Omaha, NE, [2]Pharmacy Service, Veterans Affairs Nebraska-Western Iowa Health Care System, Omaha, NE

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Health Services Research I: Digital Health and Patient, Provider Factors in Rheumatic Disease

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

Gout is the most common inflammatory arthritis worldwide. Despite its prevalence and the availability of effective therapies, studies have consistently characterized gout quality of care to be suboptimal. Suboptimal care has largely been defined by adverse events or gaps in care while few studies have identified factors to optimize gout care. The objective of this study was to develop a model of modifiable patient and provider factors associated with a well-accepted treatment target in gout, achievement of a serum urate (SU) < 6.0 mg/dL.

Methods:

For this cross-sectional study, we sent a questionnaire to 1437 gout patients receiving an allopurinol prescription during a 1-year period. Of these, 886 (62%) responded and 612 were included for the primary analysis after exclusions. Questionnaire data was linked to medical and pharmacy records. We hypothesized that five patient/provider factors would be associated with SU goal attainment < 6.0 mg/dL. The Patient Activation Measure (PAM^{TM}) was used to measure, on a 0-100 scale, the patient's knowledge, skills and confidence to engage in their own care. The proportion of days covered (PDC) was used to determine allopurinol adherence with a PDC ≥ 0.8 considered adherent. For providers, we considered dose escalation of allopurinol, anti-inflammatory prophylaxis during allopurinol initiation and low starting dose of allopurinol (≤ 100 mg/dL). Logistic regression was used to model both medication adherence and SU goal attainment. The Akaike Information Criterion (AIC) was used to determine the best model, with lower AIC values indicative of improved model performance.

Results:

Gout participants were older (mean age 72 ± 11 years), primarily Caucasian (89%) and men (98%). A vast majority (73%) were adherent to allopurinol over one year of observation. Factors associated with nonadherence in adjusted analysis were older age (p<0.001), higher BMI (p =0.007) and thiazide use (p=0.037). Considering SU goal, medication adherence (OR 2.06), a low allopurinol starting dose (OR 0.23), and dose escalation (OR 2.58) were each independently associated with attainment (Table). Importantly, a rheumatologist as the initial prescriber (OR

3.88) was associated with SU goal attainment whereas the PAM score was marginally associated and produced a lower AIC for the model.

Conclusion:

SU goal attainment with the use of allopurinol appears to be largely driven by factors related to medication dosing, such as low starting dose or dose escalation, and medication adherence. While higher patient activation did trend toward greater SU goal attainment in this study and improved model performance, it did not reach statistical significance in adjusted analyses. This study suggests that initial efforts to improve outcomes would benefit most from focus on proper dosing practices and medication adherence before addressing patient activation more broadly.

Table Multivariable Associations with Serum Urate Goal Attainment

	Coefficient (95% CI)	P
Patient Factors		
Adherence, PDC ≥ 0.8	2.06 (1.32 to 3.23)	0.002
PAM, 0 to 100 scale	1.02 (1.00 to 1.04)	0.09
Provider Factors		
Low Starting Dose	0.23 (0.14 to 0.37)	<0.001
Dose Escalation	2.58 (1.53 to 4.33)	<0.001
Anti-inflammatory Prophylaxis†	-	-
Other Factors		
GFR, mL/min/1.73 m^2	1.02 (1.01 to 1.03)	<0.001
Rheumatologist as Initial Prescriber	3.88 (1.40 to 10.7)	0.009

* Models were determined by the Akaike Information Criterion (AIC). † Anti-inflammatory prophylaxis was the only hypothesized provider factor excluded by the AIC. Proportion of days covered (PDC); serum urate (SU); confidence interval (CI); Patient Activation Measure (PAM); body mass index (BMI); glomerular filtration rate (GFR).

Musculoskeletal Ultrasound (MSK-US): Innovation or Overutilization?

Gurjit S. Kaeley[1], Dale Kraemer[2], Carmen Smotherman[3] and Sunita Dodani[4], [1]Rheumatology, University of Florida College of Medicine, Jacksonville, Jacksonville, FL, [2]Center for Health Equity and Quality Research, Department of Neurology, University of Florida College of Medicine, Jacksonville, Jacksonville, FL, [3]Center for Health Equity and Quality Research,, University of Florida College of Medicine, Jacksonville, Jacksonville, FL, [4]Cardiology and Epidemiology, University of Florida College of Medicine, Jacksonville, Jacksonville, FL

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Imaging of Rheumatic Diseases I: Ultrasound

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

MSK-US use has risen in the USA with recent disturbing findings suggesting greater utilization of interventional ultrasound by non-noradiologists compared to Radiologists. (1) This study evaluated utilization of diagnostic and interventional MSK-US within the Medicare population in the USA from 2011 – 2013. Our objectives were to estimate the rate of MSK-US utilization by MSK specialties, compare the cumulative growth of services and payments as well as determine time trends of utilization within the study period.

Methods:

A retrospective cross-sectional analysis of Medicare Physician Supplier Payment Summary (PSPS) files from 2011 – 2013 was used to tabulate services and total payments on utilization. PSPS data is aggregated by multiple factors but excludes technical costs such as those billed by Radiology. Therefore, service count data more accurately reflects utilization across specialties. CPT 76881, 76882; and 76942 were coded as diagnostic ultrasound and interventional ultrasound respectively. Non-duplicative billing claims of these codes were summed for each years and provider specialty. Descriptive and statistical (ANOVA) analysis was conducted using SAS® for Windows Ver. 9.4.

Results:

There was greater utilization of interventional than diagnostic ultrasound among all MSK providers except Podiatry. (Table, Fig) Amongst non-radiology groups, a cumulative growth of up to 205% and 273% was seen in interventional and diagnostic ultrasound respectively, while there was a decrease in Radiology interventional services. Orthopedics and Rheumatology had higher mean number of services and payments compared to all other non-radiology specialties ($p<0.05$). (Fig)

Conclusion:

Marked dissociation of interventional MSK-US services from diagnostic services was seen in most MSK specialties. Orthopedics ranked highest for MSK-US interventional services. Lack of corresponding diagnostic billing could be due to bundling of diagnostic services or inability to acquire and bill diagnostic ultrasound. Although the rapid rise of utilization of interventional MSK-US could reflect innovation in care, it is not clear if addition of MSK-US ultrasound guidance on a population level leads to better value care. Medicare reimbursement of interventional MSK-US procedures has been reduced which may lead to a better value proposition and moderated utilization.

Session Date: Sunday, November 8, 2015

Session Title: Imaging of Rheumatic Diseases I: Ultrasound

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: No consensus exists regarding which joints and tendons should be systematically assessed by ultrasonography (US) to assess inflammation in rheumatoid arthritis (RA). Validity and responsiveness must be weighted against feasibility. Our group has previously developed and validated a US joint inflammation score (Aga et al, Ann Rheum Dis 2015). The objective of this study was to optimize the score in terms of sensitivity to change and feasibility, and to perform comparative analyses versus formerly proposed US scores in a longitudinal study.

Methods: DMARD-naïve early RA patients (pts) with <2 yrs symptom duration fulfilling the 2010 ACR/EULAR classification criteria were recruited between Sept 2010 and April 2013 and started on methotrexate. Extensive US examination were performed by experienced sonographers at baseline (BL) and after 3 and 6 months, using a validated grey-scale (GSUS) and power Doppler (PDUS) semi-quantitative scoring system with scores 0-3 for GSUS and PDUS in each of the following 36 joints and 4 tendons: MCP1-5, PIP2-3, radiocarpal, distal radioulnar, intercarpal, elbow, knee, talocrural, MTP1-5, extensor carpi ulnaris and tibialis posterior (TP) tendons, bilaterally. An US atlas was used as reference (Hammer et al, Ann Rheum Dis 2011). We performed principal component factor analyses (PCA) of GSUS and PDUS changes from BL to 3 months (ΔGSUS and ΔPDUS) to identify joint groups with high internal correlation. Based on these analyses we identified several joints/tendons candidate sets to be further tested. Standardised response means (SRMs) with 95% CI (bootstrapping) were estimated at 3 and 6 months for the candidate sets and formerly proposed scores.

Results: 117 early RA pts were included; 81.2% anti-CCP pos, mean(SD) age 50.3 (13.3) yrs, median(IQR) disease duration (from onset of swollen joint) 5 (3-9) months, mean(95% CI) 36-joint GSUS score 23(21-25) and PDUS score 11(10-12). Based on the PCA 12 groups of joint/tendons were identified (Table 1). Elbow, TP-tendon and MTP1 came out as separate factors, but were omitted from the scores due to low SRMs. Table 2 shows the 3- and 6-month SRMs for the previously published candidate sets (A, B), one of the new candidate sets (C) and the formerly proposed scores.

Conclusion: We used a data-driven approach to further develop an ultrasound joint inflammation score in RA. We propose a novel candidate set of joints/tendons with improved sensitivity to change, which is feasible, and performed numerically better than formerly proposed scores. Our results show that a reduced US assessment may efficiently contribute to disease assessment in RA.

Table 1: Joint/tendon groups identified by principal component factor analyses of ΔGSUS and ΔPDUS scores after 3 months with methotrexate treatment in early RA

Group 1	Group 2	Group 3	Group 4	Group 5	Group 6	Group 7	Group 8	Group 9	Group 10	Group 11	Group 12
Radiocarpal*	MCP3*	MTP2*	Elbow	MCP2*	MCP1*	MTP3*	TP-t	ECU-t*	PIP2*	PIP3*	MTP1
Intercarpal	MCP4					MTP4					
DRUJ	MCP5					MTP5					

DRUJ = distal radioulnar joint; MTP = metatarsophalangeal; MCP = metacarpophalangeal; PIP = proximal interphalangeal joints; TP-t = tibialis posterior tendon; ECU-t = extensor carpi ulnaris tendon. *Joints/tendon included in the new candidate set C

Table 2: 3- and 6- month standardised response means (SRMs) for candidate set A, B, C and formerly proposed ultrasound joint scores for RA

GSUS	**SRM*(95%CI) 3 months**	**SRM*(95%CI) 6 months**
12-joint score Naredo[1]	- 1.01 (- 1.17 to - 0.84)	- 0.92 (- 1.08 to - 0.76)

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Imaging of Rheumatic Diseases I: Ultrasound

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: enthesitis is one of the main hallmarks of Spondyloarthritis (SpA), being heel entheses frequently involved. Different imaging modalities, such as conventional radiography (CR), ultrasound (US) and magnetic resonance imaging (MRI) are commonly used for the detection of enthesopathy. The aim was to determine the agreement between US, CR and MRI for the detection of enthesopathy in SpA.

Methods: forty patients with a diagnosis of SpA (axial or peripheral ASAS criteria) were included. All patients underwent all imaging modalities in the same day, in order to assess bilaterally both Achilles tendon and plantar fascia insertions into the calcaneous bone.

US examinations were performed using a MyLab 60 machine (6-18 MHz multifrequency broad band linear transducer). The following US findings indicative of enthesopathy were dichotomously assessed: thickening, structural changes (hypoechoic areas with loss of the typical "fibrillar" echotexture), bursitis, abnormal vascularization by power Doppler (PD), bone erosions and enthesophytes.

MRI were performed with a Signa HDe 1.5 Tesla machine (General Electric) and read by a radiologist. The following MRI findings indicative of enthesopathy were dichotomously assessed: thickening, signal intensity changes of the entheses (structural changes), adjacent bone marrow edema, bursitis, bone erosions and enthesophytes.

CR were read by a rheumatologist in order to assess the presence of bone erosions and/or enthesophytes.

Both rheumatologists and the radiologist were blinded to clinical and to the others imaging data.

Results: a total of 160 heel entheses were examined. At least one sign indicative of enthesopathy was found in 68.1% (109/160), 65.6% (105/160) and 26.9% (43/160) entheses with MRI, US and CR, respectively. Tables 1 and 2 show a detailed description about the agreement between US and MRI and between CR, US and MRI, respectively. Among non-comparable findings, US detected abnormal vascularization by PD in 57 out of 160 (35,6%) entheses while MRI revealed adjacent bone marrow edema in 36 out of 160 (22,5%) entheses.

Table1. Agreement between US and MRI, unweighted kappa (k) values (95% coefficient interval) and absolute agreement (%).

Thickenning		**US**		
		absence	presence	
MRI	absence	108	4	**k= 0.80**
	presence	9	39	**(0.69-0.90),**
				(91,8%)
Structural changes		**US**		
		absence	presence	
MRI	absence	123	7	**k= 0.66**
	presence	9	21	**(0.51-0.81),**
				(90%)
Bursitis		**US**		
		absence	presence	
MRI	absence	66	0	**k= 0.68**
	presence	6	8	**(0.45-0.91),**
				(92,5%)
Bone erosions		**US**		
		absence	presence	**k= 0.69**
MRI	absence	103	10	**(0.57-0.82),**
	presence	10	37	**(87,5%)**
Enthesophytes		**US**		
		absence	presence	
MRI	absencee	96	10	**k= 0.70**
	presence	11	43	**(0.58-0.82),**
				(86,9%)

Table 2. Agreement between CR with US and MRI, unweighted kappa (k) values (95% coefficient interval) and absolute agreement (%).

Bone erosions		CR		
		absence	presence	
US	absence	104	9	**k= 0.45**
	presence	24	23	**(0.29-0.60),**
				(79,5%)
Enthesophytes		**CR**		
		absence	presence	**k= 0.78**
US	absence	102	4	
	presence	11	43	**(0.68-0.88),**
				(90,6%)
Bone erosions		**CR**		
		absence	presence	
MRI	absence	102	11	**k= 0.38**
	presence	26	21	**(0.22-0.54),**
				(76,9%)
Enthesophytes		**CR**		
		absence	presence	**k= 0.76**
MRI	absence	102	5	
	presence	11	42	**(0.66-0.87),**
				(91,2%)

Conclusion: a good agreement between US and MRI was found for all abnormal comparable findings at heel entheses in SpA patients. Agreement was also good between the three imaging modalities concerning detection of enthesophytes, with a lower agreement in the recognition of bone erosions.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Imaging of Rheumatic Diseases I: Ultrasound

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Ultrasound is more sensitive than conventional radiographs in detecting small osteophytes in hand osteoarthritis (OA). Osteophytes can be seen prior to joint space narrowing (JSN), may be an early risk factor for OA progression, and is associated with pain. However, previous studies on the predictive value of osteophytes on disease progression is limited in numbers, have shown inconsistent results, and none of these have included ultrasound.

We believe that ultrasound can be used to detect OA at an earlier stage than conventional radiographs. Hence, the aim of this longitudinal study was to examine whether ultrasound-detected osteophytes in joints with concurrent normal radiographs at baseline could predict incident radiographic hand OA five years later.

Methods: We included 78 participants (71 women, mean (SD) age 67.8 (5.2) years) from the Oslo Hand OA cohort. The presence of ultrasound-detected osteophytes was examined at baseline by two sonographers in collaboration. In the present analysis we included the joints most likely to develop OA (the first carpometacarpal joint and the interphalangeal joints bilaterally). One reader scored the radiographs with known time sequence according to the Kellgren-Lawrence (KL) scale and the Osteoarthritis Research Society International (OARSI) atlas for osteophytes and JSN.

Associations between baseline ultrasound-detected osteophytes (independent variable) and incident radiographic OA features (dependent variables) were explored only in joints without radiographic OA at baseline (i.e. KL grade = 0 and no osteophytes or JSN) by use of Generalized Estimating Equations (GEE), expressed as odds ratio (OR) with 95% confidence intervals (CI). Analyses were adjusted for age, sex, body mass index and follow-up time, with significance level 0.05.

Results: Mean (SD) follow-up time was 4.7 (0.4) years. In total 301 joints were assessed as being normal on conventional radiographs at baseline, of which 86 had concurrent osteophytes on ultrasound; most of these were small (score 1 = 79%).

Ultrasound-detected osteophytes at baseline were strong predictors for incident radiographic OA during follow-up (table). N=40 (47%) of the joints with preliminary sonographic osteophytes had developed radiographic OA (i.e. KL score increased from 0) at follow-up, as opposed to only 17% of the joints without baseline osteophytes. The strongest association was seen for incident JSN development (OR=5.3, 95% CI 2.1-13.4).

Conclusion: In the current analysis, we demonstrated that ultrasound-detected osteophytes in joints assessed as normal on radiographs were a strong predictor for development of radiographic OA in the same joint five years later. These results support the use of ultrasound as a promising clinical tool for early detection of hand OA.

Table

Ultrasound-detected osteophytes at baseline as a predictor for development of radiographic osteoarthritis (OA)

Baseline ultrasound osteophytes	Radiographic OA development at follow-up, n (%)*	Odds ratio (95% CI) Crude	Adjusted†
	Global OA (Kellgren-Lawrence)		
Grade 0 (n=215)	37 (17.2)	1.0	1.0
Grade 1-3 (n=86)	40 (46.5)	2.9 (1.6–5.4)	4.1 (2.0–8.1)
	Radiographic joint space narrowing		
Grade 0 (n=215)	9 (4.2)	1.0	1.0
Grade 1-3 (n=86)	15 (17.4)	4.2 (1.8–10.2)	5.3 (2.1–13.4)
	Radiographic osteophytes		
Grade 0 (n=215)	28 (13.0)	1.0	1.0
Grade 1-3 (n=86)	31 (36.0)	2.9 (1.6–5.4)	4.2 (2.1–8.5)

Generalized Estimating Equations presented as odds ratios for new OA features at follow-up with separate models for each radiographic feature. CI=confidence interval. *Number and percentage of joints with/without incident OA. †Adjusted for age, sex, body mass index, follow-up time.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Imaging of Rheumatic Diseases I: Ultrasound

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: In a preliminary study on 10 patients with active rheumatoid arthritis (RA) we showed for the first time that Power

Doppler ultrasonography (PDUS) signal of metacarpophalangeal (MCP) joints has a clear diurnal variation. To test whether PDUS signal of MCP joints in RA patients actually varies according to the time of day, we undertook a larger study involving 50 patients with active RA

Methods: A total of 500 MCP joints from 50 patients with active RA were evaluated at three different times during the same day T1: between 7 and 10 a.m.; T2: 4-6 hours after T1; T3: 4-6 hours after T2. All joints were evaluated for both presence/absence of PDUS signal and according to a semiquantitative score (from 0 to 3). The results at T1, T2 and T3 were compared for each joint. The day of examination, factors that could potentially influence PDUS signal were avoided or controlled (smoke, alcohol, corticosteroids, NSAIDs, vasoactive drugs intake, room temperature, hand position). Within-patient PDUS score variation was quantified as the sum of the differences between PDUS scores in each joint at the three different examinations for each patient. Semiquantitive PDUS scores were compared with Friedman's test. Categorical data (PDUS presence/absence) were compared with Cochran's Q test

Results: Globally, 46 out of 50 patients (92%; CI : 84.48% to 99.52%) displayed some circadian variation of PDUS signal. There was a significant variation in the number of PDUS-positive MCP joints during the day ($p<0.05$), with more PDUS positive MCP joints at T0 (156) vs. T1 (144) and T2 (129) ($p<0.05$). Fifteen patients (30%; 95CI 17.3% to 42.7%) had at least one joint in which PDUS signal appeared or disappeared at different. Semiquantitative PDUS scores were significantly higher at T1 ($p<0.05$ vs. T2 and T3) with a subsequent reduction at T2 ($p<0,05$ vs. T1 and T3) and further reduction at T3 ($p<0,05$ vs. T1 and T2). This pattern of variation was not univocal and single patients and even single joints in the same patient could show higher scores at T2 or, more rarely, at T3. Median within-patient PDUS score variation was 4 (range 0 to 34). Patients with higher than the median PDUS variation had higher DAS28 ($p<0.05$), but no higher CRP vs. those with lower variation. Within-patient variation was moderately correlated with DAS28 ($r=0.4$, $p=0.01$) but not with CRP

Conclusion: PDUS signal varies significantly through the day, being higher in the morning and progressively lowering in early afternoon and evening. PDUS signal variation involved about 90% of patients, independent of disease activity. Patients with higher disease activity displayed greater variation of PDUS signal

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Imaging of Rheumatic Diseases I: Ultrasound

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Temporomandibular joint (TMJ) arthritis is a common yet widely under recognized feature of Juvenile Idiopathic Arthritis (JIA). It is often clinically silent and difficult to diagnose without the use of Magnetic Resonance Imaging (MRI). The primary objective of this study was to describe the TMJ as seen on ultrasound (US) and determine the ability to detect arthritic changes as a means to develop a rapid, bedside screening tool to aid rheumatologists in the early diagnosis of TMJ arthritis.

Methods: Subjects were recruited from the Children's Hospital of Wisconsin. The control group consisted of healthy volunteers presenting to the dermatology clinic for routine care of non-rheumatologic conditions. The study group was composed of children and adolescents with a prior diagnosis of JIA seen at the rheumatology clinic for ongoing care. US was performed in both clinics by the same pediatric rheumatologist trained in musculoskeletal ultrasonography. Images were reviewed for pathology at a later date by the ultrasonographer and a blinded radiologist. JIA patients had their TMJs examined by their primary rheumatologist with their subtype of JIA, active and previously affected joints, and history of TMJ symptoms blinded to the ultrasonographer. The dermatology patients had their TMJs examined by the ultrasonographer after the completion of the ultrasound study. All subjects filled out a questionnaire about TMJ symptoms at the completion of the study with the results blinded to the study staff until after ultrasound studies were assessed.

Results:

Full evaluations were performed on 40 subjects (80 TMJs) including 20 JIA patients and 20 healthy controls. 12 females and 8 males were

evaluated in each group with a similar age distribution (range 5-18 years old). The subset of JIA patients evaluated included 2 oligoarticular-persistent, 3 oligoarticular-extended, 4 polyarticular rheumatoid factor (RF) negative, 5 polyarticular RF positive, 1 systemic onset, 4 enthesitis related, and 1 psoriatic arthritis patient. 10 patients had active arthritis at the time of the study in at least 1 non-TMJ joint.

US revealed a small window of the laterosuperior TMJ. In JIA TMJs (N=40), abnormalities visible included erosions (30%) or irregularities (18%) of the bony contour of the mandibular condyle, hyperemia (13%), effusion (5%), and prominent synovium (25%). Doppler signal within the TMJ space correlated to symptoms 80% of the time. 6 patients (30%) with TMJ abnormality on US had active arthritis in a peripheral joint. 10 TMJs (25%) were abnormal on US in 8 asymptomatic patients (40%). 12 TMJs (30%) were abnormal on US in 9 patients with normal TMJ physical exams (45%).

Irregularity in the contour of the condyle was observed in 9 (23%) control TMJs (N=40). An erosion was noted in 1 TMJ (3%). Doppler activity was noted on two control studies (5%) on the lateral portion of the condyle.

Conclusion: Point of care US in the rheumatology clinic has potential use to screen for arthritic changes to the TMJ in JIA patients. Abnormalities to the condyle contour regularly are seen in JIA patients, some of whom are asymptomatic. This is also the first study to demonstrate Doppler signal may be an indicator of active TMJ arthritis.

Session Title: Innate Immunity and Rheumatic Disease

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Monocytes and macrophages are essential to innate immunity but also propagate the inflammatory response in autoimmune arthritis and lupus nephritis. Spontaneous development of inflammatory monocytes ($Ly6C^{hi}$ $CCR2^{+}$) and subsequent differentiation to residential monocytes ($Ly6C^{lo}$ CX_3CR1^{hi}) from murine bone marrow precursor cells is an enigmatic process that involves numerous transcription factors. Understanding the signaling pathways involved in myeloid development could help identify novel treatment targets for inflammatory diseases.

Methods: We developed a murine myeloid progenitor cell line with $CCR2^{RFP}$ CX_3CR1^{GFP} reporters to track monocyte differentiation. Small molecule library screen was used to identify biological pathways involved in monocyte development. Activation of mTOR substrates was measured by intracellular flow cytometry. Key findings were confirmed using pharmacologic inhibition and genetic disruption.

Results: Using a novel progenitor cell line that recapitulates the monocyte development continuum, we identified an essential role of mechanistic target of rapamycin complex 1 (mTORC1) on the generation of inflammatory monocyte through a small molecule library screen. Basal mTORC1 signaling was more prominent in monocytes than other cell subsets in wild-type mice and humanized mice. Inhibition of mTORC1 by rapamycin or disruption of Raptor (an essential component of mTORC1) impaired monocyte development, while deletion of TSC-1 (a negative regulator of mTORC1) accelerated the differentiation into mature macrophages. Correspondingly, Raptor $^{fl/fl}$ UBC-cre/ERT2 mice susceptible to tamoxifen-mediated deletion of Raptor demonstrated a rapid, inducibe depletion of circulating inflammatory monocytes, confirm an essential non-redundant role of mTORC1 in monocyte development *in vivo*. Curiously, Raptor-deficient progenitors in the bone marrow spontaneously differentiated into $Ly6C^{lo}$ CX_3CR1^{low} myeloid cells with characteristics of alternatively-activated macrophages.

Conclusion: Using a combination of *in vitro* and *in vivo* approaches, we identified a previously unrecognized role of mTORC1 in the normal development of inflammatory monocytes. These findings support the potential utility of mTORC1 inhibitors in monocyte- and macrophage-mediated inflammatory diseases.

Session Title: Innate Immunity and Rheumatic Disease

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Interferon Regulatory Factors (IRFs) play fundamental roles in dendritic cell (DC) differentiation and function. In particular IRFs are critical transducers of Toll-like Receptors (TLR) signaling and their dysregulation is associated with the development of autoimmune disorders. While several IRFs are expressed in DCs, their relative contribution to the aberrant phenotypic and functional characteristics that DCs acquire in lupus has not been fully delineated. Mice deficient in DEF6 and SWAP-70 (=Double-knock-out or DKO mice), two members of a unique family of molecules that restrain IRF4 function, spontaneously develop systemic lupus erythematosus (SLE)-like disease in C57BL/6 mice. Although autoimmunity in DKO mice is accompanied by dysregulated IRF4 activity in both T and B cells, SWAP-70 is also known to regulate multiple aspects of DC biology. Here we thus explored whether DEF6 and SWAP-70 regulate IRF4 activity in DCs and investigated the contribution of IRF4 to DC dysfunction in the DKO mouse model.

Methods: $CD11b^+$ and $CD8^+$DCs were analyzed *in vivo* in WT and DKO mice by FACS. We investigated the expression of Blimp-1 and IL-10 in DCs *in vivo* by using a double reporter mouse model of these markers. Bone marrow derived DCs (BMDCs) were generated *in vitro* followed by TLR-4 and TLR-9 activation. BMDC activation markers, cytokine production and gene expression were analyzed by FACS, ELISA and qPCR. CD11c-Cre $IRF4^{fl/fl}$ WT and DKO conditional knock out mice were also generated and analyzed *in vivo* and *in vitro*.

Results: We demonstrated that *in vivo* $CD11b^+$ DCs in DKO mice are expanded and express higher levels of CD86 and PDL2 compared to WT mice. By using a dual reporter mouse model we determined that $CD11b^+$DCs in DKO mice exhibit dysregulated IL-10 production, which is accompanied by aberrant Blimp1 expression in the spleen but not in skin draining lymph nodes. PDL2 expression was also upregulated in IL-10 producing DCs independently of Blimp-1 expression. Similar to our *in vivo* results, BMDCs from DKO mice show higher levels of CD86 and PDL2 compared to WT BMDCs and are hyper-responsive to multiple TLR ligands as assessed by their aberrant IL-10 and IFN-b expression. By using CD11c-Cre $IRF4^{fl/fl}$ WT and DKO mice we also demonstrated that IRF4 plays a differential role in these responses by being required for the TLR4- but not the TLR9-mediated upregulation of IL-10. Finally *in vivo* deletion of IRF4 using the CD11c-Cre transgene led to a decrease in the $CD11b^+$ DC population without any significant effects on the $CD8^+$ DC subset. The lack of IRF4 did not significantly affect the upregulation of PDL2 and CD86 or the abnormal expansion of T_{FH}, Tregs, GC B cells and plasma cells that characterize DKO mice.

Conclusion: We demonstrated that $CD11b^+$ DCs from DKO mice exhibit enhanced expression of Blimp1, PDL2 and dysregulated IL-10 production *in vivo*. Similar to other SLE mouse models, DCs from DKO mice were hyper-responsive to TLR stimulation. Deletion of IRF4 in DKO DCs *in vivo* and *in vitro* revealed that this phenotype is driven by an unexpected degree of molecular heterogeneity whereby lack of IRF4 corrected the TLR4-mediated hyper-responsiveness but exerted no effects on the TLR9-induced dysfunction.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Innate Immunity and Rheumatic Disease
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose:

Aptamers are short single stranded DNA or RNA oligonucleotides that are specifically selected to bind and neutralize a wide range of biomedically relevant proteins. Aptamers are being used in the clinic for the treatment of macular degeneration while eight others are in clinical trials. Aptamers are particularly useful in targeting cell surface and extracellular proteins. We have previously demonstrated that the nuclear chromatin binding protein DEK is actively secreted by human macrophages, serves as a chemoattractant for neutrophils, can be taken up by adjacent cells in a bioactive form, and is abundant in the inflamed synovia of patients with juvenile arthritis (JA). We now demonstrate that targeting DEK with specific anti-DEK aptamers can prevent joint inflammation induced by zymosan.

Methods:

DEK-targeting aptamers were selected from a pool of random-sequence oligonucleotides by SELEX (Systematic Evolution of Ligands by Exponential Enrichment). Two single-stranded DNAs, 40 and 42 nucleotides long with high affinity to DEK were identified. 129/B6 wild type (WT) and DEK null (KO) mice were injected with zymosan through the suprapatellar ligament into the joint cavity to induce inflammatory arthritis. To neutralize DEK, WT mice were additionally injected with either control or DEK-targeting aptamers. Neutrophils were isolated from the blood of healthy human volunteers, synovial fluid of JA patients, or mouse bone marrow. Neutrophil extracellular traps (NETs) were detected *in vivo* and *in vitro* by immunofluorescence with elastase, LL-37, myeloperoxidase (MPO) and DEK antibodies. DEK-targeting aptamers were used to neutralize DEK during *in vitro* induction of NETs.

Results:

DEK KO mice display significantly less joint inflammation than wild-type mice in a zymosan-induced arthritis model (ZIA). Targeting DEK in the joints with specific aptamers significantly reduced joint inflammation induced by zymosan. Indeed, we found a significant reduction in NET formation in joints treated with DEK-targeting aptamers compared to joints treated with control aptamers. Moreover, activation of DEK KO neutrophils demonstrated appreciably reduced NET formation compared to WT neutrophils. Interestingly, NET formation could be rescued in DEK KO neutrophils with the addition of exogenous recombinant DEK. NETs released by synovial neutrophils from JA patients stained prominently for DEK. Similar to the mouse studies, NET release from human neutrophils was drastically abrogated by treatment with DEK-targeting aptamers.

Conclusion:

These results show that the nuclear DNA-binding protein DEK is a major factor in the development of joint inflammation. Specifically, DEK is implicated in the formation of NETs, in addition to its already established role as a leukocyte chemoattractant. These results strongly support the pro-inflammatory function of extracellular DEK, a protein that is crucial to both intracellular and extracellular chromatin structure. Targeting DEK with the newly developed anti-DEK aptamers is a promising therapeutic strategy for the treatment of local and systemic inflammatory conditions such as arthritis.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Innate Immunity and Rheumatic Disease
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Mice bearing mutations affecting *Kit* (stem cell factor receptor) exhibit multiple hematologic phenotypes, including mast cell deficiency, and have been used to assess the role of mast cells in K/BxN arthritis. We observed that arthritis susceptibility in disease-resistant $Kit^{W/Wv}$ mice could be rescued not only by engraftment of cultured mast cells, but also by marrow from mast cell-deficient $Kit^{Wsh/Wsh}$ mice, implicating another lineage in addition to mast cells in the $Kit^{W/Wv}$ phenotype.

Methods: Unirradiated $Kit^{W/Wv}$ were engrafted with bone marrow from mice deficient in key lineages determinants ($GFI^{-/-}$, $IL\text{-}1^{-/-}$, $NF\text{-}E2^{-/-}$, and $GPVI^{-/-}$). 14 days after transfer, arthritis was initiated with i.p. injection of 150µl of serum from K/BxN mice on day 0 and day 2. Arthritis was graded on a 0-12 clinical scale. In other experiments, $Kit^{W/Wv}$ were engrafted i.v. with lineages of interest, including bone marrow neutrophils, platelets, and megakaryocytes (MK), prior to arthritis induction. MK were generated by culturing bone marrow cells with medium supplemented with 1% supernatant from the TPO-producing fibroblast cell line GP122.

Results: Neutrophils transfer failed to restore arthritis in $Kit^{W/Wv}$, yet transfer of marrow from neutrophil-deficient mice $GFI\text{-}1^{-/-}$ restored arthritis as well as WT B6 marrow, confirming that neutropenia is not a critical basis for arthritis resistance in $Kit^{W/Wv}$. Instead, overcoming arthritis resistance in $Kit^{W/Wv}$ required donor marrow expressing IL-1 and the platelet/MK lineage determinants GP-VI and NF-E2 (Figure 1A-B), suggesting that platelet is the lineage that restores arthritis in $Kit^{W/Wv}$. However, $Kit^{W/Wv}$ mice are not thrombocytopenic, and platelet transfer failed to restore arthritis in these mice (Figure 1C). Because $Kit^{W/Wv}$ are megakaryocytopenic, we considered the possibility that restoration of arthritis might be mediated directly by MK. Indeed, we found that MK produce IL-1 rich microparticles capable of stimulating fibroblast-like synoviocytes in manner dependent on IL-1 receptor expression. In confirmation, we found that engraftment of MK relatively incompetent in platelet production could fully restore arthritis susceptibility in $Kit^{W/Wv}$ (Figure 1D).

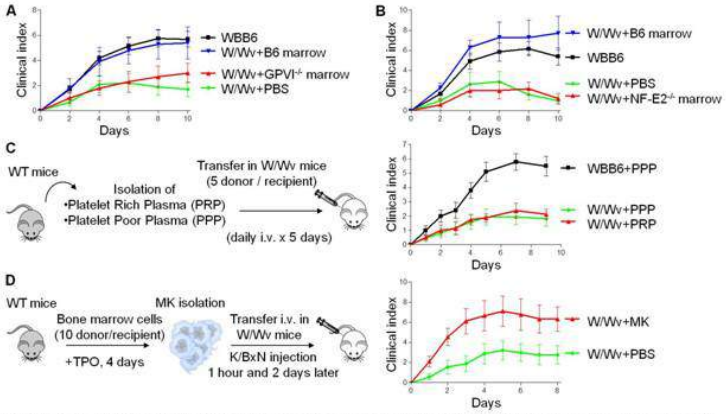

Figure 1. Megakaryocyte restore arthritis susceptibility in W/Wv mice. (A-B) W/Wv mice transferred i.v. with whole bone marrow (1 donor per 2 recipients), or corresponding WBB6 controls, were treated i.p. with K/BxN serum 150ul on days 0 and 2. (A) Clinical score after transfer of GPVI$^{-/-}$ and control B6 marrow. (B) Clinical score after transfer of NF-E2$^{-/-}$ and control B6 marrow. (C) Platelet rich plasma (PRP) and platelet poor plasma (PPP) were purified from B6 donors and transferred into recipient mice i.v. (5 donors/recipient/day on days 0-4) along with K/BxN serum 150μL i.p. on days 0 and 2. (D) W/Wv mice were injected i.v. with PBS or 2x10^5 MK cultured from pooled bone marrow. After 60 minutes, and again on day 2, mice were treated with K/BxN serum 150μL i.p. p=0.0282.

Conclusion: This study identifies megakaryocytes – likely independent of daughter platelets, but potentially mediated by MK microparticles – as a previously unrecognized participant in arthritis, and more generally, as a highly novel actor in IL-1-mediated systemic disease.

Session Title: Innate Immunity and Rheumatic Disease

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: MicroRNAs (miRNAs) have been shown to serve as important regulators for inflammatory and immune responses and are implicated in several immune disorders including gouty arthritis. The expression of miR-146a is upregulated in peripheral blood mononuclear cells in patients with intercritical gout compared to normouricaemic and hyperuricaemic controls and those with acute gout flares. However, the role of miR-146a in gout development remains unknown. Here, we use miR-146a knockout (KO) mice to test miR-146a function in monosodium urate (MSU) -induced gouty arthritis.

Methods: miR-146a KO and WT control mice were injected with MSU suspension into the foot pad (1mg/40ul) or ankle (0.5mg/20ul), respectively to induce the acute gouty arthritis. The bone marrow-derived macrophages (BMDM) were stimulated with 250ug/ml MSU and miR-146a, interleukin 1 beta (IL-1β), tumor necrosis factor-α (TNF-α) and NACHT, LRR and PYD domains-containing protein 3 (NALP3)

inflammasome gene expression were evaluated by qRT-PCR. The TNF-α and IL-1β protein level in BMDM were detected by FACS staining and western blot. Gene and protein levels of TRAF-6 and IRAK-1, the targets of miR-146a, were measured with qRT-PCR and western blot.

Results: MiR-146a expression in BMDM from C57/B6 mice was dramatically upregulated (160-folds compared to unstimulated cells) at 4 hours post MSU crystal stimulation. Significantly increased paw swelling index was observed in miR-146aKO mice compared to WT controls at 6h and 24h after MSU treatment (37.18±6.47% vs 27.03±8.03 at the 6h, $p<0.05$; 61.87±6.50% vs 37.78±3.38% at 24h, $p<0.05$, N=10 for each group). Consistent with increased paw swelling, miR-146aKO mice showed more severe ankle joint swelling compared to WT mice (40.38±2.19% vs 15.14±2.54% at 6h, $P<0.01$; 32.69 ±2.85% vs 24.75±3.96% at 24h and 8.74±3.27% vs 3.36±2.98% at 48h, $p<0.05$, N=10 for each group). The expression of IL-1β, TNF-α and NALP3 inflammatory, including of NALP3, ASC and caspase-1 were upregulated in BMDM after exposed to MSU crystals for 4 hours, compared to wild type mice. Consistent with the gene expression, the IL-1β and TNF-α protein were up-regulated in miR-146aKO mice. Finally, the qRT-PCR and western blot results showed that miR-146a targets, TRAF-6 and IRAK-1, were dramatically upregulated in BMDMs from miR-146 KO mice compared to that from WT.

Conclusion: Collectively, our data suggests that miR-146a provides feedback regulation of gout arthritis development and lack of miR-146a enhances gouty arthritis through upregulating TRAK-6/IRAK-1 and NALP3 inflammsome function (figure 1).

Figure 1. miR-146a provides feedback regulation of gout arthritis development through regulation of TRAK-6/IRAK-1 and NALP3 inflammsome

IL-1 Receptor Antagonist Maintains Intestinal Microbial Homeostasis to Prevent Overt Toll-like Receptor 4-Dependent Intestinal Th17 Differentiation and Autoimmune Arthritis

Session Title: Innate Immunity and Rheumatic Disease

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Interleukin-1 (IL-1) plays a pivotal role in inflammation and immunity. Activation of IL-1 receptor is physiologically inhibited by the IL-1 receptor antagonist (IL-1Ra). Mice lacking the IL-1Ra gene (*Il1rn*$^{-/-}$) are prone to several autoimmune diseases including arthritis; however, the mechanisms by which IL-1Ra provides protection against autoimmune disease remain unknown. Given recent evidence suggesting association of microbiome with autoimmunity, we investigated the role of IL-1Ra in regulation of the intestinal microbiome and the involvement of specific microbiota in development of arthritis.

Methods: Intestinal microbiota were characterized in wild-type and *Il1rn*$^{-/-}$ mice using high-throughput 16S rRNA pyrosequencing. Involvement of (intestinal) microbiota in arthritis dvelopment was investigated in germ-free (GF) mice and using oral broad-spectrum and selective antibiotic treatments combined with re-colonization with specific commensals. Intestinal T cell differentiation was assessed by multicolor flow cytometry on lamina propria (LP) mononuclear cells to evaluate potential correlations with arthritis. Cytokine production was determined in supernatants of LP, spleen and lymph node cells cultured with phorbol myristate acetate/ionomycin and preparations of fecal microbiota.

Results: Sequencing data showed that IL-1Ra critically maintains the diversity and the homeostatic composition of intestinal microbiota in mice. IL-1Ra deficiency caused specific taxonomic alterations characterized by overrepresented *Helicobacter* and underrepresented *Ruminococcus* and *Prevotella*. These alterations potentiated T helper 17 (Th17), but not Th1 and regulatory T cell, differentiation in intestinal lamina propria (LP). Notably, the increased LP Th17 proportion was observed in the absence of the major previously described Th17 inducers segmented filamentous bacteria (SFB). Importantly, LP Th17 expansion preceded the development and positively correlated with the severity of arthritis. The disease was markedly suppressed under germ-free condition, paralleled by a significant and specific reduction of IL-17 production in LP, spleen and lymph nodes draining the inflamed joints. Inhibition of arthritis was also achieved upon short-term treatment with broad-spectrum oral antibiotics. Interestingly, this protection was reversed by specific Th17, but not Th1, induction in LP upon colonization with SFB. In conventional *Il1rn*$^{-/-}$ mice lacking SFB, indigenous Gram-negative microbiota were surprisingly identified as disease inducers. Ablation of both IL-1Ra and Toll-like receptor 4 (TLR4) recognizing Gram-negative bacteria revealed that microbial TLR4 activation mediates intestinal and systemic Th17 differentiation and promotes arthritis by inducing mucosal IL-1β, TNFα and IL-23 while leaving IL-6 unaffected.

Conclusion: These findings outline a fascinating regulatory interplay between IL-1Ra, commensal microbiota, TLR4 and Th17 differentiation in the context of autoimmune arthritis. The data suggest a potential role for intestinal microbial TLR4 activation in the development of arthritis in addition to its previously described activation by endogenous agonists.

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases I

Session Type: ACR Concurrent Abstract Session

Background/Purpose: Cryopyrin-associated periodic syndrome (CAPS), is a rare autoinflammatory disease encompassing a spectrum of 3 phenotypes with an estimated population frequency ranging from 1-3 per million.[1,2] The β -confident Registry is a multicenter, long-term, observational study with an enrollment period of 5 years and a 1-year follow-up period to monitor the long-term safety and efficacy of canakinumab (CAN) for CAPS. The primary objective of the Registry is to monitor the overall safety of CAN, focusing on SAEs including serious infections, vertigo, malignancies, and hypersensitivity reactions. Here we report interim data of CAN in CAPS patients from the enrollment period.

Methods: The registry protocol does not mandate any visits or procedures; however, all observed and reported AEs and SAEs or AEs potentially related to CAN are recorded. Cumulative safety data are reported as incidence rate per 100 patient-years (IR/100 pyr) from the enrollment of the first patient (Nov 19, 2009) until the current data cut-off date (Dec 31, 2014). The enrollment is now complete and follow-up will continue through Dec 2015. Although only partial data are available for 11 patients owing to the cut-off date for the analysis, the data will be updated later. Efficacy was measured using physician global assessments (PGA).

Results: Overall, 288 patients were enrolled at 39 sites across 13 countries with mean patient exposure duration of 2.8 years. Of these, 21 (7.3%) discontinued CAN: 5 each due to AEs, poor efficacy, and patient preference; and 6 due to unknown reasons. The IR/100 pyr for overall AEs was 100.0. Patients with familial cold autoinflammatory syndrome (FCAS) had the lowest IR/100 pyr (60.9) compared to patients with Muckle–Wells syndrome (MWS) (IR/100 pyr 107.2), and chronic infantile neurologic cutaneous and articular (CINCA) syndrome/neonatal onset multisystem inflammatory disease (NOMID) (IR/100 pyr 120.3). The most common AEs were infections and infestations (IR/100 pyr, 36.7).

Vertigo was reported by 19 patients (IR/100 pyr, 3.7). Overall, 117 SAEs were reported by 62 patients (IR/100 pyr, 15.0), most commonly, infections (IR/100 pyr, 4.1). One death (metastatic rectal adenocarcinoma in 76-year-old MWS patient) was reported. Of 18 patients that received pneumococcal vaccination (PPV), 13 (72%) reported local post-PPV injection site reactions, of which 5 were considered as serious. Based on PGA, nearly half the patients had no disease activity, whereas most of the others experienced mild/moderate disease activity. Similarly, disease activity was mostly absent in patients with *NLRP3* mutation negative CAPS (n=14) treated with CAN. No evidence of loss of effect was observed with time. Further analyses of this cohort are ongoing.

Conclusion: The β -confident Registry is the largest CAPS cohort documented in a registry. Canakinumab demonstrated a safety profile consistent with that observed in the clinical trial program and provided continued effectiveness in patients with CAPS for up to 5 years. Canakinumab therapy was also effective in patients with *NLRP3* mutation negative CAPS.

Matteo, Pavia, Italy, [4]Hospital of Sciacca, Sciacca, Italy, [5]Novartis Pharma AG, Basel, Switzerland, [6]UK National Amyloidosis Centre, University College London Medical School, London, United Kingdom

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases I

Session Type: ACR Concurrent Abstract Session

Background/Purpose: Tumor necrosis factor (TNF) receptor-associated periodic syndrome (TRAPS) is a rare, dominantly inherited periodic fever syndrome characterized by recurrent attacks of fever associated with rash, musculoskeletal and abdominal pain, conjunctivitis, and periorbital edema.[1] Nonsteroidal anti-inflammatory drugs and high-dose corticosteroids are often used for acute symptomatic relief but are limited by their well-known side effects. TNF inhibitors have been shown to be effective in some patients, however, their efficacy tends to decrease over time.[2–4] Here we present the long-term safety and efficacy of canakinumab (CAN) in patients with active TRAPS. The primary objective was to assess if CAN induces complete or almost complete response in patients on Day 15. Secondary objectives included clinical and serological remission, changes in signs and symptoms of TRAPS and physician's global assessment (PGA) over time, as well as assessment of adverse events (AEs) and serious AEs (SAE) reported.

Methods: This was an open-label single treatment arm study with a 4-month treatment period, a 5-month follow-up period (treatment withdrawal), and a 24-month long-term treatment period. Patients with active TRAPS received monthly CAN 150 mg (2 mg/kg for patient ≤40 kg) subcutaneously.

Results: At baseline, PGA of TRAPS activity showed 13 (65%) patients with mild, 6 (30%) with moderate and 1 (5%) with severe TRAPS; with chronic TRAPS being present in 11 (55%) patients. Of all the 20 patients who received CAN, 18 (90%) completed the study. On day 15, 19 patients (95%) achieved a complete or almost complete response, while 20 (100%) and 12 (60%) patients had clinical and serological remission, respectively (Table). Disease activity decreased in the long-term treatment period, and most patients experienced absent, minimal, or mild disease activity. At the end of the long-term period, all patients had absent (84.2%) or minimal (10.5%) disease activity. CRP and SAA levels were highest at baseline and decreased rapidly with treatment. In total, 12 patients (60%) experienced study drug-related AEs, predominantly upper respiratory tract infections. Seven patients (35%) experienced SAEs; none were related to the study drug. There were no AEs leading to discontinuation and no deaths were reported during the study.

Table. Clinical and serological remission on Days 8 and 15		
Response criteria	**Canakinumab N=20, n (%)**	**95% CI***
Complete or almost complete response (Day 8)	16 (80)	(56.3, 94.3)
Complete or almost complete response (Day 15)	19 (95)	(75.1, 99.9)
Proportion of patients with complete clinical remission (PGA score ≤1; Day 8)	18 (90)	(68.3, 98.8)
Proportion of patients with complete clinical remission (PGA score ≤1; Day 15)	20 (100)	(83.2, 100.0)
Proportion of patients with both CRP and SAA ≤10 mg/L (Day 8)	7 (35)	(15.4, 59.2)
Proportion of patients with both CRP and SAA ≤10 mg/L (Day 15)	12 (60)	(36.1, 80.9)
Proportion with complete or almost complete response on Day 15 in the patient subgroup without complete or almost complete response on Day 8	4 (100)	(39.8, 100.0)
Complete response: Clinical (PGA ≤minimal) and serological (CRP and/or SAA <10 mg/L) remission Almost complete response: Clinical (PGA ≤minimal) and partial serological (≥70% reduction of baseline CRP and/or SAA) remission *95% CI (Clopper–Pearson) CI, confidence interval; CRP, C-reactive protein; PGA, physician's global assessment; SAA, serum amyloid A		

Conclusion: Canakinumab demonstrated rapid disease control in terms of clinical signs and symptoms, and serological response in patients with active TRAPS through the treatment and long-term treatment periods. No new safety signals were reported during this long-term study. Safety profile was consistent with those reported in other canakinumab studies.

Long-Term Efficacy and Safety of Canakinumab in Active Hyperimmunoglobulinemia D with Periodic Fever Syndrome

Juan Ignacio Arostegui[1], Jordi Anton[2], Inmaculada Calvo-Penedes[3], Angel Robles[4], Antonio Speziale[5], Yolandi Joubert[5], Guido Junge[5] and Jordi Yagüe[6], [1]Department of Immunology-CDB, Hospital Clínic, Barcelona, Spain, [2]Unitat de Reumatologia Pediàtrica, Hospital Sant Joan de Déu, Barcelona, Spain, [3]Hospital de La Fe, Valencia, Spain, [4]Hospital La Paz, Madrid, Spain, [5]Novartis Pharma AG, Basel, Switzerland, [6]Immunology Department, Hospital Clinic Barcelona, Barcelona, Spain

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases I

Session Type: ACR Concurrent Abstract Session

Background/Purpose: Hyperimmunoglobulinemia D with periodic fever syndrome (HIDS) is a recessively inherited disorder characterized by periodic episodes of high fever, abdominal distress, joint pain, and skin rashes.[1] Previous reports suggested interleukin (IL)-1 blockade as a potential therapy in HIDS.[2,3] Here we report the final results of a 36-month study assessing the efficacy and safety of the anti-IL-1β human monoclonal antibody canakinumab in patients with active HIDS and biallelic mevalonate kinase *(MVK)* mutations.

Methods: This was an open-label single treatment arm study with a 6-month treatment period (6mo-TP), an up-to 6-month follow-up period (6mo-FP), and a 24-month long-term treatment period (24mo-LTTP). The 6mo-TP included canakinumab administration (4 mg/kg q6w, max 300 mg, subcutaneously), with one permissible dose up-titration to 6 mg/kg (max, 450 mg) if a flare occurred in the first 6 weeks. In the 24mo-LTTP, patients received the same canakinumab dose administered at the last visit of the 6mo-TP. The primary objective of the study was to assess the reduction in frequency of flares during the 6mo-TP compared with a 6-month historical treatment-free period. Secondary objectives were evaluated for the entire study and included assessment of reduction in frequency of flares, changes in flare duration, changes in physician's global assessment (PGA) of flare severity and disease control, changes in plasmatic inflammatory markers, and adverse events (AEs).

Results: All enrolled patients (n=9) completed both the 6mo-TP and the 6mo-FP. Eight patients also completed the 24mo-LTTP. The median number of flares decreased from 5 (3-12) in the historical period to 0 (0-2) during the 6mo-TP, and persisted (0-3) until the end of the study. During the 24mo-LTTP, the median flare duration was 3.5 days (2-8) in the first year and 8.5 days (6-11) in the second. PGA of flare severity was “mild” to “moderate” at baseline (n=9) and remained the same through the TP (n=2) and 6mo-FP (n= 7). Flare severity reduced to “mild” or “minimal” and “mild” or “without signs/symptoms” in the first (n=4) and second years (n=2) of the 24mo-LTTP, respectively. PGA disease control scores improved in all patients from either “no” or “poor” control at baseline to “good” or “excellent” control by Day 4, which persisted until the end of the study. Plasma levels of C-reactive protein and serum amyloid A normalized by Day 15 and remained in normal values until the end of the study. The most frequent AEs were infections. No deaths were registered. No AE led to study discontinuation. Four patients experienced 14 serious AEs (mild to moderate), none considered as drug-related.

Conclusion: Canakinumab treatment substantially reduced the frequency of flares in active HIDS and provoked a rapid control of signs and symptoms as well as normalization of plasmatic inflammatory markers. No unexpected safety findings were observed through the study, and safety profile was consistent with those reported in other canakinumab studies.

NOD2-Associated Autoinflammatory Disease: Therapy and Outcomes

Qingping Yao[1] and Bo Shen[2], [1]Cleveland Clinic, Cleveland, OH, [2]Gastroenterology, Cleveland Clinic, Cleveland, OH

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases I

Session Type: ACR Concurrent Abstract Session

Background/Purpose:

NOD2-associated autoinflammatory disease, now redesignated as Yao Syndrome(YS) is a newly described and increasingly recognized entity. It is characterized by periodic fever, dermatitis, polyarthritis, sicca-like and gastrointestinal symptoms, and genotypically associated with *NOD2* mutations. Our aim was to evaluate the treatment and outcomes of the disease.

Methods:

A cohort of 52 adult patients with autoinflammatory phenotypes diagnosed with YS were enrolled at the Cleveland Clinic between November

2009 and March 2015. All patients were genotyped for the *NOD2*mutations. These patients were prospectively studied for treatment outcomes.

Results: All 52 patients were whites, with female accounting for 72%. The mean age at diagnosis was 38.0±12.0 years and the disease duration was 8.8±5.8 years. The clinical phenotypes included periodic occurrence, weight loss (42%), fever (67%), dermatitis (90%), inflammatory arthritis (79%), leg swelling (30%), gastrointestinal symptoms (65%), sicca-like (58%), oral ulcers (27%), and pericarditis/pleuritis (8%). All 52 patients carry *NOD2* gene mutations, including IVS8+158(98%) and/or R702W (19%). The majority (90%) of patients tried nonsteroidal anti-rheumatic drugs without obvious benefits. Nineteen (36%) received prednisone for flares, including a short course (30-40 mg/day x1-3 days) in 9 patients, with a marked reduction in disease severity and interval. Twenty-two (42%) received sulfasalazine (2g/day), with significant symptomatic improvement. Methotrexate and hydroxychloroquine were tried without noticeable benefits. For frequent flares, particularly high fever and inflammatory arthritis, three patients received infliximab with only partial clinical response in one. Two patients received anakinra with partial response in one. Two patients received canakinumab and both had partial response. One patient received tocilizumab with good response. During nearly 9 years of the disease course, most patients had intermittent disease flares. Only one patient had mild joint deformity. No inflammatory bowel disease or primary Sjögren's syndrome was found. Five patients had mild anemia, and no patients developed nephritis, liver, lung parenchymal or central nervous system disease. Seven patients had low levels of immunologobulins, four of whom had recurrent infections, and one received intravenous immunoglobulin infusions. One patient had monoclonal gammopathy of undetermined significance. Associated comorbidities with YS included fibromyalgia in 11 patients, asthma in seven, renal stones in three, and ventricular hypertrophy in two. Seven of the 52 patients had impaired physical functionality. No mortality was found.

Conclusion: Our study demonstrates that YS is a systemic autoinflammatory disease without major solid organ involvement, though it may lead to chronic pain and potential functional impairment. Glucocorticoids and sulfasalazine are effective, and IL-1 and IL-6 antagonists may be beneficial. Further study of the disease mechanisms and a search for more effective drugs are warranted.

Relationship Between Colchine Plasma Level and Frequency of Familial Mediterranean Fever Attacks

Fadime Canbolat[1], **Gulsen Ozen**[2], Selma Ozilhan[1], Samet Gulturk[3], Ayse Ozcetin[4], Ali Ugur Unal[2], Nevsun Inanc[2], Pamir Atagunduz[2], Haner Direskeneli[2] and Tuncel Ozden[1], [1]Department of Pharmacology, Uskudar University Pharmacogenetic Laboratory, Istanbul, Turkey, [2]Department of Rheumatology, Marmara University Faculty of Medicine, Istanbul, Turkey, [3]Department of Molecular Biology and Genetics, Uskudar University, Istanbul, Turkey, [4]Department of Neuroscience, Uskudar University, Istanbul, Turkey

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases I

Session Type: ACR Concurrent Abstract Session

Background/Purpose: Colchicine is the mainstay of Familial Mediterranean Fever (FMF) treatment that reduces the frequency of attacks and prevents amyloidosis in the majority of patients. Colchicine, despite its narrow therapeutic window, is a well-tolerated oral drug that is rapidly absorbed by the gastrointestinal tract. However not all patients respond to colchicine and the response is not universal at the same doses. Therefore some patients require higher doses of colchicine to suppress their attacks. In this study we aimed to investigate the relationship between colchicine plasma levels and clinical response to colchicine in FMF patients.

Methods: Forty FMF patients with normal renal and hepatic functions, receiving colchicine regularly (steady state dose for at least 3 months with good compliance) were enrolled to the study in a 6 month-period. Blood samples were collected 30 minutes before the next colchicine dose. Colchicine plasma levels have been measured by using the device consecutive high performance liquid chromatography-mass spectrometry (LCMS-MS). Internal standard was added to plasma and the solution was extracted with ether:dichlormethane. Organic phase was evaporated to dryness under nitrogen. The residue dissolved in methanol was injected into the system. Quantitation was based on monitoring precursor ion and product ion for colchicine m/z 400.2 > 310.3, and for internal standart colchicine- d3 m/ z 403.3> 359.2. The assay was linear for colchicine over the range of 0.25-8 ng/ ml, $r^2$is 0.997.

Results: Of the 40 patients using colchicine, 24 were receiving 1.5 mg/day and 16 were receiving 2 mg/day. The mean plasma colchicine concentration of the entire cohort was 1.097±0.42 ng/mL and was within the therapeutic range (0.5-3ng/mL). The mean plasma colchicine concentrations of patients who were on 1.5 mg/day (1.05 ng/mL) and 2 mg/day (1.17 ng/mL) colchicine treatment were not significantly different (P=0.40). Plasma colchicine concentrations positively correlated with daily oral colchicine dose. Before colchicine treatment, the mean attack number was 24.947±3.22 /year and after colchicine treatment was 1.631±0.42/year (P<0.0001). The patients who were on 1.5 mg/day and 2 mg/day colchicine treatment had similar % of decrease in attack frequency (85.6% vs 89.2 %, P= 0.43). Optimal clinical response (decrease in the frequency of attacks) was observed at oral doses of 1.5-2 mg/day, corresponding to plasma levels of approximately 1.097±0.42ng/ml.

Conclusion: These data indicate that colchicine plasma levels correlate with daily oral doses of colchicine. FMF patients receiving 1.5 mg/day and 2 mg/day colchicine doses have similar plasma colchicine concentrations and also similar decrease in attack frequency. To evaluate the role of colchicine metabolism and plasma concentrations on the different dose requirements for optimal suppresion of attacks and on the colchicine-refractory FMF, further data is currently being studied by our group.

Update in the Management of Biologic Response Modifiers and Disease-Modifying Antirheumatic Drugs Following Coccidioidomycosis

Usman Ajaz[1], Neil M. Ampel[2], Varun Bhalla[3], Jeffrey R. Lisse[4] and Dominick Sudano[5], [1]Department of Medicine, University of Arizona, Tucson, AZ, [2]Department of Infectious Disease, Southern AZ VA Medical Center, Tucson, AZ, [3]University of Arizona, Tucson, AZ, [4]Arizona Arthritis Center, University of Arizona, Tucson, AZ, [5]Rheumatology, University of Arizona, Tucson, AZ

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Miscellaneous Rheumatic and Inflammatory Diseases I

Session Type: ACR Concurrent Abstract Session

Background/Purpose: In the Southwestern United States, Coccidioidomycosis (cocci) or Valley fever is an endemic fungal infection. It typically presents as a self-limited pulmonary illness. Patients with autoimmune diseases on disease-modifying antirheumatic drug (DMARD) or biologic response modifier (BRM) are at higher risk of more severe infection or infection disseminated outside the thoracic cavity. Currently, there are no management guidelines for cocci in such patients; however, retrospective data from the largest cohort of patients followed longitudinally suggests that retreatment of the rheumatic disease may be safe in some patients, and a management strategy based on cocci disease activity has been developed and implemented.

Methods: A retrospective chart review was performed and identified patients at two centers in Tucson, Arizona, who developed cocci on DMARD and/or BRM therapy. Patients were seen at least once between 2007 and 2014. Review emphasized the underlying rheumatic disease, manifestations of cocci, antifungal therapy, outcome, and management of BRM/DMARD therapy.

Results: 71 patients on DMARD and BRM therapy were identified. Among these patients, 19 were on BRM therapy, 16 were on DMARD and 36 were on combination therapy. Coccidioidomycosis was asymptomatic with positive serologies only in 19; 41 had pulmonary disease; while 10 were disseminated. BRM and DMARD therapy was stopped in 37 while in 14, BRM was stopped but DMARD continued. There was no change in immunosuppressive therapy in 20 patients. 52 patients were initially treated with antifungal therapy for 3 months or longer. Two of the patients with pulmonary illness and 12 patients with asymptomatic infection did not receive any antifungal therapy.

64 patients had follow up, out of which 50 patients continued BRM and/or DMARD therapy, and 22 received antifungal therapy. Four patients with disseminated disease restarted BRM therapy. Persistent positive serology and disseminated disease were the most common reasons for continuing antifungal therapy. Conversion to negative serology was the most common reason for stopping antifungal therapy. Patients were followed for a median of 29 months (range 2-141). There was one death from the group who was on DMARD and corticosteroid therapy. The deceased patient had disseminated coccidioidomycosis and was on antifungal treatment. There have been no deaths in the last three years. One patient with history of coccidioidal meningitis had relapse of disease, which was most likely related to his non-adherence with antifungal therapy.

Conclusion: Retreating or continuing DMARD and/or BRM therapy after cocci infection appears to be safe in some patients with close monitoring. If Cocci is asymptomatic, continuation of DMARD and/or BRM can be considered. In patients with pulmonary or disseminated infection, immunosuppressive therapy should be stopped and antifungal therapy should be continued until there is evidence of control of the infection. The management strategy implemented may be effective in guiding therapy.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Muscle Biology, Myositis and Myopathies I

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Juvenile dermatomyositis (JDM) is a rare disease. International collaboration is essential for scrutiny of sufficient patient numbers. We aim to develop a core set of data for all clinicians/ researchers to collect in a standardized way, with international agreement.

Methods: Comparing variables in existing clinical registries led to a provisional minimal dataset.[1] A two-stage e-mail Delphi-process engaged the opinion of a large number of key stakeholders via established international paediatric rheumatology/ myositis organizations. Consensus that each outcome should be included in the dataset was defined by ≥70% of participants scoring 'critical for decision making'. This, together with a formalized patient / parent participation process (ongoing) informed a consensus meeting of internationally representative myositis experts. Nominal group technique was used, with agreement of ≥80% consensus required for each variable to be included. The resulting dataset will be tested for feasibility within existing databases and sent to all internationally representative collaborators for final comment.

Results: Delphi responses from healthcare professionals (n=181 in round 1, 146 in round 2; 12% attrition), patients (n=14) and parents (n=20) were used to inform a consensus meeting of experts. The expert group (n=18) determined the need to include a measure of improvement /worsening of disease as well as binary documentation (feature 'present / absent'). A visual analogue scale (VAS) was thus included for each major domain. 74 variables were included in the proposed dataset (Table 1 & 2) with further damage items under consideration. 'Optimal dataset' replaced the term 'minimal dataset'. The dataset will be developed further after testing accuracy of data capture in clinical practice and analyzing additional patient/parent questionnaires.

Conclusion: An internationally agreed optimal dataset has the potential to significantly enhance collaboration, provide a standard of care and enable analysis of the largest possible number of JDM patients to provide a greater understanding of this disease. The final approved core dataset could be rapidly incorporated into national/international collaborative efforts.

Table 1: Variables to be collected at first visit only (diagnosis):

Section headings	**Variables to be collected**
Personal factors (demo-graphics)	Date of birth
	Sex
	Age / date at first symptom of myositis
	Age / date at diagnosis of JDM
Diagnostic factors	MRI scan at diagnosis (if done) consistent with myositis
	Muscle biopsy (if done) consistent with myositis
	Myositis specific antibodies (MSA) positive at diagnosis – if taken
	Myositis associated antibodies (MAA) positive at diagnosis – if taken
Treatments received prior to diagnosis	Has this patient received systemic glucocorticoids prior diagnosis of JDM – yes / no
	Has this patient received any synthetic or biologic disease modifying anti-rheumatic drug prior to the diagnosis?

Table 2: Variables to be collected at every visit:

Section headings	Variables to be collected (details not shown)
Growth & development	Height, weight, puberty self assessment
Muscular	Symmetrical muscle weakness, Childhood Myositis Assessment Scale (CMAS), Manual Muscle Testing (MMT8)
Cutaneous	Features included in abbreviated Cutaneous Assessment Tool (CAT) score
Skeletal	Arthritis / contractures & Visual Analogue Scale (VAS) for skeletal activity
Gastrointestinal	Dysphagia, abdominal pain, gastrointestinal ulceration & VAS for gastrointestinal
Pulmonary	Pulmonary involvement / interstitial lung disease, dysphonia & VAS for pulmonary activity
Cardiovascular	Cardiovascular involvement, blood pressure & VAS for cardiovascular activity
Constitutional features	Fever, weight loss, fatigue & VAS for constitutional activity
Physician Global	Physician global VAS & extra-muscular activity VAS
Patient / parent outcome	Patient / Parent measure of function & participation
Investigations	Muscle enzymes & other specimens available
Treatment	Drug treatment & exercise routine: range of movement & muscle strength
Outcome / disease impact	Malignancy / death
Damage items (annual)	To include damage items across domains

Activity of Type I and Type II Interferons in Dermatomyositis Skin Is Correlated with Characteristic Pathologic Features

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Muscle Biology, Myositis and Myopathies I

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose :

Interferon (IFN) signaling is upregulated in dermatomyositis (DM) skin, but the relationship to classic histopathologic features is unknown.

Methods :

Thirty-nine skin biopsies from patients with dermatomyositis underwent gene expression analysis using Affymetrix arrays, as well as histologic analysis by a blinded dermatopathologist. Biopsies were scored for severity of several cardinal histopathologic features, including basal vacuolar change (BV), dermal mucin deposition, and perivascular inflammation. Type I and type II IFN scores were generated based on the average relative expression of selected genes previously demonstrated to be upregulated by IFN-alpha and IFN-gamma, respectively. Expression levels of IFN transcripts were measured by quantitative PCR. Univariate analysis was performed to evaluate the association between IFN scores and IFN transcripts with key histopathologic features, with subsequent multivariate models constructed to include potentially confounding variables such as biopsy site, medication use, age, and length of disease.

Results :

Skin biopsies were highly heterogeneous regarding both histopathologic features as well as type I or II IFN scores. Type I IFN scores correlated strongly with IFN beta expression ($r=0.75$, $p<0.0001$) but not other type I (alpha, kappa, omega) or type II IFN transcript levels. In univariate analysis, keratinocyte injury (reflected by BV score) was found to be associated with both type I and type II IFN scores ($p=0.0014$ and $p=0.004$, respectively); these associations remained significant in multivariate analysis. In contrast, dermal mucin deposition was highly correlated with the type I IFN ($p<0.0001$) but not type II IFN ($p=0.071$) activity. However, lymphocytic dermal inflammation was associated with type II IFN score ($p=0.0413$), but not the type I IFN score ($p=0.3088$). Additional histologic features, including epidermal atrophy, basement membrane thickening, and vessel damage were not statistically associated with either IFN score.

Conclusion :

Our results highlight that IFN signaling in DM skin likely represents a combination of at least type I and II IFN activity. Furthermore, our data suggest that type I and II signaling are each associated with shared as well as distinct pathologic processes in DM skin. Keratinocyte injury, the sine qua non finding in DM skin, is associated with both type I and II IFN activity. Finally, our results imply that IFN beta is the relevant IFN driving type I IFN signaling in DM skin and point to both IFN beta and IFN gamma as potential targets of pharmacologic inhibition in cutaneous DM.

Session Title: Muscle Biology, Myositis and Myopathies I

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose :

Autoantibodies are important biomarkers in the diagnosis of idiopathic inflammatory myopathies (IIM) including polymyositis (PM) and dermatomyositis (DM), inclusion body myositis (IBM) as well as overlap syndromes. Recently, it was reported that the prevalence of necrosis in patients with IIM is increasing and that the majority of the patients with necrosis exhibit autoantibodies to 3-hydroxy-3-methylglutaryl-coenzyme A reductase (HMGCR), the molecular target of statins. This is the first international multi-center study on anti-HMGCR antibodies in a large cohort of patients.

Methods:

A total of 1906 samples from IIM patients and controls were collected at 12 different sites from nine different countries. Among patients with IIM (n=1250), 69 had immune mediated necrotizing myopathies (IMNM), 406 had PM, 525 had DM, 10 had PM/Scleroderma overlap syndrome, 45 had juvenile dermatomyositis (JDM), 18 had myositis overlap syndromes (MOS), 53 had amyopathic dermatomyositis (ADM), 49 had antisynthetase syndrome (ASS), 64 had cancer-associated myositis and 11 had IBM. All samples were tested for anti-HMGCR antibodies by ELISA.

Results:

Anti-HMGCR antibodies were present in 44.9% of IMNM, 4.4% of PM, 1.9% of DM, 6.7% of JDM, in 1.2% of primary Sjögren`s syndrome (pSS) and in 0.4% of systemic lupus erythematosus patients (see Table 1).

Table 1 Prevalence of anti-HMGCR antibodies in different disease cohorts

Disease Group	N=	Prevalence	95% CI
Immune Mediated Necrotizing Myopathy (IMNM)	31/69	44.9%	33.8-56.6%
Polymyositis (PM)	18/406	4.4%	2.8-6.9%
Dermatomyositis (DM)	10/525	1.9%	1.0-3.5%
Juvenile Dermatomyositis (JDM)	3/45	6.7%	2.3-17.9%
Primary Sjögren's Syndrome (pSS)	1/81	1.2%	0.02-6.7%
Systemic Lupus Erythematosus (SLE)	1/226	0.4%	0.01-2.5%

Among the IMNM patients, statin exposure was known for 45 patients. Patients tested positive for the anti-HMGCR were more frequently statin users (21 vs. 10; $p<0.0001$), showed a higher prevalence of necrosis ($p<0.0001$) and were older ($p=0.0001$) compared to ant-HMGCR negative patients. Receiver operating characteristic analyses showed good discrimination between IMNM and controls, and between IMNM and other forms of IIM. The prevalence of anti-HMGCR antibodies was highest in statin exposed elderly individuals (>50 years) diagnosed as IMNM reaching 76.5%.

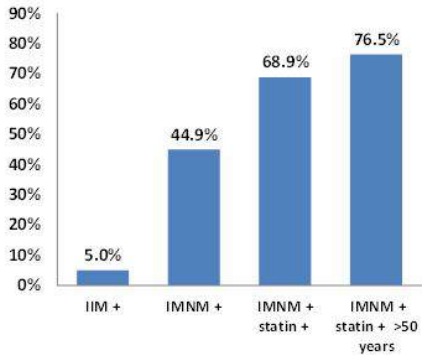

Figure 1 **Incremental prevalence of anti-HMGCR antibodies in different patient subsets**

Conclusion:

Anti-HMCGR antibodies characterize a subpopulation of IMNM patients previously exposed to statin and were significantly associated with an older age. However, it is important to note that not all patients with those autoantibodies had a history of exposure to statins indicating that different phenotypes and mechanisms exist.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Muscle Biology, Myositis and Myopathies I

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

The mechanisms that contribute to the pathogenesis of the idiopathic inflammatory myopathies remains largely unknown. This heterogeneous group of diseases involve autoimmunity toward muscles that results in tissue destruction. Previous studies on the synaptotagmin VII-knockout (Syt VII$^{-/-}$) mouse model revealed these mice develop myositis that could be exacerbated by combining the Syt VII$^{-/-}$ model with regulatory T-cell deficiency (FoxP3$^{-/Y}$) by adoptively transferring into immunodeficient (RAG1$^{-/-}$) recipients. Other studies indicate that Syt VII$^{-/-}$ mice have impaired sarcolemmal membrane resealing capacity, a defect that results in increased membrane permeability and resulting exposure of intracellular antigens to the extracellular space. Additional genes have been linked to membrane resealing, including members of the large tripartite motif (TRIM) gene family, where deletion of these genes result in myopathy. Our previous studies show that TRIM72/MG53 is essential for sarcolemmal membrane repair in striated muscles. Alteration of the expression levels of, or autoantibody responses to, TRIM72/MG53 and related TRIM proteins levels could alter membrane repair in the context of myositis and contribute to progression of the disease. Here, we examined protein expression levels of several related novel TRIM proteins in muscle tissue from this myositis mouse model and human myositis patients. Additional studies screened for autoantibody responses to these TRIM proteins in serum samples from other human myositis patients.

Methods: Muscle biopsies from myositis patients were collected and analyzed by standard Western immunoblotting and by

immunohistochemistry. Overexpression constructs for target TRIM proteins tagged with a green fluorescent protein (GFP) tag were transfected into HEK293 cells and resulting protein extracts were enriched for the TRIM proteins using co-immunoprecipitation approaches. Enriched extracts were used for Western immunoblotting using myositis patient serum samples as the primary antibody.

Results: We identified multiple TRIM family proteins that display altered expression in myositis muscle from both mice and humans. TRIM72/MG53 and other related TRIM proteins displayed altered expression in muscle extracts from both a myositis mouse model and human myositis patients. In particular, TRIM27 showed increased expression in myositis muscle from both humans and mice. We next examined if we could detect antibodies against these TRIM family proteins in the serum of human myositis patients. Autoantibodies were detected in the serum against TRIM72/MG53, TRIM27 and TRIM2 in multiple myositis patients but not in healthy controls

Conclusion: We have identified altered expression of TRIM proteins in skeletal muscle in a myositis mouse model and in muscle biopsies from human myositis patients. Autoantibodies targeting some of these TRIM proteins could be detected in the blood serum of myositis patients. These results highlight an association of decreased sarcolemmal membrane integrity in the development of myositis and suggest a mechanism that could be targeted for diagnostics and therapeutics in these diseases.

Session Date: Sunday, November 8, 2015

Session Title: Muscle Biology, Myositis and Myopathies I

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

Each myositis specific autoantibodies (MSA) are associated with unique clinical subset and useful biomarkers in polymyositis/dermatomyositis (PM/DM). Identifying new MSA will help in monitoring PM/DM patients as evidenced recently by reports on anti-TIF1gamma (transcription intermediary factor-1gamma) associated with malignancy and anti-MDA5 associated with clinically amyopathic DM with rapidly progressive interstitial lung disease (ILD). Although new autoantibody specificities have been added, ~50% of patients with PM/DM are still without known MSA, thus identifying additional MSA is relevant. A set of 3 proteins of ~120 -160kD recognized by serum from patients with DM were noticed and the antigens and clinical features of patients with this autoantibody specificity were characterized.

Methods:

A set of 3 proteins of ~120 -160kD recognized by a prototype serum was purified and identified by mass spectrometry. Sera from ~2200 patients with various diagnosis including 434 SLE, 119 scleroderma, and 514 PM/DM from 4 countries were tested by immunoprecipitation of ^{35}S-methionine labeled K562 cell extract. Sera that immunoprecipitated the same set of proteins were searched and identity of specificity was verified by immunoprecipitation and western blot using mouse monoclonal antibodies (mAb). Clinical information was from database and charts.

Results: Many peptides covering 50+% of the whole sequence for cohesion subunit SA-1, SA-2 and SMC3 (structural maintenance of chromosome) were detected from purified ~120-160kD proteins. Identity of the proteins immunoprecipitated by human autoimmune sera was confirmed by probing immunoprecipitated proteins by mouse mAb to components of cohesion complex, SA-1, SA-2, SMC1 and Rad21. IP pattern of 3 bands by anti-SA-2 mAb appeared to be same as that by human autoimmune sera. Based on these findings, it was concluded that the set of

proteins recognized by the autoimmune sera was cohesion complex, which is known to regulate the separation of sister chromatids during cell division, and also involved in various functions such as controlling gene expression, DNA replication and DNA repair. All 4 anti-cohesin autoimmune sera showed fine speckled nuclear staining sparing nucleoli by immunofluorescence antinuclear antibodies. Despite localization of cohesion on chromosomes, staining of mitotic chromosomes was not clear. Four cases with anti-cohesin were identified; 3 females (2 African Americans, 1 Latin) and a male (Japanese). A Japanese patient was amyopathic DM with ILD. A Latin patient had DM and an African American patient had PM-SSc overlap syndrome with ILD and positive for anti-U1RNP and Su/Argonaute2 antibodies. Another American patient had Raynaud's phenomenon and skin ulcer/gangrene. None of these patients had cancer or coexisting MSA or SSc-specific autoantibodies. This specificity was not found in SLE, scleroderma, or other conditions.

Conclusion: Anti-cohesin complex is a new autoantibody specificity that appears to be associated with PM/DM and ILD. Whether it has association with unique features will need to be evaluated in future studies.

Autoimmune Myopathies: Effects of Intravenous Immunoglobulin Therapy on Muscle Strength and Predictors of Response

Arash Lahoutiharahdashti[1], Iago Pinal-Fernandez[2], Jemima Albayda[1], Julie J. Paik[3], Sonye K. Danoff[4], Andrew Mammen[5] and Lisa Christopher-Stine[6], [1]Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD, [2]Autoimmune Systemic Diseases Unit, Vall D'Hebron University Hospital, Universitat Autònoma de Barcelona, Barcelona, Spain, [3]Division of Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD, [4]Medicine/Pulmonary, Johns Hopkins School of Medicine, Baltimore, MD, [5]Center Tower Ste 5300, Johns Hopkins University School of Medicine, Baltimore, MD, [6]Ste 4100 Rm 409, Johns Hopkins University School of Medicine, Baltimore, MD

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Muscle Biology, Myositis and Myopathies I

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

There is a variable response rate to Intravenous immunoglobulin (IVIG) in patients with autoimmune myopathies. The aim of this study was to determine whether the presence of individual myositis-specific autoantibodies (MSA) predicts improved muscle strength in response to IVIG.

Methods:

A total of 378 adult subjects with a diagnosis of polymyositis or dermatomyositis based on the Bohan & Peter criteria, who presented to our Center between 2004 and 2014, had been treated with IVIG. Modified MRC scores for the 16 proximal muscle groups were summed to yield a composite score of muscle strength (range 0-160). The following groups of subjects were excluded from the study: those with minimal weakness at the initiation of IVIG therapy (composite score > 156/160) (n=30), those with inadequate data on the efficacy of IVIG including those who were on IVIG therapy at presentation to our Center (n=143), those with inadequate follow-up (<5 months) (n=57), patients who did not receive a standard dose (2 g/kg, given in 2-5 days/month, for a period of 3-6 months) (n=45), and patients for whom the existing therapies had been increased or a new medication had been added during IVIG therapy (n=36). All patients were tested for MSAs by three reference laboratories using previously validated immunoprecipitation methods. A positive response was defined by a ≥4 point increase in composite score. Fisher's exact test was used to examine the effects of each MSA. Exact logistic regression was used to calculate the odds ratio.

Results:

Among the 67 subjects included in this study, 17 (25.4%) were non-responders and 50 (74.6%) were responders (Table 1). 54/67 (80.6%) of subjects had a detectable MSA. The response to IVIG was different between statin-exposed and statin-naïve anti-HMG-CoA reductase (HMGCR) subjects. All 14 (100%) statin-exposed anti-HMGCR+ patients responded but only 4 of 7 (57.1%) statin-naïve anti-HMGCR+ patients were responsive to IVIG (p=0.026) (Table2). Overall, anti-HMGCR in statin-exposed patients predicted a higher response rate to IVIG (p=0.014). In contrast, anti-SRP antibody was associated with lack of response (p=0.001). Of note, all anti-TIF-1γ positive patients responded to IVIG therapy (p=0.055). The odds ratio of response to IVIG was 8.8 (95%CI: 1.34 - [+infinity]) for anti-HMGCR+ and 0.04 (95%CI: 0-0.31) for anti-SRP positive patients.

Conclusion:

MSAs may predict a characteristic response to certain ISs. Our results indicate that while anti-SRP antibody predicts a poor response, statin-exposed anti-HMGCR+ patients are more likely to respond to IVIG therapy.

The Metabolic Syndrome, Its Elements and Knee Osteoarthritis: The Framingham Osteoarthritis (OA) Study

Jingbo Niu[1], Mary Clancy[2], Piran Aliabadi[3] and David T. Felson[1], [1]Clinical Epidemiology Research and Training Unit, Boston University School of Medicine, Boston, MA, [2]Clinical Epidemiology, BUSM, Boston, MA, [3]Radiology, Brigham and Women's Hospital, Boston, MA

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Osteoarthritis - Clinical Aspects: Treatments and Epidemiology

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Recent studies have suggested an association between knee OA and the metabolic syndrome (MetS), but in these studies the relationship of this syndrome to OA has often vanished after adjustment for BMI. Since BMI adjusts for the effect of loading on the knee, adjustment for BMI is appropriate and any association of MetS elements with OA should be present after this adjustment. In defining the MetS, its elements are dichotomized and any association of these elements with OA is more likely to be detected if they are examined over their range and not just as dichotomous measures. We used data from the Framingham Osteoarthritis Study to assess the association between MetS and each of its elements to radiographic knee OA (ROA).

Methods: The Framingham Osteoarthritis Study recruited subjects from the Offspring Cohort. At exam 7 (2002-2005), we carried out a cross sectional evaluation of MetS and OA. MetS was defined by National Cholesterol Education Program criteria as having at least three out of the five elements: waist circumference >102 cm in men and >88 cm in women), hypertriglyceridemia (>150 mg/dL), low HDL (<40 mg/dL in men and <50 mg/dL in women), high blood pressure (systolic BP >130 mmHg, diastolic BP >85 mmHg or treatment), and hyperglycemia (fasting glucose >100mg/dL or diagnosis of diabetes). ROA was defined as having KL>2 in the tibiofemoral joint on PA view radiograph, patellofemoral OA on the lateral view radiograph, or knee replacement. Among subjects 50 years and older, we used binary regress to assess the relation of MetS and each of its elements to the prevalence of ROA in men and women separately. We tested each element of MetS as dichotomous measures, quartiles, and continuous measures. Age, history of knee injury and surgery were included as covariates. We tested models with and without controlling BMI to show how the effect of MetS was affected by excessive weight. Generalized estimating equations were used to control for the correlation between two knees of a subject.

Results: Among 1091 subjects (mean age: 62.0 years, BMI 28.1 kg/m^2, 55.5% women), 41.4% of men and 28.6% of women had MetS. When adjusting for covariates other than BMI, large waist circumference, high tryglyceride and high systolic blood pressure were related to higher prevalence of ROA in both men; MetS, large waist circumference, high systolic blood pressure, and hyperglycemia were related to higher prevalence of ROA in women. After further adjusting for BMI, men with high waist circumference and tryglyceride tended to have a higher prevalence of ROA; while none of the above associations was observed in women **(Table)**.

Conclusion: The association between MetS and radiographic knee OA observed in women can be explained by excessive weight. The relation of its elements, i.e., waist circumference, high blood pressure, and hyperglycemia, to radiographic knee OA was also due to excessive weight.

Session Date: Sunday, November 8, 2015

Session Title: Osteoarthritis - Clinical Aspects: Treatments and Epidemiology

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: In osteoarthritis (OA) treatment, although chondroitin sulfate (CS) was found in a number of studies using radiography to have a structure modifying effect, to date the question is still under debate. A clinical study using quantitative magnetic resonance imaging (qMRI) is therefore of the utmost importance.

The present study has the objective to explore, as the first aim, in a two-year randomized, controlled double-blind clinical study (RCT) using qMRI, the disease modifying effect of CS treatment versus celecoxib (CE) on cartilage volume loss (CVL) in knee OA. The second aim was to investigate and compare the effect of CS and celecoxib on symptoms.

Methods: Symptomatic primary knee OA patients according to ACR criteria with Kellgren-Lawrence grades 2-3 and synovitis were included and treated with CS (1200 mg a day) or CE (200 mg once daily) for 24 months. Patients at high risk for cardiovascular and/or gastrointestinal disease were not included. MRI was performed at baseline, 12 and 24 months. CVL, bone marrow lesion (BML) size, and synovial membrane thickness were evaluated using qMRI, and presence of joint swelling and effusion clinically evaluated. Clinical symptoms were also assessed by validated questionnaires. Statistical analyses were done on the intention-to-treat (ITT) population (n=194 patients), per protocol set (n= 195) and the according-to-protocol completer population (n=120) using Student's t-test, Wilcoxon Mann-Whitney test, and ANCOVA.

Results: In the ITT population, OA patients treated with CS (n=97) had a reduction in CVL at 12 months (p=0.017) and 24 months in the medial tibiofemoral compartment (p=0.013) and global knee at 12 (p= 0.034) and 24 months (p=0.054) compared to CE (n=97). No difference in change in synovial thickness or BML size between the two treatment groups was observed over time. A marked reduction in the incidence of patients with joint swelling plus effusion was observed in both the CS (51%, 59 vs 6 patients) and celecoxib (39%, 55 vs 11 patients) groups from baseline to 24 months, without differences between treatments. Both therapeutic groups experienced a reduction in disease symptoms (WOMAC total, pain, and function, and VAS pain) over time: reduction in VAS pain at 24 months for CS and celecoxib was 48% and 55% respectively, and for WOMAC pain 43% and 54%. The overall daily consumption of rescue analgesic (acetaminophen) was not different between CS and celecoxib (584 vs 472 mg/day) groups. The incidence of adverse events was similar in both treatment groups.

Conclusion: This trial demonstrated, for the first time, the superiority of CS over CE at reducing the long term progression of knee OA structural changes. Moreover, both drugs were found equally effective at reducing the symptoms of OA. These findings have important implications regarding the usefulness of CS for long term management of knee OA and its impact on disease outcome.

Session Title: Osteoarthritis - Clinical Aspects: Treatments and Epidemiology

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Knee osteoarthritis (OA) causes long-term pain and no effective treatments currently exist. Previous trials demonstrated that Tai Chi can improve both physical and mental health among patients with knee OA. However, it has not been compared against a standard of care therapy for knee OA. We designed this novel randomized, single-blind trial to test the superiority of Tai Chi compared to a standard physical therapy (PT) regimen for treatment of symptomatic and radiographic knee OA. The study was also powered to detect differences in outcomes among different Tai Chi instructors as an important secondary objective.

Methods: Adults ≥ 40 years old satisfying ACR criteria for Knee OA were randomized to 12 weeks of classical Yang style Tai Chi (2x/week) or to the standard PT regimen (2x/week for 6 weeks, followed by 6 weeks of rigorously monitored home PT). Clinical outcomes assessments were blinded to treatment allocation. The primary outcome was change in WOMAC pain subscale (0-500) at 12 weeks. Secondary outcomes included change in pain at 24 and 52 weeks as well as change in WOMAC function scores, patient global assessment (VAS, 0-10 cm), depression (Beck II, 0-63), chronic pain self-efficacy (0-10), 20 meter walk test (sec) and 6 min walk test (meters), quality of life (SF-36, 0-100), pain medication usage and comparisons of all outcomes by instructor assignment at 12, 24 and 52 weeks. We used an intent-to-treat analysis.

Results: We randomized 204 participants: 106 to Tai Chi and 98 to PT. The mean age 60 years, disease duration 8 years, BMI 33 kg/m^2; 70% were female; and 53% were white. Treatment groups did not differ in baseline characteristics, including participant expectation of treatment benefit. At 12 weeks, WOMAC pain scores improved by 167 points (95% CI: 145, 190) in the Tai Chi group and 143 points (95% CI: 119, 167) in the PT group. There was no significant difference between groups in WOMAC pain improvement (p = 0.16). A significantly greater improvement in the Tai Chi group was found in the SF-36 Physical Component score 3.2 (95% CI: 0.8, 5.5; p=0.01) and the Beck depression score 2.7 (95% CI, 0.7, 4.8, p=0.008). No differences between groups were found for other outcomes at 12 weeks. There were no serious adverse events. Pain medication use was reduced compared to baseline at all follow-up times in both groups, but the reductions did not differ between groups. Changes in WOMAC pain did not differ among the four Tai Chi instructors (p = 0.81), though differences approached significance comparing physical therapists (p=0.05).

Conclusion: Both Tai Chi and PT led to similar improvements in pain and other outcomes for persons with symptomatic knee OA, and the benefits of Tai Chi did not differ by instructor, suggesting that standardizedTai Chi can be used as a viable therapeutic alternative to treat knee OA.

Table. Changes in Primary and Secondary Outcomes

Variables	Groups	Baseline Mean (SD)	At 12 week Change (95% CI)	95% CI and P-value for D between group

Session Title: Osteoarthritis - Clinical Aspects: Treatments and Epidemiology

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

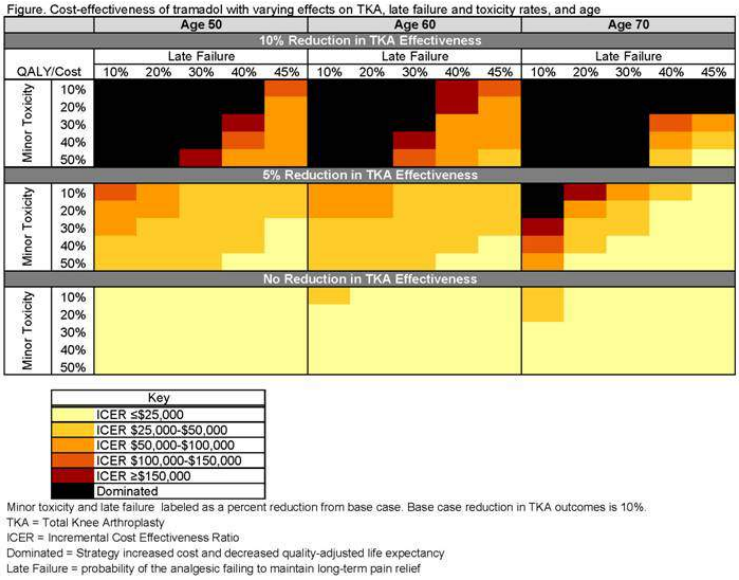
Background/Purpose: The US spends over $1 billion annually on opioids for persons with knee OA. We evaluated whether the use of opioids offers good value for money by conducting a formal cost-effectiveness analysis of the use of tramadol or oxycodone in OA patients.

Methods: We used the Osteoarthritis Policy Model, a validated computer simulation of knee OA, to evaluate long-term clinical and economic outcomes of knee OA patients with mean age 60 and no prevalent comorbidities, whose pain persists after initial treatment with non-steroidal antiinflammatory drugs (NSAIDs), physical therapy (PT), and corticosteroid injections. We evaluated 3 strategies: 1) opioid-sparing (OS, acetaminophen as needed until total knee arthroplasty [TKA]); 2) tramadol (T); and 3) tramadol followed by oxycodone for those who failed tramadol (T+O). Toxicity and efficacy were estimated from published literature. Mean WOMAC Pain change was 15 points for tramadol and 16 for oxycodone. Annual costs for tramadol ($600) and oxycodone ($2,700) included drug costs (Red Book), office visits, and, for oxycodone, diversion. Toxicities included gastrointestinal (GI) and cardiovascular (CV) events. Based on published literature, in the base case analysis we decreased the efficacy of TKA in strategies T and T+O by 10%. We adopted a societal perspective, discounting outcomes at 3%/year, and assumed a willingness to pay (WTP) threshold of $100,000 per quality adjusted life year (QALY). Strategies with incremental cost-effectiveness ratios (ICERs) below WTP were considered cost-effective. We conducted sensitivity analyses on the impact of opioid use on TKA outcomes, age at opioid initiation, and toxicity and discontinuation rates.

Results: In the base case, tramadol-treated patients were on tramadol for 2.4 years and oxycodone-treated patients were on oxycodone for 2.9 years, on average. The T and T+O strategies led to reduction in TKA use by 4% and 10% respectively and revision TKA use by 24% and 40%. In the base case, both opioid-based strategies increased cost and decreased QALYs compared to the opioid-sparing strategy. Tramadol cost-effectiveness was highly sensitive to its effects on TKA outcomes. When efficacy of TKA was reduced by 5% (base case 10%), tramadol had an ICER of $67,000/QALY (Figure). When TKA was not a treatment option, tramadol, but not tramadol + oxycodone, became a cost-effective strategy.

Conclusion: Opioids do not appear to be cost-effective in OA patients if they have an adverse effect on TKA outcomes. Despite reductions in TKA use, costs of opioids and toxicities led to an overall increase in cost for the T and T+O strategies compared to OS. Tramadol may be cost-effective in patients averse to TKA or if additional data show that its effects on TKA outcomes are minimal. The influence of chronic opioid use on TKA should be considered a research priority in order to understand the value of opioids in knee OA treatment.

Figure. Cost-effectiveness of tramadol with varying effects on TKA, late failure and toxicity rates, and age



Minor toxicity and late failure labeled as a percent reduction from base case. Base case reduction in TKA outcomes is 10%.
TKA = Total Knee Arthroplasty
ICER = Incremental Cost Effectiveness Ratio
Dominated = Strategy increased cost and decreased quality-adjusted life expectancy
Late Failure = probability of the analgesic failing to maintain long-term pain relief

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Osteoarthritis - Clinical Aspects: Treatments and Epidemiology

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Hand osteoarthritis (OA) is highly prevalent, affecting 55-70% of the population over 55 years with an age-related progressive increase. The OA of interphalangeal (IF) and carpometacarpaljoints may have varying degrees of deformity associated with pain, decreased of grip and pinch strength, decreased range of motion and functional impairment. Systematic reviews and meta-analyzes have shown the beneficial effect of exercise for lower limb OA, however for hand OA exercise is still used based on recommendations based on clinical experience and low quality studies, not allowing a conclusion about the effects of exercise in pain, function and strength in hand OA patients. The purpose of this study was to assess the effectiveness of progressive resistance strength training program on pain, function and strength in hand OA patients.

Methods: diagnostic of hand OA according to ACR of at least 1year, age over 55 years, both genders, pain in IF joints between 3-8 cm on a 10-cm numerical pain scale (NPS). Sixty patients who meet the eligibility criteria were randomized into exercise group (EG) and control group (CG). Both groups performed a session regarding joint protection and energy conservation before randomization. The EG performed a progressive resistance strength training program for intrinsic muscles of the hand for 12 weeks. The outcome measures were NPS; *Australian*/Canadian (AUSCAN) Hand Osteoarthritis Index and Cochin Hand Functional Scalefor hand function; grip and pinch strengthening using the *Jamar*Hydraulic Hand*Dynamometer and a pinch gauge dynamometer* and satisfaction with the treatment using a Likert scale. A blinded evaluator performed the evaluations at baseline, 6 and 12 weeks after treatment baseline.

Results: The groups were homogeneous at baseline except for the key pinch strength for non-dominant hand and palmar pinch strength for both hands. The comparison between groups using repeated measures ANOVA shows an statistically difference between groups in AUSCAN (total score, $p = 0.005$; pain, $p = 0.006$ and function, $p = 0.047$), COCHIN ($p = 0.042$) and Likert scale ($p = 0.001$) with better results for the EG.

Conclusion: This progressive resistance strength training program was effective for pain, function, and treatment satisfaction for patients with

hand OA.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Osteoarthritis - Clinical Aspects: Treatments and Epidemiology

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Symptomatic osteoarthritis (OA) and cardiovascular disease (CVD) commonly co-exist. Our aim was to determine the extent to which this relationship is explained by common risk factors (age and obesity), metabolic factors and self-reported functional limitations.

Methods: A population cohort aged ³55 years was recruited from 1996-98 from two communities. Age, sex, height and weight, self-reported medical comorbidities, joint complaints and functional limitations (difficulty with stair climbing, walking, and gripping) were collected by survey. Subjects with inflammatory arthritis, rheumatic disease and medical neurological conditions associated with functional disability were excluded. OA was defined as (1) swelling, pain, or stiffness in any joint lasting 6 weeks in the past 3 months; and (2) indication on the homunculus that a knee, hand and/or hip was "troublesome". CVD was defined as self-reported angina, heart disease, myocardial infarction, coronary reperfusion, heart failure, stroke, transient ischemic attack and/or carotid disease. Participants were classified into 8 mutually exclusive joint groups based on the presence/absence of knee, hand and hip complaints. Using logistic regression, we examined the relationship of CVD with knee, hand, and hip complaints, controlling for the following variables added to our model incrementally: (1) age and body mass index (BMI); (2) sex and metabolic factors (diabetes, hypertension and dyslipidemia); and (3) functional limitations (stairs, walking, grip).

Results: 20,501 participants were included: mean age 68.2±8.5 years, 58.5% female, 51.8% rural-dwelling and mean BMI of 25.9±4.5 kg/m^2. Controlling for age and BMI, the prevalence of self-reported CVD was significantly higher among individuals with a combination of knee, hand and hip OA (adj odds ratio [OR] 1.42, 1.16 – 1.72, p<0.01); combination of knee and hand OA (adj OR 1.37, 1.13 – 1.66, p<0.01); and combination of hand and hip OA (adj OR 1.46, 1.07 – 1.97, p=0.02). Further adjustment for sex and metabolic factors did not substantially impact these relationships. When functional limitations were entered into the model, the above associations were attenuated and became non-significant (Figure 1).

Conclusion: In a large population cohort aged ³55 years, the previously documented relationship between symptomatic OA (knee, hand, hip) and CVD was confirmed. This relationship remained robust after controlling for common risk factors and metabolic factors, but became non-significant after controlling for functional limitations, suggesting that the predominant mechanism driving cardiovascular risk in people with OA is functional disability. Further work is needed to investigate effective ways to improve functional limitations in people with established OA.

Session Date: Sunday, November 8, 2015
Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects I: Juvenile Idiopathic Arthritis
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Given suspected links between inflammation and malignancy, several groups have attempted to elucidate the baseline risk of cancer in various inflammatory or autoimmune conditions, including rheumatoid arthritis, where there is an increased risk of hematological malignancies (lymphoma in particular). However, there are very few studies of cancer risk in large pediatric-onset rheumatic disease cohorts. The purpose of our study was to further investigate cancer risk in JIA, based on a very large multi-centre clinical population.

Methods: We examined data from 4 pediatric rheumatology clinic cohorts in Canada and 2 in the United States, across 1971-2011. We linked patients to regional cancer registries to detect observed cancers (O) occurring after cohort entry, defined as date first seen in the JIA clinic cohort. End of follow-up was defined as the date of cancer registry linkage (thus was not truncated once subjects reached adulthood). The expected number of malignancies (E) was obtained by multiplying the person-years in the cohort (defined from cohort entry to end of follow-up) by the geographically matched age, sex, and calendar year-specific cancer rates, and summing overall person-years.

The standardized incidence ratio (SIR; ratio of cancers observed to expected) was generated, along with 95% confidence intervals (CIs), based on the assumption of cancer occurrence as a Poisson-distributed variable. **Results** were also stratified by age group of person-time (categorized into 0-19 and >20 years of age).

Results: A total of 5,108 JIA patients were studied. The mean age at cohort entry was 8.9 years (standard deviation, SD 5.0). The majority were female (68.0%) and the sample was predominantly Caucasian, reflecting the source populations. The most common JIA subtype was oligoarticular. The mean duration of follow-up (time from cohort entry to end of follow-up) was 6.7 years, resulting in 34,224 patient-years of observation.

During total follow-up, 9 invasive cancers were observed, compared to 10.1 expected, for an over-all SIR of 0.89, 95% CI 0.41-1.69. Three of these were hematological (1 Hodgkin's lymphoma, 1 Non-Hodgkin lymphoma, and 1 leukemia). For all hematological malignancies, the SIR was 1.33 (95% CI 0.27-3.88).

When stratifying SIR estimates, for the 0-19 age group, seven cancers occurred, for an SIR of 1.69 (95% CI 0.68-3.48) for all cancers and a SIR of 2.01 (95% CI 0.41-5.87) for hematological cancers.

Conclusion: Our study is one of the largest examining the relationship between malignancy risk and JIA. Cancer was a relatively infrequent outcome, and most of the cancers observed occurred during the years when patients were aged 0-19 years. Further follow-up over time, of the subjects in this JIA cohort, would be necessary to capture accurately cancer risk for JIA in the adult years.

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects I: Juvenile Idiopathic Arthritis

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

Treatment of juvenile idiopathic arthritis (JIA) has greatly changed in the past 15 years thanks to the introduction of biologic agents but little is known on the long-term safety profiles.

Methods:

Pharmachild is an ongoing, multicenter, non-interventional, retrospective/prospective observational registry of patients with JIA treated with either methotrexate (MTX) alone or in combination with one or more biologic agents as part of their standard clinical care. Three treatment groups of patients were considered: MTX only (± other synthetic DMARD or corticosteroids), MTX followed by 1 biologic agent (1Bio±MTX) and treated with more sequentially given biologic agent (>1Bio±MTX). For the purpose of the analysis we divided drug exposure into 3 phases based on the starting date of each drug: MTX phase (11239 PY), 1 bio (9158 PY), > 1 bio (2814 PY). Safety was re-coded by certified assessors according to the Medical Dictionary for Regulatory Activities (MedDRA). True incidence rate events x100 patient-years (PY) for events of special interest (ESI) or at least moderate other adverse events (AE) were calculated for all MedDRA System Organ Class (SOC).

Results:

5862/7250 (81%) of the JIA patients in the database for a total of 23211 PY, were analyzed. There were 601 (10%) systemic, 1198 (20%) oligo persistent and 865 (15%) oligo extended, 2042 (35%) poly RF neg and pos and 1156 (20%) other JIA categories. Out of 5862 JIA patients, 1674 (23%, median disease duration, DD 4 years) were treated primarily with MTX (no biologics), 3025 (42%, DD 6 years) with 1 Bio±MTX (66% etanercept, 18.5% adalimumab, infliximab/tocilizumab 5% each) and 1163 (16%, DD 8 years) with >1Bio±MTX (30% etanercept, 27% adalimumab, 14% infliximab, 9% tocilizumab).

The incidence rates (Table) of AE increase with the addition of at least 1 biologic agent (10.7, 13.9, 19.5). A similar trend was observed for infections (2.9, 4.6, 4.8) and serious infections rates (0.7, 1.4, 2.0). Incidence rates for injury, poisoning and procedural complications (such as infusion/injection related reaction) and blood and lymphatic system (such as MAS) were higher in the group treated with more than 1 biologic agent. Incidence rates for gastrointestinal and hepatobiliary disorders (e.g. Hypertransaminasaemia) were higher for the MTX only group when compared to the other 2 (1.7, 0.9, 0.5).

Conclusion:

The introduction of one or more sequential biologic agent increase the rate of adverse events, infection and serious infections, when compared to the treatment with MTX alone. This risk can be 3 times higher during the use of a second or further biological.

Session Date: Sunday, November 8, 2015

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects I: Juvenile Idiopathic Arthritis

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Gut microflora influences the development and homeostasis of the immune system. Dysbiosis has been reported in various immuno-inflammatory diseases. Pathogenesis of enthesitis-related-arthritis (ERA) category of JIA suggests an interaction between the gut and joints. Thus we studied the effect of probiotic therapy on immune and clinical parameters in children with ERA.

Methods: Forty-six children with active JIA-ERA were randomized to probiotic (VSL3 capsules) therapy or placebo along with NSAIDs for 12-weeks (CTRI/2012/08/002871). Patients, assessor and statistician were blinded to the allocation. Patients were assessed using a 6-point composite index of disease activity based on morning stiffness, joint count, enthesitis count, sacroilitis/inflammatory-back-pain, uveitis and ESR/CRP. Th1, Th2, Th17 and T-regulatory (Treg) cell frequencies were determined in blood using flow-cytometry. Cytokines IFNγ, IL4, IL17, IL10, TNFα and IL6 were measured in the serum by flow-cytometry using cytometric bead array (BD Biosciences) kit.

Results:

The average age of 46 children (44 boys) at enrollment was 15±2.5 year and duration of disease was 3.5±3 years. Most of the children were HLA-B27 positive (93.5%). All children had peripheral arthritis and 65% had associated enthesitis. 52% children had sacroilitis, 26% had inflammatory-back-pain, 9% had history of uveitis and 22% had a family member having spondyloarthritis.

There was no significant difference between the two groups at baseline. There were 2 dropouts in the probiotic-group while 4 in the placebo-group. There was a significant clinical response in both probiotic and placebo group after 12-weeks of therapy (Table) but probiotic group failed to show a significant clinical response compared to the placebo (Table). The immune parameters showed an increase in Th2 and IL-10 levels in placebo and a decrease in IL-6 with probiotics after 12 weeks (Table) but again the difference between the groups was significant only for IL10 levels (Table).

Adverse effects in the probiotic and the placebo groups were diarrhea (36 vs. 45%), abdominal pain (9 vs. 20%), minor infections (4.5 vs. 20%) and flatulence (23 vs. 15%) respectively. Two patients were withdrawn due to side effects 1 in placebo due to severe diarrhea and one in the probiotic-group due to tuberculosis.

Conclusion: Probiotic therapy in JIA-ERA children is well tolerated but failed to show any significant immunological or clinical effects over NSAID-therapy.

Table - Changes in Immune and clinical parameters in the probiotic (n=21) and the placebo groups (n=19). All values are expressed as median

with interquartile range, *p<0.05, **p<0.01 represent significance in the same group after 12 weeks. CI-ESR and CI-CRP – Composite index based on ESR and CRP respectively, PGI - patient reported global improvement, EMS – early morning stiffness, TJC – tender joint count, SJC – swollen joint count)

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects I: Juvenile Idiopathic Arthritis

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Methotrexate (MTX) is the most widely used disease modifying antirheumatic drug (DMARD) in JIA and regarded to be a safe drug, effective in around 70% of JIA cases. Therefore, strategies of withdrawing MTX therapy have become a challenging question.

Methods: Data from 1514 patients enrolled with MTX monotherapy in the national JIA biologic register BiKeR between 2005 and 2011 and prospectively observed into adulthood in the follow-up register JuMBO were considered for this analysis. Clinical characteristics, therapy, date and reasons for discontinuation of MTX were half-yearly reported by the treating physician. A recurrence of an active disease (AD) after attaining inactive disease (ID) under MTX monotherapy was defined as cJADAS-10 (Juvenile Arthritis Disease Activity Score) above five or the start of a therapy with MTX and/or a biologic DMARD. ID was defined as cJADAS-10 of lower or equal one. The time to recurrence of AD in patients withdrawing MTX due to ID was examined by a multivariable Cox-proportional hazard model.

Results: The mean age of the patients at JIA onset was 7.6 ± 4.6 years and their mean disease duration was 2.1 ± 2.8 years at inclusion in BiKeR. 27% had persistent oligoarthritis, 27% rheumatoid-factor (RF) negative polyarthritis and 68% were female. MTX was discontinued in 65% after a mean treatment duration of 2.0 ± 1.5 years during a mean follow-up of 3.5 ± 2.1 years. Reasons for MTX discontinuation were ineffectiveness including the switch to a biologic DMARD (23%), patients' request (16%), an adverse event (10%) and ID (20%). MTX was withdrawn due to ID (n=303) after a mean treatment duration of 2.3 ± 1.0 years. Among those, 172 (56.4%) experienced AD after 11.8 ± 14.9 months. Patients who had an ID for at least 12 months before discontinuation of MTX had a significantly lower recurrence rate of AD (49.4%, HR=0.67, p=0.013) than those with ID for at least 6 months (54.2%, HR=0.85, p=0.491) compared to those with ID for less than 6 months (61%) before drug discontinuation, respectively. Patients with systemic JIA (44.4%, OR=0.33, p=0.03) and patients with psoriatic arthritis (42.3%, OR=0.31, p=0.013) had the lowest recurrence of AD compared to patients with extended oligoarthritis having the highest recurrence rate of AD (70.5%).

Conclusion: Half of the patients had recurrence of active disease after MTX withdrawal, what confirms the high flare rate in JIA. Recurrence of active disease was less common in patients who spent at least 12 months in ID before MTX discontinuation, as compared to those with shorter time in ID before drug withdrawal. Thereafter, the rate of disease recurrence seems lower in prolonged MTX therapy.

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects I: Juvenile Idiopathic Arthritis

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

Systemic JIA (sJIA) in usual practice is commonly treated with several agents, including glucocorticoids (GC), methotrexate (MTX) and biologic agents, most commonly IL1 or IL6 inhibitors, which may be given alone or in combination with GC. The most effective treatment for new onset sJIA is not known. The Childhood Arthritis and Rheumatology Research Alliance (CARRA) developed standardized consensus treatment plans (CTPs) for new onset sJIA to study the comparative effectiveness of these treatments using an observational registry. A pilot study was conducted to assess the feasibility of using the CTPs for this purpose.

Methods:

New onset untreated sJIA patients (pts) enrolled in the CARRA Registry at one of 15 pilot sites were treated according to the CTP selected by the treating physician (GC alone; MTX ± GC; IL1 inhibitor (IL1i) ± GC; IL6 inhibitor (IL6i) ± GC). Deviations from the chosen CTP could occur for inadequate response at any time. If GC was started, the CTPs suggested an aggressive taper (<50% of the starting dose by 3 months). Data were collected at standard intervals consistent with usual practice and the primary outcome of clinically inactive disease (CID) and successful cessation of GC was assessed at the 9 month visit. The CTPs were compared using chi square, Fisher's exact, and Wilcoxon rank sum tests.

Results:

30 patients were enrolled and completed the study (Table). There were not major differences between patients in each CTP, but patients treated with GC CTP alone tended to be older, non-white, have oligoarthritis, and be more likely to have very high ferritin levels. 83% of the MTX CTP treated patients had physicians who reported that they always select this treatment, as did 42% of the patients in the IL1i CTP. The study outcome was achieved by 37% of patients overall. No patients in the GC or MTX CTP achieved the study outcome, while 42% and 60% in the IL1i and IL6i CTPs did, respectively. There were 2 serious adverse events; both were infections that occurred while receiving IL1i. There were 2 episodes of macrophage activation syndrome: 1 each in IL1i and IL6i CTPs. All patients recovered.

Conclusion:

The CARRA sJIA CTP pilot study was successfully completed. The patients enrolled appeared reasonably balanced at baseline. The study outcome was achieved by 37% of patients treated with a biologic, and by none treated with GC alone or MTX. Having demonstrated feasibility of the CTPs, additional patients will be enrolled as part of a larger comparative effectiveness study to determine the most appropriate treatment strategy for new onset SJIA.

Table: sJIA Patients Enrolled in CTP Pilot Study and their Outcomes

Characteristic	GC	MTX	IL1i	IL6i	Total	p value
N	2	6	12	10	30

Session Title: Pediatric Rheumatology - Clinical and Therapeutic Aspects I: Juvenile Idiopathic Arthritis

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Efficacy and safety of canakinumab (CAN) in systemic juvenile idiopathic arthritis (SJIA) have been demonstrated in two phase III trials.[1] In these trials, over 60% of the patients (pts) had received a previous biologic and were switched to CAN for either lack of efficacy or safety reasons and may be more refractory to another biologic therapy. Here, we examine CAN efficacy in CAN-naïve SJIA pts, previously exposed to anakinra (ANK) and tocilizumab (TCZ).

Methods: This was an open-label extension study with details reported earlier.[2] Adapted (a) ACR 30/50/70/90/100 responses with CAN were assessed at Day 29 and 12 months. Pts with prior exposure to ANK or TCZ exposure were compared to biologic naïve pts. Reasons for discontinuation of ANK and TCZ were recorded and safety noted.

Results: Among the 123 pts considered in this analysis, 51 pts (42%) previously received ANK and 31 (25%) TCZ, respectively. The main reason for ANK/TCZ discontinuation was lack of efficacy (ANK, 21%; TCZ, 21%). At Day 29, aACR 30/50 response rates were similar for both ANK-naïve pts and those who discontinued ANK for lack of efficacy(Table); aACR30 but not aACR50 response rates were slightly higher in ANK-naïve vs those who discontinued ANK for lack of efficacy. In the TCZ-exposed pts, aACR 30 response rates were comparable at Day 29 in TCZ naïve pts vs those who discontinued TCZ for lack of efficacy. At month 12, aACR 50 response rates were higher in pts who discontinued TCZ due to lack of efficacy vs TCZ naïve pts.

Table. Percentage of patients with adapted JIA ACR (aACR) response* at Day 29 and Month 12

	Exposure to Biologics, Anakinra							
	Day 29, n (n/m %)				Month 12, n (n/m %)			
	Group 1 (N=26)	Group 2 (N=12)	Group 3 (N=13)	Group 4 (N=72)	Group 1 (N=26)	Group 2 (N=12)	Group 3 (N=13)	Group 4 (N=72)
	m=21	m=12	m=13	m=68	m=18	m=7	m=8	m=52
aACR 30	18 (86)	10 (83)	12 (92)	58 (85)	16 (89)	7 (100)	8 (100)	50 (96)
aACR 50	16 (76)	10 (83)	12 (92)	52 (77)	16 (89)	7 (100)	8 (100)	46 (89)
	Exposure to Biologics, Tocilizumab							
	Day 29, n (n/m %)				Month 12, n (n/m %)			
	Group 1 (N=26)	Group 2 (N=3)	Group 3 (N=2)	Group 4 (N=92)	Group 1 (N=26)	Group 2 (N=3)	Group 3 (N=2)	Group 4 (N=92)
	m=25	m=3	m=2	m=84	m=21	m=3	m=2	m=59
aACR 30	21 (84)	3 (100)	2 (100)	72 (86)	20 (95)	3 (100)	2 (100)	56 (95)
aACR 50	18 (72)	2 (67)	2 (100)	68 (81)	20 (95)	3 (100)	1 (50)	53 (90)

*aACR response =ACR response level plus absence of fever; n= number of patients who satisfy the criteria; m=number of patients with an assessment in the time period; If a patient has more than one assessment in the time period, their last value is taken

Group 1: Patients who discontinued anakinra/tocilizumab due to lack of efficacy; Group 2: Patients who discontinued anakinra/tocilizumab for safety/tolerability reasons; Group 3: Patients who discontinued anakinra/tocilizumab due to other reasons; Group 4: Never exposed to anakinra/tocilizumab

Conclusion: There is a comparable initial and 12 month aACR-JIA response to CAN among SJIA patients who switched from ANK or TCZ due to lack of efficacy compared to those without previous use. These results support the consistent efficacy of CAN across different patient subtypes and demonstrate efficacy in prior biologic non-responders.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis I

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Previously, T helper (Th) cell subsets have been regarded as irreversibly differentiated endpoints. However, evidence suggests that Th cell differentiation is a plastic process in response to certain (e.g. inflammatory) conditions. Mechanisms leading to the pathogenetic important predominance of Th17 cells in rheumatoid arthritis (RA) are not yet understood. Therefore, we investigated plasticity and underlying molecular mechanisms to address the question if an altered T cell plasticity contributes to the shift towards the Th17 phenotype in RA.

Methods: A unique cohort of 40 patients with early, active and untreated RA (to exclude effects of immunosuppressive drugs on T cells) and 41 age- and sex- matched healthy controls (HC) were studied. Viable *in vivo*-originated Th1, Th2 and Th17 cells were FACS-sorted and trans-differentiated under Th1-, Th2- or Th17-inducing conditions. The cytokine Th profile of the trans-differentiated cells was assessed by flow cytometry. Epigenetic modifications including histone modifications and DNA methylation of Th cell-associated cytokine and transcription factor gene loci were analyzed by ChiP assay and bisulfite sequencing. Relative expression of cytokine and transcription factors were measured by ELISA and qRT-PCR.

Results: Th17 cells from RA patients cultured under Th1 and Th2 conditions showed a strikingly diminished trans-differentiation capacity into both Th1 and Th2 phenotypes and retained their IL-17 expression to a significantly higher degree compared to Th17 cells from HC. Vice versa, RA Th1 and Th2 cells demonstrated an enhanced capacity to re-differentiate into Th17 cells. We found higher *RORC* expression in RA Th1 cells that were trans-differentiated under Th17 conditions as a basis for increased re-differentiation of Th1 to Th17 cells in RA. With regard to epigenetic regulation, less permissive histone modifications H3K4 methylation and H3 actetylation over the repressive H3K27 methylation was found in the *Tbx21* locus of RA Th1 cells consistent with the shift from Th1 to Th17 cells. Moreover, DNA methylation of the IL-17 gene promoter was decreased in RA Th17 cells compared to HC enabling higher IL-17 expression.

Conclusion: Our data indicate that *in vivo*-originated Th17 cells from RA patients are resistant to changes in their phenotype, whereas other Th subsets are prone to Th17 cell trans-differentiation. Increased RORC expression, less DNA methylation at the IL-17A gene, and less permissive histone modifications of the Tbx21 gene might contribute to the altered Th plasticity in RA, thereby contributing to the pathogenic Th17 shift.

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis I

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

RA is associated with shared epitope (SE)+ HLA-DRB1 alleles, including HLA-DRB1*0401, and development of anti-citrullinated protein autoantibodies. The preferential binding of citrullinated vimentin to HLA-DRB1*0401 and the correlation between disease activity and the frequency of citrullinated vimentin-specific T cells suggest that citrullinated vimentin selects and expands antigen-experienced T cells in SE+ RA patients. TCR diversity is generated through gene rearrangement, insertions and deletions of the genes encoding the Vα and Vβ chains. TCR Complementarity Determining Regions (CDR) interact directly with peptide-HLA (pHLA). If selection bias has occurred as a result of TCR-pHLA interactions, different individuals may share a similar TCR repertoire to a given pHLA. While deep sequencing synovial tissue has demonstrated oligoclonality, the antigens recognised by these clones are unknown. To obtain more direct evidence that presentation of citrullinated-vimentin shapes the repertoire in SE+ individuals, we profiled TCR repertoire diversity among single vimentin(59-71)cit-64-specific CD4+ T cells.

Methods: Single vimentin(59-71)cit-64-specific CD4+ T cells were sorted from peripheral blood mononuclear cells (PBMC) of 8 HLA-DRB1*0401+ RA patients and 6 HLA-DRB1*0401+ healthy controls (HC), based on staining with fluorescent pHLA tetramers. Sorted cells were simultaneously analysed for expression of CD25 and CD127. At sampling, 2 of the 8 patients had been treated for 18 and 41 months, respectively, 1 had recent-onset untreated RA and 5 had recent-onset RA. PBMC were collected pre- and 1-9 months post-treatment with disease modifying anti-rheumatic drugs. Paired TCR TRAV and TRBV sequences were analysed using multiplex, nested PCR and sequencing.

Results:

A total of 486 vimentin(59-71)cit-64-specific CD4+ T cells with productive TRAV and TRBV sequences were analysed from 8 patients and 6 HC (255 TRAV and 370 TRBV from RA patients; 97 TRAV and 116 TRBV from HCs). Among these T cells, the repertoire encoding TCRα and TCRβ was highly diverse in all patients and HC, and included a large number of unique CDR3 sequences. However, TCR usage in the epitope-specific population differed between RA patients and HC. In RA patients, TRAV26-1 (8%) and TRBV20-1 (13%) predominated while in HC, TRAV13-2 (12%) and TRBV20-1 (12%) were dominant. We did not observe preferential usage in the length of CDR3α or CDR3β. Repeated sequences of individual clonotypes were observed in 3/8 RA patients, but in none of the 6 HC. This oligoclonality was present in pre- and post-treatment samples, and in some cases the same sequences were observed in the same individual across time-points. The repeated sequences were exclusively derived from CD25+CD127+ effector CD4+ T cells.

Conclusion: These data demonstrate a wide range of possible TCRs available for recognition of the vimentin(59-71)cit-64 epitope in PB CD4+ T cells of RA patients and HC. While CD4+ T cells recognising citrullinated self-antigens are present in RA patients and HC carrying HLA-DRB1*0401, repeated clonotypic sequences only among RA patients suggests selective citrullinated self-antigen-driven oligoclonal effector T cell expansion in disease.

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis I

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Lung disease has been associated with elevations of RA and Sjogren's-related autoantibodies (Abs), even in the absence of extrathoracic features of these diseases (Fischer 2010). In particular, in classifiable RA organized ectopic lymphoid tissue in the lung has been associated with RA related Abs (Rangel-Moreno 2006). Herein we examine the association of Abs and lung histopathology in subjects with RA lung disease, as well as subjects with non-RA lung disease.

Methods: Using materials from the NIH's Lung Tissue Resource Consortium (LTRC) we evaluated lung tissue and matched serum samples from 75 subjects with lung disease who for clinical care required lung biopsy: 10 subjects with RA and interstitial lung disease (ILD), and 65 subjects with ILD or emphysema in absence of RA based on evaluation at the time of lung biopsy. Serum was tested for Abs CCP3.1, RF isotypes IgA, IgM and IgG, and SSA and SSB. Lung tissue was evaluated by microscopy (H&E) to determine the presence of organized ectopic lymphoid tissue defined as germinal centers (GCs) by a pulmonary pathologist blinded to subjects' Ab status. Multivariate analyses were used to determine associations of Abs and GCs.

Results: The patients' characteristics grouped based on the presence of GCs are presented in the Table. RA was significantly associated with the presence of GCs, and there was a trend towards increasing age being inversely associated with GCs; smoking was not associated with the presence of GCs. In analyses adjusting for RA and age, serum positivity for CCP3.1 was strongly associated with the presence of GCs (OR 4.1, 95% CI 1.2-14.4; p=0.03). In adjusted analyses there were no significant associations with RF's or SSA/B with GCs as single Abs; however, an increasing number of positive Abs was associated with GCs. Specifically, for every increase by 1 in number of serum Abs (+), there was a 60% increase in risk of having GCs (OR 1.6, 95% CI 1.1-2.4; p=0.03).

Conclusion: In this unique sample set from the LTRC, we confirm a strong relationship between serum Abs and the presence of organized ectopic lymphatic tissue/GCs in the lung, even after adjusting for the presence of clinically apparent RA. The strongest associations were observed for anti-CCP and increasing total number of Abs. The findings suggest a mechanistic link between GCs in the lung and circulating Abs, and in particular anti-CCP, that may be due to in-situ generation of Abs within GCs in the lung or that circulating Abs perpetuate the immune response by forming organized lymphoid tissue in the lung. Future studies should assess these potential mechanisms as well as evaluate the potential that Abs may be a marker for lung GCs that could be used to understand disease prognosis and response to treatment.

Table. Characteristics of subjects with and without germinal centers			
	Germinal Center (+) N=16	Germinal Center (-) N=59	p-value
Age, median (range)	53 (40-73)	63 (40-80)	0.06
Female (%)	63%	56%	0.78
Non-Hispanic White (%)	75%	78%	0.20
Ever smoker (%)	75%	73%	1.00
Rheumatoid arthritis diagnosis (%)	**31%**	**9%**	**0.03***
Autoantibodies			
RF-IgA	25%	15%	0.46
RF-IgM	**44%**	**10%**	**<0.01***
RF-IgG	38%	24%	0.34
CCP3.1	**56%**	**22%**	**0.01***
SSA	13%	7%	0.60
SSB	6%	2%	0.38
Antibody Count	**1.5 (0-5)**	**0 (0-6)**	**<0.01***
*In analyses adjusted for age and diagnosis of RA, CCP3.1 positivity and Antibody Count were significantly associated with the presence of Germinal Centers; however, RF-IgM was not. For CCP3.1 adjusted OR 4.08, 95% CI 1.16-14.37; p=0.03. For Antibody Count adjusted OR 1.59, 95% 1.06-2.40; p=0.03.

Neutrophil Extracellular Traps Are Not Only Targets for ACPA-Positive IgG from Rheumatoid Arthritis Patients but Also Directly Trigger Pro- and Anti-Inflammatory Effects Partly Mediated By the C1q Complement Protein

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis I

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Activated neutrophils (PMN) form neutrophil extracellular traps (NET). Those structures are expelled chromatin fibers composed of DNA and associated proteins. The process, NETosis, is dependent on citrullination, and has been suggested to be pathogenic in rheumatoid arthritis (RA). RA is characterized by the production of anti-citrullinated protein autoantibodies (ACPA) which are specific for the disease. Although RA PMN show enhanced NETosis and RA autoantibodies recognize NET, the potential pathogenic mechanisms triggered by NET are not elucidated. Therefore, we have analyzed the antigenic and inflammatory properties of NET in RA.

Methods: PMN and monocytes were purified from the blood. We have used primary cells freshly isolated from 115 independent healthy donors and RA patients. IgG were purified from healthy donors, from ACPA-positive RA patients and from ACPA-negative patients with rheumatic diseases. Monocytes were differentiated into macrophages by culturing in the presence of M-CSF. Cell purity and IgG binding were estimated by flow cytometry. NETosis was induced *in vitro* by PMA on adherent PMN and was analyzed by fluorescence microscopy, together with IgG

binding. To produce soluble NET, NET were detached from glass by mild nuclease digestion. They were enriched, quantified by fluorescence and spectrophotometry, and characterized by SDS-PAGE and agarose gel. Macrophages/PMN were cultured with soluble NET in the presence/absence of LPS, IgG, NH_4Cl or C1q. C1q receptor expression and cell activation were estimated by flow cytometry and by measuring cytokine secretion by ELISA.

Results: Only low binding of IgG was observed by flow cytometry on untreated freshly isolated PMN. Upon NETosis, a strong recognition by ACPA+ IgG was observed, specifically on the NET structures, as demonstrated by fluorescence microscopy. The NET staining with ACPA from RA patients was stronger than with ACPA-negative IgG in 15 out of 19 experiments (79 %; $p < 0.05$) and normal NET were as antigenic as RA NET. Soluble NET activated both steady-state macrophages and PMN, leading to IL-8 secretion and CD11b up-regulation, independently of ACPA+ IgG. The stimulatory activity of soluble NET on macrophages was increased in the presence of C1q, whereas PMN activation was not influenced by inhibition of endosomal acidification. Soluble NET from both healthy donors and RA patients induced cell activation and have similar immuno-modulatory properties. Likewise, both PMN and macrophages from healthy donors and RA patients responded to soluble NET. On the contrary, soluble NET specifically inhibited LPS-induced IL-6 secretion by macrophages.

Conclusion: ACPA+ IgG from RA patients strongly and specifically recognize NET and not untreated PMN. NET are antigenic and possess both pro- and anti-inflammatory properties depending on the cell type, the activation level and the presence of co-factors like C1q or high expression of its receptors but independently of endolysosomal activity or ACPA. Therefore, an excess of NETosis rather than altered NETosis may be pathogenic in RA and trigger ACPA. This is probably the largest analysis comparing RA/normal NET on RA/normal cells reported so far.

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis I

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Anti-citrullinated protein antibodies (ACPA) are the main autoantibody system in rheumatoid arthritis (RA), and due to high sensitivity and specificity testing using the anti-CCP2 assay is the gold standard in RA diagnosis. Citrullinated proteins are formed when arginine residue(s) are converted to citrulline residue(s) by peptidylarginine deiminase (PAD) enzymes. Five known human PAD isoforms (PAD1-4 &6) catalyse citrullination constitutively in numerous healthy tissues, and the process is essential for many pathways. It is unknown what causes the breach of tolerance to these native proteins. Periodontitis (PD) is a known risk factor for RA, and there is increasing evidence that the link between the two diseases is due to citrullination by a unique prokaryotic PAD enzyme expressed by the keystone PD pathogen *Pophyromonas gingivalis* (PPAD). PPAD and mammalian PADs have distinct substrate specificities and low sequence homology, thus making PPAD a prime candidate for inhibition. However, the precise mechanism by which PPAD could generate potentially immunogenic peptides has remained controversial due to lack of information about the structural and catalytic mechanisms of the enzyme. By solving the 3D structure of PPAD we aim to characterize activity and elucidate potential mechanisms involved in breach of tolerance to citrullinated proteins in RA.

Methods: A library of PPAD clones was synthesized, expressed and purified from *E.coli*. Candidates for crystallization were identified based on high solubility and activity. A highly active clone $tPPAD^{WT}$ was identified and crystallized, alongside a catalytically inactive mutant $tPPAD^{C351A}$ of corresponding sequence- with the exception of a single amino acid substitution within the active site- and their 3D crystal structures solved. Both enzymes were crystallized with bound arginine containing ligands. Key residues identified from 3D structures were examined by mutations. Fibrinogen and α-enolase were incubated with $tPPAD^{WT}$ and *P.gingivalis*arginine gingipain (RgpB) and citrullinated peptides formed were sequenced and quantified by mass spectrometry.

Results: Here, we solve the crystal structure of a truncated, highly active form of PPAD, and confirm catalysis is mediated by the following residues: Asp130, His236, Asp238, Asn297 and Cys351. In addition, we identify Arg152 and Arg154 as involved in substrate binding, and using a number of mutations demonstrate they may determine the substrate specificity of PPAD for C-terminal arginines. We show RA autoantigens are

favorable substrates for PPAD and demonstrate the formation of 37 C-terminally citrullinated peptides from fibrinogen and 11 from α-enolase following incubation with $tPPAD^{WT}$and RgpB.

Conclusion: PPAD displays an unequivocal specificity for C-terminal arginine residues not shown by mammalian PAD2 or PAD4. PPAD readily citrullinates peptides from key RA autoantigens to form novel peptides, which could be involved in the breach of tolerance to native citrullinated peptides in RA. The lack of sequence homology to mammalian PADs makes PPAD and ideal target for inhibition, and this high-resolution crystal data presented here could pave the way for this.

Session Title: Rheumatoid Arthritis - Human Etiology and Pathogenesis I

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose *:* In rheumatoid arthritis (RA) a biological hypothesis has been proposed linking smoking with citrullination, the development of anti-citrulline autoimmunity and anti-citrullinated protein antibodies (ACPA) and subsequently RA[1]. The fact that smoking is associated with several autoantibodies in other autoimmune diseases raised the question if in RA smoking is solely associated with ACPA or with autoantibodies in general.

Objectives*:* To investigate if in patients with RA, smoking is specifically associated with ACPA or with the presence of other autoantibodies as well.

Methods *:* Patients from three independent early arthritis cohorts were used: the Leiden Early Arthritis Clinic (n=767), the British Norfolk Arthritis Register (n=761) and the Swedish Better Anti-Rheumatic Fharmaco Therapy cohort (n=795). All patients fulfilled the 1987 RA criteria and had symptom duration of less than two years. Smoking (ever versus never) and autoantibody status: rheumatoid factor (RF), ACPA and anti-carbamylated protein antibodies (anti-CarP), were determined at inclusion into this studies. A meta-analysis was performed calculating odds ratios and 95% confidence intervals to assess the association between number of autoantibodies and smoking, using 2x2 comparison with seronegative RA patients as reference category. In the Leiden EAC, interaction between smoking and shared epitope (SE) was assessed using the three measures of biological interaction: relative excess risk due to interaction, the attributable proportion due to interaction and the synergy index.

Results: There was no significant association between smoking and seropositive RA in patients who were positive for one autoantibody only (n=406). However, smoking was significantly associated with double (n=429) and triple autoantibody-positivity (n= 606) (figure 1). Furthermore, interaction measures between smoking and SE were not significant for patients with one autoantibody, partly significant for patients with two autoantibodies, whereas all three measures were significant in the triple-positive group (table 1).

Conclusion: Smoking and the interaction between smoking and SE is not solely associated with ACPA-positive RA, but with the concurrent

presence of all three RA-associated autoantibodies. These data indicate that current hypotheses on the role of smoking in the pathophysiology of RA may need to be refined by taking the presence of other auto-antibodies into account.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis-Small Molecules, Biologics and Gene Therapy I: Biologics

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: TNF and IL-17 independently contribute to the pathophysiology of rheumatoid arthritis (RA) acting synergistically to induce mediators of inflammation and joint destruction. Selective dual neutralization of TNF and IL-17 confers superior protection vs inhibition of either alone in mouse arthritis models. ABT-122 is a novel dual variable domain immunoglobulin (DVD-Ig™) targeting both human TNF and IL-17A and is hypothesized to provide greater clinical responses in patients with RA.

Objective: Investigate safety, tolerability and exploratory pharmacodynamics of multiple doses of ABT-122 in subjects with stable RA

Methods: Two Phase 1, placebo-controlled, multiple dose studies randomized 43 subjects with stable RA while receiving stable doses of methotrexate (7.5–25 mg/wk). Subjects were subcutaneously administered either one of 4 dose regimens of ABT-122, 1 mg/kg every other week (4 doses), or 0.5, 1.5, or 3.0 mg/kg weekly (8 doses); or placebo and evaluated through 45 days following last dose. Serum samples for a panel of inflammation markers, and chemokines based on preclinical studies with dual TNF and IL-17 neutralization, were collected at baseline through day 92 and analyzed by multiplex assays.

Results: No clinically significant safety findings were observed in subjects with RA. Rates of treatment-emergent AEs were similar in ABT-122 and placebo treatment groups with no evidence of a dose response. There were no AE or serious AE trends, systemic hypersensitivity reactions

or dose limiting toxicities with ABT-122. Infections, consistent with expectations in RA, were reported with no apparent patterns related to etiology, type, or dose in rates with ABT-122 vs placebo and no subject discontinued the study due to infection. There were no clinically significant laboratory, vital sign, or ECG abnormalities. For CXCL9 and CXCL10, rapid decreases relative to placebo occurred within 3d of ABT-122 administration (−25% and −30% from baseline for CXCL9 and CXCL10, respectively). Maximal decreases occurred by d15 (−60% and −45% for CXCL9 and CXCL10, respectively) and persisted through 14d after last dose. Serum CCL23 also decreased following ABT-122 with maximal decreases (−30%) at d64 and continued through d92. Consistent with anti-TNF inhibition, soluble E-selectin levels decreased following ABT-122 , persisting through d92 for the 3.0 mg/kg group.

Conclusion: ABT-122 demonstrated a well tolerated safety profile in subjects with RA through 8 weeks of dosing up to 3 mg/kg, consistent with previous observations in the first-in-human study in healthy subjects. Because CXCL9, CXCL10, and CCL23 are involved in lymphocyte and myeloid cell recruitment into inflamed tissues, decreases in these chemokines indicate that ABT-122 rapidly modulates potential pathophysiologic pathways in RA patients, with evidence for persistent effects after cessation of dosing. These results suggest that dual neutralization of TNF and IL-17 may provide an opportunity to control inflammation and its clinical manifestations in RA subjects and in other immune-mediated inflammatory diseases.

Session Title: Rheumatoid Arthritis-Small Molecules, Biologics and Gene Therapy I: Biologics

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

Early stages of rheumatoid arthritis (RA) may provide a therapeutic window in which biologic agents are most effective.[1] C-EARLY (NCT01519791) is a phase 3 study in DMARD-naïve patients (pts) with severe, active, progressive RA assessing efficacy and safety of certolizumab pegol (CZP)+MTX vs placebo (PBO)+MTX treatment in inducing and maintaining sustained clinical response and inhibiting radiographic damage.

Methods:

Pts in this multicenter double-blind randomized study had RA <1 year since diagnosis at baseline (BL) fulfilling the 2010 ACR/EULAR criteria; ≥4 swollen and ≥4 tender joints; DAS28(ESR)≥3.2; CRP≥10 mg/L and/or ESR≥28 mm/hr, rheumatoid factor or ACPA positive. 879 pts were randomized 3:1 to CZP (400 mg at Weeks [Wks] 0,2,4, 200 mg every 2 wks to Wk52)+MTX or PBO+MTX Q2W. MTX was initiated at 10 mg/wk and increased to 25 mg/wk by Wk8; the maximum tolerated dose per pt (optimized dose) was maintained to Wk52 in both treatment arms. Pts who could not tolerate ≥15 mg/wk MTX by Wk8 were withdrawn. Sustained DAS28(ESR) remission (sREM), defined as DAS28[ESR]≤2.6 at both Wk40 and Wk52, was the primary endpoint; sustained low disease activity (sLDA), defined as DAS28[ESR]≤3.2 at both Wk40 and Wk52, was a key secondary endpoint. Secondary efficacy variables included in the hierarchical testing were ACR50 response at Wk52, change from BL in HAQ-DI at Wk52 and change from BL at Wk52 in van der Heijde modified total Sharp score (mTSS). Pts with and without rapid

radiographic progression at Wk52 (defined as change from BL mTSS>3 or >5 based on linearly extrapolated scores)[2] were assessed post hoc.

Results:

BL characteristics were balanced between arms (Table A). 96.5% pts had high disease activity (DAS28[ESR]>5.1), median diagnosis time was 2.6 months.[3]

All hierarchical endpoints were statistically significant (Table B); 28.9% of CZP+MTX vs 15% of PBO+MTX in sREM ($p<0.001$); 43.8% of CZP+MTX vs 28.6% of PBO+MTX in sLDA ($p<0.001$). Approximately 3 times more pts progressed rapidly by >3 and >5 mTSS points in PBO+MTX vs CZP+MTX (23.3% vs 7.4% and 15.3% vs 4.2%). AE incidence rates were similar for both arms. Infections were higher with CZP+MTX vs PBO+MTX (71.8 vs 52.7/100 pt-yrs), but similar for serious infections (3.3 vs 3.7/100 pt-yrs). 2 deaths were reported with CZP+MTX (1 stroke, considered not related to study drug; 1 systemic tuberculosis, considered related to study drug); 1 with PBO+MTX (respiratory failure, considered not related to study drug). No new safety signals for CZP were reported.

Conclusion:

CZP+MTX treatment of DMARD-naïve pts with active, severe, progressive RA resulted in a greater proportion of pts in sREM and sLDA; greater improvements in RA signs and symptoms; and inhibition of structural damage vs PBO+MTX. Safety profile of CZP+MTX was similar to PBO+MTX.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis-Small Molecules, Biologics and Gene Therapy I: Biologics

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: GM-CSF mediates a range of immunological processes, such as stimulating the production of inflammatory mediators and differentiation of proinflammatory T-helper 17 cells, and may play an important role in the pathogenesis of inflammatory diseases including RA. Namilumab (AMG203) is an investigational monoclonal antibody with high affinity for the GM-CSF ligand. The aim of this Phase Ib study (PRIORA; NCT01317797) was to evaluate the safety and tolerability, pharmacokinetics/pharmacodynamics and preliminary efficacy of namilumab in patients with active RA.

Methods: This was a double-blind, placebo-controlled, randomised, dose-escalating study in patients with mild-to-moderate RA (according to ACR 1987 revised criteria) receiving stable MTX doses for ≥12 weeks prior to randomisation. Patients received 3 single subcutaneous injections of namilumab 150 or 300 mg or matching placebo on Days 0, 15 and 29, with 12 weeks' follow-up. Clinical efficacy was an exploratory endpoint and originally measured by DAS44; a pre-defined *post hoc* efficacy analysis was performed to evaluate the effect of namilumab on signs and symptoms of RA using DAS28, swelling joint counts, tender joint counts, and patient outcome measures.

Results: 24 patients were enrolled (71% female, mean age 55.9 years): Cohort 1 (n=13; namilumab 150 mg, n=8; placebo, n=5); and Cohort 2 (n=11; namilumab 300 mg, n=7, placebo, n=4). Disease activity at baseline was moderate (mean DAS28-ESR: placebo = 4.7; namilumab 150 mg = 4.9; namilumab 300 mg = 4.4). Namilumab was generally well tolerated. A total of 49 treatment-emergent adverse events (TEAEs) were observed in 14 patients (58%). The most common TEAEs were nasopharyngitis (n=4; 17%), exacerbation/worsening of RA (n=3; 13%) and musculoskeletal pain (n=2; 8%). The percentage of patients with any TEAE was similar (namilumab 150 mg: 63%; namilumab 300 mg: 57%; placebo: 56%). There was no evidence of immunogenicity. Median time to maximum observed plasma concentration (t_{max}) after the third dose of namilumab was 5–6 days. Dose-normalised exposure (C_{max}/D and AUC_{tau}/D) was similar at both namilumab dose levels. Accumulation was ongoing after the third injection (Day 43), as expected given the observed mean $t_{1/2}$ of ~3 weeks. The *post hoc* efficacy analysis included 21 patients (1 patient on namilumab 150 mg and 2 patients on placebo were excluded due to major protocol violations). In general, improvements in DAS28 scores (ESR and CRP) and joint counts were greater with namilumab than placebo as early as Day 29. Both namilumab groups were associated with greater improvements in DAS28-CRP than placebo from Day 27 until the end of the study. Furthermore, the difference in mean DAS28-CRP changes from baseline between namilumab and placebo favoured namilumab at all time points.

Conclusion: Results of PRIORA show that namilumab was generally well tolerated in active RA and preliminary efficacy was demonstrated; further evaluation is needed due to the small sample size. Two Phase II studies have been initiated in patients with moderate-to-severe RA (NEXUS, NCT02379091; TELLUS, NCT02393378).

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis-Small Molecules, Biologics and Gene Therapy I: Biologics

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: The investigational agent sarilumab is a human mAb directed against the IL-6 receptor. The phase 3 MOBILITY study (NCT01061736) evaluated the efficacy and safety of Sarilumab in combination with MTX in RA patients with inadequate response to MTX.[1] The objectives of the phase 3 TARGET study were to evaluate efficacy and safety of addition of sarilumab to non-biologic DMARD(s) (csDMARDs) in patients (pts) with active RA.

Methods: Adults with active, moderate-to-severe RA with inadequate response or intolerance to ≥1 TNF inhibitor(s) were randomized to placebo (Pbo) (n=181), sarilumab 150 mg q2w (n=181), or sarilumab 200 mg q2w (n=184) subcutaneously + background csDMARD(s) for 24 wks of treatment in a double-blind fashion. Pts who did not respond adequately to treatment, starting at wk 12, were rescued with sarilumab 200 mg q2w. Coprimary endpoints were proportion of pts achieving ACR20 response at wk 24 (nonresponder imputation) and change from baseline in HAQ-DI at wk 12 (before rescue for inadequate response). Pts were stratified by region and number of previous anti-TNFs.

Results: Baseline demographic and disease characteristics (intention-to-treat population, n=546) were balanced among treatment groups. A significantly greater proportion of pts receiving either dose of sarilumab achieved ACR20 responses and significantly improved HAQ-DI scores (Table). Similar observations were made in the proportion of ACR50, ACR70, and HAQ-DI responders (HAQ-DI ≥0.22 improvement) at wk 24.

	Placebo + csDMARD (n=181)	**Sarilumab 150 mg q2w + csDMARD (n=181)**	**Sarilumab 200 mg q2w + csDMARD (n=184)**
Primary endpoints			
ACR20 at week 24, %	34	56	61
P value vs placebo		<0.0001	<0.0001
Change from baseline in HAQ-DI at week 12, mean (SD)	-0.29 (0.54)	-0.50 (0.64)	-0.49 (0.56)
P value vs placebo		0.0007	0.0004
Other endpoints			
ACR50 at week 24, %	18	37[a]	41[a]
ACR70 at week 24, %	7	20[b]	16[b]
HAQ-DI ≥0.22 at week 24, %	35	48[b]	56[a]
q2w, every 2 wks; SD, standard deviation. [a]*P*<0.0001 vs placebo. [b]*P*<0.025 vs placebo (to adjust for multiplicity, *P* values <0.025 are considered statistically significant).			

Treatment-emergent adverse events (TEAEs; safety population, n=546) were more frequent in sarilumab groups (66% and 65% in sarilumab 150 mg q2w and 200 mg q2w vs 50% in Pbo). Although incidence of SAEs was higher than Pbo (3.3%) in the sarilumab 200-mg q2w group (5.4%), they were similar to Pbo in the 150-mg q2w group (3.3%). Infection was the most frequently reported SAE. The most frequent events leading to treatment discontinuation were infection and low absolute neutrophil count (ANC). ANC <1.0 Giga/L was observed in 9.8% of pts in the sarilumab 200-mg q2w group, 7.7% in the sarilumab 150-mg q2w group, and 0.6% in the Pbo group and was not associated with serious infection. Laboratory abnormalities included elevations in lipids and transaminases. One death due to a car accident occurred in the Pbo group.

Conclusion: In this phase 3 study, sarilumab demonstrated efficacy in pts with active RA who were inadequate responders or intolerant of anti-TNFs, as evidenced by improvements vs Pbo in signs and symptoms of RA and in physical function. TEAEs leading to treatment discontinuation were more frequent in the sarilumab-treated groups. SAEs were more frequent in the sarilumab 200-mg q2w group. Laboratory findings were consistent with IL-6 blockade and observations from the MOBILITY study.

Session Title: Rheumatoid Arthritis-Small Molecules, Biologics and Gene Therapy I: Biologics

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: The investigational drug sarilumab is a human mAb directed against the IL-6 receptor. In previous studies, sarilumab + MTX demonstrated efficacy in patients (pts) with moderate-to-severe RA and was generally well tolerated.[1] Sarilumab and tocilizumab have the same mechanism of action. Two studies, Study 1309 (NCT02097524) and ASCERTAIN (NCT01768572), described the safety and tolerability of sarilumab and tocilizumab in adults with RA.

Methods: In the 6-wk Study 1309 (N=101), adult RA pts on background MTX were randomized 1:1:1:1 to receive a single dose of sarilumab 150 mg subcutaneously (SC), sarilumab 200 mg SC, tocilizumab 4 mg/kg intravenously (IV), or tocilizumab 8 mg/kg IV. In the 24-wk ASCERTAIN study (N=202), RA pts on background DMARDs with inadequate response to or intolerant of TNF antagonists were randomized 1:1:2 to sarilumab 150 or 200 mg SC every 2 wks or tocilizumab every 4 wks starting at 4 mg/kg with an increase to 8 mg/kg if needed, based on clinical response.

Results: Study 1309 and ASCERTAIN enrolled RA patients who were predominantly female (>80%), with a mean age of 55 and 52 yrs, respectively. In ASCERTAIN, 61% of pts on tocilizumab increased their dose from 4 to 8 mg/kg during the treatment period; 42% of pts increased their dose at wk 4. Incidence of treatment-emergent adverse events (TEAEs) was similar for the sarilumab and tocilizumab groups in each study (Table). Upper respiratory tract infections and neutropenia were among the most frequently reported TEAEs. Laboratory changes in both studies included increases in lipids and transaminases and decreases in neutrophil counts. Mean changes in absolute neutrophil count (ANC) in the sarilumab groups were within the ranges observed in tocilizumab groups. There was no association between decreased ANC and incidence of infection. Study 1309 demonstrated that time to onset for decreased ANC and magnitude of decrease were comparable across the sarilumab and tocilizumab groups for all doses (Figure).

Conclusion: Overall, there was no clinically meaningful difference between the treatment groups with regards to clinical adverse events. Laboratory changes noted in the sarilumab groups were within the same range as those noted in the tocilizumab groups. Differences in incidence of ANC <1.0 Giga/L between the sarilumab and tocilizumab groups in ASCERTAIN may reflect differences in dosing interval and sampling schedule.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis-Small Molecules, Biologics and Gene Therapy I: Biologics

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

In autoimmune diseases reduced numbers and functional impairment of regulatory T cells (Tregs) have been observed (1). Tregalizumab (BT-061) is a humanized, anti-CD4 mAb, inducing selective Treg activation in vitro. Previous trials suggested efficacy in RA at doses ≥25 mg subcutaneously (SC). In a population PK/PD analysis, down-modulation of CD4 expression was identified as a biomarker to monitor CD4 target engagement in humans.

Methods:

This two-part, Phase 2b randomized controlled trial (RCT) included subjects with active RA for ≥6 months despite MTX (≥15mg/wk), with ≥6/28 TJC, ≥6/28 SJC and elevated CRP or ESR. Subjects were randomized to receive 25 mg, 100 mg, 200 mg, or PBO once-weekly SC injection + MTX over 24 wks. Primary endpoint was ACR20 at wk 12. At wk 12 (end of Main part I), non-responders were re-randomized to active treatment or higher doses. Subjects responding at wk 24 (end of Main part II) could extend treatment for an additional 24 wks. A data safety monitoring board (DSMB) was established for safety evaluation throughout the study.

Results:

Of 321 subjects enrolled from Europe, USA, Canada, Russia and Mexico, 37 (11.5%) withdrew at ≤ wk 12. Demographics and baseline disease characteristics were well balanced across groups: mean SJC and TJC 16 and 24, respectively; CRP 11.7 mg/L, DAS (ESR) 6.58 and HAQ-DI 1.56. ACR20 responders at wk 12 (42.3%/47%/44.3% vs. 35.2% in 25 mg, 100 mg, 200 mg groups and PBO, respectively), ACR20 responders at wk 24 and secondary endpoints did not differ significantly between tregalizumab groups and PBO. However, dose dependent modulation of CD4 expression on T cells occurred rapidly with BT-061 treatment, as predicted from previous analyses.

Through wk 12, TEAE (39.4% and 37.5%) and serious TEAEs rates (2.1% and 1.3%) were similar between BT-061 and PBO. For responder at wk 24, TEAEs (48.3% and 52.3%) were similar between BT-061 and PBO. Serious TEAEs were only reported in BT-061 treated subjects (2%). Three deaths occurred considered unrelated to treatment (car accident, acute coronary syndrome, death of unknown cause in a war area). There was no difference in infections between tregalizumab and PBO. One serious infection (peritonitis) occurred at wk 22 in the 25 mg dose group. Apart from acute coronary syndrome with fatal outcome, no further MACE events, Tuberculosis, opportunistic infections nor malignancies were reported.

Figure

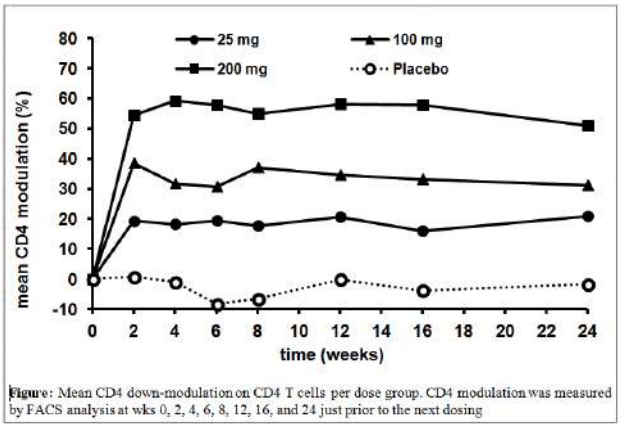

Figure: Mean CD4 down-modulation on CD4 T cells per dose group. CD4 modulation was measured by FACS analysis at wks 0, 2, 4, 6, 8, 12, 16, and 24 just prior to the next dosing

Conclusion:

No tested doses of tregalizumab demonstrated significant efficacy improving signs and symptoms of active RA based on ACR20 responses at wk 12 and 24 despite dose dependent down-modulation of CD4 expression. Tregalizumab was generally well tolerated.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment: Treatment of AS

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Anterior uveitis is a relatively frequent extra-articular manifestation in ankylosing spondylitis (AS), with a prevalence of 25.8% in a recent meta-analysis. TNF inhibitor (TNFi) treatment has been shown to reduce the rates of uveitis in this patient group. Some studies have suggested a greater protective effect with the anti-TNF monoclonal antibodies infliximab (IFX) and adalimumab (ADA) than with etanercept (ETN). Our objective was to study the effect of ADA, ETN or IFX treatment on occurrence of anterior uveitis in a cohort of patients (pts) with AS.

Methods: Data on AS pts starting ADA, ETN or IFX as their first TNFi from Jan 2003 through Dec 2010 were extracted from the Swedish Biologics Register ARTIS (follow-up data available through Dec 2011). Data on anterior uveitis, available from Jan 2001, were obtained by linkage to the National Patient Register as visits to an ophthalmologist with ICD-10 codes indicating anterior uveitis (H20, H22.1). We applied two main analytical approaches: (1) Comparison of uveitis rates (per 100 patient-years) before TNFi start (follow-up time pre-Rx 2-10 yrs) and during TNFi treatment for each TNFi, analysing (by Poisson regression): (a) total numbers of uveitis visits, (b) uveitis flares defined by a 60-day penalty from the index visit of one uveitis flare for a new flare to be counted, and (c) uveitis flares defined by a 90 day penalty from last uveitis flare follow-up visit for a new flare to be counted. (2) Cox regression analysis comparing hazard of first uveitis flare for ADA, ETN or IFX in a subgroup of pts who were uveitis-free during the 2 yrs before TNFi start, +/- adjustment for potential confounders (age, sex, prescription year, level of education, disease duration, presence of IBD, baseline CRP and use of DMARD co-medication, prednisolone and NSAIDs).

Results: 1365 AS pts were included (406 ADA, 354 ETN, 605 IFX). IFX pts more often used DMARD co-medication; ADA pts had lower baseline CRP. ADA was more frequently used towards the end of the study period. IFX doses tended to be lower than 5 mg/kg (at baseline/last registration 62%/50% used <=200 mg). A clear reduction in uveitis rates was observed for ADA, a slight reduction for IFX and a marked increase for ETN, irrespective of the method for counting flares (Table). 1127 pts were uveitis-free 2 yrs prior to TNFi start and included in the Cox regression analyses. In the adjusted analysis ADA and IFX were superior vs. ETN (Table).

Conclusion: In this large register-based study of AS pts we found reduction in uveitis rates with ADA treatment, a slight reduction with IFX and increased rates with ETN. In a subgroup free of recent uveitis, ADA and IFX were associated with significantly lower hazard for first uveitis flare than ETN. Potential caveats of this study include residual confounding, the relatively low doses of IFX used, reporting bias, and the possibility that the required uveitis-free period for pts included in the Cox regression analysis was too short.

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment: Treatment of AS

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: In MEASURE 2 (NCT01649375), subcutaneous (s.c.) secukinumab, an anti–interleukin-17A antibody, improved the signs and symptoms of ankylosing spondylitis (AS) through 16 weeks (wks) of therapy.[1] Here we report the long-term (52 wk) efficacy and safety of secukinumab in this study.

Methods: 219 patients (pts) with active AS, classified by modified New York criteria, despite therapy with NSAIDs, were randomized to s.c. secukinumab 150 or 75 mg or placebo (PBO) at baseline, Wks 1, 2, and 3, and every 4 wks from Wk 4. At Wk 16, PBO-treated pts were re-randomized to receive secukinumab 150 or 75 mg s.c. every 4 wks. The primary endpoint was the proportion of pts achieving an ASAS20 response at Wk 16. The secondary endpoints were ASAS40, hsCRP, ASAS 5/6, BASDAI, SF-36 PCS, ASQoL, and ASAS partial remission. Primary and secondary endpoints were assessed through Wk 52 using a non-responder imputation (binary variables) and mixed-model repeated measures analysis (continuous variables). A predefined hierarchical hypothesis testing strategy was used in statistical analyses at Wk 16 to adjust for multiplicity of testing.

Results: Overall, 181 pts (82.6%) completed 52 wks of treatment. ASAS20 response rates at Wk 16 were 61.1% with secukinumab 150 mg vs 28.4% with PBO (P=0.0001). Secukinumab 150 mg also significantly improved ASAS40, hsCRP, ASAS 5/6, BASDAI, SF-36 PCS, and ASQoL at Wk 16 vs PBO. Clinical responses with secukinumab 75 mg did not reach statistical significance for any of the pre-specified endpoints based on hierarchical testing. Improvements with secukinumab 150 mg were sustained through Wk 52 (Table). Using a more conservative estimate of efficacy with non-responder imputation, ASAS20/40 response rates with secukinumab 150 mg at Wk 52 were 62.5/48.6%; rates with observed data were 73.8/57.4%. ASAS20/40 response rates in pts originally randomized to PBO who received secukinumab 150 mg at week 16 (n=34) were 70.6%/52.9% at Wk 52 (non-responder imputation). Over the entire study period, exposure-adjusted SAE rates (mean secukinumab exposure: 425.8 days; mean PBO exposure: 107.6 days) were 6.6, 7.7, and 14.0. per 100 pt-years with secukinumab 150 mg, 75 mg, and PBO, respectively. The most common SAEs were infections; no pt discontinued therapy due to an infection. Three pts on secukinumab had a Candida infection (1 on 150 mg and 2 on 75 mg), 1 had a fatal myocardial infarction (75 mg), 2 had AEs of Crohn's disease (1 on 150 mg [de novo] and 1 on 75 mg [flare]), and 1 had an AE of uveitis (150 mg). There were no suicidality-related AEs with secukinumab.

Conclusion: Secukinumab 150 mg s.c. provided sustained improvements over 52 weeks in the signs and symptoms of AS, reducing inflammation, and improving physical function and health-related quality of life. Secukinumab was well tolerated; safety findings were consistent with previous reports.

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: An analysis of radiographic progression in an observational cohort has suggested that anti-TNF therapy lessens radiographic progression, especially when treatment is introduced within 5 years of AS onset, although development of new syndesmophytes was not reported[1]. We aimed to assess the impact of anti-TNF therapy on radiographic progression in an observational cohort of AS by analyzing propensity-matched patients.

Methods: In the FOllow-up Research Cohort in AS (FORCAST), 374 patients with AS from Northern Alberta attending community and academic rheumatology practices have been assessed over a mean follow up of 3.1 years for clinical and laboratory outcomes every 6 months, and had spinal radiography at baseline and follow up. Patients received standard (n=147) or anti-TNF therapy (n=227). Radiographs were scored by two readers using the mSASSS with adjudication by a third reader according to pre-specified rules. The impact of anti-TNF therapy was assessed using univariate and multivariate Tobit regression for mSASSS data and Poisson regression for development of new syndesmophytes. Propensity matching was based on a caliper of 0.1 in a logistic model using age, gender, disease duration, smoking, mSASSS, and pre-treatment BASDAI and CRP. Multiple propensity score analysis based on multinomial logistic regression was used to compare treatment groups according to disease duration before start of anti-TNF. Missing values were imputed using the multiple imputation by chained equations (MICE) method.

Results: Subjects were predominantly males (74.9%) of mean (SD) age 43.0 (11.9) years, mean (SD) disease duration 21.4 (11.6) years, mean (SD) baseline mSASSS of 17.1 (18.4), mean (SD) radiographic progression of 0.97 (1.31) mSASSS unit/year, and 38.4% developed a new syndesmophyte. After propensity matching using baseline covariates 218 and 230 patients could be included in the post-match analysis of mSASSS progression and new syndesmophytes, respectively. These numbers were 158 and 190, respectively, after tighter matching using pre-treatment covariates. In univariate analyses of propensity-matched cases, significant predictors were baseline mSASSS and pre-treatment,ASDAS for mSASSS progression, and baseline mSASSS and age for new syndesmophyte. In the final multivariable Tobit and Poisson regression models using propensity-matched data, only pre-treatment ASDAS was a significant predictor of mSASSS progression (β=0.40 [95%CI: 0.08-0.72]; p=0.014). Multiple propensity score adjusted analyses demonstrated significantly less radiographic progression in patients who received anti-TNF within 5 years of disease onset versus those on standard therapy or treated with anti-TNF after >10 years of disease (Table).

Conclusion: A beneficial effect of anti-TNF treatment may be evident in AS patients receiving treatment within 5 years of disease onset.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment: Treatment of AS

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Conflicting results have been demonstrated in axial spondyloarthritis (axSpA) with regard to whether effectiveness of a second (2°) TNFi depends on the reason of discontinuation of the first (1°) TNFi.

Methods: Patients with a clinical diagnosis of axSpA initiating a 2° TNFi in the Swiss Clinical Quality Management (SCQM) cohort were included. 2° TNFi drug maintenance and the proportion of patients achieving a moderately active or inactive disease state according to defined Ankylosing Spondylitis Disease Activity Score (ASDAS) cut-offs at 1 year (±6mo) were compared by the reason of discontinuation of the 1° TNFi (primary or secondary lack of response (PLR or SLR, defined as discontinuation of the 1° TNFi due to insufficient effectiveness before or after 6 months, respectively), adverse events (AE) or other reasons). LUNDEX values were used to indicate the proportion of patients adhering to treatment and achieving a response criterion.

Results: A 2° TNFi was started in 591 patients after inclusion into SCQM. Drug retention of 2° TNFi stratified by the reason of discontinuation of the 1° TNFi was significantly reduced after PLR in comparison to all other reasons of discontinuation, log-rank $p<0.001$ (Figure 1). Median (IQR) drug retention after PLR and SLR were 0.94 (0.58; 2.13) and 3.92 (2.46; 3.20) years, respectively. The proportion of patients achieving an ASDAS <2.1 and <1.3, respectively, in patients still on treatment (n=384) with complete follow-up visits at 1 year (n=176) are shown in Table 1. Response rates were slightly lower in patients having previously experienced PLR and AE in comparison to SLR and highest in patients having switched due to “other” reasons (e.g. remission, personal preferences). These differences were partially more pronounced after LUNDEX adjustment. An ASDAS<1.3 was reached by 2-12% of patients following a previous PLR, SLR or AE.

Conclusion: Previous PLR is associated with a strongly reduced retention of the 2° TNFi. Only a minority of patients on a 2° TNFi having previously experienced PLR, SLR or AE achieve an inactive disease state at 1 year. These findings might help guiding treatment choices after discontinuation of a 1° TNFi, as new treatment options with other modes of action will be available.

Figure 1. Retention of 2nd TNFi by the reason of discontinuation of the 1st TNFi

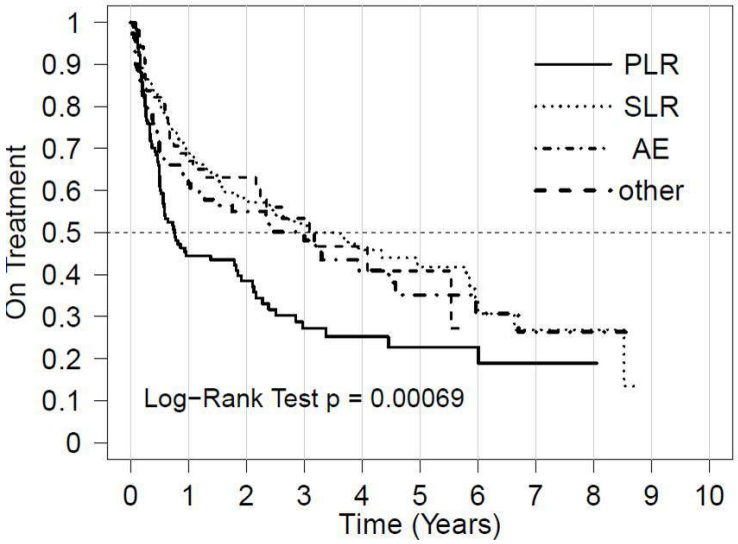

Table 1. Proportion of patients on a second TNFi achieving a moderately active or inactive disease state after 1 year (with and without LUNDEX adjustement of treatment responses for drop-outs). #Fisher's test; µNon-parametric permutation test.

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment: Treatment of AS

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Psoriatic arthritis (PsA) is a chronic immune-mediated inflammatory disease associated with psoriasis which includes peripheral arthritis, enthesitis, dactylitis, and spondylitis manifestations. Ixekizumab, under investigation for PsA treatment, is an IgG4 monoclonal antibody that binds with high affinity and specificity to the proinflammatory cytokine IL 17A.

Methods: In a phase 3 trial, 417 biologic disease-modifying antirheumatic drug (bDMARD)-naive patients with active PsA were randomized to up to 24 weeks of placebo (N=106); adalimumab 40 mg (N=101) once every 2 weeks (Q2W; active control); or ixekizumab 80 mg Q2W (N=103) or Q4W (N=107) following 160 mg initial dose at Week 0. Endpoints included American College of Rheumatology 20 response (ACR20) at Week 24 (primary), ACR50, ACR70, a 75/90/100% improvement in Psoriasis Area and Severity Index (PASI 75/PASI 90/PASI 100), Disease Activity Score (28 joint count) based on C-reactive protein (DAS28-CRP), Leeds Dactylitis Index (LDI-B) and Enthesitis Index (LEI), Health Assessment Questionnaire – Disability Index (HAQ-DI), and Van der Heijde modified Total Sharp (mTSS) score at 12 and 24 weeks. Efficacy variables were evaluated using the intent-to-treat population. Continuous data were evaluated using mixed-effects model for repeated measures. Categorical data were compared using a logistic regression model with missing values imputed by non-responder imputation, which treats inadequate responders as non-responders.

Results: A total of 382 patients completed 24 weeks of the study. A significantly greater percentage of patients treated with ixekizumab 80 mg Q2W or Q4W achieved ACR 20, ACR50, ACR70 and PASI 75/90/100 responses than with placebo at 12 and 24 weeks ($p<.01$) (Table 1). Both ixekizumab groups experienced significantly greater reductions than placebo for measures of dactylitis (LDI-B) at 12 and 24 weeks but not for enthesitis (LEI). Disease activity (DAS28-CRP) and functional disability (HAQ-DI) improved and inhibition of radiographic progression of joint structural damage (mTSS) was demonstrated with both ixekizumab doses compared to placebo ($p<.025$). Efficacy results with adalimumab versus placebo were significant on most measures, thus validating the study design. At 24 weeks, the incidence of treatment-emergent adverse events (TEAE) was greater ($p<.05$) and the rate of serious adverse events was higher ($p>.27$) with ixekizumab and adalimumab compared to placebo. Discontinuation due to a TEAE was similar across groups. No deaths occurred.

Conclusion: In bDMARD-naive patients with active PsA, ixekizumab showed significant, clinically meaningful improvements of disease activity and physical function, reduction in dactylitis, greater skin clearance of plaque psoriasis, and inhibition of structural progression. Ixekizumab was well tolerated with no unexpected safety findings.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment: Treatment of AS

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

Previously it was shown that non-steroidal antiinflammatory drugs (NSAIDs) given continuously reduce radiographic progression compared to an on demand therapy over 2 years in patient with ankylosing spondylitis (AS). A similar effect was found in an analysis from a prospective AS cohort (GESPIC). In the current study we tested whether such an effect of NSAIDs could be confirmed in another prospective randomized trial.

Methods:

AS patients were randomized to be treated with either continuous (at least 50% per day of the maximum dose of 150 mg) or on demand diclofenac for 2 years. Switching to another NSAID was possible in case of side effects or inefficacy. Eligible patients had active disease that justified the start or continuation of an NSAID and had no contraindications for an NSAID therapy. TNF-blockers were not allowed during the whole study period. Primary outcome was the difference in the increase of radiographic progression in the spine measured by the mSASSS, scored by two readers blinded to treatment arm and time point.

Results:

62 of 85 patients enrolled in the continuous arm (mean age 42 years, BASDAI 4.2, CRP 8.4 mg/l, disease duration 12.2 y, 74% male, mSASSS 11.3, HLA-B27 positivity 83.5%) and 60 of 82 enrolled in the on demand arm (mean age 44 years, BASDAI 4.5, CRP 12.9 mg/l, disease duration 15.2 y, 68% male, mSASSS 14.0, HLA-B27 84%) completed the study. Surprisingly, the mSASSS progression was numerically higher in the continuous group compared to the on demand group (1.28; 95%CI 0.68-1.92 vs 0.79; 95%CI 0.17-1.38 in the completer population), although this difference was not statistically significant (figure). When only patients were analysed who were CRP positive at baseline (54% cont., 58% demand) or had syndesmophytes at baseline (55% cont., 57% on demand), both known risk factors for radiographic progression, again there was numerically a higher radiographic progression in the continuous vs the on demand group: 1.68 vs 0.83 and 2.1 vs 0.89, respectively. We used the ASAS NSAIDs index (0-100) [3] to quantify NSAIDs intake over the 2 years, which was 75 (mean) for the continuous and 44 (mean) for the on demand group. At the end of year 2, 73% of the patients were still on diclofenac and had not switched to another NSAID. There were no differences between the 2 treatment groups regarding side effects: 19 serious adverse event occurred in the continuous group vs 19 in the on demand group.

Conclusion:

In our study continuous vs on demand treatment with diclofenac over 2 years did not prevent radiographic progression in AS. It is highly unlikely that the results would have been different with a higher number of patients because we found even a trend for less progression in the on demand group. Since 73% of patients were still on diclofenac at the end of the study we do not know whether other NSAIDs such as Celecoxib would have had a different effect on radiographic progression in our patients.

Session Title: Spondylarthropathies Psoriatic Arthritis - Pathogenesis, Etiology

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

Genes that differentiate patients with psoriatic arthritis (PsA) from those with psoriasis alone may serve as markers for the development of PsA in psoriasis patients. Psoriatic disease risk is strongly associated with variation within the HLA class I region. In this large-scale study we aimed to strengthen evidence about previously reported HLA risk alleles for PsA and to identify novel susceptibility markers to the disease.

Methods:

1677 PsA, 702 psoriasis without arthritis and 2275 healthy controls of European ethnicity from 4 sites in Canada, Ireland and Spain were included in the study. *HLA-B* and *–C* alleles were genotyped using sequence specific primers. Differences in allelic distribution for each *HLA* locus were compared using the Likelihood Ratio test by regression models with site indicator. The False Discovery Rate (FDR) approach was employed to assess the impact of multiple testing. Logistic regression analysis was performed to account for linkage disequilibrium between *HLA-B* and *-C* alleles. The association between amino acids encoded by the identified *HLA*genes and PsA was assessed using logistic regression analysis.

Results:

The following HLA alleles were confirmed as independent susceptibility markers of PsA in psoriasis patients in the multivariate analysis: *B*08* (Odds Ratio (OR) 1.48, p=0.002), *B*27* (OR 3.69, p=2.8x10^{-12}), *B*38* (OR 1.68, p=0.005), *B*39* (OR 1.80, p=0.01) and *C*06* (OR 0.47, p=6.8x10^{-13}). The following HLA alleles were confirmed as susceptibility markers for PsA in the general population: *B*27* (OR 2.37, p=2.5x10^{-13}), *B*38* (OR 3.81, p=2.5x10^{-13}), *B*39* (OR 2.17, p=9.5x10^{-6}), *B*57* (OR 2.06, p=3.6x10^{-7}) and *C*06* (OR 1.29, p=0.02). The frequency of the following alleles was reduced in PsA compared to healthy controls: *B*07*, *B*44*, *B*40*, *B*15*, *B*49*, *B*51*, *B*55*, *C*04* and *C*08*. PsA susceptibility was also associated with the presence of cysteine at position 67 (*B*27*, *B*39*, *B*38*), methionine at position 67 (*B*57*), aspartate at position 9 (*B*08*) and glutamine at position 45 (*B*08*, *B*39*, *B*38*, *B*27*). However, after inclusion of the specific *HLA* risk alleles these associations were not statistically significant.

Conclusion:

PsA susceptibility is associated with several *HLA* class I alleles. *HLA-B*38*, *B*39, B*08* and *B*27* confer an increased risk for PsA compared to psoriasis. In contrast, *HLA-C*06*, the strongest psoriasis susceptibility gene, is associated with a lower risk of developing PsA in patients with psoriasis.

Session Title: Spondylarthropathies Psoriatic Arthritis - Pathogenesis, Etiology

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

Genetic factors provide over 90% of the overall susceptibility to ankylosing spondylitis (AS) and recent studies have focused on non-major histocompatibility complex genes. The etiology of uveitis in AS has been suggested to involve two adhesion molecules including intercellular adhesion molecule (ICAM)-1 and leukocyte functional antigen (LFA)-1.

Platelet-endothelial cell adhesion molecule 1 (PECAM1) is a member of the immunoglobulin superfamily which is expressed on endothelial cells. There is emerging evidence that PECAM1 may be an important regulator of activation of lymphocytes. The β1 integrin (ITGB1) can associate with different membrane proteins and cause signal transduction by interactions in the extracellular and trans-membrane domain. Therefore, we examined the association of PECAM1 and ITGB1 gene polymorphisms with development of uveitis in patients with AS.

Methods:

We conducted a case–control study where 223 AS patients who met the Modified New York criteria and 239 ethnically matched controls were genotyped for 9 single nucleotide polymorphisms (SNPs) in the PECAM-1 promoter and gene. Genomic DNA was isolated from peripheral blood leukocytes by a standard phenol–chloroform method and a GoldenGate assay (Illumina, http://www.illumina.com) was used for genotyping.

Results:

Conditional logistic regression was used to evaluate the association between the PECAM1 or ITGB1 SNPs with susceptibility to AS, and no significant association was found on both genes. However, in the subgroup analyses between AS patients with uveitis and those without, seven SNPs in PECAM1 gene were associated with the presence of uveitis, including rs1050382 (dominant model (DM), p=0.022), rs2812 (recessive model (RM), p=0.013), rs4968721 (DM, p=0.016), rs6808 (DM, p=0.011), rs6809 (DM, p=0.013), rs9899806 (DM, p=0.013) and rs9913080

(DM, p=0.019). In addition, seven polymorphisms in ITGB1 gene including rs11009147 (DM, p=0.012; co-dominant model (CDM), p=0.034), rs17468 (DM, p=0.012; CDM, p= 0.019), rs2153875 (CDM, p= 0.030), rs2230396 (DM, p=0.012), rs2488330 (DM, p=0.004), rs3780871 (DM, p=0.031) and rs7079624 (RM, p=0.004) were associated with uveitis development.

Conclusion:

This is the first analysis of the PECAM1 and ITGB1 gene polymorphisms in AS, demonstrating a clear association with uveitis in AS. Larger studies are warranted to elucidate the association of PECAM-1 and ITGB1 in the pathogenesis of uveitis in AS.

Session Title: Spondylarthropathies Psoriatic Arthritis - Pathogenesis, Etiology

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

The IL-17 axis has been identified as a crucial pathophysiological pathway in spondyloarthritis (SpA). Targeting the IL-17 axis significantly suppressed inflammation and halted bone and cartilage destruction in clinical trials with secukinumab (anti-IL17A), brodalumab (anti-IL17RA),

and ustekinumab (anti-IL23/IL12p40) in ankylosing spondylitis and psoriatic arthritis. The potential impact of IL-17A inhibition on new bone formation, the major form of structural damage in SpA, remains unknown. Assessment of this feature requires large patient numbers treated for an extended period and appropriate control groups. Therefore, we aimed to assess the impact of anti-IL17A on new bone formation in a validated animal model of SpA.

Methods:

6 weeks old, orchiectomized, HLA-B27/huβ2m tg rats (23-1x283-2) were immunized with 45 µg heat-inactivated *M. tuberculosis*/IFA. Before the start of clinical symptoms, rats (n=6/group) were treated weekly with an anti-mouse/rat IL-17A antibody or IgG2a isotype control at 15mg/kg i.p for 5 weeks. Clinical measurements included weight, clinical scores for spondylitis and arthritis, and hind limb swelling (plethysmometry). After 6 weeks, rats were sacrificed for skeletal analysis by mCT imaging and histology.

Results:

In the control group, spondylitis and arthritis were observed in 100% of the rats at day 31 and day 19, respectively, after immunization. In contrast, only 83% and 33% of the anti-IL-17A treated rats developed spondylitis and arthritis at these time points. There was also a significant delay in the mean appearance of spondylitis (day 28 vs day 14; $p<0.05$) and arthritis (day 27 vs day 14; $p<0.05$) in treated versus control animals. Arthritis severity was lower in the anti-IL-17A-treated group compared to the controls, both by clinical scoring ($p<0.05$) and by plethysmometry ($p<0.05$). Quantitative analysis of structural damage by mCT of foot and ankle joints (figure 1) showed a significantly higher total bone volume in anti-IL-17A treated rats compared to controls (17% more, $p<0.05$), suggesting decreased bone loss. Moreover, the total volume of low density bone, reflecting newly formed bone, was significantly lower in the anti-IL-17A treated rats than in controls ($p<0.05$). Histological analysis confirmed a significant difference in structural damage in the peripheral joints, especially with respect to periosteal new bone formation, which was significantly less after anti-IL-17A treatment ($p<0.01$). In the axial joints there was a tendency towards less inflammation, destruction and new bone formation in the anti-IL-17A treated rats.

Conclusion:

IL-17A blockade significantly suppressed spondylitis and arthritis in the *M. tub*-induced diseased HLA-B27 tg rat model of SpA. Moreover, mCT data and histology indicated that IL-17A blockade also impacts structural damage, including pathological new bone formation.

Session Title: Spondylarthropathies Psoriatic Arthritis - Pathogenesis, Etiology

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: CD146, also called melanoma cell adhesion molecule (MCAM), is a cell surface adhesion molecule. A small minority of the T cell population also express MCAM. The ligand for MCAM is laminin 411. T cells expressing MCAM, are mainly responsible for IL17 production ex vivo. Furthermore, MCAM enriches for cells secreting IL-22 and IFN-γ. Thus, T cells expressing MCAM are uniquely capable of producing multiple cytokines responsible for psoriatic pathogenesis. Currently, CD4+ T cells with the capacity to secrete IL-17 (Th17 cells) have been viewed as a primary driver for psoriatic arthritis (PsA) and psoriasis; there are role for Th1 (IFN-γ) and Th22 (IL-22) T cells also. Thus it is likely that these pathologic CD4+T cells of psoriatic disease need to express CD146 for migration and localization at the disease site. Circulating CD146+ T cells have been reported to be elevated in several inflammatory diseases including in psoriasis; whether these cells play a role at the disease site of active inflammation in psoriatic arthritis remains unknown. **We hypothesized** that, in PsA, the synovial fluid and synovial tissue will be enriched with CD3+CD146+ T cells.

Methods: We studied synovial fluid mononuclear cells (SFMC), synovial tissues and psoriasis plaques from PsA (n=10) patients and have used osteoarthritis (OA) patients (n=10) as controls. Hi-D FACS studies were done to identify CD4+CD146+ and CD8+CD146+ T cells in the synovial fluid and PBMC of PsA patients. Double labeled IF study was done in synovial tissues from PsA patients and psoriasis plaques to identify CD3+CD146+ T cells.

Results: PsA patients showed significantly more CD4+CD146+ T cells in PBMC compared to OA (8 ± 2.8% vs 3.96 ± 0.6% respectively, p <0.01). Also SF of PsA had a significant higher level of CD4+CD146+ T cells (18 ± 3.1%; p <0.01) compared to PBMC. CD8+CD146+ T cells in PBMC and SFMC of PsA patients were <1%; CD146+ T cells were not identifiable in the SF of OA. CD146+ T cells were abundant within the psoriasis plaques and PsA synovial tissues and rare in non-lesional psoriatic skin.

Conclusion: 1. Here we observed that CD4+CD146+ T cells are enriched at the site of synovial inflammation in PsA (Fig 1). As CD146+ T cells are the primary source of the lesional Th-17 cytokines it is likely enrichment of these pathologic cells are critical for the disease process of PsA. 2. Also this opens up a new avenue for therapy of PsA and other autoimmune diseases. Rather than targeting individual cytokines, which often have redundant effects, targeting MCAM provides the possibility of the inhibiting the pathogenic cell itself, regardless of whether that cell is Th1, Th22 or Th17.

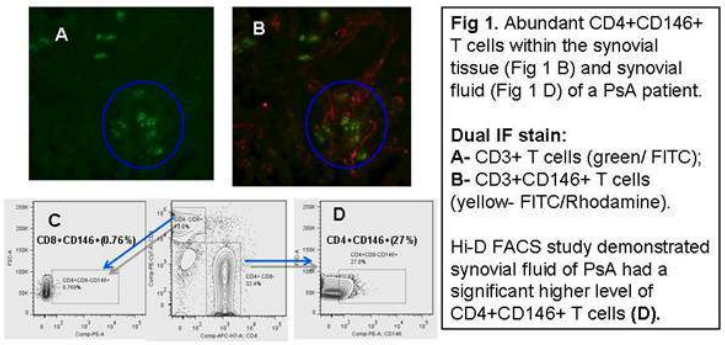

Fig 1. Abundant CD4+CD146+ T cells within the synovial tissue (Fig 1 B) and synovial fluid (Fig 1 D) of a PsA patient.

Dual IF stain:
A- CD3+ T cells (green/ FITC);
B- CD3+CD146+ T cells (yellow- FITC/Rhodamine).

Hi-D FACS study demonstrated synovial fluid of PsA had a significant higher level of CD4+CD146+ T cells **(D).**

Session Title: Spondylarthropathies Psoriatic Arthritis - Pathogenesis, Etiology

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: HLA-B27 (B27) confers a strong predisposition to spondyloarthritis (SpA), but accounts for < 25% of overall heritability of ankylosing spondylitis. Rats transgenic for HLA-B27 and human beta-2-microglobulin (B27-TG) develop SpA-like disease with gut inflammation and arthritis. Common variants in ERAP1, which trims peptide cargo for HLA class I molecules in the ER, have been associated with SpA in B27(+) and some B27(-) individuals, although the influence on heritability is much smaller than for B27. Protective variants have been associated with lower enzymatic activity and lower expression of ERAP1, although analysis of entire allotypes suggests that many AS patients express very active variants. The objective of this study is to determine how ERAP1 loss-of-function affects SpA-like disease in rats.

Methods: The first exon of the rat ERAP1 gene was edited using TALEN technology (Transposagen) causing a deletion of 29-nucleotides. The resulting frame-shift results in 3 in-frame stop codons in the first exon. ERAP1 protein expression was assessed by Western blotting, which revealed complete lack of detectable protein in ERAP1-/-, and about 50% expression in ERAP1+/- rats. ERAP1-/- or ERAP1+/- Sprague-Dawley (SD) rats (disease permissive background) were crossed with B27-TG Lewis rats to generate cohorts of B27-TG with ERAP1+/+, ERAP1+/-, and ERAP1-/- genotypes. B7-TG rats and WT rats with ERAP1+/+, +/- or -/- were used as controls. Rats were observed for arthritis, fecal scores and other disease manifestations for up to 6 months of age. Gut inflammation was accessed by histology score of gut collected from 2, 4 and 6 months old rats.

Results: B27+ males with either ERAP1+/+ or ERAP1+/- genotype developed arthritis with a frequency of 29% (5/17), and 36% (8/22), respectively, with comparable arthritis severity scores (2.0) and age of onset (4.1 months), whereas only 6.7% (1/15) of rats with an ERAP1-/- genotype developed arthritis (P=0.02). Only 13.4% of B27+ERAP1+/- females developed arthritis with arthritis score of 1.25, while ERAP1+/+ and ERAP1-/- females remained healthy. Furthermore, B7-TG and WT rats were healthy regardless of the ERAP1 genotype, except one WT ERAP1+/- male that developed arthritis. All B27+ rats developed gut inflammation as assessed by histology, with increased fecal scores, in animals that were ERAP1+/- or ERAP1-/- with an increase in frequency (i.e. 3/16 (19%) for ERAP1+/+, 6/16 (38%) for ERAP1+/-, and 3/9 (33%) for ERAP1-/-), and histology scores were slightly higher in the complete absence of ERAP1 .

Conclusion: Complete absence of ERAP1 protected B27-TG rats from arthritis, but led to an increase in gut inflammation, suggesting different effects on pathogenic mechanisms involved in arthritis and colitis. B27-TG rats heterologous for ERAP1 exhibited higher incidence of arthritis concomitant with lower inflammation in the gut as compared to ERAP1-/- .This novel model provides an opportunity to better understand the mechanism(s) by which HLA-B27 contributes to SpA pathogenesis

Session Title: Spondylarthropathies Psoriatic Arthritis - Pathogenesis, Etiology

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

Inflammation and new bone formation at entheseal sites are hallmarks of spondyloarthritis (SpA). As TNF inhibition has only limited impact on new bone formation, there is a clear need for new SpA targets.

Objectives: To assess the role of JAK-STAT inhibition in *in vitro* and *in vivo* models that mimic specific SpA aspects with special emphasis on entheseal inflammation and new bone formation.

Methods:

Mice with a specific deletion of A20 (inhibitor of the NF-kB signaling pathway) in myeloid cells ($A20^{myelKO}$) were administered tofacitinib twice a day for 14 days in one experiment and for 21 days in a second experiment. They were scored clinically and afterwards sacrificed for histopathological analysis. Reporter assays with STAT- and NF-kB dependent reporters were conducted in presence or absence of A20. Synovial fibroblasts of A20 deficient mice were stimulated with TNF and the ability of tofacitinib to modulate release of a number of proinflammatory mediators including IL-6, MMP-3, MMP-13 was monitored. Entheseal inflammation, cell proliferation and new bone formation leading to joint ankylosis was studied in the spontaneous arthritis model in aging male DBA/1 mice. Mice were treated with tofacitinib at week 10 of age and continued for 14 weeks and evaluated for clinical signs of arthritis bi-weekly. In addition the effect tofacitinib on inflammation associated new bone formation was studied in the collagen-antibody induced arthritis(CAIA) model. pSTAT3 expression was determined in injured human entheses and the effect of tofacitinib was evaluated in normal human MSC induced osteogenesis.

Results:

We found that the earliest signs of inflammation in $A20^{myelKO}$ mice occur at the synovio-entheseal complex of the hindpaws with clear signs of enthesitis. In addition to its previously described role as negative regulator of NF-kB, we found an inhibitory role for A20 on Stat-1 induction. pSTAT3 expression was demonstrated by IHC at injured human entheses. We therefore assessed the role of JAK-STAT inhibition with tofacitinib and found a profound reduction of enthesitis by histopathology ($p<0.05$). In addition, tofacitinib completely suppressed TNF induced release of known proinflammatory mediators such as IL-6, MMP-13 and MMP-3. In the spontaneous ankylosing enthesitis model we noticed a steady increase in incidence and severity in the control group, but the incidence was delayed in the tofacinitib treated groups in a dose-dependent way. Severity of disease was significantly different with the high dosage of tofacitinib compared to control mice. Furthermore, we observed a significant effect of tofacitinb on the amount of new bone formation in the resolution phase collagen antibody induced arthritis ($p<0.05$). However, no adverse effect of tofocitinib was evident during in vitro MSC osteogenic differentiation.

Conclusion:

Our results highlight the potential of JAK-STAT inhibition to modulate inflammation and new bone formation in SpA. Interestingly, enthesitis occurring in $A20^{myelKO}$ mice proceeds independently from TNF, which highlights that the effects of JAK-STAT inhibition also occur beyond TNF.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment I: Epidemiology and Prognosis

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is associated with an increased risk of mortality. However, recent mortality trends of SLE are unknown, particularly at the general population level. Our objectives were to assess mortality trends among SLE patients between January 1, 1997 and December 31, 2012 in a general population context.

Methods: Using an administrative health database from the province of British-Columbia, Canada (4.5 million), we identified all incident cases of SLE and up to 10 (3 were selected) non-SLE controls matched on sex, age, and calendar year of study entry, between 1997 and 2012. The SLE cohort was then divided in two cohorts based on year of SLE diagnosis (i.e., 1997-2004 and 2005-2012) to evaluate changes in mortality. We calculated hazard ratios (HR) for death using Cox proportional hazard model and the rate difference using an additive hazard model, while additionally adjusting for possible confounders (i.e. Charlson Comorbidity Index, number of outpatient visits, hospitalization, cardiovascular medications, glucocorticoids and NSAIDs at baseline).

Results: The early cohort (1997-2004) SLE patients had a considerably higher mortality rate than the late cohort (2005-2012) (i.e., 67.33 cases vs. 25.98 cases per 1000 person-years), as compared with only a moderate improvement in comparison cohorts between the two periods (11.39 to 7.23 per 1000 person-years, respectively). The corresponding absolute mortality rate differences were 40.3 (95% CI 33.0, 47.7) and 6.4 (95%CI 2.9, 9.9) cases per 1000 person years (p-value for interaction <0.001). The corresponding adjusted HRs for mortality were 3.95 (95% CI, 3.24, 4.83) and 2.41 (95% CI, 2.01, 2.89), respectively (p for interaction = < 0.001).

Conclusion: This population-based study shows that survival of SLE patients has improved over the past decade, suggesting the new treatments and improved management of the disease and its complications may be providing substantial benefits.

Application of New EULAR Definitions of Remission in SLE: Durable 1-Year Remission Is Rare

Theresa Fischer[1], Laurence S Magder[2] and Michelle Petri[3], [1]Charité-Universitätsmedizin, Berlin, Germany, [2]University of Maryland School of Medicine, Baltimore, MD, [3]Rheumatology, Johns Hopkins University Hospital, Baltimore, MD

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment I: Epidemiology and Prognosis

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

Developing definition(s) of remission in SLE is one of the primary recommendations on the research agenda of the treat-to-taget international task force. Definitions of remission were agreed upon by an international task force of the EULAR working group. We applied these definitions to a large clinical cohort to determine, time to remission, durability and predictors of remission.

Methods:

1555 patients with disease activity at cohort entry were followed until their first remission. 740 (48%) achieved remission. Of those who did not achieve remission, the median follow-up was 2.6 years. Remission was defined as clinical Systemic Lupus Disease Activity Index (SLEDAI) =

0, Physician Global Assessment (PGA) ² 0.5, prednisone ² 5 mg per day and no other immunosuppressants. Remission on treatment (ROT) was defined as SLEDAI = 0, PGA ² 0.5, prednisone ² 5 mg per day and allowance for immunosuppressive drugs. Hydroxychloroquine was allowed for remission and ROT. The Kaplan-Meier approach was used to estimate the time to remission. In addition, for patients on treatment, we identified variables that were predictive of remission at the next two visits.

Results:

Median time to remission was 2.8 years in women and 5.7 in men, median time to ROT was 1.3 years in women and 2.1 in men. Of those who satisfied the definition of remission, 52% had a relapse at a clinic visit within the next 90 days, and 15% more had a relapse from 90 to 180 days post remission (see table 1). Only 16% had a remission lasting over one year and only 2% over five years. Considering patients treated with immunosuppressives or prednisone greater than 5 mg/day at one visit, 2.8% successfully tapered treatment and achieved remission over the next two visits. Table 2 below shows rates of remission in various subgroups.

Conclusion:

50% of women and men with SLE achieve remission within 2.8 years and 5.7 years, respectively. However, most of them experience a relapse within the next 90 days. This reflects the relapsing-remitting nature of SLE for many patients. Remission and remisson on treatment are frequent in SLE. Durable remission is rare. Only 16% will have durability of more than one year. African-American ethnicity, anti-dsDNA and low complement predict against achieving remission. Our results provide further insights into the nature of remission in SLE and contribute towards applying the treat-to-target principle to SLE.

Table 1: Estimates of the distribution of duration of remission.

Duration of Remission	Probability
0-90 days	52%
90-180 days	15%
180-270 days	11%
270-365 days	6%
1-2 years	8%
2-5 years	6%
>5 years	2%

Session Date: Sunday, November 8, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment I: Epidemiology and Prognosis
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Lack of evidence-based recommendations about pre-emptive renal transplantation in systemic lupus erythematosus (SLE) patients with end stage renal disease (ESRD) may be unnecessarily delaying transplantation in these patients. We compared rates and factors associated with pre-emptive transplantation between incident ESRD patients with and without SLE enrolled in the United States Renal Disease Systems (USRDS).

Methods: There were 561,038 individuals in the US with new onset ESRD of any cause between 1/1/2005 and 12/31/2009**.** Adult patients with incident ESRD SLE 2005-2009 were identified from the ICD-9 code 710.0 for SLE in the Medical Evidence report. They were frequency matched by age, sex and race to 4,830 patients with incident non-SLE ESRD (type 1 diabetes, type 2 diabetes, hypertension, and other causes). Pre-emptive transplantation was defined as the initial renal replacement modality without any intervening dialysis. Multivariable logistic regression models, adjusted for socio-demographic factors and comorbidities, were used to compare the odds of pre-emptive renal transplantation in SLE and non-SLE, and to evaluate associated factors in each group.

Results:

4,830 SLE subjects and 4,830 matched non-SLE subjects were included in the final analysis. SLE patients were less likely to have atherosclerotic heart disease, congestive heart failure (CHF), peripheral vascular disease (PVD), and chronic obstructive pulmonary disease (COPD). The proportions of patients with past cerebrovascular accidents (CVA) or transient ischemic attacks (TIA) were similar (p=0.12). SLE patients were more likely to be employed, and to have private insurance.

The overall adjusted odds ratio of pre-emptive transplantation were similar in SLE and non-SLE: OR = 0.85 (95% CI: 0.67, 1.01), p=0.2. However, when comparing specific non-SLE causes of ESRD to SLE, the adjusted OR for pre-emptive transplantation was 0.19 (95% CI: 0.09, 0.42) for type 2 diabetes, 0.42 (95% CI: 0.23, 0.75) for hypertension, 1.67 (95% CI: 1.10, 2.54) in type 1 diabetes, and 2.06 (95% CI: 1.55, 2.74) for “others” (Table). Over 70% of all pre-emptive transplants were form living donors. The rates of pre-emptive transplantation were significantly higher among patients with pre-ESRD nephrology care. In contrast to non-SLE, younger SLE patients were less likely to receive a pre-emptive kidney transplant.

Conclusion: The odds of pre-emptive transplantation vary by ESRD cause. Improving pre-ESRD nephrology care and access to living donor transplants, as well as addressing disease-specific barriers to pre-emptive transplantation, may increase a likelihood of pre-emptive transplantation.

Table: Adjusted Odds Ratios (OR) and 95% Confidence Intervals (95%CI) from the Logistic Regression Model for Pre-emptive Transplantation among ESRD patients with and without SLE.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment I: Epidemiology and Prognosis

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

To study the factors associated with renal remission, relapse and renal function decline in patients with lupus nephritis treated with combined steroid and MMF or Tac.

Methods:

Data were extracted from a RCT of the efficacy of MMF vs Tac for induction treatment of lupus nephritis. All patients recruited were treated with high-dose prednisolone with either MMF (2-3g/day) or Tac (0.1-0.06mg/kg/day) for 6 months. Patients with good clinical response were shifted to azathioprine (AZA) for maintenance. Rescue therapies were given to patients who did not respond to induction. Factors associated with complete renal response (CR), relapse and renal function decline at 5 years were studied by regression analyses.

Results:

150 patients (92% women) with lupus nephritis were studied (Class III±V 36%; IVG/S±V 46; pure V 19%; age 35.5±12.8 years; SLE duration 50.2±62 months). At baseline, 59(39%) patients were hypertensive and 67% patients had CrCl <90ml/min. At 6m, 61% patients achieved CR, 24% had partial response (PR) but 15% patients had no response (NR). Logistic regression revealed that the baseline urine P/Cr ratio (OR 0.75[0.57-0.99]; p=0.04) and the presence of membranous feature on renal histology (OR 0.25[0.07-0.91]; p=0.04) were independently associated with CR at 6m. AZA maintenance was given to 59 (78%) MMF-treated (dose 82.5±24 mg/day) and 60 (81%) TAC-treated patients (dose 86.5±21 mg/day; p=0.32). Patients with NR were re-induced with CYC (N=20), low-dose combination of MMF and TAC (N=5), cross-over to TAC or MMF (N=6). After a follow-up of 60.8±26 months, proteinuric and nephritic renal flares occurred in 24% and 18% of patients treated initially with MMF and 35% and 27% in those treated with TAC, respectively. In patients who achieved CR or PR after initial treatment, Cox regression showed that the female sex (HR 10.9[1.19-101]; p=0.04), positive anti-dsDNA at month 6 (HR 4.95[1.64-14.9]; p=0.005) and the use of ACE inhibitor after 6 month (HR 8.86[1.28-61.2]; p=0.03) were independently associated with renal flares (proteinuric or nephritic). The cumulative incidence of a composite outcome of decline of CrCl by ≥30%, development of CKD stage 4/5 or death at 5 years was 21% in patients treated with MMF and 22% in those treated with TAC. Factors significantly associated with this outcome were first time lupus nephritis (HR 0.21[0.05-0.82]; p=0.03), creatinine clearance (CrCl) at 6 month (HR 0.97[0.95-0.99]; p=0.005) and the use of AZA maintenance (HR 0.23[0.49-4.30]; p=0.046). Repeat renal biopsy in 23 patients with renal flares showed that the increase in chronicity score was similar between the MMF (1.3±3.0) and TAC (1.8±2.0) groups of patients (p=0.42).

Conclusion:

Tac is non-inferior to MMF for induction therapy of lupus nephritis. More proteinuria at baseline and the presence of histological membranous features are unfavorably associated with good renal response after induction treatment. Female patients and persistent elevation of anti-dsDNA after induction therapy are associated with renal flares. Lower creatinine clearance at 6 months and the absence of AZA maintenance are associated with renal function deterioration after 5 years.

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment I: Epidemiology and Prognosis

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

Little is known about the long-term costs of lupus nephritis (LN). The annual and long-term healthcare costs were compared between SLE patients with and without LN.

Methods:

Patients from 32 centres in 11 countries were enrolled in the Systemic Lupus International Collaborating Clinics (SLICC) inception cohort within 15 months of diagnosis and provided annual data on renal function, hospitalizations, dialysis, and utilization of medications and selected procedures. LN was diagnosed by renal biopsy or fulfillment of the American College of Rheumatology (ACR) SLE classification criteria renal item. Renal function was also assessed annually based on estimated glomerular filtration rate (eGFR) or proteinuria (ePrU). Annual health resource utilization was costed using 2012 Canadian prices. Annual costs associated with renal function states were obtained from multiple regressions adjusting for age, race/ethnicity, disease duration, SLICC centre location, SLEDAI-2K and SLICC/ACR Damage Index (excluding renal components), and the SF-36. 5-year cumulative costs were estimated by determining annual costs associated with each renal function state and then forecasting the expected duration in each state. Durations were estimated using a relative risk regression model.

Results:

1645 patients participated, 89.2% females, 48.8% Caucasian, mean age at diagnosis 34.8 years (SD 13.4), mean disease duration at enrollment 0.5 years (SD 0.3), and mean follow up 6.1 years (SD 3.3). LN was diagnosed in 39.4% over follow up. Health resource utilization and annual costs (after adjustment using regression) were markedly higher in those with an eGFR < 30 ml/min or with LN (Table 1).

Table 1. Predicted Annual Health Costs Stratified by State of Renal Function

eGFR		ePrU		Lupus Nephritis	
State	Costs, Mean 95% CI 2012 CDN$	State	Costs, Mean 95% CI 2012 CDN$	State	Costs, Mean 95% CI 2012 CDN$
eGFR >60 ml/min	2234 (1503, 2965)	ePrU< 0.25g/d	2247 (1406, 3088)	No Lupus Nephritis	1588 (726,2450)
eGFR 30-60ml/min	3014 (1636, 4392)	ePrU 0.25-3.0g/d	3424 (2287, 4561)	Lupus Nephritis	3876 (2949,4803)
eGFR < 30 ml/min	12551 (10301, 14801)	ePrU > 3.0 g/d	4703 (2128, 7278)		

5-year cumulative costs stratified by baseline renal function state were calculated by multiplying the annual costs associated with each state by the expected duration in that state (eGFR example in Table 2).

Table 2. Expected Duration in Each Renal State over 5 Years

		Expected Duration in each State over 5 years		
Baseline State	Annual Costs 2012 CDN$	eGFR >60 ml/min	eGFR 30-60 ml/min	eGFR < 30 ml/min
eGFR >60 ml/min	2234	4.74 yrs	0.22 yrs	0.04 yrs
eGFR 30-60 ml/min	3014	2.60 yrs	1.88 yrs	0.52 yrs
eGFR < 30 ml/min	12551	1.03 yrs	1.09 yrs	2.88 yrs

Five year cumulative costs were greater in those with severely impaired eGFR or with LN at baseline (Table 3).

Table 3. Predicted 5-Year Cumulative Health Costs Stratified by Baseline State of Renal Function

eGFR		ePrU		Lupus Nephritis	
Baseline State	Costs, Mean 95% CI 2012 CDN$	Baseline State	Costs, Mean 95% CI 2012 CDN$	Baseline State	Costs, Mean 95% CI 2012 CDN$
eGFR >60 ml/min	11763 (7904, 15622)	ePrU< 0.25 g/d	12070 (7594, 16547)	No Lupus Nephritis	8663 (4331, 12995)
eGFR 30-60 ml/min	18008 (12348, 23667)	ePrU 0.25-3.0 g/d	13834 (8758, 18909)	Lupus Nephritis	19380 (14745, 24015)
eGFR < 30 ml/min	41732 (32998, 50467)	ePrU > 3.0 g/d	15627 (9192, 22061)		

Conclusion:

Patients with an eGFR <30ml/min and LN incur higher annual and 5-year cumulative costs. By estimating the expected duration in each renal function state and incorporating associated annual costs, disease severity at presentation can be used to anticipate future healthcare costs, critical knowledge for cost effectiveness evaluations of novel LN therapies.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment I: Epidemiology and Prognosis

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disease with heterogeneous presentations. Therefore, classification criteria are required to help improve diagnostic accuracy in clinical practice and particularly in research. This study aimed to compare the performance of 1982 and revised 1997 ACR classification criteria to the newer 2012 SLICC classification criteria.

Methods: Potential cases of incident SLE from 1993 to 2005 in a predominantly Caucasian, geographically well-defined population were identified from the health-care network diagnostic codes. Comprehensive individual medical record review was performed to determine the presence or absence of the ACR and SLICC criteria. An incident case of SLE was defined as an individual who fulfilled at least 4 out of 11, 1982 or revised 1997 ACR criteria or met at least 4 SLICC criteria (with at least 1 clinical and 1 laboratory criteria) or had biopsy-proven lupus nephritis with positive ANA or ds-DNA and had been a resident for at least 1 year prior to the first physician diagnosis of SLE. Cases with isolated cutaneous lupus, drug-induced lupus and overlapping diseases were excluded. Overall incidence was age- and sex-adjusted to the 2000 US white population.

Results: There were 59 incident cases who fulfilled the SLICC criteria, corresponding to the adjusted incidence of 3.8 per 100,000 population (95% CI, 2.8 – 4.8). The incidence was significantly higher than that of the 1982 (45 cases; 2.9 per 100,000 population; p=0.004) and revised 1997 ACR criteria (46 cases; 2.9 per 100,000 population; p=0.046). The average age of 42.8 +/- 18.6 years in the SLICC cohort was not significantly different compared to 40.9 +/- 18.0 years in the 1982 ACR cohort and 41.1 +/- 17.9 years in the revised 1997 ACR cohort (p=0.11). Arthritis (56%), followed by acute cutaneous lupus (46%), renal involvement (25%) and serositis (24%) were the most frequently observed clinical criteria while positive ANA (93%), followed by positive ds-DNA (63%) and hypocomplementemia (36% for C3, 42% for C4 and 22% for total complement) were the most common immunologic criteria. Three cases were diagnosed based on renal biopsy and positive ANA or ds-DNA without fulfilling 4 out of 17 SLICC criteria.

Conclusion: The 2012 SLICC classification criteria may be more sensitive than the 1982 and revised 1997 ACR classification criteria in

identifying patients with SLE at population level.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: T cell Biology and Targets in Autoimmune Disease I

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

The recruitment of IL-17 producing T helper (Th17) cells to the inflammatory sites has been implicated in the development of organ damage in inflammatory and autoimmune diseases. We have previously reported that IL-17 is important in the expression of anti-glomerular basement membrane Ab-induced glomerulonephritis (AIGN) (1). We have also shown that the blockage of Calcium/calmodulin-dependent protein kinase IV (CaMK4) ameliorates experimental autoimmune encephalomyelitis (EAE) and autoimmunity in lupus-prone mice (2). We have hypothesized that CaMK4 activation facilitates Th17 cells recruitment to target tissues in inflammatory settings through chemokines.

Methods:

To determine the role of CaMK4 in the infiltration of inflammatory cells to target tissues, we induced experimental AIGN in *Camk4*-sufficient or -deficient mice and compared the kidney injury, including Th17 related chemokine expressions, and the number of IL-17 producing cells in both groups. We also evaluated the efficacy of KN-93, a CaMK4 antagonist in this AIGN model. In addition, we investigated the effect of CaMK4 on the expression of CCR6 in memory CD4 T cells.

Results:

Camk4 deficient mice displayed less glomerular injury and less proteinuria at day 21 after induction of AIGN (Figure 1). Although there is no significant difference in the percentage of IL-17 producing T cells in the spleen or lymph nodes, kidney infiltration by IL-17 producing CD4 T cells along with CCR6 and CCL20 expression were decreased significantly in *Camk4* deficient mice. This observation implies that CaMK4 facilitates AIGN damage by promoting local inflammatory Th17 cells accumulation through the CCR6/CCL20 axis. In line with these observations, KN-93 treatment of mice prior to exposure to AIGN improved clinical and pathological finings in a dose-dependent manner. Finally, the expression of CCR6 in memory CD4 T cells in the peripheral blood was decreased among *Camk4* deficient mice.

Conclusion:

Collectively our results indicate that CaMK4 inhibition represents a novel therapeutic strategy for the treatment of Th17 cells-mediated tissue damage in inflammatory diseases.

Session Title: T cell Biology and Targets in Autoimmune Disease I

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Cellular metabolism controls T cell functions, with TCR-mediated activation enhancing metabolism, and substrate utilization modulating effector functions. Autoreactive CD4 T cells are key effectors in lupus by providing help to B cells to produce high-affinity class-switched autoantibodies. We have previously shown that CD4 T cells from B6.*Sle1.Sle2.Sle3* (TC) and BWF1 lupus-prone mice, as well as from lupus patients, have an elevated mitochondrial oxidation (OXPHOS) and glycolysis. A combination of metformin and 2DG, two metabolic inhibitors which target OXPHOS and glucose metabolism, respectively, normalized the cellular metabolism of these T cells *in vitro*, and *in vivo*treatments reversed all disease phenotypes in TC and BWF1 mice. These two models are genetically related and their T cells are characterized by a high production of IFNγ. In this study, we investigated the efficacy of metabolic inhibitors in BXSB.Yaa mice, an unrelated model driven by type I Interferons.

Methods: Two month old TC or BXSB.Yaa mice were treated with yhree single metabolic inhibitors for 8 weeks (N = 10-22): metformin, 2DG, or dichloroacetate (DCA, an inhibitor of glycolysis) and compared to untreated controls (N = 27). T cell glycolysis and OXPHOS were measured with an extracellular fluid analyzer. Lymphocyte activation and effector subset distribution were measured by flow cytometry. Disease progression was assessed by ELISA and ANA staining for autoantibodies and histology for renal pathology. CD4 T cells from lupus mice and controls were polarized under Th1 conditions in the presence of metformin, 2DG, or DCA, and IFNγ production was measured by flow cytometry.

Results: CD4 T cells from BXSB.Yaa mice have a significantly higher glycolysis and OXPHOS than control mice. However, OXPHOS was significantly lower in BXSB.Yaa than in TC CD4 T cells, indicating a lower contribution of OXPHOS to BXSB.Yaa T cell metabolism. All 3 metabolic inhibitors significantly reduced renal pathology, the most effective being 2DG in both strains. DCA was more effective that metformin in BXSB.Yaa mice while the reverse was true in TC mice. All 3 metabolic inhibitors also reduced lymphoid expansion and T cell activation, with again 2DG having the greatest effect. 2DG and metformin, but not DCA prevented autoantibody production in TC mice. BXSB.Yaa autoantibody results are pending. *In vitro* Th1-polarized BXSB.Yaa CD4 T cells produced significantly more IFNγ than BXSB controls, but significantly less than TC CD4 T cells. Both 2DG and metformin decreased IFNγ production from polarized cells, but DCA, which increases pyruvate oxidation, also increased IFNγ production. This is consistent with their reduced OXPHOS, which supports which IFNγ production.

Conclusion: These results showed that inhibitors of glucose metabolism are effective in murine models in which lupus arise from different etiology. They suggest however that targeting mitochondrial oxidation may have better outcomes in IFNγ-driven disease while targeting glycolysis may be more effective type I IFN-driven disease. Further investigation of these models will lead to tailored pre-clinical models that target T cell metabolism for lupus treatment.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: T cell Biology and Targets in Autoimmune Disease I

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Rheumatoid arthritis (RA) is a T cell dependent disease in which chronically activated immune cells cause progressive damage of articular cartilage and bone. RA T cells adapt their metabolic programs to support their chronic energy needs in a disease-specific pattern. Unlike healthy T cells, RA T cells fail to upregulate glycolytic flux due to suppression of the glycolytic enzyme PFKFB3, produce low concentrations of lactate and ATP and are energy deprived. The energy status of cells is monitored by AMP-activated protein kinase (AMPK), a nutrient-sensing "master-regulator" that enforces quiescence under conditions of energy stress by restraining mTORC1 activity. Here, we have explored how energy deficiency affects signaling pathways in RA T cells and how it shapes their effector functions.

Methods: Purified naïve CD4 T cells from RA patients and age-matched controls were stimulated with anti-CD3/CD28. Transcripts of AMPK components and autophagy-related genes were measured by RT-PCR. AMPK activity was assessed by Western blot analysis of AMPK targets, including p-p70-S6K and pACC1. Autophagic flux was measured by immunoblotting for LC3 conversion. Treg cells were induced under polarizing conditions with TGF-β1 and IL-2. $FoxP3^+$cells were quantified by flow cytometry 7 days after polarization.

Results: Compared to healthy CD4 T cells, RA T cells had reduced levels of p-AMPKα(Thr172) ($p<0.05$) indicating insufficient activation of the AMPK signaling axis. Protein subcomponents of AMPK, including AMPKα, β and γ were intact. Functional evidence for insufficient AMPK signaling in RA T cells came from the demonstration that mTORC1 activity was inappropriately high, captured by protein levels of p-p70-S6K ($p<0.05$) and pACC1 ($p<0.05$). Also, autophagy, an AMPK-dependent energy supply mechanism, was impaired in RA T cells ($p<0.05$).

To test whether AMPK was able to respond to stress signals, we deprived T cells of glucose by culturing them in the glucose analogue 2-DG. AMPK activation induced by energy stress was reduced in RA. To examine whether additional AMPK-dependent pathways were impaired, we examined the induction of anti-inflammatory Treg cells from naive RA T cells. Compared to healthy control T cells, RA T cells failed to differentiate into $FoxP3^+$Tregs.

Conclusion: RA T cells are energy deprived and are unable to correct their energy status due to defective responsiveness of the nutrient sensor AMPK. Functional consequences of insufficient AMPK activation include the failure of autophagy, defective upregulation of glycolysis, insufficient inhibition of lipogenesis and, most importantly, chronic hyperactivity of the immune activator mTORC1.

Session Title: T cell Biology and Targets in Autoimmune Disease I

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: In autoimmunity, T follicular helper cells (TfH) are considered drivers of autoantibody production, and T helper 17 (Th17) cells are implicated in tissue-specific inflammation. In juvenile dermatomyositis patients, the Ueno lab showed that the ratio of TfH cells expressing markers of Th17 cells was increased relative to Th1, and this Th17/TfH ratio correlated with disease activity. Although patients with rheumatoid arthritis (RA) feature joint-specific inflammation and autoantibody production, TfH cell subsets have not been well-studied in context of disease activity or therapy.

Methods: We identified seropositive RA patients receiving stable TNF inhibitor (TNFi) therapy (n = 26) or non-biologic DMARDs (n = 35), who were enrolled in the RA Comparative Effectiveness Research (RACER) registry at University of Pittsburgh. Treatment groups were matched for age, gender, ethnicity, concomitant DMARD and steroid use. 8 healthy controls were also enrolled. A second cohort of 6 subjects were identified who showed a good response following initiation of TNFi. PBMC were isolated and CD4+CD45RO+ T cell subsets analyzed by flow cytometry using chemokine receptors as functional subset markers.

Results: There were no significant differences in blood memory cell frequency between RA and healthy controls. Total Th1 (CXCR3+) and TfH (CXCR5+) cells did not differ between RA treatment groups or controls. However, the proportion of TfH cells that co-expressed the Th17 marker CCR6 (termed Th17/TfH) was increased compared to healthy controls ($p = 0.044$, t-test). Surprisingly, Th17/TfH cell negatively correlated with disease activity in the TNFi group, as assessed by CDAI (Spearman $r = -0.72$, $p = 0.0001$) and DAS28crp ($r = -0.6844$, $p = 0.0001$). However, no correlation between disease activity and Th17/TfH cells was observed in patients receiving non-biologic DMARD therapy ($r = 0.175$, $p = 0.25$ for CDAI; $r = 0.059$, $p = 0.745$ for DAS28crp). While CXCR3-expressing Th1/TfH cells showed a trend towards being decreased in RA subjects, Th1/TfH cells did not correlate with disease activity in either treatment group. Analysis of longitudinal samples from TNFi subjects showed strong correlations between visits for Th17/TfH cell frequencies ($r = 0.818$, $p = 0.006$). To confirm these cross-sectional results, we analyzed a second longitundinal cohort (n = 6) of subjects initiating TNFi therapy and showing a subsequent good clinical response. Indeed, Th17/TfH cell frequencies remained stable after TNFi therapy ($r = 0.943$, $p = 0.017$).

Conclusion: Th17/TfH cells correlate with disease activity in RA subjects receiving TNFi, but not DMARDS alone. Th17/TfH frequencies remained remarkably stable over time for each individual. These data indicate that Th17/TfH cells are not directly affected by TNFi, but rather that proportions of these cells serve as a predictor of future disease severity for patients receiving TNFi therapy. Hence different levels of Th17/TfH cell contribution to RA pathogenesis in individuals could be one factor underpinning the clinical problem of heterogeneity in RA therapy responses.

In Rheumatoid Arthritis Only a Few Expanded T-Cell Clones Dominate in Joint Inflammation: A Study in Seven RA Patients Undergoing Paired Synovial Tissue Biopsies in Multiple Joints

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: T cell Biology and Targets in Autoimmune Disease I
Session Type: ACR Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Previously we found a strong enrichment of highly expanded T-cell clones in rheumatoid arthritis (RA) synovial tissue of inflamed joints. To gain more insight into the potential role of these expanded clones in the inflammatory polyarthritis in this disease, we studied the distribution of these T-cell clones: Are they present only locally in the inflamed synovium? If not, to what extent are they also present in synovial biopsies taken from a different location in the same joint, or from a different joint?

Methods: In seven RA-patients we simultaneously obtained synovial tissue (ST) biopsies from two inflamed joints (N=7; ankle or knee) via mini-arthroscopy together with paired peripheral blood (PB; N=7) and synovial fluid samples (SF; N=5). ST biopsies were obtained from ankle (N=1) or from the infrapatellar region of the knee (N=6). In 6 patients we took additional independent suprapatellar (SP) biopsies within the same knee joint. Samples were processed for RNA-based next generation sequencing (NGS). T-cell clones were identified by their unique T-cell receptor β-chain sequence, the degree of expansion being expressed as a percentage of the total number of NGS reads. (Paired) student T-tests or Wilcoxon (matched-pair) signed rank test were performed where applicable.

Results: We identified 904,631 clones in 6,955,333 TCR-sequences. Of the top-25 most expanded clones in ST only a limited number were retrieved as top-25 clone in SF (18%; SEM 6.3) and in PB (24%, SEM 5.1). In contrast, considerable overlap was seen if we analyzed cellular infiltrate in synovial tissue biopsies from different regions of the same joint: 49% (SEM 6.2) of the top-25 ST clones were also retrieved as a top-25 clone in the suprapatellar biopsy of the same joint ($p<0.005$). When comparing different joints in the same patient, we noted that 52% (SEM 5.0) of the top-25 clones from the 1st joint were also amongst the top-25 clones in the 2nd joint (see figure 1).

Conclusion: Synovial fluid T-cells do not fully reflect the repertoire of dominant clones in the synovial tissue. Synovial tissue biopsies from different locations within the same joint or taken from different joints show substantial overlap of the most dominant T-cell clones in patients with active RA. Given the evidence pointing to T-cell involvement in the pathogenesis of RA this suggests that in individual patients a limited number of T-cell clones dominate the adaptive immune response. Detailed cellular characterization of these clones seems warranted, and may help to devise more selective strategies for therapeutic targeting.

Session Title: T cell Biology and Targets in Autoimmune Disease I

Session Type: ACR Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose:

Invariant Natural Killer T (iNKT) cells are a unique subset of T cells that shape an inflammatory response through rapid production of large amounts of cytokines following activation. Perturbation in frequency and proliferative response of peripheral blood iNKT cells have been described in rheumatoid arthritis and systemic lupus erythematosus, however the mechanism is not well understood. Metabolic reprogramming from oxidative phosphorylation to aerobic glycolysis is crucial for T cell proliferation and cytokine production. The aim of this study is to characterize metabolic reprogramming during iNKT cell activation.

Methods:

Peripheral blood iNKT cell frequency from rheumatoid arthritis patients and healthy controls were measured by flow cytometry. Cultured mouse iNKT cells were used for metabolic analysis. iNKT cell oxygen consumption and extracellular acidification were measured using a Seahorse XFe24 analyzer. Specific pharmacologic inhibitors 2-deoxyglucose (glycolysis) and oligomycin (oxidative phosphorylation) tested specific metabolic pathways for iNKT cell function.

Results:

Compared with healthy controls, rheumatoid arthritis patients had a decreased frequency of peripheral blood iNKT cells. Metabolic analysis of murine iNKT cell revealed predominant reliance on oxidative phosphorylation at basal state. Upon stimulation with the cognate lipid antigen alpha-galactosylceramide, iNKT cells exhibit significantly enhanced glycolysis and glycolytic capacity. In contrast, oxidative phosphorylation was only modestly elevated while spare respiratory capacity was suppressed following activation. Glycolysis, but not oxidative phosphorylation, has been shown to be essential for interferon-gamma production in MHC-restricted T-cells. In contrast, inhibition of either glycolysis or oxidative phosphorylation in iNKT cells resulted in dose-dependent suppression of interferon-gamma production, suggesting differential metabolic control in iNKT cells

Conclusion:

In summary, peripheral blood iNKT cells are significantly reduced in rheumatoid arthritis patients. Our data suggest that metabolic reprogramming and glucose utilization play a crucial role in iNKT cell function. Further characterization of iNKT cell metabolic state in rheumatoid arthritis patients may shed light on mechanisms of altered iNKT cell function during chronic inflammation.

Session Title: ARHP I: Exemplary Abstracts

Session Type: ARHP Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Regular evaluations of rheumatoid arthritis (RA) disease activities with disease activity score in 28 joints (DAS28) are critical steps to reach the goal of "Treat to Target". However, over-load of RA patients and short supply of rheumatologists in China made these steps impossible in the clinic. An option is to realize self-disease-evaluation by RA patient. Due to the smart phone being widely used in 66% of Chinese people, a user-friend platform of the Smart System of Disease Management (SSDM) is a potential resolution for regular evaluations of RA disease activities. SSDM includes applications of self-evaluation of DAS28, HAQ, and digital records of medication and lab test results. SSDM is developed in IOS, Android and Web format with patient and physician's interfaces. After patient entries the data, it synchronizes with the interface of authorized doctor in real time mode.

To verify the feasibility and influential factors in performing self-evaluation on DAS28 with SSDM by RA patients.

Methods: From December 14, 2014 to February 2, 2015, two phases of studies were performed and total 103 patients enrolled, with 55 and 48 patients in each phase, respectively. All patients met the 1987 ACR criteria for diagnosis of RA. Ten rheumatologists and two nurses from five hospitals in Beijing and Shanghai participated in the study.

Education courses were held in hospitals. Patients were taught how to do self-evaluations on DAS28 and HAQ with SSDM. After practice and passing the exam, the self-evaluation of DAS28 was performed and data was recorded in SSDM. The same patient was evaluated by doctor or nurse simultaneously.

Statistical analysis was performed using SAS software, version 9.4. Intra-observer reliability of tender joint counts (TJCs) and swollen joint counts (SJCs) were expressed through the intra-class correlation coefficient (ICC).

Results: Among 103 RA patients, Mean age was 55.20 ± 13.26 (23 to 72) years, mean disease duration was 8.91 ± 8.25 (1 to 34) years.

As of December 31, 2014 for phase I, the ICCs of TJCs and DAS28 scores were 0.93 and 0.94, but the ICC of SJCs was 0.68. The analysis showed that the duration of disease was the only associate factor with significant difference ($P<0.05$). Stratified analysis showed that the result of SJCs matched between patients and health professionals was in the group with disease duration of 6.86 ± 5.78 years, but mismatched group was 14.18 ± 10.26 years in disease duration which group of patients under valuated their SJCs.

In Phase II of 48 patients, the education courses were more emphasized in identification of swollen joints. As a result, the ICCs of SJCs, TJCs and DAS28 were improved to 0.93, 0.93 and 0.92, respectively.

The average time for patients to do self-evaluation on a composite of DAS28 and HAQ with SSDM was 7.11 ± 5.21 (2-30) minutes, median time for 5 minutes; and the corresponding time for health professionals was 6.55 ± 4.26 (1-20) and 2 minutes, respectively.

Conclusion: Through improving education, RA patients in China can master SSDM and perform accurate self-evaluation on DAS28 and HAQ. SSDM may serve as a valuable platform for assisting rheumatologists in rationally managing RA patients in order to reach the goal of "Treat to Target".

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: ARHP I: Exemplary Abstracts

Session Type: ARHP Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: The experience of living with a serious illness, such as systemic sclerosis (SSc), can pose challenges for an individual's self-concept and social roles. This can necessitate new patterns of interacting with others, which may lead to social anxiety. Research on the social impacts of SSc is limited, and there are few validated measures in this area. The Social Interactions Anxiety Scale (SIAS-6) was developed to assess social interactional anxiety, or distress experienced when interacting with others. The instrument has demonstrated good measurement properties, but has not been tested in SSc. The present study has the following two aims: 1) to assess the reliability and validity of the SIAS-6 in a sample of SSc patients, and 2) to explore whether scores can be meaningfully compared across the limited and diffuse subtypes of the disease.

Methods: Confirmatory factor analysis (CFA) was used to evaluate the structural validity of the one factor model of the SIAS-6 in sample of patients with SSc ($N = 596$; 59.1% limited, 40.9% diffuse) enrolled in the Scleroderma Patient-centered Intervention Network (SPIN) Cohort. Multiple group confirmatory factor analysis (MGCFA) was used to evaluate the comparability of the factor structures of the SIAS-6 for patients with limited and diffuse disease subtypes. The MGCFA evaluated configural invariance (i.e., baseline model fitting a one-factor solution for both groups), metric invariance (i.e., factor loadings constrained to equivalence), and factor variance invariance (i.e., factor loadings and variances constrained to equivalence) models. Internal consistency reliability was examined via Cronbach's coefficient alpha. Convergent validity was examined via Pearson product-moment correlations with measures of depression, body image dissatisfaction/avoidance, fear of negative evaluation, and social anxiety.

Results: Per descriptive fit indices using CFA, a one-factor model was found to fit the data (Comparative Fit Index [CFI] = 0.99, Standardized Root Mean Residual [SRMR] = 0.02, Root Mean Square Error of Approximation [RMSEA] = 0.06). The MGCFA demonstrated that the metric invariance model best fit the data (i.e., equivalent factor loadings but different variances across disease groups) based on the descriptive indices of CFI, SRMR, and RMSEA; change in CFI; and the Satorra-Bentler X^2 difference test. Internal consistency reliability was good for limited ($\alpha = 0.86$) and diffuse ($\alpha = 0.92$) groups. Convergent validity testing demonstrated significant, moderate to strong correlations in the expected directions with measures of depression ($r = 0.48$, $p < .01$), body image dissatisfaction, avoidance, and concerns ($r = 0.51$, $r = 0.42$, $r = 0.54$, respectively, all $ps < .01$), fear of negative evaluation ($r = 0.57$, $p < .01$), and social anxiety ($r = 0.58$, $p < .01$) in the total sample.

Conclusion: The present study demonstrates that the SIAS-6 can be confidently used as a one-factor measure of social interaction anxiety in patients with both limited and diffuse subtypes of SSc.

Development of Quality Indicators for Hip and Knee Arthroplasty Rehabilitation

Marie Westby[1], Deborah Marshall[2], Jane Squire Howden[3] and C. Allyson Jones[4], [1]School of Public Health, University of Alberta, Edmonton, AB, Canada, [2]University of Calgary, Calgary, AB, Canada, [3]Edmonton Musculoskeletal Centre, Edmonton, AB, Canada, [4]Physical Therapy, University of Alberta, Edmonton, AB, Canada

First publication: September 29, 2015

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: ARHP I: Exemplary Abstracts
Session Type: ARHP Concurrent Abstract Session
Session Time: 2:30PM-4:00PM

Background/Purpose: Rehabilitation before and after total hip (THA) and knee arthroplasty (TKA) surgery has been shown to decrease pain and impairment, and improve mobility, activity and participation. Yet there are reports of marked variation in clinical practices, outcomes and resources allocated for rehabilitation services. This project aimed to develop core sets of quality indicators (QIs) reflecting the minimum acceptable standard of rehabilitation care before and after elective THA and TKA for osteoarthritis.

Methods: We assembled an 18-member Canada-wide panel of clinicians, researchers and patients and used a modified RAND-UCLA Delphi approach to establish consensus on 82 proposed QIs (40 for THA, 42 for TKA). Indicators were derived from the authors' previous work and the literature and reflected the rehabilitation continuum (pre-operative, acute care and post-acute up to 1 year post-surgery). Panelists completed 2 rounds of rating using an online survey interspersed by a moderated online discussion forum over a 3-month period. Prior to rating, panelists received a synthesis of high quality evidence (practice guidelines, systematic reviews, randomized controlled trials) supporting each QI. They were instructed to review the evidence before accessing the survey. Each QI was rated for its importance and validity on a 9-point Likert scale.

Individual and group ratings from Round 1 were summarized and provided to panelists in order to inform the subsequent online discussion. During Round 2, panelists were asked to participate in the forum anonymously, share their views on the proposed QIs and debate each others' comments. This was immediately followed by the final round of ratings. Those QIs with median ratings of 7 or higher for both importance and validity, and with no disagreement were included in the final sets.

Results: Fifteen panelists representing 7 provinces and varied practice settings completed the Delphi process. Of the 82 proposed QIs, 67 (82%) were rated as both important and valid (31 for THA, 36 for TKA). For THA, 14 pre-op, 6 acute and 8 post-acute QIs were accepted. For TKA, 16 pre-op, 10 acute and 8 post-acute indicators were accepted. The majority of these QIs address assessment and screening activities (74%) while the remainder pertain to rehabilitation interventions. Three 'across-continuum' QIs were rated appropriate for THA and 2 of 3 for TKA. Engagement was high with 83% of panelists participating in the discussion forum.

Conclusion: These QIs represent an important first step in addressing rehabilitation practice and outcome variation and will serve as a tool with which to measure, report and benchmark quality of care in patients receiving rehabilitation before and after THA/TKA surgery. Online technology facilitated broad geographical representation, panelist anonymity and engagement, and decreased panelist burden and administration costs compared to the traditional RAND/UCLA method. The QIs will be further tested for reliability and feasibility before being widely disseminated in clinical settings and used to assess care gaps.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: ARHP I: Exemplary Abstracts

Session Type: ARHP Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Obesity and foot problems are common in older adults and associated with many negative health outcomes. There is limited evidence examining the relation between foot problems and obesity from a population perspective. Previous studies have found higher BMI to be linked with reduced odds of hallux valgus, a common foot disorder, but no study has determined the reason for this unexpected relation. The purpose of this study was to describe the associations between obesity categories, with foot pain and foot disorders (hallux valgus, claw, hammer, overlapping toes), and to determine if these associations differ by foot structure or by foot function in a community-based, cross-sectional study of older men and women.

Methods: We included 2445 participants (contributing 4888 feet) from the Framingham Foot Study between 2002 and 2008. A podiatric-trained examiner performed a validated examination of participantsÕ feet to determine the presence of foot disorders on each foot by comparing the foot to a laminated depiction of the disorder. Foot pain was defined by the question ÒOn most days, do you have pain, aching or stiffness in either foot?Ó Body mass index (BMI, kg/m^2) was determined at the time of the foot exam and categorized as normal (<25, referent), overweight (25-30), moderately obese (30-35) and severely obese (35+). Foot structure (cavus, planus) and foot function (pronated, supinated) were defined using the Tekscan Matscan pressure system as the modified arch index and the center of pressure excursion index, respectively. We used sex-specific logistic regression, adjusting for within person correlation, to examine the relation between foot pain and each foot disorder with obesity categories, adjusting for age and further stratified by foot structure and foot function categories in a foot-specific analysis.

Results: Average age was 68 (SD 11) years, 56% were female, BMI was 28 (SD 5) kg/m^2. 18% of feet had pain, 25% hallux valgus, 2% claw toes, 18% hammer toes, 7% overlapping toes. Severely obese men were more likely to have foot pain (OR=2.4; 95% CI: 1.4-4.3) and claw toes (OR=3.4; 95% CI: 1.1-10.7) compared to normal weight men. In women, there was an increased odds of foot pain with all categories of obesity (Table). Severely obese women were 40% less likely to have hallux valgus (OR=0.61; 95% CI: 0.4-0.9) compared to normal weight women. We

saw the same effect in men although it did not reach statistical significance. Patterns of association were the same stratified by foot structure or function in men or in women.

Conclusion: Women are more prone to foot pain and obese women, even more so. Reducing weight may reduce pain and potentially reduce foot problems. Foot structure and foot function do not change the associations between foot problems and obesity. Further studies are needed to determine the mechanism behind these associations and the role of longitudinal trajectories of BMI on foot problems.

Table. Per-foot analysis of the association between obesity categories (referent group BMI < 25 kg/m^2) and foot pain and foot disorders, adjusting for age.

	Obesity category	Men 2150 feet; 1076 people		Women 2738 feet; 1369 people	
		N	OR(95% CI)	N	OR(95% CI)

Session Date: Sunday, November 8, 2015

Session Title: ARHP I: Exemplary Abstracts

Session Type: ARHP Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: The American College of Rheumatology (ACR) strongly recommends exercise therapy as a first-line conservative treatment for individuals with knee osteoarthritis (OA).[1] Evidence supporting manual therapy for knee OA has shown varying levels of effectiveness.[1] In this population, there is minimal research regarding the use of "booster" physical therapy (PT) sessions-- visits spaced across a longer period of time to supplement initial treatments.[2]The purpose of this study was to compare the cost-effectiveness of combinations of exercise therapy and manual therapy with or without booster sessions in individuals with knee OA.

Methods: Data were collected as part of a 2-year multi-site study of 300 individuals who met ACR criteria for knee OA. A Markov model was constructed to compare 4 PT treatment strategies: (1) 12 visits of exercise therapy alone (EX); (2) 9 visits of exercise therapy plus 3 booster sessions spaced across a 12-month period (EX+B); (3) 12 visits of exercise therapy plus manual therapy (EX+MT); (4) 9 visits of exercise therapy plus manual therapy and 3 booster sessions (EX+MT+B). Total health care costs were estimated from the societal perspective using patient reported outcome measures as well as data from the Healthcare Utilization Project and the Medicare physician fee schedule. Utilities were measured using the U.S. version of the Euroqol-5-Dimension tool. Incremental cost-effectiveness ratios (ICERs) are expressed in Quality-Adjusted Life Years (QALYs).

Results: In the 2-year base case analysis, the booster strategies (EX+MT+B and EX+B) dominated (lower health care costs and greater effectiveness) the no-booster strategies (EX+MT and EX). EX+MT+B had the lowest total health care costs. The EX+B group cost $1,061 more and gained 0.082 more QALYs compared with EX+MT+B, for $12,900/QALY gained. In 1-way sensitivity analyses of all parameters, EX+B continued to be cost-effective (<$100,000/QALY gained) compared with EX+MT+B, unless the likelihood of staying in good or poor function was varied to a degree that would be highly improbable given what was observed in this study. In a preliminary model projecting costs and utilities over a 5-year period, the EX+B strategy remained well within the range that most would consider to be cost-effective by third-party payers.

Conclusion: Spacing exercise-based PT sessions over 12 months using periodic "booster" sessions was less costly and more effective over 2 years than strategies not containing "booster" sessions. Among booster strategies, the group receiving manual therapy in addition to exercise therapy (EX + MT + B) had lower costs but lower gains in QALYs than the EX + B group.

Session Title: ARHP I: Exemplary Abstracts

Session Type: ARHP Concurrent Abstract Session

Session Time: 2:30PM-4:00PM

Background/Purpose: Pain is the symptom people with rheumatoid arthritis (RA) have prioritized highest for improvement [1]. Treating to target

and aiming for remission in early RA may reduce pain, but there is limited knowledge about the impact of pain in RA patients classified using the 2010 ACR/EULAR criteria and treated according to modern treatment strategies. The objective of this study was to explore and describe changes in the degree of pain in early RA during the first year after starting treatment with DMARDs.

Methods: Patients from 11 rheumatology centers who fulfilled the 2010 ACR/EULAR classification criteria for RA, with symptom duration (from first swollen joint) less than 2 years, and were DMARD naïve with indication for DMARD treatment, were followed for 1 year. Treatment target was remission, and DMARD was prescribed according to international recommendations. Pain was recorded on a Visual Analog Scale (VAS 0-100 mm) at every visit, and grouped according to Jensen et al. [2] with cut points for no pain set at 0-4 mm, mild 5-44 mm, moderate 45-74 mm and severe pain 75-100 mm. Short Form 36 (SF-36) bodily pain was recorded, and transformed to a scale from 0-100, where high score indicates low bodily pain.

Results: A total of 205 early RA patients were included: 61.5% female, 82.4% ACPA positive, mean (SD) age 52.2 (13.4) years**.** At initiation of DMARD treatment the mean (SD) 44-swollen joint count was 10.2 (7.2), Ritchie Articular Index 8.14 (6.5), ESR 24 (19) mm/hr and Patient Global Assessment 49 (24) mm. DAS was mean (SD) 3.4 (1.1): 20.1% were in low DAS, 47.1% in moderate DAS and 32.8% in high DAS. VAS pain at baseline was median (IQR) 45 (27-68) mm, and decreased to 12 (4-27) mm after 1 month, and after 1 year to 6 (2-20) mm; see fig. 1A for details. Mean (SD) SF-36 bodily pain at baseline was 40 (21), and 73 (23) after 1 year. At baseline less than 3% of patients reported no pain, after 3/6/12 months this proportion increased to 27/32/41%, and after 12 months more than 87% of patients reported either mild or no pain (fig. 1B).

Conclusion: In this cohort of early DMARD-naïve RA patients treated according to modern treatment strategies aiming for remission, there was a significant reduction of pain after 1 month, and pain is decreased further during 12 months follow-up. Early intervention and treating to target in this population fulfills the patients' prioritized goal of minimizing pain, leading to a decreased burden of pain in RA.

Session Title: Osteoarthritis - Clinical Aspects I: Imaging and Epidemiology

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose : The association between NSAIDs use and myocardial infarction has been demonstrated in many studies. However, the relation between NSAIDs use and venous thromboembolism (VTE) remains controversial. We aimed to examine whether the current users of specific NSAIDs have an increased risk of VTE among knee OA patients.

Methods : We conducted a population-based case-control study using The Health Improvement Network (THIN), a database of patient records from general practices in the UK. For every VTE case, we identified 5 controls matched on age, sex, and calendar year of study enrolment. We used conditional logistic regression to assess the association between current use of specific NSAIDs and risk of VTE relative to remote NSAID users.

Results : Among knee OA patients with at least one NSAID prescription, we identified 4020 incident cases of VTE and 20059 matched controls. Adjusted odd ratios (OR) relative to the remote users were 1.38 (95% CI 1.32 - 1.44) for the recent users and 1.43 (95% CI 1.36 - 1.49) for current users. Among the current NSAID users, the risk of VTE was increased with diclofenac (OR 1.63 [95% CI 1.53 - 1.74], ibuprofen (OR 1.49 [1.38 - 1.62]), meloxicam (OR 1.29 [1.11 - 1.50]) and coxibs (celecoxib OR 1.30 [95% CI 1.11 - 1.51]; rofecoxib OR 1.44 [95% CI 1.18 - 1.76]); naproxen did not increase VTE risk (OR 1.00 [95% CI 0.89 - 1.12]).

Conclusion : Compared with the remote users of NSAIDs, the risk of VTE increased for current users of diclofenac, ibuprofen, and coxibs, but not for naproxen, in the knee OA population.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Osteoarthritis - Clinical Aspects I: Imaging and Epidemiology

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Historically, ankle osteoarthritis (OA) has been considered uncommon, and its development has been thought of as a consequence of primarily ankle injury. Other etiologies have not been extensively analyzed in community-based samples. Therefore, we examined the frequency of ankle OA and determined associations between body-mass index (BMI), sex, race, and other participant characteristics with the presence of ankle OA.

Methods: Complete data on OA, pain, and injuries of the ankle, as well as participant characteristics, were available for 856 participants (mean age 71 years, mean BMI 31.0 kg/m^2, 68% women, 34% African Americans) in the Johnston County OA Project. Lateral and mortise views of the ankle were obtained in standing and read for Kellgren-Lawrence grade (KLG) by a musculoskeletal radiologist (JBR). Presence of ankle OA was defined one of two ways: KLG>=2 (primary) or KLG>=1 (secondary). Ankle symptoms were considered present based on an affirmative response to the question: ÒOn most days of any one month in the last 12 months did you have pain, aching or stiffness in your left/right ankle?Ó History of ankle injury was self-reported. Chi-square statistics for categorical variables and t-tests for continuous variables were used to compare all participant characteristics by the presence or absence of ankle OA. Multiple logistic regression models were performed to examine the associations of each participant characteristic with ankle OA, adjusting for all other factors.

Results: Among the 856 participants, 56 (7%) had ankle OA, defined as a KLG of >=2, in at least one ankle. There was no significant age difference between participants with and without ankle OA (Table). Participants with ankle OA had a higher mean BMI than those without (p<0.01). Additionally, individuals with a history of ankle injury and those with ankle symptoms, were more likely to have ankle OA (p<=0.05). In adjusted models, for every 1 unit increase in BMI, the odds of having ankle OA (KLG>=2), increased by 3%. Self-reported ankle injury was associated with 80% higher odds, while the presence of ankle symptoms was associated with more than twice the odds, of ankle OA. Results were similar when ankle OA was defined as KLG>=1 (n=634, 74%), but there were also differences by race (African Americans 40% lower odds) and sex (women 60% lower odds) in associations with ankle OA .

Conclusion: In this first community-based study of radiographic ankle OA including African American and Caucasian men and women, we found that ankle OA, defined as either KLG>=2 or KLG>=1, was not uncommon, and higher BMI and ankle symptoms were important factors. The association between increased BMI and more frequent ankle OA suggest that not only post-injury changes, but also individual characteristics of BMI or ankle symptoms, should be considered in the process of ankle OA.

Session Title: Osteoarthritis - Clinical Aspects I: Imaging and Epidemiology

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: While patellofemoral (PF) OA has been found to have substantial impact on pain and function, most studies continue to

focus on tibiofemoral (TF) OA. These compartments differ in pathomechanics and the profile of factors contributing to disease course. Depending on where and how it is transmitted, increased joint stress, force transmitted through the joint averaged over articular contact area, may overload and injure cartilage in either compartment. Knee sagittal plane dynamic joint stiffness (DJS) is the interaction between the external knee flexion moment and knee flexion joint excursion during gait. In theory, greater knee sagittal DJS may increase joint stress and accelerate disease progression through elevated external knee flexion moment, reduced sagittal joint excursion and contact area, or both. We hypothesized that greater baseline knee sagittal DJS is associated with cartilage damage progression in PF and TF compartments 2 years later in persons with knee OA.

Methods: Participants all had knee OA (KL grade ³ 2) in at least one knee. Three-dimensional knee kinematics and kinetics during walking on a 35 x 4 foot walkway were captured at a rate of 120 Hz, using external passive reflective markers, an 8-camera Digital Real-Time Eagle motion analysis system, and 6 AMTI force plates. Baseline sagittal DJS of both knees was computed as the slope of the linear regression line for external knee flexion moments vs. flexion angles during the loading response phase of gait. Participants underwent 3.0T MRI of both knees at baseline and 2 years later using double oblique coronal and axial FLASH sequences, coronal T1-weighted spin-echo (SE), and sagittal, coronal and axial fat-suppressed turbo spin echo sequences. Cartilage damage progression was defined as WORMS score worsening for whole, medial, or lateral TF and PF. We assessed the association between baseline DJS and 2-year cartilage damage progression (yes vs. no), using logistic regression with GEE to account for correlations between knees, adjusting for demographics and disease covariables. **Results** are shown as odds ratios (ORs) and 95% confidence intervals (CIs).

Results: The study sample consisted of 391 knees from 204 persons: mean age 64.2 years (SD 10.0); BMI 28.4 kg/m^2 (5.7); 156 (76.5%) women. Table 1a shows the percentage of knees with cartilage damage progression. Table 1b shows the ORs for progression unadjusted, then adjusted for covariables. Greater baseline DJS was strongly associated with 2-year structural progression in the PF, specifically the lateral surface, but not in the TF.

Conclusion: Elevated baseline knee sagittal DJS was associated with increased risk of PF disease progression. Unlike frontal-plane joint mechanics, which predominantly influence the medial-lateral TF load distribution, sagittal knee mechanics during ambulation may determine PF load and disease course.

Table 1a. Number (percentage) of knees with baseline-to-2-year cartilage damage progression in each compartment (n = 391 knees; 204 persons)

Compartment:	Whole TF	Medial TF	Lateral TF	Whole PF	Medial PF	Lateral PF
Number (%)	100/391 (25.6%)	61/391 (15.6%)	48/391 (12.3%)	53/391 (13.6%)	29/391 (7.4%)	28/391 (7.2%)

Table 1b. Association between baseline predictor of sagittal DJS (%body weight*height/degree) and baseline-to-2-year TF and PF cartilage damage progression dichotomized outcomes in each compartment (n = 391 knees; 204 persons)

Unadjusted odds ratio (95% CI)	0.06 (0.001, 2.92)	0.01 (0.00, 1.15)	0.65 (0.12, 3.51)	**2.57 (1.09, 6.03)**	0.05 (0.00, 11.48)	**4.27 (2.04, 8.91)**
Odds ratio (95% CI), adjusted for age, gender, gait speed, and disease severity	0.04 (0.0005, 3.27)	**0.002 (0.00, 0.53)**	0.77 (0.19, 3.20)	**3.70 (1.79, 7.65)**	0.83 (0.14, 4.97)	**5.70 (2.62, 12.39)**
Odds ratio (95% CI), adjusted for age, gender, gait speed, disease severity, WOMAC pain, and pain meds	0.07 (0.001, 5.54)	**0.002 (0.00, 0.61)**	1.05 (0.30, 3.59)	**3.51 (1.63, 7.55)**	0.79 (0.11, 5.44)	**5.37 (2.33, 12.41)**

Bold odds ratio indicates that the associated 95% CI excludes 1
TF = tibiofemoral joint; PF = patellofemoral joint; CI = confidence interval

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Osteoarthritis - Clinical Aspects I: Imaging and Epidemiology

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: The cause of knee pain in osteoarthritis (OA) is multi-factorial, and there is increasing evidence of the role of inflammation in OA. The goal of this study was to examine the association between development of incident frequent knee pain or improvement of frequent knee pain with changes in semi-quantitative (SQ) MRI imaging biomarkers of inflammation.

Methods: Data from the Osteoarthritis Initiative (OAI) study was used for this analysis. Knees from the OAI that were at risk of developing incident radiographic OA through the 48-month OAI visit were included if they had SQMRI readings and data on frequent knee pain (KP) on at least two successive OAI annual visits. MRIs were read according to the MRI Osteoarthritis Knee Score (MOAKS) system, unblinded to order of acquisition but blinded to clinical data. Frequent knee pain was defined as "pain on most days of the past 30 days". For each pair of successive annual time points where KP was absent at the first time point, we examined the potentially increased odds of transitioning to KP (no KP to KP+) predicted by whether Hoffa synovitis (HS) had a concurrent change from absent (no HS) to present (HS+) vs other HS patterns. Concurrent effusion synovitis (ES) vs KP transition patterns were analogously compared. We also compared the HS and ES concurrent transitions when a knee went from KP+ to no KP. State transition modeling was used to estimate the odds of transitioning from no KP to KP+ in successive years predicted by HS or ES transitions. The absence of Hoffa synovitis or effusion synovitis at both time points was the referent group. Random effects mixed models were used to account for clustering of knees within a person and multiple time points for each knee. Models were adjusted for age, gender and BMI.

Results: We included 345 knees from 313 participants, 66% female and with a mean age of 60 years; 62% of knees were KLG 1 and 38% were KLG 0 at baseline (Table 1). No ES to ES+ and no HS to HS+ were the only changes associated with the transition from no KP to KP+ in multivariate analyses. When stratified by sex, the association of no HS to HS+ with the transition of no KP to KP+ was stronger for men (aOR=7.37, 95% CI: 1.54-35.32) than for women (aOR=3.95, 95% CI: 1.47-10.61), whereas for no ES to ES+, the association with transition of no KP to KP+ was significant only in men (aOR=3.98, 95% CI: 1.39-11.38), but not women (aOR=1.78, 95% CI: 0.84 -3.74). There were no significant associations of these SQMRI biomarkers with the transition from KP+ to no KP.

Conclusion: Incident frequent knee pain was associated with the presence of new Hoffa synovitis or effusion-synovitis, and these associations varied by sex. These SQMRI biomarkers of inflammation are potential targets for therapeutic interventions for pain in knee OA.

Table 1. Association between semi-quantitative MRI biomarkers of inflammation and incident knee pain

Exposure (effusion-synovitis, Hoffa synovitis transitions from one time point to the next)	**Incident Knee Pain*** aOR (95%CI)**	P-value

Session Title: Osteoarthritis - Clinical Aspects I: Imaging and Epidemiology

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Semi-quantitative scoring of magnetic resonance images (MRIs) is a valuable method for performing multi-feature assessment of the knee joint. The goal of this study was to investigate the ability of change in semi-quantitative knee MRI biomarkers over 24 months to predict knee osteoarthritis (OA) progression over 48 months.

Methods: This analysis was done as a part of the fNIH-funded OA Biomarkers Consortium case-control study. We selected a predetermined number of index knees, one knee per subject, in four different knee outcome groups: 1) knees with both radiographic and pain progression; 2) knees with radiographic but not pain progression; 3) knees with pain but not radiographic progression; 4) knees with neither radiographic nor pain progression. For the purposes of this analysis we used the single comparison, comparing knees with both radiographic and pain progression (cases) vs. everybody else (controls). MRIs were read according to the MRI Osteoarthritis Knee Score (MOAKS) scoring system in sequential order unblinded to time point of acquisition but blinded to group assignment. This analysis focused on change in several joint features: 1) bone marrow lesions (BMLs), 2) cartilage thickness, 3) cartilage surface area, 4) effusion-synovitis, 5) meniscus morphology, 6) meniscus extrusion, 7) osteophytes size, and 8) Hoffa-synovitis. We used logistic regression to examine the association between each biomarker and case status. Multivariable models were built in a hierarchical fashion, with the best performing biomarkers from univariate analyses added to the model first (performance based on p-value, OR and c-statistics). **Results:** We used the data from 194 cases and 406 controls, mean age 62 years, 59% females, 51% K-L 2 and 37% K-L 3. All joint features considered were significantly associated with case status in univariate analyses, and all features were progressed to multivariable modeling. We built several hierarchical models with c-statistics ranging from 0.686 to 0.725 (Table). Results of multivariable modeling revealed that changes from baseline to 24 months in cartilage thickness, cartilage surface area, meniscal morphology, effusion-synovitis, and Hoffa-synovitis independently predicted knee OA progression (case status). BMLs, osteophytes, and meniscal extrusion did not exhibit a statistically significant association with being a case in multivariable models when cartilage thickness and surface area and meniscal morphology were included in the model.

Conclusion: Both loss of cartilage thickness and cartilage surface area worsening over 24 months were independently associated with knee OA progression over 48 months. In addition, changes over 24 months in semi-quantitative measures on MRI related to meniscus morphology, effusion-synovitis, and Hoffa-synovitis were associated with progression of knee OA in multivariable models.

Table. Association between select knee joint features measured by semi-quantitative MRI (MOAKS) and case status: results from multivariable modeling. P-values, odds ratios (95% confidence intervals) presented in cells.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Osteoarthritis - Clinical Aspects I: Imaging and Epidemiology

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: In western countries, hip osteoarthritis (OA) is the third osteoarthritic location in terms of prevalence, with a ratio hip/knee OA of 1:2 to 1:3. However, in Asian/African countries, this ratio is much lower, of 1:27 in Algeria and 1:40 in China. A comparative study between American and Chinese hips in elderly women found more impingement and asphericity in hips of white women. We conducted this study to find out morphometric differences between Algerian and American hips that may explain such differences in hip OA prevalence.

Methods: A morphometric study was performed on 200 hips of 100 Algerian healthy female subjects, aged ³ 60 years and compared with values of 200 American female hips of the Study of Osteoporotic Fractures (SOF). Were mesured and compared the following dysplasia and impingement parameters: lateral center-edge angle, impingement angle, acetabular slope, femoral head-to-femoral neck ratio and crossover sign. Comparisons were made using t tests for continuous variables and z tests for proportions. Inta- and inter-observer intraclass correlation for Algerian measures were calculated.

Results: The intra- and inter-observer intraclass correlation were good to excellent (0.91 to 0.97 and 0.79 to 0.89, respectively). Different values are exposed on table 1.

Parameter	**Algerian subjects** **n=100, 200 hips**	**American subjects** **n=100, 200 hips**	***P value***
Age (mean ± SD) (years)	66.6 ± 6.4	71.0 ± 4.8	< **0.0001**
BMI (mean ± SD) (Kg/cm^2)	29.1 ± 5.7	26.8 ± 4.2	**0.0014**
Lateral center-edge angle (Wiberg) (°)	41.4	30.4	0.075
Impingement angle (°)	62.6	83.6	**0.029**
Femoral head-to-femoral neck ratio	0.91	0.89	0.505
Acetabular slope of T™nnis (°)	2.7	3.8	0.663
Wiberg > 35° (%)	77.5	23.1	< **0.0001**
Wiberg < 20° (%)	0.0	7.0	**0.0001**
T™nnis < 0° (%)	16.5	13.0	0.323
T™nnis > 15° (%)	0.0	1.0	0.156
Impingement angle < 70° (%)	78.0	12.1	< **0.0001**
Femoral head-to-femoral neck ratio > 1.35 (%)	0.5	4.0	**0.018**
Crossover sign (%)	3	81	< **0.0001**

Conclusion: Compared with American women > 60 years, Algerian women have distinct differences in their morphometric values, with lower mean impingement angles and more important Lateral center-edge angles. These data suggest a more common asphericity and impingement in Algerians, which theoritically predisposes to more hip OA lesions. We think that this abnormality is largely offset by the almost total lack of acetabular retroversion in Algerians (only 3% in Algerians VS 81% in Americans), which may play a protective role against the anterior femoroacetabular impingement.

Promoting Professional Development of Medical Educators in Rheumatology: Perspectives of Clinician Scholar Educators

Juliet Aizer[1] and Jeanne Bitterman[2], [1]Rheumatology, Hospital for Special Surgery, New York, NY, [2]Adult Learning and Leadership, Teachers College, Columbia University, New York, NY

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Education

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose:

Recognizing the importance of supporting educators to improve patient care, the Rheumatology Research Foundation (RRF) offers competitive awards for Clinician Scholar Educators (CSE) in rheumatology. CSE awards have provided project-based funding since 1999 and evolved to provide additional financial support for professional development (PD). By analyzing the experiences of CSE awardees we aimed to identify approaches to support PD for educators in rheumatology.

Methods:

With IRB approval, each of the 53 rheumatologists who had completed CSE awards by 2014 were invited by email to contribute his or her perspective on PD of medical educators in focus groups or individual interviews. Parallel semi-structured formats were used, probing motivation for study participation, motivation for PD, descriptions and impacts of PD, and suggestions for how to support medical educators' PD. Focus groups and interviews were audio-recorded and transcribed. The authors independently reviewed transcripts using a general inductive approach and developed codes sensitized by theories of adult learning. Investigators compared and contrasted findings, arriving at an expanded and then condensed set of themes.

Results:

In November 2014, 20 rheumatologists participated in 1-hour focus groups at the American College of Rheumatology (ACR) Annual Scientific Meeting. Focus group size ranged from 3-7 participants. Between December 2014 and May 2015, 6 rheumatologists participated in individual telephone interviews, 25-35 minutes in duration. In total, perspectives of 49% (26/53) of CSE awardees were captured. Gender distribution of participants (54% women) was similar to that of awardees (47% women). A similar number of participants had received the award in the first 7 years the CSE award was offered as in the subsequent years (12 versus 14).

Interviews captured greater detail than focus groups; overall themes from the focus groups were corroborated in the interviews. Participants cited commitment to supporting medical education, medical educators, the community of CSE awardees, an individual CSE awardee, and the ACR/RRF as motivating factors for study participation. A minority attended to hear others' experiences. PD experiences before, during and after CSE award funding were described.

Participants emphasized the value of communities of educators, including the community of CSE awardees, as well as communities of program directors, course directors, educators in formal education programs, and members of Academies of Medical Educators. PD was often triggered by new or desired responsibilities. Mentorship, collaborations, feedback, inquiry and leadership roles emerged as experiences with critical impact; these were recommended for other educators.

Conclusion:

Experiences reported by CSE awardees as having positive PD impact align most closely with theories of adult development within a constructivist paradigm. Communities of medical educators can be a key source of opportunities for mentorship, team learning, collaborative or collegial inquiry, and leadership roles to promote development of medical educators.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Education
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: The New York City Rheumatology Objective Self Assessment Clinical Exam (NYC-ROSCE) annually assesses 1st and 2nd year fellow competencies in areas such as professionalism and communication skills in a patient-interactive setting. This year's exam used inter-professional evaluators to allow for a complete 360-degree comparison of ratings from physician-evaluators (MD), nurse-evaluators (RN) and patient-actors (PT).

Methods: The 2015 NYC-ROSCE included 5 patient-centered stations focusing on rheumatic diseases. The stations focus on psychosocial dilemmas that occur in the context of clinical care in order to assess fellow professionalism and other elements of the patient-doctor relationship. Rheumatology fellows (n=25), faculty MD-evaluators (n=25) and RN-evaluators (n=25) from 7 rheumatology training programs participated. Professional actors (n=25) were trained to role-play patients. Written quantitative assessments of the fellows were made at each station (9-point Likert scale) by MD-, RN- and PT-evaluators in the areas of maintaining composure, professionalism, and empathy. Immediate oral feedback was given to each fellow by all three evaluators following each encounter. Repeated measures ANOVA was performed to compare the mean ratings among the evaluators in all three areas. Tukey's method was used to preserve the overall Type I error when making multiple comparisons. Spearman correlation coefficient was calculated to assess the relationship between ratings for professionalism and empathy at each station for each type of evaluator.

Results: When assessing the areas of professionalism, composure and empathy, there was a statistically significant difference between evaluators' mean ratings, with RN-evaluators rating fellows the lowest and patient-actors the highest, suggesting that physicians, nurses and patients may apply different criteria when assessing competencies during observed encounters (table1). The ratings for professionalism and empathy were highly correlated for all evaluators at the majority of stations (data not shown).

Conclusion: The introduction of the RN-evaluator to the MD-evaluator and patient-actor to our yearly ROSCE offered a unique inter-professional 360-degree perspective of the patient-physician encounter. When assessing specific competencies, the MD-, RN-evaluators' and patient-actors' scores were disparate, likely reflecting their differing professional experiences and the way in which those affect how they value/rate the same event. The ultimate “true” evaluation is likely a composite of these individual perspectives. As this is the first subspecialty inter-professional ROSCE to compare raters, further research will be needed to understand the significance of the differing assumptions and expectations of MDs, RNs and patients vis-à-vis the patient-physician interchange.

Table 1. Multiple Comparisons of Mean Ratings among Evaluators

	Mean Ratings (Standard error)			Adjusted P-value		
	RN	MD	PT	RN vs. MD	RN vs. PT	MD vs. PT
Professionalism	6.51 (0.12)	6.96 (0.12)	7.72 (0.12)	0.01	<.0001	<.0001
Composure	6.42 (0.13)	6.79 (0.13)	7.37 (0.13)	0.07	<.0001	0.002

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Education

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose:

The US Department of Veterans Affairs (VA) has developed a national continuing professional development program to train primary care providers (PCPs) in the evaluation and management of patients with common musculoskeletal (MSK) conditions. Although the initial phase of this project emphasized the development of providers' proficiency to perform joint injections, the appropriate use of advanced imaging technology (e.g., magnetic resonance imaging (MRI)) in evaluating knee pain is an important additional objective of this national educational initiative. The aim of this study was to investigate the impact of this educational program on providers' utilization of MRI in the evaluation of knee pain.

Methods:

Twenty-six PCPs from the Salt Lake City VA Health Care System participated in the MSK "Mini-Residency between April 2012 and October 2014. All orders for knee MRIs submitted by these providers over the 12-months prior to their participation in the mini-residency (pre-training) were reviewed, as well as all orders submitted over the 12-months following their participation (post-training). MRIs were categorized as follows:

"Inappropriate": No prior weight-bearing x-rays done within the preceding 12 months

"Probably inappropriate": Findings of OA described on x-ray report

"Possibly appropriate": No findings of OA described on x-ray report

The number of MRIs in each category was recorded for the pre-training and post-training period specific to each provider, and the number of MRIs in each category was tallied. Differences in the numbers of MRIs that were ordered post-training as compared to pre-training for each of the three categories were evaluated using Student's t-test (2—tailed).

Results:

	Pre-training	Post-training	Change (n, % of change; p)
Completed MRIs (n, % of total)	114 (100%)	62 (100%)	-52 (-54.4%; p < 0.001)
Inappropriate	70 (61.4%)	33 (53.2%)	-37 (-47.1%; p = 0.03)
Probably Inappropriate	30 (26.3%)	16 (25.8%)	-14 (-53.3%; p = 0.03)
Possibly Appropriate	14 (12.3%)	13 (21%)	-1 (-7.1%; p = NS)

Conclusion:

Following participation in the MSK Mini-Residency program, the overall number of MRI orders decreased by over 50%. The reduction in total number of MRIs is completely attributable to a decrease in orders that were categorized as either inappropriate or probably inappropriate. The number of MRIs that were categorized as possibly appropriate did not change. These findings suggest that the cost effectiveness of the MSK mini-residency program is even greater than earlier estimates, which did not consider cost savings due to more appropriate use of imaging.

Use of Social Media By Rheumatology Fellows in North America

Jonathan S. Hausmann[1,2], Jayanth Doss[3] and Laura Cappelli[4], [1]Rheumatology, Boston Children's Hospital, Boston, MA, [2]Rheumatology, Beth Israel Deaconess Medical Center, Boston, MA, [3]Division of Rheumatology, Vanderbilt University Medical Center, Nashville, TN, [4]Ste 4500, Johns Hopkins University, Baltimore, MD

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Education

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose:

Social media, now used by 79% of US adults with internet access, has the potential to change the way in which physicians, patients, and medical organizations communicate about health-related issues. What remains unclear is to what extent physicians use social media in their professional lives. The benefits of using social media professionally include connecting physicians with common interests from geographically disparate areas, collaborating on research projects, and obtaining and sharing scientific information. It is assumed that younger physicians are more involved in social media, although it is not known whether this reflects personal or professional use.

To date, only a few small studies have systematically assessed physicians' professional use of social media. We examined the use of social media for personal and professional purposes by rheumatology fellows in North America.

Methods:

Rheumatology fellows attending the 2014 ACR Annual Meeting were invited to participate. After the Fellows-In-Training educational session, Quick Response (QR) codes and web links to an online survey were provided. The survey evaluated the educational session and assessed use of and attitudes towards social media.

Results:

375 fellows attended the Fellows-In-Training educational session, and 235 (62.7%) of these fellows completed the survey. Year of training and specialty are shown in Table 1. 88.5% of fellows use social media for personal use, while 40.9% use it professionally at least

once monthly (Table 2).

Conclusion:

Facebook was the most commonly used platform, with 82% of fellows using it for personal use. Twitter, for either personal or professional use, was reported by 18% of fellows, significantly less than surveys of adults with a college education, where the rates of use are 30%.

For professional use, LinkedIn was the most commonly used platform, utilized by 20% of rheumatology fellows. This is less than in national studies, in which 50% of internet users with a college education use LinkedIn.

It is possible that warnings about potential harms of social media within healthcare institutions have made rheumatology fellows less likely to engage on these platforms. Future studies should examine the barriers to professional use of social media, as well as educate physicians about its potential benefits.

Table 1: Level and type of training of rheumatology fellows.

Year in training	n (%)

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Education

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose:

Enhancing rheumatology fellows' teaching skills in the setting of inpatient consultation may have a broad positive impact. Such efforts may improve fellows' clinical skills and overall patient care. Most importantly, effective resident-fellow teaching interactions may not only increase residents' knowledge of rheumatology, but may influence their career choice. However, a number of barriers to the resident-fellow teaching interaction have been identified, including fellows' teaching skills. We developed the Fellow As Clinical Teacher (FACT) curriculum in order to enhance fellows' teaching skills during inpatient consultation.

Methods:

The FACT curriculum was delivered over two 45-minute workshops during the three-day Winter Meeting of the Carolina Fellows Collaborative. We evaluated its effect with self-assessment surveys and fellow performance on the Objective Structured Teaching Exercise (OSTE) before and after participation in the curriculum.

Results:

Nineteen fellows from four rheumatology training programs participated in the pre and post-curriculum OSTEs. Of the 8 OSTE rating items, fellows scored higher on 5 items and the total score in the post-curriculum OSTE as compared to the pre-curriculum OSTE (Table 1). Fellows' ability to listen to the learner, encourage learner to participate actively in the discussion, evaluate learner's ability to synthesize information, present well organized material and give feedback were all rated higher during the post-curriculum OSTE. The average total OSTE score increased after participation in the FACT curriculum (35.7 versus 29.5, $p<0.01$).

Eighteen fellows completed pre and post-curriculum surveys. Following the completion of the FACT curriculum fellows reported more confidence in their ability to teach in the setting of consultation and in their ability to give feedback (Table 2). Fellows rated the curriculum highly (4.1 out of 5) and 17 of 18 fellows (94%) stated that they would teach more frequently during consultation after participating in the FACT curriculum.

Conclusion:

The FACT curriculum, focused on teaching during consultation, improved fellows teaching skills and attitudes towards teaching. Improving and increasing fellow teaching, particularly in the setting of consultation, may impact patient care, resident and fellow learning, teaching skills of future faculty and could potentially influence trainees' career choice.

Table 1 – Performance on pre and post-curriculum Objective Structured Teaching Exercise (OSTE)

Item	Pre-curriculum N=19	Post-curriculum N=19	p-value
Listened to learner	3.95	4.84	<0.01
Encouraged learner to participate actively in the discussion	3.75	4.32	0.04
Evaluated learner's knowledge of factual medical information	3.53	4.16	0.11

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Education
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Mentoring is a key contributor to success in academic medicine. In pediatric rheumatology, surveys have repeatedly identified mentoring as a major career unmet need of fellows and junior faculty. In response, in 2011 the American College of Rheumatology (ACR) and the Childhood Arthritis & Rheumatology Research Alliance (CARRA) launched a subspecialty-wide inter-institutional mentoring program for pediatric rheumatologists, the ACR/CARRA Mentoring Interest Group (AMIGO). Our objective is to evaluate if implementation of AMIGO was associated with improved access to mentoring in pediatric rheumatology.

Methods: US and Canadian pediatric rheumatology fellows, junior faculty (assistant professor and below) and senior faculty (associate professors and above) were surveyed in 2011 (pre-AMIGO) and again in 2014 (post-AMIGO). Participants were asked to report access to mentoring in domains relevant to academic rheumatology: clinical practice, teaching, research, setting career goals, and identifying how to achieve career goals. Respondents reported whether mentoring in each domain was available at the home institution, at an outside institution, at both or neither, and were asked to rate overall satisfaction with career mentoring.

Results: Respondents to each survey included >50% of pediatric rheumatologists in the US and Canada (n=277 in 2011; n=177 in 2014 and 59% AMIGO participants). By 2014, 86% of fellows and 31% of junior faculty were AMIGO mentees. In 2011, fellows were substantially less likely than senior faculty to have mentoring outside the home institution. This difference resolved by 2014. By 2014, the proportion of fellows with outside mentors increased markedly in the domains of research, setting career goals, and achieving career goals (Figure 1). No change was observed in clinical or teaching domains. Overall, fellows but not junior faculty reported an increase in satisfaction with career mentoring between 2011 and 2014.

Conclusion: The implementation of AMIGO was associated with improved access to mentoring beyond the home institution for fellows in pediatric rheumatology as well as an increase in satisfaction with career mentoring measureable at the level of the whole community. These findings support the efficacy of the subspecialty-wide AMIGO mentoring program, and suggest that AMIGO may serve as a model for mentoring programs in adult rheumatology and in other domains of medicine.

Session Date: Sunday, November 8, 2015

Session Title: Pain: Basic Aspects

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Male C57Bl/6 (WT) mice develop transient inflammation in response to K/BxN serum transfer and show a corresponding pain state, which persists beyond the resolution of inflammation. The current studies first examined the role of spinal cytokines, specifically TNF and IFNβ in the transition to a persistent, post-inflammatory pain state, which is mediated through Toll-like receptor (TLR) 4 signaling. Importantly, the contribution of TLR4 to pain states has been found to differ between male and female animals. Thus, our second aim was to examine whether female WT mice respond similarly to K/BxN serum transfer, and to examine whether TLR4 signaling associated spinal cytokines were involved in the development of tactile allodynia (TA) in female animals.

Methods: K/BxN sera (100µl) was injected into male and female WT, *Tnf*$^{-/-}$, *Tlr4*$^{-/-}$, and *Ifnar1*$^{-/-}$ mice on Days 0 and 2. Ankle width and withdrawal thresholds were examined over 28 days and then analyzed in the peak inflammatory (d3-10) and post-inflammatory (d13-18) phases. Spinal cords were collected from WT and *Tlr4*$^{-/-}$ arthritic mice and changes in gene expression were measured using qPCR.

Results: We examined spinal cords for differences in TNF and IFNβ gene transcripts on day 10 post K/BxN serum transfer, relative to day 0. IFNβ transcripts decreased in WT mice (average fold change: 0.41) and were increased in *Tlr4*$^{-/-}$ mice (average fold change: 18.84). In contrast, TNF transcripts increased in WT mice (average fold change 1.33), and remained unchanged in *Tlr4*$^{-/-}$ mice (average fold change 0.96). Next, we assessed the development of TA in male *Ifnar1*$^{-/-}$ and *Tnf*$^{-/-}$ mice. The early, inflammatory phase of pain is attenuated in *Ifnar1*$^{-/-}$ mice (1.18g threshold relative to 0.5g in WT males, $p < .05$); however these mice develop persistent pain while the late phase of pain is reduced in *Tnf*$^{-/-}$ mice (1.29g threshold, relative to 0.74g in WT males, $p < .05$).

Next, we examined female WT mice after K/BxN serum transfer. To our surprise, female mice developed an initial tactile allodynia that is indistinguishable from males (0.72g relative to 1.97g at baseline), but do *not* develop a persistent pain state (post-inflammatory threshold: 1.36g, $p < .05$). The behavioral phenotype of female WT mice resembled that of *Tlr4*$^{-/-}$ males, and we assessed whether similar cytokine signaling contributed to the K/BxN pain phenotype. Both female *Ifnar1*$^{-/-}$ and *Tnf*$^{-/-}$ mice were indistinguishable from their male counterparts in terms of both ankle inflammation and pain ($p > .05$). We then determined whether TNF and IFNβ transcripts change over

time (days 0, 3, 10, 18, and 28) by qPCR in male and female WT mice. Males showed a general increase in spinal TNF mRNA expression, and a decrease in IFNβ. Although the female mice also showed an increase in TNF transcripts, they had a transient decrease in IFNβ and then recovered to initial levels.

Conclusion: These results show persistent pain in male WT animals is associated with differential modulation by TNF and type I IFN. Female WT animals, however, fail to develop persistent pain, and show a recovery of IFNβ transcription indicating that co-modulation is important to prevent the development of persistent, post-inflammatory TA.

Collagen Antibodies Induce Pain-like Behavior in Mice Independent of Inflammation and Complement Activation but Requires FcÎ³rs

Gustaf Wigerblad[1], Katalin Sandor[1], Kutty Selva Nandakumar[2], Rikard Holmdahl[3] and Camilla Svensson[1], [1]Department of Physiology and Pharmacology, Karolinska Institutet, Stockholm, Sweden, [2]Medical Biochemistry and Biophysics, Karolinska Institutet, Stockholm, Sweden, [3]Department of Medical Biochemistry and Biophysics, Karolinska Institutet, Stockholm, Sweden
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Pain: Basic Aspects
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose:

Collagen Antibody Induced Arthritis (CAIA) is an acute mouse model of rheumatoid arthritis (RA). It is induced by an intravenous injection of a cocktail of monoclonal antibodies (mAb) against collagen type II (CII), producing a transient inflammation that typically starts around day 6-9 and peaks around day 12-15. Interestingly, in our studies aimed at characterizing pain-like behavior in the CAIA model we found that the mice displayed clear signs of nociception prior to the onset of inflammation. Thus, the purpose of this study was to characterize the pre-RA phase from a pain perspective and to investigate what drives anti-CII antibody-induced nociception.

Methods:

Male B10.RIII, B10.Q, and B10.Q $C5^{-/-}$ mice were injected i.v. with 4 mg/mouse of anti-CII mAbs cocktail, isotype control IgG, CII Ab Fab fragments, EndoS-treated CII mAbs, or CIIF4 mAbs and monitored for 5 days. Arthritis was examined by visual scoring of the paws (0-60), histological examination (H&E), and gene expression (qPCR) analysis of the ankle joints. MMP activity in the paws was visualized using MMPsense680. Pain-like behavior was monitored by measuring mechanical hypersensitivity with von Frey filaments day 0-5 and locomotion parameters by Comprehensive Lab Animal Monitoring System the night between days 2-3. Mice were injected subcutaneously (s.c.) with a peptide inhibitor (PMX53, 3 mg/kg/day) of the receptor for complement component 5a (C5aR).

Results:

Over the 5 days after injection of anti-CII mAb cocktail, only minor visual signs of inflammation (score: <10) in 3 of 14 mice was observed. Minor cell infiltration and bone erosion (in 2 and 1 mouse, respectively), while no cartilage destruction, change in mRNA expression (of examined cytokines, mast cell proteases, or MMPs), or MMP enzymatic activity was detected day 5. In contrast, all mice injected with CII mAbs, but not control mAbs, displayed a significant reduction in mechanical thresholds day 2, which remained low through day 5 and a significant decrease in ambulation, rearing, and total movement night 3. Mice lacking the C5 protein are resistant to CAIA. However, $C5^{-/-}$ mice and mice treated with C5aR inhibitor still developed anti-CII mAb-induced mechanical hypersensitivity and reduction in locomotion. The CIIF4 mAb bind cartilage but protects against arthritis, when injected with the CAIA mAbs. Injection of CIIF4 alone induced mechanical hypersensitivity to a similar degree as the anti-CII mAb cocktail. Injection of anti-CII mAbs lacking the Fc-part or the glycan at Asp297 did not induce hypersensitivity or reduce locomotion.

Conclusion:

No correlation between the arthritis scores, histological changes, gene expression of inflammatory factors, complement activation, and nociception (evoked or ongoing) was found. However, antibody treatment that diminishes the ability of the antibodies to associate with FcγRs prevented nociceptive behavior, indicating that antibody-Fc interaction is necessary for *in vivo* pain-behavior. Thus, our current work suggests that certain RA-associated antibodies have the capacity to evoke pain through mechanisms that are dependent on their binding to FcγRs but not by inducing inflammation.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Pain: Basic Aspects
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Joint pain is one of the main reasons for patients with rheumatoid arthritis (RA) to seek medical care. Collagen type II (CII) antibodies (Abs) are detectable in serum and synovial fluid of many RA patients and are thought to contribute to the inflammatory process in the joint. A common view is that factors produced during inflammation are the major cause of joint pain in RA. However, pain can appear prior to diagnosis and continue to be a significant problem even when the disease is under medical control. Earlier, we have shown that while injection of CII Abs in mice induces transient joint inflammation, pain-like behavior not only outlasts the inflammation but also precedes the onset of inflammation. Moreover, Fc gamma receptors (FcγRs), which are activated by immune complexes (ICs) on inflammatory cells, are also present on peripheral sensory neurons. The aim of this study is to examine if antibodies can directly activate sensory neurons via neuronally expressed FcγRs and thus act as pain-inducing molecules.

Methods: Male BALB/c mice (10-12 weeks) were used to prepare dorsal root ganglia (DRG) primary neuronal cell cultures. Neuronal expression of FcγRI was evaluated by immunocytochemistry. The effect of stimulation with CII mAb cocktail, control IgG2b and CII (all 1 µg/ml) and ICs formed by CII mAb cocktail and CII (CII-IC; 0.1-10 µg/ml) on neuronal excitability were examined by a) calcitonin-gene related peptide (CGRP) release in wild type (WT) and Fcγ-chain deficient mice b) electrophysiology and c) calcium imaging

Results: FcγRI expression was detected in DRG neurons and co-localized with PGP9.5, a neuronal marker. The levels of CGRP, a pain-associated neurotransmitter were increased in a bell shaped fashion in supernatants from WT DRG neurons stimulated with CII-IC, peaking at 1 µg/ml. Note that, 1 µg/ml concentration was used in subsequent studies. No increase in CGRP was detected after stimulation with CII mAb cocktail, CII or control IgG2b. CGRP release was induced by capsaicin (Cap; 50 nM), a ligand for transient receptor potential vanilloid 1 (TRPV1), was used as a positive control. In contrast, while DRG cultures from Fcγ-chain deficient mice responded to Cap, stimulation with CII-IC did not evoke CGRP release. Electrophysiological recordings in voltage clamp mode showed ionic current changes in the presence of CII-IC. Of 114 cells, 52 cells gave inward current response to Cap and 42% (22) of the Cap^+ cells gave response to CII-IC. In control experiments, none of the Cap^+ cells (18) responded to IgG2b. Calcium influx assessed by calcium imaging increased in DRG neurons stimulated with CII-IC and KCl (50 mM) (positive control to detect functional neurons) but not control IgG2b. Among the 1555 cells, 1119 cells gave response to KCl and 22.1% (247) of the KCl^+ cells responded to CII-IC, but not to control IgG2b (<1%).

Conclusion: The present study demonstrates for the first time that CII Abs in immune complex formation, presumably via activation of FcγRs expressed on DRG neurons directly contribute to nociception. These findings have the potential to define new roles for antibodies in pain transmission and open new avenues for treatment of pain in RA and other autoimmune diseases.

A 32-Mer Aggrecan Fragment Generated through Adamts-4/5 and MMP-Mediated Cleavage Can Directly Excite Nociceptive Neurons

Rachel E. Miller[1], Richard J. Miller[2], Abdelhak Belmadani[3], Suzanne Golub[4], Amanda J. SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Pain: Basic Aspects

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose:

Cleavage of aggrecan in the interglobular domain (E^{373}-^{374}A) by ADAMTS-4/5 is an early event in osteoarthritis pathogenesis. Further cleavage by MMPs (N^{341}-^{342}F) releases a 32-amino-acid fragment, FFGVGGEDDITIQTVTWPDLELPLPRNVTEGE. We recently reported that this 32-mer acts as a TLR2-dependent damage-associated molecular pattern on chondrocytes and synovial fibroblasts. Here, we hypothesized that this aggrecan fragment may directly excite nociceptors.

Methods:

DRG cells (L3-L5) were isolated from adult C57BL/6 wild-type, *Tlr4*-null, or *Tlr2*-null mice and cultured. Direct effects of synthetic 32-mer on DRG neurons were monitored by examining intracellular calcium (Ca)i mobilization or production of MCP-1. For Ca mobilization assays, cells were loaded with Fura-2 and responses to 32-mer or scrambled peptide recorded in >100 neurons. For MCP-1 stimulation assays, cells were treated overnight with 32-mer (0.3-30 μM) or with scrambled control. Supernatants were collected for MCP-1 ELISA, because we have previously shown that MCP-1 is a key mediator of pain in experimental OA.

For *ex vivo* imaging assays, intact DRG were isolated from Pirt-GCaMP3 mice, which express the fluorescent calcium indicator, GCaMP3, in 90% of sensory neurons through the Pirt promoter. Explants, placed in a perfusion chamber and imaged using a spinning disk confocal microscope, were stimulated by injecting 10 μL of 1 mM 32-mer into a continuously running perfusion chamber with a 1 mL-volume. ImageJ analysis was performed to determine change in fluorescence intensity with time.

Results:

Cultured DRG neurons rapidly responded to 32-mer, but not scrambled control peptide, as indicated by increased (Ca)i in 20% of neurons. This suggests that DRG neurons express excitatory receptors for this protein fragment. Responses were mostly seen in small-to-medium-diameter neurons (nociceptors) that were also responsive to capsaicin, which demonstrates that TRPV1-expressing nociceptors are capable of responding to 32-mer. In order to show that 32-mer responses are not an artifact of cell culture, calcium imaging was also performed using intact DRG from Pirt-GCaMP3 mice. Within DRG explants, 7% of neurons responded to 32-mer peptide, while scrambled peptide elicited no responses.

Overnight stimulation of cultured DRG cells with either 3 or 30 μM 32-mer peptide resulted in significant upregulation in MCP-1 protein production compared to unstimulated cells (3.1-fold (3 μM) and 3.5-fold (30 μM), $p<0.001$). The highest concentration of scrambled peptide (30 μM) did not induce MCP-1 production (0.8-fold, $p=0.09$ vs. unstimulated).

In order to investigate which receptor mediates the upregulation of MCP-1, DRG cells were cultured from *Tlr2* null or *Tlr4* null mice. Stimulation with 32-mer peptide (3 μM) produced increased MCP-1 in *Tlr4* null DRG cells compared to unstimulated cells (3.3-fold, $p<0.01$), but not in *Tlr2*null cells (0.9-fold, $p=0.5$), suggesting that these effects are mediated through TLR2.

Conclusion:

Nociceptors can respond to a specific 32-mer cleavage product of aggrecan through TLR2. This pathway may contribute to the development of OA-associated pain, a hypothesis currently being tested in *in vivo* models.

Brain Functional Connectivity Differentially Predicts Response to Two Centrally Acting Analgesics in Fibromyalgia

Eric Ichesco[1], Johnson Hampson[2], Lynne Pauer[3], Andrew Clair[4], Tobias Schmidt-Wilcke[5], David A. Williams[6], Daniel J. Clauw[2] and Richard E. Harris[1], [1]Anesthesiology, U. Session Date: Sunday, November 8, 2015

Session Title: Pain: Basic Aspects

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Recently, several functional brain imaging techniques including functional magnetic resonance imaging (fMRI) have been proposed to be useful in probing the mechanisms of action of centrally acting analgesics. In parallel, our group has utilized brain resting state functional connectivity (fcMRI) outcomes to predict clinical pain response in fibromyalgia (FM) to pregabalin (PGB) and milnacipran (MLN), two known efficacious compounds. While preclinical work suggests that the mechanisms of action of these drugs may differ, a key hurdle in the identification of novel acting central analgesics would be the ability to differentially predict clinical response to different compounds in humans.

Methods: 29 female FM patients were included in this study: 14 underwent a double-blind placebo-controlled crossover study with the administration of PGB, and15 were enrolled in a similar study with MLN. All patients underwent a 6 minute fcMRI scan pre-treatment for both the drug and placebo periods. Patients also reported clinical pain pre- and post-treatment using a 0-10 rating scale. fcMRI data were analyzed with an *a priori* regions of interest approach using the Conn toolbox running through SPM8 and Matlab. Regions previously identified as predictive for PGB and MLN in isolation were cross-utilized in both data sets. Seeds included: the insula, rostral and genual anterior cingulate, dorsal lateral prefrontal cortex (DLPFC), periaqueductal gray, and amygdala. Prediction results were analyzed in SPM8 with a multiple regression that included seed-to-whole brain correlation maps with clinical pain difference scores. **Results** were significant on the cluster level with a false discovery rate p value < 0.05 derived from an uncorrected voxel level p value < 0.001.

Results: Reduced functional connectivity between the right DLPFC (seed) to both the inferior parietal lobule ($r = 0.94$ $p < 0.001$) and inferior/mid temporal gyrus ($r = 0.88$, $p < 0.001$) was associated with greater subsequent reduction in clinical pain for MLN, but not PGB. In contrast, greater connectivity between the rostral ACC (seed) to the subgenual ACC ($r = – 0.91$, $p < 0.001$) and the left amygdala (seed) to the left insula/sensory motor cortex ($r = - 0.96$, $p < 0.001$) and the primary motor cortex ($r = - 0.89$, $p=0.01$) was associated with subsequent reduction in pain for PGB, but not MLN. Furthermore, connectivity between the right periaqueductal gray (seed) to the precuneus ($r = - 0.89$, $p = 0.02$) and between the right anterior insula (seed) to the precuneus ($r = -0.86$, $p = 0.042$) was associated with reduction in pain to PGB, but not MLN.

Conclusion: These data demonstrate that fcMRI can differentially predict clinical response to two efficacious analgesics in FM, thus providing evidence that these compounds may have differing mechanisms of action. As suspected from preclinical data, it appears that SNRIs such as milnacipran may be acting partly by increasing fcMRI to brain regions involved in anti-nociception, whereas gabapentinoids such as pregabalin may be acting by decreasing fcMRI to pro-nociceptive regions. This provides some rationale for the common clinical practice of using these two classes of drugs in chronic pain states.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Pain: Basic Aspects

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Myalgic encephalitis/chronic fatigue syndrome (CFS) is a debilitating disorder characterized by disabling fatigue and cognitive dysfunction. However, little is known regarding the neural mechanisms underlying fatigue in CFS. Recent work from our laboratory utilizing arterial spin labeling functional magnetic resonance imaging (ASL fMRI) indicates CFS patients have lower resting state regional cerebral blood flow (rCBF) in several areas associated with memory and attentional functioning, including parahippocampal gyrus, superior frontal gyrus, and anterior cingulate gyrus. This regional hypoperfusion may underlie CFS pathogenesis. The current report uses functional connectivity analysis to determine relationships between fatigue related brain regions in CFS patients compared healthy controls.

Methods: Participants were 16 CFS patients (M_{age}=52.33 years, SD=10.6) and 19 age/sex matched healthy controls (HC; M_{age}=48.74 years, SD=11.74). CFS was diagnosed in all patients using 1994 CDC criteria. All participants underwent T1-weighted structural MRI as well as a 6-minute pseudo-continuous arterial spin labeling (pCASL) sequence. pCASL allows the non-invasive quantification of CBF by magnetically labeling blood as it enters the brain. Imaging data were preprocessed in MATLAB 2011b using SPM version 12 and ASL tbx. 4D ASL images were realigned and coregistered to structural MRI prior to pairwise subtraction of control and label images to obtain the perfusion time series. Perfusion signal time series were then masked and normalized, and CBF was computed using the single-compartment ASL perfusion model (Wang et al., 2005). Functional connectivity analysis was conducted using the CONN toolbox. All effects noted below are significant at $p<0.01$.

Results: ROI-to-ROI functional connectivity analysis utilizing the regions previously identified as being hypoperfused in CFS patients and regions associated with affective, cognitive, and motor function indicated differential patterns of functional connectivity between CFS patients and HC for several areas. Right parahippocampal gyrus connectivity with left medial temporal gyrus was higher in CFS patients than HC, whereas left parahippocampal gyrus connectivity to parietal operculum was lower in CFS patients than controls. Left superior frontal gyrus connectivity to right lingual gyrus was higher in CFS patients than HC, but connectivity to right frontal operculum was lower. Finally, anterior cingulate connectivity to the superior parietal lobule was higher in CFS patients than controls.

Conclusion: Results of our ASL based analyses demonstrated hypoperfusion in several brain regions of CFS patients associated with higher cognitive functions. Additionally, these regions also demonstrate altered functional connectivity in CFS patients compared to their healthy counterparts. Although preliminary, additional results also suggest abnormal relationships between functional connectivity as reflected by ASL fMRI and CFS symptoms (e.g., self-reported fatigue ratings).

Session Title: Pediatric Rheumatology - Pathogenesis and Genetic
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Defective or sustained activation of Interferon (IFN) signaling has been associated with enhanced susceptibility to systemic lupus erythematosus (SLE). The cytosolic RIG-I-like receptors (RLRs), RIG-I (DDX58) and MDA5 (IFIH1) are intracellular pattern recognition receptors involved in the recognition of double-stranded RNA, leading to production of IFN type I. It is thought that overexpression of these receptors potentially promotes autoimmunity and contributes to the systemic IFN overactivation. Recent evidence showed a gain-of-function mutation in the IFIH1-gene, supporting the role of these cell-intrinsic sensors in autoimmune disease [Funabiki *et al*., Immunity 2014]. Childhood onset SLE (cSLE) is an incurable systemic autoimmune disease and medication is by far not effective enough, leaving children with significant side effects, especially due to prednisone. The aim of this study was to determine the prevalence of the IFN type I signature in cSLE, in relation to disease activity and the expression of the cytosolic RLRs.

Methods: In 34 healthy controls (HC), and 22 cSLE patients fulfilling ≥ 4 ACR criteria, whole blood (Paxgene) samples were collected. cSLE patients with a mean disease duration of 2.7 (± 1.6) years were followed-up prospectively and disease activity was assessed using the SELENA-SLEDAI score, including Physician Global Assessment and Flare-scores. Whole blood expression levels of 14 IFN-inducible genes, as determined by real-time quantitative PCR, were submitted to a principle component analysis (PCA) to identify 5 genes explaining >95% of the total variance. The IFNscore, a quantitative measure for total IFN type I bioactivity, was calculated using expression levels of the 5 indicator genes - IFI44, IFIT1, IFIT3, Ly6e and MX1 - to define the whole blood IFN type I signature in cSLE. cSLE patients positive for the IFN type I signature (IFNscore >10) were compared with patients negative for the IFN signature (IFNscore <10). Additionally, mRNA expression of the RLRs was assessed.

Results: We identified the presence of an IFN type I signature in 54.5% (12/22) of the cSLE patients. At time of inclusion, we found no significant difference in disease activity between IFNpositive and IFNnegative cSLE patients (p=0.0744). Disease activity and other biological markers are being assessed longitudinally. Interestingly the RLRs, RIG-I (p<0.001) and MDA5 (p<0.001) were significantly upregulated in IFNpositive cSLE compared to HC and IFNnegative cSLE patients. Furthermore, RIG-I (p<0.0001; r=0.954) and MDA5 (p<0.0001; r=0.904) highly correlated with the IFNscore.

Conclusion: The prevalence of the IFN type I signature in cSLE was 54.5%. Interestingly, overexpression of RIG-I and MDA5 is evident in cSLE, and strongly related to the presence of the IFN signature. Further investigating the role of these RLRs in disease pathogenesis is warranted and might offer new opportunities for selective therapeutic targeting.

Session Title: Pediatric Rheumatology - Pathogenesis and Genetic

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Juvenile idiopathic arthritis (JIA) is a complex genetic trait. While several risk variants have been identified using genome wide studies, a substantial component of the genetic risk is unexplained by known variants. We hypothesized that distantly related JIA cases might share genomic regions that harbor susceptibility variants.

Methods: Using probabilistic linking of children with JIA to the Utah Population Database, we identified distantly related JIA cases among descendants of founders with 4 or more descendants affected with JIA. We also identified distantly related controls whose degrees of relationship matched our cases. We genotyped subjects using Affymetrix 6.0 microarrays, and after stringent quality control, analyzed them using the Refined IBD program in Beagle. We identified segments greater than 1000 basepairs shared pairwise among cases. We then used GraphIBD to test for single nucleotide polymorphisms (SNPs) that fell within shared regions of case/case pairs more often control/control or case/control pairs.

Results: We identified 296 distantly related cases and 300 distantly related controls. In all 194 founders had significantly excessive number of descendants with JIA (range 4-17). We genotyped 218 cases and 148 controls, of whom 190 cases and 139 controls met our rigorous quality control inclusion criteria (excluding individuals with <95% call rate or heterozygosity outliers, close relatives, and population stratification outliers). Although no SNPs demonstrated association at genome wide thresholds of significance, many demonstrated associations at $p < 1X10^{-4}$ (Figure). Of the top 500 SNPs, 120 were on chr 6, corresponding to a gene *EYS,* (best $p < 1.8X10^{-5}$) which is implicated in retinitis pigmentosa, and acute uveitis associated with ankylosing spondylitis. Variants on chr 20, corresponding to the gene *PTPRT*, implicated in rheumatoid arthritis were also associated ($p < 8\ X10^{-5}$). Other regions of interest included *NFKRB* on chr 11, and two novel transcripts on chr 4 and 15.

Conclusion: Using a novel approach, we found variants in *EYS* and other loci that are shared more often among distantly related JIA case pairs, although the modest sample size limited our power. Investigating distantly related JIA case pairs offers a complementary approach to the search for genes underlying JIA risk. Analysis stratifying subjects by presence of uveitis, and replication of high priority variants in an independent cohort of JIA are underway.

Tumor Necrosis Factor-a (TNF-a) and Interferon Gamma Inducible Protein-10 (IP-10) As Predictors of Active Disease Status in Localized Scleroderma

Kathryn S. Torok[1], Jonathan Yabes[2], Qi Mi[3], Christina Kelsey[1] and Kelsey Magee[4], [1]Pediatric Rheumatology, Univ of Pittsburgh Med Ctr, Pittsburgh, PA, [2]Department of Medicine, University of Pittsburgh, Pittsburgh, PA, [3]Department of Sports Medicine and Nutrition, University of Pittsburgh, Pittsburgh, PA, [4]Pediatrics, University of Pittsburgh, Pittsburgh, PA

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Pediatric Rheumatology - Pathogenesis and Genetic

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Localized scleroderma has both inflammatory and fibrotic components contributing to its effect on the skin and underlying tissue. The extent and duration of inflammation during the active phase of the disease is thought to be the major contributor to long-term disease damage and disability in LS. Therefore, accurately identifying the active disease state is imperative, which may not always be apparent in subtypes with deeper tissue involvement or slowly progressive changes, such as with the Parry Romberg subtype. Current commercially available serological markers of disease activity, such as ESR and CRP, are rarely elevated in LS. Therefore, identifying new circulating biologic markers reflecting active disease status would be helpful for patient management; especially when deciding when to initiate or discontinue therapy in unclear cases.

Methods: Forty-five LS subjects with ≥ 2 serial serum samples who had active disease (Physician Global Assessment - Activity > 0) at the first sera collection and had subsequently entered inactive disease state at follow-up (remission) were included in a 31

cytokine/chemokine Luminex panel (T_H1 / 2 / 17 associated panels) run on 72 total LS subjects. The cytokine profile of active vs. inactive disease state was analyzed utilizing both statistical modeling and data mining techniques. Unadjusted and adjusted mixed effects logit models were fitted using activity status as the outcome and each of the cytokines as the primary predictor. Covariates for adjustment were included one at a time. Cytokine levels were categorized into quartiles and Association Rules Mining (web-based analyses) and Bayesian Network assessment were used as alternative analytical strategies.

Results: In unadjusted analyses, the cytokines/chemokines that were significantly elevated at the baseline active disease visit compared to the inactive disease state at follow-up were IP-10 (Odds Ratio (OR) [95% confidence interval] = 2.1 [1.4, 3.2], p <0.001), TNF-α (OR = 1.8 [1.1, 3.0], p = 0.016), and MCP-1 (OR = 2.0 [1.1, 3.9], p = 0.034). After adjusting one at a time for several clinical covariates, such as age at first sample, disease duration, gender, mLoSSI, LoSDI, ANA, Anti-ssDNA and AHA antibodies, IP-10 remained significant for all adjustments, TNF-α significant for all except mLoSSI, and MCP-1 significant for all except disease duration. Data mining approaches demonstrated similar results with elevation of IP-10 and TNF-α in the peripheral blood (4^{th} quartile) showing the strongest links in the active disease node, followed by other T_H1 associated cyto/chemokines and T_H17 associated cytokines.

Conclusion: IP-10 and TNF-α were identified as inflammatory mediators that predict disease activity when comparing paired active and inactive LS serologic cytokine/chemokine profiles. These data support earlier findings of correlations of IP-10 and TNF-α with disease activity parameters in a cross-sectional Luminex plasma study. These may serve to augment clinical decision making when disease activity status is not straightforward by clinical examination. Further study with additional longitudinal serological data points is underway.

Session Title: Pediatric Rheumatology - Pathogenesis and Genetic

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Despite widespread use, there remain no clear predictors of methotrexate (MTX) response or toxicity in Juvenile Idiopathic Arthritis (JIA). With the utilization of new assessment tools, the prevalence of MTX intolerance may be higher than previously recognized. We explore cellular folate and genotype as potential predictors of MTX intolerance.

Methods: This is a single center prospective cohort study of newly treated JIA patients on standardized doses of MTX (15mg/m^2) and folic acid (1mg/day). After obtaining informed consent, samples for assessment of intracellular erythrocyte folate ([folate]; comprised of 5-methyl-tetrahydrofolate + 5-10 methenyl-tetrahydrofolate) and MTX polyglutamate (MTXGlu) measurements by UPLC-tandem mass spectrometry are collected prior to and after 3 and 6 months on therapy. Genotype analysis for 41 SNPs, indels and repeats in 23 folate related genes are assessed by established methods. Clinical data are collected at each time point and include the methotrexate intolerance severity score (MISS) in a subset of patients (n=26). Statistical significance was tested using ANOVA, simple linear regression, and chi square, utilizing Wilcoxon Rank Sum or Spearman's correlations in non-normally distributed data

Results:

MISS scores ranged from 0-11, and the median (IQR) score was 2 (0, 5) in the 26 patients with data at 3 months; of these, 4/26 (15%) had a score of 6 or greater. Higher pretreatment RBC [folate] was associated with lower 3 month MISS scores (β: -0.005, p=0.008, R^2 0.28). Greater decreases in RBC [folate] from baseline were also associated with lower 3 month MISS scores (β: -3.033, p=0.05, $R^2$0.17).

When MISS scores were dichotomized at a cutoff of 6, patients with scores less than 6 had higher mean baseline RBC [folate] compared to patients with scores of 6 or greater (1107.5 (± 306) nmol/L vs. 767.2 (± 184) nmol/L, $p<0.05$). There were no correlations between 3 month MISS scores and MTXGlu.

The presence of at least 1 variant allele in methionine synthase reductase (MTRR) A>G (rs 1801394) appeared protective based on lower mean MISS scores (1.4 vs. 5.3, p=0.005) and decreased probability of a MISS score of ≥6 (0% vs. 50%, p=0.02). Homozygous variant patients had higher mean baseline RBC [folate] (1152.7 (± 379) nmol/L vs. 897.4 (± 304) nmol/L, p=0.01) and higher 3 month RBC [folate] (807.4 (± 241) nmol/L vs. 656.9 (± 241) nmol/L, p=0.02).

Conclusion: MTX intolerance is associated with lower baseline folate and reduced folate depletion after MTX initiation, suggesting a difference in folate homeostasis in intolerant children. Genetic variation in MTRR (rs 1801394) appears to be protective and reflects its important regulatory role in the folate pathway, restoring the activity of methionine synthase (MTR), crucial for transformation of homocysteine to methionine and important for one-carbon metabolism. The 'Methyl-trap' has been described with decreased MTR/MTRR activity due to depletion of the B_{12} cofactor, resulting in a functionall folate depleted state. Our data suggest that MTRR AA patients may be at risk for a similar 'methyl trap' state, further exacerbated with the introduction of MTX, resulting in increased intolerance.

Session Title: Pediatric Rheumatology - Pathogenesis and Genetic
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose:

STING-Associated Vasculopathy with Onset in Infancy (SAVI) is an IFN-mediated disease caused by gain-of-function mutations in *TMEM173*, the gene encoding the stimulator of interferon genes (STING). SAVI is a member of a subclass of interferon-mediated autoinflammatory disorders caused by chronic Type-I interferon (IFN) production. To evaluate genetic causes of the variable disease severity of the interstitial lung disease (ILD) in SAVI patients, we hypothesized that the severity of the interstitial lung disease may be

modulated by a common SNP (R232H, rs1131769) that is functionally associated with decreased *IFNB1* transcription.

Methods:

Twelve SAVI patients, with N154S, V155M, V147L, or V147M *TMEM173* mutations, were evaluated. Lung involvement was assessed by chest computed tomography (CT) and pulmonary function tests (PFTs) for all patients; lung biopsies were available for seven patients. Peripheral blood genomic DNA samples were obtained and *TMEM173* (NM_198282.3) gene was sequenced by Sanger technique. STING function was evaluated in the different *TMEM173* haplotypes by *IFNB1* Luciferase Reporter assays performed with cells transfected with wildtype or mutant *TMEM173* on the R232 and the H232 backgrounds.

Results:

Of twelve SAVI patients, nine had evidence of severe ILD characterized by moderate to severe abnormalities on chest CT, PFTs and/or lung biopsy. Four out of the nine patients with severe ILD succumbed to pulmonary complications. Two patients presented with mild ILD and one did not have any evidence of ILD. The only patient without ILD was homozygous for the H232 allele (H232/H232) and the two patients with mild ILD were heterozygous (R232/H232) for the SNP. On contrast, 8 out of the 9 patients with severe ILD were homozygous for R232 (R232/R232) and one was heterozygous for the SNP. Thus, the severity of interstitial lung disease seems to correlate with the STING haplotype. Transfection of HEK293T cells with the R232 *TMEM173* haplotype with or without SAVI-causing mutations results in significantly increased *IFNB1* expression in the presence of both low affinity and high affinity STING stimulator cGAMP in comparison with cells transfected with the H232 haplotype. These findings suggest that the H232 haplotype background may be protective from the development of ILD and that gain-of-function of STING in the R232 background seems to provoke a more severe lung phenotype.

Conclusion:

The variable severities of ILD in SAVI patients are associated with the *TMEM173* haplotype at amino acid position 232. Our functional data suggest that common polymorphisms can modify organ-specific disease expression and provide insights to understanding the variable disease phenotype in other IFN-mediated diseases.

Session Title: Pediatric Rheumatology - Pathogenesis and Genetic

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Systemic juvenile idiopathic arthritis (SJIA) is an autoinflammatory disease of childhood, characterized by a predominance of mononuclear phagocytic effector cells, compared to the lymphocyte driven pathogenesis in other autoimmune JIA subtypes. Monocytes respond to their cytokine milieu by adopting polarization phenotypes with distinct functions, including M1 (classical) activation and several forms of alternative activation, including M2b and M2c which have potent immunoregulatory properties. Previous

data has shown that monocytes in SJIA patients have a novel phenotype, with features of both classical activation and immunoregulatory phenotypes. Controlling factors of monocyte/macrophage differentiation in SJIA are unknown. MicroRNAs are transcriptional negative regulators which fine-tune gene expression, and have been implicated in the differentiation of monocytes/macrophages. However, microRNA expression in SJIA has not been examined.

Methods: CD14+ monocytes were isolated from children with active SJIA and clinically inactive disease (CID), and miRNA expression quantified using TaqMan MicroRNA Array. Primary human monocytes or THP1 macrophage-like cells were polarized using LPS and interferon-γ (M1), IL-4 (M2a), LPS plus immune complexes (M2b), and IL-10 or TGF-β (M2c). THP1 cells were treated with either miR-125a-5p-specific or negative control antagomir or transfected with miR-125a-5p or negative control mimic prior to polarization. Gene expression was determined using real-time PCR or TaqMan assays.

Results: We identified miR-125a-5p as the most highly upregulated microRNA in monocytes from children with active SJIA compared to those with CID. Expression of miR-125a-5p significantly correlated with markers of disease activity, including serum ferritin and white blood cell count, and systemic features such as rash and hepatomegaly. Expression of miR-125a-5p was significantly increased in both primary human monocytes and THP1 cells after polarization with M2b or M2c conditions, but not by M1 polarization. Interestingly, we found that miR-125a-5p was dispensable for M1 polarization, as treatment with a specific microRNA antagomir did not alter expression of MIG, I-TAC, TNF-α or IL-6. However, miR-125a-5p was essential for M2b polarization, as antagomir treatment significantly reduced expression of the M2b-specific chemokine CCL1 by 56%. Conversely, transfection of miR-125a-5p mimic resulted in enhanced M2b polarization with increased expression of CCL1, IL-6, and CD163. In contrast, miR-125a-5p overexpression diminished M2c polarization, and altered M1 polarization by increasing production of some M2-associated markers.

Conclusion: Our data demonstrated increased miR-125a-5p expression in active SJIA and correlation with disease activity. We also showed that miR-125a-5p serves as an essential regulator of the polarization of M2b regulatory macrophages, and may impact the balance between different forms of alternative activation. Taken together, these data suggest that miR-125a-5p could serve as an important diagnostic and therapeutic target in SJIA.

Session Date: Sunday, November 8, 2015

Session Title: Quality Measures and Quality of Care

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Treat-to-Target (T2T) recommendations for rheumatoid arthritis (RA) care include standardized frequencies of disease activity (DA) assessment based on DA level. For this study, "on time" is defined as three-month intervals for patients with moderate or high disease activity and six-month intervals for those with controlled or low disease activity. These assessments are generally performed during provider-patient encounters using a variety of clinical and laboratory measures. The actual frequencies of DA assessments in clinical practices are investigated in this study.

Methods: The Rheumatoid Arthritis Practice Performance (RAPP) Project is a voluntary collaboration of U.S. clinician rheumatologists whose goal is to provide T2T care and optimal RA disease outcomes. Of the 168 participants in the RAPP Project, 86 have enrolled their entire RA population (ICD-9 code 714.0) in a HIPAA-compliant disease population registry to this point and are entering their preferred

DA measures. Sorting these DA measures by date allows an analysis of "on-time" and "overdue" percentages in each population. The 15 RA populations in this analysis have one or more DA measures entered on at least 45% of the enrolled population, including RAPID3, a 0-10 Provider Global Assessment (PGA), Clinical Disease Activity Index (CDAI), and/or a multi-biomarker (MB) test. The on-time/overdue analysis for each registry uses multi-biomarker results, as this measure is entered for the greatest number of patients (N=11,332). The reasons for overdue DA assessments were analyzed separately in 20 practices using a visit capacity analysis methodology (provider visit slots available per month compared to slots needed for on-time assessment).

Results:

On-time DA Assessment Analysis	**Median**	**Ranges (N,%)**
Patients enrolled/registry (N,%)	662/100%	413-2120
Patients assessed/registry (N,% of enrolled)	636/81%	204-1560
DA distribution in 15 RA registry populations		
Controlled and Low DA (% of assessed)	22%	16-36
Moderate DA (% of assessed)	39%	35-45
High DA (% of assessed)	39%	28-47
On-time assessment rates (% of DA cohorts)		
Controlled and Low DA assessed within 6 months	10%	3-21
Moderate and high DA assessed within 3 months	29%	14-52

Similar on-time percentages were obtained for other DA measures.

Capacity Analysis showed that most practices had insufficient visit slots available to provide on-time DA assessments for their population.

Conclusion: 1. RA disease activity assessments in clinical practices are not being provided as frequently as recommended for T2T care. 2. Until DA assessments are on time, treatment cannot be optimized. 3. Population registries and different practice workflows are required to provide and document on-time DA assessments.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Quality Measures and Quality of Care
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: *Streptococcus pneumoniae* is a leading cause of severe infections, including pneumonia and meningitis, among immunocompromised patients. The administration of both the 13-valent pneumococcal conjugate vaccine (PCV13) and the 23-valent pneumococcal polysaccharide vaccine (PPSV23) is indicated for patients with immunocompromising conditions per U.S. Advisory Committee on Immunization Practices (ACIP) guidelines.

The SMART aim of this project was to increase the percentage of immunocompromised patients 11 years and older seen in the Rheumatology and Inflammatory Bowel Disease (IBD) clinics at Cincinnati Children's Hospital Medical Center (CCHMC) who receive PCV13 vaccine from 20% to 80%.

Methods: Providers from various specialty clinics at CCHMC recognized common barriers related to immunization administration, including knowledge gaps, access to immunization records, identification of the immunocompromised patient, sharing responsibility of vaccine administration between the primary care provider (PCP) and the specialist and the appropriate timing of vaccines.

Eligible patients included adolescents defined as immunocompromised according to Center for Disease Control and Prevention (CDC) guidelines, between 11-18 years of age, who were seen in the Rheumatology and IBD clinics between February and June 2015.

Interventions that were implemented during the study included education of clinic providers and nurses; the development of physician "talking points" for patients; easy clinic access to vaccines and pre-visit planning that included a visual reminder to the provider and a pended order for the vaccine.

Results: During the 19-week study period, 443 eligible patients were seen in both clinics. The pre-intervention immunization rate for PCV13 ranged from 0% - 20%. Pending the vaccine order increased the percentage to ~60% [Figure 1] and the addition of provider "talking points" increased it further to 80%. In total, 376 patients (84.8%) received the PCV13. At the initiation of the project, most failures were related to the preference to receive vaccine in the PCP's office. With the institution of the "talking points", the main reason for failure was a request to defer the vaccine to a later visit with the specialist (Figure 2).

Conclusion: We have demonstrated that with a few key interventions, it is possible to increase the PCV13 vaccination rate to over 80% in a heterogeneous group of immunocompromised patients. These same measures can be easily implemented in other clinics for different vaccinations.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Quality Measures and Quality of Care
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Gout is a chronic inflammatory arthritis which can be effectively managed. The American College of Rheumatology published evidenced based gout management guidelines. These guidelines are often not followed leading to unnecessary morbidity and cost. We piloted a gout management quality improvement project at one primary care site and the rheumatology department within our integrated health system.

Methods: The primary care site included 3 internal medicine providers, 11 family medicine providers, and 441 gout patients. We surveyed primary care providers for their preferred quality improvement strategies. These strategies included live or online continuing medical education (CME), electronic medical record reminders, nursing staff protocols, and a monthly National Quality Forum based outcome measure report card for each provider comparing their performance with peers. The Rheumatology Department included 15 rheumatologists and 800 gout patients. An exit survey again asked for the providers' preferred quality improvement strategies. Lastly, we compared the intervention primary care clinic results to a usual care control: another clinic that was matched for providers and gout patients. Performance data for gout patients 6 months before and after intervention were compared. Binary logistic regression models were used to obtain estimates of odds ratios with their 95% confidence intervals (CI). Post-intervention performance in the pilot site was compared to the control site.

Results: Data analysis pre- and post- intervention is presented in Table 1. Odds Ratios with their 95% confidence intervals for primary care intervention site versus usual care control are presented in figures 1 and 2. Survey results showed primary care providers rated live CME and electronic health record reminders the highest with an average 4/5 (5 being most effective). Rheumatologists chose audit and feedback of their own performance compared with peers highest at 4/5.

Conclusion: Gout management significantly improved with primary care and rheumatology intervention, education and accountability. There were significant improvements in both monitoring ($P<0.0001$) and goal uric acid level ($P<0.0001$). Gout outcome measures improved significantly in the intervention primary care site compared to the usual care site. The provider survey suggests that CME, EHR reminders and report card feedback were the most effective at changing provider behavior. We plan a system wide implementation of this gout quality improvement project.

Table 1: Odds Ratios and their 95% Confidence Intervals for Comparisons

	OR	95% CI		P-value
		Lower Bound	Upper Bound	
Primary Care Intervention Site: Average Effect Post Intervention vs. Average Effect Pre-Intervention				
Treated with urate lowering therapy	1.16	1.04	1.30	0.0089
Monitored Uric Acid in past 2 years	3.76	3.17	4.45	< 0.0001
At Goal (Uric Acid < 6.0)	2.44	2.01	2.96	< 0.0001
Rheumatology: Average Effect Post Intervention vs. Average Effect Pre-Intervention				
Treated with urate lowering therapy	1.07	0.95	1.22	0.2539

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Quality Measures and Quality of Care
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Facing fixed time for specialty visits, the time staff spends on rooming patients is a premium, but remains poorly understood. We conducted a time study, a basic systems engineering approach, to examine the frequency and duration of all visit related tasks performed by clinic staff (medical assistants (MA) or nurses) between the waiting room and the entry of the rheumatologist.

Methods: We developed a time study tool using health system policies and procedure documents, interviews and observations of pre-visit rooming. The tool measured 25 pre-determined tasks at a resolution of 15s=0.25 min. Trained engineering and medical observers measured 190 rooming sequences for a total of 1419 minutes at three rheumatology clinics in an academic multispecialty practice during Fall 2014-Spring 2015. Rooming was performed by nurses or MA at 2 sites, but otherwise by MAs. Scheduled visits varied from 20-30 minutes. We calculated descriptive statistics on tasks and times, compared frequencies using Fischer's exact test, and times using analysis of variance. We developed a task taxonomy and described variations in tasks.

Results: We observed 18 additional actions beyond 25 expected tasks. We then grouped 15 labeled tasks in 5 categories based on the sequence they occurred and clinical objectives for each task (Table 1). Total rooming time varied widely (2.5-22 min). Mean rooming time was 7.5 ± 3.1 min across clinics (Table 1) and varied between clinics, at 8.8, 6.7, and 7.6 minutes ($p<0.001$).

Vital signs (1.9 ± 0.6 min) and medication reconciliation (1.7 ± 1.3 min) accounted for half of the total rooming time. Maximum time variation was associated with questionnaire administration (±1.8 min), medication reconciliation (±1.3 min), and other conversations (± 1.2 min). Only 4 tasks were observed in >90% of the rooming sequences: initiation, pulse, blood pressure measurement, and medication reconciliation. For other tasks, frequencies varied by clinic. For instance, prescription refills occurred in 3 vs. 46% of clinic visits, and pain scores in 17 vs. 98% of visits when stratified by clinic ($p=<0.001$). Five of nine tasks with high frequency variation were identified to benefit from standardization: height, weight measurement, prescription refill cueing, pain assessment, questionnaire administration (disease activity, new patient) and tobacco history.

Conclusion: Using time study we developed a practical tool for measuring time spent on each rooming task, and created a taxonomy of rooming tasks. We found that the frequency and timing of rooming tasks varied among encounters and clinics. Implications of this work beyond our institution include methods for (A) identifying and prioritizing opportunities for standardization, (B) offering a platform for decisions regarding changing standards and (C) comparing baseline data for new scheduling or care quality initiatives.

Table 1. Duration and frequency of tasks in rooming sequence in rheumatology clinic visits

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Quality Measures and Quality of Care

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Optimal care for systemic inflammatory rheumatic diseases often hinges upon early referral from primary care physicians (PCP) to rheumatologists. Our aim was to quantify the time from symptom onset (T_0) to 1st PCP visit related to the complaint (T_1) to PCP referral to rheumatologist (T_2) to 1st rheumatologist visit (T_3), and to treatment (T_4).

Methods: We employed a novel approach to identify 1st-time rheumatology referrals from the primary care Electronic Medical Record Administrative data Linked Database (EMRALD), representing comprehensive EMR data from 168 PCPs across Ontario, Canada (32 rural, 39 suburban and 97 urban physicians). Using a standardized data abstraction tool, PCP and rheumatology consultation records were reviewed to identify diagnoses and treatments associated with each referral. Administrative data were used to identify accurate dates of the 1st rheumatologist visit subsequent to the date of referral identified in the EMR. The time in days from the date of each component of the care pathway was determined overall and for each diagnostic category.

Results: Among 2430 patients with 1st-time referrals, we identified 745 patients with systemic inflammatory rheumatic diseases (31%): RA (16%), other inflammatory arthritis (22%), connective tissue diseases (18%), gout/crystal arthropathies (16%), spondyloarthropathies (10%), psoriatic arthritis (6%), polymyalgia rheumatica (9%), and vasculitis (3%). Overall, 21% and 70% of patients were seen by rheumatologists within 3 months of symptom onset and PCP referral, respectively. Wait-time measures varied by condition (table). Comparing to established Canadian wait-time measures (target being 100%), only 38% of RA patients were seen within 4 weeks from the date of referral, 63% of AS/SpA patients were seen within 3 months; and 34% of PsA patients were seen within 6 weeks. For RA patients, the median time to be seen by rheumatologists from symptom onset and referral was 327 and 66 days, respectively. Within the 1st year, 93% of RA patients had a documented treatment initiated by a rheumatologist, and of these, 95% were prescribed DMARDs, 26% oral steroid, 15% steroid injection, and 6% biologic. The average time to DMARD was 56 days from date of first rheumatology consultation.

Conclusion: Our representative sample of PCPs revealed longer wait-times than previous reports that sampled patients from urban rheumatology clinics and exceed current Canadian recommendations. Most of the delay occurs prior to referral, where targeted efforts are needed to optimize care for more timely consultations.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Quality Measures and Quality of Care
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Hydroxychloroquine (HCQ) is an antimalarial agent used commonly to treat selected autoimmune rheumatic diseases because of its therapeutic benefits, low cost, and favorable safety profile. While minor side effects may occur, the most feared toxicity is retinal thinning with irreversible loss of vision. The February 2011 American Academy of Ophthalmology (AAO) Revised Recommendations on Screening for Hydroxychloroquine Retinopathy advise a three-component baseline evaluation prior to initiation of therapy: 1)retinal exam, 2)Humphrey 10-2 visual-fields, and 3)either multifocal-electroretinogram, spectral-domain optical coherence tomography or fundus autofluorescence.

Methods: In this descriptive study, we utilized Highmark medical and pharmacy claims data to examine adherence to baseline screening recommendations in rheumatic disease patients initiating HCQ. We also explored ophthalmologic screening patterns in patients with ≥1 risk factor for development of retinal toxicity ("high risk" patients) and in rheumatic disease diagnostic subsets.

Results: From March 2011 through June 2014, 952 rheumatic disease patients initiated HCQ; 10% received the recommended 3 component ophthalmology screening, 44% completed partial screening, and 46% had no baseline eye evaluation (Table 1). Patients with commercial type insurance are more likely to complete screening than those with other types (Table 1). Of the 367 "high risk" patients, 13% had full screening, 53% had partial screening, and 34% had no baseline evaluation (Figure 1). Adherence patterns did not substantially differ by diagnostic subsets. In multivariable logistic regression analysis, the only predictor of full baseline screening was a history of retinal disease (Table 2).

Conclusion: Adherence rates to AAO recommendations for retinal baseline screening in rheumatic disease patients initiating HCQ are quite low, though somewhat better in those with risk factors for retinal toxicity. Our findings suggest that education of practitioners and patients is warranted to improve adherence to screening guidelines and optimize safe prescribing patterns.

Novel Ligand-Independent Peptide Inhibitors of Triggering Receptor Expressed on Myeloid Cells 1 (TREM-1) and T Cell Receptor (TCR): Efficacy in a Collagen-Induced Arthritis Model Suggests New Targeted Treatment for Rheumatoid Arthritis

Zu T. Shen and **Alexander B. Sigalov**, SignaBlok, Inc., Shrewsbury, MA

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Animal Models I
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Macrophages and T cells are central to the pathophysiology of autoimmune diseases. Synovial macrophages, synovial fibroblasts and infiltrating T lymphocytes are the most abundant cell populations found in the synovium of patients diagnosed with rheumatoid arthritis (RA). Activation of these cells leads to the production of proinflammatory cytokines and mediators. Triggering Receptor Expressed on Myeloid Cells 1 (TREM-1) and T cell receptor (TCR), expressed on macrophages and T cells, respectively, play a critical role in the signal transduction pathways leading to the onset and development of RA. In this study, novel ligand-independent peptide inhibitors of TREM-1 and TCR were rationally designed by employing a new model of immune signaling, the Signaling Chain HOmoOLigomerization (SCHOOL) model, and these inhibitors, for the first time, were evaluated in a mouse collagen-induced arthritis (CIA) model.

Methods: CIA was induced by immunizing male DBA/1J mice on days 0 and 21 by bovine type II collagen in Freund's complete adjuvant. On day 24, animals were weighed, randomized across study groups and given daily intraperitoneal (IP) doses of SCHOOL TREM-1 inhibitory peptide GF-9 or TCR inhibitory peptide MG-11 in free and targeted nanoparticle-bound forms, at doses of 25 mg/kg and 2.5 mg/kg, respectively. The mice were weighed every second day and all paws were scored daily for clinical signs of arthritis.

Results: Mice treated with GF-9 or MG-11 showed a significant delay in arthritis onset as well as a striking reduction in disease severity. This effect is specific as administration of the control peptide did not affect disease onset or severity. Targeted delivery of SCHOOL peptides utilizing self-assembling lipid-peptide nanoparticles significantly increased peptide dosage efficacy.

Conclusion: This study provides clear data demonstrating that inhibition of TREM-1 and TCR signal transduction pathways using short synthetic peptides that employ a novel ligand-independent mechanism of action (SCHOOL peptides) may represent a new, targeted, and non-toxic treatment for RA. Importantly, this ligand-independent mode of TREM-1 inhibition may significantly decrease the risk of failure in clinical development because of the unknown nature of the TREM-1 ligand(s).

Session Time: 4:30PM-6:00PM

Background/Purpose: Citrullination is a post translational modification of arginine catalysed by peptidyl arginine deiminases (PADs) and may be important in generating pathogenic autoantibodies to citrullinated proteins in rheumatoid arthritis. However citrullination may control inflammation by other mechanisms, including transcriptional modulation of cytokines and generation of proinflammatory

extracellular proteins. In previous studies, the PAD inhibitor Cl-amidine was shown to have a modest anti-inflammatory effect, when given prophylactically at high doses. While much of this benefit was thought to be due to inhibition of PAD4, recent studies have highlighted the proinflammatory effects of PAD2. Therefore the objective of this study is to examine the PAD inhibitor (BB-Cl-amidine), which is 10 fold more active than Cl-amidine against PAD2. We chose collagen-induced arthritis (CIA) as a reproducible and predictive model of immune-mediated arthritis and used a therapeutic, rather than prophylactic, treatment protocol, which could be translated into human disease.

Methods: CIA was induced by immunization with bovine type II collagen (CII) in DBA/1 mice. After the onset of arthritis, mice were scored daily for severity (0-3 for each paw) and hind paw swelling using calipers. Mice were treated daily with vehicle (n=12) or BB-Cl-amidine (1 or 10 mg/kg, n=12) intraperitoneally for 9 days post onset. On day 10 post onset, mice were culled, and paws, blood and inguinal lymph nodes collected for further analysis. Cytokines were measured in serum and lymph node culture supernatants using a multiplex platform, and serum IgG1 and IgG2a anti-CII antibodies by ELISA. The phenotypes of lymph node T cells and their response to anti-CD3 antibody stimulation were determined via flow cytometry.

Results: Therapeutic administration of 10 mg/kg BB-Cl-amidine after the onset of arthritis, reversed its development. Compared with vehicle treated mice, there was reduced clinical scoring ($p<0.0001$ from 5 days treatment), paw swelling ($p<0.0001$ from 6 days treatment), with a partial response in all measures to 1 mg/kg. Histological changes were almost completely normalised by BB-Cl-amidine at 10mg/kg with significant reduction in histology scores ($p<0.01$). These effects were accompanied by a significant increase in anti-collagen IgG1 ($p<0.0001$) and no change in IgG2a antibody levels. Unexpectedly, while pro-inflammatory cytokine levels in serum remained unaffected by BB-Cl-amidine, IL-4 and IL-5 were significantly elevated. In line with this, IL-4-expressing Th2 cells were increased in the lymph nodes of BB-Cl-amidine treated mice. Further analysis revealed a significant decline in Th1 and Th17 numbers with BB-Cl-amidine treatment.

Conclusion: Our study demonstrates that BB-Cl-amidine is therapeutic in CIA. The effect appears more due to immunomodulation than simple immunosuppression, by supporting anti-inflammatory Th2 responses, while inhibiting pro-inflammatory Th1 and Th17 responses. We propose that targeting PADs is now a realistic strategy for the treatment of rheumatoid arthritis and other chronic inflammatory diseases.

Synovium-Derived microRNAs Inhibit Bone Formation in Rheumatoid Arthritis

Ellen M. Gravallese[1], Yukiko Maeda[2], Nicholas H Farina[3], Paul Fanning[4] and Jane Lian[3], [1]Lazare Research Bldg Ste 223, University of Massachusetts Medical School, Worcester, MA, [2]Medicine, University of Massachusetts Medical School, Worcester, MA, [3]Department of Biochemistry, University of Vermont, Burlington, VT, [4]Department of Orthopedics, University of Massachusetts Medical School, Worcester, MA

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Animal Models I

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Articular bone erosion in rheumatoid arthritis (RA) is a consequence of synovial inflammation that leads to disability for patients. Cells within the synovium secrete inflammatory cytokines, RANKL, and Wnt signaling inhibitors, promoting osteoclastogenesis and inhibiting osteoblast function and bone formation. MicroRNAs (miRNAs) are key regulators of skeletal remodeling and also play a role in RA pathogenesis. Therefore, we hypothesized that miRNAs derived from synovial tissues may regulate the erosive process in RA at least in part through effects on osteoblasts.

Methods: To address whether synovium-derived miRNAs regulate osteoblast differentiation and bone formation, we used the serum transfer model of RA. We performed Fluidigm high-throughput expression profiling of 750 miRNAs in pooled synovial samples from non-arthritic and arthritic mice. We also performed gene array (Affymetrix) analysis in these same RNA samples and compared gene expression and miRNA expression from array data. To identify miRNAs regulating skeletal pathways, we collected target genes of up-regulated and down-regulated miRNAs using TargetScan. We restricted downstream analysis to targets differentially expressed by gene

array. Finally, we transfected a selected miRNA in murine calvarial osteoblasts to examine its role in cellular differentiation.

Results: Our comparative analysis identified 417 up-regulated genes that are predicted targets of 72 down-regulated miRNAs (1.5 fold or >), and 536 down-regulated genes that are predicted targets of 59 up-regulated miRNAs. Gene ontology analysis of the miRNA-targeted genes revealed significant enrichment of skeletal pathways involved in osteoblast function, including Wnt/β-catenin signaling. Of the 22 most significantly regulated (ANOVA $p<0.01$) miRNAs between non-arthritic and arthritic mice, 11 were predicted to target numerous Wnt and BMP signaling pathway components. We validated their expression in isolated synovial fibroblasts and in whole synovium by qPCR and showed that 4 of these miRNAs were downregulated by TNF. Some of the target genes of these miRNAs, including GSK3β, Sfrp2 and Tob1, were up-regulated at erosion sites in bone. Among the 11 miRNAs, miR-221 was significantly up-regulated during peak inflammation. Since miR-221 is known to be up-regulated in RA synovial tissues (Pandis et al., 2012), we examined the role of miR-221 in osteoblasts. Transfection of miR-221 into primary murine calvarial osteoblasts suppressed osteoblast differentiation and mineralization. Expression of a predicted target gene of miR-221 that is essential for bone mineralization, DKK2, is suppressed by miR-221 at the protein level. Tcf-1, a downstream target of Wnt signaling, is also down-regulated by miR-221.

Conclusion: We have identified several miRNAs expressed in inflamed synovium that potentially regulate skeletal pathways, including osteoblast differentiation. Of these, miR-221 inhibits osteoblast differentiation. These results support the hypothesis that miRNAs derived from inflamed synovial tissue may regulate skeletal pathways and osteoblast function in RA.

Session Time: 4:30PM-6:00PM

Background/Purpose: MicroRNA (MiR-) 146a is a key regulator of the innate immune response and has also been shown to suppress cancer development in myeloid cells. Although in late stages of arthritis elevated expression of miR-146a in synovial tissue of rheumatoid arthritis patients was detected, the level of this miRNA was found to be down regulated in early disease, but its role in the development of inflammatory arthritis is yet unknown.

Methods: We induced K/BxN serum transfer arthritis in wild type and miR-146a$^{-/-}$ mice. As a second inflammatory arthritis model we crossed miR-146a deficient into hTNFtg mice. Disease severity was assessed clinically and histologically in both arthritis models. Blood of arthritis animals was analyzed by flow cytometry. Serum cytokine levels were measured by Elisa. RNA expression levels were measured by qPCR.

Results: Absence of miR-146a leads to increased clinical signs of the induced serum transfer arthritis. In line, higher serum levels of the proinflammatory cytokines IL-12 and TNF were measured in miR146a deficient compared to wt mice. When we crossed miR-146a$^{-/-}$ into hTNFtg mice, histological examination revealed a significant increase in synovial inflammation and even more striking a more than twofold increase in local bone destruction due to increased generation of osteoclasts in the tarsal joints in miR-146a$^{-/-}$/hTNFtg mice compared to hTNFtg mice. Interestingly, systemic bone loss was comparable in hTNFtg compared to miR-146a$^{-/-}$/hTNFtg mice, suggesting

an important local role of miR-146a. Indeed, we detected increased levels of IL-1β and RANKL and decreased expression of OPG locally in the paws of miR-146a$^{-/-}$/hTNFtg compared to hTNFtg mice. Analysing the content of myeloid cells in the blood of arthritis diseased mice, revealed significantly increased numbers of circulating CD11b^{+} as well as CD11c^{+}cells in mice lacking miR-146a. Bone marrow transplants demonstrated a pivotal role for miR-146a in mesenchymal cells in controlling local osteoclast generation and bone destruction.

Conclusion: These data demonstrate an important mitigating role of the miR-146a in inflammatory arthritis, most importantly in local bone destruction, by controlling mesenchymal expression of osteoclastogenic factors. This shows an important anti-inflammatory role of miR-146a, which might possibly be exploited for therapeutic purposes.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Animal Models I

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: We have generated a mouse line with Flip conditionally deleted in CD11c-cre expressing cells (CD11c-Flip-KO, named HUPO), which spontaneously develops erosive arthritis resembling rheumatoid arthritis (RA). HUPO mice exhibit significantly reduced conventional dendritic cells (cDC), especially its CD8α^{+} subset, as well as a reduction in the number and percent of CD4^{+} T regulatory cells (Tregs). The reduced Tregs contribute to disease pathogenesis in HUPO mice, permitting the expansion of autoreactive CD4^{+}T cells, plasmablasts, and joint specific autoantibodies. This study is focused on discovering the cause for the reduced Tregs in the HUPO mice.

Methods: Immune cell phenotyping and apoptosis/necrosis were assessed by antibody-flow cytometric analysis. HUPO mice were crossed with *Rag*$^{-/-}$ generated HUPO-*Rag*$^{-/-}$ double mutant line. Cells were adoptively transferred intravenously. Cytokines were determined by quantitative ELISA. Tregs were identified as CD4^{+}CD25^{+}Foxp3^{+}.

Results: HUPO-*Rag*-/- mice developed a very mild arthritis, which was not erosive, mediated by macrophages. Whole spleen T and B cells were isolated from 3-5 month old control or HUPO mice and adoptively transferred into *Rag*$^{-/-}$ or HUPO-*Rag*$^{-/-}$ mice. After 3 weeks, there was no difference in the percent Tregs when control lymphocytes were transferred to *Rag*$^{-/-}$ or HUPO-*Rag*$^{-/-}$ mice. Further, no difference in Tregs was observed when HUPO lymphocytes were transferred to *Rag*$^{-/-}$ mice. In contrast, when HUPO lymphocytes were transferred into HUPO-*Rag*$^{-/-}$ mice, after 3 weeks Tregs were significantly reduced compared to all the other groups. Next, isolated control CD45.1^{+}CD4^{+}CD25^{+} T cells transferred into CD45.2 HUPO mice resulted in reduced CD45.1^{+}Foxp3^{+}Tregs after 2-3 weeks compared to transfer into control mice. These data suggest that both HUPO Tregs and the in vivo environment of the HUPO mouse contribute to the reduction of Tregs. To define the potential mechanisms, in vitro culture of the total splenocytes for 7 days resulted in significantly reduced IL-2 in the HUPO, compared with the littermate control, culture supernatants. Further, significantly reduced Tregs were present in the HUPO, compared with the control, cultures. Interestingly, supplement of the culture medium with IL-2 prevented the loss of Tregs in the cultures from the HUPO, but not the control mice. The reduction of IL-2 was not due to cDCs, however, the production of immuno-reactive TGFβ, important for Treg differentiation, was significantly reduced with BM differentiated DCs from HUPO, compared with control, mice

Conclusion: HUPO mice represent a novel arthritis model that may provide insights into the mechanisms that contribute to the initiation of RA. This study suggests that the mechanisms for the reduction of Tregs in HUPO mice are multifactorial and include a reduction of cDC TGFβ and a reduction of IL-2 which is essential for maintenance of Tregs. Many earlier studied documented the reduction of IL-2 in patients with RA. Our observations suggest that IL-2 may be an effective treatment strategy in the HUPO mouse model of RA.

Session Title: Rheumatoid Arthritis - Animal Models I
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: The relationship between lung and joint inflammation in rheumatoid arthritis is poorly understood. About 10% of people with rheumatoid arthritis develop interstitial lung disease and people who have early rheumatoid arthritis or anti-citrullinated protein antibodies (ACPAs) without clinical arthritis have increased rates of subclinical lung disease. Also, citrullinated proteins can be found in diseased lungs similar to inflamed joints. Taken together, these observations suggest that one or both of two possible lung/joint relationships may exist. Lung inflammation may be an inciting event in rheumatoid arthritis development possibly by triggering ACPA formation and/or lung inflammation and arthritis may be two manifestations of a similar underlying pathology. However the true mechanism is unknown. Overexpression of TNFα in mice causes both an inflammatory destructive arthritis similar to rheumatoid arthritis as well as severe lung inflammation. We have previously shown that the citrullinating enzyme peptidylarginine deiminase 4 (PAD4) contributes to arthritis in these mice, but its role in lung disease is unknown. Here, we employ mice that overexpress TNFα to address several basic questions about the relationship between TNFα, citrullination, PAD4, arthritis, and lung inflammation.

Methods: Ankle joint and lung tissue from mice that systemically overexpress TNFα (TNF^+) and wild type littermates as well as $TNF^+PAD4^{+/+}$ and $TNF^+PAD4^{-/-}$ littermates were flash frozen and homogenized. Protein lysates were diluted in trichloroacetic acid, incubated with Rh-PG (a citrulline detection probe), quenched, washed, subjected to gel electrophoresis, imaged, stained with Coomassie, and re-imaged to determine the extent of total protein citrullination. Lungs from $TNF^+PAD4^{+/+}$ and $TNF^+PAD4^{-/-}$ littermates were fixed, sectioned, stained with hematoxylin and eosin (H&E), and scored in a blinded manner for the severity of several characteristics of lung inflammation. Ankle joints from 22 month old mice that overexpress TNFα only in the lung under the control of the surfactant promoter and littermate controls were fixed, sectioned, stained with H&E, and scored for arthritis severity.

Results: TNF^+ mice have increased gross protein citrullination in their joints and lungs at 5 months of age, but not 2 or 3.5 months of age compared to wild type. There was no difference between $TNF^+PAD4^{+/+}$ and $TNF^+PAD4^{-/-}$ mice in gross protein citrullination in either joints or lungs at 5 months of age, however $TNF^+PAD4^{-/-}$ mice had reduced lung disease severity compared to $TNF^+PAD4^{+/+}$ mice. No arthritis was detected in the mice that overexpress TNFα only in the lungs.

Conclusion: PAD4 contributes to both lung and joint inflammation downstream of TNFα, without having a required role in generalized protein citrullination in these tissues. Further, TNFα induced lung inflammation does not drive arthritis in mice.

Session Title: Rheumatoid Arthritis - Clinical Aspects I - Treatment Advances and Strategies

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose:

An Austrian multi-center study of the effect on disease activity and the safety of Tocilizumab (TCZ) in combination with Methotrexate (MTX) versus TCZ Monotherapy in patients with mild to moderate rheumatoid arthritis (RA), with inadequate response to MTX – The OPTIMISE trial (EUDRACT No. 2011-001863-39)

As only limited data are available on the efficacy of biologicals in Rheumatoid Arthritis (RA) patients in mild to moderate disease activity, particularly with respect to Tocilizumab (TCZ), this study was performed to assess the influence on disease activity of TCZ+MTX versus TCZ-monotherapy in patients with mild to moderate RA.

Methods:

Seventy-seven patients with mild to moderate RA and an inadequate response (DAS28 < 4.5 and >2.6) to a stable dose of MTX (15 – 25 mg/wk) were enrolled into the first phase and received three infusions of TCZ (8 mg/kg) iv every 4 weeks + MTX. If the patients achieved a good/moderate EULAR response after 3 months they were randomized into group A (TCZ 8 mg/kg iv/mth plus MTX) or group B (TCZ 8 mg/kg iv/mth plus Placebo (PBO) MTX). The primary endpoint was the change in DAS28 score from week 12 (time of randomization) to week 24. Secondary endpoints were the proportion of patients achieving DAS28 remission, CDAI remission, SDAI remission and RADAI-5 remission at week 24 as well as the improvement in physical & mental health and satisfaction with treatment using different questionnaires.

Results:

Sixty-five patients (84.4%; 51 female/14male; mean age 57.5 +/- 11.3 yrs) achieved a EULAR response and were included into the blinded phase of the trial. The mean DAS28 (ITT-population) at wk 12 in the MTX group (n=32) was 1.51, and in the PBO group (n=33) 1.72. The change in DAS28 score from wk 12 to wk 24 was statistically not significant between group A and group B (0.17 ± 0.83 in the MTX group vs. -0.16 ± 1.13 in the PBO group (n = 33); 95% CI for the difference [-0.16; 0.82], p =0,188). All secondary endpoints, namely the proportion of patients in remission, improvement of function, mental health, and satisfaction with treatment proved to be statistically not significantly different between MTX or PBO treated patients. Regarding tolerability no new signals could be detected.

Conclusion:

Additional TCZ treatment led to significant improvement in patients with mild to moderate RA and an inadequate response to MTX. TCZ-Monotherapy was seen as effective as combination with MTX to preserve the level of disease activity achieved at wk12.

Session Title: Rheumatoid Arthritis - Clinical Aspects I - Treatment Advances and Strategies

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose:

Analysis of long term continuation of biologics in rheumatoid arthritis (RA) is considered a valid surrogate for treatment effectiveness and safety. Only a small number of studies have investigated the long-term persistence with rituximab (RTX) in RA. Analysis of long term continuation of biologics in rheumatoid arthritis (RA) is considered a valid surrogate for treatment effectiveness and safety. Only a small number of studies have investigated the long-term persistence with rituximab (RTX) in RA.

Methods: This analysis included all patients enrolled with the British Society for Rheumatology Biologics Register for RA when starting RTX between 2008 and 2011. Baseline characteristics (demographic, disease and treatment-related data) were compared between bio-naive and experienced cohorts. RTX treatment discontinuation was defined at start of alternative biologic, death or 1 year following the most recent RTX infusion, whichever came first. Kaplan-Meier curves were used to study discontinuation rates over time and by reason, both as a whole cohort and stratified by past biologic treatment experience; discontinuation rates at 1, 2, 3 and 4 years following treatment initiation were ascertained. The association of baseline variables (age, gender, smoking status, presence of comorbidities, disease duration, DAS-28 score, HAQ score, steroid use, methotrexate (MTX) use, previous biologic use) with RTX discontinuation after 4 years was assessed using multivariate Cox-proportional hazards models.

Results: In total, 1629 patients were included (1371 [84.2%] bio-experienced patients and 258 [15.8%] bio-naïve). Bio-experienced patients tended to be younger, but have longer disease duration than bio-naïve patients (Table 1). Treatment persistence at 4 years was 43% (95% CI 40, 45) and was similar between bio-naïve and bio-experienced patients (Figure 1). For the whole cohort, baseline variables associated with RTX discontinuation after 4 years were low DAS28 score (HR 0.91 [95% CI 0.85, 0.98]), RhF negativity (HR 0.84 [0.72, 0.99]) and younger age (HR 0.99 [0.98, 0.99] per year). Higher number of previously used biologics was associated with RTX discontinuation for the bio-experienced cohort (HR 1.28 [CI 1.08, 1.50]) and smoking history was associated for the bio-naïve cohort only (HR 1.82 [1.06, 3.12]). Tocilizumab was the most commonly used subsequent biologic for both the naive and experienced cohorts: 12 (41.4%), 133 (56.8%), respectively.

Conclusion: Just over half of patients were no longer receiving RTX after 4 years, which was similar in both bio-naïve and experienced patients. In bio-experienced patients, those who started RTX after 2 or more past TNFi failures were more likely to discontinue treatment compared to only 1, which may be identifying a more refractory patient cohort. The role of risk factors in predicting treatment outcomes on RTX is again supported by these data.

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis - Clinical Aspects I - Treatment Advances and Strategies

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: To compare methotrexate based disease-modifying anti-rheumatic drug (DMARD) treatments for rheumatoid arthritis in patients naïve to or after an inadequate response (IR) to methotrexate.

Methods: We conducted a systematic review and Bayesian random-effects network meta-analysis of trials assessing methotrexate used alone or in combination with other conventional synthetic DMARDs (csDMARDs), biologics (bDMARDs) or tofacitinib in adult patients with rheumatoid arthritis. The major outcomes were ACR50 response (major clinical improvement), radiographic progression and withdrawals due to adverse events (WDAE). Trials were identified from MEDLINE, EMBASE and CENTRAL databases from inception to August 13, 2014, abstracts from 2 major rheumatology meetings from 2009-2014, 2 trial registers, and hand-searches of Cochrane reviews. The risk of bias of each study was evaluated using the Cochrane risk of bias tool, separately for each outcome. Trials judged at high overall risk of bias were excluded.

Results: 150 trials with over 34,000 patients were included. Methotrexate naïve: In methotrexate-naïve patients, 'triple therapy' (the combination of methotrexate + sulphasalazine + hydroxychloroquine), and methotrexate + several bDMARDs (abatacept, adalimumab, etanercept, infliximab, rituximab, tocilizumab) were similar to each other and significantly superior to oral methotrexate for ACR50 response. There was a 61% probability of an ACR50 response with triple therapy (moderate quality evidence), which was similar to the probability of an ACR50 response for the MTX + bDMARDs that were statistically significantly superior to oral MTX (range: 55%-67%, moderate to high quality evidence). Only methotrexate + adalimumab and methotrexate + etanercept were significantly superior to oral MTX for inhibiting radiographic progression. Triple therapy had significantly fewer WDAE compared to methotrexate + infliximab. Methotrexate-IR: In methotrexate-IR patients, several treatments were significantly superior to oral methotrexate for ACR50 response, including csDMARD combinations (triple therapy, methotrexate + hydroxychloroquine, methotrexate + leflunomide, methotrexate + intramuscular gold), methotrexate + most bDMARDs, and methotrexate + tofacitinib. There was a 61% probability of an ACR50 response with MTX + sulphasalazine + hydroxychloroquine, compared to 27% to 65% for the MTX + bDMARDs that were statistically significantly superior to oral MTX. No treatment was significantly superior to oral methotrexate for inhibiting radiographic progression. Methotrexate + abatacept had fewer WDAE than several treatments.

Conclusion: Triple therapy and most regimens combining biologic DMARDs with methotrexate were similarly effective in controlling disease activity and all generally well tolerated in both methotrexate-naive and methotrexate-exposed patients. Given cost considerations, these findings support a therapeutic trial of low-cost triple therapy prior to using biologic DMARDs.

Session Title: Rheumatoid Arthritis - Clinical Aspects I - Treatment Advances and Strategies

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: TNF-inhibitors (TNFi) are effective treatments of rheumatoid arthritis (RA). It is not clear if patients in remission or stable low disease activity need to continue their TNFi. Issues of polypharmacy and the relatively high costs of TNFi make it important to examine whether patients in remission or stable low disease activity can stop their TNFi. If patients stop TNFi and consequently flare, it is unclear whether TNFi can be restarted effectively and safely.

Methods: Pragmatic multicenter open-label randomized controlled trial. Inclusion criteria: patients diagnosed with RA according to the ACR 1987 criteria, patients using a TNFi for at least 1 year with stable dose DMARDs over the last 6 months, DAS28 <3.2 over the last 6 months. Patients were randomized to either stop or continue their current TNFi in a 2:1 ratio. Flare was defined as DAS28 ≥3.2 with an increase ≥0.6 compared to the previous DAS28. In case of flare in the stop group, TNFi could be restarted at the discretion of the treating rheumatologist.

Results: In total 817 patients from 47 centers were included: 531 patients (65%) in the stop group and 286 patients (35%) in the continuation group. At 6 months, significantly more patients in the stop group (212/531 [31.5%]) had experienced a flare than in the continuation group (36/286 [9.8%], p<0.001). At 12 months these were 267/531 [50.3%] vs 52/286 [18.2%], respectively (p<0.001). The hazard ratio for flare after stopping TNFi was 3.41 (95% CI: 2.53–4.59). Mean DAS28 scores in the stop group were significantly increased throughout the follow-up period compared with the continuation group (p<0.001). Of the 195 patients that restarted TNFi within 26 weeks, 165 (84.6%) had regained low disease activity (DAS28 < 3.2) 6 months later and median time to regained low disease activity was 12 weeks (95% Cl: 10.8-13.2).

SAEs in stop vs. continuation groups: Deaths 0 vs. 1 (0.3%) and hospitalization due to infections 11 (2%) vs. 4 (1,4%), respectively. There were no allergic reactions among the patients in the stop group that restarted TNFi.

Conclusion: Stopping TNFi treatment in RA patients in remission or stable low disease activity results in substantially more flares than continuing.

Session Title: Rheumatoid Arthritis - Clinical Aspects I - Treatment Advances and Strategies
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Randomized controlled trials (RCTs) are considered the gold standard for comparing efficacy of treatments, but the results may be less generalizable to clinical practice than observational studies. We have recently completed a Cochrane network meta-analysis that included all available RCT evidence and found a statistically significant increase in the odds of ACR50 response for triple therapy relative to methotrexate (MTX) alone in MTX-naïve patients. The objective of this study was to convert these relative treatment effects (odds ratios) into the expected probability of response for patients with different baseline characteristics, using data from an observational cohort. The overall aim was to enhance the knowledge required to achieve informed decision-making in practice.

Methods: We estimated the probability of an ACR50 response at 6 months for patients with ERA (2010 ACR criteria, symptoms ≤1-year), initiating methotrexate therapy (oral or subcutaneous) for patients in the multicenter, prospective Canadian Early Arthritis Cohort (CATCH). A multivariable logistic regression model with a candidate list of variables feasible to collect in clinic visits was developed to determine patient characteristics associated with ACR50 response. The final model was used to estimate the probability of ACR50 response with MTX monotherapy for patients with different baseline characteristics. We then determined the probability of ACR50 response for triple therapy, using the odds ratio derived from a completed Cochrane network meta-analysis of 150 trials.

Results: The population for the multivariable model included 666 patients with ERA: mean age 53 yrs, 74% female, mean DAS28 5.5, mean HAQ 1.1, swollen joint count 9.4. The mean starting dose of methotrexate was 19 mg/week. In the multivariable model, younger age, lower HAQ-DI and higher swollen joint counts were each independently associated with a higher odds of ACR50 response. The expected probability of an ACR50 response with MTX alone versus triple therapy for different patient characteristics is shown in Table 1. As the baseline chance of an ACR50 response increased, the absolute difference between MTX and triple therapy also increased.

Conclusion: By combining a predictive model from a large, prospective cohort with treatment effects from a network meta-analysis of all available RCTs, probabilities of treatment response with MTX and triple therapy can be estimated and may help inform evidence-based treatment choices for individual patients.

Table 1: Estimated probability of ACR50 response for methotrexate and triple therapy based on variable baseline characteristics

Change in baseline variables	Expected probability of ACR50 response		Absolute difference (95% CI)
	Methotrexate	Triple therapy (95% CI)	
Age increased (HAQ=1; SJC=10)			
Age 20	32%	53% (37 to 70)	21% (5 to 38)
Age 40	25%	43% (28 to 61)	18% (4 to 36)
Age 60	18%	33% (21 to 51)	16% (3 to 33)
Age 80	13%	26% (15 to 42)	13% (2 to 29)
SJC increased (Age=55, HAQ=1)			
SJC 5	14%	26% (16 to 43)	13% (2 to 29)
SJC 10	20%	36% (22 to 54)	16% (3 to 34)
SJC 15	27%	46% (31 to 64)	19% (4 to 37)
SJC 20	37%	57% (41 to 74)	20% (4 to 37)
HAQ increased (Age=55, SJC=10)			
HAQ 0.5	24%	42% (28 to 61)	18% (4 to 36)
HAQ 1.0	20%	36% (23 to 54)	16%(3 to 34)
HAQ 1.5	16%	30% (18 to 47)	14% (3 to 31)
HAQ 2.0	12%	24% (14 to 40)	12% (2 to 28)

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis - Clinical Aspects I - Treatment Advances and Strategies
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Growing evidence supports the efficacy of triple therapy (methotrexate + sulphasalazine + hydroxychloroquine) for controlling disease activity in patients with early rheumatoid arthritis (ERA), but it requires multiple pills and appears to be less effective than methotrexate + anti-TNF therapy for preventing joint damage. The GRADE approach for developing treatment recommendations has been adopted by the ACR and requires that treatment recommendations integrate the estimated treatment effects for key outcomes and patients' preferences, but methods for doing this have not been defined. The objective of this study was to apply a novel approach for jointly considering the comparative benefits and harms of treatment options and patients' preferences to estimate the preferred treatment for patients with ERA.

Methods: We determined the preferred treatment for patients with moderate-severe ERA (<2 years since diagnosis) separately for methotrexate-naïve patients (choice of triple therapy versus methotrexate) and for patients who have had an inadequate response to methotrexate (choice of triple therapy versus methotrexate + anti-TNF therapy). We used patients' preferences that we elicited through a discrete choice experiment to apply weights to 3 key outcomes from a network meta-analysis (ACR50 response, radiographic progression, withdrawals due to adverse events) and other important considerations (dosing, rare adverse events). The preferred treatment was the one that had the highest total value, which was calculated as a sum of the preference-weighted treatment characteristics. We incorporated uncertainty in both the treatment effects and individual patients' preferences by averaging the results across 10,000 samples from Bayesian models for both the network meta-analysis outcomes and the patients' preferences.

Results: Triple therapy was the most preferred treatment in methotrexate-naive patients (78% preferred triple therapy to methotrexate) or after an inadequate response to methotrexate (58% preferred triple therapy to methotrexate + anti-TNF therapy). In methotrexate-naïve patients, triple therapy provided a higher chance of benefit (ACR50 response) than methotrexate alone based on the network meta-analysis, which was most important to patients and outweighed the additional pills or other inconveniences. After failing methotrexate, triple therapy provided a similar chance of ACR50 response to anti-TNF therapy based on the network meta-analysis, but did not require injections or have an increased risk of infection/ possible increased risk of skin cancers as with anti-TNF therapy. For most patients, these issues outweighed any benefit of anti-TNF therapy on preventing joint damage.

Conclusion: Based on estimates of the comparative benefits and harms of methotrexate-based treatment options for ERA and patients' preferences, many patients would prefer triple therapy to methotrexate as initial therapy and triple therapy to methotrexate + anti-TNF therapy after an inadequate response to methotrexate. Explicitly considering patients' preferences may affect treatment recommendations made using GRADE.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis-Small Molecules, Biologics and Gene Therapy II: Small Molecular Targeted Therapies
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose:

In 2 completed phase 3 studies, baricitinib (bari) improved disease activity with a satisfactory safety profile in patients (pts) with moderately-to-severely active RA who were inadequate responders to either conventional synthetic[1] or biologic[2]DMARDs. This abstract reports results from a phase 3 study of bari administered as monotherapy or in combination with methotrexate (MTX) to pts with early active RA who had limited or no prior treatment with DMARDs. MTX monotherapy was the active comparator.

Methods: Pts with active RA (TJC & SJC ≥6, hsCRP ≥3.6 mg/L) and no previous DMARD treatment other than ≤3 doses of MTX were randomized 4:3:4 to MTX, bari 4 mg once daily (QD; bari monotherapy), or bari 4 mg QD + MTX for up to 52 wks. MTX dose, with or without bari, was up-titrated from 10 to 20 mg once weekly over 8 weeks (wks). Rescue was not allowed prior to Wk 24, the time point for primary and all major secondary efficacy endpoints. The primary objective evaluated non-inferiority of bari 4 mg monotherapy to MTX on ACR20 at Wk 24 (using a 12% margin).

Results: Of 584 randomized pts, 87%, 91%, and 89% of pts completed Wk 24 in the MTX, bari 4 mg monotherapy, and bari 4 mg + MTX groups, respectively. ACR20 response at Wk 24 was higher with bari 4 mg monotherapy vs. MTX (77% vs. 62%, p≤.01). Compared to MTX, bari 4 mg monotherapy produced significantly greater improvements in multiple secondary measures of disease activity (Table 1), many as early as Wk 1. MTX in combination with bari 4 mg did not appear to increase the benefit observed with bari 4 mg monotherapy. Clinical remission was seen in a significantly higher proportions of pts treated with bari 4 mg alone or in combination with MTX compared to MTX alone (Table 1). Rates of treatment-emergent adverse events (TEAEs) and serious adverse events (SAEs) were similar across groups (Table 2). Through 24 wks, 2 (1.0%), 6 (3.8%) and 14 (6.5%) pts discontinued the study because of an adverse event in the MTX, bari 4 mg monotherapy, and bari 4 mg + MTX groups, respectively. No GI perforations occurred during the study. Laboratory abnormalities were generally less frequent in the bari 4 mg group compared to either the MTX or bari 4 mg + MTX groups (Table 2).

Conclusion:

In pts with early RA, all treatment groups experienced improvements in disease activity with bari 4 mg monotherapy producing significantly larger and more rapid improvements and higher rates of clinical remission compared to MTX monotherapy, with a satisfactory safety profile. MTX addition to bari 4 mg did not increase the benefit observed with bari monotherapy, while it appeared to increase the frequency of laboratory abnormalities.

Session Title: Rheumatoid Arthritis-Small Molecules, Biologics and Gene Therapy II: Small Molecular Targeted Therapies

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Baricitinib, an oral inhibitor of JAK1/JAK2, improved disease activity with an acceptable safety profile in a phase 3 study (RA-BEACON) of patients with active rheumatoid arthritis (RA) and an inadequate response to tumor necrosis factor inhibitors (TNFi).[1] Oral baricitinib once-daily (QD) produced improvements that were sustained through 24 weeks. The objective of this analysis was to evaluate the effect of prior bDMARD exposure on the efficacy and safety of baricitinib in RA-BEACON.

Methods: 527 patients with moderately-to-severely active RA despite previous use of ≥1 TNFi for ≥3 months were randomized 1:1:1 to

receive placebo (PBO) or 2 or 4 mg baricitinib QD for 24 weeks. All bDMARDs were discontinued ≥28 days prior to treatment. Patients were enrolled with a history of receiving multiple TNFi including non-TNFi bDMARDs. Post hoc subgroups defined by prior biologic use [1 TNFi only, >1 TNFi (but no non-TNFi), and ≥3 bDMARDs] were assessed for evidence of qualitative and quantitative treatment interactions utilizing modified intent to treat analysis (mITT) and nonresponder imputation (NRI). The treatment-by-subgroup interaction comparing each baricitinib group to PBO was tested at the 0.1 significance level.

Results: Across the treatment arms, ~38% of patients had a history of previous treatment with ≥1 non-TNFi bDMARD, including abatacept 20%, tocilizumab 19%, and rituximab 17%. Table 1 shows the ACR20 response rate for baricitinib vs PBO in patients with prior exposure to a non-TNFi by type of biologic. Improvements in ACR response rates and proportion of patients achieving DAS28-CRP ≤3.2 were demonstrated at Weeks 12 and 24 with baricitinib in subgroups defined by prior biologic use (Table 2). Significant interaction p values were observed infrequently and inconsistently indicating minimal treatment heterogeneity across subgroups defined by prior biologic use. As with the overall study, more treatment emergent adverse events occurred in patients receiving baricitinib 2 or 4 mg vs PBO with prior exposure to 1 or 2 biologics (65%, 74%, 62%, respectively) or ≥3 biologics (84%, 87%, 70%, respectively). Serious infections were infrequent, and no TB or opportunistic infections were seen.[1]

Conclusion: In this post-hoc, exploratory analysis of prior bDMARD use in the TNFi-inadequate responder population, a beneficial treatment effect was observed across subgroups irrespective of prior bDMARD use (number or nature). In general, a consistent treatment effect was observed across the strata with no evidence of a qualitative interaction.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis-Small Molecules, Biologics and Gene Therapy II: Small Molecular Targeted Therapies

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Baricitinib (bari) is an oral, reversible inhibitor of Janus kinase (JAK)1/JAK2 being developed as QD treatment for patients (pts) with RA. In phase (ph) 1 studies, transient increases in total lymphocyte count were seen within hours of dosing and returned to baseline prior to the next daily dose;[1] ph 3 data were consistent with these observations.[2,3] The objective of this analysis was to examine changes over time in lymphocyte subsets in RA pts treated with bari or placebo (PBO) in ph 3 RA-BUILD and RA-BEACON studies.

Methods: Pts had active RA with insufficient response (IR) to conventional synthetic DMARDs (csDMARDs) (RA-BUILD; N=684) or TNF inhibitors (TNFi) (RA-BEACON; N=527). Pts were randomized 1:1:1 to receive PBO or 2 or 4mg bari QD for 24 weeks (wks). Lymphocyte subsets and natural killer (NK) cells were quantified by flow cytometry at baseline and Wks 4, 12, and 24. Total lymphocyte count was measured at all study visits. Change from baseline and differences vs PBO were evaluated. At Wks 12 and 24, phlebotomy was conducted before administering study drug (reflecting trough concentration).

Results: Compared to PBO, significant improvements in disease activity were seen for bari in both studies[2,3]. Total lymphocyte increases seen at Wk 4 for bari were generally within normal ranges. Compared to PBO, change in total lymphocyte count was similar at Wks 12 and 24, respectively, for the bari groups. Increased T cells, B cells, and NK cells were seen at Wk 4, while decreased T cells and NK cells and increased B cells were seen at Wks 12 and 24 for the bari groups (Table 1). These changes were generally within normal ranges. Changes in other T- and B-cell populations were somewhat variable, but generally reflected these patterns (Table 1). Decreased NK cell count did not appear to be associated with an increased incidence of infection (Table 2).

Conclusion: In ph 3 studies, QD oral bari produced significant clinical improvements in disease activity in csDMARD-IR and TNFi-IR RA patients. These improvements were accompanied by a variety of changes in lymphocyte counts, predominantly within normal ranges, including transient increases from baseline in total lymphocyte count, transient increases followed by decreases from baseline in T cells and NK cells, and sustained increases from baseline in B cells. Similar lymphocyte subset and NK cell assessments will be available in a long-term extension study that receives pts from the bari ph 3 RA program.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Rheumatoid Arthritis-Small Molecules, Biologics and Gene Therapy II: Small Molecular Targeted Therapies
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Filgotinib (GLPG0634) is a novel oral, potent and selective JAK1 inhibitor that has previously demonstrated efficacy in combination with methotrexate (MTX) in treating rheumatoid arthritis (RA) in 4-week phase 2A studies with an acceptable safety profile. The purpose of this study was to evaluate efficacy and safety of different doses and dose regimens of filgotinib versus placebo (PBO) in patients with active RA with inadequate response to MTX.

Methods: Patients with active RA on stable dose of MTX were randomized 1:1:1:1:1:1:1 in a double blinded manner to receive either PBO or one of three doses of filgotinib (50mg, 100mg or 200mg) as once (qd) or twice daily (bid) regimen for 24 weeks (DARWIN 1 study). The primary endpoint was the proportion of patients achieving ACR 20 response at week 12. Reported data are from the planned 12 weeks analysis.

Results: Of 594 randomized and treated patients, 76-86% were females with a mean age across groups of 52-55 years, mean duration of RA of 7-10 years and DAS28(CRP) at baseline ranging from 6.0-6.2. Patients were well distributed across different geographical regions. At week 12, a statistically significant higher ACR20 response versus PBO was observed with 200mg daily dose. For other key efficacy endpoints (ACR50, ACR-N, DAS28(CRP), CDAI, SDAI) all doses showed significant differences versus PBO. No statistically significant difference between qd and bid regimens was seen. By week 12, 24-50% of patients on filgotinib achieved low disease activity (DAS28(CRP)≤ 3.2) in a dose dependent manner, compared to 14% on PBO. Onset of efficacy was rapid for ACR-N, DAS28(CRP) and SDAI with significant differences seen from week 1 onwards at 200mg daily dose.

Table 1. Summary of the ACR/DAS28(CRP)/CDAI responses after 12 weeks treatment:

		Once-daily dosing			Twice-daily dosing		
	Placebo *n=86*	50mg *n=82*	100mg *n=85*	200mg *n=86*	25mg *n=86*	50mg *n=85*	100mg *n=84*

DAS28(CRP), mean change from BL[3], LOCF	-1.2	-1.8*	-2.2***	-2.5***	-1.9**	-2.1***	-2.8***
CDAI[4], mean change from BL, LOCF	-17	-20	-24**	-26***	-21*	-23**	-29***

* p< 0.05 vs. placebo; ** p<0.01 vs. placebo; *** p<0.001 vs. placebo; ACR scores based on ITT analysis. [1]Non-responder imputation. [2] Last observation carried forward.[3] Baseline. [4]Clinical Disease Activity Index.

Conclusion: Over 12 weeks, filgotinib in combination with MTX demonstrated consistent efficacy on signs and symptoms of active RA with a rapid onset of action. The safety profile was overall favorable and consistent with previous studies conducted in RA with filgotinib.

ACR-N, LOCF[2], %	16	35***	37***	41***
DAS28(CRP), LOCF, mean change from BL[3]	-1.0	-1.7***	-2.0***	-2.3***
CDAI[4] mean change from BL, LOCF	-11	-21***	-24***	-25***

*p< 0.05 vs. placebo; **p<0.01 vs. placebo; ***p<0.001 vs. placebo. ACR scores based on ITT analysis. [1]Non-responderimputation. [2]Last observation carried forward. [3]Baseline. [4]Clinical Disease Activity Index

Over 12 weeks, Serious Adverse events (2%) and Treatment-Emergent Adverse events (TEAE) were distributed across the groups including placebo: 38% patients on PBO and 31-42% in the filgotinib groups experienced TEAES. Most of the TEAEs were mild. In the filgotinib groups, a dose dependent decrease in mean neutrophil as well as a small reduction in platelet counts was seen without discontinuations and mild increase in mean creatinine concentration was apparent. Notably, a dose dependent increase in haemoglobin concentration was detected and no meaningful difference in transaminase changes was encountered with filgotinib.

Conclusion: Over 12 weeks, filgotinib as monotherapy demonstrated clear efficacy in treating the signs and symptoms of active RA with a rapid onset of action. Overall safety profile was favorable and consistent with previous studies conducted in RA with filgotinib.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Rheumatoid Arthritis-Small Molecules, Biologics and Gene Therapy II: Small Molecular Targeted Therapies

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Baricitinib (bari), an oral, reversible inhibitor of Janus kinase (JAK)1/JAK2, improved signs and symptoms in phase 3, placebo (PBO)-controlled studies in patients (pts) with active RA despite treatment with conventional synthetic DMARDs (RA-BUILD)[1] or TNF inhibitors (RA-BEACON)[2]. In both studies, statistically significant improvements in multiple measures of disease activity were observed for bari 4 mg QD as early as Week (Wk) 1 and were maintained through Wk 24. The objective of this analysis was to determine if clinical response to bari 4 mg at Wk 4 is highly likely to predict disease state at Wk 12 or 24.

Methods: 684 pts in RA-BUILD and 527 pts in RA-BEACON were randomized 1:1:1 to receive PBO or 2 or 4 mg bari QD for 24 wks. Improvement from baseline (BL) to Wk 4 in a number of clinical response variables, including DAS28-ESR (DAS28) and the Clinical Disease Activity Index (CDAI), was used to predict low disease activity (LDA; DAS28 ≤3.2) or remission (DAS28 <2.6) at Wk 12 or 24. Decreases from BL to Wk 4 of 0.6 to 1.2 for DAS28 and 3 to 12 for CDAI were investigated.

Results: Compared to PBO, treatment with bari 4 mg was associated with a rapid decrease in DAS28 and CDAI as early as Wk 1 ($p \leq 0.001$ for both endpoints in both studies). Across both studies, decreases from BL to Wk 4 of ≥0.6 for DAS28 or ≥6 for CDAI were the minimum levels of improvement associated with an increased probability of achieving LDA or remission at Wk 12 or 24 compared to LDA and remission rates observed in pts not experiencing these levels of improvement (Table 1). Approximately 81% and 79% of pts on bari 4 mg had a decrease in DAS28 ≥0.6 and 80% and 80% had a decrease in CDAI ≥6 in RA-BUILD and RA-BEACON, respectively. The negative predictive value (NPV) for LDA or remission at Wk 12 or 24 associated with a <0.6 decrease in DAS28 or <6 in CDAI from BL to Wk 4 almost always exceeded 90%, indicating that patients with this low degree of improvement were highly unlikely to achieve LDA or remission (Table 2). Inclusion of an acute phase reactant in the disease activity score did not appear to increase the NPV over that seen with CDAI.

Conclusion: In RA-BUILD and RA-BEACON, lack of early clinical response to bari 4 mg QD, as indicated by a failure to achieve a decrease in DAS28 ≥0.6 or CDAI ≥6 after 4 wks of treatment, was associated with very low rates of LDA or remission at 12 or 24 wks. Larger decreases in DAS28 or CDAI at Wk 4 were associated with improved clinical responses. Early identification of pts (at 4 wks) who are not likely to achieve LDA or remission may be useful in tailoring therapy to individual pts.

Table 1. Low Disease Activity and Remission After 12 and 24 Weeks of Baricitinib 4 mg Treatment in RA-BUILD[1] and RA-BEACON[2]

SESSION INFORMATION

Session Title: Sjögren's Syndrome I: Basic Insights
Session Type: ACR Concurrent Abstract Session

Background/Purpose: The relationship between atherosclerosis, traditional risk factors, disease activity and biomarkers is not well explored. We aimed to identify the association of carotid atherosclerosis with traditional risk factors, disease features, cytokine profile and calprotectin in patients with pSS.

Methods: 63 patients primary pSS and 63 age-sex-matched healthy controls underwent carotid ultrasound, clinical and laboratorial evaluation. Presence of carotid plaques was taken as carotid atherosclerosis. Covariates of carotid atherosclerosis were identified in univariate and multivariate regression. Financing from CAPES (Higher Education Personnel Improvement Coordination-Brazil) and Broegelmann Research Laboratory-Bergen.

Results: Patients with pSS had higher prevalence of carotid atherosclerosis (13% vs. 2%, p<0.05), calprotectin, tumoral necrosis factor receptor 2 (TNF-R2), Hepatocyte growth factor (HGF), and monocyte chemoattractant protein-1 (MCP-1) than controls, while sex, menopause and prevalences of traditional cardiovascular risk factors including smoking, hypertension, diabetes, dyslipidemia, obesity and metabolic syndrome (MetS) did not differ (all p>0.05). In univariate analyses, serum calprotectin (2945.16 ± 1793.36 vs. 1407.09 ± 990.66, p=0.002), most traditional cardiovascular (age, male sex, MetS, hypertension, hypertriglyceridemia, and serum creatinine), and some disease-associated risk factors (glucocorticoid or saliva substitute use, ESSDAI constitutional domain) were associated with higher risk for plaque (Table 1). In multivariate analysis, disease itself and calprotectin were independent risk factors for carotid atherosclerosis. Higher serum calprotectin was associated with carotid atherosclerosis independent of serum creatinine and systolic blood pressure (Table 2).

Conclusion: In patients with pSS, calprotectin is a biomarker of carotid atherosclerosis, which in pSS patients is modulated by traditional cardiovascular risk factors as well as the disease itself.

Table 1. Cardiovascular risk factors for carotid atherosclerosis in primary Sjögren's syndrome (pSS).

Risk Factor	OR	OR 95%CI	p-value
pSS disease	9.02	1.09-94.41	0.040

SESSION INFORMATION

Session Title: Sjögren's Syndrome I: Basic Insights

Session Type: ACR Concurrent Abstract Session

Background/Purpose: Sjögren's syndrome (SS) is a complex autoimmune disease with both environmental and genetic factors playing important roles in its pathophysiology. The goal of this study was replicate suggestive loci that failed to exceed the genome-wide significance (GWS) threshold of 5x10E-8 in our previously published work. This list included: *TNFAIP3, PTTG1, PRDM1, DGKQ, FCGR2A, IRAK1BP1, ITSN2,* and *PHIP*.

Methods: Our previous study included 1638 SS cases and 6754 population controls typed either on Illumina Omni1 or ImmunoChip arrays. In the current study, we typed an additional 212 SS cases and 2150 population controls on OmniExpress arrays yielding a combined total of 1850 SS cases and 8904 population controls for analysis. The Omni1 data and the ImmunoChip data were imputed using IMPUTE2 with the 1000 Genomes reference panels. Analysis was done using logistic regression accounting for ancestry and gender. and the results were combined using a weighted Z-score method.

Results: Two regions that have not been previously reported were found to exceed the GWS threshold. Association has been previously established with SS to a risk haplotype that spans the *TNFAIP3* coding region originally describe in lupus; however, in the current study we identified a novel effect ~230kb 5' of the TNFAIP3 coding region (rs6933404, P_{meta}= 7.79x10E-9, OR= 1.28, 95% CI=1.14-1.44), which was originally describe as a risk effect for rheumatoid arthritis. Association was observed for the haplotype previously established with SS spanning the *TNFAIP3* coding region; however, the signal peaks at rs58721818 (P=4.77x10E-4), which is correlated (r2>0.8) with rs7749323, a variant previously described in lupus. Logistic regression analysis adjusting for rs6933404 found that this variant accounted for all association in the *TNFAIP3* region. Bioinformatics data provided only limited evidence that rs6933404 might be the true functional/causal variant in this region; however, another variant on this haplotype also surpassing GWS, rs6927172, has been shown to modify 8 transcription factor binding sites, 13 bound proteins in various cell lines by ENCODE, and is located within an enhancer element in $CD4^+CD25^-IL17^+$ PMA-Ionomycin stimulated Th17 primary cells by the Epigenetics Road Map Project. The second region to surpass the GWS threshold was *PRDM1*, which peaked at rs526531 (P_{meta}= 1.24x10E-8, OR= 1.25, 95% CI=1.12-1.39). Logistic regression

adjusting for rs526531 found it accounted for all association in this region. Two additional variants on this haplotype exceeded GWS, but no clear candidate functional/causal variant has emerged based on bioinformatics data. Of the 6 remaining suggestive regions, *PTTG1*, *DGKQ*, and *FCGR2A* continue trending towards GWS.

Conclusion: These data now establish 2 new SS risk haplotypes, *TNFAIP3* and *PRDM1*. *TNFAIP3*, which codes for the protein A20, is a negative regulator of NF-kB responses. *PRDM1*, which codes for the protein BLIMP1, is an important transcription factor in regulation of the interferon-beta locus and plasma cell differentiation. Additional studies are needed to determine how these association signals function in the human genome and contribute to SS pathophysiology.

Phosphatidylinositol-3-Kinase Delta Pathway a Novel Therapeutic Target for Sjogren's Syndrome

Saba Nayar[1], Joana Campos[1], Christopher Buckley[1], Rodger Allen[2], W.A. Fahy[2], Andrew Payne[2] and Francesca Barone[1], [1]University of Birmingham, Rheumatology Research Group, Birmingham, United Kingdom, [2]UCB Pharma, Slough, United Kingdom

SESSION INFORMATION

Session Title: Sjögren's Syndrome I: Basic Insights

Session Type: ACR Concurrent Abstract Session

Background/Purpose: Sjögren's syndrome (SS) is a chronic autoimmune disease characterized by B cell hyper-activation and exocrine gland infiltration that results in loss of glandular function, systemic manifestations and autoantibody production. The phosphatidylinositol 3–kinase delta isoform (PI3Kδ) belongs to a large family of intracellular lipid kinases that regulate metabolism, survival, proliferation, apoptosis, growth, and cell migration. The PI3Kδ pathway has been successfully targeted in B cell malignancies. Given the central role of the B cell in the pathogenesis of Sjögren's syndrome we investigated evidence for the engagement of the PI3Kδ pathway in SS and the functional consequences of blocking PI3Kδ in an animal model of SS.

Methods: PI3K pathway activation was investigated in paraffin embedded salivary glands from patients with Sjogren's Syndrome and non-specific chronic sialoadenitis (NSCS). Staining for phosphorylated ribosomal protein S6 (pS6) was performed in combination with several cellular markers. UCB5857, a small molecule inhibitor of PI3Kδ, was used *in vivo* in an inducible model of ectopic lymphoneogenesis in murine salivary glands that mimics Sjögren's syndrome. Wild type (C57BL/6) murine salivary glands were cannulated with AdV5 (10^8 p.f.u.). UCB5857 or vehicle was administered by daily gavage, prophylactically or therapeutically, starting at either day 0, day 3 or day 5 p.c. 6 mice were used per group. Flow cytometry, immunofluorescence (IF) and quantitative real time PCR was used on the murine isolated salivary gland to evaluate the samples at peak of inflammation which is day 15 p.c. for all groups analyzed.

Results: Histological staining for PI3Kδ pathway activation protein, pS6 in human tissues, showed significant expression of pS6 in SS samples, as compared to non-specific sialoadenitis control, confirming engagement of the PI3K pathway. pS6 was detected within the lymphoid aggregates in both T and B cell areas and on the periphery of the lymphoid foci. Interestingly, pS6 staining was predominantly found on CD138+ plasma cells in salivary glands of SS patients.

In vivo, we observed a decrease in the number of T and B cells in cannulated salivary glands of mice prophylactically treated with UCB5857, as compared to vehicle treated mice, confirmed both by flow cytometry on isolated lymphocytes and IF. A reduction in total number of $CD45^+$, CD3, (both CD8 and $CD4^+$cells) and B cells was observed. The gene expression profile of tertiary lymphoid organ (TLO)-associated genes (CXCL13, CCL19, CCL21) was also significantly impaired in mice treated with UCB5857. This decrease was

also observed in mice treated therapeutically from day 3 or day 5 pc. Aggregates in these mice were characterized by decrease in focus score, smaller size of lymphoid aggregates and reduced T/B cell follicular organization.

Conclusion: Preliminary data suggest that PI3Kδ is engaged in several cells present in the salivary glands of patients with SS and might contribute to disease pathogenesis. Accordingly, prophylactic and therapeutic blocking of PI3Kδ results in disaggregation of the inflammatory foci and resolution of salivary gland inflammation in an animal model of SS.

SESSION INFORMATION

Session Title: Sjögren's Syndrome I: Basic Insights

Session Type: ACR Concurrent Abstract Session

Background/Purpose:

Primary Sjögren's syndrome (pSS) is an autoinmune disorder characterized by lymphocytic infiltration of salivary and lachrymal glands. Recently, it has been showed that plasmacytoid dendritic cells (pDC, main cell source of type I IFNs) are reduced in the circulation of pSS patients, although its numbers are substantially increased in the salivary glands. This suggests that pDCs migrate and are housed into the glandular tissue following a specific antigenic stimulus, possibly a viral infection.

Type III IFNs are a novel family of cytokines mainly produced by cytotoxic cells which share many biological activites with type I IFNs. Epithelial tissues are the primary target to IFN-lambda3, which possess the highest activity of all type III IFNs. The possible role that IFN-lambda3 plays in pSS pathogenesis is unknown.

Methods:

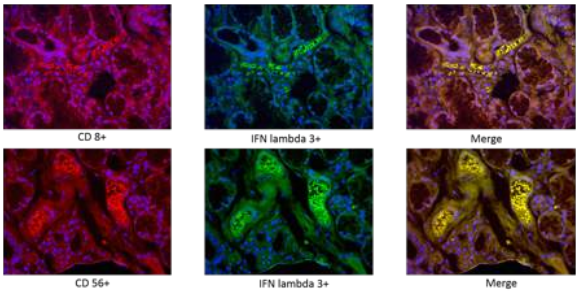
Peripheral blood mononuclear cells (PBMC) from patients with pSS and healthy controls were analyzed by conventional flow cytometry to determine the number of T cytotoxic cells (CD8+ T cells and CD56+ Natural Killers) that were also positive for IFN-lambda3. In addition, biopsies of minor salivary gland from 6 pSS and 6 non-pSS were evaluated by immunofluorescence with antibodies against CD8, CD56, and IFN-lambda3.

Results:

PBMC from 14 pSS patients and 8 healthy volunteers were included. Flow cytometry counts are presented in the Table.

Cell subtype	pSS (n=14)	Healthy (n=8)	*P*
CD8+ total cells/1«10^6 PBMC	104,757 (25,300-226,200)	71,200 (18,600-165,200)	0.3
CD8+IL28+ total cells/1«10^6 PBMC	1,478 (300-3,700)	2,742 (900-5,900)	0.06
CD8+IL28+ % of total CD8+ cells	1.73% (0.19%-5.9%)	3.96% (2.53%-6.7%)	***0.002***
CD56+ total cells/1«10^6 PBMC	39,950 (4,500-161,300)	18,085 (11,300-38,800)	0.3
CD56+IL28+ total cells/1«10^6 PBMC	871 (100-3,100)	2,900 (900-5,300)	***0.009***
CD56+IL28+ % of total CD56+ cells	3.2% (0.43-11.6%)	16% (7.8%-23.7%)	***0.0005***

On immunofluorescence, salivary tissues from pSS patients were extensively infiltrated by CD8+, CD56+, and IFN-lambda3+ cells. As noted, IFN-lambda3+ was in tightly co-localization with both CD8+ and CD56+ cells. This was not noticed in salivary glands from non-pSS individuals.



Conclusion:

The number of circulating cytotoxic cells producing IFN-lambda3 is decreased in the peripheral blood of pSS patients; however, an intense infiltration of cytotoxic cells with high expression of IFN-lambda3 was found in salivary tissue from pSS patients. This suggest the existence of an important stimulus so far unknown (probably a viral infection), causing the migration and homing of cytotoxic cells highly producing IFN-lambda3 from peripheral blood to target tissues.

SESSION INFORMATION
Session Title: Sjögren's Syndrome I: Basic Insights
Session Type: ACR Concurrent Abstract Session

Background/Purpose: $CD4^+$ T cells predominate in salivary gland (SG) focal lymphocytic infiltrates in primary Sjögren's syndrome (pSS). However, their antigen specificity, degree of clonal expansion and relationship to clinical disease features remain unknown. Here, we determined the T cell receptor (TCR) repertoire of $CD4^+$ memory T cells in SG and peripheral blood (PB) of pSS patients and assessed whether the frequencies of clonally expanded SG T cells correlate with specific measures of disease.

Methods: Multiplex single cell RT-PCR was used to amplify both the α and β TCR sequences from individual memory $CD4^+$ T cells sorted from SG lip biopsy tissue and PB of 10 patients fulfilling both the 2002 Revised American European Consensus Group Criteria and the 2012 Provisional ACR Criteria for pSS. Percentages of T cells that were part of SG clonal expansions were calculated and correlated with various measures of disease.

Results: Over 3,000 TCR sequences were obtained from 50-115 (median 91) individual SG and 75-121 (median 108) individual PB $CD4^+$ memory T cells per patient. The percentages of cells that were part of clonal expansions were significantly higher in SG (median 12%, range 0-28%) compared to PB (median 0.9%, range 0-7%, p=0.002). The TCR sequences of expanded memory $CD4^+$ T cells in SG were largely distinct from those in PB and were enriched for cells expressing dual productive TCRα transcripts ($\chi 2$=4.42, p=0.036). Sequence analysis revealed: 1) highly homologous CDR3s among different expanded SG T cell clones within single patients, suggesting antigen-driven expansion and 2) unique cases of convergent recombination among unrelated patients, where different V segments/additions/deletions were utilized to make identical CDR3 amino acid sequences. The percentages of clonally expanded $CD4^+$ memory T cells in SG correlated significantly with reduced whole unstimulated salivary flow (r=-0.758, p=0.015) and increased degree of SG fibrosis (r=0.661, p=0.044) but not with systemic features of disease.

Conclusion: SG clonal expansions detected in this study likely identify T cells involved in recognition of common antigen(s) and glandular dysfunction.

SESSION INFORMATION

Session Title: Sjögren's Syndrome I: Basic Insights

Session Type: ACR Concurrent Abstract Session

Background/Purpose: Loss of secretory epithelial function is a hallmark of primary Sjögren's syndrome (pSS). Previously we reported that bone morphogenetic protein 6 (BMP-6) inhibits cell volume regulation and is associated with the loss of salivary gland dysfunction in human and experimental pSS. The objective of this study is to understand the mechanism associated with BMP-6 induced salivary gland hypofunction and develop a novel treatment based on this to restore salivary flow.

Methods: Correlative gene expression analysis was used to identify gene expression changes that were induced by BMP6 expression. Adeno-associated vector (AAV) mediated AQP-5 and AQP-1 were transferred in BMP-6 treated human salivary gland cell (HSG) lines and membrane water permeability was detected by regulated volume decrease (RVD) assay. AAV mediated AQP-1 was delivered to either BMP-6 overexpression induced xerostomia animal model or C57BL/6.NOD-Aec1Aec2 Sjögren's mouse model.

Results: Correlation analysis identified AQP-5 expression as changing with BMP-6 induced loss in cellular regulated volume decrease. Confocal imaging confirmed a correlation between an increase in BMP6 expression and a decrease in AQP5 expression. Exogenous expression of AQP-1 or AQP-1 in HSG cells can restore the water permeability that was decreased by BMP-6. Salivary gland AAV-AQP-1 local gene therapy in animal models restored secretory function in both salivary and lacrimal glands, accompanied with decreased sailadenitis and systemic inflammation markers.

Conclusion: AAV mediated AQP-1 local gene therapy in salivary gland is a promising treatment for salivary and lacrimal epithelial hypofunction and systemic symptoms associated with pSS.

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment: Clinical Aspects and CoMorbidities

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: It is unclear whether and to what extent different phenotypes of spondylarthritis (SpA) are associated with an increased risk of cardiovascular events such as acute coronary syndrome (ACS), stroke and venous thromboembolism (VTE). Studies have indicated that ankylosing spondylitis (AS) and psoriatic arthritis (PsA) are associated with an increased risk of cardiovascular morbidity, but the results have been divergent and for undifferentiated spondylarthritis (uSpA) it has not been studied. Our objective was to investigate the incidence and risk of these cardiovascular outcomes in patients with AS, PsA and uSpA compared to each other and to general population (GP) comparators.

Methods: The study design was a prospective nationwide population-based cohort study, including an AS cohort (n=6228), a PsA cohort (n=16039), an uSpA cohort (n=4795) and a GP cohort (n=269815). The cohorts were identified between 2001 and 2009 in the Swedish Patient and Population registers. Patients with diagnoses for more than one SpA phenotype (n=1943) were excluded. The follow-up began January 1, 2004 or at the date of first diagnosis thereafter in previously undiagnosed cases and extended until the first outcome occurrence, death, emigration or December 31, 2012, whichever occurred first. Subjects with a history of each of the cardiovascular outcomes of

interest were excluded from the analysis of that outcome. Number of outcomes, person-years at risk, crude rates and age- and sexstandardized rates to the GP cohort were calculated for each outcome and cohort. Age- and sexadjusted hazard ratios (HRs) were calculated using Cox proportional hazard regression analysis.

Results: Age-and sexadjusted HRs for ACS and stroke events were significantly increased in PsA (HR (95% CI) 1.71 (1.56-1.88) and 1.41 (1.29-1.54)) and in AS (HR 1.47 (1.26-1.73) and 1.33 (1.14-1.55)), and non-significantly increased in uSpA compared to the GP cohort. For VTE the age-and sexadjusted HRs for both AS, PsA and uSpA were equally and significantly increased with about 50% compared to the GP cohort. Patients with uSpA had a significantly lower HR for ACS than patients with PsA, otherwise no significant differences in HRs were noted between the SpA phenotypes (Table).

Hazard ratio† (PsA as ref.)	1.13 (0.90-1.43)	1	1.01 (0.75-1.35)	na

Rates are presented as number of events/1000 person-years. All rates and hazard ratios are calculated with 95 % confidence interval given in parenthesis. *Age- and sexadjusted with the GP cohort as reference. †Age- and sexadjusted.

Conclusion:

We found that patients with AS or PsA had a significantly higher risk of having a first event of ACS and stroke compared to GP comparators. Both AS, PsA and uSpA patients had a nearly 50% increased risk of experiencing a first event of VTE compared to the GP. There were no significant differences between the SpA phenotypes, except for a lower risk for ACS in uSpA patients compared to PsA patients.

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment: Clinical Aspects and CoMorbidities

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose:

Increased risk of cardio-vascular disease, and osteoporosis is documented in SpA. Some of these comorbidities (e.g. cardiovascular disease risk) are subject to recommendations, with specific components relevant to rheumatic inflammatory diseases (e.g. yearly evaluation of BP, LDL-cholesterol). However, it is known that a gap exists between recommendations and their implementation in practice. The aim of this study was to evaluate: 1) the prevalence of SpA co-morbidities and risk factors for these comorbidities in different countries worldwide, 2) the gap between available recommendations and daily practice concerning prevention/management of these co-morbidities and 3) the number of risk factors detected due to the present initiative

Methods: International, cross-sectional study of consecutive SpA patients in routine care. Data comprise SpA characteristics, plus relevant cardiovascular, infection, cancer, osteoporosis and gastro-intestinal disorders.

Results:

Twenty-two participating countries (from 4 continents) included 3984 patients. Age: 44±14 years, disease duration 8±9 years, male gender: 65%, past or current axial (89%) and articular peripheral (56%) involvement; ASDASCRP: 2.0±1.1, BASFI 3.2±2.7, NSAID intake during last 3 months 68% and any past or current intake of methotrexate (33%), sulfasalazine (44%) or biologicals (44%). The most frequent diseases (past or current) found were osteoporosis (13%), gastro-duodenal ulcus (11%), cardiovascular events (myocardial infarction or stroke) (4%), solid cancers (3%), and hepatitis B infection (3%). The most frequent risk factors for these diseases were hypertension (34%), smoking (current or past (<3years)) 29%, dyslipidaemia (27%) and family history of cardiovascular disease and breast cancer (each 15%). Substantial inter-country variability was observed for the screening of co-morbidities (e.g. LDL-cholesterol measured at least in the last year from 8% (Taiwan) to 98% (Germany) or dentist visit in the last year from 0% (China) to 85% (Netherlands)). Evaluation of comorbidities and risk factors as part of this study unveiled previously undetected abnormalities [e.g. elevated blood pressure (14%), hyperglycemia (4%)] and emphasized the sub-optimal management of co-morbidities.

Conclusion:

This study suggests a) a high prevalence of co-morbidities in SpA, b) a substantial inter-country variability c) a highly variable detection of relevant risk factors. This study strongly suggests that rigorous application of systematic evaluation of co-morbidities may permit earlier detection, which ultimately may result in an improved outcome of patients with SpA.

Acknowledgements: This study was conducted under the umbrella of ASAS and thanks to an unrestricted grant from Abbvie, Pfizer and UCB.

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment: Clinical Aspects and CoMorbidities

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: There is a known association between conduction disturbances and ankylosing spondylitis (AS). The risk of conduction disturbances in other phenotypes of spondylarthritis (SpA) is less well studied. Studies have also indicated that SpA patients have an increased risk of cardiovascular morbidity. Atrial fibrillation (AF) is both an expression of cardiac disease and a risk factor for stroke. Our objective was to investigate the incidence of atrioventricular (AV) block and AF in patients with AS, undifferentiated spondylarthritis (uSpA) and psoriatic arthritis (PsA) compared to each other and to general population (GP) comparators. We also investigated the incidence of pacemaker implantation, a possible consequence of severe arrhythmia.

Methods: The study design was a prospective nationwide population-based cohort study, including an AS cohort (n=6228), an uSpA cohort (n=4795), a PsA cohort (n=16039) and a GP cohort (n=269815). The cohorts were identified between 2001 and 2009 in the Swedish patient and population registers. Patients with diagnoses for more than one SpA phenotype (n=1943) were excluded. The follow-up began January 1, 2004 or at the date of first diagnosis thereafter in previously undiagnosed cases and extended until the first outcome occurrence, death, emigration or December 31, 2012, whichever occurred first. Subjects with a history of each of the outcomes of interest were excluded from the analysis of that outcome. Number of outcomes, person-years at risk, crude rates and age- and sexstandardized rates to the GP cohort were calculated for each outcome and cohort. Age- and sexadjusted hazard ratios (HRs) were calculated using Cox proportional hazard regression analysis.

Results: Age-and sexadjusted HRs for AV block, AF and pacemaker implantation were significantly increased in both AS, uSpA and PsA compared to the GP cohort. AS patients had not only a 2-fold increase in HRs for AV block and pacemaker implantation compared to GP but also a significantly increased HR compared to patients with PsA. The increased HR for AV block was most pronounced for men in both the AS and uSpA cohort, with an over 3-fold increase compared to GP comparators (Table).

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment: Clinical Aspects and CoMorbidities

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: The ASAS Health Index (HI) is a disease-specific questionnaire (QoL) for patients with spondyloarthritis (SpA) aiming to measure functioning and health. The ASAS HI can serve as a starting point to develop a disease-specific utility reflecting the value or preference for health states specific for patients with SpA. Although it is important to measure health utility from the perspective of the patient, it is recommended worldwide to base decisions about resource allocation on utilities representing the perspective of the general population. In a first step towards a disease specific utility for the societal perspective, it is necessary to know which of the 17 aspects of health impairments included in the ASAS HI have the most influence on health according to subjects from general population and to understand whether there are differences in ratings among European countries.

Methods: An online survey was performed to conduct a best-worst experiment (BWS) based on the items of the ASAS HI in a random sample of persons from the general population from the UK, France, Germany, the Netherlands, Spain and Italy. In the BWS experiment, persons answered 17 choice tasks, each consisting each time of 4 different items of the ASAS HI. In each task, persons had to indicate which item they considered the most important and the least important for functioning and health. The mean relative importance for each item of the ASAS HI could then be generated using the estimated hierarchical Bayes method. Differences in subgroups by country, gender and age were explored. Construction of the tasks and data-analysis were performed using the Sawtooth software.

Results: In total, 3,039 (around 500/country) persons from the general population (age 46.5 years (SD 15.2), 1556 women (52.2%)) contributed to the analysis. The 5 most important aspects were pain (9.97, 95%-CI 9.79 to 10.14), sleeping (9.50, 95%-CI 9.31 to 9.69), being exhausted (8.03, 95%-CI 7.88 to 8.19), overcome difficulties (7.55, 95%-CI 7.39 to 7.70), and being able to concentrate (6.78, 95%-CI 6.63 to 6.93). The 5 least important items were washing hair (2.28, 95%-CI 2.18 to 2.39), running (3.65, 95-CI 3.50 to 3.80), driving (3.94, 95%-CI 3.80 to 4.08), contact with people (4.16, 95%-CI 4.02 to 4.29), and travelling (4.42, 95-CI 4.29 to 4.56). Figure 1 shows results and illustrates the consistency of findings across countries, age-categories and sex.

Conclusion: This study provides information of the relative impact of the items of the ASAS HI on overall health from the societal perspective. The general population states that pain, sleeping problems and being exhausted are the most important aspects of SpA that influence functioning and health. The results were comparable across sex, age and countries. This study is the first step towards a disease specific utility for health in SpA.

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment: Clinical Aspects and CoMorbidities

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Both patients with axial spondyloarthritis (axSpA) and patients with fibromyalgia (FM) are suffering from pain. The new ASAS classification criteria for axSpA have been recently challenged by arguing that FM patients could easily fulfill the clinical arm of the criteria, which could lead to overdiagnosis of axSpA and wrong treatment decisions. In this study we examined similarities and differences between axSpA and FM using different sets of classification criteria and to assess the severity of wide-spread pain in both diseases.

Methods: In this prospective study, patients were consecutively included if they were diagnosed with axSpA, or FM by a rheumatologist. Patients with rheumatoid arthritis (RA) were also included as an inflammatory control group. Patients on anti-TNF treatment were not included. Established classification and outcome parameters as well as standardized instruments were used in all patients. MRI performed in all axSpA and 20 FM patients. All axSpA and FM patients had radiographs. The Mann-Whitney-U test was used for statistical comparisons between groups.

Results: A total of 214 patients was included: 93 with FM (7.5% HLA B27+), 91 with axSpA (79.1% HLA-B27+) and 30 with RA (53.3% seropositive). The mean age was 50.7±9.1, 43.0±12 and 58.4±11.9 years, respectively, and the mean symptom duration was comparable between groups: 6.6±6.9, 6.4±7.8 and 6.2±11.3, respectively. Expectedly, the gender ratio differed: FM and RA patients were mostly female (93.4% and 76.7%, respectively), as compared to axSpA patients (28.3%). The ASAS classification criteria were not fulfilled by any FM patient. In contrast, the 1990 and 2010 FM criteria were fulfilled by 98.3% and 100% of patients with FM, but also by 14.3% and 34.1% of axSpA (no differences between AS and nr-axSpA) and 30% and 46.7% of RA patients, respectively. The Fibromyalgia impact questionnaire (FIQ) values were 69.5±13.0, 45.4±19.3 ($p<0.001$) and 49.9±22.8, respectively, while the Health Assessment Questionnaire (HAQ) values were 1.7±0.5, 1.2±0.5 ($p<0.001$) and 1.6±0.8, for FM, axSpA and RA, respectively. FM patients reported the highest pain scores on a 0-10 numeric rating scale: 7.0±1.7 vs. 6.0±1.9 and 6.1±1.9 in axSpA and RA patients, respectively, while mean CRP values (mg/dl) were higher in axSpA (1.1±1.3) and RA (0.6±0.9) patients vs. FM (0.4±0.4) (both $p<0.001$).

Conclusion: Importantly, no FM patients fulfilled ASAS classification criteria. Only a small proportion of patients with axSpA fulfilled any of the FM classification criteria. There was less overlap between patients with FM, axSpA and RA using the 1990 criteria as compared to the more sophisticated 2010 FM criteria. FM patients reported higher pain scores and more functional deficits. Some patients with widespread pain may have underlying axSpA - this differential diagnosis needs to be taken into account when dealing with the diagnosis of FM in daily practice.

Session Title: Spondylarthropathies and Psoriatic Arthritis - Clinical Aspects and Treatment: Clinical Aspects and CoMorbidities

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: The Assessment of SpondyloArthritis international Society (ASAS) cohort has been established to validate the ASAS criteria for axial spondyloarthritis (axSpA) and peripheral spondyloarthritis (pSpA), which have been released in 2009 and 2011 respectively. Since then, the criteria have received broad international acceptance, but were criticized for potential misclassification (clinical arm) and lacking data about predictive validity. Our aim was to establish the predictive validity of an ASAS SpA, pSpA or axSpA classification by either the 'imaging arm' or the 'clinical arm' at baseline, by comparing these classifications with the final diagnosis after follow up.

Methods: The ASAS-cohort included 975 patients collected from 29 ASAS centers worldwide. 22 of the original ASAS centres (N=909) participated in the follow-up study, with 10 having more than 75% of complete follow-up data. Eligible patients had either chronic (>3 months) back pain of unknown origin and age of onset below 45 years (N=658) or had peripheral arthritis and/or enthesitis and/or dactylitis (N=251). From these, 345 attended a follow-up visit and of an additional 219 information was obtained by phone [mean (range) follow-up time: 4.4 (1.9; 6.8) years]. Baseline-classification according to the ASAS criteria were tested against the rheumatologist's diagnosis at follow-up. For patients evaluated by phone, self-reported (change in) diagnosis was recorded.

Results: In total 564 patients (57.8% of the original cohort, 62.0% of the participating centers) were assessed at follow-up. 396/564 patients received a diagnosis of SpA by the rheumatologist (280 predominantly axial, 116 predominantly peripheral). Patients with- and without follow-up data available were comparable regarding the number of baseline SpA features [mean 2.5 (SD 1.4) *vs* mean 2.2 (1.4)] irrespective of the proportion of patients followed in each center. 335 patients fulfilled axSpA or pSpA criteria at baseline and of these, 309 were diagnosed by their rheumatologist as 'SpA' after follow-up (PPV SpA criteria: 92.2%). Similarly, the PPV of the axSpA and pSpA criteria was 93.3% and 89.5% respectively. 190 of the 240 (79.2%) patients fulfilling the axSpA criteria had sacroiliitis on imaging (X-ray and/or MRI) reflecting the prominent place of imaging in the criteria. Fulfillment of only the 'clinical arm' of the axSpA criteria (thus: imaging negative) yielded a PPV of 88.0%. When only considering centers with more than 75% of follow-up data available (N=291), PPV was similarly high, which pleas against 'channeling bias'.

Conclusion: The positive predictive value of both the axSpA and pSpA criteria to forecast an expert's diagnosis of 'SpA' after more than 4 years follow up is excellent. The 'imaging arm' and the 'clinical arm' of the axSpA criteria have similar predictive validity and are truly complementary.

Table: Predictive validity of the ASAS classification criteria, by testing the classification at baseline against the rheumatologist's diagnosis at follow-up (on average 4.4 years).

Criteria	Predictive values		Classification at baseline	Rheumatologist diagnosis at follow-up		
	PPV (%)	NPV (%)		SpA	No-SpA	
SpA*	92.2	62.0	Positive	309	26	335
			Negative	87	142	229
				396	168	564
pSpA	89.5	58.7	Positive	85	10	95
			Negative	31	44	75
				116	54	170
axSpA	93.3	63.6	Positive	224	16	240
			Negative	56	98	154
				280	114	394
axSpA: Imaging arm	94.7	51.0	Positive	180	10	190
			Negative	100	104	204
				280	114	394
axSpA: Clinical arm	96.0	48.9	Positive	168	7	175
			Negative	112	107	219
				280	114	394
axSpA: Imaging arm alone	86.2	31.9	Positive	56	9	65
			Negative	224	105	329
				280	114	394
axSpA: Clinical arm alone	88.0	31.4	Positive	44	6	50
			Negative	236	108	344
				280	114	394

*Combination of ASAS criteria for axSpA (in patients with predominant back pain with or without peripheral manifestations) and criteria for pSpA for patients with peripheral manifestations only. axSpA, axial spondyloarthritis; pSpA, peripheral spondyloarthritis; PPV, positive predictive value; NPV, negative predictive value.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment II: Patient-Reported Measures, Outcomes and Reporting
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Systemic Lupus Erythematosus (SLE), a chronic autoimmune disease that can affect multiple organ systems and is associated with high morbidity. Reports estimate that the cost of direct health care for patients with SLE is 3-fold higher than the national capital average. Limited data are available on the cost of in-patient care for SLE patients.

Objective: To calculate the cost of admissions, rate of readmissions and potential cost of readmissions of SLE patients at a large tertiary care center.

Methods: We conducted a financial analysis of all admissions for systemic lupus erythematosus at the 2 major hospitals affiliated with the University of Rochester of Medical Center between the July 1st of 2013 and June 30th of 2014. In-patient care for the 2 hospitals, Strong Memorial Hospital (>750 beds) and Highland Community hospital (> 120 beds) are solely provided by faculty in the Department of Allergy, Immunology and Rheumatology. The total number of admissions for the diagnosis code 710.0 as primary or secondary diagnosis, regardless of rheumatology consults, was calculated. We also estimated the total cost of admissions based on total charges and the revenue generated. Additionally, we recorded the length of stay for all admissions for SLE. To confirm the findings from the financial data search at the two hospitals, we also analyzed our admission log, maintained for all rheumatology consults received for the fiscal year from July 2013 to June 2014, based on primary diagnosis at time of admission and at discharge.

Results: The total number of SLE admissions for the year was 274, with a total cost estimated to be between $6,213,812.00 and $ 12, 182,166.00 and accounted for 2576 days of admission for all cases. The cost per admission was therefore between $22,678.15 and $ 44,460.46 and the average of length of stay per admission was calculated to be 9.4 days. The cost represented 25.5% of all rheumatology in-patient care. Moreover, 86 SLE consults recorded in the fiscal year 2014, represented about 19% of all in-patient rheumatology admissions, second only to vasculitis as a cause for admission. Of the 86 patients consulted, 12 (14%) were readmitted on multiple occasions accounting for a total of 26 admissions. Readmissions were between 1 and 5 months in duration and were estimated to cost between $317,494.10 and $622,446.44. The most common reason for readmission among these patients was lupus nephritis followed by lupus flare.

Conclusion: Hospitalization of patients with SLE is a major driver of health care costs and readmission rates for SLE are high. Development of methods to provide coordinated outpatient care and improve outpatient access and counseling are needed to optimize outcomes and decrease cost of care for these patients.

Abstract Number: 1064

Feasibility and Validity of Patient Reported Outcome Measurement Information System (PROMIS) in SLE

Shanthini Kasturi[1], Jayme C. Burket[2], Jessica Berman[1], Kyriakos A. Kirou[1], Alana B. Levine[1], Lisa R. Sammaritano[1] and Lisa Mandl[1,3], [1]Rheumatology, Hospital for Special Surgery, New York, NY, [2]Healthcare Research Institute, Hospital for Special Surgery, New York, NY, [3]Department of Rheumatology, Hospital for Special Surgery, New York, NY
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment II: Patient-Reported Measures, Outcomes and Reporting
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Accurate measurement of patient reported outcomes (PROs) is particularly important in SLE, a heterogeneous disease in which similar symptoms can have disparate impact across patients. PROMIS offers dynamic computer adaptive tests (CATs) to

precisely and efficiently measure PROs in a variety of relevant domains. The aims of this study were to: 1) assess the feasibility of administering PROMIS CATS serially to SLE outpatients; 2) correlate PROMIS CATs with legacy PRO measures, SLE disease activity and organ damage; 3) assess retest reliability of PROMIS CATs.

Methods: Adults meeting ACR SLE classification criteria were recruited from a SLE Center of Excellence. Subjects completed the Short Form-36 (SF-36), LupusQoL-US, and selected PROMIS CATs. SLE disease activity, flare, and damage were evaluated with the SELENA-SLEDAI and SLICC-ACR damage index. PROMIS domains were compared with disease activity, damage, and similar domains in legacy instruments using Spearman correlations. Retest reliability was evaluated among subjects reporting stable SLE activity at two assessments a week apart using intraclass correlation coefficients (ICC).

Results: Of 114 patients approached, 101 (89%) completed at least one assessment (Table 1), 81 (80%) completing it remotely. 91 (90%) completed a retest. Most PROMIS domains showed moderate to strong correlations with similar domains in both legacy instruments, although social function and fatigue CATs showed poor, non-significant correlations with similar SF-36 domains (Table 2). On average, flaring subjects scored a clinically meaningful half standard deviation worse on PROMIS pain and social function CATs ($p < 0.05$). However, correlations between PROMIS and SLEDAI were overall weak (mean $r = 0.24$, $p < 0.05$). SLICC scores did not consistently correlate with PROMIS. PROMIS retest ICCs were 0.78 to 0.89.

Conclusion: To our knowledge, this is the first study to assess the feasibility and validity of administering PROMIS CATs to adult SLE outpatients. These data show that PROMIS CATs can be successfully administered to diverse SLE patients at the point of care or remotely, and are valid, reliable and responsive for many SLE relevant domains. The weak correlations of social function and fatigue CATs with corresponding SF-36 domains point to a knowledge gap and the need for further study. Importantly, PROMIS scores did not correlate well with the SLEDAI. This disconnect between objective signs and symptoms and the subjective patient disease experience underscores the crucial need to integrate PROs into clinical care to ensure optimal disease management.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment II: Patient-Reported Measures, Outcomes and Reporting

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: A large multicentre multinational inception cohort was established to study risk factors for atherosclerosis (AS) in SLE. We aim to describe all vascular events and determine the predictors of atherosclerotic vascular events (AVE) in this prospectively followed cohort over a 15 year period

Methods: Patients enter the cohort within 15 months of SLE diagnosis (≥4 ACR criteria). Clinical and laboratory features of SLE are collected in a standardized protocol at yearly intervals between 2000 and 2015. Vascular events are described and attributed on a specialized form. Events recorded include myocardial infarction (MI), angina, congestive heart failure (CHF), intermittent claudication (PVD), transient ischemic attack (TIA), and stroke. Diagnosis of an event was confirmed using standard clinical criteria, relevant laboratory data and imaging where appropriate. Attribution to AS was made on the basis of lupus disease being inactive at the time of the event, and/or the presence of typical AS changes on imaging or pathology and/or evidence of AS elsewhere. Factors associated with AVE were analyzed using time to event analysis with time dependent covariates and cox proportional hazard model.

Results: Since 2000, 1848 patients have been entered into the cohort (86.8%F, age at SLE 34.7 ± 13.4 years, disease duration at enrolment 5.6±4.2 months, mean follow-up of 6.1 ± 3.9 years). Thus far there have been 202 vascular events in 142 patients. These include: MI (21), angina (29), CHF (49), pacemaker insertion (8), PVD (16), TIA (29) and stroke (50). 89 of the events were attributed to active lupus and 40 to other causes.

73 events in 51 patients were attributed to AS including: MI (15), angina (24), CHF (12), pacemaker (5), PVD (7), TIA (7), and stroke (3). Thirteen patients in the AS group had more than one event. Lupus duration at first AS event was 3.2 ± 2.9 years.

Table 1. Predictive Factors at Enrolment - Univariate Analysis

Characteristic	Patient that had a VE (N=51)	Patients that did not have a VE (N=1331)	p value

Treated with oral steroids	37 (72.5%)	928 (69.7%)	0.666
Average daily steroid dose (Mean ± SD)	14.31 ± 16.59	16.49 ± 17.09	0.371
Treated with antimalarials	31 (60.8%)	913 (68.6%)	0.239
Treated with immunosuppressives	21 (41.2%)	530 (39.8%)	0.846
Treated with antihypertensives	25 (49.0%)	363 (27.3%)	<.001
Treated with antihyperlipidemia	17 (33.3%)	123 (9.2%)	<.001

Table 2. Predictive Factors at Enrolment – Multivariate Analysis

Predictor	Hazard Ratio	95% Confidence Interval	p value
Male	2.21	1.10, 4.40	0.025
Age at SLE diagnosis	1.08	1.06, 1.10	<.0001
ACR Criteria - Serositis	2.52	4.38, 4.60	0.0026
ACR Criteria – Neurological Disorder	2.74	0.97, 7.73	0.057

Conclusion: Over the follow-up of an inception cohort with SLE there were 202 vascular events but only 73 were attributable to AS (cardiac, peripheral, CNS). Only male sex, age, and lupus disease factors (serositis) at inception remain significant risk factors of AVE in a multivariate analysis of a multicentre inception cohort followed for 7 or more years. Traditional cardiovascular risk factors likely become important over time.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment II: Patient-Reported Measures, Outcomes and Reporting
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Cardiovascular disease remains the most common cause of mortality in Systemic lupus erythematosus (SLE). Some studies suggest that mortality due to acute myocardial infarction (AMI) in SLE has decreased. We aimed to evaluate temporal trends of incidence and mortality of SLE in AMI hospitalizations in a nationally representative sample.

Methods: We reviewed Nationwide Inpatient Sample (NIS) data over 10 year period from 2002-2011 for adult AMI hospitalizations as a primary diagnosis with SLE as secondary diagnosis using validated ICD9-CM codes. We calculated unadjusted proportions of mortality yearly and used survey logistic regression to calculate adjusted odds ratios (aOR) for hospital mortality overall and after stratifying for age (≤50 vs. >50).

Results: We identified a total of 6588743 AMI hospitalizations from 2002-2011 of which 20508 (0.31%) had a diagnosis for SLE. The proportion of patients with SLE in AMI hospitalizations increased from 0.27% in 2002 to 0.39% in 2011. SLE hospitalizations were younger (60.5 vs. 67.8 years<0.01); more female (80.4% vs. 40.1%; p<0.01); with a higher proportion of African-Americans (21.4% vs. 9.2%; p<0.01) and a higher Charlson comorbidity index (Mean 2 vs. 1.5; p<0.01). The unadjusted mortality rates in SLE hospitalizations yearly were similar to hospitalizations without SLE (Figure 1). After adjusting for age, gender, race, Charlson comorbidity index, hospital level characteristics, cardiac procedures, SLE hospitalizations had similar odds-ratio for hospital mortality (aOR=0.98; 95% CI= 0.83-1.16; p=0.54) compared to non-SLE hospitalizations. In hospitalizations ≤50 years, there was no significant difference in the adjusted odds of hospital mortality (aOR=0.88; 95% C 0.56-1.37; p=0.57)

Conclusion: In hospital mortality in SLE hospitalizations with AMI was similar to non-SLE hospitalizations. This could be related to better disease recognition, newer modalities, risk modification and increased life expectancy in SLE patients.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Systemic Lupus Erythematosus - Clinical Aspects and Treatment II: Patient-Reported Measures, Outcomes and Reporting
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose:

Prior studies suggest that males with lupus nephritis (LN) may have worse outcomes than females. However, the majority of these studies, are from tertiary-care centers and there are few large cohort studies of sex differences in LN outcomes. We thus investigated risks of ESRD and death by sex in a nationwide cohort of patients with incident LN.

Methods:

Within the Medicaid Analytic eXtract (MAX) with billing claims from 47 US states and D.C., we identified individuals aged 5-65 with incident LN from 2000-4 using a previously described algorithm (>3 ICD-9 codes for SLE and > 2 codes for acute renal disease all >30 days apart, following > 12 months with none of these codes). MAX data were linked by the Centers for Medicare and Medicaid Studies (CMS) to the US Renal Datasystem (USRDS) to identify ESRD onset and subsequent deaths. The index date was the date that the incident LN definition was met. We followed individuals in the linked dataset through 12/31/2006. Deaths were captured in MAX prior to ESRD and in USRDS after ESRD. We examined baseline sex differences in sociodemographics and SLE comorbidities in the 12 months prior to the index date. We used Fine and Gray proportional hazards models to determine the subdistribution hazard ratios (HR) for ESRD by sex, accounting for the competing risk of death. Multivariable Cox proportional hazards regression models were used to estimate HRs for death by sex. To test the proportional hazards assumption, we included an interaction term for sex and follow-up time. The interaction term was statistically significant in our ESRD model and we therefore stratified follow-up time at <2 vs. >2 years post-index date where survival curves diverged.

Results: Of the 2576 Medicaid patients with incident LN, 230 (9%) were male. Mean age was 30 years (+16) among males and 34 years (+14) among females (p<0.001). More males than females were White (32% vs. 20%), and fewer Black (23% vs. 32%), p 0.02. There was no significant difference in the SLE comorbidity index (p 0.11). Mean follow-up was 2.8 (+1.5) years for both sexes (p 0.62). Among 200 females and 27 males who developed ESRD, median time to ESRD was 1.35 (range 0.11-4.62) years and 2.02 (range 0.11-4.02) years. 216 females and 17 males died in follow-up (including 31 females and 4 males who died after ESRD onset). While the HR for ESRD was similar within 2 years of incident LN, it was significantly elevated among males (HR 2.87, 95%CI 1.48, 5.24) at > 2 years after incident LN. (**Table**). HR for death did not differ by sex.

Conclusion: ESRD risk was comparable in both sexes within 2 years of LN onset, but higher among males thereafter. Mortality rates were similar in males and females. To our knowledge, this is one of the largest incident LN cohorts followed for long-term outcomes by sex. However, the relatively small number of males limits conclusions. Further study of LN outcomes by sex should be pursued.

Table. Hazard Ratios for Development of End-Stage Renal Disease (ESRD) and Death in Males vs. Females among Medicaid Patients with Incident Lupus Nephritis	
Outcome	**Hazard Ratio*** (95% CI)**
ESRD within < 2 years of Lupus Nephritis Onset*	0.94 (0.57, 1.56)
ESRD > 2 years following Lupus Nephritis Onset*	**2.87 (1.48, 5.24)**
Death following Lupus Nephritis Onset**	0.98 (0.63, 1.52)
* Subdistribution proportional hazards models, accounting for the competing risk of death in ESRD models. As the interaction between sex and follow-up time was significant (p 0.03), we stratified follow-up at the 2 year mark (< 2 years vs. > 2 years after index date). **The interaction between sex and follow-up time was not significant for analyses of death ***Mutivariable model adjusted for age, sex, race/ethnicity, calendar year of LN onset, US region, zip code-based socioeconomic status (Ward MM, *J Rheum,* 2007) and SLE Comorbidity Index (Ward MM, *J Rheum*, 2000). Females = referent.

B

Background/Purpose: In 2013 the American College of Cardiology (ACC) and the American Heart Association (AHA) developed a new formula to estimate the 10-year risk of an adverse cardiovascular event based on traditional cardiovascular risk factors. In contrast to previous formulae, this new formula focused on risk of "hard" events of myocardial infarction or stroke. Using a large cohort of patients with SLE, we derived a formula for estimating the 10-year risk of hard cardiovascular events (CVE) among patients with SLE based on both traditional and SLE-related risk factors, and compared our findings to the ACC/AHA risk estimates.

Methods: This analysis is based on data from the Hopkins Lupus Cohort since 1987. A CVE was defined as the first occurrence of a stroke or myocardial infarction (MI). Patients who had a CVE prior to cohort entry or within the first two years of cohort participation were exluded from the analysis. There were 1513 patients included, 92% female, 54% Caucasian, 39% African-American, median age at baseline was 35 and median duration of follow-up was 8 years. To derive the score, risk factors were calculated based on variables measured in the first two years of cohort participation. Cox Proportional Hazards models were constructed to determine the variables that affected the risk of a subsequent CVE. Using the results, a formula to calculate the risk of a CVE within the next 10 years was derived.

Results: 100 CVE were observed: 63 strokes, 36 MI, and 1 diagnosed with both stroke and MI. Table 1 shows the results of a multivariable Cox model used to estimate 10 year risk.

Table 1: Association between predictors and risk of a CVD event among patients with SLE.

	Hazard Ratio (95% CI)	P-value
Age (per decade)	1.3 (1.1, 1.5)	0.0050
Male (vs. female)	1.5 (0.8, 2.8)	0.17
Systolic Blood Pressure (per 10 mmHg)[1]	1.3 (1.1, 1.6)	0.0010
Cholesterol (per 25 mg/dl)[1]	1.1 (1.0, 1.2)	0.11
Current Smoking	1.6 (1.0, 2.6)	0.055
Diabetes	1.5 (0,9, 2.6)	0.12
SLEDAI (per unit increase)[1]	1.1 (1.0, 1.2)	0.028
History of Lupus Anticoagulant	2.2 (1.4, 3.3)	0.0003
Low Mean C3[1]	1.8 (1.1, 2.9)	0.027

[1] Based on mean during the first two years of cohort participation.

Table 2 shows how the estimated 10-year risk for CVE based on this model compares to the risk from the ACC/AHA risk assessment tool for selected subgroups.

Table 2: Estimated 10-year risk based on our formula, and the ACC/AHA formula for selected subgroups.

Risk Profile	Estimated 10-year risk based on our formula	Estimated 10-year risk based on 2013 ACC/AHA score[1]
White Woman, age 40, SBP=120 (treated), Chol=150, HDL=40, No other risk factors	2.6%	0.7%
White Woman, age 60, SBP=120 (treated), Chol=150, HDL=40, No other risk factors	4.2%	3.9%
White Woman, age 60, SBP=120 (treated), Chol=150, HDL=40, Mean SLEDAI=3, No other risk factors	6.9%	3.9%
White Woman, age 60, SBP=120 (treated), Chol=150, HDL=40, Low C3, No other risk factors	7.4%	3.9%
White Woman, age 60, SBP=120 (treated), Chol=150, HDL=40, Hx of Lupus Anticoagulant, No other risk factors	9.1%	3.9%

[1] Calculated at http://tools.cardiosource.org/ASCVD-Risk-Estimator/

Conclusion: Patients with SLE are generally at increased risk for myocardial infarction or stroke, especially at younger ages. The ACC/AHA score underestimates the true risk. The excess risk is highest among those with low complement, lupus anticoagulant, or high levels of disease activity. Our risk assessment tool can be useful in guiding efforts to reduce traditional and SLE-related risk factors for "hard" cardiovascular events among patients with SLE.

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis: Genetics, Gene Expression, and Epigenetics

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: SLE [MIM 152700] disproportionately affects women of reproductive age and pregnant patients are more likely to experience flares. Fetal microchimerism (FMC), or the persistence of a small population of cells in the mother, is a natural consequence of pregnancy. Risk of SLE is possibly increased through fetal HLA-antigen molecular mimicry. The causes of SLE are unknown but genetic and environmental factors, including Epstein-Barr virus (EBV) infection, are suspected. The strongest genetic association is with *HLA-DRB1* alleles **03:01, *15:01, *08:01*. We hypothesize that compared to controls, SLE cases are more likely to have children with a) *DRB1*-associated risk alleles and/or b) *DRB1*04:01*that encodes a homologous amino acid sequence to EBV.

Methods: We investigated mother-child HLA relationships in 218 SLE and 349 control mothers (and their 881 children) from the Mother-Child Immunogenetic Study (MCIS). The MCIS is a study with over 9,000 individuals: cases were recruited at UC San Francisco; controls were recruited from the Blood Centers of the Pacific, the Institute for Transfusion Medicine at the University of Pittsburgh, and from studies at the Inova Translational Medicine Institute (ITMI). Comprehensive MHC region SNP genotyping was conducted using the Illumina MHC, ImmunoChip, and 660K arrays for MCIS participants and whole genome sequencing for ITMI controls. Classical two-field HLA alleles were imputed using SNP2HLA. Clinical data were abstracted from medical records. We selected mothers of European ancestry using multidimensional scaling and ancestry informative markers to minimize any impact of population stratification. We used logistic regression models to estimate odds ratios (ORs) and 95% confidence intervals (CIs) for the association between SLE and having any children who carry *DRB1* risk alleles or *DRB1*04:01*.

Results: Initial findings reveal an increased risk of SLE among mothers with children who carry *DRB1*15:01* (OR 2.26; 95% CI, 1.39-3.66) and **04:01* (OR 1.73; 95% CI, 1.14-2.64), both adjusted for maternal genotype. Furthermore, we observed a stronger association between children who carry *DRB1*15:01*and the SLE complication lupus nephritis compared to controls (OR 2.75; 95% CI, 1.12-6.76, n=383).

Conclusion: These findings support the hypothesis that a child's genotype influences a mother's risk of disease, independent of the mother's genotype. This is the first study to demonstrate an association between a child's *DRB1* genotype and risk of SLE in the mother.

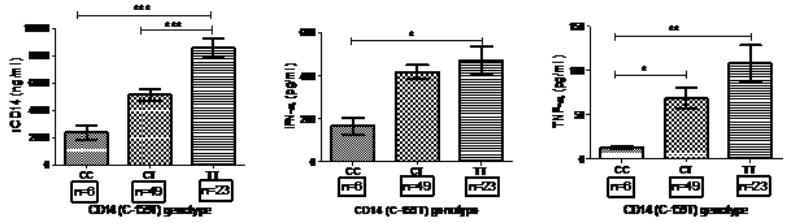
Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis: Genetics, Gene Expression, and Epigenetics
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Cluster of differentiation 14 (CD14) plays an important role in innate immune system as a co-receptor in TLRs (2, 4, 7 and 9) signaling. Host innate receptor TLR7 and 9 recognizes nucleic acids as a ligand and produce type I IFN which is believed to be associated in the pathogenesis of SLE. TLR7 and 9 require CD14 for effective signaling, we hypothesized that CD14 polymorphism and soluble CD14 levels would correlate with disease susceptibility and disease activity in SLE.

Methods: In a case control hospital based study, 130 female SLE patients fulfilling the ACR criteria and 140 age, sex matched healthy controls were enrolled. CD14 (C-159T) polymorphism was genotyped by PCR-RFLP. In 78 SLE patients and 46 healthy controls plasma sCD14, TNF-α, IFN-α levels were quantified by ELISA. Clinical, serological and other markers of disease activity (C3, C4 and anti-dsDNA) were measured by standard laboratory procedures.

Results: Prevalence of mutant genotypes (CT and TT) and allele T were significantly higher in patients of SLE. Mutants (CT and TT) for CD14(C-159T) polymorphism were associated with higher plasma sCD14, IFN-α and TNF-α compared to wild type CC. Plasma sCD14 levels were significantly high in SLE patients compared to healthy controls (P<0.001).Plasma sCD14 correlated with SLEDAI(P = 0.002, r = 0.34), proteinuria (P=0.001, r = 0.34) and negatively correlated with C3 (P = 0.003, r = -0.33) and C4 (P < 0.0001, r = -0.50). Patients with lupus nephritis displayed higher plasma levels of sCD14, and IFN-α

Conclusion: CD14 (C-159T) polymorphism is associated with SLE. Higher soluble CD14 levels is significantly associated with SLE disease activity and lupus nephritis making it a promising biomarker.



Association of CD14(C-159T) polymorphism with plasma sCD14, IFN-α and TNF-α.

Plasma concentrations (mean ± standard error of mean) of sCD14, IFN-α and TNF-α were measured by commercial kit. Plasma of 78 SLE patients were quantified for sCD14 (A), IFN-α (B) and TNF-α (C) and correlated with CD14(C-159T) polymorphism. Numbers of samples from each genotype are shown in box. Mean plasma levels in different genotypes were compared by Kruskal-Wallis test followed by Dunns post test. *P* value less than 0.05 was considered as significant. **P*<0.05, ***P*<0.01, ****P*<0.001

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis: Genetics, Gene Expression, and Epigenetics

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Currently, classification and treatment decisions in lupus nephritis (LN) are largely based on renal histology. Transcriptome analysis may accurately differentiate types of renal involvement, and better inform treatment outcome and prognosis. Single-cell RNAseq is an emerging technology that allows for resolution of differential gene expression at the single-cell level, thus facilitating the detection of expression changes that would be unnoticed in conventional bulk-tissue RNAseq. Our objectives were to determine if single-cell RNAseq can differentiate among various cell types in LN kidney, and distinguish between LN class IV and V.

Methods: RNAseq was performed on ~2 mg kidney tissue from consented clinically indicated renal biopsies in 5 SLE patients, using Fluidigm C1 Integrated Fluidic Circuits and the C1 Single-Cell Auto Prep. cDNA libraries were prepared using the Nextera XT DNA Library Prep Kit followed by HiSeq 2500 (Illumina) sequencing. Sequence-read alignments were conducted using the STAR aligner, and uniquely mapped reads were summarized at the gene level using the featureCounts software. Differential expression analysis was performed using the DESeq2 package for R version 3.2.0.

Results: A total of 155 single cells were characterized from LN kidney biopsies (n=36 pure class IV and n=108 pure class V). An average of 3500 genes/cell were identified (Fig. 1a), with 50% of reads mapping to the reference genome (Fig. 1b). Through transcriptome analysis and utilization of standard lineage markers, major renal resident and infiltrating cell types including podocytes, endothelial cells, tubular cells, macrophages, dendritic cells, and lymphocytes could be identified (Fig. 1c). Comparison of gene expression between cells from class IV and class V biopsies revealed that class IV podocytes and endothelial cells expressed significantly higher levels of complement C7 than class V cells ($p=.001$ and .01, respectively). Podocytes from class IV kidney expressed significantly higher IL-1b ($p<.01$) and TLR3 ($p<.001$) as well as IFN-γ receptor ($p<.001$) and TNF receptor ($p<.05$). Similarly, endothelial cells from class IV kidney demonstrated significant upregulation of several inflammatory molecules including NF-κB ($p=.005$), CXCL8 ($p<.05$), and IL-1b ($p<.05$). Proximal tubular cells from class IV patients expressed significantly higher levels of CXCL12 ($p<.05$) than those isolated from class V patients.

Conclusion: These findings demonstrate that single-cell RNAseq is feasible and informative in cell specific transcriptome analysis from fresh renal biopsy tissue in SLE. In this pilot study, single-cell RNAseq correlates well with histologic classification, and shows changes in gene expression that could directly drive or be influenced by disease pathogenesis. If confirmed, this novel approach may identify new therapeutic targets and track clinical responses.

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis: Genetics, Gene Expression, and Epigenetics
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Elevated Type-I interferon (IFN) signature characterizes at least 50% of adults with SLE and has been associated with autoantibodies and more severe disease in single-center studies, but association with disease severity in clinical trials of diverse populations has been controversial (Kennedy Lupus Sci Med. 2015 28;2). Therefore, we examined gene expression profiles of 1,760 randomly selected SLE patients from two worldwide Phase III trials of the anti-BAFF, IgG4 monoclonal antibody, tabalumab in SLE.

Methods: Total RNA was extracted from whole blood, collected at baseline in Tempus tubes, using the PerfectPure RNA Blood Kit. RNA quality was assessed using Ribogreen and a Bioanalyzer RNA chip. The Affymetrix WT Plus Kit was utilized for cDNA prep and labeling, and labelled cDNA was hybridized to the GeneChip Human Transcriptome Array 2. The Affymetrix HTA2.0 array has 70,753 transcript clusters. Annotation data were retrieved from Affymetrix's na34 build (www.Affymetrix.com). Only transcript clusters that represented a single protein coding gene were considered in this analysis (n=19,818). A literature review yielded 163 reported interferon responsive genes and a subset of 34 was selected to form a pre-specified signature for analysis. Kaplan-Meier time to event analysis and Cox proportional hazards regression with backward elimination (p-leave=0.05) were conducted using baseline covariates: Type-I IFN signature, SELENA-SLEDAI, low C3, elevated anti-dsDNA antibody, race and geographic region.

Results: Using the pre-specified Type-I IFN gene signature, 75% of SLE patients in the tabalumab trials had an elevated Type-I IFN

response gene signature at baseline. Type-II IFN-associated genes were also upregulated in SLE vs controls to a much lesser extent. As expected, the baseline Type-I IFN signature was associated with anti-dsDNA antibodies, low C3, low C4 and SELENA-SLEDAI score. Severe flare, as measured by the SELENA-SLEDAI Flare Index, was observed in 16.3% and 15.8% of patients in Trial-1 and Trial-2, respectively. The Type-I IFN signature at baseline was associated with risk of developing a severe SELENA-SLEDAI flare over the ensuing 52W and time to flare was highly significant in Trial-1 ($p<0.0001$) and Trial-2 ($p<0.001$). Baseline Type-I or Type-II IFN signature was not associated with SRI-5 response to either standard of care or standard of care + tabalumab. Using Cox proportional hazard analysis, the time to SELENA-SLEDAI flare predicted by the Type-I IFN signature was found to be an independent risk factor from baseline anti-dsDNA antibodies, low C3, low C4 or baseline SELENA-SLEDAI score in both Trial-1 ($p=0.0015$) and Trial-2 ($p=0.0002$).

Conclusion: 75% of SLE patients in the tabalumab trials had elevated Type-I IFN signature at baseline, associated with anti-dsDNA antibodies, low C3, low C4, SELENA-SLEDAI score and time to SELENA-SLEDAI severe flare. Time to SELENA-SLEDAI severe flare predicted by the Type-I IFN signature was found to be an independent risk factor using a Cox proportional hazard model. SRI-5 response to tabalumab could not be predicted by the IFN signature status at baseline.

Session Date: Sunday, November 8, 2015

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis: Genetics, Gene Expression, and Epigenetics

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Systemic lupus erythematosus (SLE) is characterized by multiple B cell abnormalities, including the production of autoantibodies, a major contributing factor to disease pathogenesis. Epigenetic modifications that drive the early molecular events leading to the activation of autoreactive B cells in SLE remain unclear. Therefore, we investigated the epigenetic and transcriptional signatures of SLE B cell subsets including activated naïve (aN), resting naïve (rN), late transitional (T3), switched memory (SM), and double negative (DN) B cells.

Methods: We simultaneously profiled the methylome and transcriptome of B cell subsets from SLE and healthy control (HC) African American females utilizing reduced representation bisulfite sequencing (RRBS) and RNA-seq, respectively. In addition, chromatin accessibility in SLE and HC B cells subsets was determined using assay for transposase-accessible chromatin (ATAC)-seq.

Results: Global DNA methylation analysis of total B cells identified 2,686 SLE-disease specific differentially methylated loci surrounding 951 genes. Demethylated genes in SLE B cells included IFN response genes as well as negative regulators of the viral response, while cell-cell signaling and calcium transmembrane transport genes were methylated. SLE and HC aN B cells gained DNA methylation at 2,952 loci and lost DNA methylation at 82,313 loci when compared compared to rN B cells, indicating a loss of DNA methylation during the transition from a rN to an aN B cell state. Transcriptome analysis of total B cells identified 334 differentially regulated genes in SLE patients. In individual B cell subsets, 953 genes were differentially regulated between B cell types; these cell-type transciptomes diverged from one another as cells differentiated from rN to aN to DN B cells. Integrated analysis of the methylome and transcriptome data sets identified 85 genes, 35 of which were IFN-regulated genes, whose DNA methylation changes inversely correlated with SLE disease-specific changes in gene expression.

Conclusion: DNA methylation analysis indicated the largest differences between cell types with aN B cells undergoing a genome-wide hypomethylation. Transcriptionally aN and rN B cells are more similar to each other, whereas DN B cells are more disparate. This could

reflect the cell stage of activation/differentiation, as we hypothesize that differentiation occurs in a linear manner from rN to aN to DN B cells. Although the largest differences were observed between B cell types, there were consistent SLE-specific gene expression differences (i.e.: IFN). Our results indicate that SLE B cells are epigenetically and transcriptionally distinct from HC B cells, suggesting that SLE B cells may be pathogenically programmed at an early stage of maturation.

Session Title: Systemic Lupus Erythematosus - Human Etiology and Pathogenesis: Genetics, Gene Expression, and Epigenetics
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Systemic lupus erythematosus (SLE) is a complex autoimmune disease characterized by heterogeneous clinical manifestations, autoantibody production, and epigenetic dysregulation in T cells. We sought to investigate the epigenetic contribution to the development of cutaneous manifestations in SLE.

Methods: We performed genome-wide DNA methylation analyses in SLE patients stratified by a history of malar rash, discoid rash, or neither cutaneous manifestation, and age, sex, and ethnicity matched healthy controls. We characterized differentially methylated regions (DMRs) in naïve CD4+ T cells in each disease subset, and assessed functional relationships between DMRs using bioinformatic approaches.

Results: We identified 36 and 37 unique DMRs that contribute to the epigenetic susceptibility to malar rash and discoid rash, respectively. These DMRs were primarily localized to genes mediating cell proliferation and apoptosis. Hypomethylation of *MIR886* and *TRIM69,* and hypermethylation of *RNF39* were specific to lupus patients with a history of malar rash. Hypomethylation of the cytoskeleton-related gene *RHOJ* was specific to SLE patients with a history of discoid rash. In addition, discoid rash-specific hypomethylated DMRs were found in genes involved in antigen-processing and presentation such as *TAP1* and *PSMB8*. Network analyses showed that DMRs in SLE patients with but not without a history of cutaneous manifestations are associated with TAP-dependent processing and MHC-class I antigen cross-presentation ($P = 3.66x10^{-18}$ in malar rash, and $3.67x10^{-13}$ in discoid rash).

Conclusion: We characterized DNA methylation changes in naïve CD4+ T cells specific to malar rash and discoid rash in patients with SLE. These data suggest unique epigenetic susceptibility loci that predispose to or are associated with the development of cutaneous manifestations in SLE.

The Scleroderma Lung Study II (SLS II) Shows That Both Oral Cyclophosphamide

(CYC) and Mycophenolate Mofitil (MMF) Are Efficacious in Treating Progressive Interstitial Lung Disease (ILD) in Patients with Systemic Sclerosis (SSc)

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's - Clinical Aspects and Therapeutics I
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Demonstrate that the course of forced vital capacity (FVC) over 2-years was better in SSc patients with symptomatic ILD treated with oral MMF for two years than with oral CYC for one year followed by placebo during the second year in a blinded randomized controlled trial.

Methods: Entry criteria: 1980 ACR criteria for SSc; disease duration of =< 7 years from 1st non-Raynaud sign or symptom; moderate dyspnea (Level 2 of the Magnitude of Task scale of the Mahler Baseline Dyspnea Index [BDI]; %FVC between 45% and 80%; and any ground-glass opacification on chest high-resolution computed tomography (HRCT).

At baseline and every 3 months during the 2-year trial, physical exams (including modified Rodnan skin scoring or MRSS), lung function testing and patient-reported outcomes were completed: Scleroderma Health Assessment Questionnaire (disability index [HAQ-DI] and 5 100-mm visual analogue scales); SF-36, and transition dyspnea index (TDI).

Patients were randomized to Arm A (oral CYC 2 mg/kg/day for one year followed by matching placebo for the second year) or Arm B (matching MMF up to 1500 mg BID for 2 years).

Results: 142 patients were randomized; 106 completed the 2-year evaluation. With the exception of MRSS, which was higher in the MMF group (15.3 in MMF vs 14.1 in CYC, p=xxx) the baseline characteristics were not different between treatment groups.

In preliminary analyses, -the course of FVC showed comparable improvement in both treatment groups at 24 months (see figure). Improvements in both treatment groups were noted in TDI (increase of 2.24 in CYC vs 1.86 in MMF,) and in MRSS (decline of 6.1 units in CYC vs 2.9 units in MMF).

More patients in the CYC arm withdrew from study treatment prematurely (36 in CYC and 20 in MMF) (p=0.019).Of all the subjects with end-point data 23% assigned to CYC received alternative therapy after stopping study treatment (MMF in 8, Rituximab in 1, tocilizimab in 1 and IV-CYC in 2) and 4% assigned to MMF received alternative treatment (po CYC in 1 and IV-CYC in 1) after stopping study treatment..

Weight loss (NS) and leukopenia/thrombocytopenia ($p<0.05$) occurred more frequently in the CYC arm

Conclusion: In this large, double blind, RTC, we found: 1) At 24 months the improvement in %FVC was comparable in the two treatment groups. 2) The TDI and MRSS improved in both treatment arms but there was a trend favoring improvements in the CYC group. 3) Significantly fewer premature withdrawals were noted in the MMF arm. 4) Leukopenia/thrombocytopenia were noted significantly less frequently in the MMF arm5) It is unclear how the use of alternative medications in SSc patients who withdrew prematurely from study treatments, particularly in the CYC patients, could have influenced the results.

In summary both CYC and MMF are efficacious for treatment of SSc-ILD.

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's - Clinical Aspects and Therapeutics I

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Interstitial lung disease (ILD) is the leading cause of death in patients with systemic sclerosis (SSc). Although cyclophosphamide (CYC) demonstrated beneficial treatment effects at one year on FVC and self-reported dyspnea (1), these benefits came at the expense of a high degree of adverse effects. Uncontrolled studies have demonstrated that mycophenolate (MMF) may improve SSc-ILD; however, no studies have directly compared outcomes of CYC and MMF in SSc-ILD. The present double-blind, randomized, placebo-controlled trial (RCT) compared the effects of CYC versus MMF in patients with SSc-ILD.

Methods: Between September 2009 and January 2013, 142 SSc-ILD patients from 14 US centers were randomized to receive MMF (titrated as tolerated to 3.0 g/day in divided doses) for 2 years or oral CYC (titrated as tolerated to 2 mg/kg daily) for 1 year followed by 1

year on placebo. Inclusion criteria were age ≥18 years, duration of disease ≤7 years from onset of the first non-Raynaud's SSc symptom, FVC 40-80% predicted, DLCO ≥40% predicted (or 30-39% predicted if no evidence of pulmonary hypertension on echocardiogram and/or right heart catheterization), and evidence of *any* ground glass opacity on HRCT. The primary endpoint was treatment responsiveness as measured by the course of the FVC% predicted over 24-months.

Results: Among 142 participants (Mean [SD] age 52.3 [9.7] years), 74% were female and 59% had diffuse cutaneous involvement. The mean disease duration was 2.6 [1.8] years. Baseline pulmonary function was as follows (All Mean [SD]% predicted): FVC 66.5 [9.1]; TLC 65.9 [10.9]; DLCO 54.0 [12.7]. Baseline quantitative lung fibrosis (QLF) scores were 32.5 [23.8] and 8.6 [6.8], for the zone of maximum involvement and whole lung, respectively. By 24 months, approximately half (49%) of the participants assigned to CYC (N=73) went off drug, compared with 29% of participants assigned to MMF (N=69). A greater proportion of participants assigned to MMF reached the required dosage compared with CYC, and the time to reach the maximum targeted dose was significantly longer in the CYC arm (152 days) compared with the MMF arm (92 days). Participants assigned to CYC experienced more serious adverse events (SAEs) considered to be drug-related by a morbidity and mortality committee compared with patients assigned to MMF (22% versus 7%, respectively), although the majority of SAEs were deemed to be related to underlying ILD (Table 1). During the study period, there were 11 deaths (15%) in the CYC group and 5 deaths (7%) in the MMF group.

Conclusion: The present findings demonstrate that treatment with MMF is associated with fewer SAEs deemed to be drug-related and fewer deaths compared with treatment with CYC in patients with SSc-ILD. Moreover, MMF appears to be better tolerated than CYC.

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's - Clinical Aspects and Therapeutics I

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Systemic sclerosis (SSc) carries high risk for progressive interstitial lung disease (ILD), but biomarkers for individual risk stratification are largely missing. There is an ongoing discussion about the potential of chemokine CCL18 or pulmonary and activation regulated chemokine (PARC) as a marker for (progressive) ILD in SSc. The aim of this study was to examine associations between ILD parameters and serum levels of CCL18 in a large and unselected SSc cohort with complete and data sets on pulmonary function and lung fibrosis extent by HRCT.

Methods: Sera from the prospective Oslo University Hospital SSc cohort (n=298) and healthy blood donor controls (HC; n=100) were analysed for CCL18 by enzyme immunoassay. CCL18 levels were defined as high or low using [mean 2SD] in HC sera as cut-off value. Paired pulmonary function tests and HRCT images were obtained at baseline and follow-up. All patients in the SSc cohort met the 2013 ACR/EULAR classification criteria.

Results: CCL18 was increased in SSc compared to HC, and high levels of CCL18 (>53 ng/ml) were identified in 105/298 (35%) of the SSc patients. Patients with high and low CCL18 did not differ regarding demographics, SSc subtype or auto-antibody profile (Table 1). Analysis of ILD parameters showed that high CCL18 was associated with low Forced Vital Capacity (FVC) at baseline, decline in FVC across the observation period and lung fibrosis progression; expressed as annual fibrosis progression rate (Table 2). Multivariate analyses showed associations between CCL18, FVC decline and FVC <70% at follow up (Table 3). Finally, Kaplan-Meyer analyses showed that patients with high CCL18 levels had reduced 5-and 10 year survival compared to the CCL18 low subset; (85% and 74% compared to 97% and 89%, log rank: 0.004).

Conclusion: In this prospective SSc cohort, high levels of CCL18 were associated with deterioration of lung function, higher annual fibrosis progression rate and decreased survival. Our results support the notion that circulating CCL18 has potential as marker for progressive ILD in SSc.

Table1: Demographics and clinical findings in the SSc cohort stratified by level of CCL18

	Total SSc cohort (n=298)	**Low CCL 18 (n=193)**	**High CCL18 (n=105)**	**p-value***

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's - Clinical Aspects and Therapeutics I

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Increased circulatory levels of the chemokine CXCL4 have been associated with the presence of pulmonary fibrosis (PF) by HRCT in an observational study of patients with systemic sclerosis (SSc)[1]. In addition, higher baseline levels of CXCL4 predicted faster decline in DLCO in a subgroup of patients from this study[1]. No studies have evaluated whether CXCL4 can predict both extent and progression of PF in SSc patients, all of whom have well-characterized PF and all of whom are receiving aggressive therapy with either mycophenolate (MMF) or cyclophosphamide (CYC).

Methods: Between September 2009 and January 2013, 142 SSc-PF patients from 14 US centers were randomized to receive MMF (titrated as tolerated to 3.0 g/day in divided doses) for 2 years or oral CYC (titrated as tolerated to 2 mg/kg daily) for 1 year followed by 1 year on placebo. Plasma samples were obtained at baseline, 1 and 2 years. Baseline plasma samples were examined by validated, commercially available ELISA kits (Human CXCL4/PF4 Quantikine Kit - R&D Systems). CXCL4 levels were compared between SSc-PF patients (N=136) and age- and gender-matched healthy control patients (N=67) using a Student's t test. Correlations were performed between CXCL4 levels and baseline measures of extent of PF, as well as change in DLCO (from baseline) at 12, 18, and 24 months.

Results: Among 136 participants with baseline plasma samples, 94% were ANA positive, 46% were Scl-70 positive, 13% were Anti-RNA polymerase III positive. Baseline pulmonary function was as follows (All Mean [SD]% predicted): FVC 66.5 [9.1]; TLC 65.8 [11.1]; DLCO 54.0 [12.7]. Baseline quantitative lung fibrosis (QLF) scores were 22.8 [19.6] and 8.6 [6.9], for the zone of maximum involvement (ZM) and whole lung (WL), respectively. Baseline modified Rodnan skin score (mRSS) was 14.7 [10.5] and Baseline Dyspnea Index (BDI) was 7.2 [2.2]. Baseline CXCL4 levels were higher in SSc-PF patients compared with healthy controls (Mean [SD]: 2699 [1489] versus 2233.4 [1351.1], respectively; P=0.03). There were no significant correlations between baseline CXCL4 levels and extent of PF as measured by FVC, TLC, DLCO, QLF-ZM, QLF-WL, BDI (all P-values >0.2), and extent of cutaneous sclerosis as measured by the mRSS (P=0.2). There were also no significant correlations between baseline CXCL4 levels and change in DLCO at 12 (P =0.6), 18 (P =0.4), or 24 months (P=0.6).

Conclusion: Consistent with prior studies,[1] levels of CXCL4 were higher in patients with SSc-PF compared with controls. However, CXCL4 levels were not correlated with extent of PF and progression of PF as measured by change in DLCO in patients with SSc-PF.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's - Clinical Aspects and Therapeutics I
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: There is increasing interest in cohort enrichment for clinical trials of early diffuse SSc (dcSSc). Recent EUSTAR database analysis (Maurer et al. 2015) suggests that patients with a low modified Rodnan skin score (mRss)< 22 and short disease duration (< 15 months from first non-Raynaud symptom) have the highest probability of worsening (defined as progressive skin involvement) at one year. The autoantibody profile in the US dcSSc population is different than Europe, with greater percentages of patients with anti-RNA polymerase III (RNAP) antibody in the US. Anti-RNAP positive patients often present with higher skin scores. If an upper threshold skin score is used as an inclusion criterion thenmany RNAP positive patients could be excluded. The objective of this study was to examine the effect of restricting mRss in early diffuse SSc clinical trials with respect to: 1)the percentage of patients experiencing a significant change in mRss and 2) recruitment in a US population.

Methods: We used a single-center cohort of prospectively followed early dcSSc patients seen for an initial visit between Jan. 1, 1980 and Dec. 31, 2013 at a US Scleroderma Center. Early was defined as < 18 months from the first non-Raynaud symptom. Patients had to have at least two mRss within one year of the first SScCenter visit. After descriptive baseline statistics, time to peak skin score, and the percentage of patients who had improvement or worsening of mRss over one year were calculated. Data is presented by skin score at presentation.

Results: Among 304 eligible patients, mean age at the first SSc Center visit was 51.8 ±13.5 years. The cohort was 76% female and 93%Caucasian. Overall patients were 58% RNAP positive, 21% anti-Scl70 positive, 11% other SSc-autoantibody positive and 10% unknown. The percentage of patients with improving or worsening mRss by ≥5 points,≥5 points and 25% change, and the times to peak skin score are shown in Table 1. Including patients with higher baseline skin score did not change the overall % of patients improving or worsening their mRss within one year. The median time to peak skin score was nearly identical in the patient groups. By restricting our inclusion criterion to mRss< 25 points, 27-40% of patients with worsening mRss would have been excluded with different progression.

Table 1: Skin score change at one year by baseline mRss at presentation

mRss at first SSc Center visit	N	mRssworsened by ≥5 points	mRss improved by ≥5 points (%)	< 5 point change in mRss	Median (IQR) time to peak mRss from first visit
10-25	176	87 (49%)	47 (27%)	42 (24%)	0.45 (0.00, 0.64)
10-30	217	110 (51%)	55 (25%)	52 (24%)	0.46 (0.16,0.67)
10-35	253	127 (50%)	69 (27%)	57 (23%)	0.45 (0.15, 0.66)
10-40	284	142 (50%)	82 (29%)	60 (21%)	0.42 (0.07, 0.66)
10-45	304	143 (47%)	90 (30%)	71 (23%)	0.40 (0.00, 0.63)
	N	**mRssworse ≥5 points and 25%**	**mRss improved by ≥5 points and 25%**	**< 5 point and 25% change in mRss**	
10-25	176	84 (47%)	44 (25%)	58 (33%)	
10-30	217	97 (45%)	49 (22%)	71 (33%)	
10-35	253	108 (43%)	61 (24%)	84 (33%)	
10-40	284	115 (41%)	69 (24%)	100 (35%)	
10-45	304	115 (38%)	71 (23%)	118 (36%)	

Conclusion: In one US SSc Center population expanding the allowable mRss from ≥22 to ≤45 did not decrease the percentof patients changing their mRss. Restricting mRss at≤ 22 may significantly limit our potential to recruit patients in the US. Further study of this issue should be undertaken with additional modeling and consideration to different autoantibody frequencies in geographic regions. Limitations of our data include that it is single center population.

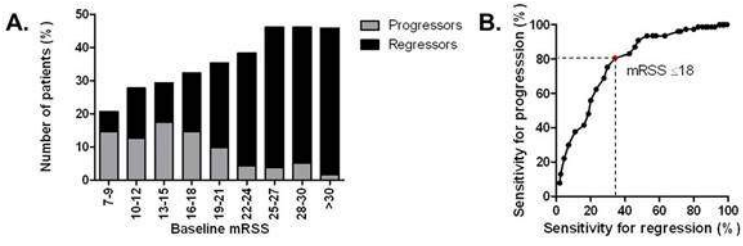
Session Title: Systemic Sclerosis, Fibrosing Syndromes, and Raynaud's - Clinical Aspects and Therapeutics I

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: The modified Rodnan skin score (mRSS) is the major outcome measure for skin fibrosis in clinical trials (CT) in diffuse cutaneous scleroderma (dcSSc). Traditionally, CT in skin fibrosis included mostly severe patients with higher mRSS. This approach is challenged by recent data showing that patients with lower baseline skin scores are more likely to progress during 1 year of follow-up (1). In this study, we explored baseline mRSS as a predictor of change in skin fibrosis in patients with dcSSc. **Methods:** This longitudinal analysis included 704 patients from the EUSTAR registry. The inclusion criteria were: expert-diagnosis of dcSSc, fulfillment of ACR1980 criteria, mRSS≥7 at baseline and available data for mRSS at 12±2 months follow-up. Skin improvement and skin progression were defined as a decrease/increase in mRSS of >5 points AND ≥25 % within 1 year, respectively (1). A comparison of the baseline mRSS in patients with/without skin improvement/progression after 1 year was performed (Wilcoxon rank sum test). Further, we explored the interdependence between different mRSS cut-offs and progression/regression of skin fibrosis. **Results:** A total of 155/704 (22%) patients showed skin improvement, whereas 77/704 (11%) showed skin progression after 1 year (Figure 1A). High baseline mRSS was strongly associated with skin improvement ($p<0.001$), with the best sensitivity and specificity for prediction of skin regression at a cut-off of 17.5 points (area under the curve 0.708). A lower baseline mRSS was confirmed as predictor of skin progression after 1 year ($p<0.001$). We analysed different mRSS cut-offs and their sensitivity for progression and regression of skin fibrosis (Figure 1B). In this cohort, an upper baseline mRSS cut-off value of 18 points performed best, including the highest proportion of progressors (80.5%) and the lowest proportion of regressors (34.2%, Figure 1B). For feasibility reasons, higher thresholds were also analyzed and, overall, a baseline mRSS between 18 and 25 allowed the inclusion of a reasonably high rate of progressors over regressors. **Figure 1. A.** Percentage of progressors and regressors per baseline mRSS range. **B.** Sensitivity for progression and regression depending on different cut-off values for baseline mRSS.



Conclusion: These results argue for a paradigm shift regarding mRSS thresholds used as inclusion criteria in CT in skin fibrosis in dcSSc. In order to preferentially include progressive patients over those prone to improve as part of the natural history of the disease, a lower mRSS at baseline should be considered. Further analyses on other cohorts will add valuable data to support the choice of a specific threshold. **References:**

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Vasculitis I
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Currently-used outcome measures in vasculitis insufficiently capture the life impact of systemic vasculitis from patients' perspectives. The Patient Reported Outcome Measurement Information System (PROMIS) is a collection of item banks designed to cover a broad range of self-reported health. This study assessed the feasibility and construct validity of selected PROMIS instruments in a longitudinal cohort of patients with vasculitis.

Methods: Data from a multicenter longitudinal cohort of subjects with systemic vasculitis from May 2014 to February 2015 were used. Instruments from 10 PROMIS item banks were selected (Table 1) with direct involvement of patient research partners and added to ongoing disease assessments. Each subject completed PROMIS instruments from 6 item banks. PROMIS instruments were administered using computer adaptive testing (CAT) intended to allow for a more precise estimate while minimizing burden on study subjects. The Short Form 36 (SF-36) and physician and patient global assessments for disease activity were also measured on an 11 point scale (0-10). Active disease was defined as a physician global assessment >0. Cross-sectional construct validity was assessed by calculating the correlations of PROMIS scores with the other disease measures at baseline and longitudinal construct validity was assessed by correlations of between-study visit differences in PROMIS scores with differences in other disease measures.

Results: 604 study subjects came for 899 study visits. PROMIS assessments were completed at 796 (88%) of the visits. The median

time to complete the set of PROMIS assessments was 8.7 minutes (IQR 6.1-12.1) for the total cohort, 15.2 minutes (IQR 11.9-19.2) for those older than 80, and 6.7 (IQR 4.9-9.6,)) minutes for those younger than 40. Mean PROMIS scores at baseline are shown in Table 1. PROMIS instruments correlated cross-sectionally with the individual scales of the SF-36, most strongly with subscales of the SF-36 addressing the same domain as the PROMIS instrument. Weaker correlations were observed in differences of scores longitudinally. The differences in all PROMIS scores during active disease vs. remission were in the expected direction for each domain (Table 2).

Conclusion: PROMIS measures have cross-sectional construct validity and help discriminate between active disease and remission. Inclusion of PROMIS instruments in disease assessment in vasculitis would enhance capture of patients' perspectives of disease burden and complement traditional physician-based outcome measures.

Table 1. PROMIS scores from CAT instruments across different forms of vasculitis expressed as mean (standard deviation)

	Forms of Vasculitis					
PROMIS Instrument	EGPA N=77	GCA N=119	GPA N=277	MPA N=35	PAN N=29	TAK N=67

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Vasculitis I
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose:

Recent studies in ANCA-associated vasculitis (AAV) have suggested that classification based on ANCA type (PR3 versus MPO) may represent a more clinically relevant division than the traditional disease type categorization (granulomatosis with polyangiitis [GPA] versus microscopic polyangiitis [MPA]). The differences between these two classifications are driven primarily by patients with GPA who are MPO-ANCA+ or ANCA-negative. However, little scrutiny of these patient subsets has been described in the literature. We analyzed the clinical features and treatment outcomes of MPO-ANCA+ patients with GPA and ANCA-negative patients with GPA enrolled in the Wegener's Granlomatosis Etanercept Trial (WGET) or the Rituximab in AAV (RAVE) trial.

Methods:

We performed a pooled analysis of patients enrolled in the WGET and RAVE trials. We compared both MPO-ANCA+ and ANCA-negative patients with GPA to two well-defined AAV subgroups: 1) PR3-ANCA+ patients with GPA and, 2) MPO-ANCA+ patients with MPA.

Results:

Among the 365 patients analyzed, 273 had PR3-ANCA+ GPA (75%), 33 had MPO-ANCA+ GPA (9%), 15 had ANCA-negative GPA (4%) and 44 had MPO-ANCA+ MPA (12%).

MPO-ANCA+ patients with GPA

MPO-ANCA+ patients with GPA were more often female than PR3-ANCA+ patients with GPA and were younger than MPO-ANCA+ patients with MPA (Table 1). The clinical features and frequency of granulomatous inflammation confirmed by histopathology were similar between MPO-ANCA+ GPA and PR3-ANCA+ patients with GPA. However, MPO-ANCA+ patients with GPA showed a complete absence of scleritis and endobronchial lesions though these differences did not reach significance. MPO-ANCA+ patients with GPA also differed from MPO-ANCA+ patients with MPA in having more frequent manifestations typically associated with GPA. The rate of relapsing disease at trial entry and relapse rate during the trial in patients with MPO-ANCA+ GPA was similar to that of PR3-ANCA+ GPA but higher than MPO-ANCA+ patients with MPA.

ANCA-negative patients with GPA

ANCA-negative patients with GPA were similar in age and sex distribution to PR3-ANCA+ patients with GPA but had lower BVAS/WG scores at trial entry (4.5 vs 7.7, $p<0.01$). Renal involvement was less frequent, while granulomatous features on histology and relapsing disease at trial entry were more frequent in ANCA-negative patients with GPA than their PR3-ANCA+ GPA counterparts.

Conclusion:

In this population of patients enrolled in clinical therapeutic trials of AAV, MPO-ANCA+ patients with GPA did not differ significantly from PR3-ANCA+ patients with GPA with respect to clinical manifestations or rate of relapse. ANCA-negative patients with GPA had more frequent relapsing disease at study entry than PR3-ANCA+ patients with GPA. This data adds to the debate on the contribution of ANCA type and disease type to clinical manifestations and treatment outcomes in AAV.

Table 1 – Patient characteristics and relapse rates of MPO-ANCA+ patients with GPA

	MPO-ANCA+ GPA (N=33)	PR3-ANCA+ GPA (N=273)	ANCA-negative GPA (N=15)	MPO-ANCA+ MPA (N=44)	MPO-GPA versus PR3-GPA	MPO-GPA versus MPO-MPA	ANCA-negative GPA versus PR3-GPA

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: Vasculitis I

Session Type: ACR Concurrent Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Granulomatosis with polyangiitis (GPA) is associated with severe end-organ damage (e.g., renal failure) and treatment-related complications (e.g., severe infection) which often lead to hospitalization with major resource use. However, no data on hospitalization trends and associated mortality are available. We evaluated recent trends in nationwide hospitalization and in-hospital mortality among patients with GPA.

Methods: We used the National Inpatient Survey (NIS) which is the largest all-payer inpatient database in the US and includes data and sampling weights from over 1,200 hospitals across 44 states. We studied all hospitalizations of adults (³18 years) with a primary discharge diagnosis of GPA (ICD 9: 446.4) between 2001 and 2011. We investigated trends in hospitalization and mortality by comparing GPA to overall inpatient hospitalization trends. All analyses were performed using hospital-level sampling weights provided by the NIS to obtain US national estimates.

Results: From 2001 to 2011, the rate of hospitalization for GPA remained stable from 0.76/100,000 persons to 0.78/100,000 persons. The mean age tended to get younger from 56.9 yrs to 55.1 yrs and there was a slight male predominance (40.6% +/- 3.1 vs. 50.0% +/- 2.9; P-for-trend=0.0001) over the study period. From 2001 to 2011, the mean length of stay remained stable, between 9.7 +/- 0.6 and 8.6 +/- 0.5 days (P-for-trend 0.24), but there was a significant decline in in-hospital death from 7.7% (+/-2.7%) in 2001 to 2.6% (+/-1.5%) in 2011 **(Figure 1)** (P-for-trend < 0.0001). Overall, the annual relative change in GPA mortality was -9.96% (95% CI: -14.3 to -5.6) and the annual absolute change was -0.46% (95% CI: -0.66% to -0.25%). This was a significantly greater decline than overall inpatient hospitalization mortality (annual relative change of -2.5% 95% CI -2.7% to -2.2% and annual absolute change of -0.06%, 95% CI: -0.06% to -0.05%). Among those who died during a hospitalization when GPA was the primary diagnosis in 2011, the most common secondary diagnoses were respiratory failure, chronic kidney disease, and lower respiratory disease.

Conclusion: Between 2001 and 2011, hospitalization and length of stay for GPA remained stable but in-hospital mortality declined in this dataset representative of all US hospitalizations. This decline was significantly greater than that of the background US in-hospital mortality rate. The declining in-hospital mortality rate may be due to earlier recognition of GPA, shifts in treatment that emphasize less cyclophosphamide use and more tempered use of glucocorticoids, and secular trends in the management of infections and end-organ complications.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Vasculitis I
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Granulomatosis with polyangiitis (GPA) is associated with an increased risk of mortality. Advances in diagnosis and treatment strategies are thought to improve outcomes in GPA. While prior reports estimate a standardized mortality rate (SMR) of 2.1-

4.8, recent GPA mortality trends in a general population context are unknown.

Methods: We conducted a matched-cohort study using data from an electronic medical record database representative of the UK general population, collected from 1992 to 2013. GPA was defined using Read codes for GPA. Cox proportional hazard regression models were used to estimate the hazard ratio (HR) of mortality among patients with GPA compared to sex-, age-, and entry time-matched non-GPA individuals, adjusting for lifestyle factors, comorbidities, medication use, and other potential confounders. The cohort was divided into two sub-groups based on the year of diagnosis (1992-2002 and 2003-2013) to evaluate changes in mortality with time; these time periods were chosen based on the timing of publications between 2000 to 2003 studying the safety and efficacy of different treatment strategies. We calculated the absolute rate difference using an additive hazard model for the two sub-cohort follow-ups and tested the additive interaction between GPA and time period.

Results: We identified 474 cases of GPA (average age 60.2 +/- 14.6 years; 52.1% male). The incidence rate of death (per 1000 person-years) in the GPA group was 43.5 (95% CI 35.4-52.9) compared to 19.3 (95% CI 17.6 to 21.0) in the control group, which resulted in a multivariate HR of 2.5 (95% CI 1.9-3.3). Patients with GPA were at the greatest risk of death in the first year following diagnosis. There was no apparent difference in the mortality HR between males and females and those older and younger than 65 years of age.

The early cohort (1992-2002) GPA patients had considerably higher mortality rates than the recent cohort (2003-2013) patients (72.0 vs. 35.7 cases per 1000 person-years), as compared with a moderate improvement in mortality rates in the comparison cohorts between the two periods (19.8 vs 17.0 cases per 1000 person-years, **Figure 1**). The HR for mortality was 4.34 (95%, 2.72-6.92) in the early cohort in contrast to 2.41 (95%, 1.74-3.34) in the recent cohort (p for interaction = 0.043).

Conclusion: In this large cohort representative of the UK population, we demonstrate that GPA survival has improved considerably over the past two decades. This trend is coincident with changes in management that minimized exposure to cyclosphophamide and emphasized earlier introduction of steroid-sparing agents.

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: Vasculitis I
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose:

Levamisole, an anti-helminth drug, has been implicated in cases of drug-induced autoimmunity in humans exposed to adulterated cocaine. Clinical manifestations of levamisole-induced autoimmunity include cutaneous vasculitis and specific autoantibodies (e.g. anti neutrophil cytoplasmic antibodies, ANCA; antinuclear antibodies, ANA). Neutrophil extracellular trap (NET) formation is a novel cell death mechanism implicated in certain idiopathic autoimmune diseases. Proteins commonly found within NETs include the specific targets of ANCA and ANA. The objective of this study was to determine the role of NET formation in the pathogenesis of levamisole-induced autoimmunity.

Methods: Human and mouse neutrophils were exposed to graded concentrations of levamisole. NET formation was visualized and quantified by fluorescence microscopy. To assess the pathways involved in levamisole-induced NETosis, in some experiments the following inhibitors were added diphenylene iodonium (DPI), an inhibitor of reactive oxygen species, and Cl-amidine, an inhibitor of peptidylarginine deiminase (PAD) enzymes. Involvement of Akt and Raf-MEK-ERK kinase pathways was tested by Western blot. The role of Toll-like receptors (TLRs) and muscarinic receptors (MR) in levamisole-induced NETosis was investigated. Pharmacologic inhibitors and MR knockout mice were used to study specific MR subtypes implicated in NETosis. MR subtype receptors on neutrophils from patient samples were assessed by flow cytometry. Autoantibodies against specific NET-components were examined among cocaine users with no overt sign of autoimmune disease.

Results: Levamisole induced prominent NETs in human and murine neutrophils that contained myeloperoxidase and proteinase 3, the targets of ANCA. NET formation induced by levamisole was dependent on phosphorylation of Akt and Raf-MEK-ERK kinase pathways. DPI and Cl-amidine significantly abrogated levamisole-induced NETosis, highlighting that levamisole stimulates NETs via generation of reactive oxygen species and activation of PAD enzymes. Both levamisole and acetylcholine induced NETs through MR engagement on the surface of neutrophils and not through stimulation of TLRs. Atropine, a non-selective MR antagonist, blocked levamisole mediated NETosis. Screening experiments with pharmacologic inhibitors and neutrophils from MR knockout mice demonstrated that levamisole-induced NETosis was mediated through engagement of M3 muscarinic receptor. In a cohort of 21 patients actively using cocaine, 100% had quantifiable levamisole in urine, and sera from these patients demonstrated novel autoantibodies against NET components. In longitudinal observations, ex-vivo spontaneous NET formation correlated with periods of active cocaine use.

Conclusion: Levamisole induces NETosis through engagement of M3 muscarinic receptors on the surface of neutrophils. These findings implicate a novel interaction between the cholinergic nervous system and innate immunity in the pathogenesis of levamisole-induced autoimmunity.

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: Vasculitis I
Session Type: ACR Concurrent Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Glucocorticoids (GC) achieve remission in most patients with systemic necrotizing vasculitides (SNVs) without poor-prognosis factors based on the 1996 Five-Factor Score (FFS; comprising creatininemia >140 µmol/L, proteinuria >1 g/24 h, specific gastrointestinal, cardiomyopathy and CNS involvement). However, more than a third of them relapse, mainly during the first 2 years after treatment onset. This study aimed to determine whether combined GC and azathioprine (AZA) could achieve higher remission and lower relapse rates than GC alone in patients with newly diagnosed eosinophilic granulomatosis with polyangiitis (EGPA), microscopic polyangiitis (MPA) or polyarteritis nodosa (PAN), without increasing adverse events.

Methods: All patients included in this multicenter, prospective, randomized, double-blind trial received GC, initially 1 mg/kg/day, then gradually tapered over 12 months (asthmatic patients' doses were lowered as much as possible while controlling asthma symptoms) and were randomly assigned to receive concomitant 12 months of oral AZA (2 mg/kg/day, increased after 3 months to 3 mg/kg/day for insufficient responses, defined as BVAS >6, persistently elevated acute-phase reactants, eosinophilia >1x10^9/L or manifestations, with FFS always 0) or placebo. Patients were followed for another 12 months, for 24 months of follow-up. The primary endpoint was combined remission-induction failures and minor or major relapses at month (M) 24. Analyses used a modified intent-to-treat strategy and were adjusted according to the vasculitis.

Results: Among the 101 eligible patients, 95(51 EGPA, 25 MPA, 19 PAN) met the inclusion criteria and received at least 1 dose of AZA (n=46) or placebo (n=49). At endpoint, 21 (45.6%) AZA-arm patients had remission-treatment failures and/or relapses compared to 24 (49.0%) placebo recipients (odds ratio [OR], 0.96; [95% CI, 0.41–2.24]). Secondary endpoints were also comparable between arms: initial remission rate (80.4% vs. 81.6%; OR, 0.90 [0.31–2.70]) and numbers of patients with minor (26.7% vs. 25.0%) or major relapses (13.3% vs. 10.4%) (OR, 1.45 [0.61–3.44]). Two (4.1%) AZA-arm patients died (1 sudden death at M12 while in complete remission, 1 86-year-old died of congestive heart failure). Mean and cumulative GC doses and area under the curve for GC use were also comparable between arms. At least 1 serious treatment-related adverse event occurred in 8 (17.4%) AZA-arm and 3 (6.1%) placebo-arm patients (OR, 3.22 [0.69-14.29]). For EGPA patients, neither the primary endpoint nor the numbers with exacerbated asthma/rhinosinusal disease differed between arms.

Conclusion: At study M24, AZA adjunction to GC induction did not lower the absolute risk of treatment failure or relapse in patients with non-severe SNVs, compared to GC alone, had no steroid-sparing effect, and, did not reduce EGPA patients' rate of asthma/rhinosinusal disease exacerbations (*CHUSPAN2 trial was funded by French Ministry of Health PHRC P060243 and sponsored by AP–HP; ClinicalTrials.gov number, NCT00647166*).

Abstract Number: 1087

“It Was Just My Right Pace”: A Qualitative Study Exploring Yoga Practice in Adults with Rheumatoid Arthritis

Heather Greysen, School of Nursing, University of California San Francisco, San Francisco, CA
First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015
Session Title: ACR/ARHP Combined Abstract Session: Rehabilitation
Session Type: ACR/ARHP Combined Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose: Physical activity is reported to improve physical function and reduce disease symptoms in adults with rheumatoid arthritis (RA); however adults with RA are less likely to participate in physical activity than adults with other chronic diseases. The dynamic mind-body physical activity of yoga may be an acceptable and beneficial way for RA adults to increase physical activity. However, little is known about how patients with RA are practicing yoga in the community and about the benefits they experience. The objective of this qualitative study was to explore yoga practice characteristics in addition to perceived benefits and facilitators of yoga practice in adults with RA.

Methods: A convenience sample of 17 adults, with rheumatologist-diagnosed RA, who had participated in yoga within the previous year, completed a semi-structured telephone interview. An interview guide was used to explore: the decision to start, continue and stop yoga; perceived benefits of yoga; importance of components of a yoga session; and general thoughts about yoga as it relates to RA. Thematic analysis was used to analyze interview transcripts.

Results: The majority of the 17 participants were white (71%), female (94%), employed full-time (53%), had mean age of 56 years, had an average disease duration of 21 years, and had bachelor’s or graduate degrees (65%). The primary style of yoga practiced was Vinyasa and Restorative/Gentle (47% combined). Four main themes were identified: (1) Facilitators, (2) Barriers, (3) Benefits, and (4) Harms of yoga practice. Facilitators included: socialization, physical fitness, and improving practice. Barriers included: finances and class mismatch. Benefits included: increased coping abilities and improved sleep, flexibility, energy, strength, balance, pain, mood, and physical function. Harms included RA flares and muscle strain injuries. There were many styles of yoga practiced and participants described various ways to adapt or change an existing yoga practice to meet the physical and emotional needs of the practitioner on any particular day. Study participant quotes illustrated how the dynamic exercise of yoga, which can be gentle with breath exercises, meditation, and relaxing stretches or can be a vigorous exercise with fast moving strenuous poses, suited their dynamic needs as a person with fluctuating symptom burden.

Conclusion: In this study RA patients described how yoga practice helped improve physical function and numerous RA disease symptoms. Yoga practice can provide many benefits for adults with RA when it is practiced at the right pace for the individual. Yoga practices vary and yoga may not be beneficial for every adult with RA, in fact it may be harmful if practiced inappropriately. Next steps include further investigating the role of the yoga teacher and the physical yoga practice environment as facilitators and barriers to practice.

Table 1. Main Themes and corresponding yoga participant quotes		
Key Theme	**SubTheme**	**Quote**
Facilitators	Desire for physical fitness	*"... I thought that it would help me stretch out and um, hopefully give me more mobility."*
	Being influenced by others	*"...the Pain Management Program, they suggested that I get into yoga"* *"...my friends said, 'why don't you give it a try'"*
	Increased benefits	*"in the beginning, my joint stuff was really bad, it was kind of hard for me to do all the poses, but as I started doing it, I did notice that there were certain poses like the triangle pose, and stuff, that, I hated at one point, but then I was able to do it, so I noticed that my flexibility did improve."*
Barriers	Financial issues	*"She recommends that I have it twice a week, but financially I just can't do that."*
	Yoga class mismatches	*"I think I would like to try yoga again but it would have to be in a therapeutic environment, meaning, I would need, probably pillows or other things that would help me to do the exercises, you know."*
Benefits	Physical and mental	*"it just helps me with my overall mobility, I just feel like I am able to move so much better...I have improvement in all of those things, pain, energy, mood…I really, really like it, I feel it's so worth it, I do enjoy it very much."* *"Well, it just made me feel better, more flexible, it made me feel, um, more calm, more better inside, stronger….it helps my mood, outlook and energy"*
	Psychosocial	*"It was, the fellowship, the people. You know, you get hear somebody else griping about their toes hurting and their elbow hurtin, and then you know, we all get in there and we start doing our exercises and stuff and then we're talking about grandkids, you know, catchin crab or salmon and we start talkin about other stuff instead of you know, whatever hurts, so that part of it is a big uplift."*
	Pride and achievement	*"I was pretty proud of myself for getting through it…when I do certain moves, I can feel pretty good about myself"*
	A tool to cope	*"I think the breathing and the meditation are a big part …it's just, when you have RA you can get a lot of negative thinking and this really helps with that…yoga is really helpful, like a tool to turn to."*
Harms	RA Flares	*"I had to stop doing yoga because of my RA. I needed something more gentle, so I do Qigong now. I actually tried yoga again recently, but it caused a flare, so I said, okay, well, I've got to stop doing that."*

Effect of Training on Knee Torsional Stiffness and Its Relationship to Tibial Compressive and Anterior Shear Forces in Recreational Female Runners

Bhushan Thakkar[1] and D. S. Blaise Williams III[2], [1]PHYSICAL THERAPY, VIRGINIA COMMONWEALTH UNIVERSITY, RICHMOND, VA, [2]Physical Therapy, Virginia Commonwealth University, Richmond, VA

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: ACR/ARHP Combined Abstract Session: Rehabilitation

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: 42 million Americans participate annually in running. In 2014, the half marathon was the most popular distance with a total of 61% females (1.2 million) finishing these races. Further, there has been a 2% increase annually in new female runners

completing a half marathon. Because medial knee osteoarthritis (MOA) is more prevalent among women, it is reasonable to investigate the mechanical impact of females training for a half marathon. Knee stiffness is related to leg stiffness which is significantly greater in individuals with MOA during walking. However, it is currently unknown how knee mechanics may be impacted by running and training for a half marathon distance. Therefore, the purpose of this study is to determine the relationship between shear and compressive forces and torsional stiffness at the knee with training.

Methods: A 16 week half-marathon training program was completed. Pre- and post-training analyses were completed. 3D gait analysis was performed during a 30-second treadmill run at self-selected pace. Retroreflective markers were placed on bilateral lower extremities. Kinematic data were collected at 240 Hz with a 5-camera motion analysis system. Commercial software was used to reconstruct 3-D coordinates for each marker and generate kinematic and kinetic variables. Torsional stiffness was calculated as the slope between the net joint moment and the angular displacement at the knee joint in the sagittal plane. Univariate regression analyses were calculated for stiffness and shear, stiffness and compression (pre and post). Welch 2 sample t tests were used to compare pre and post stiffness and pre and post shear.

Results: 21 female recreational runners between 33-56 years. (μ=47.6±8.1 yrs).There were significant differences found between pre and post stiffness (p= 0.03), pre and post compression (p=0.01), pre and post joint moment (p=0.04) and pre and post stride frequency (p=0.02). Regression models predicted a significant relationship between joint moment and shear (pre) ($p=<0.01, r^2=0.19$), and joint moment and compression (post) ($p=<0.01, r^2=0.44$). In addition, stride frequency was increased after training.

Conclusion:

With training, torsional stiffness at the knee increased but shear and compressive forces decreased. The change in joint moment was significant but there was no change in joint angle**.**We suggest that the joint moment changes existed due to a different position of vertical ground reaction force (VGRF) relative to the knee joint center, as there were no changes in magnitude of VGRF. This change in position is likely related to the increase in stride frequency and subsequent decrease in stride length. The modulation of knee stiffness in women may be protective against passive joint loading (sparing the compressive and shear forces) by increasing quadriceps muscle activation (active generation of force). Quantification of quadriceps muscle activity may aid in development of adjunct training programs for female runners

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: ACR/ARHP Combined Abstract Session: Rehabilitation

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Few instruments that measure physical activity (PA) can accurately quantify PA performed at light and moderate intensities, which is particularly relevant to older adults with OA of the lower extremities. However, evidence of their ability to capture change over time in PA is limited. Also, responsiveness has not been compared across instruments that measure PA. Such investigation would allow for a well-educated choice of tools to assess changes in PA behavior over time. Our aim was to determine and compare the responsiveness of the Actigraph (ACT), Sensewear Armband (SWA) and Community Healthy Activities Model Program for Seniors (CHAMPS) questionnaire in assessing PA from light to moderate intensities after an exercise intervention in individuals following total knee arthroplasty (TKA).

Methods: Baseline and 6 months data on PA from subjects participating in an intervention to promote PA were analyzed. Internal (distribution based) and external (anchor based) responsiveness were assessed. Changes in duration in light and moderate intensity PA from baseline to 6 months and the standardized response mean (SRM) were calculated to assess internal responsiveness, and were compared across instruments. External responsiveness was assessed by comparing changes in PA to changes perceived by the subjects

using the global rating of change in PA that was administered at 6 months. In addition, agreement between instruments on identifying subjects who were less, the same or more active based on standard error of the measurement was performed using weighted Kappa.

Results: Thirty subjects (67±6 years old, 73% female and obese [BMI=30±4 kg/m^2]) were included in the analysis. Changes in PA measured by each instrument after the intervention were small and did not reach statistical significance (Table). SRMs indicated low degree of responsiveness (SRM < 0.30) across PA intensity levels measured by each instrument. Based on the external anchor, all subjects reported being more active after the intervention, while the distribution of the changes in PA showed that some of them were less active. Using the measurement error as a threshold for change in PA, the ACT identified 37% of subjects as less active, 33% as more active, and 30% who stayed the same. Data from SWA identified 30%, 37% and 33% respectively. Data from CHAMPS identified 40%, 37% and 23% respectively. The ACT and SWA agreed on identifying changes beyond error in moderate PA (Kappa = 0.60) and number of steps (Kappa = 0.63). There was no agreement between CHAMPS and the activity monitors (Kappa ² 0.22).

Conclusion: Distribution-based method may not be appropriate to investigate changes in PA after an intervention since there were no changes on a group basis. However, as individuals, we observed relevant changes in PA. Using the measurement error as a threshold for changes in PA may be useful since it allowed for identifying those who became more or less active after an intervention.

TABLE. Daily duration of physical activity (PA) measured by the Actigraph (ACT), Sensewear Armband (SWA) and CHAMPS questionnaire, and the magnitude of changes. Data represents means ± standard deviation, unless otherwise indicated.

Characteristics and Trajectories of Child Pain, Function, and Psychological Outcomes Associated with Conversion Disorder in Intensive Interdisciplinary Pediatric Pain Rehabilitation

Cara Hoffart[1] and Dustin Wallace[2], [1]Rheumatology and Integrative Pain Management, Children's Mercy Hospital, Kansas City, MO, [2]Integrative Pain Management and Developmental and Behavioral, Children's Mercy Hospital, Kansas City, MO

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: ACR/ARHP Combined Abstract Session: Rehabilitation

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Given the degree of compromise in quality of life, there is a critical need to identify the natural history of pain and disability in association with conversion symptoms. While there is increasing recognition of comorbid conversion disorder in pediatric chronic pain, few studies investigate the effect of interdisciplinary treatment on outcomes in children with chronic musculoskeletal pain and conversion disorder. We hypothesized youth with conversion disorder would have greater pain, disability, and anxiety at baseline and throughout treatment, leading to worse function, pain, and psychological outcomes.

Methods: This outpatient program provides 5-6 hours of daily intensive PT and OT in addition to self-regulation, and behavioral health intervention. 69 participants age 11-18 (58 female) with chronic musculoskeletal pain completed Functional Disability Inventory (FDI), PROMIS anxiety, depression, and peer relationships, PRCQ-catastrophizing, CPAQ-A, and reported pain using a 100mm Visual Analog Scale (VAS 0-100) at program start, end of each week, and at 1, 6, and 12-mos follow-up. Hierarchical linear modeling (HLM) software was used to conduct time-series analyses.

Results: 19 participants (15 female) had conversion disorder. Patients with conversion had greater physical disability upon program entry (P=.02). Functional differences decreased during the program, with trends toward faster improvement among those with conversion (P=.089), and these differences resolved by follow-up. All patients significantly improved function from baseline to program end (P<.001) and continue to improve following treatment (P=.002). Similar patterns were found for peer relationships and pain acceptance. Patients with conversion had similar pain severity (M=61.5) as those without conversion (M=58.4) at baseline (P=.48) and throughout. Both groups demonstrated significant decrease in pain through follow-up (P=.001). There were no differences between groups in depression, anxiety, or catastrophizing.

Conclusion: Children with chronic pain and comorbid conversion disorder have increased disability, poorer peer relationships, and decreased pain acceptance compared to those without conversion at baseline, though differences resolve post-treatment. Patients with conversion have similar pain severity and no differences in depression, anxiety, or catastrophizing to those without conversion. Both groups demonstrate significant improvement in function, pain, and psychological outcomes post-treatment. Prospective studies are warranted to determine best practices for diagnosis and treatment of comorbid conversion symptoms in children with chronic pain.

Figure: Patient Functional Disability Inventory (FDI) demonstrates increased disability in patients with conversion at baseline (P=.02). Functional differences resolved by follow-up.

Effectiveness of Multidisciplinary Pain Rehabilitation Programs for Patients with Fibromyalgia Syndrome: A Systematic Review

Niall Halliday[1,2], Caroline Treanor[2], Rose Galvin[3] and Jason Brooks[4], [1]Medicine, Dentistry and Biomedical Sciences, Queens University Belfast, Belfast, Northern Ireland, [2]Physiotherapy, Beaumont Hospital, Dublin, Ireland, [3]Clinical Therapies, University of Limerick, Limerick, Ireland, [4]Medicine, Dentistry and Biomedical Sciences, Queens University Belfast, Belfast, Ireland
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Sunday, November 8, 2015
Session Title: ACR/ARHP Combined Abstract Session: Rehabilitation
Session Type: ACR/ARHP Combined Abstract Session
Session Time: 4:30PM-6:00PM

Background/Purpose:

Fibromyalgia syndrome (FMS) is a common, chronic pain condition with complex multiple symptoms. Combinations of therapies in a multidisciplinary pain rehabilitation program (MPRP) are recommended by several international guidelines for the management of FMS. A number of primary research studies have evaluated the impact of MPRPs. However, no study has evaluated the totality of evidence regarding the effectiveness of MPRP's for FMS.

The aim of this systematic review with meta-analysis was to examine the impact of MPRP's on levels of impairment, activity limitation and participation restriction in people with FMS.

Methods:

An electronic search was conducted and included PubMed (1950 to present)

EMBASE (1980 to present), CINAHL (1982 to present), Science Direct (1985 and Databases of existing reviews such as The Cochrane Database of Systematic Reviews (*The Cochrane Library*, latest issue) The Cochrane Central Register of Controlled Trials (CENTRAL) (*The Cochrane Library*, latest issue) as well as electronic dissertation/theses databases and a grey literature search. The references of identified articles and reviews were checked, clinical trial registers and the Science Citation Index searched. Content experts were also contacted for additional or unpublished studies.

Studies were considered eligible for inclusion if they met the following inclusion criteria: *study design*; randomized controlled trials (RCTs), *population*; individuals with FMS, *intervention*; MPRP with involvement from a physician and two other health professionals, *comparison*; less intensive MPRP or no intervention, *outcomes;* impairment, activity limitation and participation restriction.

Studies were screened based on title/abstract and irrelevant studies eliminated. Two reviewers extracted the data and assessed the methodological quality of the studies using the Cochrane risk of bias tool. Finally, both a meta-analysis and a narrative synthesis were performed to evaluate the level of scientific evidence for the effectiveness of MPRP's.

Results:

After screening 11,280 abstracts, nine RCT's (1216 patients) met the inclusion criteria. The mean age of participants was 47.1 years, the mean duration FMS was 10.29 years and the population was 90.4% female. All MPRP's consisted of both a physical and a psychological intervention. Comparison groups included waiting list control with exercise, pharmacological treatment, less intensive MPRP's, and no intervention. The methodological quality of the studies was variable. A meta-analysis revealed that MPRP's are effective in the long term at reducing to pain levels ([FEM, SMD=-0.27 (95% CI -0.45, -0.10), $p<0.01$ I^2=45%]) and disease impact [FEM, MD=-6.24 (95% CI -9.32, -5.95), $p<0.01$ I^2=47%]. The narrative synthesis revealed moderate to low quality evidence in support of MPRP's FMS.

Conclusion:

These findings suggest that MPRP have a positive impact on long-term pain levels and disease impact in people with FMS. There is also

some indication that the tailoring of treatments to specific subgroups of patients may be the most effective method of delivery. Future research should be directed towards analyzing such sub-groups analysis.

Illicit Drug Use in US Adults with Chronic Low Back Pain: Nhanes 2009-2010

Anna Shmagel[1] and Robert Foley[2], [1]Rheumatic & Autoimmune Diseases, University of Minnesota Medical School, Minneapolis, MN, [2]Renal Diseases and Hypertension, University of Minnesota, Minneapolis, MN

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Sunday, November 8, 2015

Session Title: ACR/ARHP Combined Abstract Session: Rehabilitation

Session Type: ACR/ARHP Combined Abstract Session

Session Time: 4:30PM-6:00PM

Background/Purpose: Addictive medications, such as opiates and benzodiazepines are frequently prescribed to patients with chronic low back pain (cLBP). Little is known about illicit drug use among Americans with cLBP.

Methods: We used data from the back pain survey, administered to a representative sample of US adults aged 20-69 (N = 5103) during the 2009-2010 cycle of the National Health and Nutrition Examination Survey (NHANES). Participants who reported pain in the area between the lower posterior margin of the ribcage and the horizontal gluteal fold at the time of survey with a history of pain lasting almost every day for at least 3 months were classified as having cLBP (N = 700). The drug use questionnaire included data on lifetime and current use of marijuana or hashish, cocaine, heroin, and methamphetamine. Questions were self-administered in a private room using the Audio Computer-Assisted Self-Interviewing system. Chi-square tests, analysis of variance and logistic regression models, adjusted for age, gender, race and level of education, were used for comparisons.

Results: US adults with cLBP were older, less educated, and more often Caucasian than those without cLBP. They had higher odds of unemployment, poverty, and depression. 46.5% of US adults with cLBP used marijuana vs 42% of those without cLBP (aOR 1.36, 95% CI 1.06-1.74, p=0.016). 22% vs 14% used cocaine (aOR 1.85, 95% CI 1.47-2.34, p<0.0001), 9% vs 5% used methamphetamine (aOR 2.03, 95% CI 1.30-3.16, p=0.002), and 5% vs 2% used heroin (aOR 2.43, 95% CI 1.44-4.11, p=0.001).

Conclusion: Community-based US adults with chronic low back pain had higher odds of using marijuana, cocaine, heroin, and methamphetamine than the general population. Particular caution should be exercised when prescribing medications with abuse potential to cLBP patients.

Session Date: Monday, November 9, 2015

Session Title: B cell Biology and Targets in Rheumatolid Arthritis and other Autoimmune Disease Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: B cells play a pivotal role in the pathogenesis of autoimmune diseases. Although Syk function as a key molecule in BCR signaling, the pathological role of Syk in B cells in RA remains unclear. The purpose of this study was to assess the relevance of activation of Syk in B cells to RA pathology and responsiveness to treatment with biologics.

Methods: Healthy subjects (n=36) and patients with moderate or severe RA disease activity (n=70) were studied. The phosphorylation of Syk in peripheral blood B cells was measured by flow cytometry, and the correlation with clinical characteristics and changes after administration of biological products were evaluated.

Results: Syk phosphorylation in B cells was significantly higher in RA patients compared with the control (p-Syk-positive $CD19^+$ B cells (%): control, 11.9±8.2; RA, 27.7±23.2, p=0.0019). The expression levels of p-Syk in all different treatment groups of RA patients were significantly higher than the control (control; 10.7±1.3%, treatment-naïve RA (n=12); 21.6±7.7%, MTX-treated (n=36); 24.8±3.3%, MTX+biologics-treated (n=9); 30.8±10.0%, p=0.0036). Although Btk is well-known as downstream of Syk, Btk phosphorylation in B cells was also higher in patients with RA compared with the control (mean MFI of p-Btk in $CD19^+$ B cells: control, 144±73.4; RA, 224±171, p=0.031). Syk phosphorylation was significantly higher in B cells of patients strongly positive for ACPA (p-Syk-staining among $CD19^+$ B cells (%): negative for ACPA, 22.2±24.9; positive, 19.5±21.5; strongly positive, 32.6±23.5; p=0.0335), but not correlated with indexes of RA disease activity, such as tender joints, swollen joints, CRP, ESR, MMP-3, DAS28-CRP, DAS28-ESR, CDAI, and SDAI. Autoantibody production by B cells requires the involvement of T cells and abatacept can inhibit T cell activation. Based on this background, we hypothesized that abatacept inhibits Syk phosphorylation in B cells. Interestingly, the rate p-Syk-positive cells among $CD19^+$ B cells diminished from 21.4±30.9 to 3.3±3.8 (from week 0 to week 24, p=0.0341) in the abatacept group, and from 30.0±23.1 to 42.0±34.8 (p=0.1255) in the TNF inhibitors group. Although Th1 cells ($CD4^+CXCR3^+$ cells) were not changed, abatacept significantly reduced the proportion of Tfh cells ($CD4^+CXCR5^+PD\text{-}1^+$ cells) from 5.7±5.7 at week 0 to 3.4±4.7 % at week 4 (p=0.0206).

Conclusion: Our results demonstrated that significantly high levels of Syk phosphorylation in B cells were strongly related to ACPA in RA patients. Our data suggested that abatacept seems to inhibit Syk-Btk signal in B cells as well as development of T follicular helper cells, highlighting the relevance of B-T cell interaction as a potential target of abatacept therapy in RA.

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: B cell Biology and Targets in Rheumatolid Arthritis and other Autoimmune Disease Poster
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid Arthritis (RA) autoimmunity starts years before clinically apparent inflammatory arthritis (IA) develops, and elevated disease-specific autoantibodies, including anti-citrullinated protein antibodies (ACPA) and rheumatoid factor (RF), can be detected in this period. Early responses to known and/or novel autoantigens likely drive the eventual production of pathogenic autoantibodies. We hypothesized that through characterization of circulating plasmablasts one can identify the specific antigens to which early tolerance has been broken in at-risk individuals who exhibit autoantibodies associated with future RA onset but who are currently without IA.

Methods: We have investigated the antibody-secreting plasmablasts of a characterized cohort of seropositive (Ab+) individuals (ACPA and/or RF) in comparison to seronegative (Ab-) individuals, patients recently diagnosed seropositive RA (<1 yr), and healthy controls. Plasmablasts were identified by flow cytometric analysis and defined as CD19+CD3-CD33-CD14-CD20-CD27+CD38^{hi}. As IgG-producing plasmablasts have low surface BCR expression, 'IgG+' cells were identified by the absence of IgA and IgM staining, while IgA+ plasmablasts were identified by IgM-IgA+ surface staining. The antibody repertoires of at-risk subjects were analyzed using a DNA barcode-based method of paired heavy- and light-chain gene sequencing. Cells were single-cell sorted into 96-well plates prior to adding cell-specific DNA barcodes by template switching during reverse transcription, followed by adding plate-specific DNA barcodes by PCR. Samples underwent Roche 454 sequencing or 2 x 300 MiSeq analysis. Data were demultiplexed using a custom software pipeline to separate reads from each single cell according to its unique compound (plate + well) barcode ID. The isotype of sorted cells was confirmed by gene-specific PCR and by identification of isotype-specific sequences in the final data.

Results: Total plasmablast levels were not elevated in Ab+ individuals (1%) compared to controls (0.4-1.6%). However, fitting with prior studies supporting a potential role for mucosal immune responses in RA initiation in the preclinical period, we observed markedly increased frequencies of IgA+ vs. IgG+ plasmablasts in Ab+ individuals (39% IgA+, 37% IgG+ plasmablasts) as compared to all other groups (1-9% IgA+, 71-87% IgG+ plasmablasts). Furthermore, sequencing of paired antibody heavy and light chains from Ab+ subjects revealed the presence of cross-isotype clonal families as well as similar sequence characteristics between the IgA and IgG plasmablast repertoires of seropositive subjects.

Conclusion: The IgA plasmablast dominance in these Ab+ individuals suggests that a subset of antibodies may arise from both systemic as well as mucosal immune responses which may drive clinical disease development in individuals who are at-risk for developing RA. We intend to identify and characterize antigens to which these dual isotype antibodies react with the immediate goal of identifying known and novel autoantigens, and a potential future goal of using tolerizing therapies to these autoantigens that could be effective in prevention or early treatment strategies.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: B cell Biology and Targets in Rheumatolid Arthritis and other Autoimmune Disease Poster
Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Antibodies targeting carbamylated proteins (anti-CarP) were recently identified in serum samples from patients with rheumatoid arthritis (RA). The presence of anti-CarP antibodies was associated with a more severe disease course in RA patients and correlated with the development of RA in arthralgia patients and healthy blood donors. It may therefore serve as a new biomarker in the management of early RA. Carbamylated-fetal calf serum (Ca-FCS), a complex mixture of proteins, is currently used in ELISA to identify anti-CarP antibodies. It is not yet clear which of the proteins in Ca-FCS are responsible for the reactivity of the anti-CarP antibodies. Therefore, we set out to investigate which protein(s) within the Ca-FCS mixture may function as an antigen for anti-CarP antibodies. This might serve as a method to optimize the ELISA, using a known and consistent antigen and may provide novel insights in the pathophysiological mechanisms of anti-CarP antibodies.

Methods:

Ca-FCS was fractionated using anion-exchange chromatography. Fractions containing sufficiently high protein concentrations were coated onto ELISA plates and used for the detection of anti-CarP antibodies. Fractions containing a high anti-CarP antibody binding capacity and low protein content were selected and analysed by SDS-PAGE gel-electrophoresis. Coomassie stained bands were excised and analysed by mass-spectroscopy. Human A1AT was obtained from commercial sources, carbamylated and used in ELISA. Receiver operating characteristic (ROC) analysis was used to analyse the discriminatory power of different assays.

Results:

We observed high anti-CarP binding capacity in several fractions obtained after fractionation of Ca-FCS using anion-exchange chromatography. The fraction with the best signal (ELISA) to protein concentration ratio was further separated by SDS-PAGE gel-electrophoresis, proteins bands were excised and analysed by mass-spectrometry. The most promising band was identified as bovine alpha 1 anti-trypsin (A1AT). Purified human A1AT from commercial sources was *in-vitro* carbamylated and used as antigen to coat ELISA plates. In sera of RA patients, we found a strong reactivity towards Ca-A1AT and only limited reactivity against non-modified A1AT. We detected anti-CarP antibodies directed against Ca-A1AT in around 45% of the ACPA positive RA patients. Importantly, as for the anti-CarP FCS assay, we observed around 14% anti-Ca-A1AT positive patients in the ACPA negative stratum. Using ROC analyses comparing RA patients to healthy controls we observed for anti-Ca-A1AT an AUC of 0.72 (0.65-0.78) as compared to an AUC of 0.69 (0.63-0.76) for anti-Ca FCS. We observed a good quantitative correlation between anti-Ca-FCS and anti-Ca-A1AT reactivity of anti-CarP antibodies (r=0.76 (0.67-0.86)), making A1AT a suitable new antigen for the detection of anti-CarP antibodies.

Conclusion:

Carbamylated-A1AT is a promising antigenic target of anti-CarP antibodies as an aid in the diagnosis of RA.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: B cell Biology and Targets in Rheumatolid Arthritis and other Autoimmune Disease Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a systemic autoimmune disease, which causes joint inflammation and bone loss. Inflammation-mediated joint damage is linked to the imbalance of bone-resorbing osteoclast (OC) and bone-depositing osteoblast (OB) activity. Pro-inflammatory cytokines present in the synovium have been shown to directly or indirectly stimulate OC differentiation. Although the effect of T cell, macrophage and synoviocyte-derived cytokines on bone resorption is well characterized, less is known about the impact of B cell-derived cytokines. Tumor necrosis factor α (TNFα) is a pro-inflammatory cytokine that promotes osteoclastogenesis and inhibits OB differentiation. In this study, we examined TNFα expression by B cells in RA patients and healthy controls.

Methods: PBMCs were isolated from peripheral blood of healthy controls (HC) or RA patients (n=6 each) by Ficoll-Hypaque density gradient centrifugation. RA patients fulfilled 1987 American College of Rheumatology diagnostic criteria and were CCP+. B cells were isolated by CD19+ magnetic bead selection from peripheral blood and stimulated with α-Igs (α-IgA, α-IgG, and α-IgM) and CpG2006 for 4 or 24 hours. TNFα production was measured by qPCR, flow cytometry, and ELISA. Statistical significance was determined by Mann-Whitney test. B cell populations were categorized based on the differential expression of CD27 and IgD, as naïve (CD19+CD27-IgD+), double negative (CD19+CD27-IgD-), unswitched (CD19+CD27+IgD+) and switched memory B cells (CD19+CD27+IgD-). RA synovial biopsies were immuno-stained with antibodies against CD20, CD27 and TNF.

Results: Short-term stimulation of healthy control (HC) B cells with α-Igs and CpG2006 (4 hours) induced significant production of TNFα compared to unstimulated B cells at both the mRNA (64.4±8.2 fold, $P<0.001$) and secreted protein level (ng/uL TNFα: 2.86±0.60 vs. 0.0124±0.0047, $P<0.02$) at 4 hours. At 24 hours, the secreted protein level did not further increase (ng/uL TNFα: 3.032±.40 for stimulated vs. 0.0078±0.0023 for unstimulated, $P<0.005$), and the mRNA levels were actually lower (9.1 fold over unstimulated control), suggesting the mRNA concentration peaks closer to the 4 hour time point. There was no statistically significant difference in TNFα production by HC vs. RA B cells at the mRNA (64.4±8.2 fold in HC vs 52.4±14.5 fold in RA, n=6) or protein level at 4 hours (ng/uL TNFα: 2.86±0.60 in HC vs 2.23±0.84 in RA, n=5) or 24 hours (ng/uL TNFα: 3.032±0.40 in HC vs 2.66±0.69 in RA, n=6). The synovium was enriched for memory B cells (CD27+IgD- memory 55.15±10.41 vs naïve 8.47±2.64, n=7, $P<0.001$) expressing TNFα on immuno-staining. In agreement with memory B cells being the prime producers of TNFα, preliminary data indicates that peripheral blood memory B cells have an increased propensity to produce TNFα under stimulation compared to the double negative or naïve B cell subsets (%TNFα+: 17.1 vs 8.4 and 1.2, respectively).

Conclusion: Our results suggest that TNF- producing memory B cells are enriched in the RA synovial microenvironment, potentially stimulating OC production/activity and thus enhancing bone erosion.

Session Title: B cell Biology and Targets in Rheumatolid Arthritis and other Autoimmune Disease Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Bruton's tyrosine kinase (BTK) is an important component of B cell and Fc receptor signaling and has been shown to be critical for B-cell proliferation and differentiation. Expression of BTK in cell types that are dysregulated or which play a pathological role in arthritis suggests that inhibition of BTK may be therapeutically advantageous in the treatment of rheumatoid arthritis. For use in chronic disease settings such as arthritis highly specific inhibitors are desired. However, the ATP binding site of kinases is highly conserved and it is often difficult to design competitive inhibitors exhibiting a high degree of selectivity. One approach taken by our group and others to develop highly specific BTK inhibitors is to target a cysteine residue immediately outside the ATP binding pocket. Unfortunately, the position of this cysteine is conserved in 11 kinases within the human kinome including, for example, EGFR.

Consequently many BTK inhibitors also inhibit those cysteine-containing kinases.

Methods: A novel and selective BTK inhibitor was identified using in vitro kinase assays. The compound was further characterized using in vitro ADME assays and cellular assays. In vivo efficacy was monitored using the collagen-induced arthritis model in B10 mice.

Results: We report here the characterization of AEG42766, a highly potent and selective BTK inhibitor with an apparent IC50 of 8nM against purified BTK and no significant activity against EGFR. AEG42766 inhibits IgM-mediated proliferation of murine splenocytes and purified human B cells with EC50s of 0.8nM and 0.4nM, respectively. AEG42766 shows good stability in human liver microsomes. In vivo PO administration in mice indicates oral bioavailability of >25% and results in robust, long duration inhibition of BTK. Consistent with profound inhibition of BTK, in vivo pharmacology studies demonstrate that AEG42766 is active in models of reverse passive anaphylaxis and collagen-induced arthritis.

Conclusion: AEG42766 is a highly potent BTK inhibitor suitable for further development as a candidate to treat rheumatoid arthritis and other diseases.

Interleukin-1 Reciprocally Regulates Interferon-Gamma Induced B Cell Activating Factor of the Tumor Necrosis Factor Family (BAFF) and Interleukin-6 in Human Synovial Fibroblasts

Georg Pongratz[1], Rainer Straub[2] and Torsten Lowin[3], [1]Rheumatology - Hiller Research Center Rheumatology, University Hospital Düsseldorf, Düsseldorf, Germany, [2]Laboratory of Experimental Rheumatology and Neuroendocrine Immunology, Department of Internal Medicine, University Hospital Regensburg, Regensburg, Germany, [3]Internal Medicine I, University Hospital Regensburg, Regensburg, Germany

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: B cell Biology and Targets in Rheumatolid Arthritis and other Autoimmune Disease Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: B cell activating factor of the tumor necrosis factor family (BAFF) and interleukin-6 (IL-6) are cytokines important for the stimulation and survival of autoreactive B cells and plasma cells, respectively, and play a role in several autoimmune diseases, e.g. autoimmune arthritis. It is known that synovial fibroblasts (SFs) are capable of producing BAFF and IL-6 and therefore provide survival signals to autoreactive B cells and plasma cells in the joint. Therefore, we wanted to better characterize inflammatory stimuli that modulate BAFF and IL-6 in SFs.

Methods: Fibroblasts isolated from synovial tissue of RA (n=10) and OA (n=10) patients were cultured in the presence or absence of different stimuli (interferon (IFN)g and interleukin (IL)-1). BAFF was determined by ELISA. Levels of phosphorylated and total STAT1 and STAT3 were determined by western blotting.

Results: IFN in a concentration-dependent manner induced BAFF and IL-6 in RA and OA fibroblasts. Since inflammation usually leads to hypoxic conditions, we also compared IFN-g-induced cytokine production in RA and OA SFs under normoxic and hypoxic (oxygen content 2%) culture conditions. IFN-induced BAFF was augmented in OA ($p<0.001$) and RA ($p<0.01$) SFs under hypoxic conditions, whereas there was no oxygen dependency of IFN-induced IL-6. IFN leads to a strong phosphorylation of STAT1 but to a reduction in phosphorylated STAT3 in RA and OA SFs. However, it has been suggested that concomitant phosphorylation of STAT3 further augments BAFF production. Therefore, we wanted to test if concomitant IL-1, which leads to phosphorylation of STAT3, further increases IFN-induced BAFF and/or IL-6 in SFs. However, in the presence of IL-1, INF-induced BAFF was inhibited ($p>0.001$), whereas IFN-induced

IL-6 was increased ($p<0.001$) in a concentration dependent manner independent of oxygen content in both, OA and RA fibroblasts. Furthermore, inhibition of pSTAT3 resulted in further augmentation of IFN-induced BAFF ($p=0.003$) and decrease of IFN-induced IL-6 ($p=0.04$).

Conclusion: Taken together, BAFF and IL-6 production in synovial fibroblasts are induced by IFN and reciprocally regulated by IL-1 in a STAT3 dependent manner. In contrast to IL-6, IFN-induced BAFF can be further augmented by hypoxia. These results give further insight in local regulation of the microenvironment provided for B cells in the arthritic joint.

Session Title: B cell Biology and Targets in Rheumatolid Arthritis and other Autoimmune Disease Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

The high prevalence of citrullinated protein antibodies and improvement following rituximab anti-CD20 therapy both suggest that B cells are important in the pathogenesis of RA. Nonetheless, this has been difficult to study due of the rarity of citrullinated protein-specific B cells and the lack of tools to physically isolate them. We recently developed citrullinated alpha-enolase peptide tetramer technology to identify and capture autoreactive blood B cells in RA, and now report the first whole transcriptome analysis of these autoreactive B cells.

Methods:

A female CCP+/RF+ RA patient previously shown to produce IgG against the citrullinated alpha-enolase peptide CEP-1 (CKIHA-X-EIFDS-X-GNPTVEC, where X represents citrulline) donated 60 ml of blood for further investigation (U. of Minnesota IRB Code Number: 9712M00072). CEP-1 peptide-specific B cells were then captured from PBMC using anti-phycoerythrin Miltenyi beads and a combination of CEP-1 [peptide-streptavidin-phycoerythrin] and native alpha-enolase EP-1 (CKIHAREIFDSRGNPTVEC) [peptide-streptavidin-phycoerythrin-AF647] decoy tetramers, as previously described in Taylor JJ et al., J Exp Med. 2012 Oct 22;209(11):2065-77. Both autoreactive CEP-1 tetramer- and control EP-1 tetramer-bound B cell fractions were purified by FACSAria flow cytometry, differentially stained, mixed, and loaded into a Fluidigm C1 small-cell chip. The Fluidigm C1 autoprep system was used for single cell capture and RNA from each cell was converted to cDNA. Barcoded cDNA libraries were sequenced on an Illumina Hi-Seq sequencer. Differential gene expression between autoreactive CEP-1 peptide-specific B cells and decoy tetramer-bound control B cells was analyzed using Omics office software embedded in Tibco Spotfire version 6.5.2. False discovery rate (FDR) was controlled at 0.05 using the Benjamini-Hochberg procedure, and gene lists were analyzed using Ingenuity Pathway Analysis (IPA) software to detect significantly over-represented canonical pathways.

Results:

We found 119 genes which were differentially expressed between the captured autoreactive CEP-1 peptide-specific B cells and decoy EP-1 peptide tetramer-specific sorted B cells which withstood FDR correction ($q<0.05$). Of these, only one transcript was down-regulated in autoreactive cells (IFI44L), whereas all the other 118 transcripts were up-regulated. Transcripts that were up-regulated in the autoreactive cells included genes involved in B cell receptor and calcium signaling (CALM2), B cell activation, differentiation and transmembrane signaling (CD53), and cell cycle progression (CDKN2D). Using Ingenuity Pathways Analysis, 38 of 115 mapped genes were found to be

involved with cellular proliferation (p = 0.004). Other over-represented canonical pathways included protein ubiquitination and integrin signaling.

Conclusion:

In an RA patient demonstrating serological reactivity to citrullinated alpha-enolase, a CEP-1 peptide tetramer allowed for the capture of autoreactive B cells that demonstrated an activated and proliferative gene expression signature. These results illustrate that novel analytic approaches can now be applied to isolated autoreactive RA B cells.

Session Title: B cell Biology and Targets in Rheumatolid Arthritis and other Autoimmune Disease Poster
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is characterized by the presence of anti-citrullinated protein antibodies (ACPA) in the majority of patients. ACPA represent highly disease-specific biomarkers that predict disease onset in patients with arthralgia. Experimental data suggest that ACPA could be involved in disease pathogenesis. Of interest, however, depletion of $CD20^{+}$B cells is effective in reducing disease activity, while ACPA serum titres remain rather stable. Also, interference with plasma cell development seems clinically ineffective. Therefore, we hypothesized that ACPA could be surrogate markers for a (potentially pathogenic) auto-reactive B cell response and set out to identify citrullinated antigen-specific B cells in peripheral blood and synovial fluid of patients with RA.

Methods: We generated differentially labelled streptavidin and extravidin tetramers conjugated to biotinylated CCP2 or control antigens to identify citrullinated antigen-specific B cells in peripheral blood and synovial fluid by flow cytometry. Blocking and fluorescence activated cell sorting experiments followed by in-vitro stimulation and culture were used to confirm specificity of the staining approach. Cells were further phenotypically characterized by flow cytometry.

Results: The combination of differentially labelled CCP2 and control tetramers allowed the successful separation of ACPA-expressing B cells from non-specific background signals. Tetramer-positive B cells, but not tetramer-negative cells, produced large amounts of ACPA upon stimulation. Interestingly, phenotypic analysis revealed that citrullinated antigen-specific B cells are mainly class-switched, post-germinal centre memory B cells and plasma blasts/cells expressing IgG or IgA. Only few cells exhibited a naïve phenotype. We observed a remarkably high frequency of memory B cells (up to 1 in 500) in peripheral blood, which correlated with ACPA serum titres and spontaneous ACPA production in culture.

Conclusion: We developed a novel technology that identifies ACPA-expressing B cells in peripheral blood and synovial fluid of patients with RA, providing the basis for a detailed characterisation of this immune response on a single cell level. First analyses show the presence of a high frequency of memory B cells, which is remarkable considering the continuous presence of citrullinated antigens. These data pave the path for a detailed understanding of the development and maintenance of citrullinated antigen-reactive B cells and could lead to the identification of targets for novel therapeutic interventions.

Matrix Metalloproteinase-10 (Stromelysin 2) Is a Target of Robust Autoimmune T and B Cell Responses in Antibiotic-Refractory Lyme Arthritis, but Not in Rheumatoid Arthritis

Session Title: B cell Biology and Targets in Rheumatolid Arthritis and other Autoimmune Disease Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Infection-induced autoimmunity has been hypothesized to have a pathogenic role in antibiotic-refractory Lyme arthritis (LA). We previously identified 3 autoantigens, endothelial cell growth factor, annexin A2, and apolipoprotein B-100, that are targets of T and B cell responses in Lyme disease patients. However, only about half of patients with antibiotic-refractory LA have one or more of these autoimmune responses. In the current study, we again used discovery-based proteomics and translational research to identify another novel autoantigen, matrix metalloproteinase-10 (MMP-10), in antibiotic-refractory LA.

Methods:

HLA-DR-presented peptides were isolated and identified from the synovial tissue of a patient with antibiotic-refractory LA. Immunogenicity of the peptides was measured using the case patient's PBMC in an IFN-γ ELISpot assay. Reactive peptides and their source proteins were then tested for T and B cell reactivity in large numbers of patients with early or late manifestations of Lyme disease, rheumatoid arthritis (RA), or healthy controls (HC). To gain insights into autoantibody-associated pathology, rankings of histologic findings in synovia were correlated with the magnitude of autoantibody responses.

Results:

Of the 124 HLA-DR-presented self-peptides identified from the synovial tissue of a patient with antibiotic-refractory LA, one peptide derived from MMP-10 caused his PBMC to secrete IFN-γ. When tested in additional patients, only 1 patient each with erythema migrans (EM), an early disease manifestation, or with antibiotic-responsive LA had low-level T cell reactivity with MMP-10 peptides, though 26% of patients with EM and 14% of those with antibiotic-responsive LA had autoantibody responses to full-length MMP-10. In contrast, 5 of 20 patients (25%) with antibiotic-refractory LA had robust T cell responses to MMP-10 peptides, and 25 of 114 patients (22%) with refractory arthritis had autoantibody responses to MMP-10. No HC and only 6% of RA patients had minimal autoantibody responses to this protein. Furthermore, only a few patients with LA had antibody reactivity to MMP-3 (stromelysin 1), a protein with 78% amino acid sequence homology to MMP-10, further demonstrating the specificity of reactivity with MMP-10. In refractory patients, the magnitude of the MMP-10 antibody response positively correlated with synovial lining layer thickness and fibroblast proliferation, and with greater staining for CXCL13 and larger numbers of plasma cells, suggestive of local antibody production.

Conclusion:

Identification of a single HLA-DR-presented peptide (T cell epitope) provided a bridge to the discovery of a broadly immunogenic autoantigen, MMP-10, in Lyme disease. B cell reactivity with this protein may develop early in the illness. Later in the infection, patients

with antibiotic-refractory LA may have both T and B cell responses to MMP-10, and in these patients, the autoantibody response appears to become pathogenic. The specificity of this response (not found in RA) suggests that initial interaction between the spirochete and host at disease onset is critical in immunogenicity, and not simply abundance of MMP proteins.

Session Title: B cell Biology and Targets in Rheumatolid Arthritis and other Autoimmune Disease Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

To investigate a B-cell subpopulation, exhibiting CD19+CD24-CD38hi phenotype, can be a biomarker for diagnosis and disease activity in IgG4 related disease (IgG4-RD).

Methods:

Circulating B-cell subsets from 42 untreated IgG4-RD patients, including CD19+CD24-CD38hi, CD19+CD24+CD38-, CD19+CD24intCD38int and CD19+CD24hiCD38hi B cells, were sorted by flow cytometry and their gene expression was measured by microarray. Characterizing of CD19+CD24-CD38hi B cell subset was confirmed by testing surface markers such as CD27, CD95 and HLA-DR, et al. In addition, supernatant IgG4 concentrations were measured by Cytometric Bead Array (CBA).

Results:

In untreated IgG4-RD patients, expanded CD19+CD24-CD38hi B-cell subset exhibited a significant different gene expression pattern compared with the other three B cell subsets, which showed much higher expression of Blimp-1 and IRF4, and the lower expression of PAX5 and BCL-6. In addition, CD27, CD95 and HLA-DR were highly expressed on CD19+CD24-CD38hi B-cell subset from IgG4-RD peripheral B cells. Furthermore, CD19+CD24-CD38hi B-cell subset expressed more surface IgG4 and secreted more IgG4. Finally, the level of CD19+CD24-CD38hi B-cells was decreased after therapy, which correlates with disease remission.

Conclusion:

Circulating CD19+CD24-CD38hi B-cell subset is elevated in active IgG4-RD, which shows the morphological as well as the phenotypical characteristics of plasmablasts (PB) and decreases during IgG4-RD remission. This B-cell subset might be a potentially useful biomarker for diagnosis and assessing response to treatment.

Session Title: B cell Biology and Targets in Rheumatolid Arthritis and other Autoimmune Disease Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

B cells can have a negative regulatory role, mainly mediated by interleukin 10 (IL-10) and we recently showed that IL-10 producing B cells (B10 cells) are deficient in patients with rheumatoid arthritis (RA). However, B10 cells still remain to be better characterized and finding new markers of B10 cells is an important challenge. Annexin V (AnV) is a protein binding to phosphatidylserine (PS), a phospholipid usually located on the inner leaflet of the plasma membrane that could be externalized during some process such as apoptosis. Previous works have suggested that AnV staining, a known marker for apoptosis, could also be expressed on viable and stimulated B cells. We therefore aimed to explore the relationship between PS exposure (assessed by AnV staining) and B10 cells.

Methods:

We used PBMCs from 6 healthy controls and 7 RA patients. AnV staining was compared between human B10 cells and IL-10 non-producing B cells. Levels of CpG induced B10 cells from flow cytometry sorted AnV^{pos} and AnV^{neg} B cells were compared. Apoptosis was studied in AnV^{pos} and AnV^{neg} B cells, using different methods: DAPI staining, cellular cycle study with propidium iodide (PI) and DiOC6 staining. PS was then blocked using biotynilated AnV and glyburide to evaluate the impact on B cell IL-10 production.

Results: B10 cells externalized more PS than IL-10 non-producing B cells with respectively 27.75 [17.03-44.38]% and 12.35 [9.49-14.20]% of AnV^{pos} B cells (p= 0.03; n= 6 healthy controls). In RA patients, the proportion of AnV^{pos} B cells was also significantly higher among B10 cells than among IL-10 non-producing B cells (p= 0.03; n= 6). After CpG stimulation, the differentiation into B10 cells was more important for AnV^{pos} B cells than for AnV^{neg} B cells (5.50 [2.21-8.80]% vs 2.50 [0.75-6.09]% respectively, p= 0.03; n= 6 healthy controls). This exposure of PS does not seem to be related to apoptosis since proportions of dead cells (DAPI+) were similar between AnV^{pos} and AnV^{neg} B cells (p= 0.3; n= 6 healthy controls). Moreover, the proportions of B cells in an early apoptotic stage (DiOC6-) were similar between AnV^{pos} and AnV^{neg} B cells (p= 0.4; n=4 healthy controls). Lastly, cellular cycle study showed that, compared to AnV^{neg} B cells, AnV^{pos} B cells have a higher proliferation index (p= 0.03; n= 6 healthy controls). PS blockade decreased the levels of B10 cells with 6.59 [3.71-8.12]% of B10 cells for culture medium alone; 2.99 [1.15-5.61]% with biotynilated AnV and 3.20 [1.26-4.80]% with glyburide (p= 0.03 and p= 0.06 for biotynilated AnV vs media and glyburide vs media respectively, n= 6 healthy controls).

Conclusion: This study showed that a positive AnV staining is observed on viable B cells suggesting that AnV is not only a marker for apoptosis. In healthy controls and RA patients, B10 cells have an increased AnV staining. These AnV^{pos} B cells differentiate more into B10 cells and phosphatidylserine (PS) blockade inhibits B10 cells generation. These results strongly suggest a link between PS exposure and B10 cells. This could be useful to generate B10 cells in future therapeutic issues, for example for RA patients.

Session Date: Monday, November 9, 2015
Session Title: B cell Biology and Targets in Rheumatolid Arthritis and other Autoimmune Disease Poster
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: B cells contribute to disease pathophysiology through several mechanisms, including cytokine and chemokine secretion. A wide variety of stimuli can activate B cells including B cell receptor (BCR) and Toll-like receptor (TLR) engagement. Recently, numerous observations have demonstrated the requirement of various metabolic pathways in establishing the diverse array of immune cell functions. Here, we examine the metabolic requirements of *in vitro*B cell cytokine and chemokine secretion.

Methods: B cells were isolated from the spleens of 129 mice using negative selection and magnetic bead separation. B cells were activated overnight individually by the following agents: anti-μ antibody (B cell receptor), anti-CD40 agonist antibody, poly(I:C) (TLR3), LPS (TLR4), and CpG (TLR9). Supernatants were collected and analyzed for the quantification of cytokines using the Bioplex Pro Mouse Cytokine 23-plex assay.Real-time analysis of extracellular acidification rates (ECAR) and oxygen consumption rates (OCR) of activated B cells were performed using the XF-96 Extracellular Flux Analyzer (Seahorse Bioscience).

Results: High-dose LPS and CpG activation of B cells generated the highest levels and widest breadth of cytokines and chemokines (Table 1). In addition, these stimuli generated high OCR and ECAR values, reflecting the need for oxidative phosphorylation and glycolysis respectively. Both LPS and CpG required free fatty acids and glucose as a carbon sources, as addition of etomoxir (inhibitor of fatty acid oxidation) and UK-5099 (inhibitor of pyruvate transfer into the mitochondria) abrogated both cytokine and chemokine secretion and oxidative phosphorylation. The other stimulatory agents tested minimally generated cytokine or chemokine release and did not induce oxidative phosphorylation in B cells.

Conclusion: We catalogued the breadth of cytokines and chemokine secreted by B cells via various stimulatory agents. High-dose LPS and CpG required free fatty acids and glucose for the elaboration of LPS or CpG-induced cytokine production. These data suggest that B cell cytokine and chemokine secretion can be manipulated by altering the local metabolic environment, and may represent an interesting therapeutic approach for modulating B cells in autoimmune diseases.

Session Title: B cell Biology and Targets in Rheumatolid Arthritis and other Autoimmune Disease Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose : IgG4-associated cholangitis (IAC) and autoimmune pancreatitis (AIP) are major manifestations of IgG4-related disease (IRD). Misdiagnosis and inadequate treatment are common since IAC and AIP mimic other inflammatory and malignant pancreatobiliary diseases and accurate diagnostic biomarkers are lacking. Moreover, relapse after tapering of immunosuppressive therapy is seen in 50% of patients, underscoring the need for biomarkers monitoring disease activity. Recently, using Next-Generation Sequencing, we found that dominant IgG4+ B-cell receptor clones in peripheral blood distinguish patients with active IAC/AIP from primary sclerosing cholangitis (PSC) and pancreatobiliary malignancies (CA) [Hepatology 2013;57:2340]. Therefore, we aimed to develop a quantitative PCR (qPCR) protocol for diagnosing IAC/AIP and monitoring disease activity before and after treatment.

Methods : 15 patients with IAC and/or AIP according to HISORt criteria, 7 patients with PSC and 8 with CA formed the test cohort. Intra- and extramural replication cohorts consisted of 16 IAC/AIP, 5 PSC and 13 CA patients (Dutch cohort), and 8 IAC/AIP and 8 PSC patients (British cohort). From 20 Dutch IAC/AIP patients, follow-up samples after 4 and 8 weeks of corticosteroid therapy were available. RNA was isolated, and a forward primer amplifying all IgG subtypes, together with a generic reverse primer for all IgG subtypes and a specific reverse primer for IgG4 were used to amplify the constant region of the B-cell receptor. The ratio total IgG/IgG4 mRNA was calculated and expressed as ΔC_T.

Results : ΔC_T as measure of IgG/IgG4 mRNA expression in peripheral blood of the test cohort was 2.8±1.1 (mean+SD) in IAC/AIP patients, compared to 6.8±1.6 in PSC and 7.6±1.4 in CA (Figure 1A, $p<0.0001$). ROC analysis revealed a ΔC_T cut-off value of 5.1 in the test cohort distinguishing all cases from controls. In the replication cohort sensitivity was 95% and specificity 100% ($p=8.6*10^{-21}$). ΔC_T increased after 4 weeks (5.1±0.8) and 8 weeks (7,1±0.7) of corticosteroid treatment, compared to pre-treatment (mean 3.1±1.4, $p<0.0001$, Figure 1B).

Conclusion : IgG4-related disease of the biliary tree and pancreas can accurately be distinguished from PSC or pancreatobiliary malignancies by ΔC_T based on an affordable qPCR test. ΔC_T can also be used as a marker for treatment response and disease activity in IgG4-related disease.

Session Title: B cell Biology and Targets in Rheumatolid Arthritis and other Autoimmune Disease Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Bruton's Tyrosine Kinase (BTK) is a non-receptor tyrosine kinase required for intracellular signaling pathways downstream of several key immunoreceptors, including the B cell receptor, Fc receptors, and the GPVI collagen receptor. Due to its involvement in multiple mechanisms of inflammatory disease pathogenesis, targeting BTK may be a useful strategy for indications like rheumatoid arthritis and lupus. ABBV-105 is a covalent, irreversible inhibitor that alkylates Cys481 specifically, resulting in durable BTK inhibition *in vitro* and *in vivo*. Only 10 other kinases have a cysteine at this position and ABBV-105 has greater than 30-fold selectivity versus these kinases.

Methods: To evaluate the effects and specificity of BTK inhibition *in vitro* we evaluated ABBV-105 in BTK dependent cell assays including FCεR-mediated basophil degranulation, FCγR-mediated monocyte activation, and TLR9 agonist-mediated activation of PBMC. As a consequence of the covalent nature of the binding, target engagement can be assessed both *in vitro* and *in vivo* by measuring the amount of unbound BTK associated with a biotinylated probe derived from a related covalent Btk inhibitor. BTK occupancy can be calculated by comparing the free BTK levels in a sample with or without ABBV-105 treatment. To understand the effects of BTK inhibition on inflammatory processes *in vivo*, we evaluated ABBV-105 in a rat collagen-induced arthritis (CIA) model and in an IFNα-accelerated lupus nephritis model in NZB/W mice.

Results: ABBV-105 potently and selectively inhibits the BTK enzyme and multiple BTK dependent cell-based assays including FCεR-mediated basophil degranulation, FCγR-mediated monocyte activation, and TLR9 agonist-mediated activation of PBMCs. Following oral administration of ABBV-105 *in vivo*, there is a rapid clearance of ABBV-105 in plasma while BTK occupancy of ABBV-105 in both

spleen and peripheral blood leukocytes remains. In rat CIA, ABBV-105 fully inhibits paw swelling and bone destruction comparable to prednisolone. ABBV-105 also significantly reduces proteinuria, prolongs survival, and reduces anti-dsDNA autoantibody titers in an IFNα-accelerated lupus nephritis model. Efficacy in both models correlates with BTK splenic occupancy in a dose- and exposure-dependent manner.

Conclusion: Taken together, our data confirm that selective and covalent inhibition of BTK is effective in ameliorating disease pathogenesis in preclinical models of rheumatoid arthritis and lupus and may provide a therapeutic benefit to patients.

Session Title: B cell Biology and Targets in Rheumatolid Arthritis and other Autoimmune Disease Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Systemic lupus erythematosus (SLE) is characterized by B cell hyperactivity and production of autoantibodies. Treatment of patients with moderate-to-severe SLE with epratuzumab, a humanized monoclonal antibody that targets CD22, has resulted in clinically relevant, sustained improvements in disease activity. While epratuzumab is thought to modulate B cell function, its mechanism of action has not been completely elucidated. This study was undertaken to determine how epratuzumab affects the activation of different B cell subsets in response to Toll-like receptor (TLR) and/or B cell receptor (BCR) stimulation.

Methods:

$CD20^+$ B cell subsets were isolated from human tonsils using magnetic bead cell separation and cell sorting based on their relative expression of CD10, CD27, IgD, CD38 and other surface markers. Cells were treated with anti-IgM and/or R848 (a TLR7 agonist) in the presence of epratuzumab or a human IgG control. Changes in mRNA levels of *PRDM1*, the gene encoding B lymphocyte-induced maturation protein 1 (Blimp-1), and a variety of other genes associated with B cell activation were analyzed by RT-PCR 12–24 hours after stimulation. Cell survival and plasma cell differentiation were assessed by flow cytometry after 3–5 days of *in vitro* cell culture.

Results:

Treatment of $CD20^+CD27^-CD10^-$ B cells with R848, anti-IgM, or a combination of R848 plus anti-IgM led to a significant (2–10-fold) increase in *PRDM1* expression 12 hours after stimulation. Epratuzumab dramatically inhibited *PRDM1* mRNA levels, but had no effect on the expression of a number of other genes, including *AICDA*, *PAX5*, *BCL6, XBP1*, and *ETS1*. In cell culture experiments R848, anti-IgM, or a combination of R848 plus anti-IgM stimulation did not have a significant effect on $CD20^+CD27^+CD10^-IgD^-$ (switched memory cells), or $CD20^+CD27^-CD10^-IgD^+$ (naïve B cells), but significantly induced the activation of $CD20^+CD27^-CD10^-IgD^-$ cells, as evidenced by increased cell proliferation and by the appearance of blasting $CD27^{hi}CD38^{hi}$ (pre-plasma) cells. Epratuzumab significantly inhibited CD38 expression and the generation of pre-plasma cells without significantly affecting cell survival.

Conclusion:

These results suggest that one therapeutic effect of epratuzumab may be via inhibiting the expression of *PRDM1* (Blimp-1). Since Blimp-1 is required by B cells to mature into antibody-producing cells, epratuzumab-mediated inhibition of Blimp-1 may reduce autoantibody production in SLE patients. Epratuzumab inhibits the activation of $CD20^{+}CD27^{-}CD10^{-}IgD^{-}$ tonsillar B cells, which appear highly responsive to stimulation via TLR7. This population of cells might correspond to $CD27^{-}$ memory B cells, found to be substantially increased in SLE patients. These data may have implications for understanding the effects of epratuzumab treatment on B cell function in SLE patients.

Session Title: B cell Biology and Targets in Rheumatolid Arthritis and other Autoimmune Disease Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Epratuzumab, a humanized monoclonal antibody targeting CD22, is currently in phase 3 clinical trials in patients with systemic lupus erythematosus (SLE). Previous work suggests epratuzumab down-modulates B cell receptor (BCR) function.[1,2] Inhibitory co-receptors of the BCR complex, such as CD22 and the inhibitory Fc receptor CD32B, prevent overstimulation of B cells by signaling through tyrosine (Tyr) based inhibitory motifs (ITIMs). Phosphorylation of Tyr residues on CD22 results in the recruitment of adaptor and inhibitory signaling molecules eg. Tyr^{822} binds SHP-1 and Tyr^{807} binds Grb2. In contrast CD32B contains a single ITIM motif (Tyr^{292}) that down-regulates activating signals. In this study the effects of epratuzumab on the phosphorylation of inhibitory motifs within CD22 and CD32B were assessed.

Methods:

Fluorescence-activated cell sorting (FACS) was conducted on peripheral blood mononuclear cells from healthy donors. After addition of epratuzumab (10 µg/ml; n=6) or anti-BCR (12 µg/ml; n=8) for various durations, cells were fixed, permeabilized and analyzed using a phospho-Tyr^{822} antibody and B cell markers CD19/CD20/CD27. Confocal microscopy assessed co-localization of CD22 with SHP-1 (n=3) using specific fluorescently-labelled antibodies. For immunoprecipitation (IP) experiments, B cells from human tonsils or Daudi B cells were treated ± epratuzumab or anti-BCR (both at 10 mg/mL), lysed and IP'd with epratuzumab or CD32B antibodies. Captured proteins were identified by Western blotting. Phosphorylated Tyr residues were detected using phospho-specific antibodies against p-Tyr^{807} and p-Tyr^{822} on CD22, and p-Tyr^{292} on CD32B. Signals were detected using HRP-linked secondary antibodies.

Results:

FACS experiments showed that anti-BCR induced a rapid (<5 min) increase in CD22 Tyr^{822} phosphorylation in both naïve (CD27-) and memory (CD27+) B cells. Epratuzumab stimulated Tyr^{822} phosphorylation in a similar time frame, albeit to a lesser extent than anti-BCR (52% less phosphorylation). In keeping with this, epratuzumab induced SHP-1 co-localization with CD22. An increase in CD22 Tyr^{822} phosphorylation with epratuzumab was detected in IP experiments in Daudi cells. These experiments showed increased CD22 Tyr^{807} phosphorylation at early (<10 min) time points in tonsil B cells and Daudi cells, although to a lesser extent than anti-BCR. Finally, epratuzumab induced a modest increase in CD32B ITIM Tyr^{292} phosphorylation on B cells peaking at approximately 10 min.

Conclusion:

Epratuzumab directly induced phosphorylation of inhibitory ITIM motifs within key negative regulatory B cell molecules. On CD22, these included Tyr^{822}, with a concomitant increase in SHP-1 co-localization and Tyr^{807}, both of which would inhibit BCR-driven signaling. Finally, epratuzumab induced Tyr^{292} phosphorylation on the inhibitory Fc receptor CD32B, potentially dampening a hyper-reactive B cell response. Overall, the data provide further evidence that epratuzumab down-modulates B cell activation events, of potential relevance to the treatment of SLE patients with epratuzumab.

Co-Crystal Structure of TACI and APRIL-BAFF-BAFF Heteromer Suggests That Charged Residues in APRIL and BAFF Dictate Their Receptor Binding Affinities

Session Title: B cell Biology and Targets in Rheumatolid Arthritis and other Autoimmune Disease Poster
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: The human B cell survival factor, B cell activation factor (BAFF), and its closely related homologue, a proliferation-inducing ligand (APRIL), modulate B cell functions by binding to three receptors, BAFFR, TACI and BCMA. APRIL binds more strongly to BCMA than to TACI while the opposite is true for BAFF. In addition, BAFF, but not APRIL, binds to BAFFR with high affinity. Both BAFF and APRIL are known to form homotrimers and heterotrimers, which display different affinities for their cognate receptors.

Methods: We used X-ray crystallography to determine the structural elements of the APRIL, BAFF and TACI binding sites.

Results: To understand the structural basis underlying the different binding affinities, we solved the crystal structure of the APRIL-BAFF-BAFF heterotrimer, either alone or bound to TACI.

Conclusion: Analysis of these structures and comparative analysis of previously solved structures of BAFF and APRIL in complex with BAFFR, TACI or BCMA revealed that the charged residues of BAFF and APRIL are crucial determinants of receptor binding affinities, conferring homotrimers and heterotrimers with a variety of signaling strength to modulate responses of immune cells.

Session Title: B cell Biology and Targets in Rheumatolid Arthritis and other Autoimmune Disease Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: B cells may have a negative regulatory role, mainly mediated by interleukin 10 (IL-10). We recently showed that regulatory B-cell functions are impaired in patients with rheumatoid arthritis (RA) and that mice transgenic for a proliferation-inducing ligand (APRIL) are protected against collagen-induced arthritis. We aimed to explore the effect of APRIL on human B-cell production of IL-10.

Methods: CpG induced IL-10 B-cell production was compared in presence or absence of APRIL and B lymphocyte stimulating factor (BLys). The expression of the BLyS and APRIL receptor transmembrane activator and CAML interactor (TACI) and of BLyS specific receptor (BAFF-R) was compared between IL-10 producing and non-producing B cells. The effect of APRIL stimulated B cells on T cell cytokine production was analyzed after 3 days of co-culture. Signaling pathways of B cells activated by CpG and APRIL were analyzed by western blot. Similar experiments were performed on cells of RA patients.

Results: IL-10 production by B cells was greater with APRIL than BLyS treatment or control medium (9.5 [6.8-13.2]% vs 6.2 [3.9-7.0]%, p=0.007, and 4.2 [3.3-8.0]%, p=0.002, respectively, n= 11 controls). This increase was abrogated by co-culture with APRIL inhibitors (8.4 [3.7-13.8]% vs 3.5 [1.9-8.8]%, p<0.01, n=8 controls). APRIL did not stimulate IL-10 production of monocytes and T cells. TACI expression was greater in IL-10 producing than non-IL-10–producing B cells (1.9 [1.3-4.4]% vs 0.4 [0-2.3]%; p=0.031, n= 7 controls) whereas BAFF-R expression was lower (2.3 [2.0-2.5] vs 2.7 [2.3-2.8] of mean fluorescence intensity; p=0.021, n= 7 controls). When compared with non-stimulated B cells, APRIL-stimulated B cells decreased the secretion of TNF-α (-36±13%, p=0.02) and IFN-γ (-14±3%; p=0.02) by T cells but not IL-17 (-14±14%; p=0.31, n= 8 controls). APRIL further stimulated CpG-activated STAT3 and STAT3 inhibition specifically decreased IL-10 production by B cells (-28±3%, p<0.05, n= 7 controls). APRIL also promoted IL-10 production by B cells in 11 RA patients (7.0 [4.1-11.8]% vs 6.1 [3.1-9.8]%, p= 0.024 and 3.6 [2.2-7.3]%, p= 0.009 for APRIL, BLyS and control medium respectively). Similar pattern of APRIL and BLyS receptors on IL-10 producing B cells were observed between the controls and 7 RA patients.

Conclusion: APRIL but not BLyS promotes IL-10 production by B cells and enhances the regulatory role of B cells on T cells by decreasing T-cell secretion of TNF-α and. IFN-γ. IL-10 producing B cells in RA patients are responsive to APRIL, which suggests a possible therapeutic application of APRIL for expanding IL-10 producing B cells in these patients. This could also explain the difference of clinical efficacy observed between belimumab and atacicept in RA.

Relapse of Lupus after B-Cell Depletion Therapy Is Associated with Loss of Apoptotic Cell Clearance and Elevated Type I Interferon Responses in Lupus Prone BXD2

Session Title: B cell Biology and Targets in Rheumatolid Arthritis and other Autoimmune Disease Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: B-cell depletion therapy (BCDT) is a promising therapy for autoimmune diseases but relapse can occur. In rheumatoid arthritis, patients who did not respond well to rituximab exhibited higher levels of type I interferon (IFN) signature gene expression in PBMCs but the underlying mechanisms remain unknown. Spleen marginal zone macrophages (MZMs) are essential for tolerogenic clearance of apoptotic cells (ACs). Maintenance of MZMs requires MZ B cells. The purpose of this study is to determine if anti-CD20 depletion of MZ B cells promotes the loss of MZMs, leading to excessive uncleared ACs and stimulation of autoreactive B cells by type I IFN in autoimmune BXD2 mice.

Methods: BXD2 mice and normal B6 mice were administered anti-CD20 (clone 5D2, IgG2a) or isotype control (250 µg/single dose iv). B-cell depletion and repopulation were determined over 9 weeks of time. The distribution of MZMs in the spleen was examined by confocal microscopy. The expression of type I IFN signature genes, *Usp18* and *Oasl*, in repopulated B cells was determined by quantitative PCR. The development of autoantibody titers and autoAb producing B cells was determined by ELISA and ELISPOT assays.

Results: Administration of anti-CD20 resulted in nearly complete depletion of B cells in the PBMCs but there was less complete depletion of B cells in the spleen. In the spleen, the deepest depletion occurred at week (wk) 2 and this was associated with a dramatic decline in MZMs of both strains but uncleared ACs were observed in only BXD2 but not B6 spleen. By wk 5, the spleen B-cell repopulation rate was 69% in BXD2 but was only 26% in B6 mice and MZM and AC clearance defects were found for both strains. By wk 9, there was >85% repopulation of spleen B cells in both strains. In BXD2 mice, at wk 5, there was a 1.7-fold increase in the number of $PNA^{+}Fas^{+}$ $CD19^{+}$ spleen germinal center (GC) B cells and an increased number of IgG anti-DNA and anti-histone producing B cells in the BCDT group, compared to the control group. This is associated with an increased expression of *Usp18* and *Oasl* in repopulated MZ precursor (MZ-P) B cells in the BCDT group, compared to the control group. At wk 9, serum titers of IgG autoantibodies against DNA, histone, and malondialdehyde, a lipid peroxidation product associated with apoptotic blebs, were markedly increased in the BCDT group, compared to the control group. Interestingly, despite the relatively slower repopulation of B cells and MZMs in anti-CD20 treated B6 mice, there was no elevation in GC B cells and autoantibody titers when B cells were repopulated.

Conclusion: Although BXD2 mice responded to BCDT, anti-CD20 induced repopulation of GC and autoreactive B cells. The relapse was associated with the functional loss of tolerogenic AC clearance. This is consistent with our previous findings that normal MZ B cells are required to maintain normal tolerogenic function of MZMs. The results suggest that measurement of AC by-production and type I IFN responses should be considered as biomarkers for therapeutic efficacy and timing of repeated BCDT (This worked was supported by the NIH (RO1-AI-071110, RO1-AI-083705, P30-AR-048311 and P30-AI-027767) and the VA Merit Review 1I01BX000600-01. Anti-CD20 and isotype control are generous gifts from Genentech Inc.).

Session Date: Monday, November 9, 2015
Session Title: B cell Biology and Targets in Rheumatolid Arthritis and other Autoimmune Disease Poster
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Obinutuzumab (OBZ, a Type II anti-CD20 monoclonal antibody [mAb] with afucosylated Fc portion and enhanced affinity for Fcγ receptor III) is more efficient than Rituximab (RTX, a Type I mAb) at inducing malignant B cell cytotoxicity and is approved by the Food and Drug Administration for use in chronic lymphocytic leukemia. Here we compared their effects against B cells from patients with Rheumatoid Arthritis (RA) and Systemic Lupus Erythematosus (SLE).

Methods:

We used flow cytometry to perform: in vitro whole blood B cell depletion assays to compare the efficiency of OBZ and RTX in depleting target B cells; surface fluorescence-quenching assays to determine the extent of mAb internalization; complement dependent cellular cytotoxicity (CDC) assays to assess the ability to recruit complement and lyse target cells; NK cell degranulation assays to assess surface expression of CD107a as a measure of antibody-dependent cellular cytotoxicity (ADCC); and neutrophil activation assays assessing the surface expression of CD62L and CD11B. OBZ-gly (OBZ with Fc glycosylation similar to RTX) was used to assess the effects of afucosylation. All mAb were used at 1µg/mL except for the CDC assay (10µg/mL).

Results:

Obinutuzumab (OBZ) was > 2 fold more efficient than Rituximab (RTX) at inducing cytotoxicity in B cells from patients with RA (n=31) and SLE (n=34) in whole blood assays (Figure 1A). It was also internalized by isolated B cells from SLE patients (n=6) to a significantly lower extent than RTX with a median surface accessible mAb of 75% and 59%, respectively, after 6 hours of incubation (Figure 1B). OBZ was at least twice as efficient at inducing NK cell activation, Figure 2 in RA (n=13) and SLE (n=19); and also activated neutrophils more efficiently than RTX in SLE (n=15) (Figure 3). In contrast, RTX was significantly more efficient than OBZ at evoking CDC of isolated B cells (SLE, n=6) (Figure 1C).

Conclusion:

Obinutuzumab is more efficient than rituximab at inducing B cell cytotoxicity in vitro in both RA and SLE samples. Enhanced direct cell death, reduced CD20 internalization and superior FcR-mediated effector mechanisms are observed, while complement mediated cytotoxicity is reduced. These data provide a mechanistic basis for considering obinutuzumab as an alternative B cell depleting agent in RA and SLE.

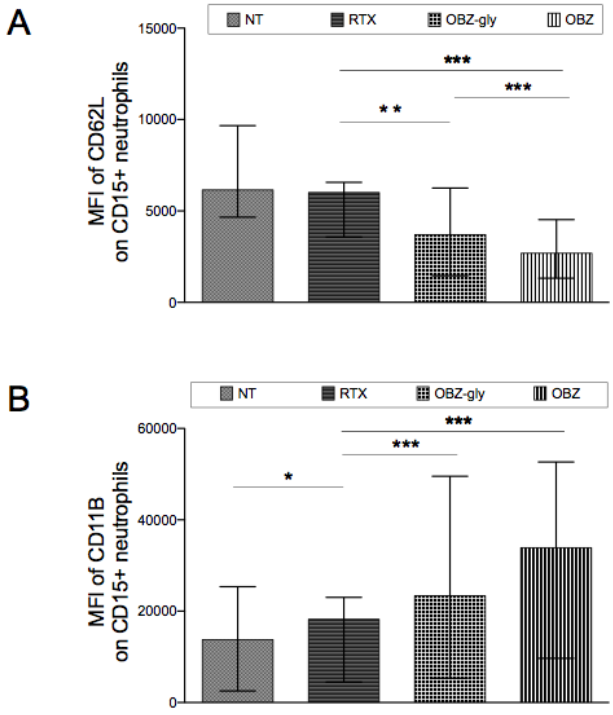

Figure 3. Obinutuzumab is more efficient than Rituximab at Activating Neutrophils in Rheumatoid Arthritis and Systemic Lupus Erythematosus. A) After 24 hour incubation of whole blood samples with mAbs at 1µg/mL, the mean fluorescence intensity (MFI) of CD62L was lower and B) that of CD11B was higher on CD15+ neutrophils, in samples incubated with mAbs when compared with samples incubated without mAbs (NT, not treated) suggesting activation of neutrophils by mAbs. The Median and interquartile ranges are represented by the error bars. There was a hierarchy in changes such that the MFI of CD62L was lowest for OBZ < OBZ-gly < RTX whereas the MFI of CD11B was highest for OBZ > OBZ-gly > RTX. RTX, rituximab, OBZ, Obinutuzumab and OBZ-WT, Obinutuzumab wild-type. * p<0.05; **, p<0.005; ***, p<0.0001.

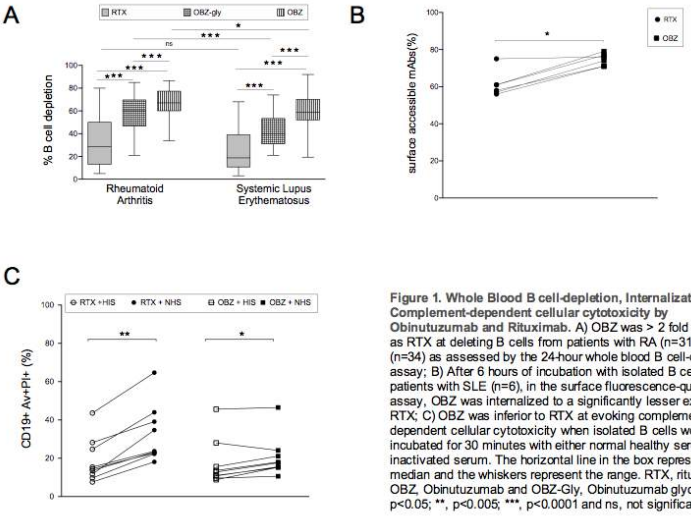

Figure 1. Whole Blood B cell-depletion, Internalization and Complement-dependent cellular cytotoxicity by Obinutuzumab and Rituximab. A) OBZ was > 2 fold as efficient as RTX at deleting B cells from patients with RA (n=31) and SLE (n=34) as assessed by the 24-hour whole blood B cell-depletion assay; B) After 6 hours of incubation with isolated B cells from patients with SLE (n=6), in the surface fluorescence-quenching assay, OBZ was internalized to a significantly lesser extent than RTX; C) OBZ was inferior to RTX at evoking complement-dependent cellular cytotoxicity when isolated B cells were incubated for 30 minutes with either normal healthy serum or heat inactivated serum. The horizontal line in the box represents the median and the whiskers represent the range. RTX, rituximab, OBZ, Obinutuzumab and OBZ-Gly, Obinutuzumab glycosylated. * p<0.05; **, p<0.005; ***, p<0.0001 and ns, not significant.

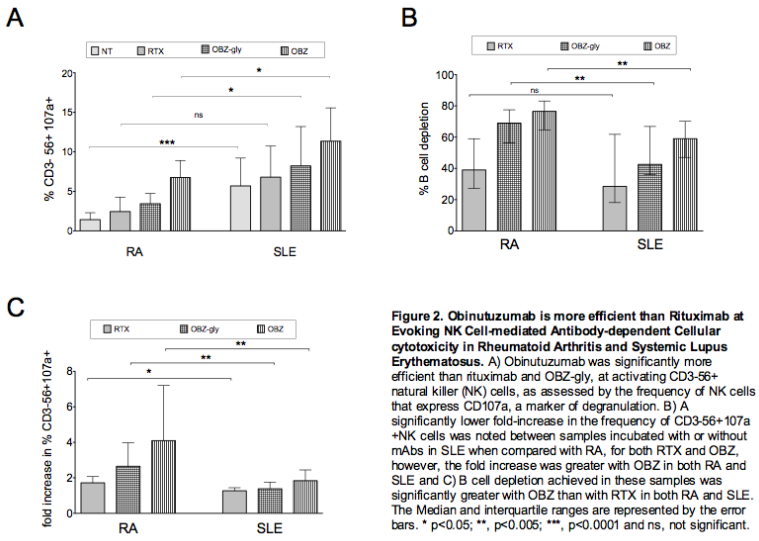

Figure 2. Obinutuzumab is more efficient than Rituximab at Evoking NK Cell-mediated Antibody-dependent Cellular cytotoxicity in Rheumatoid Arthritis and Systemic Lupus Erythematosus. A) Obinutuzumab was significantly more efficient than rituximab and OBZ-gly, at activating CD3-56+ natural killer (NK) cells, as assessed by the frequency of NK cells that express CD107a, a marker of degranulation. B) A significantly lower fold-increase in the frequency of CD3-56+107a +NK cells was noted between samples incubated with or without mAbs in SLE when compared with RA, for both RTX and OBZ, however, the fold increase was greater with OBZ in both RA and SLE and C) B cell depletion achieved in these samples was significantly greater with OBZ than with RTX in both RA and SLE. The Median and interquartile ranges are represented by the error bars. * p<0.05; **, p<0.005; ***, p<0.0001 and ns, not significant.

Session Title: B cell Biology and Targets in Rheumatolid Arthritis and other Autoimmune Disease Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The B cell pool is composed of subsets with different phenotypes and functions that mainly have effector functions to maintain immunologic tolerance. These subsets and their proportions are an individual's "B cell signature" (BCS). Systemic lupus erythematosus (SLE) is a clinically heterogeneous autoimmune disease. BCS SLE studies reveal altered immature and unswitched memory B cell numbers when compared to healthy controls (HC). BCS potentially can be a biomarker for monitoring SLE disease activity. Belimumab is B-cell activating factor inhibitor approved for use in SLE. For this study, we will determine the effect of belimumab on BCS in SLE patients.

Methods: PBMCs and plasma were collected from 5 SLE patients on belimumab, 13 SLE patients conventional non-B cell-standard therapy (ST) and 12 HC. Demographic data, medication history, disease activity and damage measurements were collected. B cell subsets including transitional, naive and memory were assessed using 7-color flow cytometry and Flowjo Analysis software. Plasma BAFF levels were evaluated using ELISA. Subset percentages within the B cell pool (CD19+) and BAFF levels were correlated with clinical parameters. Student t test to analyze differences between groups was used.

Results: Altered BCS in belimumab patients were observed. CD21/CD24 co-expression model for nonmemory subsets showed significant increase in T1 cells ($P < 0.001$) while T2 cells were significantly decreased ($P < 0.0001$) in HC and belimumab groups. When comparing HC to ST, a significant decrease in T2 cells comparable to belimumab was noted. Number of T2 derived naïve cells between HC and SLE was not significant. A significant difference in the number of naive cells between belimumab and ST ($P < 0.01$) was noted. Using IgD/CD27 co-expression to evaluate memory subsets, significant decreases in unswitched memory cells (IgD+) in both ST and belimumab compared to HC ($P < 0.01$), respectively, was noted. Assessment of switched memory cells showed significant decreases ($P > 0.01$) in ST

compared to HC, yet belimumab displayed a significant increase ($P > 0.01$) in switched memory cells compared to ST. Assessment of double negative memory (CD27neg) noted a significant increase in belimumab compared to HC ($P > 0.01$).

Conclusion: This is the first clinical belimumab study using the translational model CD21/CD24 to thoroughly evaluate B cell subsets for BCS. The model was derived from mouse studies evaluating the effect of BAFF on T1 and T2 in promoting the development of auto-reactive naive B cells. Evaluating the effect of belimumab on BCS can serve as a biomarker for patient response. Individual BCS may also allow clinicians to tailor a treatment regimen in either induction and/or maintenance therapy that is specific to their patients in the future.

Session Title: B cell Biology and Targets in Rheumatolid Arthritis and other Autoimmune Disease Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Neonatal lupus (NL) is an uncommon autoimmune disease classically manifest as permanent complete heart block and/or transient cutaneous lesions. By definition of NL, there is universal exposure to maternal autoantibodies reactive with the Ro/La ribonucleoprotein complex; however, only 2% of women with these antibodies will have an affected child. Accordingly, this study was initiated to address the hypothesis that antigen agnostic approaches (i.e. those that are antigen-independent) will have utility for identifying important functional antibodies and their targets.

Methods: Peripheral blood mononuclear cells were obtained from 10 Anti-Ro (plus or minus)/La positive mothers (asymptomatic, pauci-symptomatic, SLE, or Sjogren's Syndrome) of children with complete heart block (5 of whom died). Circulating plasmablasts were single-cell sorted and their IgH and IgL chains tagged with cell-specific DNA barcodes before sequencing with Illumina Miseq. Phylogenetic trees of the antibody repertoire were generated via binning the reads from each B cell based on the barcodes. Antibodies representative of clonal families were recombinantly expressed. Profiling of the recombinant antibodies was done by immunofluorescence (IF) using the HEp-2 cell line and ELISAs using native Ro60, recombinant Ro52 and recombinant La.

Results: From inspection of the phylogenetic usage of IgH and IgL in NL mothers, the approach captured a profile inclusive of highly mutated antibodies. Twenty three expressed antibodies representing the repertoires of two mothers were further evaluated. For the majority of monospecific immunoglobulin IgG (16/23), there was strong nuclear and/or cytoplasmic staining which correlated with reactivity on ELISA. Several antibodies showed polyreactivity for multiple antigens by ELISA. In one mother with mild dry eyes and identification of anti-Ro only after the diagnosis of heart block in her fetus, there was evidence of a convergent autoimmune-specific antibody HCDR3 signature. Interestingly, while the antibodies showing evidence of this convergent signature were both positive by IF, they were discordant regarding Ro/La reactivity.

Conclusion: While prior studies used approaches involving preselecting Ro/La antigens to further identify pathogenic autoantibodies, this is the first to define candidates based on clonal families identified through mining the plasmablast antibody repertoires in mothers with the pathogenic antibodies by virtue of their having a child with NL. Monospecific antibodies, particularly the subset with convergent specific antibody signatures, provide a platform for identifying the "pathoepitope" leading to cardiac injury.

Session Title: B cell Biology and Targets in Rheumatolid Arthritis and other Autoimmune Disease Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Type 1 interferon (IFN) is strongly implicated in lupus pathogenesis, and SLE patients frequently express a "type 1 IFN gene signature". The type 2 interferon, IFN gamma (IFN-γ), has also been implicated in lupus development via direct activation of autoreactive T cells. Although B cells are critical in lupus pathogenesis, whether these cytokines exert cell-intrinsic impacts on autoantibody-producing B cells has not been studied. We recently developed a chimeric murine lupus model in which Wiskott-Aldrich syndrome protein (WAS)-deficient B cells promote spontaneous humoral autoimmunity (Jackson, et al. *J Immunol* 2014). An important advantage of the WAS chimera model is that dysregulated immune responses are limited to the B cell compartment, allowing genetic manipulation in a B cell-intrinsic fashion. In the current study, we contrast the impact B cell-intrinsic type 1 interferon and IFN-γ signals on serum autoantibody titers, systemic inflammation and the development of lupus nephritis.

Methods: Using the WAS chimera model of spontaneous humoral autoimmunity, we deleted the type 1 IFN receptor (IFNAR) or IFN-γ receptor (IFNgR) on all hematopoietic cells ("global deletion"), or specifically on B cells ("B cell-intrinsic"). Chimeras were analyzed for autoantibodies, immune activation and immune-complex glomerulonephritis (IC GN) by ELISA, flow cytometry and immunohistochemistry.

Results: Surprisingly, although type 1 IFN enhanced B cell responses *in vitro*, B cell-intrinsic IFNAR deletion exerted minimal impacts on lupus pathogenesis. To address whether other cytokines promote B cell activation in this model, we quantified cytokine production *ex vivo*, and noted prominent CD4 T cell IFN-γ production in diseased WAS chimeras. Consistent with this, global IFNγR deletion prevented autoantibody (Ab) production and systemic inflammation in WAS chimeras. Strikingly, cell-intrinsic deletion of IFN-γR on either T cells or B cells recapitulated the phenotype of global IFNγR deficiency. Mechanistically, deletion of IFNγR on B cells prevented the formation of spontaneous germinal centers (GCs), required for class-switched Ab formation. Consistent with lack of serum autoantibodies, lupus nephritis was abrogated in B cell IFNγR-null chimeras.

In addition to Ab formation, B cells promote autoimmunity via antigen presentation and production of cytokines. Based on prominent B cell IFN-γ production in this model, we hypothesized that B cell-derived IFN-γ enhances spontaneous GC formation. In contrast, rendering B cells unable to produce IFN-γ did not alter the development of murine lupus suggesting that other cellular IFN-γ sources compensate for lack of B cell-derived IFN-γ.

Conclusion: We report the novel observation that IFN-γ, and not type 1 IFN, signals promote systemic lupus via direct actions on B cells. Mechanistically, IFN-γ promotes the formation of spontaneous autoimmune GCs via reciprocal activation of GC B cells and T follicular helper cells. To our knowledge, this study is the first to directly address the impact of B cell IFN-γ activation in murine lupus, of relevance to both the understanding of disease pathogenesis and to efforts to target IFN-γ therapeutically in SLE.

Decreased Expression of Negative Regulators of Toll-like Receptor Signaling and Increased TLR7 Responsiveness in Expanded IgD- CD27- B Cells from Systemic

Lupus Erythematosus Patients

Scott Jenks[1], Benjamin Barwick[2] and Ignacio Sanz[3], [1]Allergy, Immunology, and Rheumatology, Emory University School of Medicine, Atlanta, GA, [2]Emory University, Altanta, GA, [3]Medicine, Emory University, Atlanta, GA

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: B cell Biology and Targets in Rheumatolid Arthritis and other Autoimmune Disease Poster
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

B cell homeostasis is perturbed in SLE patients; in particular many patients with active disease have a large expansion of IgD- CD27- B cells (DN). The DN population is heterogeneous for CXCR5 expression, and CXCR5- DN are a the majority population in SLE patients with expanded DN but not in HCD. To further understand how these expanded cells differ from other B cells subsets and how they may be dysregulated in SLE, we analyzed gene transcription through RNA sequencing of sorted purified naïve, switched memory (SWM), CXCR5+ DN and CXCR5- DN (DNN) B cells from HCD and SLE patients with expanded DNN.

Methods:

RNA from sorted B cells subsets was isolated, amplified and sequenced. The resulting reads were aligned to the human genome and transcripts were assembled and quantified using edgeR. Transcripts are expressed as reads per kilobase per million (RPKM), genes that showed at least a two fold difference and a false discover rate < 0.05 were considered differentially expressed. TLR7 signalling after stimulation with R848 was measured by staining with anti- phospho-tyrosine specific anti-ERK. Changes in gene expression were evaluated by flow cytometry of purified B cells after overnight R848 stimulation.

Results:

Genes differentially regulated between SLE and HCD B cells were primarily interferon regulated genes and were up-regulated in all B cell subsets, including several positive regulators of viral pathogen sensing and TLR signaling. DNN showed several commonalities in gene expression with naïve B cells that differentiated them from memory B cells and CXCR5+ DN. These included higher expression of BCL6, IL21 receptor, and CD72 and decreased expression of the high affinity IL2 receptor, CD25, and genes associated with active cell division. Significantly, a negative regulator of TLR signaling, TRAF5, was uniquely down regulated in DNN in both HCD and SLE patients. Consistent with decreased expression of negative regulators of TLR signaling, DNN had enhanced *in vitro* sensitivity to TLR7 antagonist R848 as measured by ERK phosphorylation. Furthermore, R848 increased expressions of genes necessary for antigen presentation including HLA-DR and CD86 but decreased expression of the inhibitory receptors CD32b and CD72 in DN B cells but not naïve B cells.

Conclusion:

DNN represent a separate B cell lineage with a distinct origin and function as they differed from other B cells subsets both in uniquely expressing several genes and and a lack expression of other genes. One of the genes that is down regulated in DNN relative to all other B cell subsets is TRAF5, which in mice has been shown to negatively regulate TLR responses in B cells. Supporting the hypothesis that this gene may have a similar function in human B cells, both TLR7 signaling and responsiveness was enhanced in DNN. RNA from apoptotic cells can be internalized as immune complexes and through B cell receptors specific for auto-antigens. These antigens are powerful stimulants of TLR7 and DNN are uniquely sensitive to this signal. Furthermore, increased expression of HLA-DR and CD86 in DNN after TLR will enhance antigen presentation to CD4 T cells. DNN likely play an important role in SLE pathogenesis by linking innate TLR signaling with B cell mediated adaptive immunity.

The B Cell Survival Cytokine BAFF Promotes Systemic Lupus Erythematosus Via Activation of TACI, Not BAFF Receptor

Holly Jacobs[1], Christopher Thouvenel[1], Tanvi Arkatkar[1], Nicole Scharping[1], David Rawlings[2] and **Shaun Jackson**[1], [1]Seattle Children's Research Institute, Seattle, WA, [2]Pediatrics/Immunology, Washington, Seattle, WA

Session Date: Monday, November 9, 2015
Session Title: B cell Biology and Targets in Rheumatolid Arthritis and other Autoimmune Disease Poster
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a multisystem autoimmune disease characterized by polyclonal B cell activation and production of class-switched antinuclear antibodies (ANA). Transgenic mice (Tg) overexpressing B cell activating factor of the TNF family (BAFF, also known as BLyS) develop an autoimmune disease resembling human SLE. Consistent with this, lupus nephritis patients have increased serum BAFF levels and the BAFF-targeted monoclonal Belimumab is an approved SLE therapy. BAFF binds to distinct receptors expressed on B cells, the BAFF receptor (BAFF-R) and transmembrane activator and CAML interactor (TACI). Because BAFF-R deletion results in a loss of mature B cells, this receptor has been suggested to explain the autoimmune phenotypes in BAFF-Tg mice. However, potential important roles for TACI in lupus pathogenesis have not been addressed.

Methods: To test the impact of TACI on BAFF-driven autoimmunity, we crossed BAFF-Tg and *Taci-/-* mice. Serum autoantibodies, peripheral B cell development, splenic immune activation and development of immune-complex glomerulonephritis (IC GN) was assessed by ELISA, flow cytometry and immunohistochemistry.

Results: Surprisingly, deletion of TACI abrogated serum anti-nuclear autoantibodies (ANA) in BAFF-Tg mice. In addition, lack of TACI prevented autoantibodies targeting RNA- and DNA-associated self-antigens, including Sm/RNP and dsDNA, across all immunoglobulin isotypes and subtypes, including IgM, IgG, IgA, IgG2b, IgG2c, IgG3. Lack of autoantibodies was not explained by alterations in peripheral B cell development, since both BAFF-Tg and *Taci*$^{-/-}$.BAFF-Tg mice exhibited similar B cell hyperplasia, with equivalent expansion of the follicular (FM) and marginal zone (MZ) compartments.

Aged BAFF-Tg mice develop prominent immune-complex glomerulonephritis, characterized by mesangial expansion, glomerular basement membrane thickening and capillary occlusion. Consistent with the lack of serum autoantibodies, *Taci-/-*.BAFF-Tg were completely protected from murine lupus nephritis, as evidenced by lack of albuminuria and restoration of renal histology.

Conclusion: We report the novel observation that TACI, not BAFF-R, is the predominant B cell receptor promoting BAFF-mediated murine lupus nephritis. These findings suggest that TACI may be an important therapeutic target in SLE, particularly in patients with high serum BAFF levels.

Role of the Chemokine Receptor CXCR3 in the Function of Regulatory B Cells in Patients with SLE

Session Title: B cell Biology and Targets in Rheumatolid Arthritis and other Autoimmune Disease Poster

Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: The emerging application of B-cell directed therapies in autoimmune diseases has led to the discovery of a novel B cell population, referred to as regulatory B cells (Bregs), that exerts regulatory functions via IL-10 production. We previously showed that human Bregs are strongly induced in IgM-memory (IgMM) B cell subsets following TLR9 stimulation and Breg functions are impaired due to attenuated induction of Blimp1 in systemic lupus erythematosus (SLE). It remains, however, largely elusive about the underlying mechanisms of this phenomenon in SLE patients. Given a critical role of C-X-C chemokine receptor type 3 (CXCR3) in inflammation, in the present study we have tested whether the migratory potential of Bregs is associated with their regulatory functions in healthy donors and patients with SLE.

Methods: Human B cell subsets in healthy donors and patients with SLE were enriched by cell sorting and subjected to the analysis of gene and protein expression by quantitative PCR, ELISA and flow cytometry.

Results: CXCR3, the chemokine receptor for CXCL10 and CXCL11, is predominantly expressed on T helper type 1 cells, a T-cell subset which plays a pivotal role in the initiation and perpetuation of inflammation. In human B cells CXCR3 was mainly expressed on memory subsets. We first tested Breg potential of CXCR3+ and CXCR3- IgMM B cells in healthy donors, and found that both subsets exhibited comparable potential in IL-10 production, suggesting that CXCR3 expression itself does not affect Breg function. Intriguingly, however, stimulation of CXCL10 and CXCL11 exerted inhibitory and stimulatory effects, respectively, on IL-10 production along with alteration of Blimp1 expression. Consistent with previous findings that the serum levels of CXCL10 are elevated in patients with SLE, CXCR3+ IgMM B cells in patients exhibited decreased potential in IL-10 expression compared with this subset in healthy donors, suggesting that aberrant expression of chemokine ligands is associated with crippled Breg function in patients with SLE.

Conclusion: Together, these findings uncover not only a new aspect of regulation of Breg function in humans, but also a novel clue to the revitalization of Bregs for the treatment of SLE.

Session Title: B cell Biology and Targets in Rheumatolid Arthritis and other Autoimmune Disease Poster
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Severe lupus tubulointerstitial nephritis (TIN) is prognostic of renal failure and characterized by an *in situ* autoantibody response. By characterizing monoclonal antibodies engineered from *in situ* activated B cells and plasmablasts using mass spectrometry and whole protein arrays we identified vimentin as the dominant antigen targeted by this *in situ* immune response. Direct binding of mAbs and TIN serum IgG to vimentin, together with multi-color confocal microscopy of lupus kidney samples confirmed autoantibody reactivity and that vimentin was a dominant autoantigen expressed in the inflamed tubulointerstitium. To understand the origin and evolution of this anti-vimentin antibody response we mapped the specific epitopes these antibodies recognized and, by reversion to germline, identified their original antigenic specificities.

Methods: Twelve IgG1 mAbs previously cloned from the inflamed tubulointerstitium of 6 lupus patients were expressed. Those with the highest anti-vimentin immunoreactivity were reverted to germ-line. Selected antibodies were then screened for immunoreactivity against purified bovine vimentin, recombinant human vimentin expressed in bacteria and vimentin that had been citrullinated (and confirmed as such by mass spectrometry) by PAD4. Nimblegen peptide arrays covering the entire human proteome as overlapping 12mers were probed.

Results: Previously characterized anti-vimentin antibodies bound directly to recombinant human vimentin and this binding was strongly inhibited by *in vitro* citrullination. Immunoreactivity with recombinant human vimentin and purified bovine vimentin was similar suggesting that no post-translational modifications were required for antibody binding. Using the Nimblegen arrays, we identified two epitopes within vimentin that both contained arginines and which were potential sites of citrullination. When anti-vimentin antibodies were reverted to germline, they still recognized vimentin but with a relative affinity significantly less than the mutated parent antibody.

Conclusion: These data indicate that the *in situ* humoral immune response in lupus tubulointerstitial nephritis is specific for vimentin that has not been citrullinated and therefore is fundamentally different than that associated with rheumatoid arthritis. Furthermore, this immune response arises from a naïve repertoire already reactive with vimentin and not with the nuclear antigens most often associated with systemic lupus erythematosus. These data suggest that unique mechanisms of *in situ* antibody selection drive local inflammation in lupus tubulointerstitial disease.

Session Title: B cell Biology and Targets in Rheumatolid Arthritis and other Autoimmune Disease Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: In-depth analysis of the molecular and antigenic properties of antibody secreting cells (ASC) is critical for our understanding of autoimmune diseases. This goal however has been hampered by technological barriers imposed by low-throughput technologies to interrogate the ASC at the single cell level. We describe here the incorporation of a high throughput methodology for linking the B cell receptor's heavy and light chain variable region (VH and VL) for analyzing the plasmablast B cell population from a SLE patient. Conventional techniques for sequencing of genomic DNA or cDNA from single cells are limited by low efficiency and low cell throughput (<200–500 cells), whereas >2 x 10^6B cells per experiment can be analyzed by this single-cell, emulsion-based technology for sequencing antibody VH-VL repertoires.

Methods: We use a flow focusing apparatus to encapsulate the single B cells in to the emulsion droplets containing the lysis buffer and oligo dT magnetic beads for capturing the mRNA, followed by an emulsion RT-PCR for generating the VH and VL linked products for next generation sequencing. Approximately 50,000 plasmablasts (CD19+IgD-CD27^{high}CD38^{high}CD138^{neg}) from a SLE patient were flow sorted and VH and VL transcript were linked using emulsion RT-PCR. IgH, IgL and linked transcripts were sequenced via Illumina MiSeq.

Results: 20,000 different sequences representing over 2,200 different clonotypes were identified, thereby demonstrating a very polyclonal PB repertoire during Lupus flares. High concordance was shown with Illumina miseq data obtained from bulk PB obtained from a separate aliquot of the same blood draw. Both experiments also demonstrated the presence of substantial clonal expansions of the SLE-associated VH4-34 clones.

Conclusion: We have incorporated a high-throughput methodology of linking immunoglubulin heavy and light chain variable region (VH-VL) transcripts prior to amplification and repertoire analysis via NGS. The ability of this approach to combine deep sequencing with single cell antibody generation should greatly enhance our understanding of the antigenic triggers involved in the pathogenesis of SLE and

other autoimmune diseases.

Session Title: B cell Biology and Targets in Rheumatolid Arthritis and other Autoimmune Disease Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-DNA B cells are a primary cause of pathology in individuals with systemic lupus erythematosus (SLE), producing autoantibodies that deposit in diverse tissues and cause extensive inflammatory damage. Congenic mice generated through the introgression of New Zealand Black (NZB) chromosome 1 (C1) susceptibility loci onto the non-autoimmune C57BL/6 (B6) strain are an effective way of modelling lupus and parsing its pathogenesis. Our laboratory has previously provided evidence that a B cell defect instrumental in autoantibody production localizes to the C1d (170.8-181 Mb) region of the NZB C1 and we have further shown that additional T cell and dendritic cell (DC) defects map to the C1b-d (124-181 Mb) locus. Since B cells from both C1d and C1b-d mice with transgenes for hen egg lysozyme (HEL)-specific immunoglobulin and soluble HEL demonstrated a breach of anergy, we hypothesized that the C1d interval alone would be sufficient to breach tolerance to nuclear antigen. Here, we have used a knock-in model of anergy to ssDNA to address this question.

Methods: Genes for the 3H9 heavy chain (IgH^a) and Vκ8 light chain were knocked into their proper loci in the C1d and C1b-d congenic strains in order to generate mice with homogeneous, ssDNA-specific B cell repertoires. Female B6, C1d and C1b-d Vκ8/3H9 and wild type mice were aged to 8 months, at which time sera, splenocytes and bone marrow were collected. Serum levels of anti-nuclear autoantibody production were measured by ELISA, while T and B cell activation and localization were assessed using flow cytometry and immunofluorescence microscopy.

Results: C1d.Vκ8/3H9 mice produce significantly higher levels of anti-ssDNA $IgG2a^a$ autoantibodies compared to their B6 counterparts. In line with this increased $IgG2a^a$ production, these mice also have a significant increase in the proportion of germinal centre B cells and plasma cells compared to B6 Vκ8/3H9 mice. As anticipated, C1b-d.Vκ8/3H9 mice show an even stronger breach of anergy, with significant increases in anti-ssDNA IgG, IgM and $IgG2a^a$ autoantibodies as well as significantly higher proportions of germinal centre B cells than their B6 counterparts. These changes mirror the observed increase in the number of follicular helper and IFNγ-producing T cells, which are thought to provide support for germinal centre B cell development and subsequent autoantibody production. C1d and C1b-d mice also show evidence of defective receptor editing, with significantly lower proportions of B cells with the Igλ1 light chain in the bone marrow compared to B6 counterparts. In agreement with our previous observations of increased survival and peripheral expansion of autoreactive B cells in the HEL model, the proportions of $Ig\lambda1^+$ B cells normalize in the spleen, further supporting the observed breach of anergy.

Conclusion: Our results confirm the presence of a B cell defect to nuclear antigen in the C1d interval and further imply that this defect involves perturbation of both central and germinal centre tolerance.

Session Title: B cell Biology and Targets in Rheumatolid Arthritis and other Autoimmune Disease Poster
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with systemic autoimmune rheumatic diseases (SARD) often have a prolonged pre-clinical phase during which they are anti-nuclear antibody $(ANA)^+$ but lack clinical symptoms. It has been proposed that progression from asymptomatic autoimmunity to clinical disease is accompanied by immunologic changes that could be used as predictors of disease development. However, little is known about the cellular derangements that accompany the transition from benign to pathological autoimmunity. Previous studies indicate that a number of B cell phenotypic changes are seen in SARD patients including changes in the proportions of various naïve and memory B cell subsets, increased B cell activation and elevated levels of plasmablasts/plasma cells. Here we examined whether ANA^+individuals who lack sufficient symptoms for a SARD diagnosis share any of the B cell phenotypic changes seen in early SARD.

Methods: ANA^+individuals who: 1) lacked clinical symptoms of SARD (ANS); 2) had a least one clinical symptom of SARD (UCTD); or 3) had a recently diagnosed steroid and immunosuppressive naïve SARD (SLE, SS, SSc, MCTD, DM) were recruited from clinics at UHN/MSH hospitals. Healthy controls (HC) were also recruited. PBMCs were isolated over a Ficoll gradient, stained with various combinations of fluorescently labeled antibodies and analyzed by flow cytometry. ANAs were measured through the hospital laboratory.

Results: B cell phenotypes were examined for 35 HC, 40 ANS, 24 UCTD, and 53 early SARD (22 SS, 19 SSc, 7 SLE, 2 MCTD, 1 DM) patients. Although significantly increased proportions of $CD19^{lo/-}CD38^{+++}CD27^{+++}$ plasmablasts/plasma cells were seen in all SARD patients (except those with SSc), these were not seen in ANS and UCTD patients and significant increases in $CD138^+$ plasma cells were not seen in any of the ANA^+ subsets except SS. Patients with early SARD had a number of changes in their naïve and memory B cell subsets, as previously reported for patients with established disease including: increased proportions of mature naïve B cells (SSc); increased proportions of T1T2 cells (SLE and SS); and decreased proportions of switched memory B cells ($CD27^+IgD^-$) in all SARD. However, in contrast to some reports no changes were seen in the proportion of $CD27^+IgD^+$ un-switched or $CD27^-IgD^-$ memory cells. Similar decreases in the proportion of switched memory B cells were seen in ANS and UCTD patients, and as seen for the SARD patients these cells were activated with elevated levels of CD86 as compared to HC. Significantly increased activation of the $CD27^-IgD^-$ memory compartment was also seen in ANS, SLE and SS patients, with trends observed for the other patient subsets. When all ANA^+ individuals were examined there was a significant association between ANA titer and the proportion of $CD19^{lo/-}CD38^{+++}CD27^{+++}$ and $CD138^+$plasmablast/plasma cells as well as the reduced size and increased activation of the switched memory B cell compartment. This was also seen when the ANS subset was examined alone.

Conclusion: B cell phenotypic abnormalities appear to precede the onset of clinical disease in ANA^+ individuals and correlate with autoantibody levels as reflected by the ANA titer.

Regulatory B Cells Regulate Skin and Lung Fibrosis and Immunological Abnormalities in a Topoisomerase I and Complete Freund's Adjuvant-Induced Scleroderma Model Via an Antigen-Specific Manner

Ayumi Yoshizaki[1], Takashi Taniguchi[1], Kouki Nakamura[1], Ryosuke Saigusa[1], Takashi Yamashita[1], Takehiro Takahashi[1], Tetsuo Toyama[1], Yohei Ichimura[1], Yoshihide Asano[2] and Shinichi Sato[1], [1]Dermatology, University of Tokyo Graduate School of Medicine, Tokyo, Japan, [2]University of Tokyo Graduate School of Medicine, Tokyo, Japan

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: B cell Biology and Targets in Rheumatolid Arthritis and other Autoimmune Disease Poster
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Immune cells play a critical role in systemic sclerosis (SSc). B cells have more functions than producing antibodies, including antigen-presentation, various cytokine production, and T cell differentiation. In addition, abnormal B cell function can drive the development of autoimmunity. However, specific B-cell subsets can also play a protective role during T cell-mediated inflammation and have been termed regulatory B cells. Regulatory B cells with the ability to express the inhibitory cytokine interleukin (IL)-10 have been identified. Mice subcutaneously injected with topoisomerase-I and complete Freund's adjuvant (CFA) develop skin and lung fibrosis and inflammatory infiltration with anti-topoisomerase I antibody and fibrogenic cytokine production, which more closely mimics the features of human SSc than traditional models, such as tight-skin mouse. However, the contribution of regulatory B cells and the mechanisms underlying suppression effects of immunological abnormalities in topoisomerase I and CFA-induced SSc remain unknown. Therefore, we investigated the role of regulatory B cells, in the development of fibrosis and autoimmunity induced by topoisomerase I and CFA.

Methods: Topoisomerase I and CFA were injected 4 times subcutaneously into the shaved back of the mice at an interval of 2 weeks. To assess the antigen-specific regulatory B cell function, wild type and activation-induced cytidine deaminase (AID)-deficient mice were used. AID is important molecules for inducing immunoglobulin class switch and somatic hypermutation. CD5+ and CD1dhi regulatory B cells were obtained from topoisomerase I and CFA-induced SSc model mice and adoptively transferred to these mice. Skin and lung sections were assessed histologically. Protein and mRNA levels of IL-4, IL-6, IL-17, tumor necrosis factor-α, transforming growth factor-β, and interferon-γ were measured using ELISA and real-time RT-PCR.

Results: In AID deficient mice, topoisomerase I and CFA treatment induced lower number of topoisomerase I-specific regulatory B cells than those in wild type mice. Furthermore, regulatory B cells obtained from wild type mice significantly attenuated the development of skin and lung fibrosis, skin expression of fibrogenic cytokines, especially IL-4, IL-6, and IL-17, and hyper-g-globulinemia compared with those from AID deficient mice.

Conclusion: Regulatory B cells are potent negative regulators of antigen-specific inflammation and T-cell-dependent autoimmunity in topoisomerase I and CFA-induced SSc model mice. This study revealed fist that regulatory B cells ameliorate fibrosis and immunological abnormalities via an antigen-specific manner in SSc.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: B cell Biology and Targets in Rheumatolid Arthritis and other Autoimmune Disease Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Upon B cell receptor stimulation, B cells increase protein expression levels of the key downstream signaling molecule Bruton's tyrosine kinase (BTK). BTK-transgenic mice that overexpress BTK exclusively in B cells, spontaneously develop antinuclear autoantibodies and SLE/Sjögren-like autoimmunity. These mice exhibit increased levels of T follicular helper (Tfh) cells and T regulatory (Treg) cells in lymphoid tissues and develop lymphoid infiltrates in salivary glands and lungs, which contain ectopic germinal centers. Therefore, we aimed to investigate whether BTK expression is also dysregulated in B cells from patients with primary Sjögren's syndrome (pSS).

Methods: Twenty-six treatment-naïve pSS patients, which fulfilled the revised AECG criteria, and 26 sex- and age-matched healthy controls were included in this study. Fifteen pSS patients were treated with abatacept (i.v.) for 24 weeks. Peripheral blood mononuclear cells (PBMCs) and serum were collected from 26 patients at baseline, and from 15 treated patients at 4, 12, 24, 36 and 48 weeks after the first dose of abatacept. B and T cells were analyzed by 12-color flow cytometry. (auto-)Antibodies were measured by ELISA. Histopathological analysis was performed on parotid gland biopsies from 15 pSS patients before and after abatacept treatment.

Results: Flow cytometry analysis of PBMCs from pSS patients and healthy controls revealed that in 16 of 26 of the patients, BTK expression levels were increased in B cells, compared to levels in healthy controls ($p=0.032$). Excitingly, these levels were consistently higher in all B cell subsets, including naïve B cells. In pSS patients with high BTK expression levels, serum RF levels were also increased ($p=0.035$) and a trend towards increased levels of Ro52 and Ro60 (SSA) was found. There was no correlation between BTK levels in B cells from pSS patients and total serum immunoglobulins (IgG, IgA, IgM). Treatment of pSS patients with abatacept, which targets co-stimulation of T cells, resulted in a decrease of the elevated BTK expression levels in circulating B cells to levels in healthy controls ($p=0.003$). We further observed that abatacept treatment reduced absolute numbers of circulating Tfh and Treg cells, while numbers of Th1, Th2 and Th17 were not affected. Although abatacept did not influence the amount of infiltrate in parotid gland tissue, the number of germinal centers declined, illustrating the Tfh cell dependency of these structures.

Conclusion: We show that BTK levels in circulating B cells are increased in a large proportion of pSS patients. High BTK levels may reduce thresholds for B cell activation, and thereby contribute to B cell autoreactivity. In pSS patients, this is reflected by the positive association of elevated BTK levels in B cells with serum RF levels. The observation that abatacept treatment reduced BTK levels in pSS patients implies that high BTK levels are -at least partly- dependent on T cell co-stimulation. Our data may further suggest that Tfh cells play a pivotal role in T cell dependent BTK expression. Together, this study underlines the importance of interfering with B-T cell interaction in the treatment of pSS.

Session Title: B cell Biology and Targets in Rheumatolid Arthritis and other Autoimmune Disease Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: B cells play a central role in Sjogren's syndrome (SS) pathogenesis whereby autoreactive B-cells populate ectopic germinal centres (eGC) in SS-salivary glands (SG) and undergo somatic hypermutation (SHM) and class-switch recombination of the immunoglobulin (Ig) genes. However, the capacity of specific B cell clones to seed eGC in different SG and undergo clonal diversification is unclear. Here we aimed to unravel the dynamics of B cell recirculation among adjacent minor SG (mSG) biopsies, by investigating immunoglobulin heavy chain (IgH) gene rearrangements and SHM using a high-throughput next-generation sequencing approach.

Methods: IgH gene usage and SHM were investigated in four pairs of mSG biopsies from 4 pSS patients with high B cell infiltration and eGC. Retro-transcription of 100 ng total RNA using constant domain Ig-l, -c and -a specific primers yielded Ig-specific cDNA for use as template in producing libraries representing B cell Ig-gene rearrangements in SS mSGs. Sequencing was performed using the Roche GS-FLX titanium platform.

Results: We generated ~166,000 reads >350 bp in total, and detected 1631 clonotypes (defined as reads with the same IgHV and IgHJ gene usage and equal CDR3 length) across all eight samples. Between 5 and 9 shared clonotypes were observed among paired SG biopsies in all four patients, demonstrating the same B cell can recirculate between different glands. Lineage tree analysis revealed three different patterns of B cell circulation across the biopsies: a) unidirectional circulation of B cell clones from one biopsy to another; b) circulation between the two biopsies – circulating in both directions; c) an undefined pattern with a less-mutated and unidentified precursor migrating from one site to the other.

Conclusion: We show that B cells recirculate between mSG in SS and undergo further rounds of SHM in adjacent glands. These findings demonstrate the dynamic nature of B cell affinity maturation in SS within eCG.

Session Title: B cell Biology and Targets in Rheumatolid Arthritis and other Autoimmune Disease Poster

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: We have found that the expression level of BAFF receptor (BR3) is abnormally enhanced in peripheral monocytes of patients with pSS, and BAFF robustly increases IL-6 production in vitro by pSS monocytes. In addition, the proportion of BR3-positive monocytes to total monocytes was positively and significantly correlated with the serum IgG level of pSS patients. These data collectively suggest that the elevated expression of BR3 on monocytes is involved in the pathogenesis of pSS which is often accompanied with hypergammaglobulinemia (HgG). Our findings suggest that BR3 is a therapeutic target to treat pSS. In our previous study, we have successfully discovered two pyrrolopryimidine derivatives, BIK12 and BIK13, which inhibit binding of BAFF to BR3, by our original

high-throughput screening (HTS) system. In this study, we investigated inhibitory effects of these compounds on BAFF signaling pathways. To this end, we measured not only IL-6 production by monocytes, but also IgG production by B cells co-cultured with BAFF-stimulated monocytes. In addition, we analyzed the effects of the compounds on serum level of an anti-dsDNA antibody in autoimmune disease model mice received these compounds.

Methods: Peripheral monocytes were stimulated with soluble BAFF (sBAFF) and cultured in vitro with or without peripheral B cells in the presence of BIK-12 or BIK-13. IL-6 production by monocytes and IgG production by B cells were measured by ELISA. For examination of the effects of these compounds in vivo, MRL/lpr and NZBWF1 mice were treated with these compounds three times a week at a dose of 1 mg/kg or 0.2 mg/kg for 6 months. The titer of an anti-ds DNA antibody was measured by ELISA.

Results: sBAFF-induced IL-6 production by peripheral monocytes was significantly suppressed by BIK12 and BIK13 in a dose dependent manner. Similarly, IgG production by B cells cultured with sBAFF-stimulated peripheral monocytes was significantly suppressed by these compounds, while sBAFF itself did not increase IgG production by B cells. These data suggest that inhibition of BAFF binding to BR3 on monocytes suppressed IgG production by co-cultured B cells. Interestingly, the titer of an anti-dsDNA antibody in both MRL/lpr and NZBWF1 mice received BIK13 was lower as compared to control mice after 16 weeks of treatment, indicating that the compound was also efficacious in vivo.

Conclusion: We discovered pyrrolopyrimidine derivatives by HTS which inhibited BAFF signaling, and found that the compounds suppressed IgG production by B cells through affecting monocytes. Our findings strongly suggest that BR3 is a therapeutic target to treat autoimmune diseases which accompany HgG, such as pSS. Moreover, these compounds may provide novel tools to explore the pathological mechanism of the development of autoimmune diseases.

Session Title: Biology and Pathology of Bone and Joint Poster I: Osteoarthritis Pathogenesis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Epidemiological findings support the hypothesis that type 2 diabetes (DB) is an independent risk factor of osteoarthritis (OA). Likewise, we have recently reported a higher responsiveness to inflammatory stress of OA cartilage from DB patients and enhanced IL-1β-induced inflammation in cultured chondrocytes in a high glucose (HG) environment[1]. To investigate whether the antioxidant defense system may participate in this dysregulation, we investigated the involvement of nuclear factor-erythroid 2-related factor (Nrf-2), the master transcriptional regulator of antioxidant responses, and heme oxygenase-1 (HO-1), one of its main target gene, in OA cartilage from DB and non-DB patients, and in normal murine chondrocytes subjected to HG exposure.

Methods: Human cartilage was obtained at the time of knee replacement of DB and non-DB OA patients (with similar age and body mass index). Cartilage explants were incubated for 24h and Nrf-2 and HO-1 tissue levels were assayed by western blot (WB). Articular chondrocytes in primary culture isolated from newborn C57Bl6 mice were stimulated at 72h w/o IL-1β (5 ng/mL) under a normal (5.5 mM; NG) or a high (25 mM; HG) glucose environment. Nuclear translocation of Nrf-2 (30 min) was analyzed by WB. Gene and protein expression of Nrf-2, HO-1 and IL-6 were assessed by RT-qPCR and WB, respectively. ROS production was measured using DCFDA. To

determine the mechanistic pathways involved in cell activation by HG ± IL1β, a HO-1 inducer (CoPP; 10μM) and sulforaphane (SFN; 5mM), a natural Nrf-2 translocation activator, were used, and experiments were also performed in $Nrf2^{-/-}$ mice generated from inbred C57BL/6J background Nrf2 heterozygous mice.

Results: *Ex vivo* experiments indicated that Nrf-2 and HO-1 expressions were reduced in OA cartilage from DB patients (n=7, 0.57-fold [Nrf-2] and 0.34-fold [HO-1]) compared to non-DB patients (n=8, $p<0.05$). HO-1 expression was positively correlated with Nrf-2 levels ($p<0.05$).

In vitro, IL-1β-stimulated chondrocytes exposed to HG had lower Nrf-2 nuclear levels (0.61-fold) than those incubated in NG (n=5, $p<0.05$). In agreement, total protein expression of Nrf-2 by IL-1ß-stimulated cells was also reduced in presence of HG versus NG (0.82-fold; n=5, $p<0.05$). A decreased HO-1 protein levels (0.49-fold) was also observed (n=5, $p<0.05$). HO-1 expression was positively correlated with Nrf-2 ($r = 0.35$; $p<0.05$) and negatively with IL-6 levels ($r= -0.35$; $p<0.05$) using PCR.

CoPP reduced ROS production (-75%) and IL-6 expression (-74%) detected in HG + IL-1ß condition ($p<0.05$). The decrease of HO-1 and increase of IL-6 induced by HG was reversed in IL-1ß-stimulated chondrocytes from $Nrf-2^{-/-}$mice. SFN rescued HO-1 levels and reduced ROS production (-20%) triggered by HG + IL-1ß stimulation ($p<0.05$).

Conclusion: Nrf2/HO-1 axis is disturbed in diabetic OA cartilage and is a critical pathway involved in the hyperglucidic-mediated dysregulation of articular chondrocytes. The impairment of this anti-oxydant system could explain the higher inflammatory responsiveness observed in cartilage from DB patients and may open new opportunities for treating patients with a diabetes-related OA phenotype.

Insulin-Induced Cartilage Degradation in Osteoarthritis Is Associated to Defective Autophagy

Beatriz Carames[1], Madalena Ribeiro[1,2], Paloma Lopez de Figueroa[1], Alexandrina Mendes[2] and Francisco J. Blanco[1], [1]Cartilage Biology Group. Rheumatology Division, INIBIC-Hospital Universitario A Coruña, A Coruña, Spain, [2]Centre for Neuroscience and Cell Biology, University of Coimbra; Faculty of Pharmacy, University of Coimbra, Coimbra, Portugal

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Biology and Pathology of Bone and Joint Poster I: Osteoarthritis Pathogenesis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Autophagy, a key cellular quality control mechanism, is defective in Osteoarthritis (OA) and Type 2 Diabetes (T2D). T2D has been proposed as a risk factor for OA. Although epidemiological studies suggest a strong association between these diseases, how T2D may have an effect on the deterioration of articular cartilage is still unknown. *The objective of this study is to understand the role of autophagy in the articular cartilage function under diabetic conditions.*

Methods:

Human chondrocyte cell line (TC28a2) and primary human chondrocytes (HC) were cultivated in DMEM high glucose (25 mM) and treated with Insulin (10, 100, 500 nM) for 2, 6 and 24 hours. Activity of LC3-II, Akt and rpS6 was evaluated by Western blotting (WB). To investigate whether autophagy activation protects from diabetic conditions, autophagy was induce by Rapamycin (10 μM). Human cartilage explants were cultivated in DMEM 25mM glucose and insulin (100, 500, 1000nM) for 24 hours to evaluate histopathological changes. MMP-13 and IL-1β expression was determined by immunohistochemistry and WB, respectively. Expression of LC3 and p-rpS6 was determined by WB in human chondrocytes from Non Diabetic-OA and Diabetic-OA patients.

Results:

In the presence of high glucose and increased doses of insulin autophagy was decreased in a dose dependent-manner in human chondrocytes, as indicated by LC3II expression, the main marker of autophagy activation (TC28-a2; $p< 0.05$ at 6 hours post-treatment; HC; $p < 0.01$ at 24 hours post-treatment). To investigate the mechanism by which autophagy is reduced by insulin, Akt and rpS6 phosphorylation was analyzed. We observed a significant increase in p-AKT and p-rpS6 activity, suggesting that insulin effect is mediated by AKT/mTOR pathway (TC28-a2 $p< 0.05$ at 6 hours; HC; $p< 0.01$ at 2 hours). Autophagy activation by Rapamycin reversed insulin effects on LC3 and p-rbS6 expression (Tc28a2 and HC:$p < 0.05$), indicating that autophagy induction prevents insulin-mediated autophagy signaling downregulation. To evaluate the impact of insulin-mediated autophagy regulation in the context of articular cartilage biology, cartilage explants were treated with insulin (100, 500 and 1000 nM) for 24 hours. Histological analysis indicated a loss of proteoglycans and increased MMP-13 and IL-1β expression ($p<0.01$) after insulin treatment. Remarkably, chondrocytes from OA-diabetic patients showed decreased LC3 and increased p-rpS6 expression compared to Non-Diabetic OA patients.

Conclusion:

Our findings demonstrate that diabetic conditions decrease autophagy by an AKT/mTOR dependent mechanism. Pharmacological activation of autophagy might protect against T2D in human chondrocytes. Our data also indicate that chondrocytes from OA-diabetic patients exhibit a deficient autophagy. Taking together, these results suggest that impaired autophagy might be one of the mechanisms by which T2D diabetes accelerates cartilage degradation.

Session Date: Monday, November 9, 2015

Session Title: Biology and Pathology of Bone and Joint Poster I: Osteoarthritis Pathogenesis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Deposition of amyloid is a common aging-associated phenomenon and a key factor in the pathogenesis of several aging-related diseases. Osteoarthritis (OA) is the most prevalent joint disease and aging is its major risk factor. Transthyretin (TTR) is an amyloidogenic protein. We previously reported that amyloid and TTR deposition were increased in human OA cartilage with aging and OA grade. In addition, amyloidogenic TTR affected chondrocyte survival and induced the OA related genes such as ADAMTS4, interleukin 6 and inducible nitric oxide synthase. Here we investigated the role of TTR in vivo. Transgenic mice for wild-type human TTR (hTTR TG mice) were analyzed using an experimental OA model.

Methods:

TTR in cartilage and chondrocytes was analyzed by immunohistochemistry and Western blotting. OA was surgically induced by destabilizing the medial meniscus of the hTTR TG mice (n=26) and control mice (n=22). Mice were sacrificed 10 weeks after surgery. To investigate the effects of TTR on cartilage, 6-month-old mice were sacrificed and examined by immunohistochemistry, real-time PCR and Western blotting. In addition, quantitative analysis of cell number in cartilage was examined in 6-, 12-month-old mice, and surgical model. OA-related tissue changes were evaluated using the Glasson's semi-quantitative cartilage scoring system and Krenn's synovitis score.

Results:

TTR protein was detected in cartilage in hTTR TG mice, but chondrocytes did not express TTR mRNA, the transgene was highly overexpressed in the liver. ADAMTS4 and MMP13 mRNA were significantly elevated in cartilage in 6 month-old hTTR TG mice compared with control mice. Immunohistochemical and Western blotting analysis showed increased MMP13 expression in the hTTR TG mice 10 weeks after surgery compared with control mice. In addition, nuclear factor-κB (NF-κB) p65 and Phospho-NF-κB p65 was elevated in hTTR TG mice. In the surgical model, both histological OA score and synovitis score were significantly increased in hTTR TG mice. Additionally, cellularity was significantly lower in the 6-month-old hTTR TG mice and hTTR TG mice with surgical OA compared with control mice.

Conclusion:

These findings are the first to show that TTR deposition accelerated the development of OA in the surgically-induced murine OA model. Our observations suggested that reducing TTR amyloid formation can be a new therapeutic approach for OA.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Biology and Pathology of Bone and Joint Poster I: Osteoarthritis Pathogenesis
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoarthritis (OA) is a leading cause of chronic disability affecting a majority of individuals over age 70. Outside of cartilage, little is known regarding changes in DNA methylation that occur regionally within OA joints. Herein, we performed global DNA methylation analysis of subchondral bone underlying eroded and intact regions of the OA hip joints and compared it to our previous analysis of OA cartilage.

Methods: Twelve femoral heads were obtained from hip arthroplasty for primary OA. From eroded and intact areas of each joint, articular cartilage and 1cm-deep cores of underlying subchondral bone were dissected, frozen in liquid nitrogen, and DNA extracted. Methylation profiling of >485,000 sites was performed using Illumina HumanMethylation450 arrays; differential methylation was defined as FDR-corrected $p<0.01$ with absolute methylation difference of at least 15%. Pyrosequencing confirmed the four most differentially methylated sites.

Results: We identified 5477 hypo- and 1839 hypermethylated CpG sites in subchondral bone underlying eroded cartilage compared to intact tissue, corresponding to 2290 and 621 genes, respectively. The most hypomethylated genes included the RISC component EIF2C2, ERGIc1, the cell adhesion molecule LPP, and the MAPK deactivator DUSP1, whereas the most hypermethylated genes were HOXA7, CD4, CD6, and CD28. Pathway analysis revealed genes involved in cancer (n=96, p=1.38E-12), axonal guidance (n=104, $p=4x10^{-11}$), NFAT signaling (n=55, $p=4x10^{-10}$), and ERK/MAPK signaling (n=55, $p=1x10^{-9}$). The most highly associated upstream regulators included TGFβ1 ($p=3x10^{-39}$), TNF ($p=1x10^{-27}$), and p53 ($p=8x10^{-24}$). Comparing subchondral bone results to our OA cartilage data, 153 methylation sites from 420 genes were differentially methylated in both OA cartilage and subchondral bone. Significant overlap in upstream regulators and many shared pathways were found including ERK/MAPK-, NFAT-, IGF-1-, and PTEN-signaling. Among upstream regulators, TGFβ, miR-124, angiotensinogen, RANKL, and p38 MAPK were all highly associated with differentially methylated genes in both cartilage and subchondral bone. Four previously-identified OA susceptibility genes, COL11A2, FTO, LRP5, and NCOR2,

were differentially methylated in both subchondral bone and overlying cartilage.

Conclusion: Our data implicate epigenetic dysregulation of several genes and pathways in localized areas of subchondral bone underlying OA damage. Although relatively few differentially methylated sites were shared among cartilage and subchondral bone, there was substantial overlap among pathways and upstream regulators. Our work strengthens the notion that a dysregulated epigenome among subchondral bone and cartilage are intimately linked in the pathogenesis of OA, and reiterates that OA represents a disease of the entire joint organ.

Session Title: Biology and Pathology of Bone and Joint Poster I: Osteoarthritis Pathogenesis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Histone deacetylase inhibitors (HDACi) are a class of compounds that inhibits the histone deacetylase activity. MCPIP1 is a negative regulator of IL-6 expression and is expressed at low levels in human osteoarthritis (OA) cartilage. In the present study we tested the effects of class I and class II HDACi on the expression of MCPIP1 and IL-6 in OA chondrocytes.

Methods: OA chondrocytes were isolated by enzymatic digestion of cartilage samples obtained from OA patients who underwent total knee arthroplasty. Primary OA chondrocytes were treated with IL-1β in the absence or presence of SAHA-a class I & II HDACi. Gene expression and protein levels were measured by TaqMan assay and Western blot respectively. Expression of miR-9 was quantified by TaqMan assay. Secreted IL-6 levels were determined by ELISA. MCPIP1 promoter or 3' UTR reporter vector activity was assayed using dual luciferase reporter assay system. MCPIP1 promoter deletion mutants were generated by PCR and cloned into reporter vectors. PCR based Nuclear run-on assay was employed for the analysis of ongoing transcription. Transcription factor binding to the MCPIP1 promoter was determined by ChIP assay performed with ChIP grade antibodies.

Results: Treatment of OA chondrocytes with SAHA robustly induced the expression of MCPIP1 and inhibited the expression of IL-6 mRNAs upon IL-1β stimulation and reduced the secreted IL-6 protein level in the culture medium by ~70%. Treatment of OA chondrocytes with SAHA inhibited the IL-1b-induced expression of miR-9 by ~70%. Luciferase reporter vectors containing the 3'UTR of the MCPIP1 mRNA which contains the miR-9 "seed sequence" exhibited 25% increased luciferase activity in OA chondrocytes upon SAHA treatment compared to controls treated with IL-1β alone. Nuclear run-on assays using nuclei prepared from OA chondrocytes treated with IL-1β alone or IL-1b + SAHA demonstrated increased expression of MCPIP1 (1.4 fold) in OA chondrocytes compared to IL-1β alone-stimulated OA chondrocytes. Using MCPIP1 promoter deletion mutants a 156bp fragment was identified that encompassed sequences sufficient to enhance luciferase activity in OA chondrocytes stimulated with SAHA. *In-silico* analyses identified CEBPa binding site in the 156 bp promoter region and expression of CEBPα was significantly increased upon SAHA treatment in OA chondrocytes. Ectopic overexpression of CEBPα was sufficient to enhance the expression of MCPIP1 and increased the luciferase activity of the reporter vectors containing either the full length MCPIP1 promoter or the 156bp promoter fragment. Recruitment of CEBPα to the MCPIP1 promoter was significantly increased upon SAHA treatment. Finally we found reduced expression of CEBPa in damaged OA cartilage compared to smooth cartilage, which suggests that low level of MCPIP1 expression could be due to the reduced expression of CEBPα in damaged OA cartilage.

Conclusion: These data indicate that HDACi SAHA upregulates MCPIP1 expression and suppress IL-6 expression in IL-1β treated OA chondrocytes via upregulation of CEBPa and inhibition of miR-9 expression. Results of the present study propose a novel therapeutic role for HDACi SAHA for the management of OA.

Session Time: 9:00AM-11:00AM

Background/Purpose:

Synovial fibroblasts (SF) produce elevated levels of matrix degrading enzymes, including matrix metalloproteinase 1 (MMP1), in the joints of rheumatoid arthritis (RA) patients, leading to irreversible joint damage. The aggressive behavior of RASF has been associated with epigenetic alterations, including global DNA hypomethylation and altered histone methylation. Supplementation of SF with re-methylating agents, such as betaine, may attenuate the destructive behavior of SF. Here, we investigated the role of betaine in the regulation of MMP1 expression in SF focusing on histone dynamics at the MMP1 transcription start site.

Methods:

RASF (passages 5-8) were supplemented with 50 mM betaine for two weeks and were cultured for an additional week without betaine. The levels of HOTAIR and MMP1 mRNA were quantified by SYBR Green real time qPCR. The amount of MMP1 protein in cell culture supernatants was assessed by ELISA and normalized to the cell number. SF were transfected with HOTAIR siRNA (72h) using Lipofectamine 2000. The Roadmap Epigenomics database was used to determine regions enriched for histone 3 lysine 4 trimethylation (H3K4me3) and histone 3 lysine 27 trimethylation (H3K27me3) at the promoters of HOTAIR and MMP1 and in the region 500 bp downstream of their transcription start sites. The levels of H3, H3K4me3 and H3K27me3 were assessed using chromatin immunoprecipitation. Adhesion to cell culture plates and proliferation of SF were monitored with xCELLigence RTCA DP Instrument. Apoptosis was analyzed by flow cytometry using the Annexin V/PI assay.

Results:

The levels of HOTAIR (0.7±0.03 vs. 1 in untreated, p=0.005 n=3), MMP1 mRNA (0.54±0.27, p=0.008, n=6) and MMP1 protein (0.4±0.3, p=0.02, n=6) were significantly reduced in SF supplemented with 50 mM betaine for two weeks and were down regulated by 10%±7.8% (n=3) after an additional week without betaine. Moreover, betaine supplemented SF adhered less strongly to the cell culture plate (cell index=0.7±0.1 vs. 1 in untreated SF, n=3) and proliferated slower than untreated SF (doubling time=1.4±0.3 vs.1 in untreated SF, n=3). The number of apoptotic cells did not increase after supplementation. Silencing of HOTAIR resulted in significant up regulation of MMP1 mRNA (2.6±0.8 vs. 1 in control transfected, p<0.0001, n=8), indicating that HOTAIR is not involved in MMP1 repression in betaine supplemented SF. In contrast, the levels of activating H3K4me3 mark 74 to 220 bp downstream the transcription start site of MMP1 (0.66±0.23 vs. 1 in untreated, n=2) and at the HOTAIR promoter (-1908-2008 bp, 0.66±0.09 vs. 1 in untreated, n=2) were reduced in betaine supplemented SF, whereas the repressive H3K27me3 mark was significantly increased 74 to 220 bp downstream the transcription start site of MMP1 (2.4±0.2 vs. 1 in untreated, p=0.046, n=2). Of interest, the levels of H3 at the HOTAIR promoter diminished in supplemented SF, suggesting that betaine induced eviction of H3.

Conclusion:

We provide the first evidence that, by altering the histone dynamics at gene regulatory sites, betaine supplementation may regulate the

transcription of RA-relevant genes such as MMP1, thus significantly reducing the matrix destructive behavior of RASF.

Session Date: Monday, November 9, 2015

Session Title: Biology and Pathology of Bone and Joint Poster I: Osteoarthritis Pathogenesis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: MicroRNAs, non-coding small RNAs, reportedly regulate development, remodeling and pathogenesis activities in various tissues through silencing mRNA targets and protein translation. This study is undertaken to analyze comparative microRNA expression profiles, characterize the biological role of candidate microRNA-128 (miR-128) in articular cartilage integrity and investigate whether knockdown of miR-128 attenuated cartilage erosion, synovial remodeling, subchondral bone deterioration and osoteophyte accumulation during the pathogenesis of knee OA.

Methods: Left knees of male Spargue-Dwley rats underwent medial parapatellar arthrotomy and anterior cruciate ligament transaction (ACLT) to induce OA. Arthrography of cartilage injury and synovitis were visualized by 9.4T μMRI. Articular cartilage damage was scored by OARSI scale. Subchondral bone microarchitecture and osteophyte formation were quantified by μCT. Comparative microRNA expression of injured joints was analyzed by Megaplex™ microRNA arrays and verified by quantitative RT-PCR and in situ hybridization.

Results: miR-128 expression was increased with intensive articular cartilage destruction and chondrocyte apoptosis in the development of knee OA. Intra-articular injection of lentivirus-mediated exogenous miR-128 led to intact knee joints progressively had severe chondrocyte loss and exacerbated cartilage breakdown that recapitulated OA histopathology. Of note, intra-articular administration of exogenous miR-128 antisense oligonucleotide (miR-128-AS) attenuated the ACLT-mediated chondrocyte apoptosis, proteinase expression (MMP3, MMP9 and ADAMTS5), cartilage matrix degradation and microstructure impediment. The miR-128-AS treatment lessened the provoking effects on synovial thickening, fibroblast activation, macrophage infiltration and inflammatory regulator expression (IL-1β, TNFα, CXCL-9 and COX-2). This administration also simultaneously ameliorated subchondral plate damage, trabecular microarchitecture loss and osteophyte deposition. miR-128 decreased sirtuin-1 (SIRT1) mRNA and protein expression through targeting the 3'-UTR of sirtuin-1 in chondrocytes. miR-128-AS treatment restored SIRT1 signaling and stabilized cartilage transcription factor SOX9 through regulating acetylation state of SOX9 in affected knee joints.

Conclusion: miR-128 aggravated joint integrity in the pathogenesis of knee OA. Interruption of miR-128 maintained chondrocyte viability and metabolism through regulating SIRT1 signaling and thereby alleviated the pathogenesis of cartilage erosion, synovitis, subchondral plate damage and osteophyte development. This study sheds a new light on miR-128 deterioration of articular cartilage homeostasis and highlights the therapeutic potential of miR-128 interference for curtailing knee OA pathogenesis.

Session Title: Biology and Pathology of Bone and Joint Poster I: Osteoarthritis Pathogenesis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoarthritis (OA) is a chronic and debilitating disease of articulating joints. Mechanical stress, genetic and environmental factors play critical role in the pathogenesis of OA. Micro-RNAs (miRNA) are endogenous, short ~22-nucleotides non-coding single stranded RNAs, that act as a regulator of gene expression. In order to understand the role of miRNAs in OA pathogenesis we employed deep sequencing technology to comprehensively profile the miRNA population in OA chondrocytes.

Methods: Chondrocytes were prepared from human cartilage samples obtained from OA patients at the time of knee arthroplasty and were treated with IL-1β (2ng/ml) for 1, 12, 24 h. Total RNA was isolated using miRNeasy Mini kit (Qiagen) and a small RNA library was prepared using TrueSeq Small RNA Library Preparation Kit (Illumina). RNA purity, integrity and library integrity and purity was verified using Agilent 2100 Bioanalyzer. Cluster generation and sequencing was performed on MiSeq (Illumina). The small RNA-Seq reads were aligned to genomic reference (hg19) and subsequently miRNAs were annotated to generate the miRNA abundance profile and novel miRNA sequences from NGS data using Strand NGS software. Data was normalized followed by differential expression analyses in control and treated samples using Strand NGS software. Expression of selected miRNAs was verified by TaqMan assays. Differentially regulated miRNAs were used to construct the signaling pathways that were enriched by the treatment using DIANA-mirPath open web tool.

Results: We obtained 2.0-2.5 million reads per sample and more than 95% reads pass the quality filter. We identified 1548 miRNAs in our sequencing reads that were unique. miRNAs with less than 5 sequencing reads were excluded from the analyses which left 511 differentially expressed miRNAs. In chondrocytes, expression of 10 miRNAs (miR-100, 26a, 22, 148a, 27b,125b, 99b, 21, let-7a and 7b) on average constitute ~70% of all miRNAs expression across the samples. Differentially expressed miRNAs were identified across different time points by using 1.5 fold as cut-off criteria. We identified 46 miRNA that were upregulated and 41 miRNAs that were downregulated compared to untreated control sample at all the time points analyzed. Highest upregulated miRNA was miR-146a (30 fold) which has been implicated in OA pathogenesis and most downregulated miRNA was miR-452 (5 fold). Some miRNAs exhibited dynamic expression pattern. Fifteen miRNAs were identified as potential novel miRNAs by the Strand NGS software. One sequence (newgene 105) annotated in bovine as bta-miR-2904 was also found to be expressed in human chondrocytes. Several of the differentially expressed miRNAs were predicted to target mRNAs associated with MAPK signaling, PI3K-AKT signaling, focal adhesion and regulation of actin cytoskeleton.

Conclusion: Deep sequencing revealed several novel miRNAs in OA chondrocytes. Expression of Newgene 105 (miR-2904 in *Bos taurus*) has been documented for the first time in human chondrocytes. These newly identified miRNAs could have novel functions in OA pathogenesis. Our work deliver a clear picture of miRNA profile and associated regulatory network in OA chondrocytes.

Krüppel-like Factors (Klfs), Novel Transcriptional Regulators of Articular Chondrocytes That Are Abnormally Expressed in Osteoarthritic Cartilage

Takeshi Teramura[1], Joe Hasei[2], Hiroshi Asahara[1,3,4] and Martin K. Lotz[5], [1]Molecular and Experimental Medicine, The Scripps Research Institute, La Jolla, CA, [2]Molecular and Exerpimental Medicine, The Scripps Research Institute, La Jolla, CA, [3]Tokyo Medical and Dental University, Tokyo, Japan, [4]National Research Institute for Child Health and Development, Tokyo, Japan, [5]Division of Arthritis, The Scripps Research Institute, La Jolla, CA

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Biology and Pathology of Bone and Joint Poster I: Osteoarthritis Pathogenesis
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Krüppel-like factors (Klfs) are known to play key roles in cell cycle regulation, definition of cell fate and regulation of terminal differentiation. There is no information on expression and function of Klfs in cartilage. The objectives of this study were to analyze expression of Klfs in normal and OA cartilage and study their role in regulating chondrocyte functions.

Methods:

Klf expression in normal and OA human cartilage and in developing mouse limb buds was examined by next generation RNA sequencing and qPCR. Klf4 function in normal human chondrocytes and TC28 immortalized chondrocytes was analyzed by gene overexpression and knock down. Overexpression of Klf4 mutants and reporter constructs were used to determine critical motifs for Klf regulation of gene expression.

Results:

Next generation RNA sequencing showed that Klf2, 4, 5, 9, 10 and 15 are significantly suppressed in OA cartilage. Quantitative real time PCR for mouse limb buds showed significantly increased Klf2, 4 and 5 expression from E11.5 to E15.5. Over expression-based screening in the immortalized human chondrocyte cell line TC28 revealed that only Klf4 strongly enhanced Col2A1 and Acan gene expression. Conversely, knockdown of Klf4 resulted in suppression of Col2A1 and Acan genes in human primary chondrocytes. Luciferase reporter assays showed that Klf4 binds to consensus sequences of Col2A1 and Acan promoters and activates their expression. ChIP-qPCR for Col2A1 promoter and Co-IP study revealed that Klf4 could interact with Sox9 directly. Klf4 C-terminus, which contains three tandem zinc fingers, which are critical for this interaction are required for activation of the target genes. Finally, we demonstrated that induction of Klf4 expression could induce Col2A1 and Acan expression in various cell types including dedifferentiated chondrocytes, and the magnitude of upregulation of the target genes was attenuated by reduction of Sox9 expression.

Conclusion:

These results are the first to show that Klf factors have a tissue specific expression in articular cartilage and that OA is associated with dysregulated expression of several Klfs. Among the Klfs, Klf4 expression pattern is most closely linked with chondrogenic markers. Klf4 promotes expression of chondrocyte specific genes, in part through direct interaction with Sox9. Collectively, these findings implicate abnormal expression of Klfs as a novel mechanism of abnormal chondrocyte differentiation and activation in OA.

IL-1β-Induced Stress Granules Sequester COX-2 mRNA and Regulates Its Expression in Human OA Chondrocytes

Mohammad Ansari[1] and Tariq Haqqi[2], [1]Anatomy & Neurobiology, Northeast Ohio Medical University, Roostown, OH, [2]Anatomy & Neurobiology, Northeast Ohio Medical University, Rootstown, OH
First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Biology and Pathology of Bone and Joint Poster I: Osteoarthritis Pathogenesis
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Stress granules (SGs) are ribonucleoprotein complexes assembled in the cytoplasm of eukaryotic cells to respond adequately to stress (e.g. heat shock, UV irradiation, oxidative stress etc.). SGs sequester mRNAs to enable the cell to reprogram its translational repertoire via mRNA triage. Translational stalling of selective mRNA populations by SGs has been shown to be critical in the pathogenesis of neurodegenerative diseases. Here we studied the induction and formation of SGs in response to inflammatory stimuli, translational stalling of COX-2 mRNAs by SGs, and the mechanism of SGs clearance in human osteoarthritis (OA) chondrocytes.

Methods:

Primary human OA chondrocytes were isolated from smooth cartilage obtained from OA patients who underwent total knee arthroplasty. Chondrocytes were treated with IL-1β (10ng/ml) for different periods of time. Chondrocyte lysate was prepared in RIPA buffer supplemented with protease and phosphatase inhibitors. Immunoblotting was done using specific antibodies. Activation of the integrated stress response (ISR) was determined by studying GRP78 expression levels, phosphorylation of eIF2α by Western immunoblotting, and formation and duration of SGs by immunofluorescence staining of G3BP1, TIA-1, TIAR, Staufen1 and HuR. Association of COX-2 mRNA with SGs was determined by FISH and RNA immunoprecipitation. mRNA decay was analyzed using Actinomycin-D chase assay. Role of specific proteins in IL-1b-induced SGs formation was assessed by RNAi mediated knockdown of target mRNAs. ROS generation was measured by flow cytometry using CellROX dye. Treatment with ammonium chloride and Bafilomycin was used to block SGs clearance via autophagy. Production of PGE_2 was determined by ELISA.

Results:

Human OA chondrocytes stimulated with IL-1β showed enhanced ROS production and the expression of the ER stress marker GRP78 and activation of the ISR through phosphorylation of eIF2α and the assembly of SGs. Immunofluorescence staining using antibodies specific for G3BP1, TIA-1, TIAR, Staufen1 and HuR as well as by transient transfection with the G3BP1-GFP plasmid showed robust assembly of SGs in IL-1b-stimulated OA chondrocytes. COX-2 mRNAs were mainly localized in SGs in complex with the RNA binding protein HuR. Sequestration in SGs stalled COX-2 mRNA translation and COX-2 protein levels increased only after the disassembly of SGs. Formation of SGs was TIA-1-dependant as its knockdown resulted in loss of SGs assembly and promoted early and enhanced translation of COX-2 mRNA and protein expression. Production of PGE_2 mirrored the COX-2 protein expression. Inhibition of autophagy blocked SGs clearance and inhibited COX-2 protein expression without affecting the COX-2 mRNA levels in OA chondrocytes.

Conclusion: To our knowledge, this is the first report showing IL-1β induced assembly of SGs in human OA chondrocytes and describes a novel function of SGs in controlling the pro-inflammatory stimulus in in OA chondrocytes through subcellular trafficking of COX-2 mRNAs to SGs. These data demonstrate the importance of RNA binding proteins and SGs assembly in OA pathogenesis and identify specific RBPs/SGs as potential therapeutic targets

Low Molecular Weight Polyphenol Harpagoside Inhibits IL-1β-Induced Expression of IL-6 By Blocking the Expression and Activity of c-Fos in Primary Human Osteoarthritis Chondrocytes

Abdul Haseeb[1,2], Mohammad Ansari[3] and Tariq Haqqi[1], [1]Anatomy & Neurobiology, Northeast Ohio Medical University, Rootstown, OH, [2]Anatomy and Neurobiology, Northeast Ohio Medical University (NEOMED), Rootstown, OH, [3]Anatomy & Neurobiology, Northeast Ohio Medical University, Roostown, OH

SESSION INFORMATION
Session Date: Monday, November 9, 2015

Session Title: Biology and Pathology of Bone and Joint Poster I: Osteoarthritis Pathogenesis
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoarthritis (OA) is a multifactorial disease and is characterized by focal degradation of articular cartilage. Several components of the inflammatory pathway, such as IL-6, are found to be highly expressed in OA joints. There is growing evidence to support the involvement of IL-6 in OA progression and severity. Harpagoside is a natural compound isolated principally from the secondary roots of *Harpagophytum procumbens (Hp)*. In the present study we used an *in vitro* model of joint inflammation to study the therapeutic potential of harpagoside in OA.

Methods: Primary human OA chondrocytes were isolated from the non-affected cartilage obtained from OA patients who underwent total knee arthroplasty. Human OA chondrocytes were cultured and pre-treated with harpagoside (300 µg/ml) and then cultured with and without IL-1β (1-10 ng/ml). Chondrocyte viability was assayed using CytoTox 96® Non-Radioactive Cytotoxicity Assay (Promega). mRNA levels of 92 chemokines and chemokine-associated genes were measured by TaqMan human chemokine PCR array (Life Technologies). Secreted levels of IL-6 in the culture supernatants were assayed by ELISA and immunoblotting. Total protein levels and phosphorylation status of proteins were measured by immunoblotting using specific antibodies. mRNA levels of individual genes were quantified using the TaqMan assays (Life Technologies). Subcellular localization of c-FOS and IL-6 was studied using confocal microscopy (Olympus FV1000 microscope). Activation of transcription factor c-FOS/AP-1 was analyzed by ELISA (Active Motif). Data were analyzed and plotted using Origin 6.1 software and $P<0.05$ was considered significant.

Results: Harpagoside significantly modulated the IL-1β-induced expression of a number of chemokines in primary human OA chondrocytes. Several of the genes, including IL-6, that showed robust expression in response to IL-1β were markedly downregulated by treatment with harpagoside. Treatment with IL-1β markedly stimulated the mRNA expression as well as protein secretion of IL-6 in the culture supernatants. In contrast, OA chondrocytes pre-treated with harpagoside showed a significant reduction ($p<0.05$) in IL-1β-induced expression of IL-6. Importantly, harpagoside did not inhibit the IL-1b-induced activation of NF-κB and C/EBPb but specifically suppressed the IL-1β-triggered over-expression, phosphorylation and activity of c-FOS, one of the major components of AP-1. Further, we show here that harpagoside imparts its inhibitory effect on c-FOS activity and IL-6 production partially through suppression of IL-1β induced ROS production in human OA chondrocytes.

Conclusion: Taken together, our data showed that harpagoside markedly inhibited the IL-1β-induced expression and production of IL-6 in human OA chondrocytes. Importantly, a novel mechanism of IL-6 suppression by harpagoside which involves the inhibition of c-FOS expression was identified. These data provide strong evidence that harpagoside may have a chondroprotective effect and may be a potential therapeutic choice to prevent and/or to slow down the progression of OA.

Suppressor of Cytokine Signaling 1 Inhibits Interleukin-1β Induced Matrix Metalloproteinases Expression in Human Chondrocytes By Modulating p38-CREB-C/Ebpβ Pathway

You Jung Ha[1], **Yong Seok Choi**[2], Eun Ha Kang[3], Kichul Shin[4], Jaehyung Hur[1], Yeong Wook Song[5] and Yun Jong Lee[2], [1]Division of Rheumatology, Department of Internal Medicine, Seoul National University Bundang Hospital, Seongnam-si, South Korea, [2]Internal Medicine, Seoul National University Bundang Hospital, Seongnam-si, South Korea, [3]Department of Internal Medicine, Seoul National University Bundang Hospital, Seongnam-si, South Korea, [4]Rheumatology, SMG-SNU Boramae Medical Center, Seoul, South Korea, [5]Department of Molecular Medicine and Biopharmaceutical Sciences, Graduate School of Convergence Science and Technology and College of Medicine Seoul National University, Seoul, South Korea

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Biology and Pathology of Bone and Joint Poster I: Osteoarthritis Pathogenesis
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: CAAT/enhancer-binding protein-beta (C/EBPb) is known to be a transcription factor regulating IL-1b-induced catabolic pathways, including the expression of matrix metalloproteinases (MMPs), in chondrocytes. Suppressor of cytokine signaling 1 (SOCS1) was reported to inhibit interleukin (IL)-1b signaling in chondrocytes. However, the effect of SOCS1 on C/EBPb has not been explored.

Methods: To investigate the interaction between SOCS1 and C/EBPb, we established human chondrocyte-like SW1353 cell lines with overexpression or knockdown of SOCS1 or C/EBPb. MMP-1, MMP-3, MMP-13, and C/EBPb transcripts were measured by using quantitative real-time PCR. The expression of C/EBPb and cAMP response element-binding protein (CREB) protein was evaluated by immunoblot. To evaluate the binding of C/EBPb to MMP-13 promoter, chromatin immunoprecipitation (ChIP) assay was performed.

Results: Both SOCS1 and C/EBPb were involved in transcription of MMP-3 and MMP-13. When SW1353 cells were stimulated with IL-1b, C/EBPb levels were significantly increased by SOCS1 knockdown and decreased by SOCS1 overexpression (Fig. 1). Also, the same change in IL-1b induced C/EBPb expression was observed in SOCS1 transfected human articular chondrocytes (Fig. 1). But, C/EBPb overexpression or knockdown did not change the levels of IL-1b-inducible SOCS1 (Fig. 1). SOCS1 did not affect the ubiquitination of C/EBPb, but it regulated the levels of C/EBPb mRNA and suppressed the phosphorylation of CREB1, an active transcription factor of C/EBPb (Fig. 2). In addition, p38 MAPK, a target of SOCS1, was involved in the phosphorylation of CREB1. The ChIP assay confirmed that SOCS1 overexpression resulted in reduced binding of C/EBPb to MMP-13 promoter.

Conclusion: These results demonstrate that SOCS1 down-regulates p38-CREB-C/EBPb pathway resulting in suppression of MMPs expression in chondrocytes.

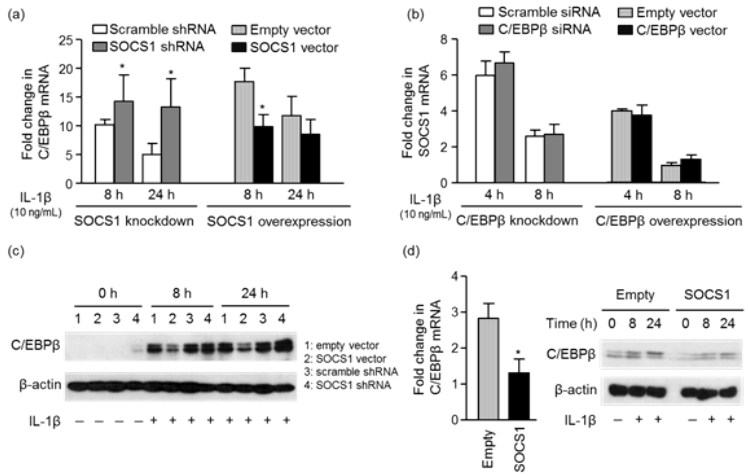

Fig. 1. SOCS1 knockdown increased and SOCS1 overexpression decreased IL-1b induced C/EBPb mRNA and protein expression in SW1353 cells (a, c), but C/EBPb knockdown or overexpression showed no alteration in SOCS1 transcript levels (b). In SOCS1-overexpressed human articular chondrocytes, IL-1b-induced C/EBPb mRNA and protein expression showed the same trends (d).

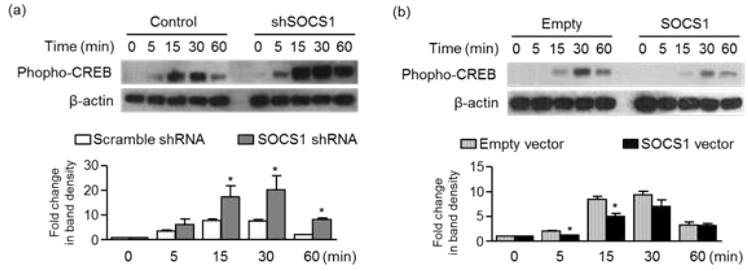

Fig. 2. Effects of SOCS1 on phosphor-CREB levels in SW1353 cells.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Biology and Pathology of Bone and Joint Poster I: Osteoarthritis Pathogenesis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: While osteoarthritis (OA) in humans is characterized by cartilage degradation, osteophyte formation and joint remodeling, inflammation and synovitis are now recognized to contribute to joint pathology. Two experimental models of OA, destabilization of the medial meniscus (DMM) and section of the anterior cruciate ligament (ACL), are commonly used in the study of OA. While these models mimic many of the changes observed in human OA, the role of synovitis and inflammation remains unclear. To address this, inflammation in DMM and ACL models was evaluated.

Methods: All murine procedures were Home Office (UK) approved. OA was induced in 10 week old C57BL/6 male mice by DMM or ACL. SHAM operated and naïve animals were used as controls. Freund's complete adjuvant (FCA) monoarthritis model was used as a positive control of inflammatory joint disease. Knee joint diameter was assessed prior to induction of arthritis and then every three days thereafter. IVIS technology was used to assess myeloperoxidase activity. After 4 weeks synovium was harvested and used for explant culture. Supernatants were collected after 4 hours and analyzed by Luminex for the presence of inflammatory mediators. In parallel experiments, joints were collected for histological analysis of CD3+ and F4/80+ cells. Data were expressed as mean ± SEM with $p<0.05$ taken as the criterion of significance, tested using 1 or 2 way ANOVA.

Results: There was no significant change in the knee joint diameter between naïve, SHAM, DMM and ACL at 4 week time point. However, knee joint diameter significantly increased in FCA compared to all other groups (figure 1A) and it was the only model demonstrating elevated myeloperoxidase activity. Also, elevated levels of IL-1β, IFNγ, RANTES and IL-10 were only detected in FCA explant cultures. While histological analysis of the joints demonstrated an absence of CD3+ T cells in both DMM and ACL models, F4/80+ cells were observed within/adjacent to the anterior cruciate ligament in ACL and at the medial collateral ligament in DMM. Importantly, MIP-1β/CCL4 was significantly increased in FCA and OA surgical models compared to naïve (figure 1B). IL-33 was elevated in FCA and ACL models but did not attain significance for DMM (figure 1C).

Conclusion: This study demonstrates that the OA inflammatory milieu within the DMM and ACL synovium differs substantially from the FCA model. Nevertheless, the presence of F4/80+ cells and high levels of MIP-1β/CCL4 within the synovium as well as elevated IL-33 suggests an ongoing low-grade inflammatory process in these OA models.

Session Title: Biology and Pathology of Bone and Joint Poster I: Osteoarthritis Pathogenesis

Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Bone destruction in rheumatoid arthritis is mediated by osteoclasts, which are derived from precursor cells of the myeloid lineage. Although there is much known about mature osteoclasts, the identity of an osteoclast precursor population and its regulation by inflammatory cytokines during arthritis is poorly understood.

Methods: HTNFtg mice were clinically scored once per week for grip strength and swelling. In addition, blood was collected every other week starting on week 4. Mice were sacrificed at week 10 - blood, spleen and bone marrow were collected for flow cytometry analysis. K/BxN Arthritis was induced in wild type mice, blood and spleen were collected 14 days after disease induction. HTNFtg/CCR2$^{-/-}$and hTNFtg mice were analyzed histologically. Different monocyte subsets were Facs-sorted and cultured in the presence of RANKL and MCSF to induce osteoclasts.

Results: Here we show that during TNF-driven arthritis monocytes, in particular resident non-classical monocytes (CD115^{+}Ly6C^{low}CCR2^{-}), are elevated in blood before the onset of clinical symptoms and remain elevated throughout. Upon sorting resident and inflammatory monocytes (CD115^{+}Ly6C^{high}CCR2^{+}) from blood, we demonstrate that resident monocytes are more potent to form osteoclasts *ex vivo*. In addition, the number of resident monocytes in blood positively correlated with histological signs of joint destruction, such as area of erosion and number of osteoclasts in arthritic hind paws, while the number of inflammatory monocytes did not correlate at all with those parameters. Of note, we observed a similar correlation of resident monocytes with histological markers of tissue damage also in another model of inflammatory arthritis, K/BxN serum transfer arthritis. Next, we crossed CCR2 deficient mice, which lack circulating inflammatory monocytes, into hTNFtg animals. In line with our hypothesis that resident monocytes are mediating local bone destruction, hTNFtg mice lacking CCR2 showed no decrease but even enhanced local bone erosion and osteoclast generation.

Conclusion: Resident non classical monocytes with osteoclastogenic potential are elevated during chronic inflammatory arthritis and the numbers in blood correlate with histological markers of joint destruction in models of inflammatory arthritis in two models of arthritis. Therefore these cells may provide a biomarker for erosive inflammatory arthritis and even a possible target for therapeutically intervention.

Synovial Ultrasound Power Doppler Enhancement Reflects Multiple Cytokine Expression in Synovial Tissue, Distinguishing Distinct High Macrophage-Associated and Low Inflammation Profiles

Session Title: Biology and Pathology of Bone and Joint Poster I: Osteoarthritis Pathogenesis
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Power doppler ultrasound provides joint level data on the risk of erosive progression in patients with inflammatory arthritis. Understanding the synovial tissue correlates of ultrasound variables may reveal factors that drive erosive disease. The purpose of this study was to examine the relationship between ultrasound variables, tissue histological variables and cytokine profiles in DMARD naïve inflammatory arthritis patients.

Methods:

Ultrasound guided synovial biopsies were obtained from patients with at least one clinically swollen joint at presentation to the Birmingham Early arthritis Cohort (BEACON) and followed for 18 months to confirm outcome as either rheumatoid arthritis fulfilling 2010 criteria (RA: n=29, median symptom duration 10 weeks), or spontaneously resolving disease (RES: n=9, median symptom duration 5 weeks). All patients underwent baseline ultrasound, clinical and serological assessment. Fractional Power Doppler pixel quantification (USPD) was performed using a custom Matlab application. Ultrasound Greyscale (USGS) synovial hypertrophy was graded on a 4 point semiquantitative scale. Synovial tissue histology variables were assessed by blinded pathologists. Synovial cellular populations were quantified by blinded cell counts of fluorescence stained tissue sections. Synovial mRNA expression of 119 cytokines was quantified using low density PCR array techniques.

Results:

Histological grading of leukocyte infiltrate complexity in biopsies correlated with USGS synovial hypertrophy (RA $p<0.05$, RA+RES combined $p<0.01$), but not USPD. Lining layer thickness did not correlate with USGS or USPD in any group. Neither infiltrate complexity nor lining layer thickness was significantly different between diagnostic groups. After correction for multiple comparisons, mRNA levels of key cytokines and chemokines were positively correlated with PDUS in RA, including IL-6 (p=0.007), IL-32 (p=0.0.025) and the chemokines CCL2 (p=0.007), CCL7 (p=0.0002), CCL8 (p=0.0161), CCL19 (p=0.024) and CXCL13 (p=0.045), while key mediators of low inflammation pathways were negatively correlated with PDUS, including IGFBP5 (P=0.048), Galectin-3 (P=0.002) , Galectin12 (P=0.043) and SFRP-1 (P=0.01). A similar pattern was seen in the RES group, and combining groups resulted in a total of 30 genes correlated with PD. Correlation of PDUS with CD68-positive joint counts in synovial biopsies revealed a positive relationship for combined groups (RA+RES p=0.03, RA alone P=0.05).

Conclusion:

Infiltrate complexity correlates most closely with the extent of synovial hypertrophy, rather than hyperaemia measured by PD. However US power doppler fraction correlates positively with key inflammatory macrophage related cytokines, chemokines, growth factors and tissue CD68 positive cell counts, providing an explanation for the link beween power doppler and joint damage.

Session Title: Biology and Pathology of Bone and Joint Poster I: Osteoarthritis Pathogenesis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Synovial fibroblasts (SF) profoundly influence physiological and pathological processes in the joint such as reaction to inflammatory stimuli and production of extracellular matrix. We recently reported that SF from different joints exhibit site specific gene expression patterns; more than 20% of all detected transcripts in RNA sequencing significantly differed between knee, shoulder and hand SF. Here we investigated how these substantial differences in transcriptional programs translate into joint specific function of SF.

Methods:

SF were isolated from synovial tissues of hip, knee, shoulder, elbow and metacarpophalangeal (MCP) joints of RA and OA patients undergoing joint replacement surgery. MetaCore (Thomson Reuters, log2 ratio=2, p=0.05) was used for pathway enrichment analysis of RNA sequencing data (Illumina HiSeq 2000). Basal and TNF-α-induced MMP1 secretion from SF was analyzed with ELISA. Transwell plates (5mm polycarbonate membrane, Corning Costar) were used to measure migration (16h) of leukocytes from healthy donors (n=2) towards supernatants of cultured SF. Adhesion to tissue culture plates 16h after seeding and proliferation of SF were measured in real time with the xCELLigence RTCA DP Instrument (ACEA Biosciences, Inc.). Synovitis was quantified in synovial tissues from hands (n=17), elbows (n=6), shoulders (n=7), knees (n=8) and hips (n=4).

Results: Pathway enrichment analysis of RNA sequencing data between joint localizations (knee, shoulder, MCP) revealed joint specific enrichment of several arthritis-relevant biological processes, such as chemotaxis, proliferation, cell adhesion and matrix degradation. SF from hands, elbows and shoulders (n=4 each) secreted higher levels of MMP1 protein compared to knee SF (n=8) under basal conditions (hand 1808±1008, elbow 1773±1450, shoulder 2073±1083 vs. knee 449±883 pg/ml) and TNF-α stimulation (hand 8431±2339, elbow 8216±2110, shoulder 7176±1428 vs. knee 5369±1515 pg/mL). While adhesion was significantly stronger in shoulder vs. hand SF (cell index 0.9±0.2 vs. 0.6±0.2, p=0.01, n=7 each), shoulder SF (doubling time: 67±15h, p=0.03, n=5) showed a significantly lower proliferative potential than hand (39±3h, n=4) and knee SF (45±9h, n=6). More leukocytes migrated towards the supernatants from cultured knee and hand SF (x fold both: 1.4±0.03 vs. control cell culture medium=1) than shoulder SF (x-fold: 1.2±0.1). The total synovitis score composed of changes in stroma, synovial lining thickness and leukocyte infiltration showed an increased value in hands and elbows (6.2±1.8, 6.2±1.3 vs. shoulder 4.4±2.8, knee 4.1±2.3, hip 4.3±1.5, p=0.06), but the influx of immune cells was significantly enhanced into the synovium of hands versus shoulders and hips (hands 2.1±0.6; shoulders 1±0.4; hips 0.8 ±0.5, p=0.02).

Conclusion:

SF from joints of different anatomic sites are functionally distinct cells and create a unique and specialized microenvironment in each joint localization. Since hand SF secrete higher amounts of MMP1 and exhibit stronger proliferative and chemotactic properties compared with SF from other joints, they may in particular contribute to joint destruction occurring in hand arthritides.

Session Title: Biology and Pathology of Bone and Joint Poster I: Osteoarthritis Pathogenesis

Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Hydrogen sulfide (H_2S) is, next to NO and CO, the third endogenous gasotransmitter. It has been shown that in some pathologies, such as hypertension, cardiovascular disease or diabetes type II, H_2S endogenous levels or biosynthesis are significantly reduced and that exogenous administration might be helpful. Previous experiments by our group have demonstrated that H_2S releasing compounds have anti-inflammatory and anti-catabolic effects on IL1β-stimulted OA chondrocytes. Therefore our hypothesis in the present work was that OA patients might also have lower endogenous H_2S levels.

Methods: Joint tissues and blood samples were obtained from patients of the Orthopedic or Rheumatology Services of the University Hospital A Coruña (CHUAC), or volunteers (blood only), after written informed consent. The mRNA expression of the H_2S production enzymes, cystathionine β-synthase (CBS), cystathionine γ-lyase (CTH) and mercaptopyruvate sulfurtransferase (MPST) was analyzed in cartilage, synovial membrane and subchondral bone. Immunohistochemistry and quantification with ImageJ was performed to evaluate the location and abundance of the CBS, CTH and MPST. Hydrogen sulfide concentration was measured using a selective ion microelectrode. Direct H_2S concentration was measured in 200 µL of fresh serum after incubation with 200 µL of an antioxidant buffer (AB) for 1h. Likewise, H_2S production from cartilage was measured by incubating cartilage disks in 200 µL of the same AB for 2 h.

Results: We found that all three enzymes, CBS, CTH and MPST were expressed in all tested joint tissues. CBS was slightly reduced in the OA cartilage, but no statistically significant differences were detected for this enzyme, nor CTH, in any tissue. Notably, however, MPST mRNA expression was significantly reduced in OA cartilage with respect to normal controls. Immunohistochemistry also showed decreased levels of this enzyme in cartilage. On the other hand, statistically significant differences were also found in the H_2S production measured from OA with respect to non OA cartilage samples. Indeed, OA cartilage H_2S production was 0.105 ± 0.042 nmoles/g of cartilage (mean ± SE, n=13) in OA tissue while that of healthy cartilage was 0.433 ± 0.110 nmoles/g of cartilage (mean ± SE, n=5), $p<0.05$. These differences, however, were not reflected in the H_2S concentrations in blood serum samples, where no statistically significant differences were found (OA serum: 56.48 ± 7.24 µM (mean ± SE, n=38) vs. N serum: 72.18 ± 10.66 µM (mean ± SE, n=28), $p>0.05$).

Conclusion: Local H_2S biosynthesis is reduced in the OA joint. This is the result, at the least, of a reduced mRNA expression and protein abundance of MPST. Since MPST is predominantly a mitochondrial enzyme, this deficit might be another factor that causes the mitochondrial dysfunction that is known to contribute to OA pathogenesis.

Session Title: Biology and Pathology of Bone and Joint Poster I: Osteoarthritis Pathogenesis
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Excessive production of reactive oxygen species (ROS) of the chondrocyte plays an important role of cartilage degradation, inflammation, and increased chondrocyte death in the development and progression of osteoarthritis (OA). Recently, many studies have demonstrated that the transduction of a therapeutic protein using protein transduction domain (PTD), which targets the lipid bilayer directly can be utilized

for therapeutic applications. GLRX (Glutaredoxins) are endogenous antioxidant systems and key players in the balance of cellular redox homeostasis. In this study we sought to investigate whether PEP-1-GLRX-1, a fusion protein of GLRX-1 with PEP-1 peptide, one of protein transduction domains, could suppress catabolic responses in primary human chondrocytes and carrageenan-induced paw edema mouse model.

Methods:

Human articular chondrocytes were enzymatically isolated from articular cartilage and cultured in monolayer. The transduction efficiency of PEP-1-GLRX1 into articular chondrocytes was measured by Western blot and immunochemistry analysis. The effect of PEP-1-GLRX1 on MMP expression and catabolic factor expressions in interleukin-1β (IL-1β)- and lipopolysaccharide (LPS)-treated chondrocytes were analyzed by real-time quantitative reverse transcription-polymerase chain reaction and Western blot analysis. The effect of PEP-1-GLRX1 on mitogen activated protein kinase (MAPK) and NF-κB signaling pathway were analyzed by Western blot analysis. The inhibitory effect of PEP-1-GLRX-1 on MMP13 production was measured in carrageenan-induced edema mouse model.

Results:

PEP-1- Efficient penetration of GLRX-1 into human and mouse cartilage was demonstrated by western blot and immunochemistry analysis. PEP-1-GLRX-1 in interleukin-1β (IL-1β)- and lipopolysaccharide (LPS)-treated chondrocytes significantly suppressed the expressions of matrix metalloproteinase (MMP)-13 and inducible NO synthase (iNOS), at both mRNA and protein levels compared with GLRX-1. In addition, PEP-1-GLRX-1 decreased IL-1β- and LPS-induced activation of mitogen activated protein kinase (MAPK) and NF-κB. In a mouse model of carrageenan-induced paw edema, PEP-1-GLRX-1 significantly suppressed carrageenan-induced MMP-13 production as well as paw edema.

Conclusion:

Therefore, these results showed that PEP-1-GLRX-1 can be efficiently transduced *in vitro* and *in vivo* and down-regulate catabolic responses in chondrocytes and in arthritis animal model through inhibiting activation of MAPK and NF-κB. PEP-1-GLRX-1 has a potential to reduce catabolic responses in chondrocytes and cartilage.

Session Title: Biology and Pathology of Bone and Joint Poster I: Osteoarthritis Pathogenesis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Xylosyltransferase-1 (XT-1), encoded by *xylt1* gene, is an essential anabolic enzyme to catalyze the initial and rate-determining step in glycosaminoglycan chain synthesis. The effect of fibronectin fragments (FN-fs), generated by proteolytic cleavage of FN and known as damage-associated molecular pattern (DAMP) molecules, on cartilage metabolism was poorly characterized. In this study we examined 29-kDa amino-terminal fibronectin fragment (29-kDa FN-f)-mediated XT-1 expression mechanism and its signaling pathway, determining the role of 29-kDa FN-f in cartilage matrix synthesis

Methods:

Human articular chondrocytes were enzymatically isolated from articular cartilage and cultured in monolayer. In 29-kDa FN-f-stimulated chondrocytes, the relative levels of mRNA and protein for XT-1 were analyzed by real-time quantitative reverse transcription-polymerase

chain reaction and Western blot analysis, respectively. In order to investigate the effects of 29-kDa FN-f on XT-1, human chondrocytes were transfected with small interfering RNAs (siRNAs) targeting TLR-2.

Results:

The level of aggrecan and XT-1 in human osteoarthritis cartilage was significantly decreased compared to normal cartilage. XT-1 expression in cultured primary articluar chondrocytes showed a periodic oscillation in both mRNA and protein level. 29-kDa FN-f significantly suppressed the mRNA and protein levels of XT-1 at 14 h and 24 h, respectively. Inhibition of mitogen activated protein kinase and nuclear factor-κB signaling pathway restored 29-kDa FN-f-inhibited XT-1 expression. Knockdown of toll like receptor-2 (TLR-2) using small interference RNA revealed that the decrease of XT-1 expression by 29-kDa FN-f is mediated by TLR-2 signaling pathway. In addition, Sp3, a repressor of XT-1 promoter, was up-regulated by 29-kDa FN-f. Knockdown and overexpression experiments revealed that XT-1 expression was modulated by 29-kDa FN-f-stimulated Sp3 in primary articular chondrocytes

Conclusion:

These results demonstrated that 29-kDa FN-f plays a detrimental role in the regulation of cartilage extracellular matrix formation including XT-1 expression.

Deficiency of TLR2 and TLR4 Impairs Autophagic Flux in Chondrocytes

Yun Wang[1], Robert Terkeltaub[2] and **Ru Liu-Bryan**[3], [1]Medicine-Rheumatology, VA Medical Ctr/UCSD, San Diego, CA, [2]Medicine-Rheumatology, VA Medical Ctr/University of California San Diego, San Diego, CA, [3]Medicine-Rheumatology, VA Medical Center/University of California San Diego, San Diego, CA

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Biology and Pathology of Bone and Joint Poster I: Osteoarthritis Pathogenesis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

We have previously demonstrated that chondrocyte deficient in both TLR2 and TLR4 almost completely abolished pro-catabolic responses to rHMGB1 and LMW-HA, which are known to be present in OA joints. Since both TLR2 and TLR4 signaling can modulate autophagy, and autophagy plays an important role in cartilage homeostasis, we investigated the role of TLR2 and TLR4 in chondrocytes *in vitro*.

Methods:

Immature knee chondrocytes were isolated from TLR2/TLR4 double knockout (dKO) and the wild type (WT) mice. Microtubule-associated protein 1 light chain 3 (LC3) conversion (LC3-I to LC3-II) was examined by Western blotting. To monitor autophagic flux (the rate at which autophagic vacuoles are processed by lysosomes), the TLR2/TLR4 dKO and WT chondrocytes were transfected with a tandem fluorescent-tagged LC3 (mRFP-EGFP-LC3). Green and red fluorescent proteins have different pH stability. The acidic environment (pH<5) inside lysosome quenches the fluorescent signal of EGFP. The transfected cells were treated with HBSS containing 1% DMEM high (for starvation to induce autophagy) or chloroquine (an inhibitor of autophagic flux by inhibition of fusion of autophagosome with lysosome) for 1-2 hours and then subjected to flow cytometry analysis for fluorescence intensity of GFP and RFP or Western blot analysis for GFP or RFP expression levels.

Results: Basal level of LC3 conversion was higher in TLR2/TLR4 dKO chondrocytes, and basal level of mean fluorescence intensity (MFI) of GFP and RFP in TLR2/TLR4 dKO chondrocytes was 2.3 and 1.9 fold higher than that in WT chondrocytes. Western blot analysis also showed significantly higher level of GFP in TLR2/TLR4 dKO chondrocytes compared to WT chondrocytes. As expected, the MFI of GFP and RFP was increased by 34.8% and 19.3% respectively by chloroquine, but was decreased by 12% and 18% respectively by starvation, compared to non-treatment control in WT chondrocytes, indicating that there was autophagic flux. In contrast, despite that chloroquine was still able to increase the MFI of GFP and RFP by 27.3% and 23% respectively, starvation did not decrease the MFI of

GFP and RFP at all, compared to non-treatment control in TLR2/TLR4 dKO chondrocytes. These data suggested that autophagic flux was impaired in TLR2/TLR4 dKO chondrocytes.

Conclusion:

Chondrocytes deficient in TLR2 and TLR4 exhibit impairment of autophagic flux. Given that autophagy is a cellular homeostasis mechanism for the removal of dysfunctional organelles and macromolecules, and autophagic pathways are constitutively targets intracellular cytosolic components for lysosomal degradation, and is essential for maintaining cellular energy and metabolic homeostasis, the diminished efflux of products from autolysosomes is likely to induce a state of metabolic insufficiency and accumulates dysfunctional organelles and aggregates of macromolecules. The fact that TLR2 and TLR4 deficiency show little chondroprotection in mouse OA model may partially result from impairment of autophagic flux in chondrocytes.

TGFß1 Blocks Chondrocyte Hypertrophy and Increases Cell Viability in Cultured Cartilage Explants but Does Not Protect Against Proteoglycan Loss

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Biology and Pathology of Bone and Joint Poster I: Osteoarthritis Pathogenesis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

In osteoarthritis, cartilage degradation is partly due to chondrocytes gaining a hypertrophy-like phenotype. TGFβ1 is considered to be a protective factor for articular cartilage by blocking this hypertrophy and by inducing production of matrix molecules like proteoglycans (e.g. aggrecan). However, these functions of TGFβ1 have been identified using very young cartilage whereas TGFβ1-signaling is known to change upon maturation (ageing). Therefore, we investigated in healthy mature cartilage the effect of TGFβ1 on chondrocyte phenotype, viability and total amount of glycosaminoglycans (GAGs, as measure for proteoglycans) in long term *ex vivo* culture.

Methods: Articular cartilage explants were isolated from the metacarpophalangeal joint of healthy 5 yr old adult cows. Subsequently, explants were cultured in DMEM/F12 alone or supplemented with either 10% Fetal Calf Serum (FCS), rhTGFβ1 or rhIGF1 for the duration of 2 weeks. To investigate via which TGFβ1 receptor, ALK1 or ALK5, the observed TGFβ1 effects run, the ALK5-kinase inhibitor SB-505124 (5 µM) was used. Sulfated-GAGs were measured using dimethylmethylene blue (DMB). Cellular viability was measured with the use of XTT. To correct for the amount of cells, total DNA content of explants was measured using PicoGreen. Furthermore, gene expression of chondrocyte hypertrophy markers was measured using qPCR.

Results: Two weeks of *ex vivo* explant culture resulted in GAG loss; total GAG content was reduced from approximately 4% of wet weight in freshly isolated explants to 1% of wet weight in cultured explants. Addition of 10% FCS fully prevented this GAG loss. In contrast, TGFβ1 (10 ng/ml) was unable to inhibit GAG loss. Replacement of 10% FCS with 20 ng/ml of IGF1 also prevented GAG loss, but surprisingly, when IGF1 was combined with TGFβ1, TGFβ1 inhibited the positive effect of IGF1 on total GAG content. Compared to freshly isolated samples, expression of the chondrocyte-hypertrophy markers *Col10a1* and *Mmp13* was profoundly upregulated in explants cultured for 2 weeks. The addition of 10% FCS to the medium did not inhibit the upregulation of these genes, and even induced expression of Alkaline phosphatase (*Alpl*), another marker of chondrocyte hypertrophy. In contrast, addition of TGFβ1 (1 ng/ml or 10 ng/ml) fully blocked induction of *Col10a1* and *Mmp13* expression, and lowered expression of *Alpl* 4-fold. Additionally, TGFβ1 induced *Col2a1* expression 16-fold. TGFβ1 also enhanced chondrocyte viability, because after 2 weeks, mitochondrial activity was 50% higher in TGFβ1 treated samples compared to 10% FCS treated samples. All these effects of TGFβ1 were blocked by 5 µM of the ALK5-kinase inhibitor SB-505124.

Conclusion:

Based on our results, we conclude that in adult cartilage TGFβ1 is a potent inhibitor of chondrocyte hypertrophy and that this inhibition runs via ALK5. Additionally, TGFβ1 profoundly induced *Col2a1* production, and maintained chondrocyte viability in long term culture. In contrast, TGFβ1 was not able to counteract GAG depletion over time and even inhibited the beneficial effect of IGF1 on total GAG-content in cartilage, demonstrating that TGFβ1 does not positively regulate GAG content in adult cartilage.

The Role of TRPC6 in CXCR2-Mediated Chondrocyte Phenotypic Stability

Joanna Sherwood[1], Jessica Bertrand[1], Francesco Dell'Accio[2] and Thomas Pap[3], [1]Institute for Experimental Musculoskeletal Medicine, University Hospital Münster, Münster, Germany, [2]EMR, Queen Mary's School of Medicine and Dentistry, London, United Kingdom, [3]Institute of Experimental Musculoskeletal Medicine, University Hospital Münster, Münster, Germany

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Biology and Pathology of Bone and Joint Poster I: Osteoarthritis Pathogenesis
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: We have recently demonstrated that ELR+ CXC chemokines signaling via the CXCR2 receptor, are produced by healthy chondrocytes and are retained within the cartilage matrix via interactions with heparan sulfate proteoglycans. They act to support articular cartilage homeostasis by increasing AKT phosphorylation, thus promoting SOX9 expression, extracellular matrix production and chondrocyte survival, particularly during conditions of physiological challenge, indicated by increased chondrocyte apoptosis and cartilage degradation in $CXCR2^{-/-}$ mice following destabilization of the medial meniscus. Importantly, the transient receptor potential channel 6 (TRPC6) mechanosensitive ion channel has been shown to be a specific mediator of CXCR2 driven cell migration via AKT signaling. This project aims to investigate whether TRPC6 activity is required for chondrocyte phenotypic stability and is involved in the mechanism of CXCR2-mediated cartilage homeostasis.

Methods: Costal chondrocytes were isolated from $CXCR2^{-/-}$ mice, $TRPC6^{-/-}$ mice and their wild type littermates and expanded in standard conditions. Gene expression was assessed using real time RT-PCR. Sulfated proteoglycan content and mineralization of micromass cultured chondrocytes was measured using Alcian blue or alizarin red staining and spectrophotometric quantification. CXCR2 was activated using murine CXCL6 whilst TRPC6 was specifically activated using hyp9, a stabilized derivative of the TRPC6-selective activator hyperforin. Intracellular calcium was chelated by treating cells with BAPTA-AM prior to receptor activation. AKT phosphorylation was analyzed using Western blot. Calcium mobilization in chondrocytes was measured using a fura-2 assay.

Results: TRPC6 mRNA was detected in wild type murine chondrocytes. Chondrocytes lacking either TRPC6 or CXCR2 expressed lower levels of the chondrocyte differentiation markers SOX9 and type II collagen in comparison to wild type. Culture of chondrocytes in micromass resulted in significantly less sulfated proteoglycan production and increased mineralization by $TRPC6^{-/-}$ chondrocytes in comparison to chondrocytes obtained from wild type littermates. Activation of CXCR2 in articular chondrocytes resulted in increased intracellular calcium mobilization. In vitro activation of TRPC6 using hyp9 led to an increased AKT phosphorylation, whereas chelation of intracellular calcium inhibited CXCL6-induced phosphorylation of AKT. Finally, activation of TRPC6 resulted in a significant increase in SOX9 and type II collagen mRNA expression, together with a decrease in type X collagen mRNA expression.

Conclusion: TRPC6 calcium channel activity is required for chondrocyte phenotypic stability. In vitro TRPC6 activation is sufficient to increase AKT phosphorylation and the expression of key chondrocyte phenotypic markers in murine chondrocytes, indicating that TRPC6 may be an ideal therapeutic target aimed at preventing cartilage degradation during osteoarthritis.

Session Title: Biology and Pathology of Bone and Joint Poster I: Osteoarthritis Pathogenesis

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoarthritis (OA) and rheumatoid arthritis are degenerative diseases of the whole joint. The extracellular matrix (ECM) turnover is highly regulated in response to the inflammatory status. This leads to an increased degradation of collagen type III in the synovium and an increased degradation of collagen type II and aggrecan in cartilage. The spleen tyrosine kinase (Syk) is involved in pro-inflammatory signaling and R406, the active metabolite of the anti-inflammatory drug, Fostamatinib inhibits Syk. Fostamatinib has been tested in both phase II and phase III clinical trials with mixed results. The aim of this study was to investigate R406 effects on the ECM turnover of the synovium and cartilage under inflammatory conditions *ex vivo*.

Methods: Cartilage turnover was investigated using a bovine cartilage explant (BEX) model. Synovial tissue turnover was investigated using a human synovial membrane OA explant (SME) model. **BEX:** BEX was cultured 3 weeks without (w/o) treatment, or in the presence of 2 ng/mL TNFα + 10 ng/mL OSM (O+T), or O+T with R406 in 7 different concentrations from 10 µM to 0.156 µM. **SME:** The explants were cultured for 2 weeks w/o treatment, or in the presence of 10 ng/mL TNFα, or TNFα with 5 µM, 0.5 µM or 0.05 µM R406. Both models were cultured with O+T or TNFα with the p38 inhibitor 10 µM SB203580. The tissue turnover was assessed with the biomarkers; C2M, C3M, acMMP3 the ARGS neo-epitope in the supernatant with ELISA.

Results: BEX) O+T increased the MMP-mediated degradation of collagen type II (C2M) after 14 days and ARGS after 7 days compared to w/o ($p<0.0001$). All concentrations of R406 inhibited the release of C2M in a dose depended manner. R406 at 10 µM ($p<0.0001$), 5 µM ($p<0.0001$) and 2.5 µM ($p = 0.0281$) decreased the release of ARGS compared to O+T, whereas lower concentrations of R406 did not affect ARGS (Figure 1A). SB202580 at 10 µM decreased C2M ($p<0.0001$), but did not affect the ARGS release compared to O+T. **SME)** TNFα increased the released of the MMP-mediated degradation of collagen type III (C3M) ($p=0.0400$) and activated MMP3 (acMMP3) ($p=0.0371$) compared to w/o. R406 at 5 µM tended to decrease the release of C3M, while R406 at 0.5 µM ($p=0.0219$) increased and 0.05 µM tended to increased C3M compared to TNFα. (Figure 1B). R406 tended to decrease the release of acMMP3 at 5 µM and had no effect at 0.5 µM and 0.05 µM compared to TNFα. SB203580 did not affect C3M or acMMP3 compared to TNFα.

Conclusion: These data show that R406 can inhibit pro-inflammatory ECM joint degradation at concentrations higher than 0.5 µM, but at 0.5 µM or lower R406 increased the inflammatory degradation of collagen type III and had no effect on aggrecan degradation. In contrast, the p38 inhibitor SB203580 had no effect on synovial ECM turnover or aggrecan degradation, underlining the importance of understanding the differences between inhibitors of pro-inflammatory mediators and their effect on the joint tissue.

Novel Chitosan Hydrogels for the Treatment of Osteoarthritis: Mechanical Support, Lubrication and Prevention of Cartilage Degradation in a Rabbit Model of Osteoarthritis

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Biology and Pathology of Bone and Joint Poster I: Osteoarthritis Pathogenesis
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Chitosan, a glucosamine polysaccharide, is a good candidate for viscosupplementation in OA joints. Herein, we report the physico-chemical properties and the effects of an innovative chitosan hydrogels in the rabbit anterior cruciate ligament model ACLT model of OA.

Methods:

The mechanical and rheological properties of animal-free ultrapure chitosan hydrogels (Vegetech inside™, Synolyne Pharma, Belgium) were characterized using a mechanical compression equipment (Instron, US) and the Discovery Hybrid DHR-2 rheometer (TA Instruments, US). The properties were compared with those of synovial fluids and of hyaluronan: injection force, capacity to absorb shocks at walk frequency, ability to lubricate (viscosity at rest), and biodegradation kinetics. In addition, the chitosan hydrogels were mixed with patient synovial fluid (in a 1:1 ratio, v/v), and the ex vivo rheological properties of the mix were characterized.

OA was surgically induced by the transection of the anterior cruciate ligament (ACLT) in female HYLA albino rabbits. One week after surgery, animals were randomly divided into 2 groups. One group (n=9) was injected intra-articularly (right knee) with 600ml saline solution (control) and the other group (n=10) with 600ml of a chitosan hydrogel (VI002, Synolyne Pharma, Belgium). X-rays from the right knee were performed at the time of sacrifice and scored with the Kellgren and Lawrence (K&L) scale. Animals were euthanized 9 weeks after surgery and a macroscopic evaluation of cartilage was done. Histological sections of cartilage areas and of synovial membrane were evaluated according to the OARSI histopathology initiative.

Results:

Chitosan hydrogels were less prone to in vitro oxidative biodegradation than crosslinked and non crosslinked hyaluronan viscosupplements. Their mechanical and lubrication capacity are higher than those of synovial fluid and of hyaluronan viscosupplements. In addition, chitosan hydrogels were easily injected through 25G to 27G needles, with an injection force lower than that of a highly cohesive hyaluronan viscosupplement. Interestingly, when the chitosan hydrogels were mixed with the synovial fluid of OA patients, the mechanical and lubrication capacity were found to be restored.

The X-rays analysis showed a significant decrease ($p=0.0079$) of the K&L score in rabbits injected with the VI002 chitosan hydrogel (0.40±0.30) compared with control (1.78±0.32). The macroscopic OA cartilage lesions significantly decreased in the lateral compartment in animals treated with VI002 compared to control (21.40±2.67 with VI002 vs. 36.89±3.79 with control; $p=0.0041$). The synovitis histological scores, mostly synoviocytes hyperplasia and inflammatory infiltrate criteria, were significantly reduced by VI002 (13.25±0.51 with VI002 vs. 14.79±0.35 with control, $p=0.0040$). Finally, the injection of VI002 hydrogel significantly improved the structure of cartilage (6.54±0.35 with VI002 vs. 8.42±0.38 with control; $p =0.0017$).

Conclusion:

These results are confirming the high potential of the *mono-dose viscosupplementation* with non crosslinked chitosan hydrogels

specifically designed to protect cartilage and decrease the symptoms associated with OA.

The Proteomic Profile of Histological Samples Derived from a Surgical Mouse Model of Osteoarthritis Reveals an Unexpected Mode of Action for the Anti-Aggrecanase-2 Monoclonal Antibody CRB0017

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Biology and Pathology of Bone and Joint Poster I: Osteoarthritis Pathogenesis

Session Type: ACR Poster Session B

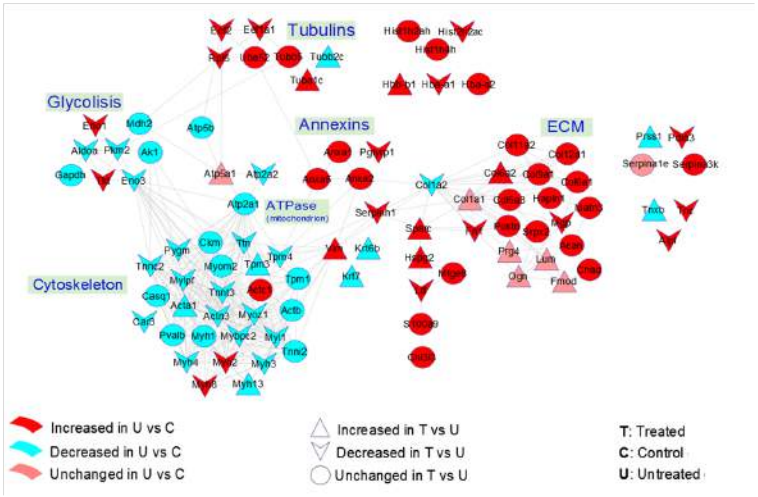
Session Time: 9:00AM-11:00AM

Background/Purpose : CRB0017 is a novel therapeutic monoclonal antibody that recognizes the spacer domain of aggrecanase-2, a key enzyme in the degradation of extracellular matrix (ECM) in osteoarthritis (OA). CRB0017 showed a marked cartilage protection in different models of OA in rodents (accompanying abstract by Caselli et al). Because CRB0017 does not recognize the catalytic domain of aggrecanase-2 and, therefore, does not simply inhibit the cleavage of aggrecan, its molecular mode of action on ECM proteins is not fully understood. So, we performed the proteomics analysis of histological samples derived from a surgical model of OA, the Destabilization of Medial Meniscus (DMM) in mice, in which intra-articularly injected CRB0017 had markedly counteracted cartilage degradation (in vivo results in the accompanying abstract by Caselli et al).

Methods : DMM was performed in C57BL/6J mice (10 weeks old at surgery; CRB0017 injection [72 µg in 4 µL] 1 week after surgery, injection repeated after 1 and 2 months, sacrifice at 3 months). At sacrifice, the femorotibial joints were explanted and processed for histology. Histological samples in paraffin from sham, DMM vehicle and DMM CRB0017 mice (9 samples/group) were processed for proteomics analysis. Briefly, samples were deparaffinized, trypsinized and analyzed by LC-MS, and lists of identified proteins were evaluated by MAPROMA cluster and network analyses.

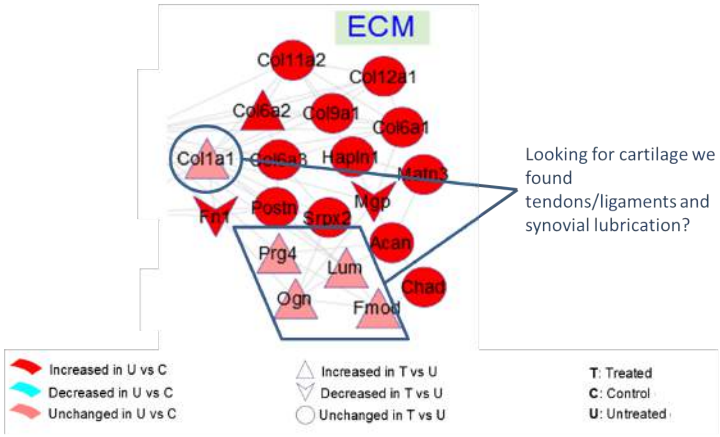
Results : About 400 proteins were identified, and the differential proteomics analysis of sham and DMM animals revealed the expected changes (i.e. general increase in ECM protein turnover, as depicted in Figure 1), confirming the validity of the selected protocol.

Figure 1 – Network analysis of differentially expressed proteins in histological samples from the femorotibial joints of sham operated control mice (**C**), DMM mice untreated (**U**) or DMM mice treated with CRB0017 (**T**)



The differential analysis between DMM mice treated with vehicle or CRB0017 revealed that the latter affected a series of proteins that have not been associated so far with aggrecanase-2 activity. In particular, (as shown in the enlarged particular in Figure 2) CRB0017 seems to preserve a homogeneous class of ECM proteins, the small leucine-rich repeat proteoglycans (SLRPs) fibromodulin, lumican and osteoglycin, and the levels of lubricin, one the most relevant components of joint lubrication.

Figure 2 – Zoom-in of Figure 1 on ECM proteins differentially expressed between DMM mice treated with CRB0017 (**T**) and untreated DMM mice (**U**); **C** are sham operated control mice.



Col1a1 = alpha-1 type I collagen; Fmod = fibromodulin; Lum = lumican; Ogn = osteoglycin; Prg4 = lubricin

Conclusion : Proteomics analysis of histological samples from joints of DMM mice treated with CRB0017 revealed that this monoclonal antibody against the spacer domain of aggrecanase-2 can modulate a series of proteins whose association with aggrecanase has not been codified yet (besides fibromodulin), but whose contribution to OA progression is well documented. These data, therefore, point out a new potential mode of action for therapeutic anti-aggrecanase antibodies.

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Biology and Pathology of Bone and Joint Poster I: Osteoarthritis Pathogenesis
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Growing interest has arisen in the search for specific pathophysiology and biomarker for rheumatoid arthritis (RA) utilizing synovial fluid (SF) proteomic analysis. However the difference of protein profiles between SF and serum is still unclear. The objective of this study was to clarify the difference of protein signatures in RASF and serum.

Methods:

SF was collected from 10 untreated RA patients and 10 osteoarthritis (OA) patients. Serum was collected from 30 untreated RA patients and 30 healthy controls (HC). Total of 1128 proteins were quantitatively measured by comprehensive high-throughput proteomics assay using nucleic acid aptamers (SOMAscan™ Assay; Somalogic Inc., CO, USA). Comparison pathway analysis was performed with Ingenuity Pathway Analysis (IPA; Ingenuity system, CA, USA) and statistically extracted differentially up- or down-regulated proteins (fold change >1.5 or <0.66, $p<0.05$) in RA SF compared to OA SF and RA serum compared to HC serum.

Results:

A total of 167 of known pathways were extrapolated from RA SF, while only 23 pathways were extrapolated from RA serum ($p<0.01$ in the Benjamin-Hochman's multiple testing correction). The inflammatory signaling pathway was extrapolated from both, RA SF and serum, however osteoblast, osteoclast and chondrocyte signaling pathway was uniquely extrapolated from RA SF (-log p value=13.2). Focusing on the SF proteins associated with bone and cartilage metabolism, bone morphogenic protein (BMP)-6, 7 which proteins promote osteogenesis and RANKL/RANK/OPG signaling proteins including osteoprotegerin were significantly lower in RA SF compared to OA SF. ($p<0.05$) Unexpectedly, dickkopf (Dkk)-1 and -4 those that negatively regulated Wnt signaling pathway were significantly suppressed in RASF. ($p<0.05$) Futhermore, BMP and Dkk family proteins negatively correlated with pro-inflammatory cytokines in RA SF especially IL-6 (range of $r=-0.613$ to -0.400, $p<0.05$).

Conclusion:

Novel proteomic analysis of the RA synovial fluid revealed the clear difference of protein expression in serum and SF, especially highlighting the distinct protein profiles of aberrant bone metabolic turnover and cartilage formation in RA affected joint.

Colonic Intraepithelial Lymphocytes Produce IL-6 in Response to Resident Bacteria to Modulate Epithelial Barrier Function

Gaurav Mehta[1], Emilie H. Regner[2], Neha Ohri[2], Sean P. Colgan[2] and **Kristine A. Kuhn**[2], [1]Division of Rheumatology, University of Colorado School of Medicine, Aurora, CO, [2]University of Colorado School of Medicine, Aurora, CO

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Dysbiosis of colon bacteria has emerged as a likely contributor to diseases such as rheumatoid arthritis and spondyloarthropathies. Interactions between the microbiota and distal gut are critical for human health. These interactions are focused at the level of the colonic mucosa, and intestinal epithelial homeostasis is regulated by multiple signals emanating from both microbes and immune cells. As intraepithelial lymphocytes (IELs) are positioned within the epithelial barrier, we hypothesized that colon bacteria can modulate epithelial barrier function through interactions with IELs.

Methods: Epithelial cells were harvested from wild type C57Bl/6 mice, and lymphocytes evaluated by flow cytometry for T cell surface markers or magnetically sorted and stimulated ex vivo with mitogen for evaluation of cytokine production by ELISA. To model dysbiosis, mice were treated with ampicillin, metronidazole, neomycin, and vancomycin in the drinking water. Recolonization of mice occurred by cohousing antibiotic treated mice with unmanipulated littermates. Epithelial barrier integrity was evaluated by paracellular permeability of indigestible FITC-dextran in vivo and in vitro using the model human colonic cell line T84. Contact of host bacteria with the epithelium was performed by FISH using a universal bacterial probe. Protein and RNA analyses were done by Western blot and qRT-PCR, respectively.

Results: Our data demonstrate the major subpopulation of IELs in the mouse colon are CD3+, CD4-CD8-, and TCRβ+, express cell surface markers consistent with activated lymphocytes, and produce large amounts of IL-6 under mitogenic stimulation. Administration of significantly decreased the number of activated, IL-6-secreting IELs. This was reversible, as recolonization resulted in normalization of the IEL numbers, IL-6 secretion, and epithelial barrier integrity. The epithelial barrier in *IL-6*$^{-/-}$ and antibiotic-treated mice was noted to have increased paracellular permeability and closer interaction with luminal bacteria. IL-6 was found to signal in colonic epithelial cells and resulted in increased epithelial barrier integrity and claudin 1 expression in model epithelia.

Conclusion: We conclude that the host microbiota provides a homeostatic role through regulation of IEL derived IL-6. In turn, IL-6 participates in a barrier protective role in which it stimulates increased tight junction protein expression and decreased contact between luminal bacteria and the host. We postulate that dysbiosis, through the loss of IEL-derived IL-6, in combination with genetic risk, results in increased immune activation at the mucosal barrier, leading to downstream autoimmune responses.

Ajulemic Acid Is a Novel Cannabinoid That Suppresses the Secretion of TNF-α and IFN-α from the Peripheral Blood Mononuclear Cells of DM Patients In Vitro

Paul Alves[1,2], Elizabeth Robinson[1,2], Muhammad Bashir[1,3], Rui Feng[4] and Victoria P. Werth[1,2], [1]Dermatology, Veterans Affairs Medical

Center, Philadelphia, PA, [2]Dermatology, University of Pennsylvania, Philadelphia, PA, [3]Department of Dermatology, University of Pennsylvania, Philadelphia, PA, [4]Biostatistics and Epidemiology, University of Pennsylvania, Philadelphia, PA

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

DM is an autoimmune disease with cutaneous symptoms often accompanied by inflammatory muscle and/or lung disease. Current therapies for DM are often toxic and ineffective. Ajulemic acid (AJA) is a synthetic, non-psychoactive cannabinoid potentially useful for treating DM. Experiments presented here quantify the capacity of AJA to suppress the secretion of TNF-α and IFN-α, two pro-inflammatory cytokines implicated in the pathogenesis of DM, from the peripheral blood mononuclear cells (PBMCs) of DM patients.

Methods:

PBMCs were isolated from the blood of 22 DM patients and then treated with 0, 3, 10 and 15 μM concentrations of AJA and incubated at 37°C and 5.0% CO_2 for 18 hours both with and without lipopolysaccharide (LPS) in the case of TNF-α and with and without CpG oligonucleotides (CpG) in the case of IFN-α. LPS and CpG were used to stimulate secretion of TNF-α and IFN-α, respectively, in order to ensure sufficient production for quantifying the effects of AJA via ELISA. Statistical analyses were performed on TNF-α and IFN-α secretion values normalized by natural log transformation, and unstimulated TNF-α secretion values below 2 pg/ml were excluded from analysis as outliers.

Results:

The LPS-stimulated PBMCs treated with 0 (n=17), 3 (n=16), 10 (n=16) and 15 (n=15) μM AJA secreted mean (standard deviation = SD) TNF-α values of 7.37 (1.33), 7.73 (1.03), 5.60 (1.91) and 4.20 (1.92) pg/ml, respectively. There was a statistically significant difference between the means using one-way ANOVA analysis ($p<0.0001$). In the *post hoc* analysis, AJA suppressed the secretion of TNF-α from LPS-stimulated PBMCs at 10 μM AJA (adjusted $p=0.0115$) and 15 μM AJA (adjusted $p<0.0001$), but not at 3 μM AJA (adjusted $p=0.9098$), when compared to LPS-stimulated PBMCs not treated with AJA. Unstimulated PBMCs treated with 0 (n=11), 3 (n=9), 10 (n=9) and 15 (n=7) μM AJA secreted mean (SD) TNF-α values of 2.27 (1.40), 2.47 (1.75), 1.83 (1.57) and 0.14 (1.72) pg/ml, respectively. Analysis by one-way ANOVA found a statistically significant difference between the means ($p=0.0303$). In the *post hoc* analysis, AJA suppressed the secretion of TNF-α from unstimulated PBMCs at 15 μM AJA (adjusted $p=0.0444$), but not at 3 μM AJA (adjusted $p=0.9925$) or 10 μM AJA (adjusted $p=0.9274$), when compared to unstimulated PBMCs not treated with AJA.

CpG-stimulated PBMCs treated with 0 (n=8), 3 (n=7), 10 (n=8) and 15 (n=7) μM AJA secreted mean (SD) IFN-α values of 5.33 (0.77), 1.38 (2.19), 1.06 (0.78) and -0.03 (1.68) pg/ml, respectively. There was a statistically significant difference between the means using one-way ANOVA analysis ($p<0.0001$). In the *post hoc*analysis, AJA suppressed IFN-α secretion from CpG-stimulated PBMCs at 3 μM AJA (adjusted $p=0.0004$), 10 μM AJA (adjusted $p=0.0010$) and 15 μM AJA (adjusted $p=0.0003$) when compared to CpG-stimulated PBMCs not treated with AJA. Unstimulated PBMCs secreted too little IFN-α to test the effects of AJA.

Conclusion:

AJA is a novel, non-psychoactive cannabinoid that suppressed secretion of TNF-α and IFN-α from the PBMCs of DM patients *in vitro*. Thus, AJA may offer patients with DM an effective therapy with less toxicity than other treatments currently available.

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

A pathophysiological link of free fatty acids (FFA) to inflammation is supported by the observation that chronically elevated serum FFA levels as found in obese patients are associated with numerous inflammatory cardiovascular and metabolic diseases. Also, FFA have been shown to induce signaling cascades and changes in gene expression in monocytes, adipocytes and hepatocytes *in vitro*. However, the influence of FFA on cells of bone metabolism is largely unknown so far. As obesity is associated with a higher risk of osteoarthritis also in non-weight bearing joints and increased amounts of visceral fat are associated with lower bone density, FFA may also play a role in bone metabolism.

Therefore, our main objective was to analyze the effect of FFA on cells of bone metabolism, specifically osteoblasts, in the context of rheumatic diseases. A further objective was to examine whether Wnt or TLR signaling is involved in FFA-mediated effects in osteoblasts.

Methods:

Primary osteoblasts were isolated from cancellous bone of rheumatoid arthritis (RA) or osteoarthritis (OA) patients undergoing knee joint surgery. The osteoblasts were stimulated with saturated and unsaturated FFA. Immunoassays were used to quantify protein secretion. mRNA expression levels were quantified by real-time PCR. Mineralization activity was measured by alizarin red S staining of mineralized matrix.

Results:

FFA induced a strong secretion of the proinflammatory cytokine IL-6 and the chemokine IL-8 in cultured osteoblasts, while showing a high variability between patients (IL-6: up to 9.1-fold ↑; IL-8: up to 221-fold ↑). On the other hand, RANKL and OPG, important regulators of osteoclastogenesis and osteoclast activity, osteoblast activity markers (ALP and collagen type I) and markers of osteoblast differentiation (SOX9, RunX2, osterix, osteocalcin) were not affected by FFA stimulation. Mineralization activity of FFA stimulated osteoblasts did not change significantly. The expression of Wnt signaling molecules (axin-2 and β-catenin) also remained unchanged. However, FFA-induced IL-8 secretion could significantly be reduced by blocking TLR4 but not by blocking TLR2. Of note, both saturated and unsaturated FFA caused a pro-inflammatory response in osteoblasts.

Conclusion:

Inflammation is centrally involved in many rheumatic diseases. Increased inflammatory activity is associated with decreased bone density. Our data therefore suggest that locally increased FFA levels may promote inflammation and thus inflammation-mediated degradation of bone via osteoblasts. These effects are at least in part mediated by TLR4, while TLR2 and Wnt signaling appear not to be involved.

Th17 Cytokines Regulate Osteoclastogenesis in Rheumatoid Arthritis

MIN-YOUNG JUNG[1], Hae-Rim Kim[2], HYUN-SOOK KIM[3], HO-YOUN KIM[1] and Sang Heon Lee[4], [1]Konkuk university hospital, Seoul, South Korea, [2]Division of Rheumatology, Konkuk University School of Medicine, Seoul, South Korea, [3]Soonchenhyang university school of medicine, Seoul, South Korea, [4]Konkuk University Hospital, Seoul, South Korea

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: This study aimed to determine the regulatory effect of Th17 cytokines on osteoclastogenesis in rheumatoid arthritis (RA).

Methods: The expression of interleukin (IL)-17 and receptor activator of nuclear factor kappa-B ligand (RANKL) was determined in synovial tissue, fibroblast-like synoviocytes (FLS), and synovial fluids of RA patients using immunohistochemical staining, ELISA and real-time PCR. Th17 cytokines-induced RANKL expression was studied in RA FLS by using real-time PCR, luciferase activity assays, and western blot. Human peripheral blood monocytes were cultured with macrophage colony-stimulating factor (M-CSF) and Th17 cytokines, following which osteoclastogenesis was evaluated by counting the number of tartrate-resistant acid phosphatase (TRAP)-positive multinucleated cells. Osteoclastogenesis was also evaluated after human monocytes were co-cultured with IL-17-prestimulated FLS.

Results: There was significant correlation between RANKL and IL-17 levels in RA synovial fluid. IL-17, IL-21, and IL-22 increased the expression of RANKL mRNA in RA FLS and the IL-17-induced RANKL expression decreased by the inhibition of Act1, TRAF6, NF-κB and AP-1. Th17 cytokines and IL-17-prestimulated FLS induced osteoclastogenesis from monocytes in the absence of exogenous RANKL. The osteoclastic effect was reduced by inhibition of TNF-a.

Conclusion: Th17 cytokines have a dual effect on osteoclastogenesis in RA: direct induction of osteoclastogenesis from monocytes and upregulation of RANKL production in RA FLS. This Th17 cytokine/RANKL axis could be a potential therapeutic target for bone destruction in RA.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Lipidomics is an emerging field in biomedical research. Free Fatty Acids (FFA) are important mediators of the lipid metabolism which can play a role in a number of biological functions other than energetic ones. FFA have been described to affect gene expression patterns in monocytes and macrophages, as well as modulation of CD4+ T-cell function. Since a role for FFA in the pathogenesis of rheumatic diseases can he hypothesized, we aimed to evaluate the serum FFA profile in Rheumatoid Arthritis (RA) patients.

Methods: serum FFA (palmitic, stearic, oleic, palmitoleic, linoleic –LA–, a-linolenic –ALA–, g-linolenic –GLA–, eicosapentanoic –EPA–, docosahexanoic –DHA– and arachidonic –AA–), were quantified by LC-MS/MS chromatography after a methyl-*tert*-butylether

extraction protocol in samples from 69 healthy controls and 129 RA patients. Moreover, 13 prospectively-followed RA patients undergoing TNFa-blockade were included. IFNg, TNFa and MCP1 serum levels were quantified by immunoassays.

Results: Lower levels of palmitic ($p<0.0001$), oleic ($p=0.005$), palmitoleic ($p=0.003$), ALA ($p=0.023$), EPA ($p<0.0001$), DHA ($p<0.0001$) and AA ($p=0.031$) were found in RA patients. Although w3-polyunsaturated FFA were mainly decreased, there was not a general pattern of FFA associated with the chain length or the degree of desaturation, but individual FFA within a given class seems to exhibit a particular pattern. Principal Component Analysis supported this observation (Figure 1). These differences were more pronounced in patients with two copies of the shared epitope (SE) compared to patients with a single copy or SE-negative. No associations with disease activity or autoantibodies status were found.

Decreased FFA were associated with disease duration, whereas stearic acid exhibited a positive correlation ($r=0.431$, $p<0.001$). Additionally, stearic acid was positively correlated with IFNg levels ($r=0.408$, $p<0.0001$), whereas EPA and DHA negatively did ($r=-0.226$, $p=0.016$ and $r=-0.237$, $p=0.011$, respectively). Equivalent results were observed with MCP-1 levels, but no associations were found with TNFa. No differences by glucocorticoid or methotrexate usage were found.

Finally, decreasing DHA, EPA and AA levels (all $p<0.050$) were found in patients who exhibited no response upon TNFa-blockade, whereas no changes were found among good-responders ($n=5$; $p>0.05$ in all cases).

Conclusion: RA patients exhibited a different serum FFA profile associated to disease duration and inflammatory cytokines. Specific FFA were found to be decreased, independently of their chemical characteristics. Decreased levels of some FFA were associated with poor clinical outcome upon TNFa-blockade. These findings could support the use of fatty acid supplementation in RA and prove this field worthy or further research.

Active Non-Canonical NF-Kappab Signaling in Microvessels of Atherosclerotic Lesions in Coronary Arteries Is Associated with Inflammatory Cell Infiltration and Myocardial Infarction

Chrissta X. Maracle[1], Rabia Agca[2], Boy Helder[1], Hans W. Niessen[3], Mike T. Nurmohamed[2] and Sander W. Tas[4], [1]Clinical Immunology and Rheumatology, Amsterdam Rheumatology and immunology Center | Academic Medical Center, Amsterdam, Netherlands, [2]Rheumatology, Amsterdam Rheumatology and immunology Center, VU University medical center, Amsterdam, Netherlands, [3]Pathology, VU University Medical Center, Amsterdam, Netherlands, [4]Clinical Immunology and Rheumatology, Amsterdam Rheumatology and immunology Center | Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands

Session Date: Monday, November 9, 2015

Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Patients with chronic inflammatory diseases (CID) have higher risk of developing cardiovascular disease which may be in part due to increased systemic inflammatory burden. In atherosclerosis, extensive neovascularization is associated with plaque instability and an increased chance for myocardial infarction (MI). We have established that the non-canonical NF-κB pathway, with its central regulator NF-κB inducing kinase (NIK), in endothelial cells (EC) contributes to pathological angiogenesis in synovial tissue of patients with various forms of arthritis, including rheumatoid arthritis (RA). Thus, we hypothesized that NIK^+EC may also contribute to neovascularization in atherosclerotic lesions.

Objective:

Evaluate expression of NIK in microvessels in atherosclerotic lesions from patients with and without CID and determine if it is associated with inflammatory cell influx, systemic inflammation or involvement of coronary arteries in MI.

Methods:

We obtained atherosclerotic coronary arteries from 11 individuals with CID (5 RA, 4 psoriasis, 2 inflammatory bowel disease) along with 11 matched controls without CID, all of whom died of fatal MI. Coronary arteries were immunohistochemically stained with antibodies against NIK, CD31/34 (EC), myeloperoxidase (neutrophils), CD45 (lymphocytes), CD68 (macrophages) and tryptase (mast cells). NIK positive vessel density (VD) (NIK^+ vessels/mm2) and immune cell density (ICD cells/mm2) were calculated for right coronary artery (RCA) (internal control; remote area) and left anterior descending artery either implicated in MI (LAD+) or not (LAD-). Differences in NIK^+ vessel density and cell densities in CID and controls, and between LAD+, LAD- and RCA, were analyzed using non-parametric Spearman's Rank correlation or non-parametric Mann-Whitney U test.

Results:

NIK^+ EC were present in atherosclerotic lesions of all coronary arteries. NIK^+VD significantly correlated with ICD of all characterized immune cells: leukocytes ($r=0.5227$; $p<0.0001$), macrophages ($r=0.3397$, $p<0.0001$), mast cells ($r=0.4205$, $p<0.0001$) and neutrophils ($r=0.2129$, $p=0.0016$). No significant differences were found in NIK^+VD in CID patients versus healthy, however, influx of leukocytes and macrophages per NIK^+ microvessel was significantly higher in CID lesions. An increase in NIK^+microvessels was also noted in LAD+ as compared to LAD- tissues ($p=0.0139$) in both healthy and CID patients.

Conclusion:

NIK^+ microvessels are present in high numbers in atherosclerotic lesions and are strongly associated with the influx of inflammatory cells. Systemic inflammation is not a prerequisite for activation of this pathway in EC in atherosclerotic lesions, but our findings suggest that non-canonical NF-κB signaling is more pronounced in patients with CID resulting in the attraction of more immune cells that may further enhance progression of atherosclerotic lesions. Since activation of the non-canonical NF-κB pathway in EC induces angiogenesis and NIK^+ vessels are increased in coronary arteries associated with MI, non-canonical NF-κB signaling in EC may drive neovascularization and plaque instability, thus increasing the chance of developing a (fatal) MI.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

SOX5 is known as a transcription factor which primarily involved in in the regulation of embryonic development, cell fate, and chondrogenesis. To date, little is known the effect of SOX5 on rheumatoid arthritis (RA). We previously reported a RANKL promoter SNP confers an elevated promoter activity after stimulation via binding to a SOX family transcription factor SOX5 and is associated with younger age at onset of rheumatoid arthritis (RA) *(Arthritis Rheum 2010; 62(10):2864-75.)*. Subsequently, we confirmed that SOX5 could up-regulate RANKL expression in RA synovial fibroblast(SF) and participate in the bone erosion of RA. Here, we examine the effect of SOX5 on the migration and invasive characteristics of RA synovial fibroblasts.

Methods:

Rheumatoid synovial fibroblasts cell line MH7A were treated with SOX5 small interfering RNA (SOX5-siRNA) and recombinant Adenovirus SOX5 expression vectors (Ad-SOX5). Migration and invasion and of RASF was assessed by transwell matrigel^{TM}invasion chambers and collagen gel assays. Modulation of MMP9 expression in RASF was analyzed by real-time PCR, western blot and luciferase assay. Collagen-induced arthritis (CIA) DBA/1 mouse locally injected with lentivirus-shSOX5 was used to examine the effect of SOX5 on MMP9 expression in vivo.

Results:

Overexpression of SOX5 significantly promoted cell migration, invasion and MMP-9 expression in RASF. Migration and invasion of RASF was markedly decreased by silencing SOX5 expression in RASF but could be reverted by added the recombinant MMP9 cytokine into RASF. Overexpression of SOX5 enhanced the promoter activity of MMP9 in Hela cell. Local silencing SOX5 in CIA mice inhibited the synovitis and bone erosion and accompanied by the reduced MMP9 expression in synovium of CIA mice.

Conclusion:

These findings indicate transcription factor SOX5 plays an important role in regulating RASF migration and invasion by modulation MMP9 expression, suggesting SOX5 as a potential therapeutic target for the treatment of RA.

DNA Hydroxylmethylation Regulates Pro-Inflammatory Cytokine Expression in Macrophages

Fangfang Sun[1,2], Renate E. Gay[1], Beat A. Michel[1], Shuang Ye[2], Steffen Gay[1], Michel Neidhart[1] and Emmanuel Karouzakis[1], [1]University Hospital Zurich, Center of Experimental Rheumatology, Switzerland, Zurich, Switzerland, [2]Department of Rheumatology, South Campus, Renji Hospital, School of Medicine, Shanghai Jiao Tong University, China, Shanghai, China
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis Poster II
Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Activated macrophages are found in the inflamed and hyperplasic synovial RA tissues. Macrophages are the main producers of high levels of pro-inflammatory cytokines such as TNF-a and IL-6. Our group has already reported a persistent global hypomethylation in RA tissues and RA synovial fibroblasts (RASF). Recent findings showed that the 5-methylcytosine (5-mC) modification of DNA can be converted to 5-hydroxymethylcytosine (5-hmC) through the activation of the family of Ten-Eleven-Translocation (TET1-3) enzymes which may explain the genomic hypomethylation in RA. In the current study, we investigated the 5-hmC modification in monocyte derived macrophages stimulated with lipopolysaccharide (LPS), and characterized the function of TET1-3 enzymes during inflammation.

Methods:

The leukemic monocytic cell line THP-1 was differentiated into macrophages in the presence of 50nM phorbol myristate acetate (PMA). Primary human monocytes were isolated using CD14 magnetic beads from peripheral blood mononuclear cells (PBMCs). Next, macrophages were prepared by culturing the CD14 monocytes with macrophage colony stimulating factor (M-CSF) for 6 days. THP-1 derived macrophages and human primary macrophages were stimulated with 100 ng/ml LPS for 2 hours. At different time points, the mRNA levels of TETs were analysed by quantitative Real-time PCR. The global 5-hmC levels were quantified by DNA dot blot assay and presented as chemiluminescence intensity in arbitrary units (AU). Hydroxymethylated DNA immunoprecipitation (hMeDIP) was applied to analyse the levels of 5-hmC in different areas of the TNF-a (TNF-a 1-4) and IL-6 promoter. THP-1 derived macrophages were transfected with TET1 siRNA and then stimulated with 100ng/ml LPS. TNF-a and IL-6 levels were measured in the supernatants by ELISA.

Results:

Global 5-hmC levels were significantly up regulated during differentiation from THP-1 cells to macrophages (Dot blot: ratio to ssDNA 0h 0.59, 48h 4.13 AU). After 48 hours of differentiation, we observed an increase of 5-hmC enrichments in four different regions of the TNF-a. (hMeDIP: TNF-a1: 2.42, TNF-a2: 2.25, TNF-a3: 2.03, TNF-a4: 2.08, fold enrichment, n=3). Stimulation of the macrophages with LPS for 0.5h showed a significant increase of TET1 mRNA (TET1: 0.5h 1.93±0.7, fold change, n=4, p=0.03). Interestingly, LPS stimulation increased 5-hmC levels in the promoter of TNF-a and IL-6 in primary human macrophages (hMeDIP: TNF-a 1.64±0.2, n=3, p=0.03; IL-6 1.74±0.2, n=3, p=0.03). Since, TET1-3 enzymes catalyze the synthesis of 5-hmC, we knocked down TET1 with siRNA in THP differentiated macrophages and found that TNF-a and IL-6 production was reduced by 46% and 44% respectively (n=4).

Conclusion:

For the first time, we showed that TET1 contributes to the activation of macrophages through the regulation of 5-hydroxymethylation in the promoter of pro-inflammatory cytokine genes. The TET1 enzyme could be a promising therapeutic target to inhibit the persistent inflammation caused by macrophages in RA.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Th-9 cells are distinct T cell subset secreting IL-9 and associated with allergic and parasitic diseases and

produced by Th9 cells. Contribution of these cells autoimmune colitis (1, 2), uveitis (3) and experimental autoimmune encephalomyelitis (EAE) has ben reported recently. However, reports on their presence or enrichment at the pathologic sites and impact on the local inflammatory cascade in rheumatoid arthritis (RA) remain unknown. Functional relevance of newly described IL-9 producing CD4+ T cells is not yet been clearly described in RA. This study is an attempt to determine the status of Th9 cells in the disease site in RA patients. Here for the first time, we show that Th9 cells or IL-9 can modulate survival of neutrophils and T cell function and enhances the local inflammatory cascade in RA inflicted joints.

Methods: We recruited treatment naïve active RA patients (n=26) with DAS28-ESR >3.5. Polymorphonuclear (PMNs/Neutrophil) and mononuclear cells (MNCs) were isolated both from the peripheral blood (PBL) and synovial fluid (SF). Neutrophils were cultured in presence of recombinant IL-9 (rIL-9), synovial fluid of RA patients (RA SF), IL-9 neutralizing antibody (aIL-9). MNCs were cultured with plate bound anti-CD3 & anti-CD28 along with rIL-9, RA SF, aIL-9. To easure apoptosis neutrophils were stained for Annexin V and their lysate was immunobloted for expression of anti-apoptotic protein MCL-1. MNCs were stained with CD4 and IL-9 to determine the frequency and function of Th9 cells. Frequencies of other cytokine (IFN-γ, TNF-α, IL-17) producing CD4+ T cells were evaluated by intracellular cytokine staining.

Results: Significant enrichment of Th9 cell was noted in synovial fluid (SF) of RA patients. Recombinant IL-9 (rIL-9) and RA SF reduced the spontaneous apoptosis of neutrophils along with higher expression of survival protein MCL-1. Blocking endogenous IL-9 of SF decreased their survival and rescued their apoptosis, suggesting the critical role of IL-9 in prolonged neutrophil survival in RA. IL-9 and RA SF also increased the frequencies of TNF-α+, IFN-γ+, IL-17+ CD4+ T cells. Interestingly, both synovial and peripheral Th9 cell frequency showed significant correlation with disease activity DAS-28 ESR score.

Conclusion: Th9 cells or IL-9 plausibly mediate synovial inflammation by prolonging the neutrophil survival and enhancing inflammatory cytokine producing T cells in the RA joint. So blocking IL-9 by specific antibody could be a possible therapy in RA. Frequency of Th9 cell may serve as objective disease severity biomarker for joint inflammation in RA patients

IL37 Reduces Pro-Inflammatory Cytokine and Catabolic Enzyme Production in Human Chondrocytes: A Protective Role in Osteoarthritis?

Ellen van Geffen[1], Arjan van Caam[2], Elly Vitters[2], Henk van Beuningen[2], Esmeralda Blaney Davidson[2] and Peter M. van der Kraan[2], [1]Experimental Rheumatology, Radboud university medical center, Nijmegen, Netherlands, [2]Experimental Rheumatology, Radboud university medical center, Nijmegen, Netherlands

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Osteoarthritis (OA) is the most common joint disease, primarily characterized by progressive articular cartilage degradation. Cartilage destruction is assumed to be mediated by pro-inflammatory cytokines, including IL-1β, IL-6, IL-8 and TNFα via induction of matrix degrading enzymes, such as matrix metalloproteinases (MMPs) and A Disintegrin-like and Metalloproteinases with Thrombospondin Motifs (ADAMTS). Recently, IL37 has come into view as an anti-inflammatory cytokine with inhibitory properties on innate immune responses by decreasing the production of pro-inflammatory cytokines. In this study we investigated if IL37 is able to reduce the expression and secretion of pro-inflammatory cytokines and catabolic enzymes in human OA chondrocytes.

Methods: Cartilage was obtained from eight OA patients undergoing total knee or hip joint arthroplasty. First IL37 expression was analyzed by immunohistochemistry. To determine if IL37 expression is responsive to pro-inflammatory cytokines, chondrocytes were stimulated with IL-1β (10 ng/ml). IL37 gene expression was measured using qPCR. The functionality of IL37 was tested in primary human OA chondrocytes by overexpression of human IL37 via an adenovirus. Subsequently, chondrocytes were stimulated with IL-1β to create an OA-like environment. The effect of IL37 on the production and secretion of pro-inflammatory cytokines and enzymes in this environment was analyzed by qPCR, Western Blot and Luminex.

Results: In cartilage of OA patients, immunohistochemical analysis indicated that IL37 protein was indeed expressed by chondrocytes. Furthermore, we found that in primary OA chondrocytes the production of IL37 is significantly *(p<0.0076)* induced through IL-1β stimulation. After overexpression, IL37 was effective to suppress IL-1β-induced gene expression of the pro-inflammatory cytokines *IL-1β (p<0.0007)*, *IL-6 (p<0.0043)*, *IL-8 (p<0.0002)* and the catabolic enzymes *MMP3 (p<0.0010)* and *ADAMTS5 (p<0.0104)* gene expression levels. In addition to gene expression analysis, we also studied the protein expression of pro-inflammatory cytokines in response to IL37 in primary OA chondrocytes. IL37 significantly reduced IL-1β-induced IL-6 *(p<0.0111)* and IL-8 protein *(p<0.0001)* levels in the supernatant of primary OA chondrocyte cultures. Furthermore, on Western blot analysis IL37 showed a reduction in IL-1β-induced IL-1β protein level.

Conclusion: In the present study, we showed basal IL37 protein expression and IL-1β- induced IL37 gene expression in human OA cartilage. This is the first study, demonstrating the enhanced expression of IL37 by primary human OA chondrocytes in an inflammatory environment. Furthermore, IL37 potently reduced the IL-1β-induced production and secretion of pro-inflammatory cytokines and catabolic enzymes. Clearly, these data implicate IL37 as a potent protective cytokine against cartilage degradation.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Enhancers are regulatory elements that modulate transcriptional rates of genes. Super-enhancers (SupE) are extremely large enhancers associated primarily with highly expressed genes that have critical functions in health and disease. The purpose of this study was to map typical enhancers and super-enhancers (SupE) in rheumatoid arthritis (RA) synovial fibroblasts (FLS).

Methods: Chromatin immunoprecipitation sequencing (ChIPseq) was used to evaluate H3K27 acetylation (Ac) genome-wide in control and TNF-stimulated FLS. Typical enhancers and SupE, were identified by H3K27Ac signal, using HOMER in a similar manner to the method described in Whyte et al. Cell 2013;153(2):307-19.

Results: The number and distribution of typical enhancers and SupE in FLS is modulated by TNF-stimulation in a time-dependent manner (Figure 1A-B). In some loci TNF-stimulation induces SupE (Figure 1C-D) and in others, baseline SupE are down-regulated or abrogated (Figure 1E). SupE-associated genes display significantly higher expression levels, compared to typical-enhancer-associated genes, in control and TNF-stimulated cells (Figure 2A). 16 RA-associated Single Nucleotide Polymorphisms (SNPs) are localized within SupE in RA FLS (Figure 2B).

Conclusion: The enhanceosome and super-enhanceosome is highly dynamic in RA FLS. TNFa has a genome-wide impact on FLS chromatin, suggesting that during the course of synovitis inflammatory mediators induce a pathogenic behavior by altering the landscape of enhancers and SupE in FLS. RA-associated SNPs are enriched in SupE of RA FLS, supporting the critical role of FLS in RA pathogenesis.

Four Types of Calcium Pyrophosphate Crystals Differentially Induce IL-1beta Production By Monocytes through ATP/Potassium Efflux/ROS Dependent Pathways

Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Monoclinic and triclinic calcium pyrophosphate (m- and t-CPP) crystals are the 2 types of CPP crystals observed in human joints. Frequently asymptomatic, it can give rise to acute arthritis. Interleukin (IL-) 1β plays a pivotal role in CPP crystal-induced inflammation but how they induce IL-1β production remains unknown. IL-1β secretion occurs after its maturation by caspase-1 which is activated by NLRP3 inflammasome. NLRP3 inflammasome can be stimulated by potassium (K^+) efflux, reactive oxygen species (ROS) generation, lysosomal or mitochondrial alterations. In this study we aimed to decipher how CPP crystals initiate IL-1β production.

Methods:

Four types of CPP crystals were synthesized *in vitro*: m- and t-CPP dihydrate (m- and t-CPPD), amorphous CPP (a-CPP) and m-CPP tetrathydrate (m-CPPT) [1]. The effects of CPP and monosodium urate (MSU) crystals – the later used as control – were assessed in human THP-1 cell line and bone marrow-derived monocytes (BMDM) from wild type (wt) and P2X7 receptor knock-out ($P2X7^{-/-}$) mice. Cells were primed before stimulation with crystals. *In vivo*, m- and t-CPPD crystal effects were evaluated in the murine air pouch model.

IL-1β production was measured in cell culture supernatants and air pouch lavages by ELISA. Expression of inflammatory mediator genes was analyzed by qPCR. ROS production and mitochondrial membrane potential were evaluated by microscopy and flow cytometry, using fluorescent probes (CellRox® and JC-1, respectively). Extracellular ATP (ATP_e) concentration was quantified in cell culture supernatants.

Results:

In vitro, we showed that m-, t-CPPD and MSU crystals differentially induced IL-1β secretion and IL-1β, IL-6, IL-8, TNF-α, COX2 gene expression (m-CPPD > MSU > t-CPPD) while a-CPP and m-CPPTβ crystals had no effect; IL-1β production was not correlated with CPP crystal specific surface area. Similarly, these 3 inflammatory crystals induced *in vivo* IL-1β secretion, neutrophil and monocyte influx into the air pouch. Then, we assessed the mechanisms of CPP crystal-induced IL-1β production. First, we found that m- and t-CPPD crystals brought on an ATP release and that IL-1β production was partially inhibited by oxidized ATP. Second, m- or t-CPPD-induced IL-1β secretion was completely abrogated when K^+ efflux was inhibited (cell culture with a K^+-enriched medium). Although ATP_e can trigger K^+ efflux through P2X7 receptor opening, crystal-mediated IL-1β production was identical between wt and $P2X7^{-/-}$BMDM. Finally, we demonstrated an early decrease in mitochondrial membrane potential following crystal stimulation combined with a higher intracellular ROS level. Moreover, ROS scavenger dramatically decreased IL-1β release (75% inhibition) induced by CPPD crystals.

Conclusion:

CPP crystals displayed different inflammatory properties, m-CPPD crystals being the most potent one. CPPD crystal-induced IL-1β maturation occurs through three major mechanisms including ATP release, P2X7 receptor-independent K^+efflux, and mitochondrial disruption/ROS production.

Session Time: 9:00AM-11:00AM

Background/Purpose: The HLA-B27/β2m transgenic rat is a leading model of Anklylosing Spondylitis (AS) and other B27-associated spondyloarthopathies. The development of both bowel and joint inflammation is dependent on the presence of intestinal bacteria and we have shown previously that adult HLA-B27/β2m rats have an altered intestinal microbiota. In this study we sought to better define age-dependent changes to immune function, host gene expression and the development of dysbiosis in this system.

Methods: Ileal, cecal and colonic contents were collected from WT and HLA-B27/β2m+ rats during the post-weaning period (3 and 6 weeks), at disease onset (10 wks) and after the establishment of disease (16wks). Microbial community structure was determined by 16s sequencing and qRT-PCR. Mucosal and systemic Th1, Th17 and Treg responses were analyzed by flow cytometry. Flow cytometry was also used to determine the frequency of IgA-coated bacteria in intestinal contents. Host expression of inflammatory cytokines and antimicrobial peptides (AMPs) was determined in intestinal tissue by qRT-PCR. Histopathological evaluation was performed on H&E stained intestinal and joint sections.

Results: Both HLA-B27/β2m rats and controls exhibited a highly age-dependent intestinal microbiota. The microbiota of these rats diverged from that of controls by 10wks of age. *Akkermansia muciniphila* was greatly expanded in the intestinal mucosa of transgenic animals. Notably, an inflammatory cytokine signature and elevated AMP expression during the post-weaning period preceded the development of clinical bowel inflammation and dysbiosis. An early and sustained expansion of the Th17 pool was specifically observed in cecal and colonic mucosa of HLA-B27/β2m rats, whereas FoxP3 +ve Treg and Th1 cells were either unchanged or decreased at these tissue sites. By contrast, CD4+FoxP3+ T cells were significantly expanded in both mesenteric lymph node and spleen of HLA-B27/ β2m rats. Strikingly, a vast expansion in the frequency of IgA-coated intestinal bacteria (30-fold over controls) was observed at a late stage (16 weeks) concurrent with the age of arthritis onset in these animals.

Conclusion: HLA-B27/β2m expression renders the host hyper-responsive to microbial antigens from infancy. Early activation of innate immunity and expansion of a mucosal Th17 signature is soon followed by dysbiosis in HLA-B27/β2m+ve animals. The study of mucosal immune response and dysbiotic changes to the intestinal microbiota strongly merit further study in both pre-diseased and diseased SpA patient populations. IgA-coating has been reported to identify colitogenic bacteria in CD patients. Efforts are ongoing to identify sIgA+ve bacteria observed in the presence of HLA-B27 expression and their arthritogenic potential.

Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The Proviral Integration site of Moloney murine leukemia virus (PIM) kinases are important mediators of cell survival and considered as attractive targets in cancer chemotherapy. Their implication has not been studied in the function of rheumatoid arthritis (RA)-fibroblast-like synoviocytes (FLS).

Methods: Immunoblot or quantitative real-time RT-PCR was performed to investigate the expression of 3 isoforms of PIM kinases (PIM-1, PIM-2, and PIM-3) in of RA- and osteoarthritis (OA)-FLS. The presence of PIM-1 was confirmed using immunostaining on synovial

tissue from RA and OA patients. After knockdown of PIM-1 using siRNA, proliferation and migration assay were carried out. Additionally, matrix metalloproteinases (MMPs) and interleukin (IL)-6 secretion was measured using ELISA from RA-FLS transfected with control or PIM-1 siRNA.

Results: Among PIM kinases, PIM-1 was most strongly induced by IL-6 stimulations in RA-FLS. The expression of PIM-1 protein was higher in RA-FLS than in OA-FLS. In the synovial tissues from RA patients, PIM-1 was immunostained in the synovial lining layer and mononuclear cells (Fig. 1). When RA-FLS with PIM-1 knockdown were stimulated with TNF-a, RA-FLS proliferation or migration was significantly decreased (Fig. 2). Moreover, the production of MMP-1, MMP-3, and MMP-13 was significantly suppressed in RA-FLSs with PIM-1 knockdown (Fig. 2). IL-6 production from PIM-1 knockdown RA-FLS was also reduced, but statistically insignificant.

Conclusion: These results suggest that PIM-1 is involved in the survival, migration, and matrix-degradation of RA-FLS and PIM-1 could be a potential target for RA treatment.

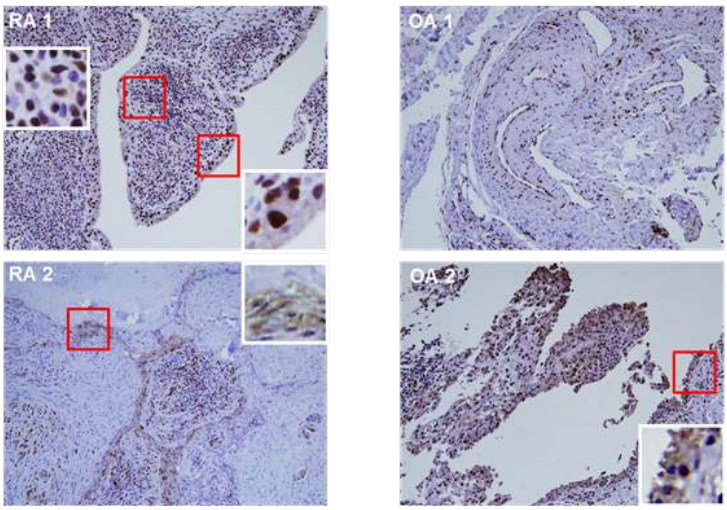

Fig. 1. The immunohistochemical staining of PIM-1 kinase in the synovial tissue from 2 RA and 2 OA patients.

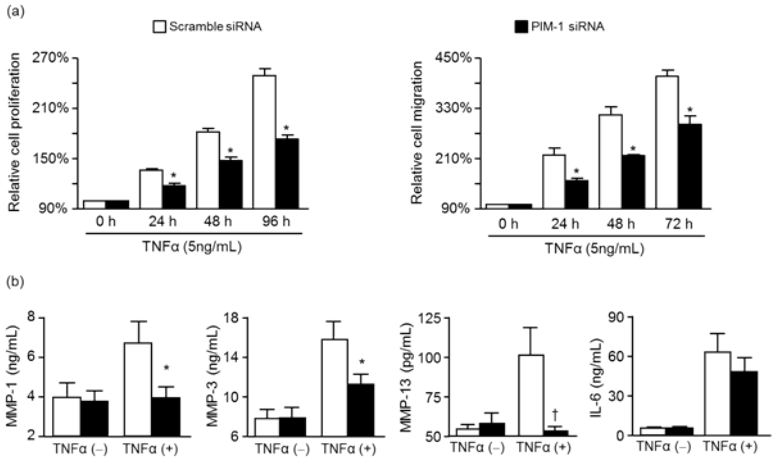

Fig. 2. The effect of PIM-1 on RA-FLS. (a) Under the stimulation with TNF-a, proliferation and migration was significantly inhibited in PIM-1 siRNA-transfected RA-FLS. (b) PIM-1 knockdown also significantly suppressed the secretion of MMP-1, MMP-3, and MMP-13 from RA-FLS stimulated with TNF-a in serum-free media.

Session Time: 9:00AM-11:00AM

Background/Purpose: Interleukin-22 (IL-22) is an IL-10 family cytokine member that was recently discovered to be mainly produced by Th17 cells. Previous studies have indicated the importance of IL-22 in host defense against Gram-negative bacteria in gut and lung. Recently, there is emerging evidence that IL-22 plays a dual role in the pathogenesis of several autoimmune diseases like psoriasis and multiple sclerosis. In this study we aimed to unravel the pathogenic effects of IL-22 on joint inflammation and destruction, and its therapeutic potential during experimental arthritis.

Methods: First, endogenous IL-22 was blocked using neutralizing antibodies during collagen-induced arthritis (CIA), and the effects were studied on X-ray and by histology. To further investigate the pathogenic effects of IL-22, an adenoviral construct overexpressing murine IL-22 (AdIL-22) or a control virus was intra-articularly injected into naïve knee joints of C57Bl/6 mice, and at various time points the knee joints were clinically and histologically assessed for inflammation and destruction. Synovial biopsies and washouts were obtained for analysis of cytokines, chemokines and MMPs on mRNA expression (RT-QPCR) and protein levels (Luminex). In addition, in vitro stimulated fibroblasts were used to confirm these IL-22 effects. Finally, IL-22 was overexpressed during experimental arthritis induced by the injection of bacterial (SCW) fragments into the knee joint, to study IL-22's contribution as Th17 cytokine in the aggravation of an acute joint inflammation.

Results: Anti-IL-22 treatment after the onset of CIA significantly reduced arthritis progression, and had even more dramatic therapeutic effects on radiographic destruction. Adenoviral overexpression of IL-22 in naïve and arthritic joints was used to further investigate the pathogenic effects of IL-22. Overexpression of IL-22 in a naïve knee joint resulted in an acute joint inflammation which was relatively mild and short-lasting in comparison to other proinflammatory cytokines like TNF and IL-1. The increased influx of cells by AdIL-22 was accompanied by elevated levels of the chemokines MCP-1 and KC, as well as IL-6 and S100A9. Overexpression of IL-22 induced significant proteoglycan depletion from the articular cartilage, but did not cause severe and irreversible destruction to cartilage and bone, in contrast to the significant upregulation of MMP3, MMP9 and RANKL in the synovial tissue and by the in vitro stimulated fibroblasts. We therefore expected that in synergy with other inflammatory stimuli during SCW-induced arthritis, IL-22 overexpression would become far more potent and destructive. Surprisingly, however, IL-22 overexpression during experimental arthritis significantly suppressed joint inflammation, suggesting a more complex mechanism of action of this dual cytokine.

Conclusion: Since both overexpression of IL-22 as well as blocking endogenous IL-22 with neutralizing antibodies provide protection against further disease progression in experimental arthritis, the exact mechanism of action of IL-22 needs to be identified before IL-22-based treatments can be applied in clinical treatment of RA.

MiR125a-5p Mediates Angiogenic Mechanisms in Inflammatory Arthritis

Mary Connolly[1], **Sarah Wade**[1], Douglas J. Veale[2] and Ursula Fearon[1], [1]St. Vincent's University Hospital, Centre for Arthritis and Rheumatic Diseases, Dublin Academic Medical Centre, Dublin 4, Ireland, [2]St Vincent's University Hospital, Centre for Arthritis and Rheumatic Diseases, Dublin Academic Medical Centre, Dublin 4, Ireland

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: MicroRNAs (miRNA) belong to a class of small, evolutionarily conserved, noncoding RNAs that function as post-transcriptional repressors of gene expression. An accumulating body of evidence suggests that up to 50% of the human genome is regulated by miRNAs. The aim of this study was to examine expression, regulation and function of miRNA-125a-5p in inflammatory arthritis (IA).

Methods: Synovial tissue biopsies and primary synovial fibroblasts (SFC) were obtained from patients with Psoriatic arthritis (PsA), Rheumatoid Arthritis (RA) and osteoarthritis (OA). MiR125a-5p levels were analyzed by real-time PCR and data was calculated by the deltaCt method using RNU6B as an endogenous control. To examine possible factors involved in regulating miR125a-5p expression, primary synovial fibroblasts (SFC) and microvascular endothelial cells (HMVEC) were cultured with candidate pro-inflammatory stimuli including; TLR ligands (PAM, PolyIC, LPS), pro-inflammatory cytokines (TNFa, IL-1b, IL-17) and growth factors (VEGF, Ang2). Overexpression/silencing of miR-125a-5p was analysed using a synthetic precursor of Pre or Anti-miR™-125, respectively. Cell invasion, tube formation and migration were examined using transwell invasion, angiogenic and wound repair assays, and pro-inflammatory mediators were quantified by ELISA.

Results: Expression of miR125a-5p was significantly higher in PsA and RA synovial biopsies and/or synovial fibroblasts compared to OA ($p<0.05$; $p<0.05$), with highest expresson observed in PsA ($p<0.05$). Angiogenic growth factor Ang2 induced miR125a-5p in synovial fibroblasts and HMVEC ($p<0.05$), with no effect observed for TLR ligands or pro-inflammatory cytokines. Silencing of miR by transfection with anti-miR-125a-5p resulted in inhibition of cell invasion, angiogenic tube formation and IL-6 expression. This is consistent with *in silico* analysis where prediction algorithms identified members of the IL-6 signalling pathway (IL-6R, gp130) as potential targets of miR-125a-5p.

Conclusion: Our data provides evidence that miR125a-5p is significantly increased in the inflammed joint, particularly in PsA. High miR125a-5p expression in PsA and regulation by key angiogenic factor Ang2, is consistent with a possible role for miR125a-5p in the regulation of angiogenic mechanisms. MiR125a-5p also mediated cell migration, angiogenesis and IL-6 expression, key processes involved in the pathogenesis of PsA and RA. In conclusion, miR-125a-5p may be an important regulator of pathogenic mechanisms in inflammatory arthritis and may represent a potential novel target for future therapeutic strategies.

Crossregulatory Mechanisms Between Synovial Fibroblasts and Macrophages Relevant in RA Pathogenesis

Jennifer Ding[1], Lionel B. Ivashkiv[2] and Laura T. Donlin[1], [1]Arthritis and Tissue Degeneration Program and the David Z. Rosensweig Genomics Research Center, Hospital for Special Surgery, New York, NY, [2]Medicine, Hospital for Special Surgery, New York, NY
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Macrophages and synovial fibroblasts function as key drivers of inflammation in rheumatoid arthritis (RA). We have developed a co-culture system that aims to define how these two cell types crossregulate within an inflammatory setting. Previously, we have shown that soluble synovial fibroblast factors suppress the macrophage TNF-induced Type I Interferon response. Here we aimed to understand the impact of macrophages on synovial fibroblasts and have identified a novel crossregulatory epidermal growth factor (EGF) pathway that is also expressed in synovial macrophages from RA patients. Through studying this EGF pathway we aim to identify potential therapeutic targets to resolve long-term inflammation in the RA synovium.

Methods:

Primary RA synovial fibroblast cell lines were plated in permeable transwell culture inserts and placed above wells with or without human blood-derived macrophages. The co-cultures were then incubated for 2 days with or without exogenous TNF. PolyA selected RNA was processed for paired-end RNAseq using the Tru-seq kits (Illumina) and Illumina HiSeq 2500. The Ingenuity Pathway Analysis and Gene Set Enrichment Analysis programs provided pathway analytics. Synovial fibroblasts were plated in Matrigel transwell invasion assays with TNF and macrophages in the chamber below. The number of invading fibroblasts was scored in the absence or presence of EGFR inhibitors erlotinib and gefitinib.

Results:

Upon TNF exposure, macrophages responding in close proximity to synovial fibroblasts altered the expression of ~1,200 fibroblast genes. Pathway analysis identified an activated EGF pathway that contributed to this altered fibroblast transcriptome. While fibroblasts are commonly considered a predominant source of growth factors, further work determined it was the macrophages that directly produced the EGF ligands responsible for the fibroblast EGF response. The rare non-canonical EGF ligands produced by the fibroblast-trained macrophages are related to a recently described macrophage activation state found in chronic inflammation, which is distinct from both the prototypical pro-inflammatory (M1) and alternative (M2) polarization states. We have detailed the mechanism by which signalling crosstalk induced massive amounts of fibroblast-generated prostaglandins that drives this unique macrophage activation state and non-canonical EGF ligand production. Synovial macrophages from RA patients exhibited increased production of non-canonical EGF ligands, suggesting this crossregulatory EGF response is present in RA synovium and supporting the disease-relevance of these results. Ultimately, the fibroblast-trained macrophages increased the invasive potential of synovial fibroblasts via the EGF response, thereby increasing pathologic fibroblast activity found in RA joints.

Conclusion:

We have identified a novel functional cross-coupling between macrophages and synovial fibroblasts that modulates TNF responses to drive production of rare non-canonical EGF ligands, which in turn induces the invasiveness of synovial fibroblasts. Our data support targeting of the EGF pathway as a possible therapeutic approach in the treatment of inflammatory diseases such as RA.

The Alarmins S100A8/A9 Induce Canonical Wnt Signaling in Naïve Joints and Experimental OA

Martijn H. van den Bosch[1], Arjen Blom[1], Rik Schelbergen[2], Thomas Vogl[3], Johannes Roth[4], Wim van den Berg[1], Peter van der Kraan[1] and Peter van Lent[1], [1]Experimental Rheumatology, Radboud university medical center, Nijmegen, Netherlands, [2]Radboud university medical center, Nijmegen, Netherlands, [3]Institute of Immunology, University of Muenster, Munster, Germany, [4]Institute of Immunology, University of Münster, Münster, Germany

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Many osteoarthritis (OA) patients show synovial activation, which is thought to be involved in joint destruction. Previously, we found increased expression of both the alarmins S100A8/A9 and members of the Wnt signaling pathway in the joints during experimental OA. Active roles in the development of the OA pathology are attributed to both groups of proteins. In this study, we investigated whether S100A8/A9 induced canonical Wnt signaling and if S100 effects run *via* activation of Wnt signaling.

Methods: Gene expression was measured in the destabilization of the medial meniscus (DMM) and collagenase-induced OA (CIOA) experimental OA models. Selected Wnts were overexpressed and expression levels of S100A8/A9 were measured. Activation of canonical Wnt signaling was determined after intra-articular injection of S100A8 into naïve mouse knee joints and after induction of CIOA in S100A9-deficient mice. Expression of Wnts was tested in macrophages and fibroblasts after stimulation with S100A8. To

determine if the effects of S100A8 injections run *via* activation of Wnt signaling, canonical Wnt signaling was inhibited *in vivo* by feeding inducible DKK-1 Tg mice a diet supplemented with doxycycline to induce overexpression of the DKK-1 transgene.

Results: qPCR analysis showed increased and coinciding expression of the alarmins S100A8/A9 and several members of the canonical Wnt signaling pathway in experimental OA models. This gave rise to the question if an interrelationship existed between these factors. Therefore, we overexpressed Wnt8a and Wnt16, two canonical Wnts, with the use of adenoviral vectors. However, this did not result in increased expression of S100A8 and S100A9, both on RNA and protein level. In contrast, we found that injection of S100A8 increased the expression of Wnt16 in the synovium and accumulation of β-catenin, a hallmark of canonical Wnt signaling, in both cartilage and synovium. In addition, the downstream mediator of canonical Wnt signaling WISP1, was increased. Furthermore, we found reduced β-catenin accumulation in the cartilage and synovium after induction of the CIOA model in S100A9 deficient mice. However, differences in inflammation as the result of divergent S100 levels could possibly explain the differences in canonical Wnt signaling. Therefore, we stimulated both murine and human macrophages and fibroblasts with S100A8 *in vitro* and found increased expression of Wnt16 and WISP1 in macrophages, but not in fibroblasts. Finally, we determined if activation of canonical Wnt signaling was required for the effects of S100A8. Therefore, we injected S100A8 into knee joints of DKK-1 Tg mice that were fed a standard diet or a diet supplemented with doxycycline, which led to overexpression of DKK-1. Injection of S100A8 significantly induced the expression of MMP3, IL-6, MIP1α and KC. However injection of S100A8 in mice overexpressing DKK-1, therefore having reduced canonical Wnt signaling, did not result in significantly induced expression of MMP3, IL-6 KC but not MIP1α.

Conclusion: The alarmins S100A8/A9 induce canonical Wnt signaling in macrophages and murine knee joints. In addition, effects of S100A8/A9 partially run via activation of canonical Wnt signaling.

Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Patients with PsA have both increased risk of subclinical atherosclerosis and lower cortical volumetric BMD (vBMD) compared with the general population, probably as a result of the dysregulated molecular pathways. We have reported that inflammation induced by the IL-33/ST2 axis was associated with carotid plaque progression in RA. Emerging data suggest that this axis may also be involved in bone homeostasis and osteoclastogenesis. In this study, we studied the association among IL-33/ST2 pathway, carotid plaque, and vBMD/bone microstructure in PsA patients.

Methods: 80 PsA patients (44 males; 53±10 years) without unstable cardiovascular diseases (CVD) or disorders that could affect bone metabolism were included. Carotid plaque was determined by ultrasound. vBMD and microstructure of the distal radius were measured using high-resolution peripheral quantitative CT (HR-pQCT). Plasma IL-33 and its decoy receptor soluble ST2 (sST2) levels were determined by ELISA.

Results: Plasma sST2 levels were significantly higher in 33 (41%) patients with carotid plaques (11.2±4.5 vs 7.7±3.7 ng/ml, $p<0.001$). The patients with plaques were also older (57±9 vs 50±10 years, $p=0.002$), had longer PsA duration (17±7 vs 12±7 years, $p=0.006$), and an increased prevalence of high CVD risk (Framingham 10-year CVD risk >10%: 64% vs 34%, $p=0.013$). The prevalence of hyperlipidemia was higher (36% vs 19%, $p=0.085$) and more patients were put on statins (27% vs 11%, $p=0.046$). After adjusting for these confounding factors, sST2 was an independent explanatory variable associated with the presence of carotid plaques (odds ratio: 1.3,

95% confidence interval [CI]: [1.2, 1.5]; p=0.003). Using linear regression, plasma sST2 level was negatively associated with cortical vBMD (coefficients: -5.4, 95%CI: [-8.6, -2.3], p=0.001), and positively associated with cortical porosity index (0.25, [0.12, 0.38], p<0.001) and cortical pore volume (3.0, [1.4, 4.6], p<0.001). The associations remained significant after adjusting for confounding factors[1](Table 1). On the other hand, plasma IL-33 levels were not associated with the presence of carotid plaque or vBMD/microstructure.

Conclusion: Plasma sST2 levels are independently associated with both carotid plaque and compromised cortical vBMD/microstructure in PsA patients, indicating that IL-33/ST2 axis may contribute to both atherosclerosis and bone loss. The detailed mechanism should be further investigated.

Single Cell Sequencing of Non-Lesional Non-Sun Exposed Skin from SLE Patients with Proteinuria Supports Widespread Endothelial Activation

Robert Clancy[1], Evan Der[2], Kemal Akat[3], Anna R. Broder[4], H. Michael Belmont[5], Peter M. Izmirly[6], Beatrice Goilav[7], Thomas Tuschl[3], Chaim Putterman[8] and Jill P. Buyon[1], [1]Medicine, Division of Rheumatology, New York University School of Medicine, New York, NY, [2]Albert Einstein College of Medicine, Bronx, NY, [3]Rockefeller University, New York, NY, [4]Rheumatology-Forchheimer 701N, Albert Einstein College of Medicine/Montefiore Medical Center, Bronx, NY, [5]New York University School of Medicine, New York, NY, [6]Rheumatology, NYU School of Medicine, New York, NY, [7]Division of Nephrology, Children's Hospital at Montefiore, Bronx, NY, [8]Division of Rheumatology, Albert Einstein College of Medicine, Bronx, NY

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Given the widespread vasculopathy present in SLE, endothelial cell activation in the renal tubulointerstitium in lupus nephritis (LN) may be accompanied by similar activation in other tissue beds, even non-lesional skin. Faithful reflection of a relevant pathway in renal tissue by a more readily accessible compartment would be an advance. Single-cell transcriptional states as performed in this study may provide a framework for understanding how in vivo biological function emerges from complex cell ensembles. Accordingly, this study utilized single-cell RNAseq as a novel approach to identify whether non-lesional non-sun exposed skin reflects diffuse activation of the microvasculature in patients with LN.

Methods:

Single-cell RNAseq was performed on cell suspensions prepared from ~2 mm punch biopsies of non-lesional non sun-exposed skin from the buttocks of 5 SLE patients with proteinuria and known ISN/RPS Class and 1 healthy control. The libraries were prepared on the Fluidigm C1 platform followed by sequencing on an Illumina HiSeq 2500. We generated 192 single-cell data sets with on average 3500 genes/cell and 50% of reads mapping to the reference genome. The profile of differential expression analysis was used to assign in vivo cell-type compositions through unsupervised sampling and modeling of transcriptional states in single cells. Data are expressed as transcripts per million.

Results:

Based on expression of PROCR, F2R, VWF, CD34, SERPINE1, ESAM and MCAM (CD146), assignments yielded 36 endothelial cells from 5 patients. From the two Class II subjects there were 10 single-cell transcriptomes. The other three subjects (1- Class IV,V; 1- Class V, 1-Class IV) yielded 26 single cell transcriptomes. Further consideration used evaluations of broad signatures involving the NFkB pathway (reflected by expression of SELE, ICAM1 & VCAM1) and IFNa response/Stat genes (IFI27, IFI44L, IFIH1, IFIT1, IFIT3, CXCL14 & SOCS3). The endothelial cells from patients with Class II had a significantly lower expression of NFkB-related genes compared to those with more advanced disease (4 of 10, i.e. 4 cells expressed at least one transcript and 6 none, vs 20 of 26, $p<0.001$). Both groups strongly expressed at least one IFNa response gene (10 of 10 vs 26 of 26). In addition, standard lineage markers identified the major skin resident and infiltrating cell types including keratinocytes, and lymphocytes. In contrast to the endothelial cells, these cells all displayed low expression of NFkB transcripts, independent of biopsy Class. However, IFNa responsive genes were strongly represented in all 5 patients. The skin biopsy from the healthy control showed neither NFkB nor IFNa responsive genes.

Conclusion:

Single-cell RNAseq is feasible and informative in cell specific transcriptome analysis of fresh non-lesional skin biopsies from SLE patients with a spectrum of active renal disease. Insidious expression of endothelial activation and genes reflective of cytokine exposure support application of this novel approach to study readily accessible tissue. Insight into disease progression should facilitate earlier identification and treatment, critical to tissue survival in organs such as the kidney.

G Protein Coupled Receptor Kinase 3 Regulation of Inflammatory Arthritis

Matthew J. Billard[1], Roman Timoshchenko[2], D. Stephen Serafin[2] and Teresa K. Tarrant[3], [1]Medicine, University of North Carolina, Chapel Hill, NC, [2]Thurston Arthritis Research Center, University of North Carolina, Chapel Hill, NC, [3]Rheumatology, University of North Carolina, Chapel Hill, NC

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Chemokine receptors are G Protein Coupled Receptor (GPCR) family members that direct cell migration, differentiation, and survival in inflammatory conditions, but neutralization strategies have had mixed results in autoimmunity and even less efficacy in Rheumatoid Arthritis (RA). This has been partially attributed to chemokine receptor/ligand redundancy in inflammation, and it

has been proposed that a regulator of GPCR signaling should be targeted rather than neutralization of singular chemokines or their receptors. G protein coupled receptor kinase 3 (GRK3) activity negatively regulates GPCR activation, but also helps recruit downstream signaling machinery to coordinate leukocyte responses. GRK3-deficient mice were previously shown to be protected from disease in two acute models of inflammatory arthritis (K/BxN serum transfer and Collagen Antibody Induced Arthritis) by altering granulocyte migration and innate responses. In this study, we examine the effects of GRK3 knockdown in the chronic, HLA-restricted Collagen Induced Arthritis (CIA) model.

Methods: The Collagen-Induced Arthritis (CIA) model of inflammatory arthritis was used to test *in vivo* disease progression in GRK3-deficient DBA mice. To examine the biological basis for protection in GRK3 knockout mice, an interdisciplinary approach was used. Traditional migration and survival assays were performed on leukocytes *ex vivo* and a mathematical model of GRK3 signal regulation was developed.

Results: Results showed that GRK3-deficient DBA mice are protected from developing CIA *in vivo*. Serum antibody is decreased in GRK3-deficient mice and PCR of the joint revealed greatly reduced levels of IL-17, IL-23, TNFα, and IL-1β transcript expression, suggesting a lack of inflammatory cell infiltration. *Ex vivo* assays describe altered migration and survival of immune cells. A mathematical model was created to further examine and test the mechanisms of signal regulation.

Conclusion: Proinflammatory functions of leukocytes critical to RA development require GRK3 function. Having a single protein target for RA therapeutic intervention that appears to selectively prevent infiltration into the joint represents a compelling target for therapeutic attempts at single cytokine or chemokine neutralization.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

The semaphorin family is a large group of proteins initially described as axon guidance molecules that play crucial roles in the development of the nervous system. However, semaphorins also play a role in other processes such as the regulation of immunity, angiogenesis, apoptosis and cell migration and invasion. Moreover, semaphorins have been related with the pathogenesis of diseases like multiple sclerosis, myocarditis, atherosclerosis and cancer. Importantly, class 3 semaphorins Sema3B and Sema3F have been defined as important tumor suppressors. However, the potential role of class 3 semaphorins in rheumatoid arthritis (RA) remains unknown.

The aim of this study is analyze the role of class 3 semaphorins in the pathology of RA.

Methods: mRNA expression of class 3 semaphorins in the synovial tissue of early, DMARD-naive arthritis patients was analyzed by low-density (q)uantitative PCR array. RA FLS were stimulated for 4h with IL-1β (1 ng/ml), TNF (10 ng/ml) or LPS (1 μg/ml). RNA was isolated, transcribed to mRNA and expression of class 3 semaphorins was analyzed by qPCR. FLS were stimulated with Sema3A, Sema3B or Sema3F (100 ng/ml) in the presence or absence of PDGF (10 ng/ml) and cell migration and invasion were determined using wound closure motility and transwell invasion assays, respectively.

Results: mRNA expression of class 3 semaphorins in the synovial tissue of early arthritis patients negatively and significantly correlated with the mRNA expression of inflammatory mediators and the disease activity parameters of these patients. Moreover, Sema3B, Sema3C, Sema3F and Sema3G mRNA expression was significantly lower in early arthritis patients who developed persistent diseases compared with patients with self-limiting disease after two year follow-up. Also, Sema3F and Sema3B expression was significantly lower in the patients that after 2 years of follow-up progressed to RA compared to those who remained as undifferentiated arthritis patients. FLS expression of Sema3A was significantly induced after IL-1, TNF or LPS stimulation, while the expression of Sema3B and Sema3F was down-regulated. Finally, functional assays showed that Sema3A significantly induced the migration and invasion of FLS. In contrast, Sema3B and Sema3F reduced spontaneous FLS migration and PDGF-induced cell invasion.

Conclusion: these data show that class 3 semaphorins are differently expressed in the synovium of early patients depending of the severity and the progression of the disease and that Sema3A, Sema3B and Sema3F play an important role in the invasiveness ability of RA FLS. Together, class 3 semaphorins and their receptors could be useful biomarkers and promising therapeutic targets for the treatment of RA.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Vascular complications are a key pathological feature of systemic sclerosis (SSc) affecting the microcirculation and arterioles. Under normal circumstances the endothelium acts as a biological barrier supporting controlled permeability, immune surveillance and cellular trafficking. In SSc endothelial damage, contributes to barrier dysfunction and elevated immune cell infiltration and inflammation. The cause(s) of the initial endothelial dysfunction in SSc is unclear. Blood outgrowth endothelial cells (BOECs) are thought to home to sites of vascular injury and differentiate into endothelial cells, aiding the repair and restoration of normal endothelial functions. Circulating levels of BOECs have been shown to be reduced in SSc patients, and recent studies suggest that BOECs may be dysfunctional in vascular diseases. Here we sought to assess SSc-BOECs and their contribution to vascular dysfunction in SSc.

Methods:

BOECs were established from peripheral blood PBMCs from healthy donors (HD) and SSc patients. BOECs from HD (n=5) and SSc patients (n=6) were profiled using Illumina HT12 gene arrays and secreted inflammatory cytokines profiled by meso discovery scale (MSD) arrays. The capacity of SSc-BOECs (n=4) and HD-BOECs (n=4) to: 1) Establish biological barriers alone or in co-culture with mature endothelial cells, was assessed using electric cell-substrate impedance sensing (ECIS); 2) Support PBMC (n=4) trans-endothelial migration, by forming monolayers in 24-well transwell inserts stimulated with or without TNFα (10ng/ml).

Results: Using gene set enrichment analysis, it was determined that SSc-BOECs exhibit a significantly altered gene expression profile including inflammatory chemokines and cytokines. In addition SSc-BOECs exhibited significantly elevated pro-inflammatory cytokine secretion compared to HD-BOECs, including IL-6 ($P<0.05$; 0.003ng/ml vs 0.73ng/ml) and IL-8 ($P<0.01$; 0.294ng/ml vs 1.7ng/ml). SSc and HD-BOECs exhibited a similar paracellular and transcellular barrier functions alone or in co-culture with mature endothelial cells as determined by ECIS. In contrast SSc-BOECs supported significantly elevated basal trans-endothelial PBMC migration ($P<0.05$) compared HD-BOECs. Whereas TNFα significantly induced trans-endothelial cell migration in both BOEC cell types ($P<0.01$ HD vs $P<0.05$ SSc).

Conclusion:

We have demonstrated that BOECs isolated from SSc patients exhibit a significantly altered gene profile compared to that of BOECs isolated from HC donors. Additionally, SSc-BOECs exhibit a pro-inflammatory profile, secreting high levels of cytokines including IL-6 and IL-8.BOECs isolated from SSc patients exhibited a similar capacity to form biological barriers compared to those from HDs. Conversely, SSc-BOEC monolayers supported a higher level of immune cell trans-endothelial migration. Our data suggests that BOECs integrated into the endothelium in SSc patients are dysfunctional and may promote immune cell infiltration and exacerbate the pro-inflammatory environment in vascular fibrotic lesions in SSc patients.

Interleukin-37 Prevents New-Onset Joint Inflammation but Does Not Inhibit Existing Experimental Arthritis

Marije I. Koenders[1], Debbie M. Roeleveld[1], Charles Dinarello[2], Peter M. van der Kraan[1] and Leo Joosten[3], [1]Experimental Rheumatology, Radboud university medical center, Nijmegen, Netherlands, [2]Department of Medicine, Division of Infectious Diseases, University of Colorado, Denver, CO, [3]Internal Medicine, Radboud university medical center, Nijmegen, Netherlands
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Interleukin-37 (IL-37) is a recently identified cytokine with potent anti-inflammatory and immunosuppressive functions. This cytokine has been shown to be expressed in synovial tissue of patients with rheumatoid arthritis (RA) as well as osteoarthritis (OA), and plasma levels of IL-37 in RA have been correlated with TNF, IL-17, and disease activity during DMARD treatment. The objective of this study was to investigate the therapeutic potential of IL-37 in various mouse models and stages of experimental arthritis.

Methods: Mice transgenic for human IL-37 (IL-37tg) were generated on a C57Bl/6 background and antigen-induced arthritis (AIA) was elicited by two immunizations with methylated bovine serum albumin (mBSA) as an antigen in Freund's complete adjuvant, and subsequently intra-articular injection with mBSA. This mono-arthritis was studied by ^{99m}Technetium measurements to detect joint swelling in the arthritic knee joint, and synovial washouts were collected to assess cytokine and chemokine production by Luminex. Second, recombinant IL-37 protein was administered either prophylactic or therapeutic during collagen-induced arthritis (CIA) in DBA-1J mice (1ug/mouse/day i.p. for 2 weeks), and arthritis development was scored macroscopically three times per week. In addition, joints were collected for radiographic and histological analysis.

Results: Mice transgenic for human IL-37 demonstrated suppressed joint swelling compared to C57Bl/6 control mice early after AIA induction. In addition, these IL-37tg mice had reduced synovial levels of IL-6 and KC compared to wild-type controls, and showed a trend towards suppressed IL-17. In line with this protective effect of IL-37, exogenous recombinant IL-37 administered before onset of collagen-induced arthritis resulted in significant protective effects on the macroscopic clinical scores, although these effects were not observed on radiographic analysis. Luminex to detect serum cytokine levels demonstrated an 80% reduction in systemic IL-6 levels, while anti-TNF treatment only caused a 50% suppression. In addition, serum levels of KC seemed to be slightly reduced (P=0.06). In contrast, a therapeutic approach with exogenous IL-37 after the onset of CIA did not have any beneficial effects on further disease progression, suggesting that the therapeutic window of IL-37 treatment in arthritis is limited to new-onset or early arthritis.

Conclusion: This study is the first to show that the anti-inflammatory effect of IL-37 during experimental arthritis is limited to new-onset disease, and that IL-37 is not capable to block arthritis progression during an existing inflammation.

Characterization of Different Phosphorylation Sites of Mcl-1 in Human Rheumatoid Arthritis Synovial Fibroblasts and Their Correlation with RA Pathogenesis

Nahid Akhtar and Salahuddin Ahmed, Department of Pharmaceutical Sciences, Washington State University College of Pharmacy, Spokane, WA

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Cytokines, Mediators, Cell-cell Adhesion, Cell Trafficking and Angiogenesis Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Myeloid cell leukemia (Mcl-1), a Bcl-2 family anti-apoptotic protein, is a critical determinant of rheumatoid arthritis synovial fibroblasts (RA-FLS) resistance to apoptosis. Phosphorylation of Mcl-1 at different sites may influence its stability and function, however, it's implication on RA pathogenesis is not fully studied. In the present study, we evaluated the expression levels of phospho- and total Mcl-1 in FLS from RA, osteoarthritis (OA), and non-diseased (NL) donors and in the joints of rat adjuvant induced arthritis (AIA) model.

Methods:

FLS were obtained from RA (n=10) and OA (n=6) patients undergoing synovectomy or joint replacement surgery. NL samples (n=9) were obtained at the time of autopsy/amputation with no known history of OA or RA. Basal cell lysates (n=6) from NL-, OA-, and RA-FLS were prepared and analyzed for phosphorylated and total Mcl-1, and its endogenous regulators such as Noxa, Bak, and Bax using Western immunoblotting. Correlation between Noxa and Mcl-1 mRNA expression in NL-, OA-, and RA-FLS (n=6) and in synovial tissues (ST; n=5) was determined using qRT-PCR. A Bcl-2/Mcl-1 inhibitor (AT101; 1μM) was used as a control. Findings from human RA-FLS were further validated in rat AIA model. $p<0.05$ was considered significant.

Results:

Our results showed that Mcl-1 mRNA and protein expression was significantly higher, whereas Noxa expression was markedly reduced in OA- and RA-FLS compared to NL-FLS. In addition, a significantly higher Mcl-1/Noxa mRNA ratio (~20-fold) was also observed in RA-ST suggesting the resistance of RA-FLS to apoptosis compared to NL-ST. Studies in the rat AIA model showed an increase in Mcl-1 (~88%) and a decrease in Noxa (~55%) expression in the joints of AIA rats on day 18 compared to the naïve group. Studies suggest that the phosphorylation of Mcl-1 at Thr163 inhibits its anti-apoptotic activity and phosphorylation at Ser159 destabilizes Mcl-1. Our results showed a significantly lower phosphorylation state of Mcl-1 at Ser159/Thr163 (~63%) and specifically at Mcl-1 Ser159 (~60%) sites in RA-FLS indicating their pro-survival nature compared to NL-FLS. RA-FLS also showed an increase in p-Mcl-1 Ser64 protein expression which enhances its anti-apoptotic property. A similar decrease in p-Mcl-1 Ser159/Thr163 and p-Mcl-1 Ser159, and an increase in p-Mcl-1 Ser64 was observed in the joints of AIA rats compared to the naïve group. Pretreatment of RA-FLS with AT101 markedly inhibited TNF-α-induced Mcl-1 as well as pSer159/Thr163, pSer159 and pSer64 protein expression in RA-FLS. Moreover, this increase in Mcl-1 expression was in contrast to the paucity in the expression of pro-apoptotic proteins Bak and Bax in RA-FLS and in the joints of AIA rats compared to their respective controls.

Conclusion:

This study provides a novel evidence for higher Mcl-1/Noxa ratio and increased phosphorylation of Mcl-1 at Ser64 as a potential mechanisms of Mcl-1 stability and RA-FLS survival in RA pathogenesis.

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Education Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Office orthopedics, and community-based rheumatology overlap in the care of patients with regional pain syndromes. A thorough understanding of these syndromes requires proficiency in clinical anatomy. Previous data indicated a deficient knowledge of clinical anatomy among rheumatologists and rheumatology fellows. In this study, we compared the level of anatomic knowledge between orthopedic and rheumatology trainees and studied the educational impact of a clinical anatomy workshop in both groups of fellows.

Methods: All first-year rheumatology fellows and a convenience sample of first-year orthopedic fellows from Mexico City, all in the 9th month of training, were invited to the workshop. Fourteen of 15 orthopedic fellows and 17 of 20 rheumatology fellows agreed to participate. A pre- and the post- workshop test consisted of 20 questions in which fellows identified or demonstrated relevant anatomical structures in a live human body. These questions, arranged by anatomical regions, were identical in the pre- and post-workshop tests and implemented in 5 stations.

Results: (Table) Overall, the 31 participants showed an increase in correct answers, from a median of 6 (range 1 to 12) of 20 in the pre-workshop test, to a median of 14 (range 7 to 19) in the post-workshop test. Orthopedic fellows scored a median of 7 (range 2-12) and rheumatology fellows 5 (range 1 to 10) in the pre-workshop test. Corresponding scores in the post-workshop test were 15 (10 to 19) and 12 (7 to 18). Intra-group comparisons showed a statistically significant improvement in both the orthopedic and the rheumatology fellows. Inter-group comparisons, from comparable scores in the pre-workshop test, favored the orthopedic group in the post-workshop test.

Conclusion: We found baseline knowledge in clinical anatomy to be deficient in both orthopedic and rheumatology fellows in their first year of training. Our clinical anatomy workshop was useful, in the short term, as a teaching instrument for both groups of trainees. There is a need for a better training in clinical anatomy in orthopedic and rheumatology programs.

An Evidence-Based Analysis and Revision of a Pediatric Rheumatology Academic Half-Day Program

Mercedes Chan[1] and Kristin Houghton[2], [1]Pediatrics, Division of Pediatric Rheumatology, University of Alberta, Edmonton, AB, Canada, [2]Rheumatology/Pediatrics, British Columbia's Children's Hospital, Vancouver, BC, Canada

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Education Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

The pediatric rheumatology (PR) academic half-day (AHD) is a weekly 2-hour block of protected time in our training program for trainees to discuss topics relevant to their future practice. Topics reflect the Royal College of Physicians and Surgeons of Canada's (RCPSC) objectives of training and are covered in a 1-year curriculum. Instructional formats vary with trainees' preference. Weekly topics are assigned to trainees who lead discussions using PowerPoint, cases, or articles with faculty supervision. Medical education practices recommend regular evaluation of curricula to ensure they meet objectives and align with educational theory and evidence-based patient care. As part of a medical education quality assurance exercise, we aimed to:

1) Evaluate a PR AHD curriculum.

2) Make evidence-based recommendations for AHD program development using feedback from curriculum analyses and an instructional design model.

Methods:

The AHD program was evaluated using Posner's framework for curriculum analysis to determine its strengths and weaknesses. Data collected: curriculum descriptions (origin, content), program evaluations, and interviews with staff and trainees regarding teaching and learning experiences. Hidden curricula and epistemological assumptions were elicited.

Feedback from analyses was used to guide plans for a formally structured AHD program based on the Dick and Carey instructional model (instructional goals, learner characteristics, performance objectives, instructional strategy).

Results:

Strengths: flexible learning formats, identified core topics, learner independence, regular assessments.

Weaknesses: inconsistent structure, lack of level-specific tasks for junior/senior learners, vague performance objectives.

A revised AHD program was developed around a 2-year spiral curriculum based on RCPSC core topics. Topics are organized into units of 1-4 modules, e.g., a lupus unit includes modules on neonatal lupus, lupus nephritis, outcome measures, and cutaneous disease. Modules are case-based to situate learning, have junior/senior-level goals, and include performance objectives based on authentic tasks, requiring learners seek out the latest evidence behind practice.

E.g., You are a pediatric rheumatologist recommending a joint injection for a child with monoarticular juvenile idiopathic arthritis. What drug will you use to inject and what risks/benefits will this have for the child?

Modules end with a quiz based on the principle that assessment drives learning. Each AHD session concludes with a request for staff and trainees to write instructional objectives and questions on the current topic. In this way, the AHD modules are continuously updated and participants are engaged in the development of the curriculum.

Conclusion:

Regular curriculum analyses can reveal strengths and weaknesses of programs to guide revision of instructional strategies. The caveat exists that new instructional designs undergo piloting and evaluation for efficacy (improved knowledge, patient care) and acceptability, and are regularly revised to maintain currency.

Effective Knowledge Transfer: A Demonstration of Video Illustration in the Immunology Curriculum for Rheumatology Trainees

Dharini Mahendira[1], Arthur A. M. Bookman[2], Heather McDonald-Blumer[3], Jerry Won[4] and Carolina Landolt-Marticorena[5], [1]Rheumatology, St. Michael's Hospital, University of Toronto, Toronto, ON, Canada, [2]Rheumatology,, Toronto Western Hospital, University of Toronto, Toronto, ON, Canada, [3]Rheumatology,, Mount Sinai Hospital, University of Toronto, Toronto, ON, Canada, [4]Biomedical Sciences, University of Toronto, Toronto, ON, Canada, [5]Rheumatology, Toronto Western Hospital and University of Toronto, Toronto, ON, Canada

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Education Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: A proper foundation in immunology is essential for the understanding and management of rheumatic conditions. An effective immunology curriculum is required for rheumatology trainees to meet the core competencies mandated by the Royal College of Physicians and Surgeons of Canada. However, we have demonstrated that Canadian Rheumatology Program Directors and trainees believe that current immunology curricula, teaching and resources require significant improvement. We have developed a short video clip highlighting a well-defined immunology topic and assessed its role in facilitating relevant knowledge acquisition in rheumatology trainees.

Methods: We enlisted an Education Information Technology (EIT) student to create a five-minute immunology video clip on T cell development. The topic was identified as “high yield” by rheumatology Program Directors and trainees across Canada. Adobe Illustrator and After Effects were used to design the video. Immunology and rheumatology experts assisted in the creation of the video content. The video was piloted on adult and pediatric rheumatology trainees at the University of Toronto and semi-structured qualitative feedback was obtained. Additionally, a quiz based on contents of the video was administered to the trainees before and after its viewing. The teaching effectiveness of this tool was evaluated by comparing pre and post video scores.

Results: A total of fourteen rheumatology trainees (eleven adult and three pediatric) participated in the video testing. All participants identified the immunology video as easy to follow and stimulating. Participating residents described the immunology video as “engaging, excellent and effective.” All trainees agreed that similar immunology video clips would be a valuable addition to their current immunology curriculum. There was a significant improvement observed between pre and post-testing ($p < 0.0001$). The average pre-test score was 50.6% (+/- 26.9), compared to an average post test score of 85% (+/- 14.9). There was an average improvement in scores of 34.4% (+/- 22.2) with a 95% confidence interval of 22.7%-46.0%. While only 5/14 participants received a passing score as set by our departmental guidelines (≥ 70%) on the pre-test, 13/14 participants successfully passed the post-test. Thirteen rheumatology trainees (10 adult and 3 pediatric) participated in repeat post-testing approximately three months later. Knowledge retention was demonstrated, with an average quiz score of 77.15 % (+/- 14.61).

Conclusion: Our pilot immunology video clip was an effective tool for improving short-term comprehension of a focused immunology topic amongst rheumatology trainees. Furthermore, knowledge was retained three months thereafter. These results are encouraging, and support the development of further immunology videos. This teaching aid has great potential as an educational deliverable, helping to improve and standardize immunology training.

Ambulatory Rheumatology Curriculum: Effect of Fellow Teaching Multimodal Simulation Curriculum Enhancement

Oana E. Zaha[1], Susan A. Harwell[2], Cecilia P. Chung[3], Mario A. Davidson[4], D. Alan Johnstone[5], Laura A. Skaug[5], Charlene M. Dewey[6] and Susan F. Kroop[2], [1]Rheumatology and Immunology, Vanderbilt University School of Medicine, Nashville, TN, [2]Division of Rheumatology, Vanderbilt University School of Medicine, Nashville, TN, [3]Division of Rheumatology & Immunology, Vanderbilt University School of Medicine, Nashville, TN, [4]Department of Biostatistics, Vanderbilt University School of Medicine, Nashville, TN, [5]Center for Experiential Learning and Assessment, Vanderbilt University School of Medicine, Nashville, TN, [6]Internal Medicine, Vanderbilt University School of Medicine, Nashville, TN

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Education Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Internal medicine (IM) trainees should be proficient in rheumatologic knowledge and skills. Our prior data show that a curriculum including an attending-led multimodal simulation training session (MSTS) improves residents' self-confidence in rheumatologic history, physical exam, procedures, and patient care. This academic year, we elected to have the second year rheumatology fellows lead the MSTS. To assess effectiveness, we conducted pre/post self-assessment surveys of residents completing the rheumatology curriculum and compared them to the prior year.

Methods:

All Post Graduate Year 1(PGY 1) IM residents rotating on the ambulatory rheumatology block during the 2014 and 2015 academic years participated in a two-part training session. Residents performed a rheumatologic history and exam on a standardized patient presenting with knee pain and practiced knee joint aspiration with a mannequin. In 2015, second year rheumatology fellows completed a six session teaching training period. After this training, fellows directed the MSTS program for PGY1 trainees.

All PGY 1 residents completed an online, self-assessment survey on self-confidence (0=not confident, 100=extremely confident) in performing a rheumatologic history, physical examination, common procedures, and interpreting rheumatologic lab tests pre/post their rheumatology block in addition to a MSTS evaluation. We compared the pre/post survey results in residents' self-assessed confidence from the 2014 and 2015 academic years using the Wilcoxon signed-rank test. The Institutional Review Board approved the study.

Results:

A total of 40/44 (91%) and 25/29 (86%) PGY1 trainees from 2014 and 2015 respectively completed the pre/post-surveys. Both cohorts increased their self-assessed confidence ratings from pre to post in all variables (Table 1). There was no significant difference in improved self-confidence levels on pre/post rotation in performing a rheumatologic history or exam and in interpreting common rheumatologic labs. However, compared to the 2015 fellow-taught cohort, the 2014 faculty-taught cohort had a significantly higher improvement in median self–assessed confidence in performing knee injection [median 44; IQR (20-57.5) vs. 26; IQR (16-37)] and knee aspiration [median 50, IQR (25-64) vs. 25; IQR(3-40)] (Table 1). In both cohorts, over 98% of PGY1 IM residents strongly agreed or agreed that the MSTS was a valuable training exercise.

Conclusion:

Our results indicate that the fellow-led MSTS enhanced curriculum is as effective as an attending-led MSTS enhanced curriculum in

improving residents' self-confidence in performing a rheumatologic history and exam, but not in knee aspiration and injection. These results suggest that a fellow-led MSTS program can be effective, however, alternative methods for training fellows to teach joint injections and aspirations should be investigated.

Table 1: Comparison of Change in Median Self-assessed Confidence Levels of PGY1 IM Residents: Faculty vs. Fellow-led MSTS Enhanced Curriculum

	2014 Change in Median (IQR) Faculty-led	2015 Change in Median (IQR) Fellow-led	Difference of change in median (95% CI)
Self-assessed confidence in performing:			
Rheumatology history	31 (20, 52)	35 (22, 55)	2 (-10, 15)
Rheumatology exam	34 (24, 51)	34 (20, 53)	-2 (-12, 9)
Knee injection	44 (20, 58)	26 (16, 37)	-17 (-29, -3)
Knee aspiration	50 (25, 64)	25 (3, 40)	-22 (-34, -5)
Shoulder injection	13 (1, 29)	17 (-1, 27)	-2 (-12, 8)
Trochanteric bursa injection	13 (0, 32)	13 (0, 27)	-1 (-11, 6)

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Education Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

To describe the confidence and training experience acquired during rheumatology training in 21 core competences across the different European countries.

Methods:

As part of a European project to evaluate the differences and similarities in training in rheumatology across Europe, we developed an online survey to assess the training experience. The target population was trainees in rheumatology and rheumatologists certified in the past 5 years. We selected 21 competences, core to rheumatology clinical practice, from the UEMS European curriculum framework (1). For each competence, respondents were asked to assess the confidence in their abilities (0-10 numerical rating scale), the existence of formal education (yes/no), the experience with patients (0; 1-10; 11-50; 51-100; 101-150; >150) and the existence of an assessment (yes/no) where appropriate. All questions referred to the training period. The survey (June-December 2014) was disseminated in each country by a national PI.

Results:

We gathered 1433 answers to the survey of which 1079 could be included in the analysis (24% of overall target population). Respondents came from the 41 EULAR countries with rheumatology training (30% male, 52% trainees). A summary of the results is presented in Table 1.

Competence	Confidence mean (SD)	Very low confidence (NRS<3)	Education (yes)	Limited practical experience (<10)**	Assessment (yes)
MSK exam	8.97 (1.5)	3 (0.3%)	785 (75%)		517 (51%)
Detect synovitis	9.04 (1.4)	4 (0.4%)	783 (75%)		521 (52%)
Inerpret lab tests	9.38 (1.1)	2 (0.2%)	836 (81%)		578 (58%)
Disease activity measures	8.90 (1.5)	10 (0.9%)	802 (77%)		537 (54%)
Monoarthritis*	9.10 (1.4)	3 (0.3%)	831 (80%)	126 (12%)	569 (57%)
OA*	8.90 (1.6)	7 (0.7%)	764 (74%)	70 (7%)	519 (52%)
Gout*	9.12 (1.4)	3 (0.3%)	855 (83%)	144 (14%)	544 (54%)
Early RA*	9.04 (1.4)	3 (0.3%)	925 (89%)	97 (10%)	604 (60%)
SpA*	9.00 (1.4)	2 (0.2%)	939 (91%)	83 (8%)	597 (60%)
CTD*	8.02 (1.9)	17 (1.6%)	821 (79%)	214 (21%)	568 (57%)
Vasculitis*	7.45 (2.2)	37 (3.5%)	768 (74%)	450 (44%)	513 (51%)
OP*	8.66 (1.6)	7 (0.7%)	816 (79%)	93 (9%)	536 (53%)
bDMARD*	8.84 (1.8)	18 (1.7%)	814 (78%)	170 (17%)	527 (52%)
Knee aspiration	8.96 (2.0)	35 (3.3%)	828 (80%)	186 (18%)	483 (48%)
Hand X-ray	8.15 (1.9)	18 (1.7%)	725 (70%)	104 (10%)	473 (47%)
Crystal ID	6.07 (3.8)	285 (26.6%)	545 (53%)	622 (61%)	295 (29%)
MSK US	5.83 (3.4)	252 (23.8%)	721 (70%)	391 (39%)	434 (43%)
Multidisciplinary team	8.11 (2.3)	47 (4.4%)			376 (37%)
Interpret research paper	7.84 (2.1)	26 (2.4%)	648 (62%)		407 (41%)
Presentations	8.06 (2.1)	28 (2.6%)	618 (59%)	408 (40%)	472 (47%)
Communication	8.94 (1.5)	8 (0.7%)	547 (53%)		418 (42%)

* Questions on diseases referred to the management of a patient with a given rheumatic disease

** Practical experience refers to patients managed during training. Managing was defined as having some degree of responsibility in their treatment and/or follow-up.

SD: standard deviation; NRS: numerical rating scale; ID: identification

For any given competence, mean confidence was higher in respondents who had received formal education than in those who had not. Similarly, for all clinical competences and rheumatologic techniques, mean confidence was also higher amongst those who had a higher patient experience than in those who managed ≤10 patients during their training with that given disease. Mean acquired confidence was also higher in respondents who had a longer training period (internal medicine plus rheumatology) than in those with a shorter training period for all competences except osteoporosis and hand Xray interpretation. The level of confidence was also higher for specialists (vs trainees).

Conclusion:

The acquired confidence in competences during the rheumatology training program considered core for rheumatology practice is variable, but high for most competences. Most of the trainees seem to receive formal education and have some patient experience in all competences, though only around half are assessed in each competence.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Education Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

To assess the association between the country where rheumatology training takes place and the acquired confidence, exposure to education, practical experience and competence assessments in 21 core competences

Methods:

As part of a European project to evaluate the differences in training in rheumatology across Europe, we developed an online survey to assess the training experience. The target population was rheumatology trainees and rheumatologists certified in the past 5 years. We selected 21 competences, core to rheumatology: 13 clinical (MSK examination, detecting synovitis, managing a patient with monoarthritis, lab test interpretation, managing a patient with OA, gout, early RA/undifferentiated arthritis, SpA, CTD, vasculitis, OP, with a biologic DMARD, using disease activity measures), 4 procedures (knee arthrocentesis, crystal identification, hand X-ray interpretation, performing an MSK US) and 4 generic competences (engaging in a multidisciplinary team, interpreting a research paper, performing a scientific presentation, and patient communication). For each competence, respondents were asked to assess the confidence in their abilities (0-10), the exposure to formal education (yes/no), the amount of patient experience (0; 1-10; 11-50; 51-100; 101-150; >150) and assessment (yes/no) where appropriate. For each competence, regression models (linear or logistic, as appropriate) were developed to assess the influence of country of training on the level of confidence, education, practical experience and assessment for that given competence.

Results:

1079 answers were included in the analysis (30% male, 52% trainees) from the 41 EULAR countries that offer rheumatology post-graduate training. For all given competences, the country of training was significantly associated with the acquired confidence. For example, trainees from the UK (arbitrary reference) had on average 1.4 points higher confidence in their ability to manage a patient with early RA than a trainee from France (Table 1). Education and managing >10 patients were also associated with the acquired confidence for all competences. The existence of an assessment was associated to the level of confidence for only some competences (MSK exam, managing a patient with CTD, with vasculitis, crystal ID, MSK US, multidisciplinary team and interpreting a paper).

	44 - Turkey (Physical therapy)	-0.40	-1.17, 0.38
	46 - Ukraine	-1.54	-2.95, -0.13
Education (yes vs no)		0.54	0.28, 0.81
Assessment (yes vs no)		-0.05	-0.22, 0.12
Patient exposure (>10 vs ≤10)		0.88	0.60, 1.15
* $p<0.0001$ for overall effect of country variable (with all dummies in the model)			

The country of training was also associated with a higher odds of receiving formal education, of being exposed to >10 patients and of being assessed in a given competence (all separate multivariable models).

Conclusion:

The European country where rheumatology postgraduate training is performed is associated with the level of confidence acquired, the odds of receiving formal education, the odds of acquiring patient experience and the odds of being assessed in core rheumatic competences. Further attempts are needed to harmonize educational outcomes of rheumatology training across Europe.

First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Education Poster I
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Patients have many reasons for medical non-adherence. Finances often contribute where even the insured may find the cost of medications prohibitively high. In rheumatology, with the advent of multiple biologic medications, the cost of treatment regimens has soared. We therefore devised a structured clinical encounter for rheumatology fellows to assess how well they address non-adherence in a patient that has stopped his/her biologic medication secondary to a loss of insurance.

Methods: The 9thannual 2013 New York City Rheumatology Objective Self Assessment Clinical Exam (NYC-ROSCE) featured 5 stations each focusing on rheumatic diseases. In one of the stations we devised a scenario where a trained actor portrayed a patient with rheumatoid arthritis that had previously been well controlled on a biologic medication. The patient though in the encounter now comes into the office with a disease flare after having stopping their regimen because of unemployment and losing his/her insurance. The actor was instructed to be embarrassed at addressing this awkward financial issue. The fellows were then asked to assess why the patient had now become non-adherent with their biologic and offer potential solutions to the patient.

Results: 24 fellows participated from 7 NYC-area rheumatology fellowships. Fellows were observed and evaluated on a 9-point Likert scale (9:excellent) by both a patient-actor and an MD evaluator. At this station, the mean patient-actor scores for composure (7.38), partnering with the patient (7.29), professionalism (7.67) and empathy (7.04) were high and not significantly different from the MD evaluators. Fellows were also evaluated on a 4-point scale as to how well they assessed financial burden and whether the patient-actors felt judged regarding their financial status (1: not at all, 4: extensively). On average all fellows addressed finances to a certain extent (2.95) and the patient-actors did not feel very judged (1.8). Interestingly though only 58% of the patient-actors felt that the fellows truly found the cause of the non-adherence v 92% of the MD evaluators (p=0.02). If assistance with finances was offered, patient-actors were most offered a referral to social work (11/24), referral to a patient assistance program (11/24) and a referral to the Medicaid office (7/24).

Conclusion: In our OSCE encounter, while the fellows were all very professional, the patient-actors felt that only 58% of them had truly addressed the root cause of non-adherence: a lack of insurance. All of the fellows addressed finances to a some extent which is perhaps

why the MD evaluators felt that more fellows addressed the cause of non-adherence when compared to the actors. This difference in perception is key given that potentially fellows may not be sufficiently trained to examine the psychosocial issues that lead to non-adherence.

Assessment of a Rheumatology Curriculum Utilizing Multiple Learning Modalities

Joshua Scott[1] and Daniel Battafarano[2], [1]Internal Medicine/Rheumatology, San Antonio Military Medical Center, JBSA - Ft Sam Houston, TX, [2]Rheumatology, San Antonio Military Medical Center, JBSA - Ft Sam Houston, TX

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Education Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Graduate medical education has evolved to incorporate more interactive learning modalities, such as audience response, problem based learning, and patient encounters. We have incorporated these modalities into the rheumatology series of the internal medicine (IM) residency didactic sessions at our institution. This curriculum was assessed utilizing survey data from participants evaluating self-assessment of rheumatology knowledge and preference of learning modality.

Methods: Over a 4 week period IM residents attended 12 hours of didactic sessions dedicated to rheumatology education taught by the rheumatology department. The didactic sessions were divided into lecture, interactive lecture with audience response, rheumatology patient encounters, case based learning, and arthrocentesis simulation lab (Table 1). The effectiveness of our curriculum was measured utilizing survey data collected from participants evaluating pre-curriculum and post-curriculum self-assessment of rheumatology knowledge on a 10 point Likert scale (0=very poor, 10=very good). The survey tool also evaluated preferred learning modality on a 10 point Likert scale (0=not preferred, 10=most preferred). The learning modality preference data was analyzed utilizing a four factor repeated measures ANOVA and Bonferroni corrected post hoc analysis between modalities.

Table 1 Rheumatology Curriculum for IM residents

	Day 1	*Day 2*	*Day 3*	*Day 4*
Hour 1	Lecture[1]	Interactive Lecture[3]	Lecture	Case Based Learning
Hour 2	Arthrocentesis Simulation Lab[2]	Patient Encounter[4]	Case Based Learning	Case Based Learning
Hour 3	Arthrocentesis Simulation Lab	Case Based Learning[5]	Patient Encounter	Interactive Lecture

Definitions: [1]Lecture is a PowerPoint style. [2]Arthrocentesis Simulation Lab utilizes joint models to teach arthrocentesis/injection. [3]Interactive Lecture is a PowerPoint style with audience response or knowledge bowl style. [4]Patient Encounter is interaction with a patient who has a rheumatic disease and discussion led by rheumatology staff/fellow. [5]Case based learning is a small group discussion of ACR Rheum2Learn modules.

Results: A total of 65 participants attended the didactic sessions, 44/65 (67.7%) completed the survey. The participant's pre-curriculum self-assessment mean was 3.98 and post assessment mean was 6.61. This increase of 2.63 was statistically significant ($p < 0.001$). The results of the learning modality assessment are presented in table 2, the most preferred learning modality was rheumatology patient encounters and least preferred was lecture.

Table 2 Learning Modality Preference Results

	Mean (n=44)	Range	p-value*
Lecture	6.07	1-9	-
Arthrocentesis Simulation Lab	6.75	3-10	0.196
Interactive Lecture	6.93	3-9	<0.001
Rheumatology Patient Encounter	8.07	3-10	<0.001
Case Based Learning	7.55	3-10	<0.001

*from post-hoc comparison of each modality to lecture

Conclusion: IM residents found a curriculum utilizing multiple educational modalities very effective to improve rheumatology knowledge. IM residents prefer interactive teaching modalities to basic lecture. The most preferred method of instruction included the use of direct patient encounters guided by a rheumatology interview, examination, and discussion.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Education Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

A 2008 survey involving 46 responding rheumatology fellowship program (RFP) directors (PDs) (46/135, 33% responder rate) found that 41% included some aspect of musculoskeletal ultrasound (MSUS) in their training. Although not a RFP requirement, more programs have since incorporated MSUS training. Our goal was to assess the current state and ascertain the needs for MSUS education among RFPs, in addition to determining methods of curricular integration.

Methods:

Two surveys (S1, S2) were developed and sent via the online survey tool Qualtrics™. S1 is a 13-item needs assessment [ultrasound (US) machine accessibility, faculty training, and institutional support] sent to all PDs of current RFPs. S2 is a 32-item curricular assessment sent to lead MSUS faculty designated by PDs.

Results:

S1: Out of 113 currently active RFPs, 103 (91%) PDs responded; 94% of RFPs are currently offering some form of MSUS training. Lead MSUS faculty were identified as: key clinical faculty (KCF) (44%), PDs (24%), and other non-KCF (15%). US machine access was reported as follows: owns (76%), leases (5%), shares with another division (15%), no access (5%). 84% of RFPs reported at least 1

faculty competent in MSUS. Of 6 programs not engaged in MSUS, all would like to eventually offer training. 66 (63%) of PDs felt that inclusion of MSUS into the RFP curriculum should be optional; 33 (32%) preferred for it to be mandatory, while 4 (3.8%). felt it should be excluded.

S2: Out of 97 RFPs offering MSUS training, 71 (73%) responded. Of the respondents, 41% have a formal written curriculum. 81% would share curricula, and 69% would collaborate in curriculum development. At least 1 faculty member in each RFP has been described as having received MSUS training (34%), certification (32%), and are actively teaching fellows MSUS (52%). Overall, ACR certification was obtained by 88%. Common training avenues were the: ACR Fundamentals Course (52%), USSONAR Train-the-Trainers Course (38%), and faculty instruction (39%). Common curriculum topics were anatomy, procedures, image optimization, and sonopathology. Common instructional strategies were hands-on-clinic-teaching (HOCT), USSONAR fellowship program, and online materials. Procedure logs were the most common evaluation method. HOCT was accomplished via dedicated faculty US clinic in 49%. Fellow access to machines was available in continuity clinics, dedicated US clinics, and faculty clinics. Of 65 programs with an identified MSUS clinic, more teaching emphasis was on diagnostic US (41%), US-guided procedures (22%), or an equal emphasis in both areas (41%). While 86% of RFPs reported time for self-directed learning/practice, this occurred primarily in the second year of training in 54%. MSUS is a graduation requirement in 7% of programs. The major barriers to MSUS integration were inadequate clinic time, and lack of training funding for faculty and fellows.

Conclusion:

MSUS has become prevalent in RFPs. Most programs have access to equipment and educators. Curricular integration is heterogeneous. Curricular and assessment tool standardization is widely desired among PDs. Information from these surveys will inform educators moving forward.

Comprehensive Musculoskeletal Exam Curriculum for Rheumatology Fellows

Sonali Narain, Shanthini Kasturi and VP Bykerk, Rheumatology, Hospital for Special Surgery, New York, NY

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Education Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The musculoskeletal exam (MSKE) is an integral part of rheumatology training, both as a diagnostic aid, and as a predictor of disease activity. Formal structured training in MSKE is not given priority at various levels of medical education including rheumatology fellowship. Our aim was to design and implement a formal structured program in MSKE for rheumatology trainees that would: 1) improve fellows' comfort and confidence in performing joint examinations and assessing disease activity and 2) improve fellows' knowledge of the diagnosis of MSK pathology through physical exam.

Methods: Applying Fleming's Visual Auditory Kinesthetic model, we devised a structured program covering a systematic approach to examination of all major joints/joint areas as well as inflammatory arthritis disease activity indices. Adult and pediatric rheumatology fellows at a single teaching hospital were invited to participate. Success of the curriculum was measured by the likelihood of attendees to recommend the training and by an overall rating of >5 on a 10 point scale. Participants also completed pre- and post-curriculum questionnaires containing subjective (comfort and confidence) and objective (knowledge) domains. Content knowledge was assessed using validated questions in the literature, many of which had an orthopedic focus.

Results: Of the 8 fellows who participated in the program, 75% reported no prior formal MSKE training. All participants felt that training in the MSKE should be part of fellowship and over 80% of fellows were likely or extremely like to recommend the course to others. The

average rating of the curriculum was 8/10. The post-curriculum assessment showed: 1) modest increase in the percentage of fellows endorsing comfort in their exam skills and confidence in their ability to assess disease activity; 2) decrease in the percentage of participants endorsing confidence in diagnosing MSK pathology (Figure 1a); 3) slight improvement in objective scores (Figure 1b).Over 60% of participants felt they could benefit from more practice time.

Conclusion: We successfully implemented a structured MSKE curriculum that was received with enthusiasm and engagement among participants as reflected in their overall rating of the program. The modest improvement in both subjective and objective components of the post course assessment questionnaire may have been due to limitations of the questionnaire. The decline in the participants' confidence in diagnosing MSK pathology may reflect fellows' heightened awareness of limitations in their knowledge at the end of the curriculum. An observed structured clinical assessment may more effectively measure skills relevant to rheumatology and thus improve trainees' confidence.

Comprehensive Musculoskeletal Course Improves Post-Graduate Trainees' Confidence in Performing Joint Injections

Erica Jaffe[1], Andrea M. Barker[2], Grant W. Cannon[3], J. Peter Beck[4] and Michael J. Battistone[5], [1]Internal Medicine, Salt Lake City VA Medical Center and University of Utah, Salt Lake City, UT, [2]General Internal Medicine, Salt Lake City VA Medical Center and University of Utah, Salt Lake City, UT, [3]Division of Rheumatology, Salt Lake City VA Medical Center and University of Utah, Salt Lake City, UT, [4]Orthopaedics, Salt Lake City VA Medical Center and University of Utah, Salt Lake City, UT, [5]Rheumatology, Salt Lake City VA Medical Center and University of Utah, Salt Lake City, UT

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Education Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Developing confidence in procedural skills is an important aspect in improving procedural competency. Although a number of studies have explored effective methods to teach arthrocentesis, the relationship between the number of injections performed and confidence in injection skills has not been researched. We investigated the number of subacromial (SA) and knee injections required for a learner to become confident in procedural skills.

Methods:

Internal Medicine (IM) interns at our program participate in a week-long musculoskeletal skills course that takes place at a VA Medical Center. The course is open to post-graduate residents of other specialties. During the course SA and knee injection techniques are introduced through didactics and reinforced through simulation, peer-teaching and supervised ambulatory experiences. A total of 45 trainees participated in the course in 2014-15 (IM (32), physical medicine & rehabilitation (6), occupational medicine (5), orthopedics (2)). The number of SA and knee injections performed by each trainee was tallied. Before and after the course participants used a 5-point

Likert scale to rate confidence in performing joint injections. Data were divided into two categories for analysis (1-4 = less confident, 5 = highly confident). Chi squared analysis was used to compare the number of injections performed versus post-course self-assessment of confidence.

Results:

In addition to simulator training, trainees performed an average of 1.1 SA injections (range 0-3, median 1) and 1.6 knee injections (range 0-5, median 2). Mean confidence scores markedly increased from 2.4 pre-course to 4.5 post-course for SA injections and from 2.7 to 4.3 for knee injections. Of the participants who started as less confident in SA injections, only 1 (2%) decreased in confidence; 5 (11%) did not change. Of the participants who started as less confident in knee injections, only 1 (2%) decreased in confidence; 2 (4%) did not change. Table 1 shows association between the number of supervised joint injections performed and self-reported confidence post-course.

Table 1. Association of Number of Supervised Joint Injections with Self-Reported Confidence Post-Course

		Number of Joints Injected		
		≤ 1	≥2	Total
Subacromial	Less Confident	20 (44.4%)	5 (11.1%)	24 (53.3%)
	Highly Confident	7 (15.6%)	13 (28.9%)	21 (46.7%)
	Total	27 (60%)	18 (40%)	45 (100%)
				p=0.0022
Knee	Less Confident	9 (20%)	10 (22.2%)	19 (42.2%)
	Highly Confident	13 (28.9%)	13 (28.9%)	26 (57.8%)
	Total	22 (48.9%)	23 (51.1%)	45 (57.8%)
				p= NS

Conclusion:

Our MSK course increased confidence in performing SA and knee injections. Participants who performed at least 2 SA injections had a statistically significant association with ranking themselves as highly confident post-course. There was no statistical significance association between the number of knee injections performed and self-assessment as highly confident post-course. Our next step will be confirming that the self-assessment of confidence is valid by comparing scores to external measures (e.g. objective structured clinical exam).

Internal Medicine Subspecialty Fellows' Attitudes Towards Teaching and Learning How to Teach: A Needs Assessment

Eli Miloslavsky[1] and Jakob McSparron[2], [1]Division of Rheumatology, Massachusetts General Hopsital, Boston, MA, [2]Divsion of Pulmonary and Critical Care Medicine, Beth Israel Deaconess Medical Center, Boston, MA

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Education Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Clinical fellows can have a major educational impact on students and residents. However, a number of barriers to teaching during inpatient consultation exist in the hospital environment, making it challenging to initiate teaching interactions, provide a positive environment for learning and deliver effective teaching. Improving fellows' teaching skills has been proposed as a strategy to enhance teaching during consultation. Within Internal Medicine (IM) subspecialties, fellows' attitudes towards teaching and interest in programs to improve teaching skills has been largely unexplored. We conducted a needs assessment to evaluate IM subspecialty fellows' interest in teaching and improvement of their teaching skills.

Methods:

379 IM subspecialty fellows from three academic medical centers (Massachusetts General Hospital, Brigham and Women's Hospital, Beth Israel Deaconess Medical Center) were invited to complete a survey assessing their attitudes towards teaching, assessment of barriers to teaching during consultation, interest in training related to teaching skills, and the current practices of assessment and improvement of teaching skills during fellowship.

Results:

179 fellows from ten subspecialties responded to the survey (47% response rate), including 15 rheumatology fellows. 80% of fellows anticipate teaching during their careers, and 22% plan to participate in medical education scholarship (Table 1). Fellows reported a strong interest in teaching and programs aimed at improving their teaching skills (Table 2). Fellows who anticipated teaching during their career had more interest in teaching and teacher training. However, the majority of subjects (68%) reported no specific training focused on teaching skills during their fellowship and 37% have never received feedback about their teaching.

Conclusion:

Among a large sample of IM fellows participating in this study, the majority anticipate teaching during their careers. Fellows expressed a strong interest in programs aimed at improving their teaching skills. However, the majority of fellows did not have the opportunity to participate in such programs during fellowship and a significant minority reported that they did not receive feedback on their teaching. A need exists among fellows for programs focused on improving their teaching skills.

Table 1 – Fellows' anticipated career activities

Activity	Total (n=179)	Percentage
Patient care	152	84.9%
Teaching	143	79.9%
Clinical research	123	68.7%
Basic science research	63	35.2%
Administration	45	25.1%
Medical education scholarship	40	22.3%
Not sure	7	3.9%

Table 2 – Fellows' attitudes towards teaching

Question	Planning to teach during career		Not planning to teach during career		p-value
	Disagree-neutral	Agree or strongly agree	Disagree-neutral	Agree or strongly agree	
I enjoy teaching residents and medical students	6 (4.3%)	134 (95.7%)	5 (14.3%)	30 (85.7%)	0.04
If I had more time I would do more teaching	4 (2.9%)	135 (97.1%)	5 (13.9%)	31 (86.1%)	0.02
My teaching skills can be improved	6 (4.3%)	134 (95.7%)	7 (19.4%)	29 (80.6%)	<0.01
I want to receive more feedback about my teaching	31 (22.1%)	109 (77.9%)	15 (42.7%)	21 (58.3%)	0.02
I am interested in receiving training to improve my teaching skills	32 (23.0%)	107 (77.0%)	12 (33.3%)	24 (66.7%)	0.2

Developing an Introductory Musculoskeletal Ultrasound Curriculum for Rheumatology Fellows

Ekaterini Zapantis and Maria-Louise Barilla-LaBarca, Rheumatology, North Shore - Long Island Jewish Health System, Great Neck, NY
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Education Poster I
Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Musculoskeletal ultrasound has been increasingly recognized as a cost-effective, sensitive diagnostic bedside tool that rheumatologists can utilize across a wide spectrum of inflammatory and non-inflammatory diseases. It is rapidly becoming a highly requested elective during fellowship, though few curricular components exist for fellows not enrolled in a dedicated year-long course of training track. We report on our newly designed curriculum that features intermittent, short intense bursts of interactive teaching exercises that utilize formative assessment, flanking each session as a means to not only assess effectiveness of learning across several months, but also to reinforce important concepts from previous weeks and lead to a more durable retention of material when daily practice is not feasible.

Methods: Six two-hour teaching sessions were developed over a four month period of time. Fellows personal goals were assessed initially to guide the curriculum development. Each session focused on a different joint area and consisted of a de-identified pre-assessment and cumulative assessment, short framing lecture, modeling of scanning technique, hands on scanning (with a 1:1 or 2:1 fellow:machine ratio), and post-assessment. All questions were reviewed with the fellows at the conclusion of every session. The cumulative assessment consisted of 10 multiple choice questions related to key concepts from prior sessions and the pre-assessment contained 5 multiple choice questions about the day's session. The post-test consisted of 5 multiple choice questions which covered the sessions's content. A final assessment was administered about a month after the last session which consisted of 53 multiple choice questions to assess retention of knowledge.

Results: Three rheumatology fellows (two first years, one second year) with at most minimal experience, participated in the curriculum. Participants' personal goals included understanding the mechanics of ultrasound as well as identifying normal structures and pathology. A poll after the course revealed that all objectives were met. The average score of the six pre-assessments was 43.5% and 85% on the post-assessments with an average percent improvement of 41.5%. The cumulative pre-assessments (not including the final assessment) average score was 71%. The final assessment average was 80%. It was observed that the fellows scored equally on first order and higher order questioning.

Conclusion: Effective implementation of a musculoskeletal ultrasound curriculum can be easily introduced into a training program where routine daily practice is not possible. Intermittent, short intense bursts in coordination with spiraling content review, was shown to be a successful teaching method with fellows demonstrating durability of knowledge.

	Pre-Assessment Average (%)	Post Assessment Average (%)	Cumulative Assessment Average (%)
Session One (Introduction) Time zero	58	81	
Session Two (Knee) 3 weeks	28	94	80 (Range: 70-90)
Session Three (Hand and Foot) 6 weeks	39	94	70 (Range: 50-90)
Session Four (Wrist) 7 weeks	20	53	80
Session Five (Elbow) 10 weeks	60	90	55 (Range: 40-70)
Session Six (Shoulder) 14 weeks	56	100	80 (Range: 77-85)

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Education Poster I

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Validity Evidence for 2 Objective Structured Clinical Examination Stations to Assess Core Examination Skills of the Shoulder and Knee **Background/Purpose:** A multi-disciplinary group developed two objective structured clinical examination (OSCE) stations to train and assess trainee's skills in the evaluation and management of shoulder pain and knee pain. Our objective was to examine the validity of these two OSCEs. **Methods:** *Content* Two orthopaedists, two rheumatologists, and a primary care provider developed checklists of physical exam maneuvers and criteria for guiding rater observations. Content was proposed by faculty, supplemented by literature review, and finalized through a modified Delphi process. Simulated cases representing common causes of shoulder pain and knee pain were constructed. *Response Process* A multi-disciplinary cohort of 69 trainees participated in the OSCEs in 2014-15. To promote accuracy of the simulated patient (SP) responses to assessment prompts, one faculty member served as SP and another as rater; ratings were recorded in real time. *Internal Structure* Two faculty members independently rated a portion of the cases. Percent agreement was calculated and Cohen's kappa corrected for chance agreement on binary outcomes. *Relationship to Other Variables* Relationship to self-assessment of ability to evaluate shoulder pain and knee pain was explored by written surveys utilizing a 5-point Likert scale. Responses were stratified into 3 categories – low, medium, and high – and compared with similarly stratified OSCE scores. **Results:** Checklists were developed for the shoulder (21 items) and knee (26 items); scoring rubrics converted each checklist to a 5-point scale. Using the examination approach in the checklists, trainees correctly identified rotator cuff pathology 61/69 (88%) and meniscal disease 62/69(89%) of the time. Inter-rater agreement was 89% for the knee (k = 0.55) and 96% for the shoulder (k = 0.51). Relationship of stratified self-assessment and OSCE scores is shown in Table 1; Pearson's coefficient indicated no correlation for either shoulder (0.02) or knee (-0.07). Table 1.

SHOULDER		OSCE Rating			
		Low	Med	High	Total
Self-Assessment Rating	Low	0	0	5	5
	Med	4	5	20	29
	High	5	5	25	35
	Total	9	10	50	69
KNEE		OSCE Rating			
		Low	Med	High	Total
Self-Assessment Rating	Low	0	0	2	2
	Med	11	12	12	35
	High	10	13	9	32
	Total	21	25	23	69

Conclusion: The two station OSCE is responsive and consistency in test performance across a range of trainees over time, with good inter-rater reliability. Lack of correlation with self-assessment suggests that these OSCEs measure a construct that is different than learners' self-confidence to support the continuing use of these two shoulder and knee OSCE stations in a structured educational program. The next steps will search for additional validity evidence of these experiences.

The F-Word: Why Is Talking about Fatigue so Hard?

Ruth Hart[1], Katie Hackett[2], Julia Newton[3], Wan-Fai Ng[3,4] and Ben Thompson[4,5], [1]Institute of Health and Society, Newcastle University, Newcastle upon Tyne, United Kingdom, [2]Institute of Cellular Medicine, Newcastle University, Newcastle upon Tyne, United Kingdom, [3]Newcastle University, Newcastle upon Tyne, United Kingdom, [4]Newcastle-upon-Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, United Kingdom, [5]Newcastle University, Newcastle-upon-Tyne, United Kingdom
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Education Poster (ARHP): Education/Community Programs
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Fatigue is a common symptom for people with inflammatory arthritis and associated auto-immune conditions. Its impact is wide-ranging and significantly reduces health-related quality of life. Research evidence, however, suggests that neither clinicians nor patients consistently raise the issue in clinic. In-depth discussion of fatigue and support from professionals to manage its impacts are rare. Arthritis Research UK developed a booklet, 'Fatigue and Arthritis', intended to help patients help themselves. Our study has explored patients' approaches to managing fatigue and the impact this booklet has upon them.

Methods: Twelve patients from a rheumatology outpatient service in north-east England took part in in-depth, qualitative interviews before and after being given the 'Fatigue and Arthritis' booklet. Patients were recruited purposively to ensure variation in diagnosis (rheumatoid arthritis (RA), ankylosing spondylitis (AS), and primary Sjögren's Syndrome (pSS)), fatigue severity, and demographic characteristics. Data, in the form of transcripts, was analysed thematically using coding, mapping and memoing techniques.

Results: This study confirms both the impact of fatigue and evidence that neither clinicians nor patients routinely raise the matter in consultations. Our data suggests patients face significant barriers to communicating their fatigue, including: reliance on a diverse, colloquial vocabulary to define the problem; uncertainty how it relates to their condition; doubts to its place on the consultation agenda; and a belief that nothing can be done about it. These barriers affect both if and how patients raise their concerns and are reinforced where clinicians' responses do not invite elaboration.

None of our participants, even those who had discussed fatigue with a clinician, reported having seen the 'Fatigue and Arthritis' booklet before. Not all found it of practical help in improving their day-to-day management and experience of fatigue (criticisms including the familiarity and/or unsuitability of advice). However, most reported gaining something from the booklet. Benefits included: improved understanding of a distressing symptom; validation of their concerns; and a sense that things could be done to manage fatigue. These gains made it easier to discuss fatigue and its impacts with clinicians and with family, friends and colleagues.

Conclusion: Our research adds to the limited evidence on barriers to fatigue communication in the rheumatology clinic. In detailing patients' difficulties, it reinforces prior recommendations that clinicians need to be prepared both to initiate discussions and respond sensitively to concerns about fatigue. It suggests that information materials such as the booklet featuring in this study may be a useful tool for improving communication. We encourage clinicians to give this booklet (or a similar resource) to patients reporting fatigue, and to commit to discussing it at future appointments. More effective communication about fatigue would improve clinicians' understanding of the burden of disease individual patients bear and facilitate improved (shared) decision-making about management options.

The Effectiveness of Low-Impact Exercise Program on Musculoskeletal Health of Asian Older Adults

Huijuan Huang[1], Titilayo Ologhobo[1], Vicky Jin[1], Sandra Goldsmith[2] and Laura Robbins[1], [1]Education & Academic Affairs, Hospital for Special Surgery, New York, NY, [2]Public and Patient Education, Hospital for Special Surgery, New York, NY
First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Education Poster (ARHP): Education/Community Programs

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

The Center for Disease Control and Prevention (CDC) showed that in 2010-2015, 50% of adults 65 years or older reported an arthritis diagnosis. Studies have shown that participation in low-impact physical activity improves pain, function, mood and quality of life without worsening arthritis symptoms or disease severity. Despite this, the people with arthritis are less likely to be physically active. Nearly 44% of adults with arthritis report no leisure-time physical activity. In 2010, 25% of Asian seniors age 65 and older in NYC lived in poverty and were affected by musculoskeletal conditions. Asian women are at increased risk for developing osteoporosis since they tend to be slender with lower bone mass and avoid consuming dairy due to lactose intolerance. To help Asian seniors in underserved communities better manage musculoskeletal conditions, Hospital for Special Surgery developed its Asian Community Bone Health Initiative (ACBHI) in 2011. This study attempts to show that ACBHI improves musculoskeletal outcomes in Asian older adults.

Methods:

This eight week low-impact exercise program led by bilingual certified instructors, is held once a week in community-based organizations largely serving Asian older adults. Program impact was evaluated with a pre-post design using validated instruments to assess musculoskeletal outcomes. The 11-point Numeric Pain Rating Scale quantified the intensity of muscle or joint pain. Pain interference on seven daily activities was measured using the 11- point Brief Pain Inventory. The SF-36 measured physical function, while the 6-item self-efficacy scale for managing chronic disease was used to measure self-efficacy to exercise. Stiffness and fatigue levels were measured on an 11- point Numeric Rating Scale and 11- point Brief Fatigue Inventory respectively. Demographics such as age, gender and race/ethnicity were also collected. Paired t-test and chi square tests were used for statistical analysis.

Results:

Between 2011 and 2014, there were 311 participants in the exercise program; 175 responded to bilingual (English/Chinese) surveys. Respondents were mostly female (91%) between 65 and 84 years (75%). Physical function improved with a 69% increase in participants who could lift and carry groceries ($p < 0.001$); 88% increase in participants that could climb several flights of stairs ($p < 0.001$); 67% increase in participants who could bend, kneel, or stoop ($p < 0.001$). Participants' muscle and joint pain decreased by 32% ($p < 0.001$). The mean pain intensity rating reduced from 5.6 to 4.4 ($p < 0.001$). Mean fatigue level dropped from 3.9 to 2.3 ($p < 0.001$) while the mean stiffness level also dropped from 3.8 to 2.6 ($p < 0.001$). Reductions in mean pain interference were seen in all seven daily activities. Participants reported that their exercise confidence increased from 6.9 to 8.5 ($p <0.001$).

Conclusion:

Results indicate that this community-based low-impact exercise program is successful in helping Asian seniors in underserved communities improve musculoskeletal outcomes. Providing free exercise programs to the community can play an important role in improving exercise, and managing musculoskeletal disorders.

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Education Poster (ARHP): Education/Community Programs
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Treatment guidelines for the management of mild to moderate hip and knee osteoarthritis (OA) recommend exercise, weight management and pain medication as first-line treatment to manage and limit symptoms, structural damage and disability. However, delivery of programs within the context of these guidelines by health professionals, such as physiotherapists, poses significant challenges in many countries, largely related to access and cost, as many health care systems do not provide or provide very limited coverage for rehabilitation services. While linking the wellness and health sectors provides an opportunity to increase the availability of programs for people with OA, there is a need to determine if people are willing to participate in programs delivered by trainers delivered in community centers and gyms. The purpose of this survey was to elicit public opinion related to interest in and willingness to attend such community programs, including willingness to pay.

Methods: We conducted an online public survey during September and October 2014. Our sample included the general public in Canada, >30 years of age experiencing hip or knee pain. The 15 question survey could be completed in less than five minutes and included: age; sex; language spoken at home; province/territory of residence and proximity of community/fitness centers; no/yes to pain, aching or discomfort in or around one or both knees/hips/shoulders, hands, neck, back on most days of the past three months; ever told you have arthritis; ever told you have OA or 'wear and tear' in your joints; ever had a hip or knee replacement surgery; membership at a community or fitness center; frequency of exercise at a center or at home; interest in attending a program twice a week for 6 weeks; and, amount willing to pay for such a program. We calculated descriptive statistics with 95% confidence intervals for all variables. Chi-square tests were used to evaluate factors that might be associated with willingness to pay.

Results: After removing duplicate records, 751 completed the survey. 363 (51%) reported knee pain and 247 (34%) reported hip pain. Pain in other joints was reported by 482 (65%). Fifty-seven percent (423) reported that they had been told they had arthritis and 374 (51%) reported OA. Most respondents (79%) resided in British Columbia, 10% in Ontario, with the remainder in the other Canadian provinces. Those with hip or knee replacement surgery (73, 10%) were excluded from further analysis. The results were similar irrespective of joint for the remaining 408 likely to have hip and/or knee OA. Age ranged from 30 to >75 years with 260 (63.7%) aged 45 to 64 years. 86% were female. Only 2 (<1%) reported it took more than an hour to drive to a community center. 156 (38%) reported they currently had a center membership with 203 (50.4%) reporting exercise 3 days/week, 120 (29.8%) <3 days and 80 (19.9%) reporting no exercise. 297 (73.7%) were willing to attend a program and, of these, 26% were willing to pay 100 Cdn$ or more.

Conclusion: Targeted programs delivered in community/fitness centers may be a viable option to support people in managing their hip and or knee OA.

Rheumatology Nurse Advice Line in Singapore Tertiary Hospital – Pilot Study

Sow Ling Yee[1], Xiaohui Xin[2], Rong Fang Zhang[3], Hui Yang[4] and Siaw Ing Yeo[5], [1]Nursing, Singapore General Hospital, Singapore, Singapore, [2]Academic Clinical Programme, Division of Medicine, Singapore General Hospital, Singapore, Singapore, [3]Nursing, Singapore General Hospital, S, Singapore, [4]Division of Medicine, Singapore General Hospital, Singapore, Singapore, [5]Department of Rheumatology & Immunology, Singapore General Hospital, Singapore, Singapore
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Education Poster (ARHP): Education/Community Programs
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

To evaluate the role of the rheumatology nurse advice line service and the patterns of calls for patient management in an outpatient setting.

Methods:

This is a prospective descriptive study. The rheumatology nurse advice line service is meant for addressing non-emergency queries from patients. This service is delivered through an answerphone service. Response times to the calls are kept within 24 hours. Administrative data and patient demographics (November 2013 to May 2015) were collected. The service utilization rate, purpose of call and time taken to respond to patients were also collected and analyzed to assess the demand and the benefit of this service for patients.

Results:

Forty-seven calls were received over the study duration with 79% (37) of the calls made by patients themselves. Seventy-two percent (34) of the calls made were related to clinical issues, while the rest were administrative enquiries. The top three reasons for utilizing this service were: disease-related symptoms (32%), side effect from drugs(19%), and enquiry on procedures or medications(15%). Sixty-eight percent (32) of the cases were made by patients diagnosed with Rheumatoid Arthritis with 50% of their queries pertaining to disease flare and side effects related to immunosuppressive therapy. The mean time taken to respond to a patient's enquiry was 527 min / 8 hours 47 min.

Conclusion:

These results suggest that there is a need for clinical advice pertaining to disease flares and medication side effects as provided by the rheumatology nurse advice line in the management of rheumatoid arthritis patients in an outpatient setting. These interventions may play a significant role in encouraging adherence to therapy, prevent major flares, promote self-management in patients, and improve patient satisfaction. We plan to study the relationship between availability of the rheumatology nurse advice line with management of mild disease flare and adherence to medications.

The current uptake is low as the RNA is a new service and recruitment was not open to all patients. To improve the uptake, we plan to allow access to all patients and increase the awareness of this advice line of referring physicians.

Patient Education in Spondyloarthritis Should be Guiding, Reliable and Available and Presented in Varied Formats

Emma Haglund[1,2,3], Ann Bremander[1,2,3], Stefan Bergman[1,3,4] and Ingrid Larsson[3,5], [1]Department of Clinical Sciences, Lund, Section of Rheumatology, Lund University, Lund, Sweden, [2]School of Business, Engineering and Science, Halmstad University, Halmstad, Sweden, [3]Spenshult Research and Development Center, Halmstad, Sweden, [4]Primary Health Care Unit, Department of Public Health and Community Medicine, The Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden, [5]School of Health and Welfare, Halmstad University, Halmstad, Sweden

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Education Poster (ARHP): Education/Community Programs

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

The treatment target for axial spondyloarthritis (SpA) is to maximize health-related quality of life (HRQoL) by controlling disease activity and improving functioning. The treatment cornerstones are a combination of patient education, pharmacological and non-pharmacological treatment. Health professionals are familiar with providing patient education but the knowledge is scarce concerning how this education is experienced by the patients.

The aim was to describe patients' experiences of education in SpA management.

Methods:

The study had a descriptive design with a qualitative conventional content analysis approach performed in seven steps in accordance with Graneheim & Lundman (1). The analysis aimed to describe and preserve contextual meanings. After coding and subgrouping meaningful parts of the text were merged into categories. Eleven interviews were conducted between 2014-2015 in patients with SpA based on a strategic sampling in order to achieve variation with regard to sex (7 men, 4 women), age (38-66 years), subdiagnoses (5 patients with AS, 6 with USpA), quality of life (EQ5D 0.29-1.0), disease activity (BASDAI 1-6), physical function (BASFI 0-5), and global health (BASG 0-7) .

Results:

Three categories representing patients' experiences of patient education in disease management emerged; guiding education, reliable education and available education. *Guiding education* comprised SpA management including disease knowledge such as symptoms, prognosis, treatment, self-management, climate impact, heredity, and assisting devices. *Reliable education* meant how and by whom the education was communicated and was considered reliable if it was based on science and communicated by specialists, for example by physician, nurse, PT, dietician and senior patients with experience of rheumatic diseases. The patients experienced difficulties in assessing the large flow of education coming from various sources. Individualized education also increased the reliability. *Available education* meant that the education can and should be presented in varied formats, and that the amount of information could be chosen. The education could be given orally (through meetings, videos, lectures), in writing (by pamphlets, e-mails, journals, webpages) or obtained through own personal experiences. There were requests to utilize newer media like skype, video and chat forums. Furthermore, individual contacts with healthcare professionals when needed were of importance.

Conclusion:

This study highlights the importance of obtaining a guiding, reliable and available patient education for management of SpA. Health care professionals need to consider the importance of presenting varied formats of education based on patients' experiences and expectations.

Abstract Number: 1197

Two Strategies for Recruiting Rural Faith-Based Organizations for a Fall-Prevention Exercise Intervention in a Population with High Rates of Arthritis

Dina L. Jones[1], Rachael E. Whitley[2] and Jennifer L. Eicher[1], [1]Orthopaedics, West Virginia University, Morgantown, WV, [2]Marshall University, Huntington, WV

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Education Poster (ARHP): Education/Community Programs

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Rates of falls are higher in older adults, rural areas, and people with chronic conditions such as arthritis. Translating evidence-based, fall-prevention programs into practice is a public health priority in these populations. The Tai Ji Quan: Moving for Better Balance (MFBB) program is an evidence-based, community-delivered, fall-prevention exercise intervention for older adults. There is a need to translate MFBB into more diverse settings, such as faith-based organizations (FBOs). A sample of 237 older adults, of which 63% had arthritis, enrolled in a 16-week translational study of MFBB in 20 rural FBOs. This study describes the methods and outcomes of the 2 strategies used to recruit the FBOs.

Methods: The FBOs in 7 rural counties were eligible to participate if they could secure a space for the class, identify a leader, host a 16-week class, recruit up to 15 class participants, and wanted to continue class after the study ended. The intervention was delivered in 2 rounds. The FBOs in round 1 were identified via mailing lists, internet and newspaper searches, Chambers of Commerce, Extension Service Agents, a Community Partnership Board, and a faith-based consultant. We used multi-stage purposeful random sampling to select

55 of the 164 FBOs in round 1 to receive a recruitment packet by mail. A follow-up mailing was sent to non-responders, as well as the 109 FBOs not targeted in the first mailing. Due to low response rates, we switched to a non-probability sampling method, snowball sampling, which relied on networking and word-of-mouth. We "knocked on doors" of community constituents (e.g., clergy, congregants, fitness centers, senior centers, etc…) and attended church/prayer services, ministerial association meetings, and festivals, and volunteered at potluck dinners and food pantries. We tracked response rates to the mailings, the number of trips and miles traveled, and the number of communications needed to recruit the FBOs.

Results: The study counties had higher rates of rural older adults and arthritis as compared to the US average. Only 6% and 2% of FBOs responded to the first and second mailings, respectively, which resulted in 3 (15%) of the 20 needed FBOs enrolling in the study. Snowball sampling took 12 months, during which we made 289 telephone calls, sent 193 e-mails and 215 mailings, distributed brochures to 69 FBOs, and held 118 meetings, all to recruit the remaining 17 (85%) FBOs. This process involved 20 trips over 31 days for a total of 8933 miles traveled. It took between 1 and 280 days (average 62 days) to recruit a FBO. The FBOs were predominantly Mainline Protestant churches/organizations (70%). Two-thirds of the FBOs were small with fewer than 100 members.

Conclusion: There is a need for fall-prevention interventions in rural older adults with arthritis. In this study, FBO recruitment rates were greater when relying on networking and word-of-mouth rather than mailings. The snowball sampling approach, however, took 1 year to complete with substantial investments in time and travel. Future studies may want to factor in the additional time and costs associated with recruiting FBOs using this method during the planning phase of the study.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Education Poster (ARHP): Education/Community Programs

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Adherence is a complex behavior and rates among patients with rheumatic diseases are especially poor. To date, the impact of interventions on adherence and disease outcomes has been inconsistent. We developed a patient-centered intervention using navigators, college-educated individuals trained to provide education, advocacy, mental health support and care coordination services tailored to each patient's needs, to understand and improve adherence to disease modifying antirheumatic drugs (DMARDs).

Methods: Two board-certified rheumatologists designed a training curriculum for the navigators that included education about systemic rheumatic diseases. Collaborating with a pharmacist, materials were developed on DMARD pharmacokinetics, administration, drug interactions, monitoring, and adverse effects. The drug and disease-specific training consisted of three two-hour modules. A health behavior epidemiologist provided a two-day motivational interviewing training. To familiarize the navigators with available resources, meetings were arranged with a social worker, psychiatry department leadership, a financial counselor, clinic administrators and outpatient pharmacists. Individual structured interviews were conducted between the navigators and four rheumatologists to better understand the needs and perspectives of providers. The navigators also shadowed nurse practitioners during medication education sessions and rheumatologists during clinic visits.

Results: We identified and trained three patient navigators, one of whom is fluent in Spanish. Patients receiving care at an academic medical center with a rheumatic disease who recently started an oral DMARD were eligible. Patients could self-refer, be referred by their

rheumatologist, or be identified by electronic medical record review and were contacted after approval from their rheumatologist. 25 of the 32 practicing rheumatologists referred patients. We sent letters to 553 patients, 313 of whom were reached by a navigator. Of these, 114 enrolled and 102 completed baseline surveys. During the ongoing two-year study, patients are followed for a 6-month period. There have been 360 patient encounters (phone calls or in person meetings) and 20 patients have completed the 6-month intervention. Navigators have established a rapport with rheumatologists and opened a channel of communication between patients and providers. They have identified medication errors, recognized and addressed mental health issues and adverse events, and coordinated care across providers to facilitate adherence to rheumatologists' recommendations. They developed a system with the psychiatry department to expedite referrals based on needs they uncover and routinely work with pharmacies, insurance companies and the financial counselor to ensure that patients obtain their prescribed medications.

Conclusion: A patient navigator program is a feasible strategy to facilitate care coordination and promote adherence to oral DMARDs. Next steps include evaluation of the impact of rheumatology-specific navigators on clinical outcomes and long-term adherence.

The Charla De Lupus (Lupus Chat)® Program: An Evaluation of a Lupus Support Program for Teens, Young Adults and Parents

Melissa T. Flores[1], Jillian A. Rose[1], Roberta Horton[1], Dariana M. Pichardo[1], Lillian Mendez[1] and Lisa F. Imundo[2], [1]Social Work Programs, Hospital for Special Surgery, New York, NY, [2]Assoociate Professor of Pediatrics in Medicine - Rheumatology, Columbia University Medical Center, New York, NY

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Education Poster (ARHP): Education/Community Programs

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Research shows that chronic illnesses such as lupus have a multi-level impact on the entire family; it can be challenging for both patients & caregivers to find support, cope & manage the illness. An evaluation was conducted of a monthly hospital-based psychoeducation program, ongoing since 1994, for teens & young adults with lupus & their loved ones. The program provides a platform for support strategies for coping with lupus. Each 2-hour program includes a professionally-led presentation, hands-on workshop or open discussion on a lupus-related topic.

Methods:

A 46-item survey with Likert scale & open-ended questions was mailed to 290 members. Items included demographics, topic choices, satisfaction, impact & areas for program improvement. Separate analyses on satisfaction & impact were conducted for teens/young adults (Ts/YAs) & parents (Ps).

Results:

53 surveys (18%) were returned. Over half (55%) of the respondents identified as Ts/YAs, 41% Ps & 4% support persons. 86% were female, 63% Latino(a), 26% African American, 7% Asian, and 7% White. 58% attended some college or some high school. 23% reported annual income < $5,000. 92% had health insurance; average # years since diagnosis was 6.

100% of respondents were satisfied with the group overall & the group staff. 98% strongly agree/agree they were satisfied with the topics overall; 96% of respondents strongly agree/agree that the topics presented contributed to their understanding of lupus-related issues. 88% of Ts/YAs strongly agree/agree that the topics helped them cope with lupus.

Satisfaction rated by topic was high overall, but Ps consistently reported higher satisfaction than Ts/YAs. 92% of respondents were satisfied with topic "Caring for the Caregiver" (100% Ps, 86% Ts/YAs); 90% satisfied with "Kidneys and Lupus" (94% Ps, 86%

Ts/YAs); 85% satisfied with "Body Image and Lupus" (94% Ps, 77% Ts/YAs); 89% satisfied with "Lupus, Tattoos & Piercings" (100% Ps, 82% Ts/YAs).

We assessed impact for Ts/YAs group in 4 areas: coping, support, knowledge & management of lupus as a result of group participation. 79% strongly agree/agree they were better able to cope with their illness. 97% strongly agree/agree they had a better support system. 89% strongly agree/agree they know more about lupus & treatments. 93% strongly agree/agree they can better manage lupus. For parents, 88% agree they have a better support system & 83% agree they know more about lupus & treatments.

Results demonstrate the key role that the program plays in providing support & education not only to Ts/YAs but also their caregivers. The high levels of satisfaction & agreement reported by parents highlight the benefit of using a family model in support programs. Responses to open-ended questions underscored that parents value "information & sense of family," "the interaction, support & fellowship," & "knowledge to know how to treat lupus."

Conclusion:

Despite limitations due to a small sample size, our results underscore the success of the program & next steps for program enhancement. The evaluation of this family model of support provides lessons to rheumatology health professionals who work with teens/young adults with lupus to help improve overall quality of life for the entire family.

Use of Focus Groups and Patient Partners to Revise an Internet Self-Management Program

Sharon Newbill[1], Dinesh Khanna[2], Jennifer Serrano[3], Josephine Battyany[4], Dana Rosson[5], Cynthia Maxwell[6], Mary Alore[7], Laura Dyas[8], Saville Kellner[9], Luke Evnin[10], Dennis Raisch[11], Richard Silver[12] and **Janet L. Poole**[13], [1]University of New Mexico, Albuquerque, NM, [2]Division of Rheumatology, University of Michigan, Ann Arbor, MI, [3]University of Michigan, Ann Arbor, MI, [4]Scleroderma Foundation Southern California, Culver City, CA, [5]Medical University of South Carolina, Charleston, SC, [6]Patient Partner, Charleston, SC, [7]Patient Partner, Shelby Township, MI, [8]Scleroderma Foundation Michigan Chapter, Southfield, MI, [9]Scleroderma Research Foundation, Henderson, NV, [10]Scleroderma Research Foundation, San Francisco, CA, [11]College of Pharmacy, University of New Mexico, Albuquerque, NM, [12]Division of Rheumatology and Immunology, Medical University of South Carolina, Charleston, SC, [13]Health Sciences Ctr OT Program, 1 University of New Mexico, Albuquerque, NM

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Education Poster (ARHP): Education/Community Programs

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Taking Charge of Systemic Sclerosis (TOSS) is an internet self-management program developed for people with systemic sclerosis (SSc). The purpose of this qualitative study was to engage patient partners, stakeholders and people with SSc in focus groups to assess whether the current program has the information people with SSc perceived they need to manage and effectively cope with their disease.

Methods:

Six focus groups with a total of 30 participants with SSc were conducted: 2 telephone groups and 4 face-to-face groups. Prior to the focus group meetings, participants reviewed the current website. A semi-structured interview guide was used to elicit participants' responses about additional content needed. Interviews were audio-recorded and transcribed verbatim. Content analysis of de-identified open transcripts occurred in two stages: 1) initial coding by the qualitative researcher to create a coding structure using NVIVO version 10 software that conformed to the topics in the interview and/or focus group guides and 2) an iterative team process which verified and expanded the original coding into emergent themes and categories. The principal investigator conducted an independent review of transcripts. Edits of the initial coding structure, internal audits and member checking were conducted through one discussion.

Results:

The participants were 63% female, 70% Caucasian, 23.3 % African American, 67% had diffuse systemic sclerosis, the mean age was 48.8 years, mean disease duration was 11.4 years, and the mean education level was 15.8 years. Each focus group lasted 2.0-2.5 hours in duration. Dominant themes for additions to the current website: format changes and additional pictures, additional materials on affect and positive affirmation; disease and symptom management; self-advocacy; information for use by caregivers, families, coworkers and strangers; tracking systems for medical records, tests and symptoms; and information about local support groups. Although the focus group questions concentrated primarily on additional content needed, participants were positive regarding the audio voice over, exercise module, content, and the logs and checklists.

Conclusion:

Persons with SSc identified additional content to improve the internet self-management program. Many of the suggestions will be incorporated into the current program as modifications and additions to existing modules, patient testimonials, worksheets, resources sheets, and/or links to additional websites.

A Short Training on Solution Focused Approach May be Helpful in Providing Psychological Support Skills to Nurses Involved in Rheumatoid Arthritis

Mie Fusama[1], Tomoko Shiratori[2], Kayoko Higashi[1] and Hideko Nakahara[1,2], [1]NTT West Osaka Hospital, Osaka, Japan, [2]Kansai Health Administration Center, NTT West Corporation, Osaka, Japan

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Education Poster (ARHP): Education/Community Programs

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Patients with rheumatoid arthritis (RA) often suffer from psychological problems, which may exacerbate pain and disease activity [1]. Bad emotional reaction to the diagnosis of RA contributes to the onset of depression symptoms [2]. However, hospitals cannot readily provide psychological support for patients because of insufficient specialists. Therefore, based on EULAR's recommendations, nurses should acquire the necessary skills to provide psychological support in busy clinical settings.

The aim of this study is to assess if nurses who receive a single short training session from a clinical psychologist can attain confidence and competence in providing psychological support for patients.

Methods:

A clinical psychotherapist provided psychological support training to the participants only once for a period of one hour. This lecture was divided into 2 parts: (1) basic attitudes toward patients, such as "agreeableness", "acceptance" and "empathic understanding"; (2) Solution Focused Approach (SFA), a new method in the RA field, consisting of the miracle, coping and scaling questions.

We evaluated nurses' opinions regarding their confidence and competence in providing psychological support for patients by utilizing a 0-10 scale (0 = none, 10 = full agreement). Participants were asked regarding the necessity and feasibility of psychological support by nurses and their motivation for training. Client Satisfaction Questionnaire-8 (CSQ-8J) was utilized to assess satisfaction with the lecture; while the General Self-Efficacy Scale(GSES)was used to evaluate self-efficacy of nurses. Data analyses were performed with the Paired t-test and Wilcoxon rank sum test.

Results: Nurses involved in treatment of patients with RA were selected randomly between May and June, 2015. 55 nurses (0 male/ 55 female) were included in this study. The average of ages, clinical experience and clinical experience in RA were 42.4 years old, 17.8 and 5.8 years, respectively. Agreement about necessity and motivation was high and there were no statistically significant differences before and after the lecture (mean±SD; necessity: 9.55±1.07, 9.43±1.36, respectively, p=0.591, motivation: 9.24±1.4, 9.14±1.74, respectively, p=0.481). However, agreement regarding feasibility after the lecture was statistically significantly higher than that before the lecture (mean ±SD; 7.88±2.07, 7.16±2.19, respectively, p<0.05). Nurses showed high levels of satisfaction with the lecture. The only question for which satisfaction was low concerned short length and lack of more detailed explanations. There were no statistically significant differences in nurses' evaluations of self-efficacy before and after the lecture.

Conclusion: This is the first study indicating that even short training may be helpful in providing nurses with psychological support and SFA skills. This strategy could be appropriate in busy clinical settings. Further studies of repeated training and of nurses' application of the skills acquired in such training are ongoing.

Knowledge and Perception of Cardiovascular Disease Risk in Patients with Psoriatic Disease

Dennis Wong[1], Daniel Pereira[2], Sutha Shanmugarajah[1], Renise Ayearst[2], Dafna Gladman[2], Cheryl Rosen[3] and Vinod Chandran[2], [1]University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, [2]Rheumatology, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada, [3]Dermatology, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Education Poster (ARHP): Education/Community Programs
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: The prevalence of cardiovascular diseases (CVD) is higher in patients with psoriatic disease. Psoriatic disease is known to be an independent risk factor for the development of CVD. CVD knowledge and risk perception is a key predictor of patients' likelihood of adopting a healthy lifestyle. However, it is not clear whether patients with psoriatic disease have adequate knowledge and what the barriers are that prevent them from understanding CVD risk. Thus, the aim of this cross-sectional study was to assess psoriatic patients' knowledge and perception of CVD and examine their relationship with demographic and clinical characteristics.

Methods: Psoriatic arthritis (PsA) patients, who have had psoriasis diagnosis confirmed by a dermatologist, were recruited from the PsA clinic. Patients with psoriasis without PsA (PsC), were diagnosed by a dermatologist and evaluated by a rheumatologist to exclude PsA. All patients completed the knowledge level questionnaire based on the validated Heart Disease Fact Questionnaire for Rheumatoid Arthritis (HDFQ-RA), and risk perception was measured by the validated Perception of Risk of Heart Disease Scale (PRHDS). Framingham Risk Score was calculated as a measure of the estimated risk of CVD. The relationships between CVD knowledge and variables such as perceived risk, estimated risk, demographic and clinical characteristics were examined with Spearman correlation.

Results: 200 patients (102 PsA and 98 PsC), who did not have a history of CVD, completed the questionnaire (Mean age = 51.9±13.6 years, 53% females and 78% Caucasians). The mean score in CVD knowledge among psoriatic patients was 60.4% (SD±15.5). Patients scored significantly lower ($p < 0.001$) in questions addressing psoriatic-specific risk factors and CVD symptoms (Mean score = 42.2% and 43.4%, respectively) as compared to questions on traditional risk factors and diet (Mean score = 68.8% and 71.5%, respectively). CVD knowledge was found to have a significant correlation with education level (Spearman's rho $r_s = 0.271$, $p < 0.001$). Significant difference in knowledge level was found between patients who only completed grade school (Mean score = 43%) and those who completed post-secondary degrees (Mean score = 62.7%) ($p = 0.001$). Furthermore, CVD knowledge level and perception of risk has a

weak but significant positive correlation ($r_s = 0.277$, $p < 0.001$). No significant correlation between patients' perceived risk and estimated CVD risk was found ($r_s = 0.157$, $p = 0.221$).

Conclusion: Improving CVD knowledge and risk perception and developing CVD risk reduction interventions are imperative for psoriatic patients. Educational programs on psoriatic-specific risk factors and CVD symptoms might help encourage active participation in disease management and maintenance of healthy lifestyle, particularly among patients with lower education level.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Education Poster (ARHP): Education/Community Programs

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose : Disease specific self-management interventions are rare. After a needs assessment, focus group discussions, and *Plan, Do, Study, Act* (PDSA) model we developed and tested the *Self Management for Ankylosing Spondylitis* (SMAS) program, for people with Ankylosing Spondylitis (AS). We examined the benefits of an SMSA program for people with AS regarding change in health status, quality of life, and disease activity.

Methods: 134 people were recruited in this case cohort intervention. Exclusion criteria: <18yo; non-English speaking; co-morbid inflammatory musculoskeletal disease; and/or visual, auditory, or cognitive impairment. Participants attended a weekly 2.5 hour self-management education session facilitated by same two health professionals over 6 weeks. The scripted content included multidimensional strategies including stretches; and optional 7th week supervised exercise class.

Demographic, AS disease management characteristics, medication patterns, and outcomes were measured at baseline, 6 weeks, 3 and 6 months using repeated measures ANOVA for: back pain (VAS), fatigue (MAF), anxiety and depression (HAD), health distress (HDq), fatigue severity scale (FSS), pain self-efficacy (PSEQ), quality of life (SF-36) and Evaluating Ankylosing Spondylitis Qol (EASIQol), global perceived health (GPH), patients disease global assessment (PDGA). AS outcomes were analysed using repeated measures ANOVA for: Bath Ankylosing Spondylitis – Global, Disease Activity Index, and Functional Index (BAS-G, BASDAI, & BASFI), and Ankylosing Spondylitis QoL (ASQol).

Results: At baseline, 43.3% were male, and the mean age was 47.2 ± 15.1 years. The median time to AS diagnosis from the index

symptom experience was 3 years with an IQR (1-6). The BAS-G improved between baseline and 3 months (p=0.011) and were sustained at 6 months (p=0.039). The BASDAI improved between baseline and 3 months (p=0.01) and were sustained at 6 months (p=0.009). The ASQol improved between baseline and 6 months (p=0.051). A positive trend were seen for the MAFs GFI, back pain (i.e. nocturnal and total), and the PDGA over the 6 months although these trends were not statistically significant. The composite SF-36 (physical and mental), HADs, HDq, FSS, composite Easiqol (physical, disease activity, wellbeing, and social), PSEQ demonstrated no improvement over the study. There was no significant change in medication usage over the 6 months.

Conclusion:

SMAS for AS is independently effective in improving AS specific Disease activity, but global QOL scores did not change.

Measuring the Effectiveness of Patient Education of Patients Receiving Injectable Biologic Medications

Victoria Ruffing[1], Ana-Maria Orbai[2] and Clifton O. Bingham III[3], [1]Medicine JHAAC, Johns Hopkins University, Baltimore, MD, [2]Rheumatology, Johns Hopkins University, Baltimore, MD, [3]Johns Hopkins University, Baltimore, MD

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Education Poster (ARHP): Education/Community Programs

Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Injectable biologic medications have become part of the routine treatment rheumatoid arthritis (RA), and other inflammatory arthritides. These medications are associated with potentially serious risks. Patients must receive adequate education on disease states, medication administration, common and side effects, and when to contact a health care professional with problems. Aim: Examine the sources from which information concerning biological drug safety is obtained by patients. Identify specific knowledge gaps concerning biologic drug administration and crucial aspects of safety

Methods: Surveys were administered to a random group of patients receiving injectable biological therapies and seen at 2 different clinical settings. We captured basic demographics, disease characteristics, and current and past biologics used. We assessed the type, and method of education received regarding drugs and disease, satisfaction with education, and the level of retained medical knowledge concerning critical aspects of injectable biologics. Questions covered injection technique, storage and handling, side effects, signs of infection, and what to do for elective surgery. Questions were asked using Visual Analog Scales (VAS), Likert scales, with additional comments recorded. Frequencies were compared using Chi-square (X^2) tests. We calculated odds ratios of satisfactory medication safety knowledge (answered all questions correctly) using logistic regression adjusted for demographics (age, sex, race).

Results: Table 1. Participants correctly identified appropriate injection sites, technique, and storage and handling of biologics 100% of the time. There was considerable variability in knowledge concerning basic aspects of relevance to biologic safety. Among the overall group 30% were unable to correctly answer all 4 knowledge questions concerning biologic safety issues related to infections, elective surgery, and when to contact the rheumatologist. Level of education (≤HS vs >HS) was not associated with medication safety knowledge (X^2 1.05, p=0.31). Patients who had received their education from a nurse were more likely to answer all questions correctly (X^2 8.20, p<0.01). Safety knowledge was significantly associated with receiving biologic education from a nurse (OR 8.9, 95%CI 1.9, 42.4, p=0.006) after adjustment for demographic characteristics.

Conclusion: Critical gaps in knowledge exist regarding safe use of biologics. HCPs bear responsibility for educating patients about the safety aspects of biologic medications. In this small study, education provided by a nurse was associated with greater knowledge by patients. Further study is needed to identify the optimal methods of delivering patient education that will be applicable across care settings and to develop a standardized patient curriculum.

Session Title: Epidemiology and Public Health Poster II: Pathogenesis and Treatment of Systemic Inflammatory Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

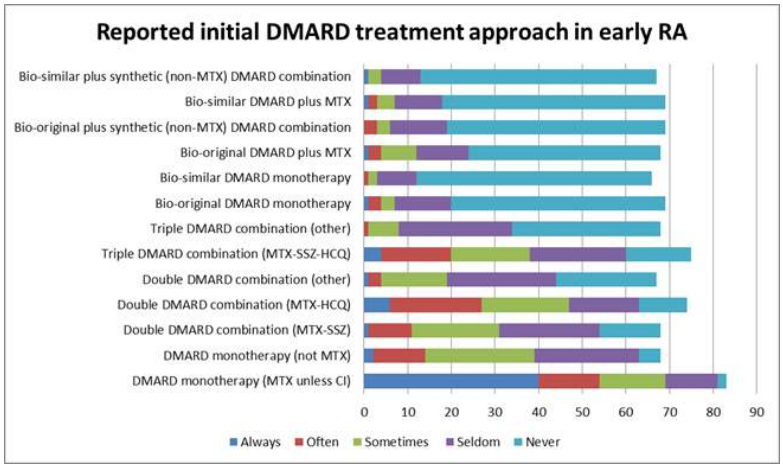
Early diagnosis & treatment are crucial to the management of rheumatoid arthritis (RA). Despite this, the approach to early RA management appears to be inharmonious across countries, although this has not been systematically evaluated.

Methods:

An online survey was emailed to practising rheumatologists in all QUEST-RA countries & also made accessible on social media platforms between April & May 2015. Questions (n=38) assessed the structure & setting of early RA clinics, times to diagnosis & treatment, patient monitoring, use of guidelines & data recording.

Results:

Participants: 212 from 39 countries (76% European). 62% had an early RA clinic based at a university hospital. Patient referral to rheumatology was mainly (78%) via primary care. 44% had an agreed early RA local referral pathway, 15% a national pathway; 27% no pathway. 71% reviewed early RA patients in general rheumatology clinics. Only 16% had dedicated clinics, 76% of which were practitioners in European countries (64% northern Europe) who had access to local or national referral pathways. 42% collected patient data for research purposes. Over 50% reported patients being seen within 4 weeks from primary care referral, a third within 2 weeks. DMARD initiation at first review & within 4 weeks was reported by 47% & 31% respectively. The rheumatologists' satisfaction levels significantly differed by clinic appointment duration (P=.005) satisfaction increasing with longer duration. 43% had radiographs of the hands & feet available at the patient's first review. MSK US was 'always' provided on site by a rheumatologist (18%) or when considered necessary (37%). Over 50% reported having ESR/CRP & antibody results available at the first patient visit. Guidelines were followed by the majority of rheumatologists, especially European (P<=.001). Treatment decisions were reported to be influenced by international &/or national guidelines in 71% & 61%. Figure 1 shows the initial treatment strategies used. Steroid use was reported as 'always'/'often' per os by 26/24% & intra-articularly by 2/11%.



Conclusion:

These data are the first to provide comparative benchmark information regarding the global provision of early RA care. Substantial variations exist in referral & early assessment pathways. Guidelines play a key role, although their impact is most apparent in Northern Europe. This survey is the first of its kind providing invaluable insights that could help harmonize early RA management across countries.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Epidemiology and Public Health Poster II: Pathogenesis and Treatment of Systemic Inflammatory Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Anti-citrullinated protein antibodies (ACPA) status provides important information regarding the diagnosis and prognosis of Rheumatoid Arthritis (RA). By using samples from blood bank donors that later developed RA it was shown that ACPA can already be present many years prior to the clinical onset of RA. However, little information is available on the presence of ACPA in the general population and the actual predictive power of ACPA positivity towards development of RA in the future. In this study, we determined the prevalence of ACPA in 40.227 participants from the LifeLines (LL) population based study (1).

Methods: The LifeLines cohort consists of 167.729 persons divided over 3 generations in the northern provinces of The Netherlands. Participants were recruited with help of general practitioners from both rural and non-rural areas and from different economic classes.For this cross-sectional study, 40.136 LL participants were tested for serum levels of ACPA from March 2012 until September 2013 The detection of ACPA was performed by measuring anti-CCP2 (by EliA-CCP test) on the Phadia 250 analyzer. ACPA levels ≥ 5 U/ml are considered positive. An extensive questionnaire on demographic and clinical information, including smoking, periodontal health, and early symptoms of musculoskeletal disorders was sent around as well in 2012 and 2013. RA was defined by a combination of self-reported RA, medication use (DMARDs, NSAIDs and/or steroids) for the indication of rheumatism and visiting a medical specialist within the last year. Mann-Whitney U and Chi-square tests were performed to assess differences between the ACPA positive and negative and LL participants.

Results: Of the total 40.136 individuals, 666 (1.7%) had an ACPA level ≥ 5 U/ml and 306 (0.8%) had an ACPA level ≥ 10 U/ml. Of the participants with ACPA level ≥ 5 U/ml, 14.4% had self-reported RA and 9.3% were defined as having RA.Within the group of self-reported and defined RA patients, ACPA-positivity (≥ 5 U/ml) was seen in 96 (11.5%) and 62 (44.9%) participants, respectively. In participants without self-reported/defined RA, 570 (1.5%) were ACPA positive. ACPA-positive participants reported significantly more pack years of smoking, were more often female and were significantly older compared to ACPA-negative participants (Table 1). When excluding all RA patients, differences in gender and smoking remained statistically significant, whereas age was comparable between both groups (data not shown).

Table 1 baseline characteristics of all participants				
	All (n=40.136)	ACPA-positive (≥ 5 U/mL) (n=666)	ACPA-negative (n=39,470)	P-Value
Age (yrs)	44(18-92)	46(19-80)	44(18-92)	< 0.001
Gender (female)	58%	65%	58%	< 0.001
Smoking Pack years	0.00(0-139)	0.90(0-86)	0.00(0-139)	< 0.001
Smoking status never	49%	43%	49%	0.006
Smoking status former	30%	32%	30%	
Smoking status current	21%	25%	21%	
Self-reported RA	2.0%	14.0%	1.9%	< 0.001
Defined RA	0.3%	9.3%	0.2%	< 0.001
BMI, alcohol use, periodontitis, first degree relatives of RA patients, and in women, nulliparity, menopausal status, early menarche and regular menses were not significantly associated with ACPA status.				

Conclusion: In this large population based study, the prevalence of ACPA levels ≥ 5 U/ ml as estimated by the Phadia analyzer was 1.7% for the total group and 1.5% when excluding RA patients. Smoking, female gender and older age were more frequently present in ACPA-positive LL participants.

Predictive Utility of Anti- Citrullinated Peptide Antibodies and Rheumatoid Factor – a Retrospective Dataanalysis

Miriam Gärtner, Mathias Schneeweiss, Josef S. Smolen and Klaus Machold, Department of Rheumatology, Medical University of Vienna, Vienna, Austria

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Epidemiology and Public Health Poster II: Pathogenesis and Treatment of Systemic Inflammatory Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Antibody profiling encompassing rheumatoid factor (RF) and anti-citrullinated peptide antibodies (ACPA) supports diagnosis in patients with Rheumatoid arthritis (RA). However, RF and ACPA are not specific for RA, and predictive values of tests depend heavily on the population in which such tests are performed. Because testing for these antibodies is frequently ordered by non-Rheumatologists, at substantial costs, we sought to determine the predictive values of such testing in patients of a large tertiary hospital.

Methods: Results of all RF and ACPA tests performed in the Vienna General Hospital between 2006 and 2012 were obtained from the Department of Laboratory Medicine and the ordering departments were determined. Diagnoses were extracted from the hospital-wide database. Positive and negative predictive values (PPV and NPV) of RF and ACPA were evaluated.

Results: Between 2006 and 2012 50.138 RF and ACPA tests in 5496 patients were performed. Among these, 31.2% were positive for RF,

23.5% for ACPA and 21.6% were positive for both antibodies. For 3146 patients (57% of all patients in whom RF/ACPA was tested) the tests were not ordered by the Department of Rheumatology. The tests were requested by the Departments of Infectiology (32%), Angiology (11%), Nephrology (8%), Cardiology (4%), Gastroenterology (3%), Oncology (3%), Endocrinology (2%), Pneumology (1%), Hematology (1%), Pediatrics (2%), Ophthalmology (2%), Dermatology (6%), Pediatric Psychiatry (5%) and the Department of Orthopedics (8%). 2251 of the 3146 patients had a documented diagnosis. (Figure 1).

Among the 3146 patients 218 (8.8%) were positive for RF, 118 (3.2%) for ACPA and 56 (2.3%) patients tested positive for both antibodies. PPV and NPV for the presence of musculoskeletal diseases were 31.7% and 80.9% for RF and 42.4% and 81.5% for ACPA testing. However, for presence of chronic inflammatory musculoskeletal diseases (ICD-10-Codes M05.X to M09.X and M30.X to M35.X) PPV were only 16.1% for RF and 30.5% for ACPA. NPV were 94.7% and 94.4%, respectively.

Conclusion: RF and ACPA testing was frequently ordered by non-Rheumatologists. In this patient group, we found a relatively high NPV (95%) but a very low PPV of 16-30%. Thus, >70% of positive tests did not contribute to a diagnosis of inflammatory musculoskeletal disease. This observation underscores the necessity to use such testing only in the appropriate clinical context.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Epidemiology and Public Health Poster II: Pathogenesis and Treatment of Systemic Inflammatory Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Anti citrullinated protein antibodies (ACPA) are highly specific for rheumatoid arthritis (RA), but the distribution

and diagnostic accuracy of ACPA in general population has not been thoroughly investigated. We aimed to evaluate the distribution and diagnostic accuracy of ACPA in in the general population.

Methods:

Unselected serum samples from a large population-based twin cohort consisting of 12 590 individuals were analyzed for the presence of ACPA using anti-CCP2 ELISA. All ACPA-positive samples (n=350) were further tested for four peptide-specific ACPAs. C reactive protein (CRP), information on SE and smoking were also available. RA cases were identified by linkage to the Swedish National Patient Register.

Results:

Three hundred fifty individuals had a positive ACPA test and 102 of these ACPA-positive individuals had an RA diagnosis at the time of blood donation (prevalent ACPA positive RA). Among the remaining 248 ACPA positive individuals an additional 22 individuals developed RA between blood donation and diagnosis follow-up (incident ACPA negative RA). 53 individuals had an RA diagnosis without testing positive for ACPA at the time of blood donation (prevalent ACPA negative RA) and an additional number of 15 individuals developed ACPA negative RA between blood donation and diagnosis follow-up (incident ACPA negative RA).

Beside smoking and SE, female sex was an important factor associated with ACPA positivity independent of RA diagnosis. The proportion of females was 55% in the entire cohort, 61% among ACPA-positive individuals without RA and 71% among those with prevalent ACPA-positive RA. Female sex was associated with ACPA occurrence (OR=1.6, 95% CI 1.2-2.0) and increased the risk of also having ACPA-positive RA (OR=1.8, 95% CI 1.1-3.1). ACPA-positive individuals without RA had lower ACPA titers and fewer peptide specific ACPAs than both individuals that later developed (incident) ACPA-positive RA and those having prevalent ACPA-positive RA. ACPA-positive individuals had also higher CRP levels than ACPA-negative individuals without RA.

Based on the distribution of ACPA positivity among the 155 cases of prevalent RA at the time point of blood donation, the sensitivity and specificity of ACPA for RA was 66% and 98%, respectively. ACPA high test had a sensitivity of 62% and a specificity of 99%. The positive predictive value (PPV) was 29% (95% CI: 24-34) for ACPA overall, and 48% (95% CI: 41-54) for ACPA high test. The negative predictive values (NPVs) were similar for ACPA test and ACPA high test (99.5% and 99.6 respectively).

Conclusion:

ACPAs associate with female sex and have a high diagnostic accuracy for an RA diagnosis in a population setting.

Session Title: Epidemiology and Public Health Poster II: Pathogenesis and Treatment of Systemic Inflammatory Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Physical activity in RA patients is significantly less than in counterparts without RA, and many live just above the muscle strength threshold needed for activities of daily living. It is not known whether physical activity declines prior to the onset of RA, potentially because of joint swelling and tenderness or because of the inflammatory processes associated with preclinical autoimmunity. Therefore, we first sought to determine whether RA-related autoantibodies, and joint tenderness and swelling, were associated with physical activity in first-degree relatives (FDRs) of RA patients, a population at increased risk for future RA.

Methods: In the Studies of the Etiology of RA (SERA) (a multicenter prospective study of preclinical RA), we evaluated associations between RA-related autoantibodies (Abs), swollen and tender joint count (SJC, TJC) and hours of physical activity in 233 FDRs. We defined RA-related autoantibody positivity as being positive (+) for any of 5 RA-related Abs: rheumatoid factor (RF), RF isotypes – IgM, IgG, IgA, or anti-cyclic citrullinated peptide (anti-CCP2). Positivity for a High-Risk Profile (HRP) was defined as being (+) for anti-CCP2 and/or 2 or more RF isotypes (IgM, IgG, IgA), which has been shown to be 96% specific for future RA. Hours sleeping, sitting, and engaging in slight, moderate, or heavy activity during a typical 24-hour day were obtained through questionnaire, weighted to reflect metabolic expenditure, and calculated as follows: PA score = $(1.0*h_{sleep} + 1.1*h_{sedentary} + 1.5*h_{slight} + 2.4*h_{moderate} + 5.0*h_{heavy})$. ANCOVA was used to evaluate associations between continuous PA score and Ab and HRP positivity, adjusting for age, sex, race, body mass index (BMI), smoking, and TJC. These same methods were used to evaluate associations between SJC and TJC and PA score. Logistic regression was used to evaluate associations between the dichotomous median-and-above (versus < median) PA score and Ab and HRP positivity adjusted for these same covariates.

Results:

Mean age was 47±17 years. 70% were female, 67% were White, 25% were Ab+, and 7% were HRP(+). Mean SJC was 0.3±1 and mean TJC was 1±2 for all FDRs. Average PA score was 37.4. Neither Ab(+) status nor HRP(+) status were associated with PA score or median-and-above PA score in fully adjusted analysis (PA Score: $\beta_{Ab(+)}$=0.20±1.3, p=88; $\beta_{HRP(+)}$=-0.27±0.6, p=0.66) (Median-and-above PA Score Odds Ratios (ORs): $OR_{Ab(+)}$=1.33, 95% CI=0.67-2.67; $OR_{HRP(+)}$=0.43, 95% CI=0.14-1.30)

Neither SJC nor TJC were significantly associated with PA score in fully adjusted analysis (PA Score: β_{SJC}= -0.54±0.6, p=0.38 β_{TJC}= 0.03±0.3, p=0.91).

Conclusion:

In FDRs of RA patients, neither the number of swollen and tender joints nor autoantibody status was associated with physical activity in cross-sectional analysis.

Session Title: Epidemiology and Public Health Poster II: Pathogenesis and Treatment of Systemic Inflammatory Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Family history of RA in a first-degree relative increases RA risk 4-fold. Determining risk factors for inflammatory joint signs (IJS) in this high risk population may elucidate the transition from genetic susceptibility to inflammatory arthritis in pre-clinical RA. We examined whether genetic, environmental, and serologic RA factors were associated with IJS among relatives without RA.

Methods: We evaluated RA factors and IJS in a prospective cohort of first-degree relatives in the Studies of the Etiology of RA (SERA). At enrollment, subjects in SERA did not have RA according to the 1987 ACR criteria by clinical exam. Genetic RA risk factors, including 5 *HLA-DRB1* (**04* or **01*) shared epitope alleles and 45 risk alleles validated among Caucasian populations, were combined into a weighted genetic risk score (GRS50). Smoking, BMI, education, parity, CCP, and RF were assessed at baseline. Physical examination at baseline (n=966) and 2-year follow-up (n=396) assessed IJS as tender or swollen joints at sites typical for RA (**Table)**. We evaluated the association of RA factors with IJS at baseline and follow-up using logistic regression, adjusting for confounders and tested for effect modification.

Results: We analyzed 966 non-Hispanic Caucasian subjects at baseline. In addition, incident IJS at 2-year follow-up was analyzed in 262 subjects after excluding 134 with IJS at baseline. At baseline, mean age was 47.2 years (SD 15.5), 71% were female, 55% were shared epitope-positive, 18% smoked >10 pack-years, and 8% were CCP/RF positive. Smoking >10 pack-years was associated with IJS at baseline (OR 1.59, 95% CI 1.09-2.32) and incident IJS at 2 years (OR 2.66, 95% CI 1.01-7.03). Current (OR 2.12, 95% CI 1.33-3.38) and past smokers (OR 1.61, 95% CI 1.12-2.33) had significantly higher odds of baseline IJS. BMI, education, sex/parity, GRS50, and RF/CCP were not associated with IJS at baseline or follow-up. Among those aged <50 years, subjects who smoked >10 pack-years had 4-fold increased odds of IJS (OR 4.39, 95% CI 2.22-8.66, **Figure**) compared to never smokers (*p*, interaction 0.02).

Conclusion: In a high-risk cohort of first-degree relatives without RA, smoking was associated with both prevalent and incident inflammatory joint signs at sites typical for RA. Those <50 years old who smoked >10 pack-years had the highest risk of IJS with a significant interaction between smoking and age. Neither genetic nor serologic RA factors were significantly associated with IJS in this sample. These results suggest that smoking plays a role in inflammatory arthritis development. Longitudinal studies are needed to further investigate transitions of pre-clinical RA phases.

Table. Age-adjusted odds ratios for inflammatory joint signs at sites typical for RA[1] at baseline (n=966) and two-year follow-up among relatives without inflammatory joint signs at baseline (n=262) among first-degree relatives without RA in the Studies of the Etiology of RA.

Model	Covariates	OR (95% CI)[2] at baseline visit (n=966)	OR (95% CI)[2] at two-year follow-up visit (n=262)
Age	Per year	**1.03 (1.02-1.04)**	**1.05 (1.02-1.08)**
Cigarette smoking	Never to ≤10 pack-years	1.0 (Ref)	1.0 (Ref)
	>10 pack-years	**1.59 (1.09-2.32)**	**2.66 (1.01-7.03)**
Body mass index category	Normal/underweight	1.0 (Ref)	1.0 (Ref)
	Overweight/obese	0.93 (0.68-1.28)	1.49 (0.61-3.64)
Education	≤High school graduate	1.0 (Ref)	1.0 (Ref)
	Some college or greater	0.76 (0.53-1.10)	1.37 (0.42-4.46)

	Female/nulliparous	1.21 (0.76-1.95)	2.52 (0.76-8.35)
	Male	0.77 (0.54-1.11)	0.91 (0.34-2.44)
RA GRS50[3]	Low (≤Median)	1.0 (Ref)	1.0 (Ref)
	High (>Median)	0.99 (0.73-1.35)	1.25 (0.55-2.83)
RA-related antibodies	CCP2 ≤5 units and negative RF	1.0 (Ref)	1.0 (Ref)
	CCP2 >5 units or positive RF	1.20 (0.66-2.19)	1.62 (0.55-4.80)

[1]Inflammatory joint signs were considered as any tender or swollen joints at metacarpophalangeal, proximal interphalangeal, wrist, elbow, and metatarsophalangeal joints. First metacarpophalangeal or first metatarsophalangeal joints and findings deemed to be due to trauma or degenerative disease by the examiner were not included.
[2]All models were adjusted for age in continuous years.
[3]RA GRS50: 5 *HLA* shared epitope alleles and 45 non-*HLA* single nucleotide polymorphisms weighted by known RA risk. GRS5 (5 *HLA* shared epitope alleles), GRS45 (45 non-*HLA* single nucleotide polymorphisms), and shared epitope positivity were not significantly associated with inflammatory joint signs at baseline or follow-up.

CCP2, anti-cyclic citrullinated peptide (2nd generation); CI, confidence interval; GRS, genetic risk score; OR, odds ratio; RA, rheumatoid arthritis; RF, rheumatoid factor. Bolding indicates $p<0.05$.

Figure. Combined effect of age and cigarette smoking on inflammatory joint signs at sites typical for RA among first-degree relatives without RA at baseline in the Studies of the Etiology of RA (n=966).

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Epidemiology and Public Health Poster II: Pathogenesis and Treatment of Systemic Inflammatory Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Previous studies from Western countries have demonstrated that the incidence of rheumatoid arthritis (RA) increases with age and the age of RA onset was about 59 years. However, in Japan, Imanka et al demonstrated that it increased from 37.5 years of age in the period of from 1960 to 1965 to 46.9 years of age in the period of from 1985 to 1990. Japan has faced a demographic change with a rapidly aging population in recent decades. In our experience in daily clinical practice over the past decade, we felt that we have encountered more patients who developed RA late in life than previously. In the present study, we aimed to determine whether there was a shift in the age of RA onset toward elderly onset based on a nationwide cohort database (National Database of Rheumatic Diseases by iR-net in Japan, NinJa) between 2003 and 2013.

Methods: We analyzed the data of RA patients who were newly registered in the NinJa database as early RA (disease duration of less than 2 years) in 2003, 2008 and 2013. The numbers of patients who developed RA in 2002–2003, 2007–2008 and 2012–2013 were 536, 812 and 1,864, respectively. The age composition of the Japanese population in the corresponding periods was obtained from the database of the Ministry of Internal Affairs and Communications. Student's t-test was used to compare the average ages.

Results: The average age of RA onset increased significantly over the past decade from 55.7 years in 2003 to 57.0 years and 59.9 years in 2008 and 2013, respectively. Regarding the distribution of the age of RA onset, the peak age shifted from the 50s in 2003 to the 60s in 2013 (Figure). There was no difference in the age of RA onset between male and female RA patients. It should also be noted that the

prevalence of RA was disproportionately higher in persons in their 50s in 2003, which included the so-called first baby boomers who were born after the world war, compared with persons in their 30s and 40s, even with consideration of the shift in age distribution of the general population.

Conclusion: We have clearly demonstrated that the age of RA onset has significantly increased over the last decade in Japan. This may be attributed to the increase in the aging population, as a birth cohort effect. However, the smoking rate is higher among the first baby boomers than among persons of the following generations. Thus, in addition to the birth cohort effect, alteration of environmental factors, such as cigarette smoking, may contribute to the shift of age of RA onset in Japan.

Session Title: Epidemiology and Public Health Poster II: Pathogenesis and Treatment of Systemic Inflammatory Diseases
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Vitamin D has immunomodulatory properties, and could be a protective factor against rheumatoid arthritis (RA). Anti-cyclic citrullinated peptide (anti-CCP) autoantibodies and swollen small joints of the hand (wrist and metacarpophalangeal [MCP] joints) are characteristics of RA that can be present years prior to the development of classifiable RA by established criteria. We investigated the associations between anti-CCP2 positivity and swollen joint symptoms with self-reported vitamin D supplement use in a population without RA, but at risk for development of RA.

Methods: The multicenter Studies of the Etiology of RA (SERA) cohort study recruited subjects who are classified as RA-free at visit,

but at increased genetic and/or family risk for RA. At baseline, we assessed the association between self-reported vitamin D supplement use over the past year and presence of the two preclinical outcomes, anti-CCP2 positivity and having >= 1 swollen wrist and/or MCP joint. Three vitamin D exposure variables were created including a yes or no response, source of vitamin D (none, multivitamin or single supplement), and total months of use (0 months, 1-12 months or >12 months [i.e. those taking more than one vitamin D supplement]). These self-reported variables were found to be associated with 25-hydroxyvitamin D (25OHD) plasma concentrations that were available in a subset of the study population. Logistic regression models were used to estimate the independent association between the three exposure variables and the two outcomes, adjusting for age, sex, race, shared epitope, current smoking, cohort (first degree relative vs not), site of recruitment and use of other supplements.

Results: The analysis cohort (n=2,383 at-risk subjects) was 69% female, 80% non-Hispanic white, with a mean age of 44.6 years. We identified 44 anti-CCP2 subjects and 57 subjects with >= 1 swollen joint at baseline. Vitamin D supplement use was not associated with anti-CCP2 positivity (Table). A marginally significant association was seen with joint signs, where those with >= 1 swollen joint were about half as likely to have been taking vitamin D supplements in the previous year (Table).

Table: Odds ratios (OR) for anti-CCP2 positivity and >=1 swollen joint in relation to each vitamin D exposure variable.

	Outcome			
	Anti-CCP2 n=44 positive subjects		**>= 1 swollen joint*** n=57 positive subjects	
Any Vitamin D Supplement	**OR (95% CI)**	**p-value**	**OR (95% CI)**	**p-value**
No	1.00	Ref	1.00	Ref
Yes	1.92 (0.47-7.92)	0.37	0.47 (0.22-1.01)	0.07
Vitamin D Source				
No vitamin D supplement	1.00	Ref	1.00	Ref
From a Multivitamin only	1.80 (0.43-7.55)	0.42	0.47 (0.22-1.04)	0.08
From a Single supplement containing vitamin D	2.37 (0.49-11.43)	0.28	0.47 (0.17-1.32)	0.19
Vitamin D Duration				
0 Months (no vitamin D supplement)	1.00	Ref	1.00	Ref
1-12 Months	1.15 (0.26-5.05)	0.85	0.46 (0.22-1.05)	0.07
>12 Months	2.45 (0.46-13.08)	0.29	0.45 (0.14-1.38)	0.16

Adjusted for age, sex, race, cohort, recruitment site, current smoking status, Shared Epitope, and other supplement use.

*The sample size for the joint outcome analysis is n=1955, which is reduced because our off-site visits did not include a joint examination.

Conclusion: Vitamin D supplement use was not associated with RA-related autoimmunity in at-risk subjects. An inverse trend between joint signs and vitamin D supplement use suggests the need for further research to examine the role of vitamin D in the later stages of pre-clinical RA.

Session Title: Epidemiology and Public Health Poster II: Pathogenesis and Treatment of Systemic Inflammatory Diseases
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Although some individual dietary factors have been identified to be associated with the development of rheumatoid arthritis (RA), few studies have examined the effects of overall eating patterns on RA. We examined overall dietary patterns in relation to the risk of RA in a large prospective cohort, the Nurses' Health Study II (NHSII).

Methods: We prospectively followed 93,859 women free of RA at baseline who provided dietary data from 1991 to 2011 in the NHS II. Dietary data were obtained from validated food frequency questionnaires in 1991 and every 4 years during follow-up. Two dietary patterns were identified using principal component analysis: the Prudent dietary pattern characterized by high intakes of fruit, vegetables, legumes, whole grains, poultry, and fish; the Western pattern characterized by high intakes of red meats, processed meats, refined grains, French fries, desserts and sweets, and high-fat dairy products. The cumulative average pattern scores over time were categorized into quartiles. Incident RA cases were validated by medical record review. Time-varying Cox proportional hazards models were used to calculate hazard ratios (HR) after adjusting for age, census-track income, smoking, body mass index (BMI), total calories, alcohol use and physical activity.

Results : During 1,509,033 person-years of follow-up, 626 incident cases of RA developed with the mean diagnosis age of 49. In the multivariable adjusted model, the Prudent pattern was associated with a reduced risk of RA, while the Western pattern was associated with an increased risk of RA (Table). The HRs (95% CI) across increasing quartiles of the Prudent pattern score were 1.00, 0.81(0.60,1.09),0.69(0.51,0.95), and 0.71(0.52,0.98) (p trend 0.04), and for the Western pattern, HRs ((95% CI) were 1.00, 1.41(1.01,1.98), 1.61(1.14,2.27), and 1.57(1.09,2.67) (p trend 0.03). After additional adjustment for BMI, the associations were attenuated.

Conclusion: In this female cohort study, dietary patterns were association with RA risk. A negative association was found between a Prudent diet rich in fruit, vegetables, and fish, and the risk of RA, whereas a positive association was found between a Western diet rich in refined grains, processed and red meats, desserts, and French fries, and the risk of RA. Further analysis of BMI as a potential confounder or mediator of these associations is warranted.

Table. Hazard ratios (95% CIs) of rheumatoid arthritis according to dietary pattern scores in the Nurses' Health Study II (1991-2011)[1]

	Dietary pattern scores (quartiles)				p for trend[2]

Rheumatoid Arthritis in Female Spouses in the Agricultural Health Study:

Associations with Pesticides and Other Farm Exposures

Christine G. Parks[1], Jane Hoppin[2], Karen H. Costenbader[3] and Dale Sandler[4], [1]Epidemiology Branch, National Institute of Environmental Health Science, Research Triangle Park, NC, [2]Biological Sciences, North Carolina State University, Raleigh, NC, [3]Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [4]Epidemiology Branch, NIH/NIEHS, Research Triangle Park, NC

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Epidemiology and Public Health Poster II: Pathogenesis and Treatment of Systemic Inflammatory Diseases
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Farming has been associated with rheumatoid arthritis (RA), but the role of pesticides is not known. We examined associations between RA, pesticides and other exposures among female spouses of licensed pesticide applicators in the Agricultural Health Study.

Methods: Women were enrolled 1993-1997 and followed through 2010. RA cases (n=275 total, 132 incident) were confirmed by a physician or self-reported use of specific disease modifying anti-rheumatic drugs, and were compared with non-cases (n=24,019) who never reported RA. Pesticide use was self-reported at enrollment. We estimated odds ratios (OR) and 95% Confidence Intervals (CI) using logistic regression models adjusted for age, state (NC/IA) and smoking pack-years.

Results: A suggestive association with RA was seen for use of any pesticides (overall OR=1.2; 95%CI 0.97, 1.6; incident only OR=1.4; 95%CI 0.99, 2.1). Of 15 pesticides examined, higher RA risk was associated with the fungicide maneb/mancozeb (OR=3.3; 95%CI 1.5, 7.1) and the herbicide glyphosate (OR=1.4; 95%CI 1.0, 2.1). Elevated (OR ≥1.5) but non-significant associations were seen for RA with the insecticides permethrin and DDT and the fungicide captan. DDT was significantly associated with RA in women who grew up on a farm (65% of cases, 61% of non-cases; OR=2.0; 95%CI 1.0, 4.2). RA risk was also associated with chemical fertilizers (OR=1.7; 95%CI 1.1, 2.7) and solvents for cleaning (OR=1.6; 95%CI 1.1, 2.4), but inversely associated with livestock exposure both as a child and adult (OR=0.48; 95%CI 0.24, 0.98) compared with no animal exposure.

Conclusion: Our results suggest that specific agricultural pesticide and fertilizer exposures may increase risk of RA in women, while others related to animal handling may be protective. These findings warrant replication and future studies including information on timing of exposures.

Air Pollution and the Rheumatic Diseases: A Systematic Review and Meta-Analysis

Gavin Sun[1], Glen Hazlewood[2], Sasha Bernatsky[3], Gilaad Kaplan[4], Bertus Eksteen[5] and Cheryl Barnabe[2], [1]Department of Internal Medicine, University of Calgary, Calgary, AB, Canada, [2]Division of Rheumatology, University of Calgary, Calgary, AB, Canada, [3]Rheum/Clin. Epid., McGill MUHC/RVH, Montreal, QC, Canada, [4]Division of Gastroenterology, University of Calgary, Calgary, AB, Canada, [5]Division of Hepatology, University of Calgary, Calgary, AB, Canada

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Epidemiology and Public Health Poster II: Pathogenesis and Treatment of Systemic Inflammatory Diseases
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Environmental risk factors, such as air pollution, have been studied in relation to the risk of development of

rheumatic diseases, including rheumatoid arthritis (RA), systemic autoimmune rheumatic diseases (SARDs), vasculitis and juvenile idiopathic arthritis (JIA). We have performed a systematic literature and meta-analysis to summarize the existing knowledge.

Methods: Medline (1950 to May 2015) and EMBASE (1980 to May 2015) databases and rheumatology conference abstracts (2012-2015) were searched using MeSH terms and keywords to identify cohort and case-control studies reporting risk estimates (hazard ratios, relative risks, odds ratios) for the development of select rheumatic diseases in relation to exposure to measured air pollutants. Meta-analysis was completed using the generic inverse-variance approach with random effects models using RevMan version 5.3.

Results: A total of 103 non-overlapping publications were identified of which 20 underwent full-text review, with 9 studies included in qualitative synthesis and 2 studies used for meta-analysis. Three studies included subjects with RA (one cohort study, two case-control studies) and examined associations with exposure to nitrogen dioxide (NO_2), sulfur dioxide (SO_2) and particulate matter up to 10 micrometers in size (PM_{10}). An association with particulate matter up to 2.5 micrometers in size ($PM_{2.5}$) was studied in the RA cohort study, and additional pollutants (carbon monoxide, nitrous oxide, ozone and black carbon) in one case-control study. In the RA cohort study, there was no definite evidence for increased RA risk related to NO_2, SO_2, PM_{10} or $PM_{2.5}$ exposures. In the case-control studies, there was no evidence of an increased risk for the development of RA with exposure to NO_2 (pooled OR 0.93, 95%CI 0.86 to 1.01) or SO_2 (pooled OR 0.94, 95%CI 0.82 to 1.08), but possibly a protective effect with exposure to PM_{10} (pooled OR 0.93, 95%CI 0.88 to 0.97, Figure 1). Both case-control studies in SARDs indicated higher odds of having SARDs in relation to increasing $PM_{2.5}$ exposure. Two studies examined vasculitis conditions (ANCA vasculitis and PM_{10} exposure, Kawasaki Disease and $PM_{2.5}$ exposure) but were unable to draw definitive conclusions regarding associations. One study of found an increased relative risk for JIA related to $PM_{2.5}$ exposure but only in American children <5.5 years of age; the results were inconclusive when studying a broader JIA population in America and Canada.

Conclusion: The existing studies do not support an association between air pollutant exposures and the development of RA, SARDs, or vasculitis, and uncertain effects in JIA. The measurement of cumulative and time-varying exposures are important considerations for future studies.

The Clinical and Ultrasonographic Presentation of Seronegative RA Is More Severe Compared to Seropositive RA in an Inception Cohort of DMARD-Naïve Patients Classified According to the 2010 ACR/EULAR Criteria

Lena B. Nordberg[1], Siri Lillegraven[1], Elisabeth Lie[1], Anna-Birgitte Aga[2], Inge C Olsen[2], Hilde Berner Hammer[3], Till Uhlig[1], Désirée van der Heijde[4], Tore K. Kvien[1], Espen A. SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Epidemiology and Public Health Poster II: Pathogenesis and Treatment of Systemic Inflammatory Diseases
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: The development of the 2010 ACR/EULAR classification criteria for rheumatoid arthritis (RA) has led to a

redefinition of the patient population, including classification of seropositive versus seronegative patients. Studies have yielded conflicting results on whether seropositive and seronegative RA represent different disease entities.

Our aim was to compare the disease characteristics of seropositive and seronegative DMARD-naïve early RA patients classified according to the 2010 ACR/EULAR criteria.

Methods: RA patients who fulfilled the 2010 ACR/ EULAR classification criteria were recruited at 11 rheumatology centers between 2010 and 2013. All patients had symptom duration (from first swollen joint) <2 years, and were DMARD naïve with indication for DMARD treatment.

Patients were stratified as seropositive (rheumatoid factor (RF)+, anti-citrullinated peptide antibody (ACPA)+, or both) or seronegative (both RF- and ACPA-) and disease characteristics were compared across the groups using t-test or Mann-Whitney U test as appropriate.

Results: A total of 237 patients were included with mean (SD) age 51.5 (13.7) years, median [25-75 percentiles] disease duration 5.7 [2.8-10.2] months and 61.6% female gender. Thirty-five patients (14.8%) were seronegative.

The seronegative patients were older (mean age 56.9 yrs) than seropositive patients (50.5 yrs, p=0.01), while gender distribution was similar. 43% of the seronegative patients and 31% of the seropositive patients did not fulfill the 1987 ACR criteria for RA (p=0.17). Ultrasonography (US) scores, number of swollen joints, DAS44 and Physician Global were significantly higher in seronegative subjects compared to seropositive. However, Richie articular index and patient reported outcome measures were similar between groups.

RAID score[2]	4.9 (2.4)	4.4 (2.1)	0.21

[1]Median [25-75 percentiles]. [2]Mean(SD). [3]US examinations were performed by experienced sonographers using a validated gray-scale (GS) and power-Doppler (PD) semi-quantitative scoring system with ranges 0-3 for GS and PD in 32 joints. [4] Original DAS-ESR based on 44-SJC and Ritchie articular index.

Conclusion: In this cohort of DMARD naïve early RA patients classified according to the 2010 ACR/ EULAR criteria, only 15% of patients were seronegative. We found that the seronegative patients had higher disease activity, assessed both clinically and by US, than

seropositive patients. This may in part be due to the strong weighting of RF and ACPA status in the 2010 criteria, requiring seronegative patients to have involvement of many joints, and thus high disease activity, to fulfill the criteria.

Session Title: Epidemiology and Public Health Poster II: Pathogenesis and Treatment of Systemic Inflammatory Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

RA patients develop autoantibodies against a spectrum of antigens. However, the clinical significance of these autoantibodies after RA diagnosis is unclear. The Phenome-Wide Association Study (PheWAS) is one approach to studying the clinical significance of novel biomarkers. The PheWAS was designed to analyze biomarker data linked with electronic medical records (EMR), allowing for high-throughput screening of potential associations between biomarkers and phenotypes. Using the PheWAS approach, we examined the association between variations in autoantibodies and subphenotypes of RA.

Methods:

We conducted this study in an electronic medical record (EMR) based RA cohort with patients from 2 large academic institutions. Using a validated multiplex bead assay, we measured 36 autoantibodies targeting epitopes from 10 antigens (citrullinated & non-citrullinated) implicated in RA (Figure). We extracted all unique ICD9 codes for each subject. ICD9 codes were then grouped using a published method into disease categories or PheWAS codes. For example, Felty's syndrome (ICD9 714.1) was included in the 'RA' PheWAS code along with RA (ICD9 714.0), while juvenile idiopathic arthritis (ICD9 714.3) was not. Autoantibody data were grouped by antigen target, e.g. fibrinogen. We studied all PheWAS codes with ≥3% prevalence in the cohort. Association analyses were performed between each autoantibody group and all PheWAS codes, adjusting for age, gender, race and correlation between individual autoantibody tests. A false discovery rate (FDR) <0.1 was considered significant. For significant associations, we reviewed the medical records of 50 subjects with each PheWAS code to determine the positive predictive value (PPV) of the PheWAS code.

Results:

We studied 1006 RA subjects, mean age 61 years (SD 12.9) and 79% female. The RA cohort had 3,568 unique ICD9 codes grouped into 625 PheWAS codes; 206 PheWAS codes had a prevalence of ≥3%. The PheWAS grouped by autoantibody target identified 13 associations with FDR<0.1 (Figure). Among the associations, the PheWAS code with the highest PPV (96%) on chart review was 'Other alveolar and parietoalveolar pneumopathy', which included diagnoses of cryptogenic organizing pneumonia, obliterative bronchiolitis, lipoid pneumonia, and alveolitis. These data suggest a link between autoantibodies targeting fibrinogen, both citrullinated & non-citrullinated, with chronic inflammatory lung diseases ($p=2.6x10^{-4}$) in RA.

Conclusion:

We demonstrated the application of a bioinformatics method, the PheWAS to screen for the clinical significance of novel autoantibodies in RA. The PheWAS identified a potential link between autoantibodies targeted at fibrinogen and inflammatory lung conditions in RA. These findings are of particular interest since pulmonary disease is recognized as a major cause of mortality in RA.

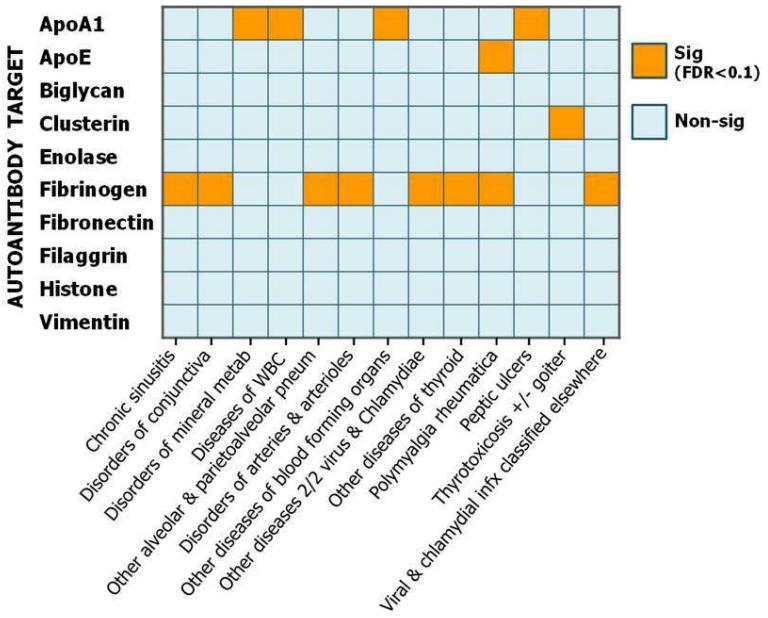

Figure. Results from PheWAS analysis of autoantibodies grouped by antigen target in an RA cohort.

Session Date: Monday, November 9, 2015

Session Title: Epidemiology and Public Health Poster II: Pathogenesis and Treatment of Systemic Inflammatory Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

To investigate the influence of education (achieving university/college degree (high) or not (low)) on the outcomes of early RA, in terms of disease activity, pain, and functional impairment.

Methods:

We used DMARD-naïve RA patients recruited in the Epidemiological Investigation of RA (EIRA) study with outcomes followed in the Swedish Rheumatology Quality (SRQ) register (N=3021). Outcomes were categorized in three ways: 1) scores equal to/above median *vs.* below median; 2) DAS28-based low disease activity, good response, remission; 3) scores decreased over the median *vs.* less than median. Associations between education and outcomes were calculated by Poisson regressions, at diagnosis and at each of the three (3, 6, 12 months) follow-up visits.

Results:

High and low educated patients had similar symptom durations (195 days) and anti-rheumatic therapies at baseline, and comparable treatment patterns during follow-up. Higher educated patients had less pain, less functional disability at baseline and throughout the whole follow-up period (VAS-pain: baseline: 49 (28-67) *vs.* 53 (33-71), p<0.0001; 1-year-visit: RR=0.81 (95% CI 0.73-0.90). HAQ: baseline: 0.88 (0.50-1.38) *vs.* 1.00 (0.63-1.50), p=0.001; 1-year-visit: 0.84 (0.77-0.92)). They also had greater chances to achieve pain remission (VAS-pain≤20) after one year (1.17 (1.07-1.28)). Adjustments for smoking and BMI altered the results only marginally. Education did not influence DAS28-based outcomes.

Conclusion:

In Sweden, with tax-financed, general health-care system, higher educated RA patients experienced less pain, less functional disability, and achieved pain remission more often during the first year receiving standard care. Education affected neither time to referral to rheumatologists nor anti-rheumatic treatments.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Epidemiology and Public Health Poster II: Pathogenesis and Treatment of Systemic Inflammatory Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

The prevalence of rheumatoid arthritis (RA) in Europe varies from a geographical standpoint. Knowledge of the occurrence of RA is valuable for policy makers and health professionals. There are no reliable data regarding the prevalence of RA in Poland.

Methods:

The study consists of two independent stages. The first stage is a survey on a nationwide representative sample of 3000 people (ages 15 and over), covering RA related symptoms, risk factors, and treatment. The questionnaire is validated for Polish RA population. The second stage of the study is a survey for characteristics of RA patients evaluated by a retrospective analysis of a group of 1957 RA patients in routine clinical practice.

Results:

The overall RA prevalence in Poland was 0.9% (95% CI 0.6-1.2%), 1.06% in women, 0.74% in men. A total of 1957 patients with RA were analyzed: 78% were female, mean age 56, and mean disease duration approximately 7 years. The most frequently associated diseases were: hypertension, 49%; ischemic heart disease, 22%; diabetes, 17%; interstitial lung disease, 7%. The ratio of employed to unemployed patients from the ages of 51-60 was almost 1:1; however, younger patients (<50) remained professionally active in approximately 90% of cases. Over 30% of patients were diagnosed within 3 months of first RA symptoms, while for 16% of patients diagnosis took more than one year. 56% of newly diagnosed patients were characterized by a high disease activity of DAS-28>5.1. Presently, low disease activity of DAS-28<3.2 could be found in approximately 40% of patients; however, there was still a majority with DAS-28>3.2. In Poland, 94% of patients have been treated with NSAID (Nonsteroidal anti-inflammatory drugs), and diclofenac was most frequently prescribed. Almost 80% of patients have been treated with glucocorticoids, and 56% of patients have continued with this treatement. Our study confirms that Methotrexate is an anchor drug in Poland.

Conclusion:

This is the first cross-sectional population-based epidemiological study regarding RA in the adult Polish population. The results demonstrate a high prevalence of RA, however they fall within the upper bound estimates for Europe. Retrospective analysis of RA patients indicates that despite ongoing treatment, the majority still have moderate to high disease activity.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Epidemiology and Public Health Poster II: Pathogenesis and Treatment of Systemic Inflammatory Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Oral glucocorticoids (GCs) are commonly used in the treatment of rheumatoid arthritis (RA). Although GPs don't typically alter DMARD prescriptions, changes to GC therapy are commonly made in primary care. It is important to assess how GCs are used in this setting, including variability in dose and duration of treatment, so that rheumatologists understand how their patients are being treated. The objective of this study was to describe the patterns of GC prescribing for patients with RA in primary care.

Methods:

Patients with incident RA were identified from the Clinical Practice Research Datalink, a large UK general practice database. For patients who received GCs, the mean, minimum and maximum prednisolone equivalent doses were calculated. To determine the population distribution, the median of these values across all treated patients was then calculated. A GC course was defined as back-to-back GC prescriptions where the end date of the first prescription was not more than one calendar day different from the start date of the next prescription. The median number of courses per year was then determined. The proportion of patients to receive greater than 5mg, 10mg, 20mg, 30mg, 50mg and 75mg per day was determined as was the proportion of total time on GCs these doses were prescribed for.

Results:

Of the 16 536 patients with incident RA, 7749 patients (47%) received at least one GC prescription during the follow up period. The mean

duration of follow up was 4.8 years per patient. In GC users, the median proportion of time spent on GCs was 24.3% (IQR 36.2%-64.2%). Of those receiving GCs, the population distribution was a median of 7.5mg per day (IQR 5-15.7mg) for the mean dose, 5mg per day (IQR 2.5-7.5mg) for the minimum dose and 15mg per day (IQR 7.5-30mg) for the maximum dose.

Of those that received GCs, the median number of courses per year was 1.4 (IQR 0.4-3.0) and 39.4% received more than 2 GC courses per year. The median duration of each GC course was 46 days (IQR 28-81).

Of those that were prescribed GCs during follow up, 79.9% received a prednisolone equivalent daily dose of more than 5mg per day and 56.2% received more than 10mg per day. 38.2% received more than 20mg per day, 17.3% received more than 30mg per day, 3.5% received more than 50mg per day and 1.4% received more than 75mg per day. The median proportion of total time on GCs that patients received these doses is shown in the table below.

	Proportion of total time on GCs (%)
Dose per day	Median (IQR)
>5mg	58.0 (19.5-100)
>10mg	25.7 (5.5-100)
>20mg	20.0 (3.2-100)
>30mg	12.7 (2.3-66.7)
>50mg	5.6 (1.0-24.1)
>75mg	5.9 (1.0-28.8)

Conclusion: Half the patients with incident RA were prescribed GCs in primary care. They received GCs for 25% of the time they were observed. Of those who received GCs, 80% received doses greater than 5mg per day and 40% more than 20mg/day. Patients spent 60% of their total duration on GCs taking doses greater than 5mg per day. The extent of GC prescribing for RA patients in primary care may be surprising to many rheumatologists and highlights the need to be aware of GC use in this setting in order to avoid excess exposure and associated side effects.

Session Title: Epidemiology and Public Health Poster II: Pathogenesis and Treatment of Systemic Inflammatory Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Recently biosimilar infliximab was approved in South Korea and it has been commonly used for rheumatoid

arthritis (RA) patients who are resistant to conventional DMARDs. The biosimilar infliximab have been shown to be equivalent to original infliximab in equivalent efficacy and safety in RA through several clinical trials, but its effectiveness and safety in daily practice has not yet been reported. This study aims to compare the characteristics of RA patients who use biosimilar infliximab with those of patients who start original infliximab and to identify the effectiveness and safety of biosimilar infliximab for RA patients in clinical practice.

Methods: Using the prospective biologic DMARDs registry in Korea: BIOlogics Pharmacoepidemiologic StudY (BIOPSY), we selected RA patients who started either biosimilar or original infliximab. Baseline characteristics including sociodemographics, disease activity, previous or concurrent medications, and comorbidities of two groups were compared. Treatment outcomes such as DAS28-ESR and HAQ-DI scores observed in 6 or 9 months after starting infliximab were compared between two groups. Drug retention rates of both groups were also compared using Kaplan-Meier analysis and the reasons of discontinuation were described in each group.

Results: A total of 98 RA patients who started either original or biosimilar infliximab were included in this analysis; 52 for biosimilar infliximab users (33.8 PY) and 46 of original infliximab users (50.2 PY). Baseline characteristics of two groups were quite similar in age, disease duration, and previous or current medications. Although baseline DAS28-ESR and HAQ-DI scores were not differed between two groups, swollen joints count was lower in biosimilar users than original users (6.1 ± 4.9 vs. 8.2 ± 5.4, *P*=0.05). Biologics-naïve patients were more common in biosimilar users but not significant statistically (92.3 % vs. 84.8 %, *P*=0.39). Early DAS28-ESR remission rate observed in 6 or 9 months after starting biosimilar and original infliximab were 18.6% and 15.6%, respectively (*P* =0.75). HAQ-DI changes were not different between two groups (0.4 ± 0.8 vs. 0.4 ± 0.7 P=0.85). The drug retention rates during 20 months were higher in biosimilar users, but there was no statistical significance (68.4% in biosimilar users vs. 53.1% in original users, p=0.16 by log-rank test). The most common reason of drug discontinuation was ineffectiveness in both groups (61.5% in biosimilar and 68.2% in original infliximab). Discontinuation due to infusion related reaction was only one case in each group.

Conclusion: There was no significant difference in baseline characteristics of biosimilar infliximab users compared to original infliximab users in South Korea. Drug persistency of biosimilar infliximab for 20 months was comparable to that of original infliximab, and the reasons of drug discontinuation were similar between two groups.

The Risk of Tuberculosis (TB) in Rheumatoid Arthritis Patients Treated with TNF Inhibitors and the Safety of Resuming Biologic Dmards for Patients Who Developed TB after Anti-TNF Treatment

Soo-Kyung Cho[1], Dam Kim[1], Hye-Jin Jeong[2], Il Woong Sohn[2], Soyoung Won[3], Minkyung Han[3], Jiyoung Lee[3], Eun Jin Jang[4], Sang-Cheol Bae[1] and **Yoon-Kyoung Sung**[1], [1]Department of Rheumatology, Hanyang University Hospital for Rheumatic Diseases, Clinical Research Center for Rheumatoid Arthritis (CRCRA), Seoul, South Korea, [2]Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea, [3]Clinical Research Center for Rheumatoid Arthritis (CRCRA), Seoul, South Korea, [4]Information Statistics, Andong National University, Andong-si, South Korea

Session Date: Monday, November 9, 2015

Session Title: Epidemiology and Public Health Poster II: Pathogenesis and Treatment of Systemic Inflammatory Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: The association between TNF inhibitor (TNFI) treatment and the development of tuberculosis (TB) has been confirmed through several observational studies. Current guidelines strongly recommend latent tuberculosis infection (LTBI) screening treatment before starting TNFI and they might reduce the risk of development of active TB in TNFI users. However, there is still limited evidence of the risk of TB in RA patients who used TNFI after introduction of LTBI screening and treatment guidelines. Moreover, the safety of resuming biologic DMARDs for RA patients who developed TB after anti-TNF treatment has not been well-known. This study aims to estimate the incidence of TB in RA patients who used TNFI after introduction of LTBI screening and treatment guidelines and to evaluate the safety of resuming biologic DMARDs for patients who developed TB after anti-TNFtreatment.

Methods: A retrospective cohort of RA patients who started TNFI was established using Korean national healthcare claims database between January 2009 and December 2013. There was 1 year wash-out period of biologic DMARDs to determine the incident users of biologic DMARDs. After excluding the patients who started biologics other than TNFI, we made an inception cohort for RA patients who started TNFI as a first biologic DMARD. Patients were followed for the development of TB or the last observational date (December 31, 2013). The development of the TB was defined as the appearance of ICD 10 code of TB plus at least 3 among 4 agents of isoniazid, rifampin, ethambutol, and pyrazinamide. Through this definition, the incidence rate (IR) per 100,000 person-year (PY) and standardized incidence ratio (SIR) of TB for TNFI starters based on total RA patients were calculated. We also classified the patients who developed TB into two groups; resuming biologic DMARD group vs. conventional DMARD group. After comparing the characteristics between two groups, the TB relapse rate among patients who resumed biologic DMARDs was estimated.

Results: We included 4,638 RA patients who had started TNFI as the first biologic DMARD, contributing 8,542 PYs of follow-up. A total of 81 patients had been developed TB infection during follow-up. The IR and the SIR of TNFI users based on total RA patients were 1,100 per 100,000 PY [860-1,340/100,000 PY, 95% confidence interval (CI)] and 2.04 (1.62-2.54, 95% CI). If we restrict the maximal follow-up period in 1 year, the IR and SIR of TNFI starters increased to 1,660/100,000 PY and 3.08, respectively. Among the 81 patients who developed TB during follow-up, 30 patients (37.0%) had continued or resumed biologic DMARDs. Mean interval between TB development and resuming biologic DMARDs was 3.3 months. Two cases of TB were developed in 30 patients with observational period of 45.7 PY.

Conclusion: The risk of TB in RA patients who start TNFI is still higher than that of total RA patients after introduction of LTBI treatment guidelines. Resuming biologic DMARDs after TB development should be undertaken with careful monitoring of TB relapse.

Session Date: Monday, November 9, 2015

Session Title: Epidemiology and Public Health Poster II: Pathogenesis and Treatment of Systemic Inflammatory Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Few HIV-infected patients have been treated with tumor necrosis factor (TNF)-α inhibitor therapy for autoimmune diseases refractory to conventional therapies. Evidence supporting the safety of TNF-α inhibitor therapy in HIV-infected individuals is limited and based on isolated case reports and small series.

Objective:

To estimate the incidence of serious infections in patients with HIV infection who are treated with TNF-α inhibitors therapy for concomitant autoimmune diseases, and to compare these rates between certain CD4+ cell count and viral load levels.

Methods:

Using a unified search strategy of the electronic medical record EPIC, four centers identified HIV infected patients exposed to TNF-α

inhibitors. Patient characteristics and infection data were assessed via chart review in all HIV-infected patients who are ≥ 18 years old and have received TNF-α inhibitor therapy after HIV diagnosis between January 1999 and March 2015.

Results:

The inclusion criteria were met in 23 patients with 26 uses of TNF-a inhibitor therapy, 16 treated with Etanercept, 6 with Adalimumab and 4 with Infliximab. The median (range) age was 47 (20-66). The median (range) CD4+ cell count and viral load at therapy initiation was 541.5 (1-1100) and undetectable (undetectable to 298,281), respectively at time of biologic therapy initiation. These individuals provided 86.7 person-years of followup. Two (8.7%) experienced at least 1 serious infection episode (SIE) (pneumonia with empyema and MSSA chest tube infection), an overall incidence rate for all treatment courses of 2.3 per 100 patient-years (95% CI [Confidence Interval] 0.26-8.33). Both of them were on Etanercept before infectious episodes; at the time of the infection in both, viral load was < 50 and CD4+ cell count was increased from the time of TNF inhibitor initiation (209 and 804 cells/mm3 at time of SIE). There were no opportunistic infections. The incidence rate per 100 patient-years was 3.28 (95% CI 0.04-18.26) among patients with viral load > 500 copies/mL at therapy initiation and 2.08 (95% CI 0.03-11.6) among patients with viral load ≤ 500 copies/mL. One of them was on TNF inhibitor monotherapy while the other was on low-dose corticosteroid.

Conclusion:

This study suggests that TNF-α inhibitor therapy may have reasonable rates of SIEs in the range of those observed in registry data bases when used in patients with HIV infection under active care.

Long-Term Use of Biological Therapy and Discontinuation Rates in Rheumatoid Arthritis – Real World Patient Data

Laurent Chanroux, Joan Casellas and Fara Mboge, Therapy Watch, Research Partnership, London, United Kingdom
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Epidemiology and Public Health Poster II: Pathogenesis and Treatment of Systemic Inflammatory Diseases
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Biologics (bDMARDs) have been shown to control disease progression in RA however there is still no cure for the disease and in many cases long-term use of these agents is required. Their cost and toxicity can be problematic over time and immunogenicity may cause their efficacy to diminish.

The aim of our research is to better understand long-term bDMARD survival to guide disease strategies and maximise patient outcomes.

Methods:

We used data collected as part of an online treatment survey conducted among a panel of 288 US rheumatologists between July 2011 and December 2014. We analysed a total of 6,113 patient forms and focused our research on 4,557 bDMARD patients with complete treatment information and analysed their current DAS, joint count and perceived disease severity to assess their response to therapy over time. A discriminant analysis was also performed to understand the relationship between four different groups of patients (based on their time on a bDMARD) and a number of patient characteristics to understand their associated with sustained response to bDMARDs.

Results:

The 1st stage of our analysis showed that on average patients spent 29.5 months on their bDMARD (21.3 for switch patients). We observed

differences in the mean drug survival of bDMARDs: 36.1 months for etanercept, 28.2 for adalimumab, 42.2 for infliximab, 23.1 for rituximab, 21.7 for abatacept, 11.9 for tocilizumab, 16.6 for certolizumab pegol and 15.1 for golimumab. The reported drug survival rates at 1, 2, 3, 4 and 5 years were 60.8%, 40.2%, 27.5%, 19.7% and 14.0% respectively. These results matched the primary reasons given for switching bDMARD. Lack of long-term efficacy (> 6 months) was the most common reason (36.0%) followed by lack of initial response defined as ≤ 6 months (14.6%). Safety/tolerability issues were only chosen as a primary reason for switching in 10.9% of cases and immunogenicity was reported for 0.9% of patients.

We saw little significant difference between patients based on their length of time on treatment. Patients on bDMARDs for ≤ 12 months were significantly more likely to be aged below 24 years ($p<0.05$) while those who had been treated for > 12 months were more likely to be aged > 60. The latter were also significantly more likely to be retired. However, patients treated for > 6 months were more likely to be considered to have mild RA by their Dr and while patients treated for > 12 months had higher mean DAS they typically had lower mean joint counts.

The discriminate function showed a significant association between groups and the patient variables, accounting for 51.1% of between group variability. Closer analysis of the structure matrix showed only 2 significant associations, time since 1st ever bDMARD initiation (.832) and time since diagnosis (.712). The cross validated classification showed that 60.7% of cases were correctly classified.

Conclusion:

Our research emphasizes the fact that long-term response to bDMARDs varies considerably by patient and by drug. Lack of long-term efficacy is the most common reason for switching away from a bDMARD but immunogenicity is chosen in <3% of all cases (total reasons). More research is needed to better understand how to ensure sustained response with bDMARDs and optimise patient outcomes.

Assessing the Possible Association of Anti-TNF Use with New Neoplasms: An Important Methodological Consideration

Yesim Ozguler[1], Yusuf Yazici[2], Gulen Hatemi[1] and **Hasan Yazici**[3], [1]Division of Rheumatology, Department of Internal Medicine, Cerrahpasa Medical Faculty, University of Istanbul, Istanbul, Turkey, [2]Department of Medicine, Division of Rheumatology, New York University School of Medicine, New York, NY, [3]Rheumatology, Istanbul University, Cerrahpasa Medical Faculty, Istanbul, Turkey
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Epidemiology and Public Health Poster II: Pathogenesis and Treatment of Systemic Inflammatory Diseases
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Whether anti- TNF agents increase the frequency of neoplasms remains debated. The drug regulatory agencies still mandate black boxes on the related package inserts or drug advertisements. We hypothesized that one important reason for this continuing concern was that the majority of studies addressing this issue had methodological weaknesses. Specifically, we had the impression that tabulating the number of cancers in the comparator groups (CGs), the expected number of cancers, was especially problematic. In observational studies when the CG is a national registry like SEER, the expected cancer incidence is given as new cancers/number of population rather than the number of patients with a new cancer which is the common method in assessing the observed incidence. Since multiple primary cancers, (around 1/6th) of all new cancers in the general population (1), are not separately tabulated as such in the national registries, a fair comparison of the cancer incidence between a patient cohort and a national registry is prone to important error. This potential error is further compounded by the fact patients with a previous history of cancer are not usually prescribed anti-TNF agents. Thus we set out to formally test our impression that the issue of multiple primary cancers is not accounted for in the debate about whether anti-TNF agents increase the incidence of neoplasms.

Methods: To test our hypothesis we first selected a recent comprehensive review (2) related to this debate which had concluded that anti-TNF agents did not increase cancer rate. All references to human studies were reanalyzed by 2 independent observers seeking whether the issue of multiple primary cancers was considered in studies which used cancer rates in the background general population as comparator. Any discrepancies between observers were to be settled by combined reassessment.

Results: Thirty-six references were selected for analyses. 24 were observational studies and 12 were meta-analyses or systematic reviews of controlled clinical trials and/or observational studies. 19 studies used national general population databases such as SEER as CGs. In none of these studies the issue of multiple primary cancers in the national database was addressed, causing a potential decrease in SIR for cancers in the anti-TNF using group, due to counting patients with multiple cancers in the general population more than once. There were no discrepancies in data assessment between the 2 observers.

Conclusion: The important issue of multiple primary cancers have not been given due consideration in studies comparing the cancer incidence associated with anti-TNF use. We propose that all previous related studies which had used this problematic methodology should be reanalyzed and reinterpreted.

Session Date: Monday, November 9, 2015

Session Title: Epidemiology and Public Health Poster II: Pathogenesis and Treatment of Systemic Inflammatory Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Selective outcome reporting may bias treatment effect estimates of clinical trials. Registration of clinical trials was established to improve transparency in their conduct and reporting. We studied the discrepancies between the registered and published primary outcomes (PO) of rheumatoid arthritis (RA) randomized controlled trials (RCTs).

Methods: RA RCTs that were registered at ClinicalTrials.gov (CTG) with completion date before January 1, 2010 and ≥ 1 publication in a peer-reviewed journal were studied. Registered and published POs were extracted, and two authors independently categorized presence and type of PO discrepancies using standardized method (see Table) with resolution of differences by consensus. Associations of presence of PO discrepancies with RCT characteristics were assessed by Chi-square or Fisher's Exact test.

Results: Among 95 eligible RCTs, 56 (58.9%) had identical registered and published POs. PO discrepancies could not be assessed for 10 RCTs (3 had missing PO in CTG records; while ambiguous/unclear PO were recorded in 4 CTG records and 3 manuscripts). 29 (30.5%) had explicit discrepancies between the registered and published POs (Table). Discrepant or ambiguous PO reporting was associated with funding source [Industry funding (21/65, 32.3%) vs non-profit source funding (18/30, 60%), p = 0.011). No association was found with study phase; year of study registration; and number of study centers. Among 39 RCTs with ambiguous/explicit PO changes, discrepancies were considered to be clinically relevant in 8 RCTs [7 with shorter published PO assessment time (5 non-profit & 2 industry funded); 1 with statistically significant published PO but insignificant CTG PO (industry funded)]; not clinically relevant in 12 RCTs (both CTG and published POs had identical statistical significance); and were unable to assess clinical relevance in 19 RCTs (10 with missing or ambiguous PO, 7 where only difference was published PO time assessment specification, and 2 with statistically significant published POs not specified in CTG).

Conclusion: More than quarter of RA RCTs had ambiguous or explicit PO discrepancies, and 8 (5.6%) were clearly considered to be of

potentially clinical relevance. Industry funding was associated with less likelihood of ambiguous/discrepant PO reporting. Improvement in reporting of registered and published POs is needed to improve utility of trial registries.

Table. Types of discrepancies between CTG registered and published POs.

Type of PO discrepancy	n (%) of RCTs (N = 95)*
None	56 (56.8)
Unable to assess	10 (10.5)
PO assessment time discrepancy	9 (9.5)
PO assessment time explicitly specified in manuscript	7 (5.1)
Deletion of ≥ 1 CTG efficacy PO	6 (6.3)
Deletion of ≥ 1 CTG safety PO	5 (3.5)
PO completely different than CTG PO reported in manuscript	4 (4.2)
Published PO described as secondary outcome in CTG	1 (0.7)

*5 RCTs had > 1 PO discrepancies, hence total (%) RCTs > 95 (100%)

Estimating Under-Diagnosis of Rheumatoid Arthritis in Primary Care Data from the UK Clinical Practice Research Datalink

Julian Gardiner[1], Bowen Su[1], Benjamin Ellis[2] and **Michael Soljak**[1], [1]Department of Primary Care and Public Health, Imperial College London, London, United Kingdom, [2]Arthritis Research UK, London, United Kingdom

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Epidemiology and Public Health Poster II: Pathogenesis and Treatment of Systemic Inflammatory Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

The prevalence of rheumatoid arthritis (RA) in primary care electronic health records (EHRs) is much lower than patient self-reports from population surveys, which may be due to under-diagnosis. The objectives of this study were to identify possible RA cases using a diagnostic algorithm developed from the 2010 EULAR/ACR criteria, and to compare them with EHR RA diagnosis cases, in order to estimate potential under-diagnosis rates.

Methods:

Patients' EHRs in the UK Clinical Practice Research Datalink (CPRD) contain diagnostic, clinical and test information. We extracted relevant data to identify patients with diagnosed RA and possible additional RA cases using an algorithm consisting of four parts, including joint involvement and symptom duration, acute phase reactants, and serology tests. Clinical findings, diagnostic labels and results of tests

ordered by consultant rheumatologists are not available in CPRD. In the EULAR/ACR classification criteria patients can score up to five points for any joint involvement, up to three points for positive serology, one point for positive acute phase reactants and one point if the duration of symptoms is greater than six weeks. In line with the classification criteria we defined those with a score of six or more as "algorithm-diagnosed RA cases". The incidence of RA was calculated from the number of CPRD patients receiving a new RA diagnosis in that year divided by the denominator. The prevalence was calculated from the cumulative number of patients receiving an RA diagnosis up to and including a given year (as far back as CPRD records allow, with patients who have died being removed).

Results:

A total of 88,299 patients had a primary care EHR diagnosis of RA, and an additional 12,928 were defined as algorithm-diagnosed RA cases. The prevalence of RA was 0.49% for EHR-diagnosed RA, rising to 0.58% if algorithm diagnosed cases are included (**Table 1.**). This has risen steadily over time, possibly because of more complete diagnostic coding. The incidence of EHR-diagnosed RA is approximately 30.4/100,000 over the period 2005-14 compared with 6.0/100,000 algorithm-diagnosed cases, an overall incidence rate of 36.4/100,000. There were 3,091 patients diagnosed by both a doctor and the algorithm. The mean age of EHR-diagnosis patients was 60.2 years compared with 57.7 years for the algorithm-diagnosis group, which may suggest diagnostic delay.

Table 1. Incidence and prevalence of RA in the CPRD. Figures are per 100,000 people.

Year	Incidence of doctor diagnosed RA	Incidence of algorithm diagnosed RA	Total incidence of RA	Prevalence of doctor diagnosed RA	Prevalence of algorithm diagnosed RA	Total prevalence of RA	Denominator
2000	21.16	4.55	25.71	220.46	18.65	239.12	11,915,756
2001	24.19	5.29	29.48	236.13	23.89	260.02	11,982,172
2002	24.99	5.94	30.93	252.24	29.63	281.86	12,042,662
2003	27.10	7.13	34.22	269.58	36.47	306.05	12,096,190
2004	31.78	6.96	38.74	290.88	42.94	333.82	12,151,149
2005	30.49	6.92	37.41	310.31	49.56	359.87	12,204,412
2006	29.50	6.67	36.17	329.37	55.67	385.03	12,258,669
2007	28.40	6.43	34.84	346.74	61.35	408.09	12,311,226
2008	27.83	7.12	34.95	363.32	67.65	430.97	12,363,171
2009	28.15	6.37	34.52	380.32	73.05	453.37	12,411,546
2010	25.79	6.14	31.93	394.83	78.38	473.21	12,457,701
2011	25.96	5.65	31.60	409.49	83.02	492.51	12,499,758
2012	27.90	5.50	33.40	427.27	87.48	514.75	12,535,602
2013	38.84	4.87	43.71	455.23	91.19	546.42	12,563,940
2014	41.01	4.10	45.11	487.74	94.21	581.94	12,585,816

Conclusion:

The algorithm developed from the 2010 ACR/EULAR criteria identified a significant number of possible RA cases, or patients who may be at high risk of developing RA, in addition to those with a coded diagnosis. Insufficiently accurate coding of joint involvement by general practitioners prevented more precise scoring and classification. Delayed or under-diagnosis has implications for prognosis in these patients.

Regional Variation in Measured Detection of Ankylosing Spondylitis

Jason Shafrin[1], Jin Joo Shim[1], Caroline Huber[1], **Jenny Griffith**[2], Arijit Ganguli[2] and Wade Aubry[3], [1]Precision Health Economics, Los Angeles, CA, [2]AbbVie Inc., North Chicago, IL, [3]University of California, San Francisco, San Francisco, CA

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Epidemiology and Public Health Poster II: Pathogenesis and Treatment of Systemic Inflammatory Diseases
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Patients suffering from ankylosing spondylitis (AS) often receive a delayed or mis-diagnosis, as this condition is frequently confused with mechanical back pain from other causes. If AS is not properly identified, patients can receive inadequate care, delaying disease-specific treatment, which may contribute to decreased physical functioning, quality of life, excessive use of narcotic analgesics, and disease progression. This study looks at regional variation in AS detection and examines whether regions that are better able to detect AS also are less likely to provide inappropriate care.

Methods:

A large commercial claims database covering the years 2008 through 2013 was used to measure geographic variation in AS and back pain detection and potentially inappropriate health resource utilization. All adults with 12 months of continuous eligibility in the dataset were included. Measured detection was defined as the prevalence of AS (ICD-9 codes: 720.0) and measured detection for back pain was defined as (720.1-720-.9, 721.x, 722.x, 723.0-723.8, 724.x, 739.1x-739.4x, 846.x, 847.x). We measured the share of patients with back pain who used narcotic analgesics and corticosteroid injections as a proxy for unnecessary healthcare utilization, as well as medical and pharmacy costs within each metropolitan statistical area (MSA) using generalized linear models adjusting for age, gender, and comorbidities. Geographic variation across MSAs was evaluated using standard deviation (SD), interquartile range (IQR) and coefficient of variation (CV).

Results:

In the data, 21,215,151 patients were diagnosed with back pain or AS. Nationally, 37 per 100,000 (0.037%, SD: 0.023%, IQR: 0.024%-0.043%) individuals were diagnosed with AS. A majority of MSAs (74.9%, 293 of 391 MSAs) had AS measured detection below the average in the data, and all MSAs (391 of 391) had AS measured detection below the 0.55% US AS prevalence estimate from the 2009-2010 National Health and Nutrition Examination Survey (NHANES). The CV for AS measured detection (0.631) was almost 2.5 times higher than the CV for measured detection of back pain alone (0.256). Based on our regression model, moving from an MSA at the 10^{th} percentile of AS measured detection to one at the 90^{th}percentile would decrease the share of patients using narcotic analgesics (-1.0%) and steroids (-7.9%), but would increase spending on disease-modifying antirheumatic drugs (+14.4%). The net effect would be a decrease in both total pharmacy costs (-7.1%) and total costs (-2.1%).

Conclusion:

Detection of AS varies dramatically across MSAs in the US and is significantly below prevalence estimates from large national surveys. Further, areas with higher rates of AS measured detection were less likely to use narcotic analgesics and steroids, suggesting that patients with back pain from AS who are not accurately diagnosed with AS may be receiving inadequate care. Increased patient and provider awareness regarding the treatment of inflammatory conditions—such as AS—that cause back pain is needed to ensure appropriate and timely care.

Only One-Third of Patients with Spondyloarthritis Are Managed By Rheumatologists

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Epidemiology and Public Health Poster II: Pathogenesis and Treatment of Systemic Inflammatory Diseases
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: The prevalence of Ankylosing Spondylitis (AS) in Europe has been estimated in a number of studies, some based on clinic populations, others from general population surveys, and prevalence has been shown to range between 9 and 49/10,000. However, to date, none have attempted to determine the prevalence in primary and secondary care within the same population. Knowing, not only the prevalence, but also the proportion of patients managed in specialist services has important implications in terms of health service planning and resource allocation. Thus, the aim of the current study was (a) to determine, in a single population, the prevalence of AS plus the proportion of patients actively managed in secondary care; and (b) to examine differences in basic characteristics of these patients.

Methods: Data from the Primary Care Clinical Informatics Unit (PCCIU) and the Scotland Registry for Ankylosing Spondylitis (SIRAS) were utilised to estimate the prevalence of AS in Scotland, in primary and secondary care respectively.

Established in April 2000, and covering around a third of the entire population, the PCCIU collected data from a representative sample of general practices across Scotland, UK, via Read Codes: a coded thesaurus of clinical terms used to document all diseases (including AS). SIRAS is a registry collecting clinical and patient-reported outcomes on all patients with a clinical diagnosis of AS being seen within secondary care clinics in Scotland. Patients were identified via clinic lists, if available, or through a review of recent physician correspondence for evidence of an AS diagnosis.

Data for the denominator was taken either from the PCCIU database (total patients) or the mid-year population estimate for Scotland, published by the National Records of Scotland.

Results: In April 2007, the PCCIU comprised 1,469,688 persons, of whom 1,964 had received a diagnostic code for AS (prevalence: 13.4 per 10,000; 95%CI 12.8-14.0 per 10,000). The SIRAS registry identified 1,686 patients in secondary care; from a population of 3,578,984 (prevalence: 4.7 per 10,000; 4.5-4.9 per 10,000).

There was no difference in sex between the two populations, although patients managed in secondary care were more likely to be younger (mean age 51 vs 62yrs; $p<0.001$), received their diagnosis earlier (mean age 35 vs 38yrs; $p<0.001$) and were more likely to experience extra-spinal manifestations of disease (uveitis 34% vs 22%, inflammatory bowel disease 12% vs 6% and psoriasis 14% vs 6%; all $p<0.001$).

Conclusion: As far as we are aware, this is the first study to estimate the prevalence of AS simultaneously in primary and secondary care, in the same population. We have shown that nearly two-thirds of AS patients in Scotland are managed solely in primary care, without rheumatology input. This group are less likely to have extra-spinal manifestations, but are older with a longer time since diagnosis. This, not only has important ramifications in terms of health service resource planning, but highlights the importance, in a progressive disease, of ascertaining whether some of these individuals have serious spinal pathology that is currently inadequately managed.

Session Title: Epidemiology and Public Health Poster II: Pathogenesis and Treatment of Systemic Inflammatory Diseases

Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: The diagnosis of Ankylosing Spondylitis (AS) is delayed by >10 years after the symptoms develop, as by definition the modified NY criteria for classification of AS requires radiographic sacroiliitis (X-ray SI). However, patients continue to suffer and have similar disease burden even before radiographic changes are evident. The new Assessment of SpondyloArthritis international Society (ASAS) classification criteria for non-radiographic axial spondyloarthritis (nr-axSpA) helps to identify many of these patients. The purpose of this epidemiological study was to estimate the prevalence of nr-axSpA among patients with inflammatory back pain (IBP) presenting to rheumatology clinics in Latin America, Africa, Europe, and Asia.

Methods: Consecutive patients with IBP from 51 participating rheumatology clinics in 19 countries were enrolled. Data were collected using medical records, self-completed questionnaires, physician evaluation (for SpA features), magnetic resonance imaging (MRI), X-ray SI, human leukocyte antigen B27 (HLA-B27), and CRP results. Patients with IBP were classified as nr-axSpA or AS using the ASAS and modified New York criteria, respectively. In addition, ASDAS - ESR and CRP, BASDAI, BASFI, and BASMI were evaluated.

Results: Data from 914 patients with IBP were collected; of which 266 (27.3%) had nr-axSpA with the highest prevalence in Asia (36.5%). HLA-B27 results were available for 544 (59.5%) patients with IBP; 135/189 (71.4%) with nr-axSpA patients were HLA-B27 positive. Baseline characteristics of patients with nr-axSpA, and the efficacy assessments are shown in Table 1. The BASFI and BASMI scores were lower among patients with nr-axSpA than those observed in patients with AS. However, considerable disease burden (as measured by ASDAS and BASDAI) was noted in patients with nr-axSpA (Table 1).

Conclusion: Approximately 30% of patients referred to rheumatology clinics with IBP in all regions studied met the classification criteria for nr-axSpA. The prevalence of nr-axSpA varies by region, with the highest in Asia and the lowest in Africa, possibly due to limited access to MRI and HLA-B27 testing in these regions. The overall disease burden in nr-axSpA is substantial and similar to AS. These findings justify the need for intensive therapy, which may have positive long-term benefits. However, as this was an epidemiological study, these data may have some selection bias and should be interpreted with caution.

Abstract Number: 1232

Prevalence of Idiopathic Inflammatory Myopathies in Sweden in 2012 – a National Register Study

John Svensson[1], Anna Tjärnlund[2], Ingrid E. Lundberg[3] and Marie Holmqvist[4], [1]Karolinska Institutet, Stockholm, Sweden, [2]Rheumatology Unit, Department of Medicine, Karolinska University Hospital in Solna, Karolinska Institutet, Stockholm, Sweden, [3]Medicine, Department of Medicine, Rheumatology Unit, Karolinska University Hospital, Karolinska Institutet S-171 76, Stockholm, Sweden, Stockholm, Sweden, [4]Dept of Medicine, Clinical Epidemiology Unit, Dept of Medicine, Karolinska Institutet, Stockholm, Sweden

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Epidemiology and Public Health Poster II: Pathogenesis and Treatment of Systemic Inflammatory Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Overall prevalence of idiopathic inflammatory myopathies (IIM) is commonly reported at 10 per 100,000 but worldwide estimates vary between 1 and 25 per 100,000 depending on region, population, sub-diagnosis, methodological considerations and case sources. In this study we aimed at assessing the prevalence of IIM in Sweden on January 1st, 2012, using population-based registers.

Methods:

Linking of multiple national registers was possible using each Swedish resident's unique personal identification number. Through this linkage we identified all individuals with an inpatient- or non-primary outpatient visit with an ICD-10 code indicating IIM, relevant IIM medication dispensation or registration in the Swedish Rheumatology Quality Register (SRQ).

IIM cases were defined by three progressively strict definitions; *(1) liberal* requiring ≥1 relevant specialist[1] visit, *(2) base case* requiring ≥2 specialist visits and *(3) strict,* also requiring dispensation of glucocorticoids or DMARDs. If a patient was registered in the SRQ he/she fulfilled all three definitions.

Prevalence was calculated for respective case definition and stratified by age group, sex, and clinical sub-diagnosis, in addition to county of residence for the base case definition. Corresponding Swedish population as of January 1st2012, retrieved from census data at Statistics Sweden was used in the denominator.

Results:

Overall prevalence varied between 35 (liberal), 19 (base case) and 13 (strict) per 100,000. Using the base case definition, overall female to male ratio was 1.4 and varied between 0.6, for inclusion body myositis (IBM), to 2.6, for juvenile dermatomyositis (JDM)**.** Prevalence per clinical sub-diagnosis was 8, 6, 4, 2 and 1 per 100,000 for polymyositis (PM), unspecified myositis, dermatomyositis (DM), IBM and JDM respectively.

Prevalence increased with age and peaked between 70-79 years (44 per 100,000). Overall women to men ratio was 1,5 and prevalence was highest in women for all age groups except for 70-79 and >80 year groups. Regional variations were observed between the 25 different Swedish counties (between 11 and 24 per 100,000 for Gotland and Västmanland county respectively).

Conclusion:

Estimated prevalence, 19 per 100,000 for the base case definition, was higher than what have been historically reported for IIM but corresponded well to results from recently published register studies. One challenge with this study was to determine which ICD-10 codes correspond to, primarily IIM, but also to correct clinical subgroups.

Epidemiology of GCA in Bergen (Western Norway) 1972-2012

Lene K Brekke[1], Andreas P Diamantopoulos[2], Elisabet L Esperø[1], Bjørg-Tilde Fevang[3,4], Johan G Brun[3,4] and Clara G Gjesdal[3,4], [1]Haugesund Hospital for Rheumatic Diseases, Haugesund, Norway, [2]Rheumatology, Haugesund Hospital for Rheumatic Diseases, Haugesund, Norway, [3]Department of Rheumatology, Haukeland University Hospital, Bergen, Norway, [4]Department of Clinical Science, University of Bergen, Bergen, Norway

Session Date: Monday, November 9, 2015

Session Title: Epidemiology and Public Health Poster II: Pathogenesis and Treatment of Systemic Inflammatory Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Giant cell arteritis (GCA) is the most common systemic vasculitis in persons older than 50 years. The highest incidence rates of the disease have been reported in the Scandinavian countries. However, the epidemiology is changing as the elderly population is increasing. The aim of this study was to investigate the epidemiology of GCA in an expected high-incidence region over time.

Methods:

This is a retrospective cohort study of patients diagnosed with GCA in the hospitals of Bergen Health Area (Helse Bergen) during 1972-2012. The International Classification of Diseases (ICD)-coding system was used to identify patients from hospital records, ICD-8 (446.4) for 1972-1987, ICD-9 (446.5) for 1987-1998 and ICD-10 (M31.5-6) for 1999-2012. The diagnosis was verified according to ACR classification criteria by review of patient charts. The 820 patients who satisfied these criteria were selected for initial analyses. Long term patient outcomes were documented by review of patient charts from time of diagnosis until time of death or end of study (31 Dec 2012). Information on time and cause of death was collected from the Norwegian Cause of Death Registry. Incidence was calculated by using population data for Hordaland County from Statistics Norway.

Results:

Among 820 identified GCA patients there were 585 females (mean age 73.4 years, SD 8) and 235 males (mean age 71.7, SD 9). Five-hundred twenty-eight patients (64 %) had a positive temporal artery biopsy and 206 patients (25 %) had a negative biopsy. For the remaining 86 patients (11 %) biopsy was not performed or biopsy results were inconclusively or insufficiently reported. Patient characteristics and outcomes are presented in table 1.

The average annual incidence rate for GCA was 15.7 per 100 000 > 50 years (females 20.4 and males 9.9). There were large fluctuations in incidence according to year of diagnosis with a tendency of progressive increase. The highest annual incidence rate observed was 35.1 in 2007. The lowest annual incidence rate was 2.6 in 1976 and 1978. Yearly distribution of incidence rates is displayed in figure 1.

Four-hundred forty-three patients (54 %) of our cohort died during the follow-up period.

Conclusion:

An increasing cumulative incidence throughout the period 1972-2012 was observed in our study. Higher awareness of GCA among clinicians could be an explanation. This interesting finding warrants further investigation.

Table 1. Patient characteristics and outcomes

	Overall	Female	Male

Epidemiology of Sarcoidosis 1976-2013: A Population-Based Study

Background/Purpose: The epidemiology of sarcoidosis is not well-described. Only coding-based studies with point estimates over relatively short periods, without detailed case information or verification based on individual medical record review have been reported. This study aimed to characterize the epidemiology of sarcoidosis, with emphasis on annual incidence and mortality, from 1976 to 2013.

Methods: An inception cohort of patients with incident sarcoidosis in 1976-2013 in a geographically well-defined population was identified based on comprehensive individual medical record review. Inclusion required physician diagnosis supported by histopathology and radiologic features of intrathoracic sarcoidosis, compatible clinical presentation, and exclusion of other granulomatous diseases. Tissue samples are considered positive if they demonstrate non-caseating granuloma without evidence of acid-fast bacilli or fungi. The only exception to the requirement of histopathological confirmation was stage I pulmonary sarcoidosis that required only radiographic evidence of symmetric bilateral hilar adenopathy. Isolated granulomatous disease of the skin without other features of sarcoidosis was not considered. Incidence rates were age and sex adjusted to the US white 2010 population.

Results: In 1976-2013, 345 incident cases of sarcoidosis were identified (mean age 45.6 years and 50.4% female). The annual incidence of sarcoidosis was 10.8 per 100,000 population (11.0 per 100,000 population in female and 10.5 per 100,000 population in male). The peak incidence was observed in those who were 35 to 64 years old. The numbers of minorities were too low to establish separate estimates by self-assigned ethnicity. Significant changes of incidence over time were not observed (Figure 1).

97% of cases had intra-thoracic involvement (87% intra-thoracic lymphadenopathy and 50% pulmonary parenchymal infiltration). Only 43% of patients had respiratory symptoms. The most common extra-thoracic manifestations were skin rash, arthralgia, ophthalmologic and hepatic involvement (18%, 14%, 7% and 6%, respectively). Isolated extrapulmonary sarcoidosis was diagnosed in 10 (3% of patients).

During median follow-up of 12.2 years (5002 total person-years), 50 patients died. The overall mortality of patients with sarcoidosis was not different from general population (standardized mortality ratio: 0.85; 95% CI, 0.63-1.13). Significant changes of mortality over time were not observed as well.

Conclusion: Sarcoidosis occurred in about 11 persons per 100,000 per year. Most of the patients had intra-thoracic involvement, although less than half had respiratory symptoms. Overall mortality was not different from general population.

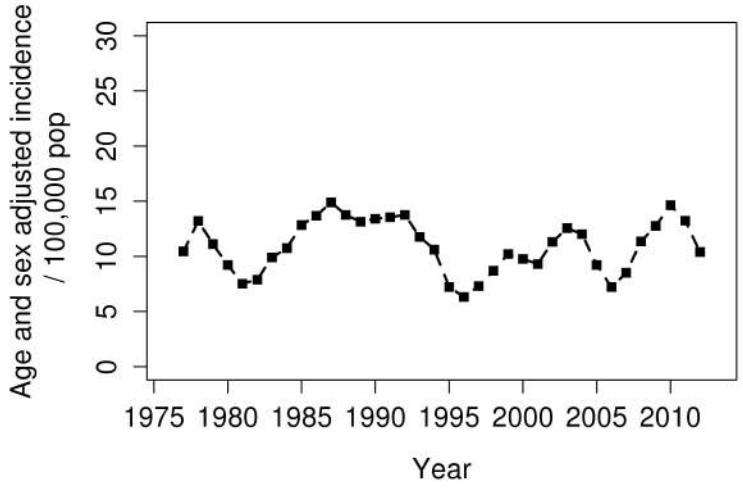

Figure 1. Trends in incidence of sarcoidosis 1976-2013 overall

Session Date: Monday, November 9, 2015

Session Title: Epidemiology and Public Health Poster II: Pathogenesis and Treatment of Systemic Inflammatory Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Kikuchi-Fujimoto disease (KFD) is a rare histiocytic necrotizing lymphadenitis affecting mainly Asian young women, associated to systemic lupus (SLE) in less than 25% of the cases. There is no epidemiology and no series devoted to African descent patients. Our objectives were to study (1) the incidence in the population of Martinique, (2) the characteristics of KFD afro-Caribbean patients from the 3 French American dependencies.

Methods:

A retrospective study including all patients with KFD compatible pathology report during a first episode or a recurrence in Martinique between 1991 and 2013 by three sources: (1) database of the two pathology units in the island (one public, one private), (2) the healthcare coding system of the academic hospital, (3) the departments of internal medicine, rheumatology, hematology and otorhinolaryngology files. In a second time, for a more comprehensive description of the disease's characteristics, we explored by the same way two other overseas French departments (Guadeloupe, French Guiana) and also included more afro-Caribbean patients in the cohort. Inclusion criteria were a biopsy with compatible pathology report for the epidemiology in Martinique, adding for the whole series description, an auto-declared afro-Caribbean ethnicity. SLE was defined by the presence of 1997 ACR criteria.

Results: Thirty-six cases of KFD were included, all afro-Caribbean: 26 from Martinique, 8 from Guadeloupe, 2 from French Guiana. The mean age at KFD diagnosis was 30.5 years (range: 5-59) and the female/male sex ratio was 3/1 (27 females, 9 males). Initial features were: fever (25/30; 83.3 %), asthenia (19/26; 73 %), weight loss (16/25; 64.4 %). Lymph nodes were cervical in 88.8 % (32/36), inguinal in 16.1% (5/31), only axillary in 8.3%, only abdominal in 2.8 %. Lupus was underlying in 4/36 patients (11.1%), diagnosed concomitantly with KFD in 6 (16.7%) and after KFD in 1 (2.8%). Recurrence was noted in 9 (25 %) of the patients but 15 KFD (14 non SLE related and 1 SLE related) were lost to follow up. At the time of KFD diagnosis, ANA were available for 22 patients, and 12 were ≥ 1/320 (54.5 %). The evolution was a spontaneous regression in 16/29 (55.1%) and 12/28 (42.8 %) of the patients received oral steroids. 11/30 KFD cases (36.6 %) were associated with lupus: 9 SLE (30%) and 2 pure cutaneous lupus (6.6%). Twenty four cases were diagnosed in Martinique between 1991 and 2013 (women: n=16, men: n=8): the crude average annual incidence was 2.77 cases for 10^6inhabitants (95%CI: 1.73-3.93), 3.5 for women (95%CI: 1.97-5.25) and 1.96 for men (95%CI: 0.74-3.43). Other autoimmune diseases were associated to KFD:

primary Sjögren syndrome (n=1) and juvenile idiopathic arthritis (n=1, her mother had SLE).

Conclusion:

We report here the first KFD epidemiology. This study confirms: (1) the presence of KFD in the afro-Caribbean population, to be confirmed in other African heritage populations, (2) the strong association with autoimmune diseases (mainly lupus) in our black population. But, KFD epidemiology is difficult to carry out because of the usual transient nature of this disease, leading to no lymph node biopsy and frequent lost to follow up after diagnosis.

Session Title: Epidemiology and Public Health Poster II: Pathogenesis and Treatment of Systemic Inflammatory Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Systemic autoimmune diseases (SAD) are characterized by a wide spectrum of demographic patterns with respect to the age at diagnosis, gender distribution and ethnic differences. Studying the distribution of these diseases across geographic regions and ethnic groups using a big data-driven approach may facilitate understanding of the corresponding genetic and environmental underpinnings, and help obtain a more "high-definition resolution" of these complex diseases.

Methods:

We explored the potential of the Google search engine to collect and merge cohorts (>100 patients) of patients with systemic lupus erythematosus (SLE) reported in the Pubmed library. We made a text-word search in Google (www.google.com) between 8th and 15th May 2015 using the following text algorithm: "systemic lupus erythematosus" and "100...100000000 patients" and "site:http://www.ncbi.nlm.nih.gov/pubmed". We analyzed potential links between epidemiological features (age, gender ratio), ethnic distribution and geographical variables (total population, nominal gross domestic product –GPD-, the pollution index –PI- and the exponential pollution index –expPI- of the country of origin of each cohort of SLE patients).

Results:

We merged the data of 133 SLE cohorts including 171,000 patients; gender was detailed in 130 cohorts: 150,937 (88%) women and 17,958 (12%) men (female: male ratio, 8,4). mean age at onset (29.89 ± 3.48), at diagnosis (32.33 ± 2.99), and at protocol (40.57 ± 5.01). SLE was diagnosed according to ACR criteria in 89% of cohorts, and according to ICD codes in 11%. The countries contributing the most cohorts were the USA (31), Japan (8) and Spain (5). A higher female: male ratio was found in cohorts with a higher frequency of Asian patients (r = 0.386, p=0.015), a higher number of participant countries (ratio of 14.5 in cohorts from more than one country vs. 10.7 in cohorts from one country), cohorts from countries with a greater population (r=0.189, p=0.043), cohorts that recruited patients in the 21st century (ratio of 11.7 vs. 8.9 in cohorts that recruited patients in the 20th century) and cohorts in which the time of recruitment was < 10 years (11.7 vs. 8.9 in cohorts with a time of recruitment > 10 years). The PI (r=-0.416, p=0.035) and the expPI (r=-0.414, p=0.036) were inversely associated with the mean age at diagnosis of SLE.

Conclusion:

This analysis is the first to show the potential benefits of a combined search using Google and Pubmed to seek geographical factors that influence the phenotypic expression of SLE. This approach is an example of multidisciplinary collaboration that could involve clinical researchers, epidemiologists, mathematicians, and health informatics experts. The approach used here is a first, exploratory step which will require significant improvement and refinement. Using a "big data" approach enabled hitherto unseen connections between the environment and SAD to emerge.

Session Title: Epidemiology and Public Health Poster II: Pathogenesis and Treatment of Systemic Inflammatory Diseases

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: There is a paucity of information about the incidence and prevalence of systemic lupus erythematosus (SLE) in United Arab Emirates (UAE) and Arab countries. The aim of this study was to determine the incidence of SLE and point prevalence among native population of Al Ain city, UAE.

Methods: Al-Ain city population are provided with health services in 2 major hospitals and multiple primary health care clinics all belong to a governmental Abu Dhabi Health Services (SEHA) and are linked with one Health Information System (HIS). New cases of SLE (2009-2012) were identified using hospital records and a serology database as follows: 1) the two major hospitals inpatients and outpatients medical records (2009-2012) were searched for patients with ICD-9 codes related to diagnosis of SLE , and discoid lupus ; 2) electronic records for patients with a positive DsDNA test (ELISA, cutoff value of 50 U/ml) , or two positive ANA test (one hospital provide all the immunological testing for the city); 3) we searched the skin and renal biopsy records for diagnosis of SLE, discoid lupus or lupus nephritis. The electronic charts of these cases identified were reviewed for fulfilling the American College of Rheumatology (ACR) criteria for SLE. Incidence and prevalence were calculated based on the yearly census of Al Ain city (Statistics Center- Abu Dhabi). The standardized age incidence ratio was estimated using WHO standard population as a reference.

Results: Sixteen new cases (13 females and 3 males) fulfilled the ACR SLE criteria and were diagnosed between January 2009 and December 2012. The point prevalence of SLE among native population in Al Ain city according to 2012 population was 23.7/100,000. The incidence ratio for each year is shown in (Table 1). The mean age at time of diagnosis was 28.6 ± 12.4 years (range of 4 to 47). Age-

standardized incidence per 100,000 population is shown in Figure 1. Most common manifestations during the first year of diagnosis were positive ANA and positive immunological tests (anti-DsDNA, anti-Smith, anti-cardiolipin or lupus anticoagulant) which were present in all patients (100%) followed by arthritis (62.5%) and malar rash (56%).

Conclusion: This is the first population-based incidence and prevalence report of SLE in UAE. Although the prevalence of SLE is higher than reported from a similar Arab population from Saudi Arabia, it is similar to Caucasian populations.

Table 1. The Incidence of SLE in Al Ain city, UAE, between 2009 and 2012

Year	No. of cases		Native Population	Incidence per 100,000		
	Male	Female		Male	Female	Overall
2009	2	4	170,400	2.3	4.6	3.5
2010	0	2	177,100	-	2.2	1.1
2011	1	3	186,000	1.1	3.3	2.1
2012	0	4	194,200	-	4.2	2.1

Incident Systemic Lupus Erythematosus in Males in a Northern California County Hospital

Jorge A. Uribe[1], Julia F Simard[2], Laura Tarter[3] and Thomas M. Bush[1], [1]Medicine/Rheumatology, Santa Clara Valley Medical Center, San Jose, CA, [2]Division of Epidemiology, Health Research and Policy Department, and Division of Immunology & Rheumatology, Department of Medicine, Stanford School of Medicine, Stanford, CA, [3]Rheumatology, Stanford University Hospital, Stanford, CA
First publication: September 29, 2015

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Epidemiology and Public Health Poster II: Pathogenesis and Treatment of Systemic Inflammatory Diseases

Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Little is known about males with systemic lupus erythematosus (SLE), particularly among those with a recent diagnosis. To better understand the presentation and outcomes of adult males with SLE we describe the demographic, clinical and immunological manifestations, and treatment profiles in a small inception cohort of men with SLE at Santa Clara Valley Medical Center (SCVMC), a 574-bed medical center in Santa Clara County.

Methods: Electronic records were searched to identify adult males diagnosed with SLE at SCVMC between January 2004 and August 2014 with at least 2 rheumatology clinic visits and documented SLE diagnosis within one year of their initial visit. Medical record review of these incident cases confirmed the diagnosis using ACR classification criteria. Additional data collected included socio-demographic variables, history of comorbidities at diagnosis (e.g. myositis, hypertension), clinical and immunological SLE manifestations, clinical events after diagnosis (e.g. avascular necrosis, cerebrovascular event, pulmonary embolism) and treatment profiles. Individuals were followed until either the end of follow-up (August 2014), death, or loss to follow-up.

Results: Of the 16 incident male SLE patients identified, the average age at diagnosis was approximately 32 years and the majority of patients were Hispanic (69%). At initial presentation the majority of patients had arthritis (81%), history of hyperlipidemia (69%), and history of hypertension (63%). 44% had a documental serum creatinine >1.5mg/dl with biopsy-confirmed lupus nephritis (LN) in 6 patients (2 with class 3/4 and 4 with class 5). In the first year 81% were prescribed hydroxychloroquine, 75% corticosteroids, 38% mycophenolate mofetil, and 31% cyclophosphamide. Among the 15 contributing more at least 2 years of follow-up the use of most of these medications increased (93% hydroxychloroquine, 80% corticosteroids, 47% mycophenolate mofetil, and 20% (n=3) started azathioprine) and no patients remained on cyclophosphamide (the one patient with less than 1yr follow-up was not on this). Of the 6 men with documented cyclophosphamide treatment during follow-up, all 6 had LN plus 2 had vasculitis and 2 had myositis. Nine of 16 (56%) men had a notable clinical or catastrophic event during follow-up (Table 1).

Conclusion: In this case series of 16 men with recently onset SLE nearly half of the patients had elevated serum creatinine documented and 37.5% biopsy confirmed LN. This is similar to reported LN incidence (44.8%) among a Spanish subset of male SLE patients (Casas I, et al. ACR Abstract 2014 #2622). More than half experienced at least one catastrophic event and over 37% of subjects required cyclophosphamide at one point. This is one of the first studies to look at treatment of male SLE and more information is needed both with respect to sex differences and male SLE outcomes.

Table 1. Documented clinical outcomes and catastrophic events during follow-up among SCVMC males with incident SLE (n=16), presented as %

Myocardial infarction	0
CAD/ischemia	0
Avascular necrosis	12.5
Cerebrovascular accident/TIA	18.8
CHF	6.3
Blindness	0
APLS	12.5
History of hemodialysis	12.5
Pulmonary embolus	12.5
Death	6.3

Session Title: Genetics, Genomics and Proteomics Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: MicroRNA (miRNA), a short endogenous noncoding RNA, has a major role in the degradation and translational repression of a specific gene through its binding to 3' UTR of such target mRNA. While biological contribution of miRNA has been reported, its impact on the genetics of human complex traits, especially in the context of miRNA-target gene networks, has not been assessed.

Methods: We developed a novel analytical method that comprehensively evaluates enrichment of genome-wide association study (GWAS) signals in miRNA-target gene networks. We obtained GWAS results of the 19 human complex traits, that comprises in total >1.75 million subjects. The association signals of the SNPs (i.e. p-values) were converted into the gene-based or miRNA-based association signals, adjusted by local linkage disequilibrium structures and gene/miRNA sizes. Relative enrichment of the association signals between miRNAs and target genes predicted by the multiple public databases (miRDB, miRmap, PITA, and TargetScan) was evaluated through permutation test (x10,000 iterations).

Results: Of the 19 evaluated human complex traits, rheumatoid arthritis (RA), estimated glomerular filtration rate (eGFR), and adult height showed significant enrichment of the association signals in miRNA-target gene networks ($P < 0.05/19 = 0.0026$; **Figure 1**). RA demonstrated the most significant results with 1.77-fold relative enrichment compared to the null hypothesis ($P = 1.7 \times 10^{-4}$ [illegible] G**Figures 1** and **2**). Our method also provides a list of miRNA and target gene pairs with excess genetic association signals, part of which included drug target genes.

Conclusion: Our method clearly indicated significant impacts of miRNA-target gene networks on the genetics of human complex traits, especially implying their important roles in biology and drug discovery of RA.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Genetics, Genomics and Proteomics Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

The idiopathic inflammatory myopathies (IIM) are autoimmune diseases characterised by acquired proximal muscle weakness, inflammatory cell infiltrates in muscle and myositis-specific/associated autoantibodies (MSA/MAA). The cornerstone of IIM treatment is prompt control of inflammation with immunosuppressive therapy, before irreversible tissue damage ensues from muscle atrophy and fatty replacement of tissue. Despite treatments, many patients become progressively disabled with co-morbidities due to both the underlying disease and treatment. There is thus a clear need to identify pathways involved in IIM pathogenesis to develop future treatment approaches. We therefore conducted protein-protein interaction and pathway analyses using myositis autoantibody targets and gene products of IIM associated loci.

Methods:

Protein-protein interactions were analysed using Disease Association Protein-Protein Link Evaluator (DAPPLE). Gene ontology and pathway analyses were conducted using Database for Annotation Visualisation and Integrated Discovery (DAVID) and Gene Relationships Across Implicated Loci (GRAIL). Three analysis strategies were used, including: i) the targets of all published MSAs and the MAA anti-PMScl-75/100; ii) significant and suggestive single nucleotide polymorphisms (SNPs) from a recently reported IIM association study; iii) SNPs plus MSA/MAA targets combined.

Results:

The protein-protein interaction networks formed by MSA/MAA targets and associated SNPs showed significant direct and/or indirect connectivity. Inclusion of both MSA/MAA targets and associated SNPs resulted in more significant indirect and common interactor connectivity than the separate networks, identifying TRAF6 as a hub protein, and suggesting interaction between MSA/MAA targets and proteins encoded by IIM associated loci. Protein-protein interaction analysis of associated loci also identified *UBE3B, HSPA1A, HSPA1B* and *PSMD3*as genes with significant connectivity. DAVID pathway analyses confirmed previous knowledge of MSA target involvement in translational processes. 'Ubiquitin' was the sole keyword strongly linking significant genes in each region in all three GRAIL analyses of MSA/MAA targets and IIM associated SNPs.

Conclusion:

Autoantibody targets and associated loci in IIM show significant connectivity and inter-relatedness and identify several key genes in IIM pathogenesis, possibly mediated via the ubiquitination-proteasome pathway.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Genetics, Genomics and Proteomics Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: The recent advances in metabolomics have allowed the study of the regulatory processes linked to metabolism. The comprehensive analysis of the metabolome in biological samples can provide new insights to identify pathological processes and to develop new biomarkers. The present study represents the first high-throughput metabolomics analysis of immune-mediated inflammatory diseases (IMIDs). The objective of the study is the identification and validation of diagnostic and activity biomarkers through the analysis of the urine metabolome within two independent cohorts of >2,500 individuals including healthy controls

and IMID patients.

Methods: The metabolomics analysis was performed using nuclear magnetic resonance on 2 independent cohorts. The discovery cohort included 100 controls and 200 patients per IMID: rheumatoid arthritis (RA), psoriatic arthritis (PsA), psoriasis (Ps), ulcerative colitis (UC), Crohn's disease (CD), and systemic lupus erythematosus (SLE). The validation cohort included 200 controls and 200 patients per IMID. The patients of each IMID were selected to define 2 groups: low and high disease activity patients. A total of N=37 metabolites were accurately quantified. The association analyses were performed at 3 levels: diagnostic -comparing each IMID vs controls-, differential -comparing similar IMIDs between them-, and activity -comparing low and high activity patients of each IMID-. The statistical analysis was performed using linear regression adjusted by epidemiological and sample collection variables.

Results: The diagnostic analysis identified n=28 metabolic associations, from which n=26 were replicated in the validation cohort. These associations involved n=10 different metabolites from which n=6 were jointly associated to ≥3 IMIDs. When analyzing differences between IMIDs, we validated n=3 associations when comparing CD vs UC. At the nominal level, n=2 further associations were validated when comparing RA vs PsA. The analysis of disease activity identified and validated n=3 associations related with disease activity in CD patients. We also validated at the nominal level n=2 associations in UC and n=1 association in PsA, SLE and CD.

Conclusion: We have identified and validated significant differences in metabolite concentrations when comparing IMID patients vs healthy controls. CD, UC and RA gathered the largest number of metabolic associations. Relevantly, n=6 metabolites were associated to ≥3 IMIDs. These metabolites are then candidate proxies for the physiopathological processes shared by these diseases. Regarding to the discrimination between related IMIDs, the urine metabolome has shown significant differences when comparing CD vs UC and RA vs PsA. The disease activity analysis also identified significant associations but with a lower impact than that from the diagnostic analysis.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Genetics, Genomics and Proteomics Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Parent-of-origin effects refer to the differential risk or pathogenicity of a disease that depends on the sex of the disease-transmitting parent. Excessive paternal transmission has been described in psoriasis and psoriatic arthritis (PsA) patients. Genomic imprinting or other germ line epigenetic phenomena have been hypothesized to mediate this effect. This study aimed to investigate the presence of germ line epigenetic variants associated with psoriasis and PsA.

Methods: Male psoriasis (n=24) and PsA (n=13) patients were recruited from the University of Toronto Psoriatic Disease Program. Psoriasis patients were diagnosed by a dermatologist and examined by a rheumatologist to verify the absence of PsA. PsA patients were diagnosed by a rheumatologist and satisfied the CASPAR criteria. Unaffected male controls (n=19) with no family history of psoriasis or PsA were also recruited. Sperm cells were isolated from semen samples and genomic DNA was extracted and bisulfite converted. DNA methylation was measured at 485,577 CpG sites using Illumina HumanMethylation 450k arrays. Methylation differences were assessed by Student's t-test using M-values and then converted to percent differences in methylation (β diff) between groups.

Results: Differential methylation analysis performed on 331,258 unique CpG sites retained after filtering identified 57 differentially methylated CpG sites between psoriasis patients and controls, and 97 between PsA patients and controls ($p<0.05$). Top hits in psoriasis patients vs. controls included CpG sites near the long non-coding RNA *TINCR* (β diff=0.14, p=0.03) and *IRF6* (β diff=0.16, p=0.03), which are necessary for epidermal differentiation. Top CpG sites in PsA vs. controls were located near *LCP1* (β diff=0.16, p=0.01), which regulates polarization and migration of chemokine-stimulated T lymphocytes, and PsA susceptibility locus *HLA-B* (β diff=-0.25, p=0.03) on 6p21.3. The inflammasome component *NLRP13* was differentially methylated in both PsA (β diff=0.11, $p=1.8x10^{-3}$) and psoriasis (β diff=0.09, $p=7.6x10^{-3}$) patients compared to controls. There were 84 differentially methylated CpGs between PsA vs. psoriasis patients ($p<0.05$). Top CpGs were located near *TPPP* (β diff=0.25, $p=1.4x10^{-4}$), involved in tubulin polymerization, and *HCG26*, a non-coding RNA that lies between *MICA* and *MICB* on 6p21.3 (β diff=-0.22, $p=4.0x10^{-3}$). Upon combining the results of all three analyses, five hits mapped to a 2.1 Mb interval on chromosome 8p23.3 that we previously identified as differentially methylated in whole blood of PsA patients with paternally vs. maternally-transmitted disease. Hits in this region were located near the genes *ERICH1-AS1*, *MYOM2, CSMD1*, and *DLGAP2*, which has been computationally identified as a putative paternally imprinted gene.

Conclusion: We identified several differentially methylated CpG sites in the germ line of psoriasis and PsA patients. These preliminary results require further experimental verification and replication in somatic tissues, to determine their relevance to the parent-of-origin effect and the aetiopathogenesis of psoriasis and PsA.

Session Title: Genetics, Genomics and Proteomics Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Employing genome-wide gene transcription on a unified platform, to identify molecular signatures for predicting therapeutic effects for rheumatoid arthritis (RA) with three biologics, infliximab (IFX), tocilizumab (TCZ), and abatacept (ABT).

Methods: Two hundred and three RA patients who were methotrexate-inadequate response and the first biologic administered were enrolled (IFX: 139, TCZ: 34, ABT: 30). Whole blood gene transcription data of each patient were obtained using a unified platform, Agilent Whole Genome Microarray 44K prior to administration of drugs. Using gene set enrichment analysis (GSEA), a priori defined functional set of genes, such as Reactome pathways and blood cell subtype-specific transcripts, were analyzed to find the difference of biological characteristics between remittors and non-remittors based on CDAI at 6th month of treatment. "Signature scores" of the gene sets

derived from the GSEA results was calculated for each patient and then was reviewed using logistic regression and ROC analysis.

Results: Based on GSEA, innate immunity pathways (inflammasomes and negative regulators of RIG-I/MDA5 signaling) were significantly upregulated in baseline peripheral blood of non-remitters in IFX (table 1). In TCZ, genes specifically expressed in B or T cells were significantly upregulated in remitters. Apoptosis related or NK cells-specific genes were related with ABT treatment outcome. Univariate logistic regression of signature scores supported the GSEA results. Multivariate logistic regression adjusting to clinical background showed inflammasomes genes for IFX, CD19 cells-specific genes for TCZ, CD56 cells-specific genes for ABT as significant independent predictive factors. The AUCs of ROC curve of each signature score were 0.638 (95% CI: 0.538-0.739), 0.769 (95% CI: 0.596-0.943), and 0.764 (95% CI: 0.575-0.953) for IFX, TCZ, and ABT, respectively.

Table 1 GSEA results
IFX, infliximab; TCZ, tocilizumab; ABT, abatacept.
SIZE: Number of genes found in the gene set from expression dataset.
NOM p-val: Statistical significance of the enrichment score. Nominal p value is not adjusted for gene set size or multiple hypothesis testing.
FDR q-val: False discovery rate; that is, the estimated probability that the normalized enrichment score represents a false positive finding. A FDR q-val <0.25 was considered statistically significant.

Reactome gene sets	IFX	Up-regurated in non-remittors at baseline			
		Gene set name	SIZE	NOM p-val	FDR q-val
		Inflammasomes	16	0.0020	0.1854
		Negative regulators of RIG-I/MDA5 signaling	30	0.0042	0.2431
	ABT	Up-regurated in non-remittors at baseline			
		Gene set name	SIZE	NOM p-val	FDR q-val
		Regulation of apoptosis	54	0.0039	0.1008
Blood cell gene sets	TCZ	Up-regurated in remittors at baseline			
		Gene set name	SIZE	NOM p-val	FDR q-val
		Specific-CD19 (Watkins 2009)	140	0.0101	0.0487
		T cells-induced (Allantaz 2012)	25	0.0243	0.0735
		B cells-induced (Allantaz 2012)	56	0.0359	0.0966
	ABT	Up-regurated in non-remittors at baseline			
		Gene set name	SIZE	NOM p-val	FDR q-val
		NK cells-induced (Allantaz 2012)	78	0.0021	0.0157
		Specific-CD56 (Watkins 2009)	51	0.0265	0.0430

Conclusion: We have shown a long sought objective means to predict the therapeutic effects of biologics using multiple expression markers expressed in peripheral blood. Each signature is shown to be associated with biological function underlying the therapeutic mechanism.

Extracellular MicroRNAs in Synovial Fluid Reveal a Marked Proliferative Signature in Patients with Antibiotic-Refractory Lyme Arthritis

Robert B. Lochhead, Nancy D. Kim, Sheila Arvikar, Klemen Strle and Allen C. Steere, Division of Rheumatology, Allergy & Immunology, Massachusetts General Hospital, Harvard Medical School, Boston, MA

First publication: September 29, 2015

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Genetics, Genomics and Proteomics Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Lyme arthritis (LA), caused by a tick-borne spirochete *Borrelia burgdorferi*, usually resolves appropriately with antibiotic treatment, called antibiotic-responsive LA. However, in some patients, arthritis persists for months or years after spirochetal killing with oral and IV

antibiotic therapy, called antibiotic-refractory LA. Synovial lesions in these patients show marked synovial proliferation, inflammation, and vascularization, accompanied by pathogenic autoimmunity. MicroRNAs (miRs) regulate many biological processes including inflammation, immune responses, and cell proliferation, and are effective biomarkers that may reveal molecular mechanisms of disease. Our objective here was to identify extracellular miRs (ex-miRs) in synovial fluid (SF) that distinguish regulated (responsive) from dysregulated (refractory) immune responses in LA, thereby providing insights into underlying biological processes and potential diagnostic biomarkers to distinguish between these disease courses.

Methods:

Using an unbiased systems approach, SF was screened for the expression of 372 ex-miRs commonly found in biofluids, using qPCR, in patients with responsive LA (n=6) or refractory LA (n=5), and for comparison, in those with rheumatoid arthritis (RA, n=4) or osteoarthritis (OA, n=4). A cluster analysis algorithm (Qiagen) was used to identify ex-miR signatures present in one or more patient groups. Statistically significant differences in miR expression between groups were determined by ANOVA ($p<0.05$).

Results:

In SF from patients with responsive or refractory LA or RA, miRs reflective of an inflammatory signature (miR-146a, miR-155) and a vascularization signature (miR-30fam) were significantly up-regulated compared with that of OA patients. Furthermore, up-regulation of the inflammatory ex-miR signature was more pronounced (~4-6-fold higher) in patients with refractory LA than in those with responsive LA, consistent with the greater expression of inflammatory cytokines in SF of refractory patients. However, the most novel finding in refractory LA was marked up-regulation of a cell proliferation signature, which included miR-223, miR-142, and miR-17-92fam, miRs associated with oncogenesis. For miR-223 and miR-142, two of the most abundant ex-miRs, the amounts were ~3-to-6-fold greater in refractory LA compared with that in responsive LA and OA, and similar to the levels observed in RA SF. Preliminary cell culture experiments suggest that some of these ex-miRs are transferred to fibroblast-like synoviocytes where they alter target gene expression.

Conclusion:

Cell proliferation ex-miR signatures were a key component that distinguished antibiotic-refractory LA or RA from antibiotic-responsive LA or OA. Thus, in antibiotic-responsive LA, a localized inflammatory response to *B. burgdorferi* infection is down-regulated appropriately, whereas in antibiotic-refractory LA, the greater inflammatory response in joints appears to activate marked synovial proliferation that persists after spirochetal killing. It will be important to determine whether miR-223 and miR-142 may be used as biomarkers to identify patients at risk for a refractory disease course.

Session Title: Genetics, Genomics and Proteomics Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Genetic and epigenetic factors contribute to the progression of systemic lupus erythematosus (SLE). We have the ability to identify these factors and their influence on SLE manifestations. Few studies have examined epigenetic marks associated with

lupus nephritis. In contrast to genetic polymorphisms which are heritable and fixed, epigenetic modifications are heritable but also modifiable by environmental factors. Therefore epigenetic modifications can provide new insights into the development and progression of SLE nephritis. The focus of this study is to determine whether differentially methylated DNA sites are associated with lupus nephritis.

Methods: We previously enrolled 326 consecutive Caucasian non-smokers with SLE, 80 (25%) of whom met the ACR classification criterion for lupus nephritis (LN) or had evidence of LN on renal biopsy. We used the Illumina Infinium HumanMethylation450 BeadChip to examine ~480,000 epigenetic marks (i.e. methylation marks) on the genomic DNA of each patient. This high-throughput array profiles CpG sites in ~23,000 genes and assesses methylation for sites in promoters, 5' and 3' regions, gene bodies, CpG islands, CpG island shores, and outside of CpG islands.

Results: Using multivariate analysis controlling for age, disease duration and other variables, we previously identified 7 methylation sites that were significantly differentially methylated among patients with LN compared to those without LN ($p<1 \times 10^{-6}$). These 7 sites were present in 4 unique genes (*PRR4*, *HIF3A*, *KLF13*, and *SYNGR1*), with *HIF3A* having three methylation sites that were significantly associated with LN. None of these genes have been previously associated with lupus nephritis. However, *HIF3A* has been implicated in renal cell carcinoma and *KLF13* has been previously associated with lupus. We also examined candidate genes that are known to play roles in the development of SLE or LN and found differential methylation of sites in *HIVEP3* ($p=0.006$) and in *FRMD4A* ($p=9.05 \times 10^{-5}$). Here, we extended our analysis to include additional significant methylation marks (top 6,000) and found functional enrichment for: "response to interferon gamma," "regulation of Th2 differentiation" and "positive regulation of kidney development." We compared our results to those of a smaller study examining differential methylation in naive CD4+ T cells in LN patients and were able to replicate a significant number of their differentially methylated genes in our study ($p<0.001$).

Conclusion: These results demonstrate that DNA methylation levels are reproducibly associated with lupus nephritis. Additionally, pathogenesis of LN may involve epigenetic modification of the interferon gamma pathway, Th2 differentiation and genes involved in renal development. These findings may be useful in stratifying patients to determine their risk of lupus nephritis.

Session Title: Genetics, Genomics and Proteomics Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

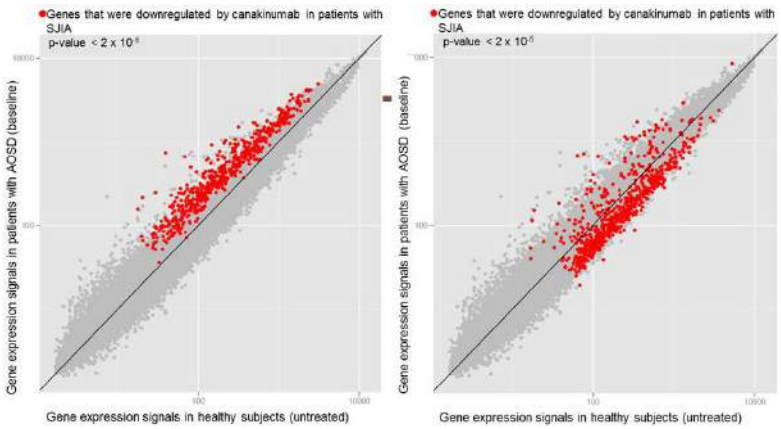
Background/Purpose: Adult-onset Still's disease (AOSD) is a rare auto-inflammatory disorder.[1] The superimposable systemic clinical features of AOSD and the pediatric syndrome known as systemic juvenile idiopathic arthritis (SJIA) suggest both clinical phenotypes represent the same disease continuum with different ages of onset. Previous reports have shown that canakinumab repressed several inflammation- and innate immunity-related genes, including those in interleukin (IL)-1 signaling pathways in SJIA patients.[2] To evaluate if AOSD may be also an IL–1-driven condition, we investigated how genes that respond to canakinumab in patients with SJIA behave in patients with active AOSD, relative to healthy subjects.

Methods: For the gene expression analysis, blood samples were obtained from 17 patients with active AOSD and 19 healthy controls. Gene expression profiles were compared using Affymetrix U133Plus 2 DNA microarrays. The probe sets identified in the blood samples

of patients with SJIA were used for supervised visualization of gene expression levels in untreated patients with AOSD and healthy subjects. The data were median-centered per gene for clearer visualization of the direction of differential expression.

Results: An analysis of the average gene regulation in overall patients showed that genes that were downregulated in patients with SJIA following canakinumab treatment were upregulated in patients with active AOSD, relative to healthy subjects (**Figure**). Comparison of the gene expression patterns with neutrophil counts showed a correlation between elevated neutrophil numbers and upregulation of canakinumab-responsive genes. Most genes that were upregulated following canakinumab treatment in patients with SJIA were downregulated in a majority of patients with AOSD (**Figure**).

Figure. Comparison of gene expression data in patients with Adult Onset Still's Disease prior to canakinumab treatment and healthy subjects



Conclusion: The results of this gene expression analysis are consistent with and further support the concept of a Still's disease continuum that includes both pediatric/juvenile (SJIA) and adult (AOSD) onset of the disease. Genes that respond to canakinumab treatment in patients with SJIA appear to be inversely dysregulated in those with AOSD. These findings support further clinical evaluation of anti-IL-1β therapy in patients with AOSD.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Genetics, Genomics and Proteomics Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Our focus has been on the potential role of the epigenetic processes, mainly of the methylation, on the development of Behçet syndrome (BS) using family data. We have previously studied global methylation in a group of concordant and disconcordant 8 BS twins (4 monozygotic, 4 dizygotic) along with healthy controls twins and found no difference within or between groups (average dC:5-mdC ratio=0.032 sd=0.0006 for BS twins, and average dC:5-mdC ratio=0.030 sd=0.0001 for control twins). Further analysis on the role of HLA-B51 carrier risk and its methylation mark using locus specific methylation analysis on HLA-B region had indicated indicated increased methylation levels of BS twins compared to healthy controls (p=0.0024) (Ozkõlõnc M. et.al., Methylation Pattern of Twin Groups with Behçet Syndrome. International Congress- ASHG Annual Meeting 2012, San Francisco, California, USA).

In this study, we wanted to take further our preliminary findings among familial BS cases and more directly examine the influence of HLA-B51 frequency and its methylation upon the presence of the clinical phenotype.

Methods: : About 850 BS patients seen consecutively at the Cerrahpasa Medical Faculty, rheumatology outpatient clinic between 2013 and 2015 were asked if they had an affected relative with BS. About 150 cases were familial and we studied 15 index patients including their BS relatives (n=17) and their healthy relatives (n=16). All were ³ 20 years of age. Age-gender matched healthy controls were also included (n=25). Peripheral blood samples were collected and genomic DNA was isolated from leukocytes. HLA-B51 genotyping was performed by sequence-specific PCR and random samples were confirmed with Sanger sequencing. HLA-B locus specific methylation levels were analysed using Real-Time based OneStep qMethyl Kit. Chi-square tests were performed to determine significance levels of genotyping results among groups. Statistical analyses were performed using Graphpad Prism 6th Version programme (GraphPad Software, La Jolla California USA).

Results: HLA-B51 carrier rate was significantly higher among index patients (13/15), affected relatives (13/17) and healthy relatives (13/16) compared to healthy controls (8/25), ($p<0.0001$). As seen in the Table 1, both index BS patients and their affected relatives had statistically higher methylation levels for exon-1-intron-1-exon-2 region of HLA-B gene compared to their healthy relatives and healthy controls ($p=0.0044$). Methylation levels of index patients and affected relatives were similar. This was also true for the methylation level of healthy relatives and healthy controls.

Conclusion: These findings point to a role of allele-specific methylation on BS pathogenesis and deserve further scrutiny.

Table 1: Mean methylation levels and mean age for four groups.

	Mean age	**Mean Methylation Levels** (exon-1-intron-1-exon-2 region of HLA-B gene) **(%)**	**95 % CI values**
Index patients (n=15)	37.3 ± 7.0	112.4 ± 14.5	82.66 - 142.2
Affected relatives (n=17)	44 ± 8.5	122.0 ± 15.4	90.72-153.3
Healthy relatives (n=16)	39.8 ± 15.3	70.5 ± 7.5	55.14-85.79
Healthy controls(n=20)	40.7 ± 7.5	69.3 ± 7.3	54.61-84.00

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Genetics, Genomics and Proteomics Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Osteoarthritis (OA) is the most common rheumatic disease. Despite active research in the OA biomarker field, no single protein is sufficiently reliable for its use in diagnosis. This is mainly due to the lack of validation studies in large populations, which makes the findings questionable to be considered as robust biomarkers.

In this work we have undertaken a large-scale study in order to find novel serum proteins that could serve as potential indicators of OA.

Methods:

Antibody suspension bead arrays were applied to profile serum samples from patients with OA (n=288), and compare them to patients with rheumatoid arthritis (RA, n=288), psoriatic arthritis (PSA, n=288) and control (n=96) subjects. The serum protein content was labelled and the protein profiles were obtained using 174 antibodies from the Human Protein Atlas, targeting 78 different proteins. The panel of proteins proposed and analysed for this study was selected on the basis of previous protein profiling studies in the context of rheumatic diseases. A focused bead array was then built to further profile 46 selected protein targets as a replication of the first findings, and also to validate these results in an independent cohort of samples composed by patients with OA (n=196), RA (n=192), PSA (n=192) and control individuals (n=92). For the statistical analysis, a lineal regression analysis adjusting by sex, age and BMI was applied to observe differences in protein profiles between groups. These were denoted statistically significant if they concordantly revealed p.values < 0.05 in the different assays and cohorts.

Results:

Four proteins were found elevated in serum from OA patients compared to controls: S100 calcium binding protein A6 (S100A6), leptin (LEP), Complement 3 (C3) and Inter-Alpha-Trypsin Inhibitor Heavy Chain (ITIH1); and two proteins, Apolipoprotein A-I (APOA1) and Vitamin D-binding protein (GC) were significantly increased in controls compared to OA patients. C3 protein levels also can discriminate among OA, RA and PSA patients being increased in OA patients. ITIH1, a hyaluronic protein carrier, also shows higher protein levels in OA sera compared to RA serum samples. Interestingly, S100A6, a protein involved in chondrocyte differentiation, was also found increased in K&L>2 scores compared to controls (K&L 0 and 1) in both cohorts of samples.

Conclusion:

Broad-scale profiling of protein levels in serum enables the discovery of potential novel biomarkers in osteoarthritis. Using antibody suspension bead arrays we have defined an interesting panel of seven biomarker candidates, which allows distinguishing serum samples from control individuals, OA patients and patients from other rheumatic diseases. The alterations of these proteins provide new potential serum biomarkers of disease, bringing new insights to the OA biomarker field and contributing to a better understanding of OA pathology. Moreover, we have found that S100A6 can be a novel potential early biomarker in OA.

Session Title: Genetics, Genomics and Proteomics Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a complex genetic autoimmune disease characterized by autoantibody production and up-regulation of type 1 interferons (IFNs). The strongest genetic association in Europeans is tagged by the *HLA-DRB1*03:01* extended haplotype, located in the MHC region on chromosome 6. Due to tight linkage disequilibrium and high polymorphism, the molecular mechanisms underlying the *DRB1*03:01* association remain elusive. Coding and non-coding variants arising from this haplotype may play a role in disease susceptibility through regulating gene expression in a context-specific manner.

We therefore sought to investigate the effect of the SLE susceptibility factors (i) IFN-α and (ii) the *DRB1*03:01* haplotype on gene expression in *ex vivo* B cells.

Methods: Fifty healthy European women harbouring *DRB1*03:01* homozygous (n=17), heterozygous (n=3) and non-*DRB1*03:01* (n=30) haplotypes were included in the study. RNA was extracted from negatively-selected *ex vivo*B cells at rest (n=49) and after stimulation with IFN-α (n=33). Genome-wide gene expression levels were quantified using the Affymetrix Human Exon 1.0 ST array and TaqMan qPCR. Differential expression was calculated using an ANOVA in Partek Genomics Suite and R (FDR<1%).

Results: Thirty-three per cent (5,163 / 15,468) of genes genome-wide are differentially expressed between resting and IFN-α-treated cells. Forty per cent of SLE ($p=4x10^{-2}$) and 53% ($p=6x10^{-6}$) of RA susceptibility genes from genome-wide association studies are significantly enriched in this data set, compared to IBD (30%, p=0.07).

As expected, these include members of the type 1 IFN pathway, such as the SLE risk genes *IRF7* (fold change, FC=7.2) and *STAT4* (FC=6.8). Interestingly, a number of SLE genes outside canonical type 1 IFN pathways are significantly down-regulated in response to IFN-α, including *FCGR2B* (FC=-2.7), *ETS1* (FC=-1.7) and *NCF2* (FC=-2.3). In addition, IFN-α decreases the expression of genes implicated in familial SLE, such as the B cell survival gene, *PRKCD* (FC=-1.2).

Furthermore, we find that the MHC class II gene, *HLA-DPB1*, is significantly up-regulated in *DRB1*03:01* haplotypes compared to non-*DRB1*03:01*haplotypes at a similar level in resting cells and IFN-α-stimulated cells (FC=1.2).

Conclusion: Stimulation of B cells with IFN-α significantly alters expression of genes associated with idiopathic and familial SLE not previously reported to be involved in the type 1 IFN response. Down-regulation of a number of these genes by IFN-α parallels previously reported loss-of-function polymorphisms associated with SLE susceptibility. We also report a *cis*-eQTL (expression quantitative trait locus) between the *DRB1*03:01* haplotype and *HLA-DPB1*, implicating a role for this haplotype in gene regulation. These data shed light into the role of IFN-α in the aetiopathogenesis of SLE and implicate *HLA-DPB1* as an additional candidate gene underlying the *DRB1*03:01* association with autoimmunity.

Session Title: Genetics, Genomics and Proteomics Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: DNA methylation represents an important potential mediator of environmental influences on autoimmunity, including rheumatoid arthritis (RA). Genome-wide methylation in the context of clinical phenotypes is most commonly performed using Illumina Human 450K methylation arrays. These assay only about 1% of dynamic methylome in the genome and underestimate the impact of methylation differences distal to CpG-rich regions as well as intergenic functional elements. To overcome these limitations, we developed a comprehensive approach to study blood (immune cell) methylomes. We used this to compare DNA methylation in subjects positive vs. negative for anti-cyclic citrullinated peptide (anti-CCP, a key serological marker of RA risk).

Methods: Using banked serum from a random subset of a general population cohort, we identified 22 subjects who were anti-CCP positive and 24 who were anti-CCP negative. Custom capture of target regions by SeqCap Epi (Roche) allows targeting of desired genomic regions as we described earlier (Allum et al. Nat Comm. 2015) to conduct genome-wide bisulphite sequencing. For this study we have established an "immune-methylome" panel that targets regulatory elements in approximately 20 immune cell subsets along with content of 450K arrays and regions genetically associated with autoimmune/inflammatory diseases. Altogether approximately 120Mb of genomic DNA harboring 4.6M CpG sites were interrogated by our assay.

Results: First-pass data analyses in peripheral blood of 22 anti-CCP positive and 24 anti-CCP negative subjects (sequenced to 10-15x average depth) show the clear advantages of comprehensive methylome assessment. We detected 2600 significant CpGs, of which only about 8% were represented in Illumina 450K arrays. The variation among the groups was depleted at proximal promoters and enriched in gene distal regions. The annotation of immunologic signatures by GREAT for the differentially methylated sites show distinct gene sets impacted by relative hyper- or hypo-methylation in anti-CCP positive vs. negative subjects.

Conclusion: These novel methods represent a comprehensive tool to assess methylation variation and its relation to immunological phenotypes in peripheral blood, with clear differences being shown in anti-CCP positive vs. negative subjects.

Session Title: Genetics, Genomics and Proteomics Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Presence of a type I interferon (IFN) signature is described for several autoimmune diseases, including systemic lupus erythematosus (SLE), multiple sclerosis (MS), myositis (IIM) and rheumatoid arthritis (RA). While IFNα contributes to SLE pathology, IFNβ therapy is beneficial for many MS patients, implying different immunoregulatory roles for these IFNs. This study aims to investigate potential diversification of the IFNα- and IFNβ-mediated response programs in autoimmune diseases.

Methods: Peripheral blood gene expression of 23 known type I IFN response genes (IRGs) was determined in healthy controls (n=54), SLE (n=47), IFNβ-treated MS (3 months, n=72), untreated MS (n=164), IIM (n=78) and RA patients (n=76) by multiplex qPCR. An IFN score was calculated and patients with a type I IFN signature –defined as an IFN score above the mean+2SD in HC– were selected for analysis.

Results: Unsupervised cluster analysis of SLE (IFNα-driven) and IFNβ-treated MS patients showed excellent separation based on two IRG clusters. Statistical testing revealed increased expression of 5 IRGs in SLE (Gene cluster (GC-)A, $p \leq 0.006$) and 13 IRGs in IFNβ-treated MS (Gene cluster (GC-)B, $p \leq 0.044$), believed to reflect IFNα- and IFNβ-specific response programs, respectively. Concordantly, the GC-A/GC-B log-ratio was positive for all SLE patients and negative for virtually all IFNβ-treated MS patients.

Using this information, we determined the nature of type I IFN signature in IIM, RA and untreated MS. IIM displayed relative GC-A dominance as reflected by positive GC-A/GC-B log-ratios, indicating predominant IFNα activity in this disease. The GC-A/GC-B log-ratio in RA was lower and approached zero in part of the patients, implying relative importance of both clusters. Remarkably, GC-A/GC-B log-ratios appeared most heterogeneous in untreated MS; half of the patients displayed GC-A (IFNα) dominance, whereas others showed GC-B (IFNβ) dominance or log-ratios near zero.

We confirmed these results for SLE, RA and MS using two public microarray datasets containing 22 SLE patients, 112 RA patients, 58 IFNβ-treated MS patients and 62 untreated MS patients.

Exploring functional differences between GC-A and GC-B genes revealed enrichment of the ISGF3-binding response element ISRE and IRF8 binding sites only in GC-B, suggesting that IFNβ is more potent in activating these transcription factors than IFNα.

Conclusion: We provide physiological evidence for diversification of the type I IFN response in SLE (IFNα-driven) and IFNβ-treated MS patients. Using this information we demonstrate that IIM appears IFNα-driven, supporting the previously described pathogenic role of IFNα in IIM. RA patients exhibited less distinct IFNα/IFNβ dominance. Untreated MS patients displayed interindividual variation in GC-A or GC-B dominance, suggesting a different pathogenic role of the type I IFNs in these patients.

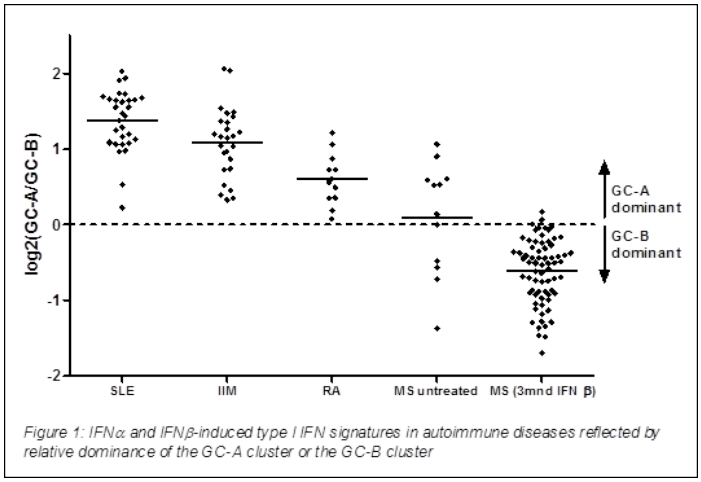

Figure 1: IFNα and IFNβ-induced type I IFN signatures in autoimmune diseases reflected by relative dominance of the GC-A cluster or the GC-B cluster

Session Title: Genetics, Genomics and Proteomics Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: A recent POC, open label trial (TOPAS)[1] showed efficacy of ustekinumab (a monoclonal antibody against IL12 and IL23p40 in pts with active AS. To identify novel serum biomarkers associated with disease activity and response to ustekinumab treatment in pts with AS.

Methods: We profiled 20 AS pts from the TOPAS study[1] (treated with 90 mg ustekinumab SC at baseline, wk 4 and wk 16) and compared to an independent cohort of 30 healthy normal volunteers (HNV). Samples collected at wk0 and wk24 were assayed using the SOMAmer^{TM} (Slow Off-rate Modified Aptamer)-based proteomic assay[2], which measured 1129 analytes. A general linear model was applied to identify analytes that differed between AS and HNV and within subjects before and after treatment using a fold change (FC) cutoff of $|FC|>1.3$ and p value cutoff of $p<0.05$. Correlation between serum markers and disease activity scores was evaluated by the Spearman rank correlation test. **Results** were interpreted via Ingenuity Pathway Analysis (IPA). Disease activity was specified by Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Ankylosing Spondylitis Disease Activity Score (ASDAS) and Osteitis MRI Scores (Berlin method) for sacroiliac joints and spine. Clinical response to ustekinumab was defined as 50% improvement in BASDAI at wk24 as compared to baseline.

Results: 113 analytes were differentially expressed in AS compared to HNV. The top dysregulated pathways were Acute Phase Response Signaling, Role of Macrophages, Fibroblasts and Endothelial Cells and Inflammation. Following ustekinumab treatment, proteins involved in Acute Phase Response Signaling were significantly modulated and C-reactive Protein (CRP) decreased (p=0.009) in BASDAI 50 responders but not non-responders. At baseline, Stanniocalcin-1 (STC1, p = 0.0012), Thyroid Stimulating Hormone (p=0.0051), Tumor Necrosis Factor Receptor Superfamily 2 (TNFRSF2, p=0.0132) and Spondin-1 (SPON1, p= 0.0135) correlated to BASDAI score, and Interleukin 13 Receptor alpha 1 (IL13RA1, p=0.0019), and Bone Morphogenetic Protein Receptor 1A (BMPR1A, p= 0.0036) correlated to ASDAS. Chk protein kinase 1 (CHEK1, p=0.0017), and ADAM metallopeptidase 5 (ADAMST5, p=0.0024) correlated to baseline osteitis on MRI and markers known to be involved in bone remodeling i.e. Dickkopf Like Protein 1 (DKKL1, p=0.0092), Semaphorin 3E (SEMA3E, p= 4.29E-05), SPON1 (p= 0.0002), ADAM12 (p=0.0002), and CLIC1 (p= 0.0003) correlated with wk24 change in osteitis and spinal osteitis scores. Baseline levels of acute phase markers showed a trend for association with response. BASDAI 50 responders had decreased Complement component 3 (C3, p=0.0120) and fibronectin (FN, p=0.0131), increased Haptoglobin (HP, p=0.0095) and predicted inhibition of Colony Stimulating Factor 1 (CSF-1, implicated in osteoclast differentiation) at baseline.

Conclusion: Evidence for significant dysregulation of inflammatory pathways and bone remodeling can be demonstrated from the serum of AS patients. Novel serum markers associated with AS disease activity and response to ustekinumab, were identified. We plan for future assessment of these markers in an expanded placebo controlled cohort.

Identification and Validation of Novel Putative Salivary Proteomic Biomarkers in Sjögren's Syndrome and Different Disease Subsets

Chiara Baldini[1], Daniela Martini[1], Nadia Ucciferri[2], Silvia Rocchiccioli[2], Letizia Mattii[3], Antonietta Raffaella Maria Sabbatini[3], Francesca Sernissi[1], Francesco Ferro[1], Nicoletta Luciano[1], Leonardo Lorenzini[1], Marta Mosca[4], Stefano Bombardieri[1] and Antonella Cecchettini[3], [1]Rheumatology Unit, University of Pisa, Italy, Pisa, Italy, [2]Institute of Clinical Physiology, Pisa, Italy, Pisa, Italy, [3]Department of Clinical and Experimental Medicine, University of Pisa, Italy, Pisa, Italy, [4]University of Pisa, Pisa, Italy

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Genetics, Genomics and Proteomics Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Salivary proteomics has recently appeared as a promising tool for the identification of novel diagnostic biomarkers for primary Sjögren's syndrome (SS). However, to date the vast majority of the studies have focused the attention essentially on a restricted panel of high-abundance proteins, partially limiting the diagnostic potentiality of salivary proteomics. Moreover, the clinical inter-subject variability of SS seem to be reflected in the variability of the proteomic profiling. Aims of this study were: 1) to identify and validate putative salivary biomarkers in SS by using LC-MS/MS. 2) to highlight a specific fingerprint able to discriminate between different SS phenotypes, defined on the basis of the focus score (FS) and on the variation of the salivary flow rate (USFR).

Methods: USFR was collected from 18 patients with SS (AECG criteria, 2002). Six patients presented a high focus score (FS≥3) and normal USFR (group A), six patients presented a FS≥3 and an USFR<1.5 ml/15 (Group B), and 6 patients a low focus score (FS<3) and USFR <1.5 ml/15 (group C). Six healthy volunteers (CTRL) represented the controls. ProteoPreop Immunoaffinity Albumin and IgG depletion kit (Sigma) was used for high-abundance proteins removal. A high-throughput liquid chromatography tandem mass spectrometry (LC-MS/MS) was used for the proteomic analysis. Western Blotting (WB) and immunohistochemistry on minor salivary gland biopsies were used to validate proteomics results. Principal component analysis (PCA) was utilized for statistical analysis.

Results: Overall, 100 differentially expressed candidate biomarkers were identified. When compared to CTRL, the salivary proteomic profile of SS patients was characterized by 20 proteins which were significantly decreased and 113 proteins which were significantly increased. Among the differentially expressed proteins, of interest were: proline-rich proteins, cystatins, calcium-binding proteins, antigen binding proteins, profilin and other cell motion-related proteins, proteins involved in apoptosis, defence- and inflammatory-response. PCA distinctively discriminate between CTRL and SS patients stratified as previously described. Preliminary validation by WB and immunohistochemistry of prolactin-inducible protein precursor, cystatins C, S and SA, S-100A7 protein, kallikrein-6 and histhidine-rich glycoprotein indicated similar expression profile trends to those identified by LC-MS/MS.

Conclusion: The proteomics workflow was able to detect novel candidate biomarkers potentially related to specific phenotypes of SS disease. These candidate biomarkers might be useful to improve SS non-invasive diagnosis and clinical stratification.

Session Title: Genetics, Genomics and Proteomics Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

We have previously described (*Nature Medicine, PNAS, A&R, Nature Rheum, Lancet*) how oral treatment with the pro-inflammatory, heat shock protein-derived dnaJP1 peptide induces detectable clinical amelioration in Phase I and IIa clinical studies in rheumatoid arthritis. In previous work, we have also identified T effector (Teff) immune deviation and an increase in PD-1 Treg subsets as some of the immune mechanisms leading to clinical improvement. Clinical and immunological data also emphasized a synergistic effect with hydroxychloroquine (HCQ). Our previous studies, however, did not capture, yet, the complexity of the dynamic interactions among subsets of immune cells. Here, we apply a novel approach aiming at addressing this unmet need.

Methods:

Patient selection, randomization treatment and assessment of clinical outcomes were previously described (Koffeman, et al 2009, Arthritis & Rheumatism). Antibody panels were designed, based on previous specific experience and data, to encompass the major subsets of immune cells and employed to study by flow cytometry PBMCs from two treatment cohorts: (a) dnaJP1-HCQ responders (n=6) (b) Placebo HCQ Non Responders (n=10) We have substantially modified and adapted for use in translational research the clustering software ACCENSE (Shekhar, et al, 2014, PNAS). The work flow is presented in Fig. 1, and FD is defined as fold difference percentage of responders over non responders cells.

Results:

T cell subsets which were significantly more represented in dnaJP1 responders were antigen experienced, activated T cells which displayed tolerogenic/regulatory characteristics ($CD4^{+}CD45RO^{+}TGF\text{-}B^{int}CD69^{int}$, FD= 17) and ($CD4^{+}HLA\text{-}DR^{hi}GITR^{int/high}$, FD = 27). Intriguingly we also detected $FoxP3^{hi}$ T cells which may represent regulatory subsets transiting between inflammatory ($CCR5^{hi}CXCR3^{hi}$, FD = 9) and mucosal ($CD103^{hi}CD27^{hi}CD62L^{hi}$, FD = 7) compartments.

Analysis of the antigen presentation cells (APCs) compartment revealed two functionally distinct subsets which are significantly elevated in dnaJP1 clinical responders, both subsets probably the outcome of cross talk between tolerized/regulatory T cells and APC: (a) $CD14^{+}CD16^{+}CD303^{hi}CD141^{hi}$ (FD = 10) monocytes that exhibit $CD86^{hi}$ expression, which has been described to relate to and augment Treg function, (b) APCs which manifest a mature phenotype ($CD83^{+}$), subdivided into 3 lineages (i) $CD19^{hi}$ B cells (FD = 9), (ii) dendritic cells $CD1c^{hi}$ (FD = 72) and (iii) $CD1c^{lo}$ (FD = 19).

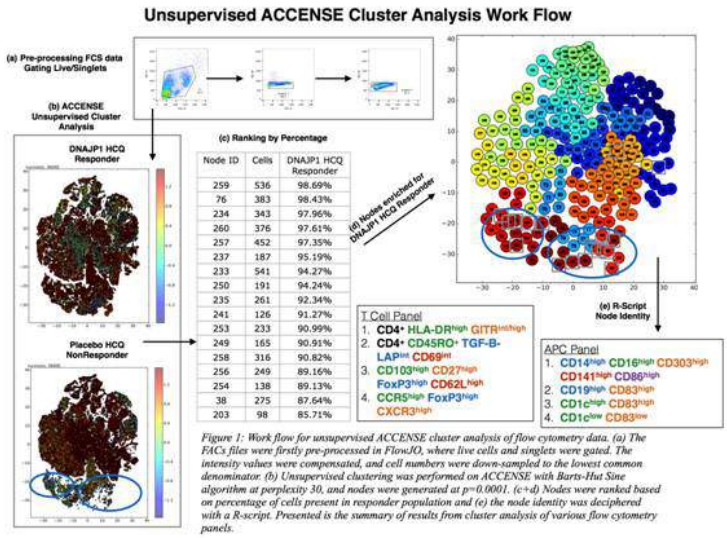

Figure 1: Work flow for unsupervised ACCENSE cluster analysis of flow cytometry data. (a) The FACs files were firstly pre-processed in FlowJO, where live cells and singlets were gated. The intensity values were compensated, and cell numbers were down-sampled to the lowest common denominator. (b) Unsupervised clustering was performed on ACCENSE with Barts-Hut Sine algorithm at perplexity 30, and nodes were generated at p=0.0001. (c+d) Nodes were ranked based on percentage of cells present in responder population and (e) the node identity was deciphered with a R-script. Presented is the summary of results from cluster analysis of various flow cytometry panels.

Conclusion:

A holistic approach to the immunome confirmed the specificity and complexity of the immune tolerization mechanism, which relies on the interplay between effector and regulatory T cells and APC. This approach has a dual translational value, as it provides mechanistic knowledge and also potential biomarkers directly related to the therapeutic intervention.

Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is an autoimmune disease that causes chronic inflammation of the joints. Recent evidence showed more and more importance of the epigenetic contribution, especially the DNA methylation, to the pathogenesis of rheumatoid arthritis. Identification of aberrant DNA methylation regions in RA would provide important for the comprehensively understand to the pathogenesis of rheumatoid.

Methods: We performed a genome-wide DNA methylation study in CD4+ T cells in 12 rheumatoid arthritis patients compared to 12 matched normal healthy controls. CD4+ T cells were prepared from freshly isolated PBMCs by depleting cells expressing CD8, CD14, CD16, CD19, CD36, CD56, CD123, γ/δ T cell receptors, and glycophorin A using No-Touch T cell isolation kits (Miltenyi Biotec). The purity of the CD4+ T cells was 95–98%, as determined by flow cytometry using specific antibodies.Cytosine methylation status was quantified with Illumina methylation 450K microarray (HM450K, 485512 CpG sites). Beta-mixture quantile normalization, batch effect correction, outlier probe imputation were applied in the data pre-processing to keep the data creditable for the follow analysis.

Results: We identified 810 hypomethylated and 392 hypermethylated CG sites in RA CD4+ T cells compared to normal controls, representing 383 and 785 genes hypermethylated and hypomethylated in RA patients ($P<3.4\times10^{-7}$). Cluster analysis based on significantly differential methylated loci showed distinct separation between RA and normal controls. Gene ontology analysis showed alternative splicing ($P=1.2\times10^{-7}$, FDR) and phosphoprotein (1.7×10^{-2}, FDR) were significantly aberrant in RA patients, indicating the abnormal of transcript alternative splicing and protein modification mediated by DNA methylation might play important role in the pathogenesis of rheumatoid arthritis. What's more, the result showed human leukocyte antigen (HLA) region was frequently hypomethylated in RA patients, including HLA-DRB6, HLA-DQA1 and HLA-E, however, HLA-DQB1 showed different methylation profiles with significant hypermethylation in CpG island region and hypomethylation in CpG shelf region. Outsite of the MHC region, the most hypermethylated genes in RA included HDAC4, NXN, TBCD and TMEM61 while the most significant hypomethylated genes included ITIH3, TCN2, PRDM16, SLC1A5 and GALNT9.

Conclusion: Genome-wide DNA methylation patterns revealed significant DNA methylation change in CD4+ T cells from patients with rheumatoid arthritis which might provide contribution to the pathogenesis of rheumatoid arthritis

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Genetics, Genomics and Proteomics Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic systemic autoimmune disease characterized by synovial inflammation and hyperplasia. Fibroblast-like synoviocytes (FLS) in RA exhibit a tumor cell-like aggressive phenotype and have a major role in the initiation and perpetuation of joint inflammation. The metabolomic approach enables the elucidation of the current physiological or pathological states of individual cells that result from the interactions between genes and the environment. A systematic characterization of the metabolic pathways in transformed RA FLS is currently lacking. Thus, gas chromatography/time-of-flight-mass spectrometry (GC/TOF-MS) was employed to identify the characteristic metabolic profiling of RA FLS compared to that of osteoarthritis (OA) FLS.

Methods: Metabolite profiling of RA FLS and OA FLS ($N = 6$, respectively) was performed using GC/TOF-MS in conjunction with univariate and multivariate statistical analyses. We performed metabolite set enrichment analysis (MSEA) to establish which pathways are affected.

Results: A total of 129 metabolites were identified and were classified into sugars and sugar alcohols (20.9% of identified metabolites), amino acids (20.2%), organic acids (19.4%), fatty acids (15.5%), amines (10.9%), phosphates (7.0%), and miscellaneous compounds (6.2%). A principal component analysis based on cellular metabolites showed very clear discrimination between the intracellular metabolite profiles of the two groups ($R^2X = 53.9\%$ and $Q^2 = 59.5\%$). The levels of 35 metabolites that belonged to the amines, fatty acids, phosphates, and organic acids class were significantly increased in RA FLS compared to those in OA FLS. Also, the levels of 26 metabolites that belonged to the amino acids, sugars, and sugar alcohols class were significantly decreased in RA FLS compared to those in OA FLS. MSEA demonstrated that the sugar metabolic pathways such as glycolysis, galactose metabolism, gluconeogenesis, and the pentose phosphate pathway; the amino acid metabolism pathways such as tyrosine, phenylalanine, and catecholamine biosynthesis; protein biosynthesis, and the urea cycle were severely disturbed in RA FLS compared to OA FLS.

Conclusion: Our metabolic results suggested that the alteration of sugar metabolism, lipolysis, and amino acid metabolism in RA FLS is related to synovial hyperplasia and inflammation. This is the first metabolomic study to determine metabolic changes characteristic of RA FLS, which will provide valuable information to gain in-depth insights into the pathogenesis of RA.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Genetics, Genomics and Proteomics Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: Sjögren's Syndrome (SS, OMIM #270150) is a chronic, multi-system autoimmune disease characterized by progressive destruction of the exocrine glands, with subsequent mucosal and conjunctival dryness. A growing body of evidence indicates that many epigenetic changes are associated with disease status and that epigenetic marks can provide unique insights into complex disease mechanisms. We report on results of a case-control study of DNA methylation (DNAm) differences within labial salivary gland tissue, using biopsies sampled from 13 severe SS cases and 13 controls in the Sjögren's International Collaborative Clinical Alliance (SICCA; http://sicca.ucsf.edu/; HHSN268201300057C) registry.

Methods: We have methylotyped gland tissue and sorted PBMCs from these subjects using the Illumina HumanMethylation450 (450k) BeadChip platform. In addition to standard background correction and normalization techniques, we applied an adaptive normalization scheme to adjust for residual associations between DNAm and control measures.

Results: Principal component analysis (PCA), applied to the 404,353 CpG sites passing strict QC criteria, clearly distinguishes glands of primary SS cases from those of controls. We find over 10,000 significant differentially methylated positions (DMPs) that show significant overlap with the promoters of genetic risk loci as a whole, with particular enrichment seen in the promoters of *CXCR5* and *BLK*. We also observe an extended region of differential methylation surrounding *PSMB8* and *TAP1* in the MHC class II region. Despite a previous report of association between global DNAm and ICAM1 expression in the context of SS, we fail to detect differential methylation in the promoter of the *ICAM1* locus. On the other hand, differential methylation patterns surrounding several non-coding RNAs suggest many indirect consequences of the observed salivary gland *hypo*-methylation in SS. Transcription factor motif enrichment analysis highlights the specific nature of these methylation differences, demonstrating co-localization of DMPs with interferon- stimulated response element (ISRE) and PU-Box motifs. DNAm signatures derived from sorted PBMCs show that disease-associated changes in DNAm are linearly correlated with cell-type specific patterns, resolving differential lymphocyte proportions.

Conclusion: Our results emphasize the utility of CpG methylation not only as a biomarker of disease status, but also as an independent probe of underlying disease processes.

Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: The goal of treatment in OA is to reduce pain and improve function. There is no cure for the disease, but some attempts to slow the progression of the disease. We have previously demonstrated that a mixture of curcuminoids extract, hydrolyzed collagen and green tea extract (COT) inhibited inflammatory and catabolic mediator's synthesis by osteoarthritic human chondrocytes in monolayer [1]. The objective of this study was to identify new targets of COT using genomic and proteomic approaches.

Methods: Enzymatically isolated primary human chondrocytes were cultured in monolayer until confluence and then incubated for 24 or 48 hours in the absence or in the presence of human interleukin-1β (10^{-11} M) and with or without COT, each compound at the concentration of 4 µg/ml. Microarray gene expression profiling between control (ctrl), COT, IL-1β and COT IL-1β conditions was performed. The biological relevance of regulated genes was determined with Ingenuity Pathway Analysis. Immunoassays (ELISA) were used to confirm the identified genes that were differentially expressed.

Results: 2549 genes were differentially expressed between ctrl and IL-1β conditions, 2280 genes were differentially expressed between IL-1β and COT IL-1β conditions and 1907 genes were differentially expressed between ctrl and COT conditions. The key regulated pathways were related to inflammation, cartilage metabolism and angiogenesis. In the inflammatory pattern, the IL 1β stimulated chemokine (C-X-C motif) ligand 6 (CXCL6) gene expression and protein production were strongly down-regulated by COT ($p<0.001$). The most IL-1β up-regulated enzyme in the catabolic pattern was matrix metalloproteinase-13 (MMP-13). Both gene and protein were significantly down regulated by COT ($p<0.001$). The IL 1β-stimulated bone morphogenetic protein-2 (BMP-2) gene expression and protein production were down-regulated by COT ($p=0.001$). In the angiogenesis pathway, one of the most up-regulated factors by IL-1β was stanniocalcin 1 (STC1) ($p=0.005$). This IL 1β stimulating effect was significantly down regulated by COT ($p<0.001$). Moreover, COT significantly decreased STC1 production in basal condition ($p=0.030$). Finally, serpin E1 gene expression and protein production were down-regulated by IL 1β ($p<0.001$). COT fully reversed the inhibitory effect of IL-1β ($p=0.028$). Serpin E1 gene expression was up-regulated by COT in basal condition ($p<0.001$).

Conclusion: The mixture COT has beneficial effect on OA physiopathology by regulating the synthesis of key catabolic, inflammatory and angiogenesis factors. These findings give a scientific rationale for the use of these natural ingredients in the management of OA.

Session Time: 9:00AM-11:00AM

Background/Purpose:

The current diagnosis of osteoarthritis (OA) relies on the description of pain symptoms, affected joint stiffness, and radiography used as the reference technique for determining the grade of joint destruction. Limitations of the presently available diagnostic tests have provided an impetus for the substantial increase in interest in finding new specific biological markers for OA to facilitate the early diagnosis, evaluate disease progression and improve disease prognosis. Recently, there has been a remarkable development in mass spectrometry-based methodologies for the verification and validation of biomarkers with high specificity and sensitivity, since the multiple reaction monitoring (MRM) assay can measure several targets (peptides) with high sensitivity and throughput in biological samples. The aim of this work was to verify a panel of OA biomarker candidates in serum samples using the MRM technology.

Methods:

Serum samples were obtained from OA patients at different stages of the disease (K/L grade II=38, K/L grade IV=39 and control donors=39). Proteins were quantified and digested with trypsin. The peptide mixture was separated by nano-LC coupled to a 5500 QTRAP mass spectrometer. A single multiplexed MRM assay was used to quantify the levels of seven proteins (identified as putative OA biomarker candidates in shotgun proteomics experiments performed previously by our group) at different stages of OA, and compared to control donors: Pigment epithelium derived factor, Haptoglobin, Von Willebrand factor, Fructose-bisphosphate aldolase A, Insulin-like growth factor-binding protein complex acid labile subunit, C-type lectin domain family 3 member A and matrix metallopeptidase 2. Von Willebrand factor and Haptoglobin were found quantitatively altered in the serum of OA patients compared to control donors. The relative quantification values of peptides were determined by calculating the ratio of peak areas from transitions of target peptides in OA and control samples, normalized to the peak area of the internal standard. Data analysis was performed using the Skyline software. Kruskal–Wallis and Mann–Whitney *U* test were used for the statistical analysis.

Results:

Haptoglobin was found to discriminate between the different K/L grades of OA, and it was found to be altered between early OA compared to controls with a significant p-value. Therefore, this protein could be a putative diagnostic biomarker. On the other hand, Von willebrand factor was found altered in OA vs control samples with a significant p-value ($p<0,05$), but showed no differences between the different K/L grades of OA.

Conclusion:

A multiplexed method for the simultaneous quantification of a panel of seven proteins in serum has been developed, which is based on liquid chromatography-multiple reaction monitoring (LC-MRM) mass spectrometry. By these means, two novel putative OA serum protein biomarkers, Von Willebrand factor and Haptoglobin, were verified in a cohort of individual serum samples. Further qualification studies will be necessary to establish their usefulness for OA diagnosis and progression studies.

Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

DNA methylation is the most characterized epigenetic mechanism and has been recently linked to knee osteoarthritis (OA) pathogenesis. The present study was design to comprehensively compare the methylome and transcriptome of normal and OA knee articular cartilage using the Illumina Infinium HumanMethylation450 beadchip array and next generation RNA sequencing, respectively. Furthermore, we used different *in vitro*approaches to experimentally validate the link between DNA methylation and gene expression in human chondrocytes.

Methods:

Genomic DNA was isolated from human macroscopically preserved (N=11) and OA (N=12) knee articular cartilage. After bisulphite treatment, DNA was profiled using the Illumina Infinium HumanMethylation450 beadchip. For transcriptomic analysis, RNA isolated from normal (N=8) and OA (N=10) knee articular cartilage was sequenced using the Illumina HiSeq 2000 platform. In both cases, normalized data was analyzed using a custom-made R bioconductor package. For *in vitro*experiments, primary chondrocytes isolated from donors with normal (N=5) cartilage, and TC28 immortalized chondrocytes were used. Cells were cultured in monolayer until confluence, treated with different doses of the DNA methylation inhibitor 5-Aza-2-deoxycytidine (5'Aza) or vehicle, and gene expression was assessed by qPCR.

Results: DNA methylation profiling revealed 2833 differentially methylated sites (DMS) between normal and OA cartilage ($p<0.05$, FDR<1%, delta β-value>0.15). DMS were significantly enriched in gene bodies and enhancer regions of the genome, and comprised a total of 1279 genes. Among these, 102 transcription factors that harbored DMS were identified. Integrative analysis and subsequent validation showed a subset of 8 transcription factors that were significantly hypermethylated and downregulated in OA cartilage (ATOH8, FOXO3, KLF15, MAFF, NCOR2, RARA, TBX4, and ZBTB16). Upon 5'Aza treatment, TC28 cells showed a significant increase in gene expression for all eight transcription factors. In primary chondrocytes, ATOH8, FOXO3 and TBX4 were increased after 5'Aza treatment

Conclusion:

Our findings reveal that normal and OA knee articular cartilage have significantly different methylomes. The identification of a subset of epigenetically regulated transcription factors with reduced expression in OA may represent an important mechanism to explain changes in the chondrocyte transcriptome and function during OA pathogenesis.

Session Title: Genetics, Genomics and Proteomics Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Vascular remodeling play a major role in the pathophysiology of giant cell arteritis (GCA) and the mechanisms underlying it are poorly understood.

Methods:

Vascular smooth muscle cells (VSMC) were cultured from temporal artery biopsies (TAB) obtained from patients suspected of GCA: patients with biopsy proven GCA (TAB^+-GCA), patients with biopsy-negative GCA (TAB^--GCA), and patients with another diagnosis than GCA (GCA-control). Two-dimension DIGE (2D-DIGE) and affymetrix chips were used in order to analyze proteomes and gene expression profile of VSMC from the different groups. Normal human aorta VSMC (HAoSMC) were used as control in proteomic experiments. Proliferation of VSMC was analysed using a BrdU proliferation assay ELISA kit. Immunohistochemistry with ET-1, ET_AR and ET_BR were also performed on temporal artery biopsies from TAB^+-GCA and GCA-control patients.

Results:

2D-DIGE analysis of VSMC protein extracts revealed 16, 30 and 2 protein spots differentially expressed between TAB^+-GCA and GCA-control patients, between TAB^+-GCA and TAB^--GCA patients and between TAB^--GCA and GCA-control patients, respectively (fold change$\geq$1.5 and p-value$\leq$0.05). Among the 153 differentially expressed between VSMC from TAB^+-GCA and HAoSMC, a lot of them were linked with endothelin-1.

Genes differentially expressed between VSMC from patients with TAB^+-GCA, TAB^--GCA and GCA-control were involved in proliferation. Endothelin-1 was also identified as a link between genes of interest. Proliferation of VSMC from TAB^+-GCA patients was reduced in the presence of macitentan, an endothelin receptor antagonist and its active metabolite and was not modified with bosentan or ambrisentan. Interestingly, in immunochemistry analysis, patients who had a transmural expression of endothelin-1 on TAB received a significantly increased glucocorticoid daily dose after a 6-month follow-up.

Conclusion:

Inhibition of the increased proliferation of VSMC during GCA with macitentan might represent a promising therapeutic approach in patients with GCA, in combination with glucocorticoids.

Session Title: Genetics, Genomics and Proteomics Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Chronic fatigue is a common, often disabling, and poorly understood phenomenon of many diseases. Recent studies indicate that epigenetic mechanisms may be involved in the expression of fatigue, which is a prominent feature of primary Sjögren's syndrome (pSS), a chronic autoimmune disease. The aim of this study was to investigate whether DNA methylation profiles of whole blood are associated with fatigue in patients with pSS.

Methods:

48 pSS patients with high (n=24) or low (n=24) fatigue were included. Genome-wide DNA methylation was investigated using the Illumina HumanMethylation450 BeadChip array. After quality control, a total of 383 358 CpG sites remained for further analysis. Age, sex, and differential cell count estimates were included as covariates in the association model. A false discovery rate–corrected $p<0{\cdot}05$ was considered significant, and a cut-off of 3% average difference in methylation levels between high- and low-fatigue patients was applied.

Results:

251 differentially methylated CpG sites were associated with fatigue (166 hypomethylated sites annotated to 117 genes and 85 hypermethylated sites annotated to 65 genes). The CpG site with the most pronounced hypomethylation in pSS high fatigue compared with pSS low fatigue annotated to the SBF2-antisense RNA1 gene. The most distinct hypermethylation was observed at a CpG site annotated to the lymphotoxin alpha gene. Functional pathway analysis of genes with differently methylated CpG sites in subjects with high versus low fatigue revealed enrichment in several pathways associated with innate and adaptive immunity.

Conclusion:

Some genes involved in regulation of the immune system and in inflammation are differently methylated in pSS patients with high versus low fatigue. These findings point to functional networks that may underlie fatigue. Epigenetic changes could constitute a fatigue-regulating mechanism in chronic inflammatory diseases such as pSS.

SESSION INFORMATION
Session Date: Monday, November 9, 2015
Session Title: Genetics, Genomics and Proteomics Poster II
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

There have been many reports showing that saliva could be a source of biomarkers capable of detecting certain diseases. However, very few studies have been conducted to profile autoantibody isotypes in the saliva of various autoimmune diseases except Sjogren's syndrome. This study was performed to establish protein microarray for saliva diagnostics in autoimmune diseases and to identify distinct profiles of salivary autoantibody in patients with systemic lupus erythematosus (SLE).

Methods:

We constructed antigen microarrays and probed healthy saliva spiked with commercial antibodies (Abs) (monoclonal mouse anti-La, anti-Ro52 and anti-Ro60 and polyclonal rabbit anti-U1-70). To investigate whether saliva destroys Abs existing in patients' serum, we used serum from clinically confirmed SLE and mixed connective tissue disease (MCTD) patients diluted from 250 to 8000 fold with healthy

saliva and PBST containing 5% fetal calf serum. Following proof-of-concept experiments, we developed another array with a panel of canonical antigens of SLE as well as cytokines (interferon α-2b, interferon γ, BAFF and CXCL13) to characterize autoantibodies in matched saliva and serum derived from 17 SLE patients and 13 healthy controls. The autoantibody IgG and IgA isotypes were assayed using goat anti-human IgG (AF647 conjugated) and goat anti-human IgA (Cy3 conjugated). The Axon Scanner and GenePix Pro 7.0 were used to determine median fluorescence intensities (MFI) of features and background. Data were analyzed using MultiExperiment Viewer and Significance Analysis of Microarray (SAM) algorithm.

Results:

The dynamic range of detection on the array was 1-10^4 ng/mL for commercial Abs spiked into saliva. We observed a high degree of specificity and each Ab was specific for its target antigen. In the experiments investigating the effect of saliva on the reactivity of Abs existing in patients' serum (anti-Ro52 and anti-La in SLE, anti-U1-70 and anti-U1-A in MCTD), saliva made the MFI signals a little bit weaker than buffer, but it was not significantly different. The optimal dilution rate of saliva for protein microarray turned out to be 1:4 to 1:8. Matched saliva and serum samples from 17 SLE patients and healthy controls were incubated with anti-IgG and anti-IgA secondary Abs. IgG Ab reactivity against specific antigens was found mainly in serum, while IgA Ab reactivity to given antigens was predominant in saliva, suggesting the possibility of isotype switching between saliva and serum. SAM identified 7 antigens including BAFF, Ro60, U1-A and Sm/RNP that were significantly more reactive to IgA Ab in the saliva of SLE patients than in healthy controls (false discovery rate<0.01). The hierarchical clustered heat-map successfully placed SLE patients into close subgroups.

Conclusion:

Protein microarrays facilitate detection of autoantibody in human saliva as well as serum. Saliva profiling revealed that elevated IgA autoantibody reactivity to several targets including BAFF was associated with SLE compared with controls. The noninvasive nature of saliva collection with protein microarray highlights the efficacy of pursuing saliva as a diagnostic medium.

Session Title: Genetics, Genomics and Proteomics Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Systemic lupus erythematosus (SLE) is a heterogeneous disease characterized by autoantibody formation in which multiple genetic, epigenetic and environmental risk factors have been implicated. We previously demonstrated that methylation levels differ significantly among SLE patients according to auto-antibody status and presence/absence of lupus nephritis. The study of epigenetics provides a mechanistic bridge to understand the effects of environmental exposures with disease risk and outcome. Air pollution has been linked not only to an increase in overall mortality but also to an increased incidence of rheumatoid arthritis. There are few studies evaluating air pollution and SLE development and outcomes. However, anti-dsDNA antibody titers have been associated with high levels of air

particulate matter. The goal of this study was to evaluate methylation differences in relation to residential proximity to highways in patients with SLE.

Methods:

We studied 307 Caucasian females with SLE, all non-smokers, who were previously enrolled in a Lupus Genetics Project. Residence at the time of blood draw was recorded and geocoded. The distance to the nearest roads from the geocoded locations were calculated for the four major Tele Atlas Feature Class Codes (FCC) road classes. The Geographic Data Technology, Inc. (GDT) road network data were used for these calculations. Genome-wide methylation profiling was performed using the Illumina Infinium HumanMethylation 450 BeadChip. After quality control measures 467,314 CpG sites were analyzed.

Results:

Patients residing within a 300 meter radius from a major highway were defined as at high risk for significant hazardous health outcomes[1]. Thirty-eight patients (12.4%) were residing in a high risk area. Multivariate analysis did not reveal any statistically significant association between proximity to highways and disease phenotypes, however there was a trend for higher incidence of malar rash (OR 2.4, CI[1.1, 5]) and photosensitivity (OR 2.7, CI[1.2, 5.9]). Analysis of genome-wide methylation data revealed 3 methylation sites that were significantly hypomethylated in patients who resided in a high risk zone (P value <**1.7 E-07).** These three sites belonged to a single gene, *UBE2U,* which encodes one of the E2 enzymes involved in the ubiquitination of proteins and histones, as well as DNA repair. Genome wide association studies (GWAS) in SLE have identified a risk variant at *UBE2L3*, also an E2 ubiquitination enzyme. In a large ongoing GWAS marked overexpression of UBE2L3 was seen in plasmablasts of patients of SLE with an associated upregulation of NF-κB.

Conclusion:

Hypomethylation of *UBE2U* was associated with residing close to a highway in our cohort of SLE patients. To our knowledge, this study represents the first genome-wide assessment of DNA methylation in relationship to residential proximity to highways. Additional work is warranted to confirm these findings, examine other potentially relevant exposures, and determine whether these epigenetic changes are associated with SLE severity and outcome.

SESSION INFORMATION

Session Date: Monday, November 9, 2015

Session Title: Genetics, Genomics and Proteomics Poster II

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose:

Genome wide association studies (GWAS) studies from rheumatoid arthritis patients have identified SNPs, which are associated with changes in gene expression levels. Recent studies revealed epigenetic changes in DNA methylation associated with rheumatoid arthritis

synovial fibroblasts (RASF). Now, we want to identify genetic variations in RASF that are associated with quantitative changes in DNA methylation at very early disease state of RA.

Methods:

SF were obtained from patients with undifferentiated arthritis (symptom duration <3 months). Patients were classified as resolving arthritis or very early RA (VeRA) depending on whether they fulfilled the ACR criteria for classification within the subsequent 18 months. Methylation immunoprecipitation (MeDIP) and high throughput sequencing was used for the analysis of differentially methylated regions (DMRs) between resolving and very early RA (n=2). The DMRs were visualized with Integrative genome viewer (IGV) and biological pathway analysis was performed by DAVID bioinformatics tools. Rheumatoid arthritis single nucleotide polymorphisms (SNPs) associated with CpG sites were mapped together with the DMRs sequencing data.

Results:

The high throughput methylome sequencing of samples from VeRA versus resolving arthritis revealed >1000 DMRs that are associated with nearby gene promoters or introns. The gene ontology analysis of the DMRs showed significant enrichment of extracellular matrix, cell adhesion and joint development pathways. Genomic loci of WNT6, WNT8A and WNT1 secreted proteins were found to be altered by DNA methylation in very early RA disease. Next, we mapped genotypic data from RA associated CpGs SNPs with the DMRs sequences of very early RASF. Thereby, we found that the region containing the IL6R introning SNPs rs4576655 and rs4537645 were hypomethylated in VeRASF versus resolving arthritis SF.

Conclusion:

In this study, we clearly show that changes in DNA methylation in RASF occur even before diagnosis and differ between RA and resolving arthritis. The overlap of DMR with RA risk SNPs suggests that genetic/epigenetic interactions play a role in disease development.

Rheumatologic Diagnoses, Characteristics and Needs of Somali Patients Referred to a Rheumatology Clinic Serving the Somali Population

Elizabeth Miller[1], Elie Gertner[2], Rosemary Quirk[1] and Maribet McCarty[1], [1]Hennepin County Medical Center, Minneapolis, MN, [2]Section of Rheumatology, Regions Hospital and University of Minnesota, St. Paul, MN

SESSION INFORMATION

Session Title: Health Services Research Poster II (ACR): Healthcare Access, Patterns of Medication Use and Workforce Considerations

Session Type: ACR Poster Session B

Background/Purpose: With the growing immigrant and refugee population in the United States, the landscape of medicine is constantly changing. In order to provide quality healthcare, it is crucial that we investigate disease patterns and continue to monitor the quantity and quality of resources available. Somali immigrants live in many areas of the United States with the largest number in the Minneapolis-St Paul area. There are no data available to define rheumatologic disease or attendance with rheumatology specialists in this population in the United States. To better characterize the disease patterns for an emergent immigrant community, we investigated the clinical characteristics of Somali patients referred to the principal rheumatology clinic serving this population over a 5-year period. We evaluated the rheumatologic and non-rheumatologic diagnoses made after referral in this cohort as well as follow-up.

Methods: A retrospective chart review from 2010-2014 for patients of Somali origin presenting to Hennepin County Medical Center (HCMC) rheumatology clinic in Minneapolis, MN. We collected data from one hundred consecutive Somali patients seen in clinic, including population characteristics, diagnoses and follow up (see table 1).

Results: Over a 5-year period, 100 patients of Somali origin were referred to the clinic. 81% were female. 1/3 (33/100) did not have a rheumatologic syndrome. 1/3 (32/100) had OA or myofascial pain. 1/3 (35/100) had an inflammatory or immunologic CVD. Coexisting mental health disorders were present in 44% of those with OA or myofascial pain. In addition, an average of 90% of patients had low vitamin D levels. Of all 100 patients, 64% were asked to return to clinic for follow up and over half did not. See tables 1-3.

Conclusion: Of 100 Somali patients referred to our rheumatology clinic, 1/3 had no rheumatologic disease. Additionally, 1/3 had non-inflammatory conditions (OA and myofascial pain). These also had a high incidence of mental health diagnoses (44%). Hypovitaminosis D was highly prevalent. The no-show rate for return visits was more than 50%. More effort is needed in education of primary care physicians regarding non-rheumatological disease, OA and myofascial pain as well as hypovitaminosis D in this population. Awareness of mental health issues and provision of such services as well as working with the community to improve attendance at clinic is important

Drug Survival of Second Biologic DMARD Therapy in Patients with Rheumatoid Arthritis: Comparison of a Second Anti-TNF with a Second Non-Anti-TNF after Discontinuation of a First Anti-TNF

T Wilke[1], S Mueller[1], I Majer[2], M Heisen[2], A Fuchs[3] and U Maywald[3], [1]Institut für Pharmakoökonomie und Arzneimittellogistik (IPAM), Hochschule Wismar, Germany, [2]Pharmerit International, Rotterdam, Netherlands, [3]AOK PLUS, Dresden, Germany
First publication: September 29, 2015

SESSION INFORMATION
Session Title: Health Services Research Poster II (ACR): Healthcare Access, Patterns of Medication Use and Workforce Considerations
Session Type: ACR Poster Session B

Background/Purpose: There is limited information on drug survival (i.e., continuation versus discontinuation of drug treatment) of RA patients who received a 2nd bDMARD therapy after 1st anti-TNF therapy. The objective of this study was to compare continuation, discontinuation, re-start and switch rates of RA patients who received an anti-TNF versus a non-anti-TNF as 2nd bDMARD. **Methods:** Our analysis was based on a German claims data set (AOK PLUS) that included all insured RA patients (at least one RA diagnosis: ICD-10 M05 or M06; aged >18 years). RA patients were included if they received at least one anti-TNF and, additionally, one 2nd bDMARD (anti-TNF or non-anti-TNF) during 01/01/2010–31/12/2012 with a requested follow-up of at least 12 months. Percentages of patients who discontinued (treatment gap >90 days), switched to a 3rd bDMARD, re-started (at least one prescription of the 2nd bDMARD after discontinuation) or continued therapy during a 12-month follow-up were analyzed. A multivariate Cox regression model, adjusting for baseline confounding variables (age, sex, Charlson Comorbidity Index [CCI], prior and concomitant medications, anti-TNF/non-anti-TNF as 2nd biologic treatment), was used to assess factors associated with discontinuation or switch (combined outcome, irrespective of a later re-start) of 2nd bDMARD. In all analyses, patients who had received rituximab (RTX) as a 2nd bDMARD were excluded because this agent is not given on a continuous basis after the initial two doses. **Results:** 3140 RA patients received at least one prescription of an anti-TNF. Of these, 451 patients received at least one prescription of a 2nd non-RTX bDMARD (340 anti-TNF: 116 adalimumab, 42 certolizumab, 120 etanercept, 46 golimumab, 16 infliximab; 111 non-anti-TNF: 40 abatacept, 3 anakinra, 68 tocilizumab). Mean age of the anti-/non-anti-TNF groups was 52.6/55.9 years (p=0.053) and 77.4/79.3% were female (p=0.792), respectively. After 12 months, 53.4% of patients receiving a 2nd anti-TNF vs 66.7% (p=0.016) receiving a 2nd non-anti-TNF continued their therapy, 3.8 vs 1.8% (p=0.387) re-started their therapy after discontinuation, 14.1 vs 19.8% (p=0.179) discontinued the therapy without re-start, and 28.7 vs 11.7% (p<0.001) had switched to a 3rd bDMARD. Figure 1 presents the Kaplan–Meier curves for the two patient groups showing time to switch or discontinuation. In the multivariate Cox regression model, independent variables significantly associated with earlier therapy discontinuation or switch were higher CCI (hazard ratio [HR]=1.127 per CCI score point; 95% CI: 1.036, 1.226), concomitant gout medication (HR=1.444; 95% CI: 1.046, 1.993) and prescription of an anti-TNF as 2nd bDMARD (HR=1.513; 95% CI: 1.052, 2.175).

Conclusion: Our results suggest that patients are at higher risk of treatment discontinuation or switch to a 3rd bDMARD after 12 months if they have received an anti-TNF versus a non-anti-TNF as 2nd bDMARD therapy.

Figure 1: Drug survival of 2nd bDMARD

	Estimated mean survival time[a]	Std. Error	p-value[b]
Anti-TNF	264 days (8.7 months)	6.8	0.016
Non-anti-TNF	295 days (9.7 months)	10.5	

a. Main outcome of this analysis is percentage of patients still continuing 2nd bDMARD therapy (separately for anti-TNF/non-anti-TNF). Patients were assumed to discontinue treatment if a gap >90 days (irrespective of whether therapy was later re-started) or a switch to a 3rd DMARD was observed. Patients having died during the follow-up were censored. Patients still on the treatment were censored at 1 year of follow-up.
b. Test of equality of survival distributions for the two treatment groups (log-rank/mantel cox).

Utilization of Viscosupplementation: 2011 – 2013

Gurjit S. Kaeley[1], Myint Thway[1] and Sunita Dodani[2], [1]Rheumatology, University of Florida College of Medicine, Jacksonville, Jacksonville, FL, [2]Cardiology and Epidemiology, University of Florida College of Medicine, Jacksonville, Jacksonville, FL
First publication: September 29, 2015

SESSION INFORMATION

Session Title: Health Services Research Poster II (ACR): Healthcare Access, Patterns of Medication Use and Workforce Considerations

Session Type: ACR Poster Session B

Background/Purpose:

Viscosupplementation (VS) is approved in the USA as an option for knee osteoarthritis (OA) pain. Recent American Academy of Orthopedic Surgeons (AAOS) guidelines have strongly recommended against use of hyaluronic acid because of lack of clinical improvement compared with placebo. (1) OA has a higher prevalence and impact in the elderly population necessitating use of therapies to relieve pain and maintain mobility. Use of VS as one of the therapies for knee OA may be an important cost driver for Medicare. **Objective**: To estimate and compare the prevalence and cost of VS utilization amongst Medicare Beneficiaries from 2011 -2013.

Methods:

A retrospective cross-sectional analysis of Medicare (CMS) Physician Supplier Payment Summary (PSPS) files from 2011 – 2013 was used to tabulate volume and total payments on utilization. Non-duplicative billing claims for five types of VS were calculated for all three years by provider specialty and by State. Aggregated specialties that billed the majority of the services were included as shown in Table. Number of services submitted were standardized to reflect unique doses (One dose of Synvisc=16mg, Synvisc One = three doses). Descriptive summary analysis was conducted using R-Studio (Version 0.98.1102).

Results:

Orthopedists received 63% of the VS payments from 2011-2013, and compared to 2011, the rate of growth in payments was 12% (Table). Strikingly, there was minimal increase in utilization amongst Rheumatologists from 2011 to 2013 whereas other provider groups showed a payment growth from 24% - 56%. Amongst the five brands, Synvisc and Hyalgan were the most utilized. 2.1 million doses of each drug was used over the three years. Payments for Synvisc were $322.6 million and Hyalgan $146 million. The overall payments for VS over 3 years was $708,675,805. Utilization in the Top 10 States with the greatest number of payments is presented in Figure 1. Orthopedists were the dominant providers and Synvisc payments predominated in these states.

Conclusion:

This study highlights the significant cost of VS in the Medicare population. Orthopedists and Physician assistants were the greatest utilizers of these drugs whereas three other provider groups show robust increases in utilization. In view of the negative recommendations by the AAOS against the use of Hyaluronic acid joint injections, the current trajectory of use of Hyaluronic acid may not represent optimal value care.

SESSION INFORMATION

Session Title: Health Services Research Poster II (ACR): Healthcare Access, Patterns of Medication Use and Workforce Considerations

Session Type: ACR Poster Session B

Background/Purpose: Given the rising burden of arthritis care, there is concern about access to rheumatologists in many regions. To better characterize the rheumatologist workforce, the Canadian Rheumatology Association (CRA) launched the Stand Up and Be Counted survey in March 2015.

Methods: Following a literature review of existing workforce studies to identify gaps in knowledge, a working group including the research team, CRA staff and adult and pediatric rheumatologists from academic and community practices developed and pilot-tested English and French versions of the survey. The survey consisted of 63 questions including demographic and practice information, questions on provision of care to rural and remote communities, and allocation of time for clinical care. The survey was distributed to the CRA membership, with non-CRA members identified through the Royal College of Physicians and Surgeons, provincial licensing bodies, and snowball recruitment from other CRA members. To increase survey uptake, periodic electronic reminders were sent out to non-respondents and study updates were provided at regional meetings.

Results: The survey was sent to 657 individuals of whom 456 were expected to be practicing rheumatologists (400 adult, 56 pediatric) based on CRA membership information. As of May 2015 there were 320 respondents (49%), of which 33 were excluded, as they were not actively practicing rheumatologists or did not complete enough of the survey to determine this. There were 287 respondents included in this preliminary analysis, including 244 adult rheumatologists, and 43 pediatric rheumatologists, representing 61% and 76% of the expected respondents respectively. The median age was 50 years and nearly a third (90, 31%) plan to retire within the next 10 years. Sixty percent were affiliated with a university: 136 had a university-based clinic and an additional 37 had an academic appointment but practiced in a private community-based setting. Of the remaining respondents, 103 had community-based clinics and 11 reported other types of practice settings. Thirty-one percent of rheumatologists did not use an electronic medical record. With respect to rheumatologists' clinical practices and workload: the majority of the respondents' caseloads were comprised of patients with inflammatory arthritis (70%) and the median number of ½ day clinics offered per week was 8. The majority of rheumatologists' time was devoted to clinical practice (70%) while the remainder was spent on research, teaching or administration activities (10% each). Two-thirds participate in a call roster within their centers. To provide care to rural and remote communities 48 rheumatologists offer travelling clinics (16%), and 42 participate in Telehealth or eConsultations (15%).

Conclusion: The Stand Up and Be Counted survey is the first CRA national rheumatology workforce survey in Canada. The results highlight an ongoing need for training rheumatologists given that 1/3 of the workforce will be retiring in the next 10 years. Adoption of alternative models of care may be an option to increase clinical capacity, and enhanced use of technology to deliver care to remote and rural populations should be considered.

Abstract Number: 1270

Low Socioeconomic Status As a Predictor of Long-Term Direct Medical Costs Following Diagnosis of Granulomatosus with Polyangiitis: A General Population-Based Cohort Study

Natalie McCormick[1], Carlo Marra[2] and J Antonio Avina-Zubieta[3], [1]Faculty of Pharmaceutical Sciences, University of British Columbia/Arthritis Research Canada, Vancouver, BC, Canada, [2]Pharm Sciences, Univ of British Columbia, Vancouver, BC, Canada, [3]Arthritis Research Canada / University of British Columbia, Vancouver, BC, Canada
First publication: September 29, 2015

SESSION INFORMATION
Session Title: Health Services Research Poster II (ACR): Healthcare Access, Patterns of Medication Use and Workforce Considerations
Session Type: ACR Poster Session B

Background/Purpose:

Estimates of the healthcare costs of Granulomatosus with polyangiitis (GPA) and predictors of costs are scarce. In particular, while socioeconomic status (SES) is associated with costs in general populations, its impact in GPA is unknown. To address these gaps, we estimated the incremental (extra) direct medical costs of a general population-based cohort of incident GPA for the first five years after diagnosis, and examined the relationship between SES at diagnosis, and medical costs in GPA.

Methods:

Data Source: Our administrative data captured all provincially-funded outpatient encounters and hospitalizations (1990-2010) and all dispensed medications for ALL residents of the province of British Columbia, Canada.

Sample: We assembled a population-based cohort of all cases of GPA who had a new diagnosis of GPA from at least one hospitalization or rheumatologist visit, or two non-rheumatologist visits, between Jan 1996 and Dec 2010, and no prior GPA diagnosis between Jan 1990 and Dec 1995. Ten controls matched by age at diagnosis (±2 years), sex, and calendar year of diagnosis were selected for each case from the general population. SES was defined from Statistics Canada neighbourhood income quintile data for the year of GPA diagnosis.

Cost Calculation: Outpatient and prescription costs were summed directly from billing data. Case-mix methodology was used for hospitalizations.

Statistical Analysis: We estimated the unadjusted incremental costs of GPA (difference in per-patient-year (PY) costs between cases and controls). Generalized linear models were then used to:

1. Further adjust for differences in SES, urban/rural residence, and Charlson-Romano comorbidity index between cases and controls; and
2. Evaluate the relationship between SES and direct medical costs among GPA cases.

Results: We matched 441 incident GPA cases to 4,410 controls (54% female, mean age 61 ±16.0 years, median comorbidity score=1).

Unadjusted incremental costs of GPA for the first 5 years after diagnosis averaged $81,603 per-PY (2010 Canadian), with 80% from hospital, 15% from outpatient, and 5% from medications. 74% of cases (vs. 17% of controls) were hospitalized during the first year after diagnosis, with GPA cases averaging 0.86 more admissions per-PY than controls (excluding the index admission). Following adjustment, costs for GPA cases were 5.3-times higher than matched controls (95% CI: 4.6-6.1).

Amongst GPA cases, age ($p < 0.001$), comorbidity score ($p < 0.001$), and being in the lowest SES group (vs. the highest, $p < 0.001$) were significantly associated with higher costs. This was driven mainly by hospitalizations for GPA (see **Table**). Predicted mean costs for lowest SES cases ($121,358/PY) were 1.9-times greater than the highest-SES.

Conclusion:

The medical costs of GPA cases over 5 years are substantial (averaging $81,603/PY more than matched controls from the general population), with lower SES a predictor of higher costs.

Unadjusted Mean Per-Patient-Year (PY) Costs for the First Five Years After GPA Diagnosis (2010 Canadian) (95% CI)						
Socioeconomic Status (SES) at GPA Diagnosis

Cost Savings and Interest in Pediatric Rheumatology Telemedicine Visits

Elizabeth A Kessler[1], Chelsey Smith[1], Ashley Sherman[2] and Mara L Becker[1], [1]Rheumatology, Children's Mercy Kansas City, Kansas City, MO, [2]Research Development and Clinical Investigation, Children's Mercy Kansas City, Kansas City, MO

SESSION INFORMATION
Session Title: Health Services Research Poster II (ACR): Healthcare Access, Patterns of Medication Use and Workforce Considerations
Session Type: ACR Poster Session B

Background/Purpose: Nearly 1 in 250 children live with arthritis, yet less than 300 board certified, practicing pediatric rheumatologists exist in the United States, approximately 90% of whom are located in large cities. Clinic travel can be a significant time and monetary commitment for families. Telemedicine (TM) may improve patient access to pediatric rheumatology (PR) clinics and reduce the cost of care. The objective of this study is to describe the cost to families associated with PR visits and identify interest in TM.

Methods: Surveys were offered to parents and patients aged 18 or older in PR clinics in Kansas City, Missouri (KC) and at a TM outreach site 160 miles away, in Joplin, Missouri. Survey questions included the distance traveled to the appointment, amount of work and school missed, meal and lodging costs, and interest in a TM clinic. Joplin patients were asked to answer the survey questions in relation to

appointments located currently in Joplin as well as previously in KC. Statistical analyses were conducted on patients seen in KC (n=256) and Joplin (n=24), as well as on a subsample of the KC respondents living at least 50 miles from the KC clinic. Different survey versions resulted in a variable number of total responses for each question. Descriptive and inferential analyses were performed using SPSS 20 and SAS 9.4, including chi-square and Wilcoxon rank sum tests for categorical and continuous variables, respectively.

Results: At the main KC clinic, the median distance traveled one-way was 41 miles [IQR=20-82]. Sixty-one percent of respondents missed work for the appointment, 52% purchased meals and 6% spent money on lodging. Overall, 42% were interested in a TM option. When stratified by distance, respondents living at least 50 miles from the KC clinic were more interested in TM than those less than 50 miles away (63% vs. 28%, $p<0.0001$). Among respondents who missed work, those who spent more hours away from work were more likely to endorse interest in TM ($p=0.004$). The number of hours of school missed and amount of money spent were not associated with increased interest in TM.

In the Joplin sample, the median distance traveled was 60 miles [IQR=20-85] when seen via TM vs. 175 miles [IQR=160-200] when seen in KC ($p<0.0001$). Thirty-eight percent spent money on food related to the TM visit in contrast to 92% with a KC visit ($p<0.0001$). Joplin respondents were more likely to spend money collectively on food, lodging and/or child care when traveling to KC as compared to Joplin (92% vs. 38%, $p<0.0001$). Respondents missed an average of 5.5 ± 3.4 hours of work when seen in TM vs. 8.7 ± 1.6 hours when traveling to KC ($p=0.018$). Patients missed a mean of 4.8 ± 2.8 hours of school when seen via TM in Joplin compared to 8.4 ± 2.3 hours for an appointment in KC ($p=0.001$).

Conclusion: Children with rheumatic diseases often travel substantial distances to receive subspecialty care and incur significant costs with this travel. Interest in TM is associated with greater distance traveled and more time away from work. In our established TM Joplin clinic, respondents were less likely to spend money on travel, food, and lodging as well as time away from work and school. TM is an effective way to lessen financial burden for families that travel considerable distances for PR care.

Utilization of Ambulatory Physician Encounters, Emergency Room Visits and Hospitalizations By SLE Patients: A 13 Year Population Health Study

John G. Hanly[1], Chris Skedgel[2] and Kara Thompson[3], [1]Rheumatology, Division of Rheumatology, Capital Health and Dalhousie University, Halifax, NS, Canada, [2]Division of Rheumatology, Dalhousie University and Capital Health, Halifax, NS, Canada, [3]Nova Scotia Rehab Site, Division of Rheumatology, Capital Health and Dalhousie University, Halifax, NS, Canada

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Health Services Research Poster II (ACR): Healthcare Access, Patterns of Medication Use and Workforce Considerations

Session Type: ACR Poster Session B

Background/Purpose: Resource utilization has been examined in various geographic locations and utilizing different research methodologies including secondary use of heath care administrative data. Our objective was to determine total physician encounters, emergency room visits and hospitalizations in an incident cohort of systemic lupus erythematosus (SLE) cases and matched controls over 13 years.

Methods: A retrospective cohort study was performed utilizing administrative health care data from approximately 1 million people with access to universal healthcare. Using ICD-9 and ICD-10 diagnostic codes, 7 SLE case definitions were used and each SLE case was matched by age and gender to four randomly selected controls. Information on physician billings, emergency room visits and hospital discharges over 13 years was obtained. Analysis included descriptive statistics, linear regression and negative binomial models to examine differences in utilization between cases and controls. Models were also adjusted for the index year of utilization.

Results: The number of incident SLE cases varied from 564 to 4,494 depending upon the case definition. The mean ± SD age was 50.4 ± 16.4 with 77.9% females. For all case definitions there was significantly higher utilization of all physician groups by SLE cases compared

to controls (p<0.001). For SLE cases the utilization was highest in the index year and fell thereafter, although never to the level of utilization in the matched controls. By the fourth year, encounters with subspecialty physicians fell by 60% (Rheumatologists), 50% (Internal medicine) and 31% (other physicians). In contrast, visits to family physicians fell by only 9%. Regardless of which case definition for SLE that was used, visits to the emergency room were significantly more frequent for SLE cases (P<0.001). This was most apparent early in the disease and fell to within the range seen in the controls by the end of the study. Likewise, the hospital admission rate for SLE cases was significantly higher (P<0.001) than controls, especially early in the disease course.

Conclusion: In SLE patients, health care utilization is highest in the first few years following the diagnosis, which coincides with the highest frequency of visits to rheumatologists. Utilization declines over time and encounters with patient's family physicians predominate over other physician groups.

Uptake of the First Biosimilar Infliximab Since Its Approval in South Korea

Seoyoung C. Kim[1], Nam-Kyong Choi[2], Joongyub Lee[2], Kyoung-Eun Kwon[3], Wesley Eddings[4], Yoon-Kyoung Sung[5], Hong Ji Song[6], Aaron K. Kesselheim[4] and Daniel H. Solomon[7], [1]Div. of Pharmacoepidemiology and Pharmacoeconomics, Div. of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Boston, MA, [2]Seoul National University Hospital, Seoul, South Korea, [3]Seoul National University College of Medicine, Seoul, South Korea, [4]Division of Pharmacoepidemiology and Pharmacoeconomics, Brigham and Women's Hospital, Boston, MA, [5]Hospital for Rheumatic Disease, Hanyang Univ Medical Center, Seoul, South Korea, [6]Hallym University Sacred Heart Hospital, Anyang, South Korea, [7]Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Harvard Medical School, Boston, MA
First publication: September 29, 2015

SESSION INFORMATION
Session Title: Health Services Research Poster II (ACR): Healthcare Access, Patterns of Medication Use and Workforce Considerations
Session Type: ACR Poster Session B

Background/Purpose: Development of tumor necrosis factor (TNF) inhibitors has been a major advance in treatment of systemic inflammatory diseases, such as rheumatoid arthritis. While TNF inhibitors are highly effective in controlling systemic inflammation, their high cost limits their use in developing countries and raises concerns in the U.S. as well. The FDA is currently considering an application for a biosimilar version of infliximab, which has been available in South Korea since November 2012.

Methods: Using the medical claims data (4/2009-3/2014) of the Korean Health Insurance Review and Assessment Service database, which includes the entire Korean population, we assessed the uptake of biosimilar infliximab. A segmented linear regression was used to examine utilization patterns of infliximab (the branded and biosimilar) and other branded TNF inhibitors (adalimumab and etanercept) before and after the introduction of biosimilar infliximab. The model included the number of claims by drug each month as the outcome variable, as well as an intercept and two slope terms that described the trend in use of TNF inhibitors per month before and after the introduction of biosimilar infliximab in November 2012.

Results: We identified a total of 20,976 patients with mean age of 44 (SD 16) years who used adalimumab, etanercept, infliximab, or biosimilar infliximab during the study period. Since its introduction, there were 983 users of biosimilar infliximab. Among all the claims for any infliximab version, the proportion of biosimilar infliximab claims increased to 19% through 3/2014. The use of all TNF inhibitors increased significantly with the number of claims approximately tripling from 3,117 in April 2009 to 9,278 in March 2014. Prior to introduction of biosimilar infliximab, each month there were 33 (95%CI, 32-35) more infliximab claims, 44 (95%CI, 40-48) more etanercept claims, and 50 (95%CI, 47-53) more adalimumab claims (**Figure**). After the introduction of biosimilar infliximab, there was a significant change in the slopes with an additional increase in the use of both branded and biosimilar infliximab (9 claims/month, 95%CI, 2-17) and a decrease in the use of etanercept (-52 claims/month, 95%CI, -66 to -38) and adalimumab (-21 claims/month, 95%CI, -35 to -

6).

Conclusion: During the 15 months since its introduction in South Korea, one-fifth of all infliximab claims were for the biosimilar. Our results show that introduction of biosimilar infliximab may affect the use of other TNF inhibitors. These results suggest that an approved biosimilar infliximab product could have a major impact in the U.S., where about 40% of rheumatoid arthritis patients get treated with a biologic drug.

Figure. Trends in use of all TNF-α inhibitors before and after market introduction of biosimilar infliximab

Factors That Impact Job Selection in Pediatric Rheumatology

Mara L Becker[1], Meredith Riebschleger[2], Holly S. Ruch-Ross[3], 'Laura Laskosz[4], Carrie Radabaugh[5], Polly J. Ferguson[6], Kenneth N. Schikler[7] and Sandy D. Hong[8], [1]Rheumatology, Children's Mercy Kansas City, Kansas City, MO, [2]Pediatric Rheumatology & Health Services Research, University of Michigan, Ann Arbor, MI, [3]Independent Research and Evaluation Consultant, Evanston, IL, [4]Division of Technical and Medical Services, The American Academy of Pediatrics, Elk Grove Village, IL, [5]Department of Education, American Academy of Pediatrics, Elk Grove Village, IL, [6]Dept of Pediatrics--Rheum, University of Iowa, Iowa City, IA, [7]Pediatrics, University of Louisville, Louisville, KY, [8]Pediatrics-Rheumatology, U of Iowa Children's Hosp, Iowa City, IA
First publication: September 29, 2015

SESSION INFORMATION
Session Title: Health Services Research Poster II (ACR): Healthcare Access, Patterns of Medication Use and Workforce Considerations
Session Type: ACR Poster Session B

Background/Purpose: There remain valid concerns about the capability of the pediatric rheumatology (PR) workforce to meet the clinical needs of U.S. children and to absorb the imminent retirement of senior practitioners. The American Academy of Pediatrics Section on Rheumatology (AAPSORh) performed a survey to characterize current PR work force patterns and identify factors in employment

selection.

Methods: Eligible PR survey recipients were identified using the AAP SORh member list and American Board of Pediatrics certified PR practitioners. An electronic survey was fielded from 9/2014-12/2104. Survey domains included demographics, training, practice characteristics, distribution of professional time, call responsibilities, and plans for retirement. Respondents reporting current PR practice were eligible for analyses. Descriptive analyses utilized frequency distributions and measures of central tendency as appropriate. Statistical significance was tested using ANOVA for comparison of means and chi square for cross tabulations.

Results: 151/317 (48%) identified PR responded to the survey, however, 137 (55% female) identified important factors in employment selection and were included in this analysis. Of factors listed, location (59%) was ranked most frequently and salary (18%) was ranked least frequently as "most important" by respondents (Table 1). Females significantly rated "mentorship" as a very important factor compared to males (37% v 17%, p=.02) (Figure 1). Many factors were significantly correlated with one another and could be grouped including: "Life" factors which included: location and spouse/partner employment; "University" factors which included: research, university affiliation, and mentorship; and "Job" factors which included: salary and practice size. Although there was a clear order of importance, there was overlap between groups (Table 1). Significantly more females than males rated one or more "Life" factors as very important (80% v 60%, p=.01).

Conclusion: As the PR current and future workforce plays an important role in access to care, understanding what fuels employment decisions may assist in the development of workforce initiatives. The current PR workforce survey suggests "Life" factors as most important in decision making about employment. Incentivizing practice locations, making larger efforts in spouse/partner recruitment, and targeting future trainees from underrepresented areas to return to these areas may be worthwhile investments for future workforce priorities.

Figure 1:

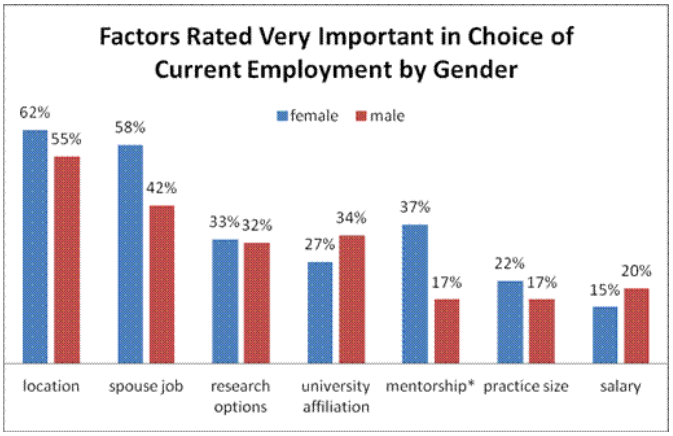

Table 1

	Factors in order of frequency with which they were rated "very important"	Rated "very important"		
		N	%	
Life	Location	81	59.1%	67% rated at least one of these "very important;" 31% said both
	Spouse/partner employment	67	50.4%	
University	Research opportunities	44	33.1%	About 50% rated at least one of these "very important;" 26% said 2 or more
	University affiliation	41	30.4%	
	Mentorship	39	28.9%

SESSION INFORMATION

Session Title: Health Services Research Poster II (ACR): Healthcare Access, Patterns of Medication Use and Workforce Considerations
Session Type: ACR Poster Session B

Background/Purpose:

Developing countries face serious socioeconomics problems, and pediatric rheumatic illnesses are not seen as priority by health programs. The PANLAR Pediatric Rheumatology Study Group conducted a web based survey in order to assess the specific reality in Pediatric Rheumatology care in Latin America (LA), to gather individual data from all Pediatric Rheumatologists (PRs) in LA, their training history, practice, and characteristics of Juvenile Idiopathic Arthritis (JIA) patients as well as access to drug therapy and other health services.

Methods:

An international wide web based survey involving LA PRs. All performed a baseline evaluation, including 54 questions to assess in the following domains: demographics, practice status, training history, functional status of JIA and access to treatment and monitoring resources. Data captured began December 30, 2014 and closed on February 28, 2015.

Results:

A total of 169 (47%) responded to the survey sent to 356 PRs in LA, from Argentina, Bolivia, Brazil, Chile, Colombia, Cuba, Ecuador, El Salvador, Guatemala, Mexico, Nicaragua, Paraguay, Peru, Puerto Rico, Dominican Republic, Uruguay, Venezuela. There were: 16 countries without PRs, all from Antilles and some countries of Central America. The largest number (68%) of PRs works in countries with larger populations and training centers as Argentina, Brazil, Colombia and Mexico. Forty five percent of PRs has been in practice for less than 10 years. Twenty percent of LA children are seen by a Rheumatologist untrained in Pediatrics. Most PRs work in urban areas and under the Public Health System. Of the total available time, 90% is spent in patient care and 10% in research. JIA subtypes distribution matches other series. The median time from the beginning of first symptoms to diagnosis was 6 (3-11) months in 50% of LA JIA patients. A Steinbrocker functional class III and IV was observed in 18% of patients at presentation. In almost 50% of countries, PRs are solo practitioners. Full adherense to treatment is around 61%; DMARDs requirement: 70%; Biologics use: 40%. Access to biological therapy was graded as “very difficult” in 20% and covered by State or Social Security in 80%.

Conclusion:

The Survey data suggest a need to: 1. increase the number of pediatric rheumatologists, 2. Improve PR training, 3. Foster access to care, earlier referral and availability of effective medication. A cross sectional study of functional status in JIA is needed. With adequate funding PANLAR is well positioned to promote development of educational programs and to carry on epidemiologic prospective research.

First publication: September 29, 2015

SESSION INFORMATION
Session Title: Health Services Research Poster II (ACR): Healthcare Access, Patterns of Medication Use and Workforce Considerations
Session Type: ACR Poster Session B

Background/Purpose:

The impact of rheumatoid arthritis (RA) and ankylosing spondylitis (AS) on paid work is measured on the basis of employed people missing time from work (absenteeism) and reduced performance while at work (presenteeism) which leads to reduced routine working hours through changing or even losing jobs (employment status change). Work loss due to disabling rheumatic conditions is an important medical and social issue and various epidemiological studies explored the impact on the productivity, but there are few studies conducted in Turkey. We planned a non-interventional study on the basis of geo-demographic representation and explored the effects of treatment.

Methods:

In this study work disability and productivity loss was investigated through collecting data on worked hours per week and lost hours per week for paid work and household activity in RA and AS patients treated with anti-TNFs. Work and household productivity was also measured with Work Productivity and Activity Impairment Index (WPAI) scores. A total of 713 patients who were >18 years of age and with proven diagnosis of AS or RA in accordance with ACR and Modified New York Criteria were analysed. Additional parameters of quality of life (QoL) measurements by SF-36 (RA and AS), ASQoL (AS); disease scores by DAS-28 (RA) and BASDAI (AS) and functional assessments by HAQ-DI (RA), BASFI (AS) were evaluated.

Results:

A total of 713 patients enrolled (481 AS, 232 RA patients) where AS patients were younger compared to RA patients (37.6 + 10.0 versus 48.7 + 11.7 years, ns). Absenteeism decreased (14.1 hours to 3.3 hours for RA, 18.9 hours to 6.4 hours for AS patients) during 15 months follow-up and presenteeism increased towards the end of the study ($p<0.001$). WPAI evaluations also revealed significant decreases in four assessed parameters for RA and AS ($p<0.001$) except for missed hours in AS patients ($p=0.006$). During follow-up, both RA and AS patients experienced major and significant improvements in their health and quality of life with anti-TNF treatment combined with DMARDs and with or without NSAIDs. Disease activity scores of DAS-28 and BASDAI were significantly improved ($p<0.001$). Health related information by means of patient reported outcomes (SF-36 for AS and RA, ASQoL for AS, and HAQ-DI for RA) showed significant improvements in all parameters for both group of patients at 15 months ($p<0.001$). Disease related functional assessment were evaluated by means of BASFI in AS patients and improvements in all functional disability categories were reported ($p<0.001$). Treatments were well tolerated, cessation of anti-TNF treatment due to adverse events were infrequent (3.0% in AS and 1.6% in RA patients).

Conclusion:

In this study we have shown that overall work loss was significantly reduced with anti-TNF treatment during the follow-up period along with improvements in disease activity scores, QoL surveys and in disease related functional assessment outcomes.

SESSION INFORMATION

Session Title: Health Services Research Poster II (ACR): Healthcare Access, Patterns of Medication Use and Workforce Considerations

Session Type: ACR Poster Session B

Background/Purpose: To assess the attitudes and common practices of adult rheumatologists in US regarding transition of young adults with rheumatic diseases from pediatric to adult care.

Methods: An online survey was sent to adult and combined adult and pediatric rheumatologist members of the ACR who practice in U.S. The anonymous questionnaire included demographic data, questions about attitudes and common practices regarding the transition process.

Results: 203 of 4064 (5%) rheumatologists completed the survey. Among them, 178 (87.7%) were board certified in rheumatology and 11 (5.4%) were certified in adult and pediatric rheumatology; 14 (16.9%) were fellows. 92 (45.7%) work in a university clinic and 85 (42.9%) in private practice, 67 (34%) had practiced <10 years and 113 (57.6%) >15 years. 88 (45.1%) were never trained in transition practices, and 133 (74.7%) were not familiar with the American Academy of Pediatrics consensus statement about transition care for youth with special healthcare needs. 71 (37%) had not developed a plan for integrating former pediatric patients into their practice; 43 (22.4%) do not have a written transition policy, but follow an informal procedure and 27 (14.1%) do not think that a transition policy is needed. Only 105 (56.15%) feel comfortable caring for former pediatric patients. The vast majority do not have a multidisciplinary team to integrate new young adults into their practice [175 (90.7%)]; 165 (86.8%) do not have a designated staff responsible for coordinating the integration. For 153 (80.1%), the patient is referred by a pediatric rheumatologist, or adult primary care [111; (58.1%)] for 106 (55.5%), the patient is self-referred. The median age of transition is 18-20 years. Time from last pediatric rheumatology visit to first adult rheumatology visit is 3-6 months in 70 (40.7%) and between 6-12 months in 67 (38.9%). The physicians were dysatisfied with the following data received: previous treatments 85 (48.9%), hospitalization history 83 (48%), disease activity index 78 (45.1%), medical history summary 76 (43.9%), co-morbidities 63 (36.4%), medication list 59 (34.1%) and disease classification 56 (32.6%). Only a minority were satisfied with the current integration process [12 (7.14%)], have sufficient resources and personnel [15 (8.93%)] and time in clinic [22 (13.1%)]. The 3 major barriers to the integration process are lack of insurance reimbursement [57 (33.9%)], lack of knowledge about community resources to support patients [52 (31.3%)] and lapse in care between primary provider and specialist [47 (28%)]. The vast majority need tools to facilitate transition 133 (79.6%) and desire a specific rheumatology consensus statement with guidelines for transitioning adolescent rheumatology patients to adult-centered care 141 (83.9%). No significant differences were noted between practitioners in university clinics vs private practice or between those practicing for less or more than 15 years.

Conclusion: This survey of rheumatologists caring for adults demonstrated substantial gaps in knowledge and resources regarding transition from pediatric to adult care for young adults with rheumatic diseases. Practice guidelines may be an effective way to address these gaps.

Abstract Number: 1278

An Underlying Diagnosis of Osteoarthritis Is Associated with Better Outcomes after Total Hip Arthroplasty Than Avascular Necrosis of Bone

Jasvinder A. Singh[1], Jason Chen[2], Maria Inacio[2], Robert Namba[2] and Elizabeth Paxton[2], [1]University of Alabama at Birmingham,

Birmingham, AL, [2]Kaiser Permanente, San Diego, CA
First publication: September 29, 2015

SESSION INFORMATION

Session Title: Health Services Research Poster II (ACR): Healthcare Access, Patterns of Medication Use and Workforce Considerations
Session Type: ACR Poster Session B

Background/Purpose:

We recently showed that underlying diagnosis of RA was associated with higher readmission rate compared to osteoarthritis. Studies of adequate sample size assessing post-THA outcomes in patients with avascular necrosis are lacking. The objective of our study was to examine whether avascular necrosis as an underlying diagnosis was associated with a higher adjusted risk of complications and readmissions after primary THA, compared to OA.

Methods:

: We analyzed prospectively collected data from an integrated healthcare system Total Joint Replacement Registry of adults with avascular necrosis (AVN) vs. osteoarthritis (OA) undergoing unilateral primary THA during 2001-2012. We examined mortality (90-day), revision (ever), deep (1 year) and superficial (30-day) surgical site infection (SSI), venous thromboembolism (VTE, 90-day), and unplanned readmission (90-day). Age, gender, race, body mass index, American Society of Anesthesiologists class, and diabetes prevalence were evaluated as confounders. Logistic and Cox regression models were fit with variables significant in univariate models for each outcome. Odds ratios (OR) and hazard ratios with 95% confidence intervals (CI) were calculated.

Results:

Of the 47,523 primary THA cases, 45,252 (95.2%) had OA, and 2,271 (4.8%) had AVN. Compared to the OA cohort, the AVN patient cohort was younger (median age 55 vs. 67 years), had more male (57.5% vs. 41.7%), and less White (59.8% vs. 77.4%). Compared to the OA cohort, the AVN cohort had higher crude incidence of 90-day mortality (0.7% vs. 0.3%), revision (3.1% vs. 2.4%), SSI (1.2% vs. 0.8%), and unplanned readmission (9.6% vs. 5.2%). After multivariable-adjustment for significant factors, AVN patients had a higher likelihood of mortality (OR:2.48; 95% CI:1.31-4.72), SSI (OR:1.67, 95%CI:1.11 - 2.51), and unplanned readmissions (OR:2.20; 95% CI:1.67-2.91) than OA patients.

Conclusion:

OA was associated with better outcomes than AVN post-THA. Detailed discussion with AVN patients regarding the risk of complications is needed during the informed consent.

Racial Variation in Total Knee Replacement in a Diverse Community-Based Clinical Trial

Lindsey MacFarlane[1], Nancy Cook[2], I-Min Lee[2], Jeffrey N. Katz[3] and Karen H. Costenbader[4], [1]Rheumatology, Brigham and Women's Hospital, Boston, MA, [2]Department of Medicine, Brigham and Women's Hospital, Boston, MA, [3]Brigham and Women's Hospital and Harvard Medical School, Boston, MA, [4]Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Harvard Medical School, Boston, MA
First publication: September 29, 2015

SESSION INFORMATION

Session Title: Health Services Research Poster II (ACR): Healthcare Access, Patterns of Medication Use and Workforce Considerations
Session Type: ACR Poster Session B

Background/Purpose:

Total knee replacement (TKR) surgery is common with > 700,000 surgeries performed annually in the United States. Racial variation in TKR utilization has been documented in population-based studies, however, there is a paucity of prospective data on disparities in TKR use in patients with osteoarthritis (OA). We aimed to evaluate racial disparity in incident TKRs in a cohort of patients with physician-diagnosed OA followed in a current clinical trial.

Methods:

Vitamin D and Omega-3 Trial (VITAL) is an ongoing nationwide, racially diverse, community-based, randomized controlled trial of 25,874 males age ≥50 and females age ≥55. We identified a knee pain subgroup with probable knee OA based on: a) self-reported knee pain symptoms in walking 2-3 blocks; b) pain > 1 day/week for > 1 year; and c) a doctor's diagnosis of OA. This subgroup completed a modified Western Ontario and McMaster's Universities Osteoarthritis Index (WOMAC) questionnaire, and reported prior TKR and laterality (103 people with bilateral TKR at baseline were excluded.) Participants reported new TKR, laterality and date, over the 2 year follow-up. We compared baseline WOMAC scores by race using t-tests. In multivariable-adjusted logistic regression analyses, we investigated the association of race with TKR risk, adjusting for potential confounders including age, sex, race, geographic location, WOMAC pain, function and stiffness, body mass index, income, education level, and self-reported depression.

Results:

At baseline, 1508 (5.8%) of trial participants were eligible for the knee pain cohort. Of those, 1241 (94.7% of mailed) returned a baseline knee pain questionnaire and 1019 (82%) returned a follow-up questionnaire, a mean of 27 (±4) months after baseline. Within this group, 133 (13%) reported TKR in follow-up. Among those who underwent TKR, mean age was 68 (±7) years, 65% were female, and 13% were Black. Among those who did not have TKR, mean age was 67 (±7) years, 66% were female and 24% Black. All baseline WOMAC score means were significantly higher among Black than White patients. (**Table)**In multivariable logistic regression analyses, only race and WOMAC pain score were related to TKR incidence. The odds ratio of TKR among Black compared to White patients was 0.40 (95% CI 0.22, 0.74). After adjustment for baseline WOMAC pain and stiffness scores, the odds of TKR among Black patients was further reduced to 0.32 (0.18, 0.58).

Conclusion:

Despite having worse self-reported worse knee pain, function and stiffness at baseline, and having demonstrated a high level of engagement by virtue of volunteering for a large randomized trial, Black patients had much reduced odds of undergoing TKR compared to White patients. This community-based, racially diverse cohort is unique as subjects have physician-diagnosed OA, and have been followed prospectively. Our data highlights the need for further efforts to correct this large racial disparity.

Table. Baseline WOMAC Scores in Black vs. White Patients

	Blacks	Whites	p**
WOMAC Pain score*, mean (SD)	44.81(20.94)	32.21 (15.79)	p<0.0001
WOMAC Function score*, mean (SD)	44.39 (21.15)	32.12 (17.54)	p<0.0001
WOMAC Stiffness score*, mean (SD)	51.46 (22.87)	40.19 (20.69)	p<0.0001

Odd Ratios for TKR in Black vs. White Patients

	Multivariable Model 1*** Odds Ratio (95% CI)	Multivariable Model 2*** Odds Ratio (95% CI)

Abstract Number: 1280

Comparison of Health Service Utilization Costs Between Aboriginal and Non-Aboriginal Patients with Rheumatoid Arthritis Requiring Biologic Therapy

Cheryl Barnabe[1], Yufei Zheng[2], Arto Ohinmaa[2], Brenda Hemmelgarn[3], Gilaad Kaplan[4], Liam Martin[5] and Walter Maksymowych[6], [1]Cumming School of Medicine, University of Calgary, Calgary, AB, Canada, [2]Institute of Health Economics, Edmonton, AB, Canada, [3]Division of Nephrology, University of Calgary, Calgary, AB, Canada, [4]Division of Gastroenterology, University of Calgary, Calgary, AB, Canada, [5]Medicine, University of Calgary, Calgary, AB, Canada, [6]Medicine, Medicine, University of Alberta, Edmonton, AB, Canada

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Health Services Research Poster II (ACR): Healthcare Access, Patterns of Medication Use and Workforce Considerations

Session Type: ACR Poster Session B

Background/Purpose: Logistical issues and poor cultural environments in tertiary care create barriers to specialized care for Aboriginal patients with rheumatoid arthritis (RA). Aboriginal patients are thus more likely than non-Aboriginal patients to see a primary care provider and less likely to see a rheumatologist for their RA care, and may result in differences in disease management and clinical outcomes. We used health services data to estimate the effect of these differences reflected in health system costs.

Methods: The Alberta Biologics Pharmacosurveillance Program (ABioPharm) is a longitudinal RA cohort study, linked to population-based administrative databases. These databases capture hospitalization, emergency room, and outpatient clinic visits which have an associated clinical modifier group, and physician visits which have an associated claim cost, from which health service utilization costs are estimated. Given the skewed nature of the data and that it may contain many zero values, we used a two-part modeling strategy for mixed discrete-continuous outcomes. In the first part, a binary choice model was estimated for the probability that the patient has had (or not had) health costs (dichotomous). In the second part, a generalized linear model with gamma family (with propensity score analysis) was used to estimate the difference in health costs between Aboriginal and non-Aboriginal groups, conditional on a cost having been incurred. Costs were adjusted for inflation to 2011/2012 using the Canadian Consumer Price Index from Statistics Canada.

Results: The cohort included 1,545 patients (n=83 Aboriginal) with 8,145 person-years of follow-up. Mean and median total costs and specific RA-related costs for hospitalizations, emergency room, outpatient clinic and physician costs are presented in Table 1, demonstrating the skewed nature of the data. Emergency room costs were higher in Aboriginal patients using standard analysis (median $1,003 CAD (IQR 2,833) vs $262 CAD (IQR 1,071) per patient per year, Mann-Whitney $p<0.001$). In the two-part model (Table 1), cost estimates for Aboriginal patients showed a numerical trend to lower hospital, outpatient clinic and physician visit total and RA-related costs, but with higher emergency room costs compared to non-Aboriginal patients, although not reaching statistical significance.

Conclusion: Health service utilization costs did not vary between Aboriginal and non-Aboriginal patients, although with limitations of sample size. Differences in health service use may explain disparate clinical outcomes observed in our cohort, which could be remedied by increased collaboration with primary care providers, and creating health care environments that deliver culturally competent care.

Table 1. Health Service Utilization Costs (annual cost per patient), in Canadian Dollars (CAD)

	Hospital	Emergency Room	Outpatient Clinic	Physician Visits
Total Costs, mean (SD)	$14,152 (43,111)	$1,114 (2,556)	$4,565 (7,569)	$7,731 (8,427)
Total Costs, median (IQR)	$0 (0)	$280 (1,162)	$2,631 (4,917)	$5,280 (7,721)
RA-Related Costs, mean (SD)	$5,860 (19,950)	$323 (757)	$1,431 (2,495)	$3,301 (3,477)
RA-Related Costs, median (IQR)	$0 (0)	$0 (272)	$539 (1,756)	$2,027 (3,419)
Model Coefficient*, Total Costs (95%CI) p value	-5,406 (-11,552 to 740) p=0.08	660 (-38 to 1,357) p=0.06	-1,037 (-2,300 to 226) p=0.1	-1,072 (-2,986 to 843) p=0.2
Model Coefficient*, RA-Related Costs (95%CI) p value	-2,561 (-5,315 to 193) p=0.06	163 (-50 to 375) p=0.1	-295 (-731 to 141) p=0.1	-107 (-972 to 758) p=0.8

* Aboriginal vs non-Aboriginal; a negative value indicates lower costs in Aboriginal patients

Abstract Number: 1281

Reduction in Rural-Urban Disparity in Discharge Disposition to Home after Total Knee Arthroplasty in the U.S

Jasvinder A. Singh and Rekha Ramachandaran, University of Alabama at Birmingham, Birmingham, AL
First publication: September 29, 2015

SESSION INFORMATION
Session Title: Health Services Research Poster II (ACR): Healthcare Access, Patterns of Medication Use and Workforce Considerations
Session Type: ACR Poster Session B

Background/Purpose:

Rural-urban disparities in outcomes after total joint arthroplasty are of great interest, given the differences in health care access and social support between those two settings. Our objective was to compare the discharge disposition after Total Knee Arthroplasty (TKA) in a nationally representative sample of patients.

Methods:

We used the U.S. Nationwide Inpatient Sample from 2003-2010 to compare outcomes after total knee arthroplasty (TKA). The study period was divided into two, 2003-2006 and 2007-2010 to assess changes in outcomes over time. Rural versus urban residence was determined based on patient's residence at the time of surgery. We compared post-TKA outcomes including discharge disposition and the length of hospitalization by rural vs. urban patient residence. Patient discharge was categorized as home (with or without home health care) or to an inpatient facility (short term hospital, skilled nursing facility, intermediate care facility or another type of inpatient facility). Unadjusted and adjusted logistic regression and analyses of variance (ANOVA) were used to make rural-urban comparisons. We adjusted for age, race, gender, Charlson score and hospital TKA volume.

Results:

Overall, 61.3% of patients undergoing TKA in 2003-2010 were discharged to home and the mean length of stay was 3.6 days. During the 2003-2006 period, significantly higher proportion of patients residing in rural locations were discharged to home compared to urban location, 61.6% vs. 54.3%. Differences were still significant in 2007-2010 period, 69.6% vs. 65.1%, but the rural-urban disparity decreased significantly from 2003-2006 to 2007-2010 (p<0.0001; Table 1). There were no significant differences in hospital length of stay between rural and urban residents in 2003-2006 or 2007-2010 and no significant changes were noted over time (Table 1).

Table 1. Rural-urban differences in TKA outcomes and time-trends

	All combined	Rural		Urban			
	2003-2010	2003-2006	2007-2010	2003-2006	2007-2010	Unadjusted p-value	Adjusted p-value*
Discharged home, n (%)	532,618 (61.3%)	50,527 (61.6%)	76,480 (69.6%)	157,201 (54.2%)	241,452 (65.1%)	<0.0001 <0.0001 <0.0001	<0.0001 <0.0001 <0.0001
Length of stay, mean (SD or range)	3.6 (1.9)	3.9 (0, 70)	3.4 (0, 108)	3.8 (0, 172)	3.4 (0, 215)	0.78 0.61 0.59	0.16 0.17 0.69

*Adjusted for age, race, gender, Charlson score, hospital TKA volume

For p-values: first p-value denotes rural/urban disparity in 2003 -2006; second the rural/urban disparity in 2007 -2010 and the third denotes the change in the disparity magnitude between 2003 – 2006 and 2007 – 2010.

Conclusion:

In this study, we noted rural-urban disparity in post-TKA discharge to home. This disparity decreased over time. Future studies should investigate the factors responsible for this favorable time-trend in discharge disposition, and continue to investigate whether further improvements can be made in the proportion discharged to home.

Abstract Number: 1282

Persistence with Osteoporosis Therapies in Postmenopausal Women in a Large US National Health Plan

Benjamin Chastek[1], Lung-I Cheng[2], John C. White[3], Leslie Spangler[4], Darshan Mehta[5] and Richard Barron[6], [1]Optum Insight, Eden Prairie, MN, [2]Amgen, Thousand Oaks, CA, [3]Optum Life Sciences, Eden Prairie, MN, [4]Amgen Inc., Thousand Oaks, CA, [5]University of Southern California, Los Angeles, CA, [6]Amgen, Inc., Thousand Oaks, CA

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Health Services Research Poster II (ACR): Healthcare Access, Patterns of Medication Use and Workforce Considerations

Session Type: ACR Poster Session B

Background/Purpose: Persistence and compliance with oral osteoporosis therapies are generally suboptimal; however, limited persistence data exist for newer injectable therapies that have become available in recent years. The objective of this study is to examine persistence and compliance of osteoporosis therapies using real-world data from a large national health plan in the United States (US).

Methods: Women affiliated with a large US national health plan who newly initiated an osteoporosis medication (alendronate, denosumab, ibandronate, raloxifene, risedronate, or teriparatide) between January 2012 and December 2012 were identified using the Optum Research Database. The index date was the first qualifying claim date. Patients were required to be ≥ 50 years of age at index and have ≥ 12 months of pre-index and ≥ 12 months of post-index continuous enrollment in the health plan. Patients with Paget's disease of the bone, osteogenesis imperfecta, hypercalcemia, malignant cancer and metastasis, HIV, and patients receiving preventive treatment for risk of breast cancer were excluded. Persistence (continuous use of index therapy with no gap > 60 days) and compliance (proportion of days covered by therapy ≥ 80%) were assessed during the 12-month follow-up period. Multivariable logistic regression models were used to estimate and compare persistence and compliance for the therapies of interest, adjusting for demographic and clinical characteristics (reference = group with highest persistence/compliance).

Results: A total of 27,040 patients were eligible and included in the study (mean [SD] age: 67.2 [10.1] years). 12-month persistence was highest for denosumab (subcutaneous every 6 months) at 59.9% and lowest for risedronate (oral weekly) at 23.8%; 12-month compliance was highest for denosumab at 62.2% and lowest for risedronate (oral daily) at 16.0% (Figure). The multivariable logistic regressions showed that the odds of being persistent and compliant across treatments favored denosumab (odds ratios from 1.4 to 4.9, $p<0.001$ for persistence; 1.9 to 8.8, $p<0.001$ for compliance).

Conclusion: In a large US national health plan, persistence and compliance over 12 months were higher among patients initiating denosumab compared to those initiating other osteoporosis therapies.

Abstract Number: 1283

The Burden of Non-Radiographic Axial Spondyloarthritis from the Employer Perspective: A Real World European Study

Tim Holbrook[1], Robert Wood[1], **Christopher Black**[2], Xiaohan Hu[2] and Sumesh Kachroo[2], [1]Adelphi Real World, Macclesfield, United Kingdom, [2]CORE, Merck & Co., Inc., Rahway, NJ

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Health Services Research Poster II (ACR): Healthcare Access, Patterns of Medication Use and Workforce Considerations

Session Type: ACR Poster Session B

Background/Purpose: Non-radiographic axial spondyloarthritis (nr-axSpA) is a burdensome disease to both the patient and the healthcare system, as previous research has indicated. However, the societal burden is less well understood, particularly from the employer perspective. The aim of this analysis was to quantify the burden nr-axSpA patients have on employers.

Methods: Data were taken from the 2014 nr-axSpA Disease Specific Programme a cross-sectional, multi-national survey of nr-axSpA patients and their rheumatologists conducted in France, Germany, Italy, Spain and the UK. Rheumatologists completed patient record forms containing patient demographics and treatment history. These patients completed patient self-completion (PSC) forms containing the Work Productivity and Activity Impairment questionnaire and annual income. Patients who were biologic treatment naïve, yet were considered eligible for biologic treatment by the physician, were compared to patients who had been receiving their current biologic treatment for 6 months or more. Questions regarding income had banded responses and so the midpoint was used in all calculations. Observations were weighted to ensure findings were more representative of the patient population. The weight was applied when calculating all percentages, means and SDs. The human capital method was applied in order to calculate the burden of productivity-loss.

Results: A total of 310 patients were included in the analysis (mean age 42.5±11.8 [SD], 74.8% male), with 123 biologic-naïve patients and 187 patients currently receiving a biologic. Only 76 patients completed a PSC in total. Over half (59.8%) of biologic-naïve patients were employed compared to 78.8% of the biologic-treated patients. The most frequently stated reason for having not yet prescribed biologic treatment in a candidate was “Very recent diagnosis” (32.5%). Biologic-naïve patients had greater overall work impairment

compared to biologic-treated patients (means: 37.1% vs. 18.8%; diff.=18.4%). The mean annual income for the biologic-naïve cohort was 30,171.83€ and the mean duration between diagnosis and first biologic to be prescribed was 17.4 months for the biologic-treated cohort. Therefore, productivity-loss associated with biologic-naïve patients compared to biologic-treated patients equates to 10,834.92€ from the employer perspective, per-patient.

Conclusion: The burden on the economy due to productivity-loss per nr-axSpA patient is substantial. This burden is avoidable to some extent where patients are eligible for biologic treatment. Moreover, biologic treatment was withheld in a third of eligible patients due to a recent diagnosis, suggesting earlier initiation of biologic treatment could be considered.

Burden of Illness Associated with Non-Radiographic Axial Spondyloarthritis: A European Real World Database Analysis from the Clinical and Healthcare System Perspective

Tim Holbrook[1], Robert Wood[1], **Christopher Black**[2], Xiaohan Hu[2] and Sumesh Kachroo[2], [1]Adelphi Real World, Macclesfield, United Kingdom, [2]CORE, Merck & Co., Inc., Rahway, NJ

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Health Services Research Poster II (ACR): Healthcare Access, Patterns of Medication Use and Workforce Considerations

Session Type: ACR Poster Session B

Background/Purpose: Whilst the burden of axial spondyloarthritis (axSpA) is well known, non-radiographic (nr)-axSpa has only recently been identified as a distinct spondyloarthritic indication with its own associated burden. As such, evidence demonstrating the clinical and healthcare system burden of illness is sparse.

Methods: Data were taken from the 2014 nr-axSpA Disease Specific Programme (DSP) a cross-sectional, multi-national survey of nr-axSpA patients and their rheumatologists in France, Germany, Italy, Spain and the UK. Rheumatologists completed patient record forms containing patient demographics, clinical results, symptomology, information on acute episodes and consultations and hospitalisations in the last 12 months. Patients were defined to be non-responsive to current treatment if they were currently experiencing an acute episode, or had worsened in severity or remained severe since initiation of current therapy, or the physician was dissatisfied with their current level of control. Responders were defined as the inverse of non-responders. To adjust for the design bias of the DSP, the number of consultations in the last 12 months was used as an inverse probability weight. The weight was applied to all percentages, means and standard deviations.

Results: A total of 631 patients were included in the analysis (mean age 41.8±12.0 [SD], 70.4% male). Mean age at onset was 35.0±11.2, while 27.3% were classified as having moderate or severe disease state. Over half (56.7%) of patients were currently suffering from inflammatory back pain (IBP) ranging from 43.4% in Spain to 68.4% in Germany, and 18.1% were asymptomatic. On average patients were receiving 1.7 pharmacological products, with little variation across countries. Mean number of consultations with a primary care provider in the last 12 months varied from 1.0 in the UK to 3.2 in Italy. The UK also had the lowest mean number of consultations with a specialist while Germany had the highest (1.8 vs. 3.6). Minimal time was spent in hospital as a result of nr-axSpA with only 0.1 nights spent in hospital on average. Under a quarter (22.9%) of patients were defined to be non-responders. Only 22.5% of non-responders were currently receiving biologic therapy compared to 43.2% of responders.

Conclusion: Nr-axSpa patients suffer from various chronic and acute symptoms and associated pain, while a considerable proportion of patients were non-responsive to their nr-axSpA treatment. Inter-country patient management differences were observed, and may be associated with corresponding unmet clinical needs.

SESSION INFORMATION

Session Title: Health Services Research Poster II (ACR): Healthcare Access, Patterns of Medication Use and Workforce Considerations

Session Type: ACR Poster Session B

Background/Purpose: We previously published quantitative definitions of the ASAS AS management recommendations designed for use with observational data.[1] The definitions, developed by consensus with expert rheumatologists, are comprised of one or more clinical actions considered to be markers of 'non-compliance with' ASAS recommendations. The DESIR cohort, a longitudinal study of early SpA patients, provides 3 years of observational data suitable for measuring non-compliance according to these definitions.

Methods: We used DESIR cohort data to describe the number of patients with markers of non-compliance at each of 6 follow-up visits (months 0, 6, 12, 18, 24, 36) and at any point over 3 years. We calculated the number of patients with any marker of non-compliance; any 'core' marker of non-compliance (i.e., markers applicable to all patients at all times); any marker of non-compliance minus that pertaining to physiotherapy (for which consensus was not achieved); the number of follow-up visits at which patients had at least one marker of non-compliance; and the total number of markers of non-compliance in each patient at each visit. Non-compliance pertaining to anti-TNF agents was analyzed among patients satisfying ASAS criteria for anti-TNF agents. The analysis included all DESIR patients who satisfied ASAS criteria for axial SpA.

Results: A total of 486 patients satisfied ASAS criteria for axial SpA and were included in the analysis. The most frequently observed marker of non-compliance pertained to lack of physiotherapy, noted among 236 patients (48.6%). When including physiotherapy, 311 patients (64.0%) had at least one marker of non-compliance over 3 years; when excluding physiotherapy, 137 patients (28.2%) had at least one marker of non-compliance over 3 years. Among 153 patients who satisfied ASAS criteria for anti-TNF agents, the marker of non-compliance (i.e., failure to receive an anti-TNF when indicated) was noted among 88 (57.5%). Markers of non-compliance unrelated to physiotherapy or anti-TNF agents were infrequently observed.

Conclusion: In a cohort of early SpA patients, almost half had not had physiotherapy in the first 12 months, while over half of those satisfying the criteria for anti-TNFs did not receive one as soon as indicated. This study suggests areas for improvement in SpA care.

Table 1. Quantitative Definitions of ASAS Recommendations as Markers of Non-Compliance

ASAS Recommendation Category	Marker(s) of Non-Compliance in Category	Marker Included in Analysis?	Marker Number (Label)
Non-Pharmacological Therapy	a. If by the 12-month follow-up visit, patient has had 0 visits to the physiotherapist	Yes	1 (Physiotherapy)
Extra-Articular Manifestations and Co-	a. If at a given study visit, a patient has a new	Yes	2 (Ophthalmologist)

Morbidities	diagnosis of uveitis AND has not had an opthamologist consult by the next study visit		
	b. If at a given study visit, a patient has a new diagnosis of psoriasis AND has not had a dermatologist consult by the next study visit	Yes	3 (Dermatologist)
	c. If at a given study visit, a patient has a new diagnosis of pustulosis AND has not had a dermatologist consult by the next study visit	No (insufficient data)	4 (NA)
	d. If at a given study visit, a patient has a new diagnosis of IBD AND has not had a gastroenterologist consult by the next study visit	Yes	5(Gastroenterologist)
	e. If at a given study visit, a patient has a new cardiovascular event and has not had a cardiologist consult by the next study visit	No (too few cardiovascular events)	6 (Cardiologist)
Non-Steroidal Anti-Inflammatory Drugs	a. If patient received their first DMARD before their first NSAID	Yes	7 (DMARD)
	b. If patient has diagnosis of renal insufficiency (i.e., creatinine clearance < 30 ml/ min) and NSAID use is not interrupted within 15 days of that diagnosis (as assessed at next study visit)	No (insufficient data)	8 (NA)
	c. If patient has history of GI event other than	Yes	9 (PPI)

	dyspepsia and receives an NSAID or Cox inhibitor without a concomitant PPI		
Glucocorticoids	a. If at a given study visit, a patient is receiving oral prednisone or equivalent and has no history of uveitis, peripheral arthritis or inflammatory bowel disease	Yes	10 ('Prednisone')
Disease-Modifying Anti-Rheumatic Drugs	a. If patient has synovitis ³3 at two consecutive visits and is not prescribed a DMARD at either of these visits	No (too few synovitis ³3)	11 (NA)
	b. If at a given study visit, a patient is receiving MTX and has no history of peripheral arthritis or psoriasis	Yes	12 (MTX)
	c. If at a given study visit, a patient is receiving SSZ and has no history of peripheral arthritis, IBD, or uveitis	Yes	13 (SSZ)
Anti-TNF Agents	a. If at two consecutive study visits, patient has had at least 2 adequate therapeutic trials of NSAIDs (i.e., minimum two NSAIDs over a 4-week period in total since symptom onset), BASDAI is ³4, Physician's Global Assessment of Disease is ³4 AND an anti-TNF agent has	Yes	14 (Anti-TNF)

	not been prescribed at the 3rd visit		
	b. If patient is receiving a biological agent other than anti-TNF (*EXCEPTION: psoriatic patients may receive a biologic other than anti-TNF, but then cannot receive a concomitant anti-TNF)	No (0 patients receiving other biologics)	15 (NA)

Table 2. DESIR Patients with Markers of Non-Compliance Over 3 Years of Follow-Up

	Number of patients with non-compliance by time point						
Marker	**Baseline**	**6M**	**12M**	**18M**	**24M**	**36M**	**Ever**

Persistent Individual and Neighborhood Poverty Are Independent Risk Factors for Accumulated Lupus Damage

Laura Trupin[1], Stephanie Rush[2], Jinoos Yazdany[3] and Edward H. Yelin[4], [1]Medicine/Rheumatology, University of California San Francisco, San Francisco, CA, [2]UCSF, SF, CA, [3]University of California, San Francisco, San Francisco, CA, [4]Medicine/Rheumatology, UC San Francisco, San Francisco, CA

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Health Services Research Poster II (ACR): Healthcare Access, Patterns of Medication Use and Workforce Considerations

Session Type: ACR Poster Session B

Title: Persistent Individual and Neighborhood Poverty Are Independent Risk Factors for Accumulated Lupus Damage

Background/Purpose: Previous research in systemic lupus erythematosus (SLE) has shown that individual poverty and living in an area of concentrated poverty are both associated with poor health outcomes. The present study evaluates whether persistent poverty or persistently living in a neighborhood with a high concentration of poverty is associated with accumulated disease damage in SLE, in comparison to those who are intermittently or never in those circumstances.

Methods: Data derive from the UCSF Lupus Outcomes Study, a national cohort of persons with SLE interviewed annually since 2003. Interview data were augmented through geocoding with data from participants' census block group (600-3000 residents), the study definition of a neighborhood. The survey includes measures of demographic characteristics, socioeconomic status, technical and interpersonal quality of healthcare, and disease status. Individual poverty status was calculated annually, defined as household income ≤125% of the Federal poverty level (<FPL). Concentrated poverty was calculated for each address, and defined as living in a census block group in which >30% of households <FPL. Persistent individual and neighborhood poverty were defined as being poor or in a poor neighborhood at each of the five or more interview years. The Brief Index of Lupus Damage (BILD), a validated self-report measure, was collected in 2012-13 and 2014-15. We modeled the 2 year change in BILD as a function of the proportion of interviews in which participants' incomes were <FPL, and the proportion in which they lived in concentrated poverty, controlling for gender, age, racial/ethnic minority status, disease duration, education, and two measures of quality of care (pass rate of ≥ 85% on technical quality of care indicators vs. not and summary of ratings of interactions with providers and health systems).

Results: Analysis included 501 participants with ≥ 5 interviews and complete data on all variables of interest. Mean age was 54 ± 12 yrs., mean duration 20 ± 9 yrs., 35% were non-white, 25% had ≥ 1 year in individual poverty, and 14% lived in a concentrated poverty neighborhood for ≥ 1 year. Mean BILD score at baseline was 2.9 ±2.6 (range 0-18); mean 2-year change in BILD was 0.44 ± 0.75 (range 0-5). Persistence in both individual and neighborhood poverty were associated with increased BILD scores. Results from the multivariable linear regression model shown in table.

Conclusion: In this national sample of individuals with SLE followed for up to 11 years, persistent individual and neighborhood poverty were independently predictive of increased accumulated lupus damage, even after adjustment for other characteristics known to affect SLE outcomes. Persistent individual and neighborhood poverty are strong markers for future accumulation of damage.

Adjusted mean change (95% Confidence Intervals; CI) in Brief Index of Lupus Damage (BILD) scores over 2 years, by proportion of study years spent in household or neighborhood poverty.

	Household poverty		Neighborhood poverty	
% of time in poverty	n	Mean BILD change (95%CI)	n	Mean BILD change (95%CI)
Never	375	0.58 (0.41, 0.74)*	433	0.56 (0.43, 0.70)*
<50% of years	73	0.57 (0.36, 0.78)*	17	0.53 (0.17, 0.90)
>50% of years	23	0.80 (0.53, 1.08)	26	0.84 (0.54, 1.14)
All years (persistent)	20	0.94 (0.59, 1.29)	25	0.95 (0.64, 1.26)

Means adjusted for both poverty measures, age, gender, race/ethnicity, education, disease duration, technical and interpersonal quality of care.
*p<0.05 compared to 'persistent' group.

Impact of Participation in Adalimumab Patient Support Program (PSP) on Clinical Outcomes and Predictors of PSP Utilization Among Patients with Rheumatoid Arthritis

Filip van Den Bosch[1], Siegfried Wassenberg[2], Andrew Östör[3], Nupun A. Varothai[4], Vishvas Garg[4] and Jasmina Kalabic[4], [1]Ghent University Hospital, Ghent, Belgium, [2]Fachkrankenhaus, Ratingen, Germany, [3]Addenbrooke's Hospital, Cambridge, United Kingdom, [4]AbbVie, North Chicago, IL

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Health Services Research Poster II (ACR): Healthcare Access, Patterns of Medication Use and Workforce Considerations

Session Type: ACR Poster Session B

Background/Purpose: Adalimumab (ADA) treated rheumatoid arthritis (RA) patients (pts) are offered patient support programs (PSP) to manage their disease. The purpose of this study is to assess the impact of PSP utilization on clinical outcomes of ADA treated RA pts and examine the predictors of PSP utilization among pts in clinical settings.

Methods: This is a post-hoc analysis based on interim data from PASSION (NCT01383421); a post-marketing observational study of pts with moderate to severe RA with an insufficient response to ≥1 disease-modifying antirheumatic drug (DMARD) and initiated ADA at participating sites in the EU, Israel, Mexico, Puerto Rico, and Australia. Pts had to be ADA-naïve and treated with ≤1 prior biologic

DMARD. Pts were prescribed ADA according to the local product label and had an option to utilize the PSP while participating in the study. The elements of PSP comprised of starter pack, call center/hotline, nursing services, educational material, injection guide, refill reminders, email, newsletters, support groups, home delivery, and financial assistance. Using multiple regression analysis DAS28, SDAI, and CDAI (mean change at week 52 from baseline [BL]) were compared between PSP-users and PSP non-users from 1-year time-horizon, after adjusting for the pts demographics (age, gender, race) and clinical characteristics (RA duration , prior biologic DMARD use, HAQ-DI, TJC28, SJC28, CRP [mg/l]) at the BL. In a separate multivariate logistic regression analysis, the following variables were assessed as the predictors of PSP usage among ADA treated RA pts: age, race, gender, RA duration , BL DAS28(CRP), BL HAQ-DI, prior biologic DMARD use, and PAM-13 level.

Results: A Total of 852 pts were included in this analysis of which 49.9% were PSP-users while treated with ADA. The mean age at BL was 54.1 y; 76.1% were female, and the mean duration of RA was 7.8 y. Mean BL disease scores were 5.3 for DAS28(CRP), 35.8 for SDAI, and 33.4 for CDAI. Prior biologic DMARD exposure was 17.4%. As shown in the figure, after adjusting for pts BL demographics and clinical characteristics, significant higher improvements ($P \leq 0.005$) from BL to wk 52 were observed for PSP-users vs PSP non-users in DAS28(CRP), SDAI, and CDAI scores. Independent predictors of PSP utilization were found to be: white race (3.856, [2.092, 7.108]), male gender (0.630, [0.426, 0.934]), higher BL HAQ (1.321, [1.019, 1.717]) and DAS28 (1.016, [1.016, 1.379]) values and use of prior biologic DMARD (2.331, [1.484, 3.660]).

Conclusion: Moderate to severe RA pts who were treated with ADA and used PSP showed significantly better clinical outcomes compared to ADA treated PSP non-users. Several demographic and clinical characteristics independently predicted PSP utilization. These findings indicate toward the potential role of ADA PSP in better disease management among moderate to severe RA pts.

Figure: Changes from baseline in DAS28 (CRP) (A), SDAI (B) and CDAI (C) over time between Non-PSP and PSP users.

Dual Care Utilization in Patients Enrolled in the Veterans Affairs Rheumatoid Arthritis Registry

Pascale Schwab[1], Harlan Sayles[2], Debra Bergman[3], Grant W. Cannon[4], Kaleb Michaud[5], Ted R. Mikuls[2] and Jennifer Barton[1], [1]VA Portland Health Care System, Portland, OR, [2]University of Nebraska Medical Center, Omaha, NE, [3]Rheumatology, University of Nebraska Medical Center, Omaha, NE, [4]Division of Rheumatology, Salt Lake City VA Medical Center and University of Utah, Salt Lake City, UT, [5]Rheumatology & Immunology, University of Nebraska Medical Center and National Data Base for Rheumatic Diseases, Omaha, NE
First publication: September 29, 2015

SESSION INFORMATION

Session Title: Health Services Research Poster II (ACR): Healthcare Access, Patterns of Medication Use and Workforce Considerations

Session Type: ACR Poster Session B

Background/Purpose: While use of multiple health care systems may allow rapid access to medical care, the practice results in fragmented and redundant treatments at a higher cost. A common source of dual care in the US is characterized by health care provided by both the Veterans Affairs (VA) Healthcare System and any additional federal or private health care coverage. In a 2010 survey of VA enrollees, 75% of those 65 or older and 51% of those under 65 received dual care. The objective of this study was to evaluate dual care use by patients enrolled in the Veterans Affairs Rheumatoid Arthritis Registry (VARA), a longitudinal multi-site disease registry and to compare patient characteristics of dual users (DUs) and non-dual users (NDUs).

Methods: A questionnaire based on the National Data Bank for Rheumatic Diseases inquiring about dual care utilization was sent to veterans with RA enrolled in VARA at 3 sites characterized by beneficiaries from both urban and rural settings (Oregon, Nebraska, and Utah). Veterans reported medical services from a non-VA primary care provider or non-VA subspecialist. Information on co-morbidities, non-VA medications, and non-VA hospitalizations was also collected. T-tests for continuous variables and Pearson chi-square tests for categorical variables were performed to compare characteristics of DUs versus NDUs. Fisher's exact test was used to compare comorbidities between the two groups.

Results: Of 526 veterans surveyed, 310 (59%) responded (74%, 69%, and 52% in Oregon, Nebraska, and Utah respectively). Data on the initial 251 responders are presented here. Approximately one-fourth (26%) of enrollees reported having a non-VA primary care physician, 22% reported having a non-VA subspecialist (a third of these were cardiologists) and 5% reported having a non-VA rheumatologist. With respect to medication use, 24% of respondents received non-VA non-RA medications and only 5% reported receiving a non-VA synthetic DMARD, biologic DMARD, or corticosteroids. Overall, nearly 1 in 10 veterans had been hospitalized at a non-VA facility within 6 months prior to the survey. A comparison of patient characteristics revealed that DUs were older, had more years of education, and were more likely to have never been smokers compared to NDUs; additionally, DUs reported more comorbidities and orthopedic procedures than NDUs (Table).

Conclusion: VARA participants have a lower rate of dual care utilization than previously reported for the overall VA population, with very few patients receiving dual rheumatology care or non-VA RA medications. This survey suggests that the majority of US veterans enrolled in VARA utilize the VA as their single source of RA care.

Characteristics of US Veterans with Rheumatoid Arthritis: Dual Users v. Non-Dual Users

Characteristic	Dual User (n=99)	Non-Dual User (n=152)	P-value
Age, mean years (SD)	71 (10)	67 (8)	<0.001
Male, N (%)	91 (92)	142 (93)	0.65
Caucasian, N (%)	91 (92)	138 (91)	0.76
Education, mean years (SD)	14 (2)	13 (2)	0.04
Never smoker, N (%)	28 (29)	25 (16)	0.03
Comorbidities, N (%)			
- Heart condition	17 (17)	12 (8)	0.03
- Stroke	4 (4)	0 (0)	0.02
- Cancer	25 (25)	21 (14)	0.03
- Cataract	33 (33)	30 (20)	0.02
- Thyroid disorder	24 (24)	19 (13)	0.03
- Any orthopedic procedure	26 (26	18 (11)	0.004

SESSION INFORMATION

Session Title: Health Services Research Poster II (ACR): Healthcare Access, Patterns of Medication Use and Workforce Considerations

Session Type: ACR Poster Session B

Background/Purpose: Past studies suggest that males with lupus nephritis (LN) may have increased rates of end-stage renal disease (ESRD) and mortality compared to females. Most prior studies have focused on biological differences and few have examined variations in healthcare use and access. We investigated potential sex differences in healthcare utilization in the period surrounding onset of LN in a nationwide incident LN cohort.

Methods: We utilized the Medicaid Analytic eXtract (MAX) with billing claims from 47 U.S. states and Washington, D.C.to identify children and adults ages 5-65 with incident LN from 2000-2004. We used a previously validated ICD-9 code algorithm for LN (PPV 80%), and required 12 months without any LN codes to define incident cases. MAX data were linked to the US Renal Data System to identify ESRD onset. The index date was the date the incident LN definition was met and we followed individuals in both datasets through 2006. Subjects were censored at death, ESRD, Medicaid disenrollment, or end of follow-up. We evaluated sociodemographics by sex and calculated sex-specific proportions of SLE and renal medication use, renal biopsies and preventive care in the period 3 months prior through 12 months after the index date. We estimated incidence rates of all emergency department, outpatient, and inpatient visits during this period. We used Poisson regression models to calculate incidence rate ratios for healthcare utilization by sex, adjusting for baseline sociodemographic and clinical characteristics.

Results: Of 2576 patients with incident LN, 230 (9%) were male. Mean follow-up was 2.8 (±1.5) years for both sexes. Mean age was 30 years (±16) among males and 34 years (±14) among females (p<0.001). More males were White (32% vs. 20% of females) and fewer Black (23% vs. 32%, p 0.02). Geographically, a higher proportion of males lived in the West (p 0.006) and in higher socioeconomic status areas (p 0.02). There was no significant difference in the SLE comorbidity index (p 0.11). 31% of men and 37% of women underwent renal biopsy (p 0.06), while 10% of males and 16% of females received azathioprine (p 0.02). There were no statistically significant differences by sex in use of immunosuppressives overall, hydroxychloroquine, glucocorticoids, angiotensin-converting enzyme inhibitors, angiotensin receptor blockers, erythropoetin, or in influenza or pneumoccocal vaccine uptake. Incidence rates of inpatient admissions were similar for both sexes, but the rates of outpatient and emergency department visits were significantly lower among males (**Table**).

Conclusion: In this large incident LN cohort, males had modestly lower rates of outpatient and emergency department visits than did females. Further studies are needed to understand whether the observed variation is related to differences in SLE activity or in health-seeking behavior, and how it relates to long-term outcomes.

Table. Incidence Rates and Adjusted Rate Ratios for Healthcare Utilization among Medicaid Patients with Incident Lupus Nephritis, by Sex

	Female (N=2346)			Male (N=230)			Adjusted IRR* (95% CI) Female=referent
	Events	Person-years	IR (95%CI)	Events	Person-years	IR (95%CI)	
Emergency Department Visits	8619	2719.4	316.9 (310.2-323.6)	722	262.4	275.2 (255.1-295.2)	**0.81 (0.68-0.98)**
Outpatient Visits	33964	2719.4	1248.9 (1235.6-1262.2)	2973	262.4	1133.2 (1092.5-1174.0)	**0.88 (0.79-0.99)**
Inpatient Admissions	5958	2719.4	219.1 (213.5-224.7)	726	262.4	276.7 (256.6-296.9)	1.13 (0.98-1.31)

Burden of Rheumatoid Arthritis in the US Elderly Population: Comorbidities, Healthcare Resource Utilization, and Cost

Chieh-I Chen[1], Li Wang[2], Wenhui Wei[3], Huseyin Yuce[4] and **Kristine Phillips**[5], [1]Regeneron Pharmaceuticals, Inc., Tarrytown, NY, [2]Director, Analytic Research, STATinMED Research, Plano, TX, [3]Sanofi-Aventis, Bridgewater, NJ, [4]New York City College of Technology (CUNY), New York, NJ, [5]Rheumatology, University of Michigan, Ann Arbor, MI
First publication: September 29, 2015

SESSION INFORMATION
Session Title: Health Services Research Poster II (ACR): Healthcare Access, Patterns of Medication Use and Workforce Considerations
Session Type: ACR Poster Session B

Background/Purpose: Rheumatoid arthritis (RA) is a systemic inflammatory disease resulting in significant healthcare resource utilization (HRCU) and cost. Data on elderly RA patients are generally limited. This study aimed to estimate the burden of RA in the US elderly by comparing comorbidities, HCRU, and cost among elderly RA patients with elderly non-RA patients.

Methods: Using Medicare fee-for-service claims data from 2010 through 2013, this was a retrospective study of RA patients aged ≥ 65 years with ≥ 2 medical claims with a diagnosis of RA (ICD-9-CM 714.xx) and ≥ 1 pharmacy claim for a disease-modifying antirheumatic drug (DMARD, biologic and/or conventional synthetic), and a control cohort of non-RA elderly patients, 1:1 matched on age, gender, race, and region. The index date was the date of the first prescription DMARD for RA patients, and randomized assigned for non-RA patients. Prevalence of comorbidities was assessed for a 12-month period prior to the index. All-cause and RA-related (defined based on RA diagnosis and treatment) HCRU and costs during the 12-month post-index period were compared between elderly patients with RA and matched controls.

Results: The matched cohorts included a total of 231,734 patients (elderly RA, n = 115,867; control, n = 115,867) with average age 75.2 years, 79.4% women, 86.2% Caucasian, and 41.3% living in the South. Compared with non-RA elderly, RA elderly had significantly greater overall comorbidity burden (Charlson Comorbidity Index excluding RA: 1.86 vs. 1.00, $P < 0.0001$) and individual baseline comorbidities including hypertension, hyperlipidemia, diabetes, respiratory disease, osteoporosis, and cardiovascular diseases (all $P < 0.0001$). The top 5 non-bone/joint-related diagnoses among RA patients were essential hypertension, disorders of lipid metabolism, general symptoms, symptoms involving the respiratory system and other chest symptoms, and other disorders of soft tissue (Figure). Elderly RA patients had significantly more HCRU than non-RA patients, resulting in nearly 3-fold higher annual healthcare costs, with half being RA-related (Table). After controlling for differences in patient characteristics and comorbidities, the adjusted total mean annual costs for RA patients were still more than double as that of non-RA patients ($16,374 vs. $6,712, $P < 0.0001$).

Conclusion: Among US elderly patients, RA was associated with significantly greater burden of comorbidities, HCRU and costs, as compared with elderly patients without RA. RA was a major driver of the overall healthcare use and cost.

Table. Annual Healthcare Resource Utilization and Cost

	Case Group (RA)		Control Group (Non-RA)
	All-cause	RA-related	All-cause
	Mean (SD)	Mean (SD)	Mean (SD)
Annual Healthcare Utilization			
No. of Inpatient/ER Visits	0.96 (1.75)	0.49 (1.11)	0.40 (1.13)
No. of Outpatient Visits	31.28 (19.83)	9.17 (6.97)	11.99 (16.99)
No. of Prescription Fills	35.64 (19.83)	12.52 (7.05)	22.29 (17.89)
Length of Hospital Stay(days)	4.38 (16.20)	2.66 (10.77)	0.97 (4.92)
Annual Healthcare Costs			
Inpatient/ER Costs	$6,103 ($17,134)	$4,198 ($13,050)	$2,142 ($9,757)
Outpatient Costs	$9,022 ($9,795)	$4,719 ($8,964)	$2,607 ($6,315)
Pharmacy Costs	$5,794 ($8,969)	$2,670 ($6,755)	$2,449 ($4,263)
Total Costs	$20,919 ($23,888)	$11,587 ($16,920)	$7,197 ($15,094)

Note: All RA vs. non-RA comparisons were statistically significant at the 0.001 level. ER = emergency room

The Pediatric Rheumatology Workforce in 2015: A Survey of Pediatric Rheumatologists

Meredith Riebschleger[1], Mara L Becker[2], Holly S. Ruch-Ross[3], 'Laura Laskosz[4], Carrie Radabaugh[5], Polly J. Ferguson[6], Kenneth N. Schikler[7] and Sandy D. Hong[8], [1]Pediatric Rheumatology & Health Services Research, University of Michigan, Ann Arbor, MI, [2]Rheumatology, Children's Mercy Kansas City, Kansas City, MO, [3]Independent Research and Evaluation Consultant, Evanston, IL, [4]Division of Technical and Medical Services, The American Academy of Pediatrics, Elk Grove Village, IL, [5]Department of Education, American Academy of Pediatrics, Elk Grove Village, IL, [6]Dept of Pediatrics--Rheum, University of Iowa, Iowa City, IA, [7]Pediatrics, University of Louisville, Louisville, KY, [8]Pediatrics-Rheumatology, U of Iowa Children's Hosp, Iowa City, IA

First publication: September 29, 2015

SESSION INFORMATION

Session Title: Health Services Research Poster II (ACR): Healthcare Access, Patterns of Medication Use and Workforce Considerations

Session Type: ACR Poster Session B

Background/Purpose: Pediatric Rheumatology (PR) is among the smallest pediatric subspecialties, with only ~300 clinically active board-certified Pediatric Rheumatologists in the US. To better characterize the work patterns of the US PR workforce, the American Academy of Pediatrics (AAP) performed a survey of Pediatric Rheumatologists.

Methods: A list of Pediatric Rheumatologists was generated using the membership list of the AAP Section on Rheumatology and the PR certification list of the American Board of Pediatrics. An electronic survey was fielded 9/2014-12/2014. Survey domains included demographics, practice characteristics, distribution of professional time, and future plans. Only respondents reporting current PR practice were eligible for analyses. SPSS 18.0 was used for analyses, including frequency distributions, measures of central tendency, ANOVA,

and χ^2.

Results: 151/317 (48%) identified Pediatric Rheumatologists responded to the survey. 138 respondents reported current PR practice and were included in analyses. Of those, 25 (18%) reported part-time PR practice. Part-time respondents worked fewer hours/week than full-time respondents (mean 44 vs. 52 hours/week, p<.001), but % clinical time, half-day clinic sessions/week, and patients seen/week were not significantly different between the two groups (table 1). Overall, 99% of respondents reported spending time in direct patient care, 78% reported time in administration, 88% reported time in teaching, and 75% reported time in research. The breakdown of apportioned time for part- and full-time respondents is detailed in table 1. For all respondents combined, hours worked/week was inversely related to % time spent in direct patient care (table 2, p=.016).

Conclusion: A significant minority of the PR workforce report part-time PR practice, and more than half of full-time respondents spend ≤60% of their time in direct patient care. Providers who spend more time on non-clinical duties average more hours of work/week, illustrating the extra time required for an academic career. As most Pediatric Rheumatologists work in medical school/University affiliated practices, with academic requirements for promotion, it is critical to account for non-clinical time in estimates of future PR workforce requirements.

Table 1 – Comparison of part-time and full-time Pediatric Rheumatology respondents

	Respondents reporting PART-TIME PR practice (N=25)	Respondents reporting FULL-TIME PR practice (N=113)	All respondents (N=138)	p-value (part-time vs. full-time)
Sex				NS

SESSION INFORMATION

Session Title: Health Services Research Poster II (ACR): Healthcare Access, Patterns of Medication Use and Workforce Considerations

Session Type: ACR Poster Session B

Background/Purpose:

Rheumatoid arthritis (RA) is a chronic, progressive inflammatory disease which has been associated with an increased incidence of disability and unemployment over time. The aim of this analysis was to evaluate the prevalence of unemployment due to work disability in RA patients initiating treatment with infliximab (IFX) or golimumab (GLM) and to identify determinants of disability.

Methods:

BioTRAC is an ongoing, prospective registry of patients initiating treatment for RA, AS, or PsA with IFX or GLM as first biologics or after having been treated with a biologic for <6 months. Data were obtained from RA patients treated with IFX (2002-2014) or GLM (2010-2014). Between employment group differences were assessed for statistical significance with the independent samples t-test or the chi-square. Time to employment and time to unemployment were assessed with the Kaplan-Meier (KM) estimator of the survival function. Cox regression was used to identify predictors of time to unemployment.

Results:

A total of 581 RA patients were included; 374 (64.4%) employed and 207 (35.6%) unemployed due to disability. The following baseline parameters were associated with significantly increased likelihood of being unemployed due to disability: female vs. male gender (40.1% vs. 27.6%; P=0.006), earlier enrolment period (2002-05 vs. 2006-09 vs. 2010-14: 49.3% vs. 30.5% vs. 22.4%; P<0.001), insurance type (provincial vs. private vs. both: 54.9% vs. 23.8% vs. 20.0%; P<0.001), older age (P=0.033), and increased disease activity as evidenced by the higher DAS28 (P<0.001), SJC (P<0.001), TJC (P<0.001), HAQ (P<0.001), MDGA (P<0.001), PtGA (P<0.001), CDAI (P<0.001), SDAI (P<0.001), pain (P<0.001), and ESR (P<0.001).

Among disabled patients, 10.1% were able to return to work upon treatment with TNF a mean KM-based duration of 119.5 months from baseline; whereas 6.4% of employed patients became disabled (2002-05 vs. 2006-09 vs. 2010-14: 7.0% vs. 10.1% vs. 1.7%; P=0.021) with a mean time to unemployment of 113.4 months. Multivariate survival analysis showed that, upon adjusting for enrolment period, higher baseline HAQ [HR (95%CI): 3.59 (1.64, 7.87), P=0.001], and higher baseline SJC [HR (95%CI): 1.09 (1.02, 1.16), P=0.011] were significant predictors of unemployment due to disability.

Conclusion:

A significant proportion of RA patients are unemployed due to disability in Canada. At anti-TNF initiation, work disability was associated with higher disease activity, female gender, earlier enrolment period, and provincial insurance. Increased HAQ and higher SJC were significant predictors of progression to unemployment highlighting the importance of early anti-TNF initiation in order to prevent work disability. Anti-TNF treatment was effective in enabling a considerable portion of disabled patients to return to employment.

SESSION INFORMATION

Session Date: Monday, November 9, 2015
Session Title: Health Services Research Poster (ARHP)
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose:

Women who had JIA in childhood and adolescence may be at higher risk for adverse neonatal and maternal outcomes. Our objective was to examine aspects of prenatal care in women who had JIA versus those who did not have JIA, and to evaluate the association between prenatal care and risk of adverse outcomes.

Methods:

We designed a cohort study using data from physician billing and hospitalization data covering Québec, Canada. The cohort contained all females with JIA with a first-time birth between 01/01/1983 and 12/31/2010 (n=1681) and a control cohort of first-time mothers without JIA from the same administrative data, matching 4:1 for date of first birth, age of mother and area of residence (n=6724). Using the revised

G-INDEX (which is based on the American College of Obstetricians and Gynecologists recommendations for prenatal visits for low risk pregnant women), we determined prenatal care as adequate, intermediate, inadequate, and a group with no care or missing data. This latter group may contain those mothers that receive no prenatal care or those that see salaried physicians, midwives or nurses whose services are not recorded in the physician billing data. We described and compared prenatal care in mothers with JIA and those who did not have JIA and used logistic regression analysis to determine the association between prenatal care levels and adverse outcomes (prematurity, small for gestational age, and major congenital malformations) adjusted for maternal age, education and socioeconomic status (deprivation index).

Results:

In our entire cohort 1.4% of mothers in the JIA group and 4.6% in the non JIA group were classified as receiving inadequate care. Adequate, and intermediate care were 32.9 and 8.4% respectively in the JIA group and 57.7 and 21.9% in the non-JIA group. Nearly a quarter of our cohort (24.1%) had missing data or received no prenatal care, and this was substantially higher in the JIA group (57.4% vs 15.8% in the non-JIA group). We were unable to detect an increased risk of an adverse event in the JIA or non-JIA group when comparing adequate/intermediate care to inadequate prenatal care . However, being in the no care/ missing group was associated with having a child with a major congenital malformation in both the JIA group (adjusted Relative Risk (RR), 1.95; 95% Confidence Interval (CI) 1.37,2.79) and non-JIA groups (adjusted RR 1.81; 95% CI 1.14,2.87).

Conclusion:

Mothers with a history of JIA differ from those without JIA in terms of prenatal care patterns. In both groups, having no record of prenatal care was associated with having an adverse birth outcome.

Session Title: Health Services Research Poster (ARHP)

Session Type: ACR Poster Session B

Session Time: 9:00AM-11:00AM

Background/Purpose: Bacterial and fungal infections (e.g., tuberculosis, histoplasmosis) have been associated with the use of TNF-α inhibitors (TNFI). Although screening for specific infections prior to initiating TNFI has been recommended, the costs associated with screenings and treatment of these infections has not been well described in the literature. Thus, the study aim was to describe the costs associated with screenings for and the treatment of targeted fungal or mycobacterial infections in patients taking TNFI.

Methods: A case-control study ($N = 436$) was conducted using deidentified patient health claims information from a dataset representing a commercially-insured, U.S. population of 15 million patients annually (1/1/2007-12/31/2009). To begin, all patients who obtained a TNFI for any indication were extracted from the dataset which resulted in 25,949 unique patients. These patients were then followed forward in time and defined as a case if they received medical care (inpatient or outpatient) for one (or more) targeted fungal or mycobacterial infections (i.e., tuberculosis, histoplasmosis, unspecified mycosis, coccidioidomyocosis, cryptococcal) and 124 unique patients were identified. Fifteen of these patients had cancer and were excluded from the analyses; thus, 109 patients were defined as cases. Controls were randomly selected to frequency match cases on age and length of follow-up in a 3:1 ratio. Descriptive statistics were used to summarize standardized costs of screening and medical treatments attributed to targeted infections.

Results: Of the 436 patients in our sample the median cost for screening was $23.05 (Interquartile Ranges: Q1 = $10.20, Q3 = $46.73) for the total sample; $20.40 (Q1 = $10.20, Q3 = 46.73) for controls and $32.52 (Q1 = $10.2, Q3 = $46.73) for cases. See Table 1 for the cost per screening procedure. The median cost of infection treatment was $100.97 (Q1 = $45.12, Q3 = $276.56). See Table 2 for the cost per infection.

Conclusion: Although few patients in this study were diagnosed with a targeted infection (0.48%), from a cost perspective, the high cost of these infections relative to the low cost of the more frequently used screenings likely warrants their continued use in clinical practice.

Table 1. Standardized Cost Per Screening (Total Sample = 436; Screened = 126)

Screening	Median (Interquartile Ranges)
Bronchoalveolar lavage (*n* = 1)	$619.60
CT of the chest (*n* = 7)	$375.97 (Q1 = $375.97; Q3 = $555.36)
Interferon gamma release assay (*n* = 1)	$61.75
Fungal cultures (*n* = 3)	$27.40 (Q1 = $27.40; Q3 = $116.02)
Chest x-ray (*n* = 63)	$45.12 (Q1 = $16.65; Q3 = $45.12)
Coccidioidal serologic test IgG and IgM (*n* = 8)	$25.78 (Q1 = $27.78; Q3 = 34.37)
Tuberculin skin test (*n* = 84)	$10.20 (Q1 = $10.20; Q3 = $10.20)
Crytococcal serum antigen (*n* = 0)	-
Histoplasmosis culture/serologic specific antibodies (*n* = 0)	-
Histoplasmosis polymerase chain reaction (*n* = 0)	-
Urine/serum/broncholavage for histoplasmin antigen (*n* = 0)	-

Table 2. Aggregated Standardized Cost Per Infection

Targeted Infection	Median (Interquartile Ranges)
Tuberculosis (*n* = 46)	$79.11 (Q1 = $45.12; Q3 = $156.30)
Histoplasmosis (*n* = 46)	$154.42 (Q1 = $62.84, Q3 = $1103.30)
Fungal Culture Unspecified (*n* = 10)	$56.13 (Q1 = $48.88, Q3 = $351.25)
Coccidioidomyocosis (*n* = 6)	$124.47 (Q1 = $33.30; Q3 = $259.43)
Cryptococcal (*n* = 2)	$379.19 (Q1 = $256.73; Q3 = $501.65)

Session Title: Health Services Research Poster (ARHP)
Session Type: ACR Poster Session B
Session Time: 9:00AM-11:00AM

Background/Purpose: China has no primary medical care and referral system. Patients can choose any hospitals or any doctors they like to seek medical care. As a result, most patients with rheumatic diseases rushed to a few large cities on their own cost.

Survey shows more than 40% of the rheumatic disease patients are unnecessary to go to hospital and they only need advices from specialist.
